the **antrum** (“cave”), an event that distinguishes the early **vesicular follicle** from the late secondary follicle and all prior follicles (*preantral follicles*).

The antrum continues to expand with fluid until it isolates the oocyte, along with its surrounding capsule of granulosa cells called a **corona radiata** (“radiating crown”), so the oocyte is “sitting proudly” on a stalk on one side of the follicle. When a follicle is full size (about 2.5 cm, or 1 inch, in diameter), it bulges from the external ovarian surface like an “angry boil.” This usually occurs by day 14.

As one of the final events of follicle maturation, the primary oocyte completes meiosis I to form the secondary oocyte and first polar body (see Figure 27.19). Once this has occurred, the stage is set for ovulation. At this point, the granulosa cells send another important signal to the oocyte that says, in effect, “Wait, do not complete meiosis yet!” It is estimated that follicle growth from the primordial stage to this stage takes about a year. So each follicle that ovulates actually began to grow some 10–12 ovarian cycles earlier.

### Ovulation

**Ovulation** (stage ⑤ in Figure 27.20) occurs when the ballooning ovary wall ruptures and expels the secondary oocyte, still surrounded by its corona radiata, into the peritoneal cavity. Some women experience a twinge of pain in the lower abdomen when ovulation occurs. The precise cause of this pain, called *mittelschmerz* (mit’el-shmārts; German for “middle pain”), is not known, but possible reasons include intense stretching of the ovarian wall during ovulation and irritation of the peritoneum by blood or fluid released from the ruptured follicle.

In the ovaries of an adult female, there are always several follicles at different stages of maturation. As a rule, one follicle outstrips the others and is at the peak stage of maturation when the hormonal (LH) stimulus is given for ovulation. FSH is a survival factor for antral follicles and plays a role in selecting the so-called *dominant follicle*, but how this follicle is selected, or selects itself, is still uncertain. It is probably the one that adds the most gonadotropin receptors and so attains the greatest FSH sensitivity the quickest. The others degenerate (undergo apoptosis) and are reabsorbed.

In 1–2% of all ovulations, more than one oocyte is ovulated. This phenomenon, which increases with age, can result in multiple births. Since, in such cases, different oocytes are fertilized by different sperm, the siblings are *fraternal*, or non-identical, twins. *Identical twins* result from the fertilization of a single oocyte by a single sperm, followed by separation of the fertilized egg’s daughter cells during early development. Additionally, it now appears that in some women oocytes may be released at times unrelated to hormone levels. This timing may help to explain why a rhythm method of contraception sometimes fails and why some fraternal twins have different conception dates.

### Luteal Phase of the Ovarian Cycle

After ovulation, the ruptured follicle collapses and the antrum fills with clotted blood. This *corpus hemorrhagicum* is eventually

absorbed. The remaining granulosa cells enlarge, and along with the internal thecal cells they form a new, quite different endocrine structure, the *corpus luteum* (“yellow body”) (Figure 27.20, stage ⑥). It settles right into its role and begins to secrete progesterone and some estrogen.

If pregnancy does not occur, the corpus luteum starts degenerating in about 10 days and its hormonal output ends. In this case, all that ultimately remains is a scar called the *corpus albicans* (al’bī-kans; “white body”) as shown in Figure 27.20, ⑦. The last two or three days of the luteal phase, when the endometrium is just beginning to erode, is sometimes called the *luteolytic* or *ischemic phase*.

On the other hand, if the oocyte is fertilized and pregnancy ensues, the corpus luteum persists until the placenta is ready to take over its hormone-producing duties in about three months.

30. How do identical twins differ developmentally from fraternal twins?
31. What occurs in the luteal phase of the ovarian cycle?

For answers, see Appendix H.

## Hormonal Regulation of the Ovarian Cycle

✓ Describe the regulation of the ovarian and uterine cycles.

Ovarian events are much more complicated than those occurring in the testes, but the hormonal controls set into motion at puberty are similar in both sexes. Gonadotropin-releasing hormone (GnRH), pituitary gonadotropins, and, in this case, ovarian estrogen and progesterone interact to produce the cyclic events occurring in the ovaries.

However, in females another hormone plays an important role in stimulating the hypothalamus to release GnRH. The onset of puberty in females is linked to the amount of adipose tissue, and the messenger from fatty tissue to the hypothalamus is leptin. If blood levels of lipids and leptin (better known for its role in energy production and appetite) are low, puberty is delayed.

### Establishing the Ovarian Cycle

During childhood, the ovaries grow and continuously secrete small amounts of estrogens, which inhibit hypothalamic release of GnRH. Provided that leptin levels are adequate, the hypothalamus becomes less sensitive to estrogen as puberty nears and begins to release GnRH in a rhythmic pulsatile manner. GnRH, in turn, stimulates the anterior pituitary to release FSH and LH, which prompt the ovaries to secrete hormones (primarily estrogens).

Gonadotropin levels continue to increase for about four years. During this time, pubertal girls are still not ovulating and cannot become pregnant. Eventually, the adult cyclic pattern is achieved, and hormonal interactions stabilize. These events are heralded by the young woman’s first menstrual period, referred to as **menarche** (mē-nar’ke; *men* = month, *arche* = first). Usually, it is not until the third year postmenarche that the cycles become regular and all are ovulatory.

**Figure 27.21 Regulation of the ovarian cycle.** Numbers refer to events listed in the text.

Note that all feedback signals exerted by ovarian hormones are negative except one—that exerted by estrogens immediately before ovulation. Events that follow step 6 (negative feedback inhibition of the hypothalamus and anterior pituitary by progesterone and estrogens) are not depicted, but involve a gradual deterioration of the corpus luteum and, therefore, a decline in ovarian hormone production. Ovarian hormones reach their lowest blood levels around day 28.

### Hormonal Interactions During the Ovarian Cycle

Next, let's look at how the waxing and waning of anterior pituitary gonadotropins (FSH and LH) and ovarian hormones and the negative and positive feedback interactions regulate ovarian function. **Figure 27.21** shows these events in a 28-day cycle.

- 1 GnRH stimulates FSH and LH secretion.** GnRH secreted by the hypothalamus stimulates the anterior pituitary to produce and release follicle-stimulating hormone (FSH) and luteinizing hormone (LH).
- 2 FSH and LH stimulate follicles to grow, mature, and secrete sex hormones.** FSH exerts its main effects on the granulosa cells of late secondary and vesicular follicles,

causing them to release estrogens, whereas LH (at least initially) prods the theca cells to release androgens (actually the steroid hormone androstenedione). These hormones diffuse through the basement membrane, where the granulosa cells convert them to estrogens. Only tiny amounts of ovarian androgens enter the blood, because they are almost completely converted to estrogens within the ovaries.

- 3 Negative feedback inhibits gonadotropin release.** As estrogen levels in the plasma rise, they exert *negative feedback* on the hypothalamus and anterior pituitary, inhibiting release of FSH and LH. Within the ovary, estrogen enhances output of estrogens by intensifying the effect of FSH on

follicle maturation. *Inhibin*, released by the granulosa cells, also exerts negative feedback controls on FSH release during this period. Only the dominant follicle survives this dip in FSH—the other developing follicles fail to develop further, and they deteriorate.

- ④ **Positive feedback stimulates gonadotropin release.** Although the initial small rise in bloodborne estrogen inhibits the hypothalamic-pituitary-gonadal axis, the high estrogen level produced by the dominant follicle has the opposite effect. Once estrogen reaches a critical blood concentration, it briefly exerts *positive feedback* on the brain and anterior pituitary.
- ⑤ **LH surge triggers ovulation and formation of the corpus luteum.** The high estrogen level sets a cascade of events into motion. There is a sudden burstlike release of accumulated LH (and, to a lesser extent, FSH) by the anterior pituitary about midcycle (also see Figure 27.22a).

The LH surge rouses the primary oocyte of the dominant follicle from its resting state and it completes its first meiotic division, forming a secondary oocyte that continues on to metaphase II. Around day 14, LH—aided by intraovarian paracrine factors—stimulates many events that lead to ovulation: It increases local vascular permeability and triggers an inflammatory response that promotes release of metalloproteinase enzymes that weaken the ovary wall. As a result, blood stops flowing through the protruding part of the follicle wall. Within minutes, that region of the follicle wall thins, bulges, and ruptures, forming a hole or *stigma*. The oocyte, still surrounded by its corona radiata, exits, accomplishing ovulation. The role (if any) of FSH in this process is unknown.

Shortly after ovulation, estrogen levels decline. This probably reflects the damage to the dominant estrogen-secreting follicle during ovulation.

The LH surge also transforms the ruptured follicle into a corpus luteum (which gives LH its name, “luteinizing” hormone). LH stimulates this newly formed endocrine structure to produce large amounts of progesterone and some estrogen almost immediately after it is formed. Progesterone helps maintain the stratum functionalis and is essential for maintaining pregnancy should conception occur.

- ⑥ **Negative feedback inhibits LH and FSH release.** Rising progesterone and estrogen blood levels exert a powerful negative feedback effect on the hypothalamus and the anterior pituitary release of LH and FSH. *Inhibin*, released by the corpus luteum and granulosa cells, enhances this inhibitory effect. Declining gonadotropin levels inhibit the maturation of new vesicular follicles and prevent additional LH surges that might cause additional oocytes to be ovulated.

In cycles in which fertilization does not occur, the stimulus for luteal activity ends when LH blood levels fall and the corpus luteum degenerates. As goes the corpus luteum, so go the levels of ovarian hormones, and blood estrogen and progesterone levels drop sharply. The marked decline in ovarian hormones at the

end of the cycle (days 26–28) ends their blockade of FSH and LH secretion, and the cycle starts anew.

We have just described ovarian events as if we are following one follicle through the 28-day cycle, but this is not really the case. What is happening is that the increase of FSH at the beginning of each cycle allows several vesicular follicles to continue to mature. Then, with the midcycle LH surge, one (or more) vesicular follicles undergo ovulation. However, the ovulated oocyte would actually have been activated up to 12 months before, not 14 days before.

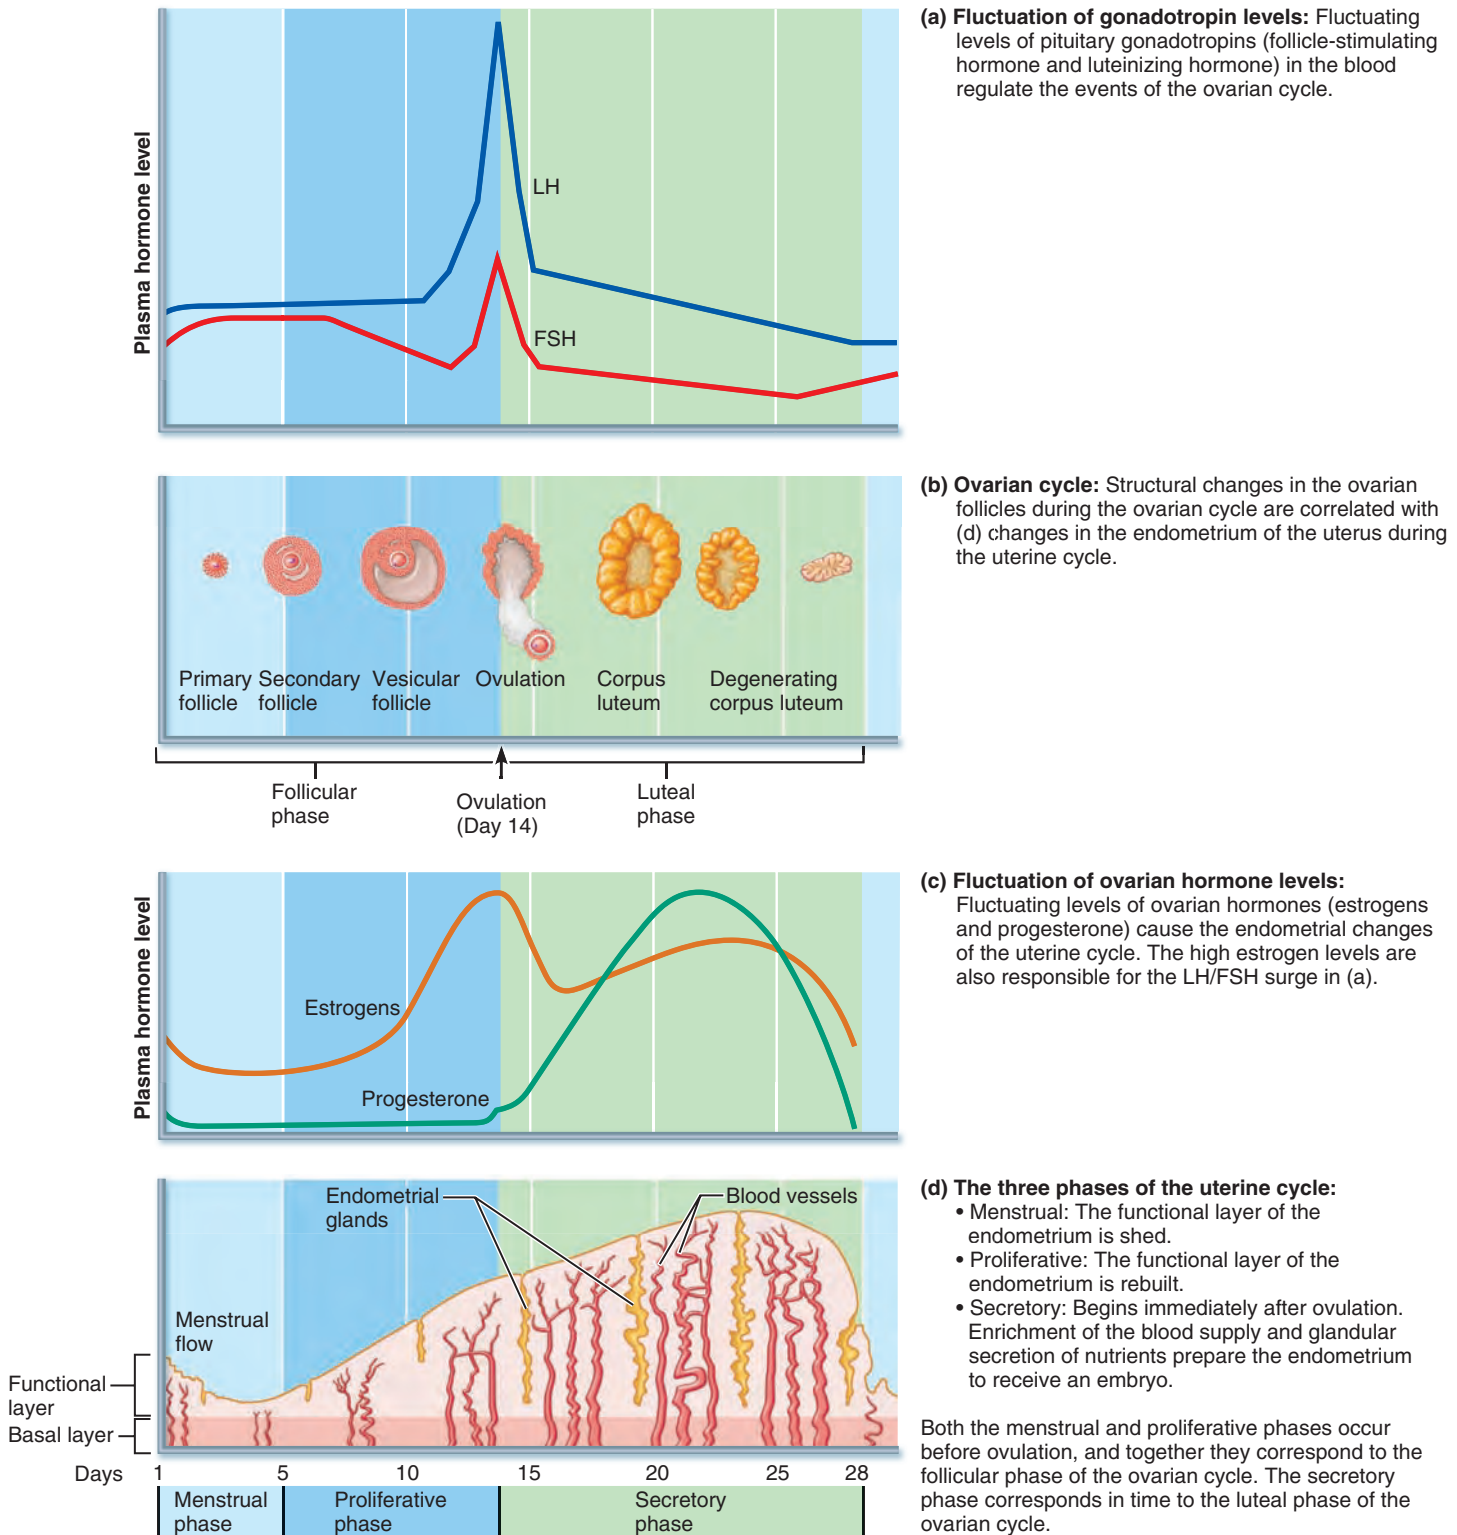

## The Uterine (Menstrual) Cycle

Although the uterus is where an embryo implants and develops, it is receptive to implantation for only a short period each month. Not surprisingly, this brief interval is exactly the time when a developing embryo would normally begin implanting, six to seven days after ovulation. The **uterine**, or **menstrual** (men'stroo-al), **cycle** is a series of cyclic changes that the uterine endometrium goes through each month as it responds to the waxing and waning of ovarian hormones in the blood. These endometrial changes are coordinated with the phases of the ovarian cycle, which are dictated by gonadotropins released by the anterior pituitary.

Changes in ovarian steroid hormone levels drive the events of the uterine cycle (**Figure 27.22d**) as follows:

1. **Days 1–5: Menstrual phase.** In this phase, **menstruation** (men'stroo-a'shun) or **menses**, the uterus sheds all but the deepest part of its endometrium. (Note in Figure 27.22a and c that at the beginning of this stage, ovarian hormones are at their lowest normal levels and gonadotropins are beginning to rise.) The thick, hormone-dependent functional layer of the endometrium detaches from the uterine wall, a process accompanied by bleeding for 3–5 days. The detached tissue and blood pass out through the vagina as the menstrual flow. By day 5, the growing ovarian follicles start to produce more estrogen (Figure 27.22c).
2. **Days 6–14: Proliferative (preovulatory) phase.** In this phase, the endometrium rebuilds itself: Under the influence of rising blood levels of estrogens, the basal layer of the endometrium generates a new functional layer. As this new layer thickens, its glands enlarge and its spiral arteries increase in number (also see Figure 27.15). Consequently, the endometrium once again becomes velvety, thick, and well vascularized. During this phase, estrogens also induce the endometrial cells to synthesize progesterone receptors, readying them for interaction with progesterone.

Normally, cervical mucus is thick and sticky, but rising estrogen levels cause it to thin and form channels that facilitate sperm passage into the uterus. *Ovulation*, which takes less than five minutes, occurs in the ovary at the end of the proliferative stage (day 14) in response to the sudden release of LH from the anterior pituitary. As we saw earlier, LH also converts the ruptured follicle to a corpus luteum.

**Figure 27.22** Correlation of anterior pituitary and ovarian hormones with structural changes of the ovary and uterus. The time bar at the bottom of the figure, reading Days 1 to 28, applies to all four parts of this figure. (For a related image, see *A Brief Atlas of the Human Body*, Plate 53.)

**3. Days 15–28: Secretory (postovulatory) phase.** This 14-day phase is the most constant timewise. During the secretory phase the endometrium prepares for an embryo to implant. Rising levels of progesterone from the corpus luteum act on the estrogen-primed endometrium, causing the spiral arteries to elaborate and converting the functional layer to a secretory mucosa. The endometrial glands enlarge, coil, and begin secreting nutrients into the uterine cavity that will sustain the embryo until it has implanted in the blood-rich endometrial lining.

As progesterone levels rise, the cervical mucus becomes viscous again, forming the *cervical plug*, which helps to block entry of sperm and pathogens or other foreign materials. Progesterone also plays an important role in keeping the uterus “private” in the event an embryo has begun to implant. Rising progesterone (and estrogen) levels inhibit LH release by the anterior pituitary.

As noted earlier, if fertilization has not occurred, the corpus luteum degenerates toward the end of the secretory phase as LH blood levels decline. Progesterone levels fall, depriving the endometrium of hormonal support, and the spiral arteries kink and go into spasms. Denied oxygen and nutrients, the ischemic endometrial cells die and the glands regress, setting the stage for menstruation to begin on day 28. The spiral arteries constrict one final time and then suddenly relax and open wide. As blood gushes into the weakened capillary beds, they fragment, causing the functional layer to slough off. The uterine cycle starts over again on this first day of menstrual flow.

Figure 27.22b and d also illustrate how the ovarian and uterine cycles fit together. Notice that the menstrual and proliferative phases overlap the follicular phase and ovulation in the ovarian cycle, and that the uterine secretory phase corresponds to the ovarian luteal phase.

### Homeostatic Imbalance 27.8

Extremely strenuous physical activity can delay menarche in girls and disrupt the normal menstrual cycle in adult women, even causing *amenorrhea* (a-men"o-re'ah), cessation of menstruation. Female athletes have little body fat, and adipose cells help convert adrenal androgens to estrogens and are the source of leptin which, as noted above, plays a critical permissive role in the onset of puberty in females. Leptin informs the hypothalamus whether energy stores are sufficient to support the high energy demands of reproduction. If not, the reproductive cycles are shut down.

Amenorrhea is usually reversible when the woman discontinues athletic training, but it has a worrisome consequence in young, healthy adult women: dramatic losses in bone mass normally seen only in osteoporosis of old age. Once estrogen levels drop and the menstrual cycle stops (regardless of cause), bone loss begins. +

### ✓ Check Your Understanding

**32.** Which hormone plays an important role in “letting the brain know” that puberty may occur in girls?

- 33.** Which hormone(s) prompt follicle growth? Which hormone prompts ovulation?
- 34.** Which gonadal hormone exerts positive feedback on the anterior pituitary that results in a burstlike release of LH?

For answers, see Appendix H.

## Effects of Estrogens and Progesterone

✓ Discuss the physiological effects of estrogens and progesterone.

With a name meaning “generators of sexual activity,” estrogens are analogous to testosterone, the male steroid. As estrogen levels rise during puberty, they (1) promote oogenesis and follicle growth in the ovary and (2) exert anabolic effects on the female reproductive tract (**Table 27.1**). Consequently, the uterine tubes, uterus, and vagina enlarge and become functional—more ready to support a pregnancy. The uterine tubes and uterus exhibit enhanced motility; the vaginal mucosa thickens; and the external genitalia mature.

Estrogens also support the growth spurt at puberty that makes girls grow much more quickly than boys between the ages of 11 and 12. But this growth is short-lived because rising estrogen levels also cause the epiphyses of long bones to close sooner, and females reach their full height between the ages of 13 and 15. In contrast, the aggressive growth of males continues until ages 15 to 19, at which point rising estrogen levels cause epiphyseal closure.

The estrogen-induced secondary sex characteristics of females include:

- Breast development
- Increasing deposition of subcutaneous fat, especially in the hips and breasts
- Development of a wider and lighter pelvis (adaptations for childbirth)

Estrogens also have several metabolic effects, including maintaining low total blood cholesterol levels (and high HDL levels) and facilitating calcium uptake, which helps sustain the density of the skeleton. These metabolic effects begin under estrogen's influence during puberty, but they are not true secondary sex characteristics.

Progesterone works with estrogen to establish and then help regulate the uterine cycle and promotes changes in cervical mucus (see Table 27.1). Its other effects are exhibited largely during pregnancy, when it inhibits uterine motility and takes up where estrogen leaves off in preparing the breasts for lactation. Indeed, progesterone is named for these important roles (*pro* = for, *gesta-tion* = pregnancy). However, the source of progesterone and estrogen during most of pregnancy is the placenta, not the ovaries.

## Female Sexual Response

✓ Describe the phases of the female sexual response.

The **female sexual response** is similar to that of males in most respects. During sexual excitement, the clitoris, vaginal mucosa, bulbs of the vestibule, and breasts engorge with blood and the

**Table 27.1** Summary of Hormonal Effects of Gonadal Estrogens, Progesterone, and Testosterone

SOURCE, STIMULUS, EFFECTS	ESTROGENS (MOSTLY ESTRADIOL)	PROGESTERONE	TESTOSTERONE
Major source	Ovary: developing follicles and corpus luteum.	Ovary: mainly the corpus luteum.	Testes: interstitial endocrine cells.
Stimulus for release	FSH (and LH).	LH.	LH and declining levels of inhibin produced by the sustentocytes.
Feedback effects exerted	Both negative and positive feedback exerted on anterior pituitary release of gonadotropins.	Negative feedback exerted on anterior pituitary release of gonadotropins.	Negative feedback suppresses release of LH by the anterior pituitary and release of GnRH by the hypothalamus.
Effects on reproductive organs	Stimulate growth and maturation of reproductive organs and breasts at puberty and maintain their adult size and function. Promote the proliferative phase of the uterine cycle. Stimulate production of watery cervical mucus and activity of fimbriae and uterine tube cilia.  Promote oogenesis and ovulation by stimulating formation of FSH and LH receptors on follicle cells. Stimulate capacitation of sperm in the female reproductive tract.  During pregnancy stimulate growth of the uterus and enlargement of the external genitalia and mammary glands.	Cooperates with estrogen in stimulating growth of breasts. Promotes the secretory phase of the uterine cycle. Stimulates production of viscous cervical mucus. Progesterone surge after ovulation enhances beating of cilia in the uterine tube, promoting meeting of sperm and oocyte.  During pregnancy, quiets the myometrium and acts with estrogen to cause mammary glands to achieve their mature milk-producing state.	Stimulates formation of male reproductive ducts, glands, and external genitalia. Promotes descent of the testes. Stimulates growth and maturation of the internal and external genitalia at puberty; maintains their adult size and function.  Required for normal spermatogenesis via effects promoted by ABP, which keeps its concentration high near spermatogenic cells. Suppresses mammary gland development.
Promotion of secondary sex characteristics and somatic effects	Promote long bone growth and feminization of the skeleton (particularly the pelvis); inhibit bone reabsorption and then stimulate epiphyseal closure. Promote hydration of the skin and female pattern of fat deposit.  During pregnancy act with relaxin (placental hormone) to induce softening and relaxation of the pelvic ligaments and pubic symphysis.		Stimulates the growth spurt at puberty; promotes increased skeletal and muscle mass during adolescence. Promotes growth of the larynx and vocal cords and deepening of the voice. Enhances sebum secretion and hair growth, especially on the face, axillae, genital region, and chest.
Metabolic effects	Generally anabolic. Stimulate Na <sup>+</sup> reabsorption by the renal tubules, hence inhibit diuresis. Enhance HDL (and reduce LDL) blood levels (cardiovascular sparing effect).	Promotes diuresis (antiestrogenic effect). Increases body temperature.	Generally anabolic. Stimulates hematopoiesis. Enhances the basal metabolic rate.
Neural effects	Along with DHEA (an androgen produced by the adrenal cortex) are partially responsible for female libido (sex drive).		Responsible for libido in males; promotes aggressiveness.

nipples become erect. Increased activity of the vestibular glands and “sweating” of the vaginal walls lubricate the vestibule and facilitate entry of the penis. These events, though more widespread, are analogous to the *erection* phase in men. Touch and psychological stimuli promote sexual excitement, which is mediated along the same autonomic nerve pathways as in males.

The final phase of the female sexual response, *orgasm*, is not accompanied by ejaculation. However, muscle tension

increases throughout the body, pulse rate and blood pressure rise, and the uterus contracts rhythmically. As in males, orgasm is accompanied by a sensation of intense pleasure followed by relaxation. But unlike what is seen in males, a refractory period does not follow orgasm, so females may experience multiple orgasms during a single sexual experience. Female orgasm is not required for conception. Indeed, some women never experience orgasm, yet are perfectly able to conceive.

Although the female libido was formerly believed to be prompted by testosterone, new studies indicate that dehydroepiandrosterone (DHEA), an androgen produced by the adrenal cortex, is in fact the male sex hormone associated with desire in females.

35. Which gonadal hormone causes the secondary sex characteristics to appear in a young woman?
36. Which gonadal hormone promotes epiphyseal closure in both males and females?

For answers, see Appendix H.

## Sexually Transmitted Infections

- ✓ Indicate the infectious agents and modes of transmission of gonorrhea, syphilis, chlamydia, trichomoniasis, genital warts, and genital herpes.

**Sexually transmitted infections (STIs)**, also called *sexually transmitted diseases (STDs)* or *venereal diseases (VDs)*, are infectious diseases spread through sexual contact. The United States has the highest rates of infection among developed countries. Over 12 million people in the U.S., a quarter of them adolescents, get STIs each year. Latex condoms can help prevent the spread of STIs, and their use is strongly encouraged.

As a group, STIs are the single most important cause of reproductive disorders. Until recently, the bacterial infections gonorrhea and syphilis were the most common STIs, but now viral diseases have taken center stage. AIDS, the most notorious STI, is caused by HIV, the virus that cripples the immune system (see Chapter 21). Here we focus on other important bacterial and viral STIs: gonorrhea, syphilis, chlamydia, trichomoniasis, genital warts, and genital herpes.

### Gonorrhea

The causative agent of **gonorrhea** (gon"o-re'ah) is *Neisseria gonorrhoeae*, which invades the mucosae of the reproductive and urinary tracts. These bacteria are spread by contact with genital, anal, and pharyngeal mucosal surfaces. Commonly called "the clap," gonorrhea occurs most frequently in adolescents and young adults.

In men, the most common symptom of gonorrhea is *urethritis*, inflammation of the urethra accompanied by painful urination and discharge of pus from the penis (penile "drip"). Symptoms vary in women, ranging from none (about 20% of cases) to abdominal discomfort, vaginal discharge, abnormal uterine bleeding, and occasionally, urethral symptoms similar to those seen in males.

In men, untreated gonorrhea can cause urethral constriction and inflammation of the entire male duct system. In women, it causes pelvic inflammatory disease and sterility. With the advent of antibiotics these complications have declined, and cases of gonorrhea in the United States have dropped to the lowest

rate ever recorded. However, antibiotic-resistant strains are becoming increasingly prevalent. Currently, ceftriaxone is the antibiotic used most often to treat gonorrhea.

### Syphilis

**Syphilis** (sif'i-lis), caused by the corkscrew-shaped bacterium *Treponema pallidum*, is usually transmitted sexually, but it can be contracted congenitally from an infected mother. Fetuses infected with syphilis are usually stillborn or die shortly after birth.

The bacterium easily penetrates intact mucosae and abraded skin. Within a few hours of exposure, an asymptomatic body-wide infection is in progress. After an incubation period of two to three weeks, a red, painless primary lesion called a *chancre* (shang'ker) appears at the site of bacterial invasion. In males, this is typically the penis, but in females the lesion often goes undetected within the vagina or on the cervix. The chancre ulcerates and becomes crusty, and then it heals spontaneously and disappears within a few weeks.

If syphilis is untreated, its secondary signs appear several weeks later. A pink skin rash all over the body is one of the first symptoms. Fever and joint pain are common. These signs and symptoms disappear spontaneously in three to twelve weeks. Then the disease enters the *latent period* and is detectable only by a blood test. The latent stage may last a person's lifetime (or the immune system may kill the bacteria), or it may be followed by *tertiary syphilis*.

Tertiary syphilis is characterized by *gummas* (gum'ahs), destructive lesions of the CNS, blood vessels, bones, and skin. Penicillin is still the treatment of choice for all stages of syphilis, but the number of recorded cases continues to increase in the U.S.

### Chlamydia

**Chlamydia** (klah-mid'e-ah; *chlamys* = cloak) is a largely undiagnosed, silent epidemic that is currently on the rise in college-age people. It infects perhaps 4–5 million people yearly, making it the most common bacterial sexually transmitted infection in the United States.

Chlamydia is responsible for 25–50% of all diagnosed cases of pelvic inflammatory disease (and, consequently, at least a one-in-four chance of ectopic pregnancy). Each year more than 150,000 infants are born to infected mothers. About 20% of men and 30% of women infected with gonorrhea are also infected by *Chlamydia trachomatis*, the causative agent of chlamydia.

*Chlamydia* is a bacterium with a viruslike dependence on host cells. Its incubation period within the body cells is about one week. Symptoms include urethritis (involving painful, frequent urination and a thick penile discharge); vaginal discharge; abdominal, rectal, or testicular pain; painful intercourse; and irregular menses. In men, it can cause arthritis as well as widespread urogenital tract infection. In women, 80% of whom suffer *no* symptoms from the infection, it is a major cause of sterility. Newborns infected in the birth canal tend to develop conjunctivitis (specifically, *trachoma*, a painful eye infection that leads to corneal scarring if untreated (often the case in

nonindustrialized countries) and respiratory tract inflammations including pneumonia.

Chlamydia can be diagnosed by cell culture techniques and is easily treated with tetracycline. In 2010, reported cases of chlamydia in the United States reached a record high of 1.2 million cases.

### Trichomoniasis

**Trichomoniasis** is the most common *curable* STI in sexually active young women in the United States. Accounting for about 7.4 million new cases of STI per year, this parasitic infection is easily and inexpensively treated. Trichomoniasis is indicated by a yellow-green vaginal discharge with a strong odor. However, many of its victims exhibit no symptoms.

### Genital Warts

**Genital warts** due to the *human papillomavirus (HPV)*—actually a group of about 60 viruses—is the second most common STI in the United States. About 6.2 million new cases of genital warts develop in Americans each year, and it appears that HPV infection increases the risk for cancers in infected body regions. Indeed, the virus is linked to 80% of all cases of invasive cervical cancer. Importantly, most of the strains that cause genital warts do not cause cervical cancer.

Treatment is difficult and controversial, and the warts tend to reappear. Some clinicians prefer to leave the warts untreated unless they become widespread, whereas others recommend their removal by cryosurgery or laser therapy, and/or treatment with alpha interferon.

### Genital Herpes

The cause of **genital herpes** is the *herpes simplex virus 2*, and these viruses are among the most difficult human pathogens to control. They remain silent for weeks or years and then suddenly flare up, causing a burst of blisterlike lesions. The virus is transmitted via infectious secretions or direct skin-to-skin contact when the virus is shedding. The painful lesions that appear on the reproductive organs of infected adults are usually more of a nuisance than a threat. However, congenital herpes infections can cause severe malformations of a fetus.

Most people who have genital herpes do not know it, and it has been estimated that one-quarter to one-half of all adult Americans harbor the herpes simplex virus 2. Only about 15% of that population displays signs of infection.

The antiviral drug *acyclovir*, which helps the lesions heal faster and reduces the frequency of flare-ups, is the treatment of choice. However, once contracted, genital herpes never leaves. It just goes into periodic remissions.

### ✓ Check Your Understanding

- Which pathogen is most associated with cervical cancer?
- What is the most common bacterial STI in the United States?

For answers, see Appendix H.

## Developmental Aspects of the Reproductive System

So far, we have described the reproductive organs as they exist and operate in adults. Now we are ready to look at events that cause us to become reproductive individuals. These events begin long before birth and end, at least in women, in late middle age.

### Embryological and Fetal Events

- ✓ Discuss the determination of genetic sex and prenatal development of male and female structures.

#### Determination of Genetic Sex

Aristotle believed that the “heat” of lovemaking determined maleness. Not so! Genetic sex is determined at the instant the genes of a sperm combine with those of an ovum, and the determining factor is the **sex chromosomes** each gamete contains. Of the 46 chromosomes in the fertilized egg, two (one pair) are sex chromosomes. The other 44 are called **autosomes**.

Two types of sex chromosomes, quite different in size, exist in humans: the large **X chromosome** and the much smaller **Y chromosome**. The body cells of females have two X chromosomes and are designated XX, and the ovum resulting from normal meiosis in a female always contains an X chromosome. Males have one X chromosome and one Y in each body cell (XY). Approximately half of the sperm produced by normal meiosis in males contain an X and the other half a Y.

If the fertilizing sperm delivers an X chromosome, the fertilized egg and its daughter cells will contain the female (XX) composition, and the embryo will develop ovaries. If the sperm bears a Y chromosome, the offspring will be male (XY) and will develop testes. A single gene on the Y chromosome—the **SRY** (for sex-determining region of the Y chromosome) **gene**—is the master switch that initiates testes development and hence maleness. Thus, the father’s gamete determines the genetic sex of the offspring. All subsequent events of sexual differentiation depend on which gonads form during embryonic life.

However, some of the genes present in autosomes are necessary for a male to become a functional male. Mutation of the SRY gene can result in XY individuals with the male chromosome but female sex characteristics.

### Homeostatic Imbalance 27.9

When meiosis distributes the sex chromosomes to the gametes improperly, an event called **nondisjunction**, abnormal combinations of sex chromosomes occur in the zygote (fertilized egg) and cause striking abnormalities in sexual and reproductive system development.

For example, females with a single X chromosome (XO), a condition called *Turner’s syndrome*, never develop ovaries. As a rule, females carrying four or more X chromosomes are mentally retarded and have underdeveloped ovaries and limited fertility.

*Klinefelter’s syndrome*, which affects one out of 500 live male births, is the most common sex chromosome abnormality.

Affected individuals usually have a single Y chromosome, two or more X chromosomes, and are sterile males. Although XXY males are normal (or only slightly below normal) intellectually, the incidence of mental retardation increases as the number of X chromosomes rises. Males with no X chromosome (YO) die during embryonic development. +

### Sexual Differentiation of the Reproductive System

The gonads of both males and females begin their development during week 5 of gestation as masses of mesoderm called the **gonadal ridges** (Figure 27.23). These ridges bulge from the dorsal abdominal wall just medial to the mesonephros (a transient kidney system, see p. 983). The **paramesonephric**, or **Müllerian, ducts** (future female ducts) develop lateral to the **mesonephric (Wolffian) ducts** (future male ducts), and both sets of ducts empty into a common chamber called the *cloaca*. At this stage of development, the embryo is said to be in the **sexually indifferent stage**, because the gonadal ridge tissue can develop into either male or female gonads and both duct systems are present.

Shortly after the gonadal ridges appear, **primordial germ cells** migrate to them from a different region of the embryo, the hindgut, presumably guided by a gradient of chemical signals (chemokines). There they seed the developing gonads with stem cells destined to become spermatogonia or oogonia. Once these cells are in residence, the gonadal ridges form testes or ovaries, depending on the genetic makeup of the embryo.

The process of forming the testes begins in week 7 in male embryos. Seminiferous tubules form in the internal part of the gonadal ridges and join the mesonephric duct via the efferent ductules. Further development of the mesonephric duct produces the duct system of the male. The paramesonephric ducts degenerate.

In female embryos the process of gonad formation begins about a week later. The outer, or cortical, part of each immature ovary forms follicles, and the paramesonephric ducts differentiate into the structures of the female duct system (the uterine tubes and uterus). The mesonephric ducts degenerate.

Like the gonads, the external genitalia arise from the same structures in both sexes (Figure 27.24). During the sexually indifferent stage, all embryos exhibit a small external projection called the **genital tubercle**. The urogenital sinus, which develops from subdivision of the cloaca (future urethra and bladder), lies deep to the tubercle. The **urethral groove**, the external opening of the urogenital sinus, is on the tubercle's inferior surface and is flanked laterally by the **urethral folds** and then the **labioscrotal swellings**.

During week 8, the external genitalia begin to develop rapidly. In males, the genital tubercle enlarges, forming the penis. The urethral folds fuse in the midline, forming the spongy urethra in the penis. Only the tips of the folds remain unfused to form the **urethral orifice** at the tip of the penis. The labioscrotal swellings also fuse medially to form the scrotum.

In females, the genital tubercle gives rise to the clitoris and the urethral groove persists as the vestibule. The unfused urethral folds become the labia minora, and the unfused labioscrotal folds become the labia majora.

Differentiation of accessory structures and the external genitalia into male or female structures depends on whether testosterone is present. When testes form, they quickly begin to release testosterone, which continues until four to five days after birth and which causes the development of male accessory ducts and external genitalia. In the absence of testosterone, the female ducts and external genitalia develop.

### Homeostatic Imbalance 27.10

Any interference with the normal pattern of sex hormone production in the embryo results in abnormalities. For example:

- If the embryonic testes do not produce testosterone, a genetic male develops female accessory structures and external genitalia.
- If a genetic female is exposed to testosterone (as might happen if the mother has an androgen-producing tumor of her adrenal gland), the embryo has ovaries but develops the male ducts and glands, as well as a penis and an empty scrotum.

It appears that the female pattern of reproductive structures has an intrinsic ability to develop (it is the default condition). In the absence of testosterone it proceeds to do so, regardless of the embryo's genetic makeup.

Individuals with external genitalia that do not “match” their gonads are called *pseudohermaphrodites* (soo-do-her-maf'ro-dīts). (True *hermaphrodites* who possess both ovarian and testicular tissue are rare.) Many pseudohermaphrodites have sought sex-change operations to match their outer selves (external genitalia) with their inner selves (gonads). +

### Descent of the Gonads

About two months before birth, the testes begin their descent toward the scrotum, dragging their supplying blood vessels and nerves along behind them. They finally exit from the pelvic cavity via the inguinal canals and enter the scrotum. Testosterone made by the fetus's testes stimulates this migration. The migration is mechanically guided by a strong fibrous cord called the **gubernaculum** (“governor”), which extends from the testis to the floor of the scrotal sac.

Initially the gubernaculum is a column of soft connective tissue, but it becomes increasingly fibrous as it continues to grow. By the seventh month of fetal development, it stops growing and its inferior part fills the inguinal canal. The gubernaculum's cessation of growth, coupled with the rapid growth of the fetal body, helps to pull the testes into the scrotum.

The *tunica vaginalis* covering of the testis is derived from a fingerlike outpocketing of the parietal peritoneum, the *vaginal process*. The accompanying blood vessels, nerves, and fascial layers form part of the *spermatic cord*, which helps suspend the testis within the scrotum.

Like the testes, the ovaries descend during fetal development, but in this case only to the pelvic brim, where the tentlike broad ligament stops their progress. Each ovary is guided in its descent by a gubernaculum (anchored in the labium majus) that later divides, becoming the ovarian and round ligaments that help support the internal genitalia in the pelvis.

**Figure 27.23** Development of the internal reproductive organs. (*SRY* = sex-determining region of the Y chromosome.)

**Figure 27.24** Development of homologous structures of the external genitalia in both sexes. The two pictures at the bottom of the figure show the fully developed perineal region.

### Homeostatic Imbalance 27.11

Failure of the testes to make their normal descent leads to *cryptorchidism* (*crypt* = hidden, concealed; *orchi* = testicle). Because cryptorchidism causes sterility and increases the risk of testicular cancer, surgery is usually performed during early childhood to rectify this problem. +

### Check Your Understanding

39. If a fertilized egg contains X and Y sex chromosomes, a baby girl will develop, right?
40. What is the sexually indifferent stage of development?

41. Which structure guides the descent of the testis into the scrotum?

For answers, see Appendix H.

### Puberty

-  Describe the significant events of puberty and menopause.

FSH and LH levels, elevated at birth, fall to low levels within a few months and remain low throughout the prepubertal years. Between the ages of 10 and 15 years, a host of interacting hormones bring on the changes of puberty.

**Puberty** is the period of life when the reproductive organs grow to adult size and become functional. As puberty nears, these changes occur in response to rising levels of gonadal hormones (testosterone in males and estrogen in females). Earlier we described secondary sex characteristics and regulatory events of puberty. But it is important to remember that puberty represents the earliest time that reproduction is possible.

The events of puberty occur in the same sequence in all individuals, but the age at which they occur varies widely.

In males, secretion of adrenal androgens, particularly dehydroepiandrosterone (DHEA), begins to rise several years before the testosterone surge of puberty and initiates facial, pubic, and axillary hair growth and other pubertal events. The major event that signals puberty's onset in males is enlargement of the testes and scrotum between the ages of 8 and 14. The penis grows over the next two years, and sexual maturation is evidenced by the presence of mature sperm in the semen (see Figure 27.11). In the meantime, the young man has unexpected erections and occasional nocturnal emissions ("wet dreams") as his hormones surge and the hormonal control axis struggles to achieve a normal balance.

In females, the first sign of puberty is budding breasts between the ages of 8 and 13, followed by the appearance of axillary and pubic hair. Menarche usually occurs about two years later. Dependable ovulation and fertility await the maturation of the hormonal controls, which takes nearly two more years.

Epiphyseal plate closure and termination of skeletal growth in height occurs in response to rising estrogen levels late in puberty in both boys and girls.

## Menopause

Most women reach the peak of their reproductive abilities in their late 20s. After that, ovarian function declines gradually, presumably because the ovaries become less and less responsive to gonadotropin signals. At age 30, there are still some 100,000 oocytes in the ovaries but the quality (hence fertility) has begun to decline. By age 50, there are probably 1000 eggs left (the pantry is nearly bare).

As estrogen production declines, many ovarian cycles become anovulatory, while in others 2 to 4 oocytes per month are ovulated, a sign of declining control. Increasingly frequent multiple ovulations explain why twins and triplets are more common in women who have deferred childbearing until their late 30s. In the perimenopausal period, menstrual periods become erratic and increasingly shorter. Eventually, ovulation and menstruation cease entirely. This normally occurs between the ages of 46 and 54, an event called *menopause*. **Menopause** is considered to have occurred when a whole year has passed without menstruation.

Although the ovaries continue to produce estrogen for a while after menopause, they finally stop functioning as endocrine organs. Without sufficient estrogen the reproductive organs and breasts begin to atrophy, the vagina becomes dry, and vaginal infections become increasingly common. Other sequels due to lack of estrogen include irritability and depression (in some women); intense vasodilation of the skin's blood vessels, which causes uncomfortable, sweat-drenching "hot flashes"; gradually thinning skin; and loss of bone mass. Slowly rising total blood

cholesterol levels and falling HDL levels place postmenopausal women at risk for cardiovascular disorders. At one time physicians prescribed low-dose estrogen-progesterone preparations to help women through this period and prevent skeletal and cardiovascular complications. This seemed like a great idea and by 2002, approximately 14 million American women were taking some form of estrogen-containing hormone replacement therapy (HRT). Then, the Women's Health Initiative (WHI) abruptly ended a clinical trial of 16,000 postmenopausal women, reporting that those who took a popular progesterone-estrogen medication had an increased risk of 51% in heart disease, 24% in invasive breast cancer, 31% in stroke, and a doubled risk of dementia compared to those taking placebos.

The backlash of this information (aired in the popular press) is still spreading through physicians' offices and research labs. It is restricting funding and the ability to find new volunteers for future studies, and has dampened enthusiasm for HRT in both the medical community and postmenopausal women. However, newer data suggest that the smallest dose of HRT for the shortest time is OK to reduce symptoms in women who do not have existing breast cancer or mutated *BRCA* gene(s).

There is no equivalent of menopause in males, and healthy men are able to father offspring well into their eighth decade of life thanks to their small but enduring population of stem cells (spermatogonia). However, aging men do exhibit a steady decline in testosterone secretion and experience a longer latent period after orgasm, a condition sometimes called *andropause*, and testosterone replacement therapy is currently being prescribed for more older men. Additionally, there is a noticeable difference in sperm motility with aging. Sperm of a young man can make it up the uterine tubes in 20–50 minutes, whereas those of a 75-year-old take 2½ days for the same trip.

### ✓ Check Your Understanding

42. What are the early signs of puberty's onset in boys?
43. What is the definition of menopause?

For answers, see Appendix H.

The reproductive system is unique among organ systems in at least two ways: (1) It is nonfunctional during the first 10–15 years of life, and (2) it is capable of interacting with the complementary system of another person—indeed, it *must* do so to carry out its biological function of pregnancy and birth. To be sure, having a baby is not always what the interacting partners have in mind, and we humans have devised a variety of techniques for preventing this outcome (see *A Closer Look* on pp. 1090–1091).

The major goal of the reproductive system is ensuring the healthy function of its own organs so that conditions are optimal for producing offspring. However, as illustrated in *System Connections*, gonadal hormones do influence other body organs, and the reproductive system depends on other body systems for oxygen and nutrients and to carry away and dispose of its wastes.

Now that we know how the reproductive system prepares itself for childbearing, we are ready to consider the events of pregnancy and prenatal development of a new living being, the topics of Chapter 28.

## Homeostatic Interrelationships Between the **Reproductive System** and Other Body Systems

### **Integumentary System** Chapter 5

- Androgens activate oil glands that lubricate skin and hair; gonadal hormones stimulate characteristic fat distribution and appearance of pubic and axillary hair; estrogen increases skin hydration, and during pregnancy it enhances facial skin pigmentation
- Skin protects all body organs by external enclosure; mammary gland secretions (milk) nourish the infant

### **Skeletal System** Chapters 6–8

- Androgens masculinize the skeleton and increase bone density; estrogen feminizes the skeleton and maintains bone mass in females
- The bony pelvis encloses some reproductive organs; if narrow, the bony pelvis may hinder vaginal delivery of an infant

### **Muscular System** Chapters 9–10

- Androgens promote increased muscle mass
- Abdominal muscles active during childbirth; muscles of the pelvic floor support reproductive organs and aid erection of penis/clitoris

### **Nervous System** Chapters 11–15

- Sex hormones masculinize or feminize the brain and influence sex drive
- Hypothalamus regulates timing of puberty; neural reflexes regulate events of sexual response

### **Endocrine System** Chapter 16

- Gonadal hormones exert feedback effects on hypothalamic-pituitary axis; placental hormones promote maternal hypermetabolism
- Gonadotropins (and GnRH) help regulate function of gonads; leptin signals the hypothalamus about the body's state of energy availability (in fat stores)

### **Cardiovascular System** Chapters 17–19

- Estrogens lower blood cholesterol levels and promote cardiovascular health in premenopausal women; pregnancy increases workload of the cardiovascular system
- Cardiovascular system transports needed substances to organs of reproductive system; local vasodilation involved in erection; blood transports sex hormones

### **Lymphatic System/Immunity** Chapters 20–21

- Developing embryo/fetus escapes immune surveillance (not rejected)
- Lymphatic vessels drain leaked tissue fluids; transport sex hormones; immune cells protect reproductive organs from disease; IgA is present in breast milk

### **Respiratory System** Chapter 22

- Pregnancy impairs descent of the diaphragm, promotes dyspnea
- Respiratory system provides oxygen; disposes of carbon dioxide; tidal volume increases during pregnancy while residual volume declines

### **Digestive System** Chapter 23

- Developing fetus crowds digestive organs; heartburn, constipation common during pregnancy
- Digestive system provides nutrients needed for health

### **Urinary System** Chapters 25–26

- Hypertrophy of the prostate inhibits urination; compression of bladder during pregnancy leads to urinary frequency and urgency
- Kidneys dispose of nitrogenous wastes and maintain acid-base balance of blood of mother and fetus; semen discharged through the urethra of the male

## Chapter Summary

1. The function of the reproductive system is to produce offspring. The gonads produce gametes (sperm or ova) and sex hormones. All other reproductive organs are accessory organs.

### Anatomy of the Male Reproductive System (pp. 1019–1026)

#### The Scrotum (pp. 1019–1020)

1. The scrotum contains the testes. It provides a temperature slightly lower than that of body temperature, as required to produce viable sperm.

#### The Testes (pp. 1020–1022)

2. Each testis is covered externally by a tunica albuginea that extends internally to divide the testis into many lobules. Each lobule contains sperm-producing seminiferous tubules and interstitial endocrine cells that produce androgens.

#### The Male Perineum and the Penis (pp. 1022–1023)

3. The male perineum which suspends the scrotum and penis, is the region encompassed by the pubic symphysis, ischial tuberosities, and coccyx.
4. The penis is largely erectile tissue (corpus spongiosum and corpora cavernosa). Engorgement of the erectile tissue with blood causes the penis to become rigid, an event called erection.

#### The Male Duct System (p. 1024)

5. The epididymis hugs the external surface of the testis and serves as a site for sperm maturation and storage.
6. The ductus (vas) deferens, extending from the epididymis to the ejaculatory duct, propels sperm into the urethra by peristalsis during ejaculation. Its terminus fuses with the duct of the seminal gland, forming the ejaculatory duct, which empties into the urethra within the prostate.
7. The urethra extends from the urinary bladder to the tip of the penis. It conducts semen and urine to the body exterior.

#### The Male Accessory Glands (pp. 1024–1026)

8. The accessory glands produce the bulk of the semen, which contains fructose from the seminal glands, an activating fluid from the prostate, and mucus from the bulbo-urethral glands.

#### Semen (p. 1026)

9. Semen is an alkaline fluid that dilutes and transports sperm. Important chemicals in semen are nutrients, prostaglandins, and antibiotic chemicals.

### Physiology of the Male Reproductive System (pp. 1026–1035)

#### Male Sexual Response (pp. 1026–1027)

1. Parasympathetic reflexes control erection.

2. Ejaculation is expulsion of semen from the male duct system, promoted by the sympathetic nervous system. Ejaculation is part of male orgasm, which also includes pleasurable sensations and increased pulse and blood pressure.

#### Spermatogenesis (pp. 1027–1033)

3. Spermatogenesis, the production of male gametes in the seminiferous tubules, begins at puberty.
4. Meiosis, the basis of gamete production, consists of two consecutive nuclear divisions without DNA replication in between. Meiosis reduces the chromosomal number by half and introduces genetic variability. Events unique to meiosis include synapsis and crossover of homologous chromosomes.
5. Spermatogonia divide by mitosis to maintain the germ cell line. Some of their progeny become primary spermatocytes, which undergo meiosis I to produce secondary spermatocytes. Secondary spermatocytes undergo meiosis II, each producing two haploid ( $n$ ) spermatids.
6. Spermiogenesis converts spermatids to functional sperm, stripping away superfluous cytoplasm and producing an acrosome and a flagellum (tail).
7. Sustentocytes form the blood testis barrier, nourish spermatogenic cells, move them toward the lumen of the tubules, and secrete fluid for sperm transport.

#### Hormonal Regulation of Male Reproductive Function (pp. 1033–1035)

8. GnRH, produced by the hypothalamus, stimulates the anterior pituitary gland to release FSH and LH. FSH causes sustentocytes to produce androgen-binding protein (ABP). LH stimulates interstitial endocrine cells to release testosterone, which binds to ABP, stimulating spermatogenesis. Testosterone and inhibin (produced by sustentocytes) feed back to inhibit the hypothalamus and anterior pituitary.
9. Maturation of hormonal controls occurs during puberty and takes about three years.
10. Testosterone stimulates maturation of the male reproductive organs and triggers the development of the secondary sex characteristics of the male. It exerts anabolic effects on the skeleton and skeletal muscles, stimulates spermatogenesis, and is responsible for male sex drive.

### Anatomy of the Female Reproductive System (pp. 1035–1043)

1. The female reproductive system produces gametes and sex hormones and houses a developing infant until birth.

#### The Ovaries (pp. 1035–1036)

2. The ovaries flank the uterus laterally and are held in position by the ovarian and suspensory ligaments and mesovaria.
3. Within each ovary are oocyte-containing follicles at different stages of development and possibly a corpus luteum.

#### The Female Duct System (pp. 1037–1041)

4. The uterine tube, supported by the mesosalpinx, extends from near the ovary to the uterus. Its fimbriae and ciliated distal end along with peristalsis create currents that help move an ovulated oocyte into the uterine tube.
5. The uterus has fundus, body, and cervical regions. It is supported by the broad, cardinal, uterosacral, and round ligaments.

- The uterine wall is composed of the outer perimetrium, the myometrium, and the inner endometrium. The endometrium consists of a functional layer (stratum functionalis), which sloughs off periodically unless an embryo has implanted, and an underlying basal layer (stratum basalis), which rebuilds the functional layer.
- The vagina extends from the uterus to the exterior. It is the copulatory organ and allows passage of the menstrual flow or a baby.

#### The External Genitalia and Female Perineum (p. 1041)

- The female external genitalia (vulva) include the mons pubis, labia majora and minora, clitoris, and the urethral and vaginal orifices. The labia majora house the mucus-secreting greater vestibular glands.

#### The Mammary Glands (pp. 1041–1043)

- The mammary glands lie over the pectoral muscles of the chest and are surrounded by adipose and fibrous connective tissue. Each mammary gland consists of many lobules, which contain milk-producing alveoli.

### Physiology of the Female Reproductive System (pp. 1043–1053)

#### Oogenesis (pp. 1043–1045)

- Oogenesis, the production of eggs, begins in the fetus. Oogonia, the diploid stem cells of female gametes, are converted to primary oocytes before birth. The infant female's ovaries contain about 1 million primary oocytes arrested in prophase of meiosis I.
- At puberty, meiosis resumes. Each month, one primary oocyte completes meiosis I, producing a large secondary oocyte and a tiny first polar body. Meiosis II of the secondary oocyte produces a functional ovum and a second polar body, but does not occur in humans unless a sperm penetrates the secondary oocyte.
- The ovum contains most of the primary oocyte's cytoplasm. The polar bodies are nonfunctional and degenerate.

#### The Ovarian Cycle (pp. 1045–1047)

- During the follicular phase (days 1–14), several primary follicles begin to mature. Generally, only one follicle per month completes the maturation process, becoming the dominant follicle. Late in this phase, the oocyte in the dominant follicle completes meiosis I. Ovulation occurs about day 14, releasing the secondary oocyte into the peritoneal cavity. Other developing follicles deteriorate.
- In the luteal phase (days 15–28), the ruptured follicle is converted to a corpus luteum, which produces progesterone and estrogen for the remainder of the cycle. If fertilization does not occur, the corpus luteum degenerates after about 10 days.

#### Hormonal Regulation of the Ovarian Cycle (pp. 1047–1049)

- Beginning at puberty, the hormones of the hypothalamus, anterior pituitary, and ovaries interact to establish and regulate the ovarian cycle. Establishment of the mature cyclic pattern, indicated by menarche, takes about four years. Leptin serves a permissive role in puberty's onset, stimulating the hypothalamus when adipose tissue is sufficient for the energy requirements of reproduction.
- The hormonal events of each ovarian cycle are as follows: (1) GnRH stimulates the anterior pituitary to release FSH and LH, which stimulate follicle maturation and estrogen production. (2) When blood estrogen reaches a certain level, positive feedback exerted on the hypothalamic-pituitary-gonadal axis causes a sudden release of LH that stimulates the primary oocyte to continue meiosis and triggers ovulation. LH then causes

conversion of the ruptured follicle to a corpus luteum and stimulates its secretory activity. (3) Rising levels of progesterone and estrogen inhibit the hypothalamic-pituitary-gonadal (HPG) axis, the corpus luteum deteriorates, ovarian hormones drop to their lowest levels, and the cycle begins anew.

#### The Uterine (Menstrual) Cycle (pp. 1049–1051)

- Varying levels of ovarian hormones in the blood trigger events of the uterine cycle.
- During the menstrual phase of the uterine cycle (days 1–5), the functional layer sloughs off in menses. During the proliferative phase (days 6–14), rising estrogen levels stimulate its regeneration, making the uterus receptive to implantation about one week after ovulation. During the secretory phase (days 15–28), the uterine glands secrete nutrients, and endometrial vascularity increases further.
- Falling levels of ovarian hormones during the last few days of the ovarian cycle cause the spiral arteries to become spastic and cut off the blood supply of the functional layer, and the uterine cycle begins again with menstruation.

#### Effects of Estrogens and Progesterone (p. 1051)

- Estrogen promotes oogenesis. At puberty, it stimulates the growth of the reproductive organs and the growth spurt and promotes the appearance of the secondary sex characteristics.
- Progesterone cooperates with estrogen in breast maturation and regulation of the uterine cycle.

#### Female Sexual Response (pp. 1051–1053)

- The female sexual response is similar to that of males. Orgasm in females is not accompanied by ejaculation.

#### Sexually Transmitted Infections (pp. 1053–1054)

- Sexually transmitted infections (STIs) are infectious diseases spread via sexual contact. Gonorrhea, syphilis, and chlamydia are bacterial diseases. Syphilis has broader consequences than most other sexually transmitted bacterial diseases since it can infect organs throughout the body. Trichomoniasis is a parasitic infection. Genital herpes and genital warts are viral infections; genital warts, caused by the HPV virus, are implicated in cervical cancer.

### Developmental Aspects of the Reproductive System (pp. 1054–1058)

#### Embryological and Fetal Events (pp. 1054–1057)

- Genetic sex is determined by the sex chromosomes: an X from the mother, an X or a Y from the father. If the fertilized egg contains XX, it is a female and develops ovaries; if it contains XY, it is a male and develops testes.
- Gonads of both sexes arise from the mesodermal gonadal ridges. The mesonephric ducts produce the male accessory ducts and glands. The paramesonephric ducts produce the female duct system.
- The external genitalia arise from the genital tubercle and associated structures. The development of male accessory structures and external genitalia depends on the presence of testosterone produced by the embryonic testes. In its absence, female structures develop.
- The testes descend into the scrotum from the abdominal cavity.

#### Puberty (pp. 1057–1058)

- Puberty is the interval when reproductive organs mature and become functional. It begins in males with penile and scrotal growth and in females with breast development.

## Menopause (p. 1058)

6. During menopause, ovulation and menstruation cease. Hot flashes and mood changes may occur. Postmenopausal events include atrophy of the reproductive organs, bone mass loss,

and increasing risk for cardiovascular disease. Men experience andropause with milder signs and symptoms of testosterone deficit.

## Review Questions

## Multiple Choice/Matching

(Some questions have more than one correct answer. Select the best answer or answers from the choices given.)

- The structures that draw an ovulated oocyte into the female duct system are (a) cilia, (b) fimbriae, (c) microvilli, (d) stereocilia.
- The usual site of embryo implantation is (a) the uterine tube, (b) the peritoneal cavity, (c) the vagina, (d) the uterus.
- The male homologue of the female clitoris is (a) the penis, (b) the scrotum, (c) the penile urethra, (d) the testis.
- Which of the following is correct relative to female anatomy? (a) the vaginal orifice is the most dorsal of the three openings in the perineum, (b) the urethra is between the vaginal orifice and the anus, (c) the anus is between the vaginal orifice and the urethra, (d) the urethra is the more ventral of the two orifices in the vulva.
- Secondary sex characteristics are (a) present in the embryo, (b) a result of male or female sex hormones increasing in amount at puberty, (c) the testis in the male and the ovary in the female, (d) not subject to withdrawal once established.
- Which of the following produces the male sex hormones? (a) seminal glands, (b) corpus luteum, (c) developing follicles of the testes, (d) interstitial endocrine cells.
- Which will occur as a result of nondescent of the testes? (a) male sex hormones will not be circulated in the body, (b) sperm will have no means of exit from the body, (c) inadequate blood supply will retard the development of the testes, (d) viable sperm will not be produced.
- The normal diploid number of human chromosomes is (a) 48, (b) 47, (c) 46, (d) 23, (e) 24.
- Relative to differences between mitosis and meiosis, choose the statements that apply *only* to events of meiosis. (a) tetrads present, (b) produces two daughter cells, (c) produces four daughter cells, (d) occurs throughout life, (e) reduces the chromosomal number by half, (f) synapsis and crossover of homologues occur.
- Match the key choices with the descriptive phrases below.  
Key: (a) androgen-binding protein (e) inhibin  
(b) estrogens (f) LH  
(c) FSH (g) progesterone  
(d) GnRH (h) testosterone  
\_\_\_\_ (1) Hormones that directly regulate the ovarian cycle  
\_\_\_\_ (2) Chemicals in males that inhibit the hypothalamic-pituitary-testicular axis  
\_\_\_\_ (3) Hormone that makes the cervical mucus viscous  
\_\_\_\_ (4) Potentiates the activity of testosterone on spermatogenic cells  
\_\_\_\_ (5) In females, exerts feedback inhibition on the hypothalamus and anterior pituitary  
\_\_\_\_ (6) Stimulates the secretion of testosterone
- The menstrual cycle can be divided into three continuous phases. Starting from the first day of the cycle, their consecutive order is (a) menstrual, proliferative, secretory, (b) menstrual, secretory, proliferative, (c) secretory, menstrual, proliferative,

- (d) proliferative, menstrual, secretory, (e) secretory, proliferative, menstrual.
- Spermatozoa are to seminiferous tubules as oocytes are to (a) fimbriae, (b) corpus albicans, (c) ovarian follicles, (d) corpora lutea.
- Which of the following does not add a secretion that makes a major contribution to semen? (a) prostate, (b) bulbo-urethral glands, (c) testes, (d) ductus deferens.
- The corpus luteum is formed at the site of (a) fertilization, (b) ovulation, (c) menstruation, (d) implantation.
- The sex of a child is determined by (a) the sex chromosome contained in the sperm, (b) the sex chromosome contained in the oocyte, (c) the number of sperm fertilizing the oocyte, (d) the position of the fetus in the uterus.
- FSH is to estrogen as estrogen is to (a) progesterone, (b) LH, (c) FSH, (d) testosterone.
- A drug that “reminds the pituitary” to produce gonadotropins might be useful as (a) a contraceptive, (b) a diuretic, (c) a fertility drug, (d) an abortion stimulant.

## Short Answer Essay Questions

- Why is the term *urogenital system* more applicable to males than to females?
- Describe the major structural (and functional) regions of a sperm.
- Oogenesis in the female results in one functional gamete—the egg, or ovum. What other cells are produced? What is the significance of this rather wasteful type of gamete production—that is, production of a single functional gamete instead of four, as seen in males?
- Describe the events and possible consequences of menopause.
- Define menarche. What does it indicate?
- Trace the pathway of a sperm from the male testes to the uterine tube of a female.
- In menstruation, the stratum functionalis is shed from the endometrium. Explain the hormonal and physical factors responsible for this shedding. (Hint: See Figure 27.22.)
- Both the epithelium of the vagina and the cervical glands of the uterus help prevent the invasion and spread of vaginal pathogens. Explain how each of these mechanisms works.
- Some anatomy students were saying that the bulbo-urethral glands of males act like city workers who come around and clear parked cars from the street before a parade. What did they mean by this analogy?
- A man swam in a cold lake for an hour and then noticed that his scrotum was shrunken and wrinkled. His first thought was that he had lost his testicles. What had really happened?

## Critical Thinking and Clinical Application Questions

- Gina Marciano, a 44-year-old mother of eight children, visited her physician complaining of a “bearing down” sensation in her pelvis, low backache, and urinary incontinence. A vaginal examination showed that the external os of her cervix was just inside the vaginal orifice and her perineum exhibited large

- keloids (masses of scar tissue). Her history revealed that she was a member of a commune located in the nearby mountains that shunned hospital births (if at all possible). What do you think Gina's problem is and what caused it? (Be anatomically specific.)
- Harry, a sexually active adolescent, appeared in the emergency room complaining of a penile “drip” and pain during urination. An account of his recent sexual behavior was requested and recorded. (a) What do you think Harry's problem is? (b) What is the causative agent of this disorder? (c) How is the condition treated, and what may happen if it isn't treated?
  - A 36-year-old mother of four is considering tubal ligation to ensure that her family gets no larger. She asks the physician if she

- will become “menopausal” after the surgery. (a) How would you answer her question and explain away her concerns? (b) Explain what a tubal ligation is.
- Mr. Scanlon, a 76-year-old gentleman, is interested in a much younger woman. Concerned because of his age, he asks his urologist if he will be able to father a child. What questions would a physician ask of this man, and what diagnostic tests would be ordered?
  - Lucy had both her left ovary and her right uterine tube removed surgically at age 17 because of a cyst and a tumor in these organs. Now, at age 32, she remains healthy and is expecting her second child. How could Lucy conceive a child with just one ovary and one uterine tube, widely separated on opposite sides of the pelvis like this?

## AT THE CLINIC

### Related Clinical Terms

**Dysmenorrhea** (dis'men-ō-re'ah; *dys* = bad, *meno* = menses, a month) Painful menstruation; may reflect abnormally high prostaglandin activity during menses.

**Endometrial cancer** Cancer that arises from the uterine endometrium (usually from uterine glands). Most important sign is vaginal bleeding, which allows early detection. Risk factors include obesity and HRT.

**Endometriosis** (en'do-me'tre-o'sis) An inflammatory condition in which endometrial tissue occurs and grows atypically in the pelvic cavity. Characterized by abnormal uterine or rectal bleeding, dysmenorrhea, and pelvic pain. May cause sterility.

**Gynecology** (gi'nē-kol'o-je; *gyneco* = woman, *ology* = study of) Specialized branch of medicine that deals with the diagnosis and treatment of female reproductive system disorders.

**Gynecomastia** (gi'nē-ko-mas'te-ah) Development of breast tissue in the male; a consequence of adrenal cortex hypersecretion of estrogens, certain drugs (cimetidine, spironolactone, and some chemotherapeutic agents), and marijuana use.

**Hysterectomy** (his'tē-rek'to-me; *hyster* = uterus, *ectomy* = cut out) Surgical removal of the uterus.

**Inguinal hernia** Protrusion of part of the intestine into the scrotum or through a separation in the abdominal muscles in the groin region. Since the inguinal canals represent weak points in the abdominal wall, inguinal hernia may be caused by heavy lifting or other activities that increase intra-abdominal pressure.

**Laparoscopy** (lap'ah-ros'ko-pe; *lapar* = the flank, *scopy* = observation) Examination of the abdominopelvic cavity with a laparoscope, a viewing device at the end of a thin tube inserted through the anterior abdominal wall. Laparoscopy is often used to assess the condition of a woman's pelvic reproductive organs.

**Oophorectomy** (o'of-o-rek'to-me; *oophor* = ovary) Surgical removal of the ovary.

**Orchitis** (or-ki'tis; *orcho* = testis) Inflammation of the testes, sometimes caused by the mumps virus.

**Ovarian cancer** Malignancy that typically arises from the cells in the germinal epithelial covering of the ovary. The fifth most common reproductive system cancer, its incidence increases with age. Called the “disease that whispers” because early symptoms are nondescript and easily mistaken for other disorders (back pain, abdominal discomfort, nausea, bloating, and flatulence). Diagnosis may involve palpating a mass during a physical exam, visualizing it with an ultrasound probe, or conducting blood tests for a protein marker for ovarian cancer (CA-125). However, medical assessment is often delayed until after metastasis has occurred; five-year survival rate is 90% if the condition is diagnosed before metastasis.

**Ovarian cysts** The most common disorders of the ovary; some are tumors. Types include (1) *simple follicle retention cysts* in which single or clustered follicles become enlarged with a clear fluid; (2) *dermoid cysts*, which are filled with a thick yellow fluid and contain partially developed hair, teeth, bone, etc.; and (3) *chocolate cysts* filled with dark gelatinous material, which are the result of endometriosis of the ovary. None of these is malignant, but the latter two may become so.

**Polycystic ovary syndrome (PCOS)** The most common endocrinopathy in women and the most common cause of anovulatory infertility. Affects 5–10% of women; characterized by signs of androgen excess, increased cardiovascular risk (evidenced by high blood pressure, decreased HDL cholesterol levels, and high triglycerides); and linked to extreme obesity and some degree of insulin resistance. Treated with insulin-sensitizing drugs.

**Salpingitis** (sal'pin-ji'tis; *salpingo* = uterine tube) Inflammation of the uterine tubes.

### Case Study Reproductive System

We are back to look in on Mr. Heyden today. Since we last saw him (Chapter 26), he has had an X ray to determine the cause of his back pain, and his blood test results have come in. According to

the note recorded at radiology: X irradiation of skeleton displays numerous carcinomatous metastases in his skull and lumbar vertebrae. The hematology note of interest here reads: PSA levels abnormally high.

- What is carcinoma? What do you suppose is the primary source of the secondary carcinoma lesions in his skull and spine?
- On what basis did you come to this conclusion?
- What other tests might be of some diagnostic help here?
- What type of therapy do you predict Mr. Heyden will be given to treat his carcinoma? Why?

**T**he birth of a baby is such a familiar event that we tend to lose sight of the wonder of this accomplishment: How does a single cell, the fertilized egg, grow to become a complex human being consisting of trillions of cells? The details of this process can fill a good-sized book. Our intention here is simply to outline the important events of gestation and to consider briefly the events occurring immediately after birth.

**Figure 28.1** Diagrams showing the approximate size of a human conceptus from fertilization to the early fetal stage. The embryonic stage is from fertilization through week 8; the fetal stage begins in week 9. (Measurements are crown to rump length.)

Let's get started by defining some terms. The term **pregnancy** refers to events that occur from the time of fertilization (conception) until the infant is born. The pregnant woman's developing offspring is called the **conceptus** (kon-sep'tus; "that which is conceived"). Development occurs during the **gestation period** (*gestare* = to carry), which extends by convention from the last menstrual period (a date the woman is likely to remember) until birth, approximately 280 days. So, at the moment of fertilization, the mother is officially (but illogically) two weeks pregnant!

From fertilization through week 8, the *embryonic period*, the conceptus is called an **embryo**, and from week 9 through birth, the *fetal period*, the conceptus is called a **fetus** ("the young in the womb"). At birth, it is an infant. **Figure 28.1** shows the changing size and shape of the conceptus as it progresses from fertilization to the early fetal stage.

## From Egg to Zygote

- ✓ Describe the importance of sperm capacitation.
- ✓ Explain the mechanism of the slow block to polyspermy.
- ✓ Define fertilization.

Before fertilization can occur, sperm must reach the ovulated secondary oocyte. The oocyte is viable for 12 to 24 hours after it is cast out of the ovary. The chance of pregnancy drops to almost zero the next day. Most sperm retain their fertilizing power for 24 to 48 hours after ejaculation. Consequently, for successful fertilization to occur, coitus must occur no more than two days before ovulation and no later than 24 hours after. At this point the oocyte is approximately one-third of the way down the length of the uterine tube.

## Accomplishing Fertilization

**Fertilization** occurs when a sperm's chromosomes combine with those of an egg (actually a secondary oocyte) to form a fertilized egg, or **zygote** (zi'gōt; "yoked together"), the first cell of the new individual. Let's look at the events leading to fertilization.

### Sperm Transport and Capacitation

During copulation, a man expels millions of sperm with considerable force into his partner's vaginal canal. Despite this "head start," most sperm don't reach the oocyte, even though it is only about 12 cm (5 inches) away. Millions of sperm leak from the vagina almost immediately after being deposited there. Of those

remaining, millions more are destroyed by the vagina's acidic environment. Millions more fail to make it through the cervix, unless the thick "curtain" of cervical mucus has been made fluid by estrogens.

Sperm that do reach the uterus, propelled by their whiplike tail movements, are then subjected to forceful uterine contractions that act in a washing machine-like manner to disperse them throughout the uterine cavity, where thousands more are destroyed by resident phagocytes. Only a few thousand (and sometimes fewer than 100) sperm, out of the millions in the male ejaculate, are conducted by reverse peristalsis into the uterine tube, where the oocyte may be moving leisurely toward the uterus.

These difficulties aside, there is still another hurdle to overcome. Sperm freshly deposited in the vagina are incapable of penetrating an oocyte. They must first be **capacitated** over the next 2 to 10 hours. Specifically, their motility must be enhanced and their membranes must become fragile so that the hydrolytic enzymes in their acrosomes can be released. As sperm swim through the cervical mucus, uterus, and uterine tubes, secretions of the female tract remove some of their protective membrane proteins, and the cholesterol that keeps their acrosomal membranes "tough" and stable is depleted. Even though the sperm may reach the oocyte within a few minutes, they must "wait around" (so to speak) for capacitation to occur.

This elaborate mechanism prevents the spilling of acrosomal enzymes. But consider the alternative. Fragile acrosomal membranes could rupture prematurely in the male reproductive tract, causing some degree of autolysis (self-digestion) of the male reproductive organs.

How do sperm navigate to find a released oocyte in the uterine tube? This question is an area of active research. It now appears that they "sniff" their way to the oocyte. Sperm bear proteins called *olfactory receptors* that respond to chemical stimuli. It is presumed that the oocyte or its surrounding cells release signaling molecules that direct the sperm.

### Acrosomal Reaction and Sperm Penetration

The ovulated oocyte is encapsulated by the corona radiata and by the deeper zona pellucida, a transparent layer of glycoprotein-rich extracellular matrix secreted by the oocyte. Both must be breached before the oocyte can be penetrated. Once in the immediate vicinity of the oocyte, a sperm weaves its way through the cells of the corona radiata. This journey is assisted by a cell-surface hyaluronidase on the sperm that digests the intercellular cement between the granulosa cells in the local area, causing them to fall away from the oocyte (*Focus on Sperm Penetration and the Cortical Reaction*, **Figure 28.2** ①, p. 1068).

After breaching the corona, the sperm head binds to a ZP3 glycoprotein of the zona pellucida, which functions as a sperm receptor. This binding opens calcium channels, which leads to a rise in  $\text{Ca}^{2+}$  inside the sperm that triggers the acrosomal (ak'ro-so'mal) reaction (**Figure 28.2** ②). The **acrosomal reaction**

involves the release of acrosomal enzymes (hyaluronidase, acrosin, proteases, and others) that digest holes through the zona pellucida. Hundreds of acrosomes must undergo exocytosis to digest holes in the zona pellucida. This is one case that does not bear out the adage, "The early bird catches the worm." A sperm that comes along later, after hundreds of sperm have undergone acrosomal reactions to expose the oocyte membrane, is in the best position to be *the* fertilizing sperm.

Once a path is cleared, the sperm's whiplike tail gyrates, forcing the sperm's head to rock and move toward the oocyte membrane. There the sperm's postacrosomal "collar," the rear portion of the acrosomal membrane, binds to the oocyte's plasma membrane receptors (**Figure 28.2** ③). This binding event has two consequences. (a) It causes the oocyte to form microvilli that surround the sperm head, and the sperm and oocyte membranes to fuse (**Figure 28.2** ④), and then (b) like a snake crawling out of its skin, the cytoplasmic contents of the sperm enter the oocyte, leaving the sperm's plasma membrane behind (**Figure 28.2** ⑤). The gametes fuse together with such perfect contact that the contents of both cells are combined within a single membrane—all without spilling a drop.

### Block to Polyspermy

**Polyspermy** (entry of several sperm into an egg) occurs in some animals, but in humans only one sperm is allowed to penetrate the oocyte, ensuring **monospermy**, the one-sperm-per-oocyte condition. Once the sperm head has entered the oocyte, waves of  $\text{Ca}^{2+}$  are released by the oocyte's endoplasmic reticulum into its cytoplasm, which activates the oocyte to prepare for the second meiotic division. These calcium surges also cause the **cortical reaction** (**Figure 28.2** ⑤), in which granules located just inside the plasma membrane spill their enzymes into the extracellular space beneath the zona pellucida. These enzymes, called *zonal inhibiting proteins* (ZIPs), destroy the sperm receptors, preventing any more sperm from entering.

Additionally, the spilled material binds water, and as the material swells and hardens, it detaches all sperm still bound to receptors on the oocyte membrane, completing the so-called *slow block to polyspermy*. In the rare cases of polyspermy that do occur, the embryos contain too much genetic material and die.

### Completion of Meiosis II and Fertilization

As the sperm's cytoplasmic contents enter the oocyte, the sperm loses its plasma membrane. The centrosome from its midpiece elaborates microtubules which the sperm uses to locomote its DNA-rich nucleus toward the oocyte nucleus. On the way, its nucleus swells to about five times its normal size to form the **male pronucleus** (pro-nu'kle-us; *pro* = before). Meanwhile the secondary oocyte, activated from its semidormant state by the calcium surges, completes meiosis II, forming the ovum nucleus and the second polar body (**Figure 28.3a** ① and ②, p. 1070).

This accomplished, the ovum nucleus swells, becoming the **female pronucleus**, and the two pronuclei approach each other.

As a mitotic spindle develops between them (Figure 28.3a ③), the pronuclei membranes rupture, releasing their chromosomes together into the immediate vicinity of the newly formed spindle.

The true moment of fertilization occurs as the maternal and paternal chromosomes combine and produce the diploid *zygote*, or fertilized egg (Figure 28.3a ④). Some sources define the term fertilization simply as the act of oocyte penetration by the sperm. However, unless the chromosomes in the male and female pronuclei are actually combined, the zygote is never formed in humans. Almost as soon as the male and female pronuclei come together, their chromosomes replicate. The zygote, the first cell of a new individual, is now ready to undergo the first mitotic division of the conceptus.

### ✓ Check Your Understanding

1. What has to happen before ejaculated sperm can penetrate an oocyte?
2. What is the cortical reaction and what does it accomplish?

For answers, see Appendix H.

## Events of Embryonic Development: Zygote to Blastocyst Implantation

Early embryonic development begins with fertilization and continues as the embryo travels through the uterine tube, floats free in the cavity of the uterus, and finally implants in the uterine wall. Significant events of this early embryonic period are *cleavage*, which produces a structure called a blastocyst, and *implantation* of the blastocyst.

### Cleavage and Blastocyst Formation

✓ Describe the process and product of cleavage.

**Cleavage** is a period of fairly rapid mitotic divisions of the zygote without intervening growth (Figure 28.4, p. 1071). The goal of this first phase of development is to produce small cells with a high surface-to-volume ratio, which enhances their uptake of nutrients and oxygen and the disposal of wastes. It also provides a large number of cells to serve as building blocks for constructing the embryo. Consider, for a moment, the difficulty of trying to construct a building from one huge block of granite. If you now consider how much easier it would be if instead you could use hundreds of bricks, you will quickly grasp the importance of cleavage.

Some 36 hours after fertilization, the first cleavage division of the zygote has produced two identical cells called *blastomeres*. These divide to produce four cells (Figure 28.4b), then eight, and so on. By 72 hours after fertilization, a loose collection of

cells that form a berry-shaped cluster of 16 or more cells called the **morula** (mor'u-lah; "little mulberry") has been formed (Figure 28.4c). All the while, transport of the embryo toward the uterus continues.

By day 4 or 5 after fertilization, the embryo consists of about 100 cells, has begun accumulating fluid within an internal cavity, and floats free in the uterus (Figure 28.4d). The zona pellucida now starts to break down and the inner structure, now called a blastocyst, "hatches" from it. The **blastocyst** (blas'to-sist) is a fluid-filled hollow sphere composed of a single layer of large, flattened cells called **trophoblast cells** (tro'fo-blast) and a small cluster of 20 to 30 rounded cells, called the **inner cell mass**, located at one side (Figure 28.4e).

Soon after the blastocyst forms, trophoblast cells begin to display L-selectin adhesion molecules on their surface. They take part in placenta formation, as suggested by the literal translation of "trophoblast" (nourishment generator). They also secrete and display several factors with immunosuppressive effects that protect the trophoblast (and the developing embryo) from attack by the mother's cells.

The inner cell mass becomes the *embryonic disc*, which forms the embryo proper, and three of the four extraembryonic membranes. (The fourth membrane, the chorion, is a trophoblast derivative.)

### ✓ Check Your Understanding

3. Why is the multicellular blastocyst only slightly larger than the single-celled zygote?
4. What is the function of the trophoblast cells?

For answers, see Appendix H.

## Implantation

✓ Describe implantation.

While the blastocyst floats in the uterine cavity for two to three days, it is nourished by the glycoprotein-rich uterine secretions, which also contain steroids and various nutrients including iron and fat-soluble vitamins. Then, some six to seven days after ovulation, given a properly prepared endometrium, **implantation** begins. The receptivity of the endometrium to implantation—the so-called *window of implantation*—is opened by the surging levels of ovarian hormones (estrogens and progesterone) in the blood. If the mucosa is properly prepared, integrin and selectin proteins on the trophoblast cells bind respectively to the extracellular matrix components (collagen, fibronectin, laminin, and others) of the endometrial cells and to selectin-binding carbohydrates on the inner uterine wall, and the blastocyst implants high in the uterus. If the endometrium is not yet optimally mature, the blastocyst detaches and floats to a lower level, implanting when it finds a site with the proper receptors and chemical signals.

(Text continues on p. 1070.)

**Figure 28.2** Sperm use acrosomal enzymes and receptors to approach, bind, and enter the oocyte. The cortical reaction prevents further sperm entry, ensuring that only two copies of each chromosome are present in the fertilized ovum.

**② Acrosomal reaction.** Binding of the sperm to sperm-binding receptors in the zona pellucida causes the  $\text{Ca}^{2+}$  levels within the sperm to rise, triggering the acrosomal reaction. Acrosomal enzymes from many sperm digest holes through the zona pellucida, clearing a path to the oocyte membrane.

**③ Binding.** The sperm's membrane binds to the oocyte's sperm-binding receptors.

**④ Fusion.** The sperm and oocyte plasma membranes fuse, allowing sperm contents to enter the oocyte.

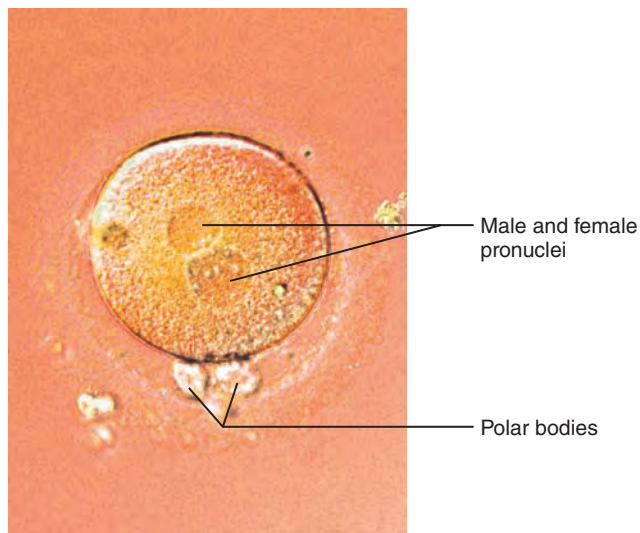

**⑤ Block of polyspermy.** Entry of the sperm's contents causes  $\text{Ca}^{2+}$  levels in the oocyte's cytoplasm to rise, triggering the cortical reaction (exocytosis of cortical granules). As a result, the zona pellucida hardens and the sperm receptors are clipped off (slow block to polyspermy).

(a)

(b)

**Figure 28.3 Events of fertilization.** (a) Events from sperm penetration to zygote formation. (b) Micrograph of an oocyte in which the male and female pronuclei are beginning to fuse to accomplish fertilization and form the zygote. Occurs in time between steps ③ and ④ of (a).

The trophoblast cells overlying the inner cell mass adhere to the endometrium (Figure 28.5a, b) and secrete digestive enzymes and growth factors against the endometrial surface. The endometrium quickly thickens at the point of contact and takes on characteristics of an acute inflammatory response—the uterine blood vessels become more permeable and leaky, and inflammatory cells including lymphocytes, natural killer cells, and macrophages invade the area.

The trophoblast then proliferates and forms two distinct layers (Figure 28.5c). The cells in the inner layer, collectively called the **cytotrophoblast** (si'to-tro'fo-blast) or **cellular trophoblast**, retain their cell boundaries. The cells in the outer layer lose their plasma membranes and form a multinuclear cytoplasmic mass called the **syncytiotrophoblast** (sin-sit'e-o-tro'fo-blast; *syn* = together, *cyt* = cell) or **syncytial trophoblast**. This syncytial region sends out long protrusions that invade the endometrium and rapidly digest the uterine cells it contacts. As the endometrium is eroded, the blastocyst burrows into this thick, velvety lining and is surrounded by a pool of blood leaked from degraded endometrial blood vessels. Shortly, proliferation of the endometrial cells covers and seals off the implanted blastocyst from the uterine cavity (Figure 28.5d).

In cases where implantation fails to occur, a receptive uterus becomes nonreceptive once again. It is estimated that a minimum of two-thirds of all zygotes formed fail to implant by the end of the first week or spontaneously abort. Moreover, an estimated 30% of implanted embryos later miscarry due to genetic defects of the embryo, uterine malformation, or unknown problems.

When successful, implantation takes about five days and is usually completed by the 12th day after ovulation—just before the endometrium normally begins to slough off. Menstruation would flush away the embryo as well and must be prevented if the pregnancy is to continue. Viability of the corpus luteum is maintained by an LH-like hormone called **human chorionic gonadotropin (hCG)** (ko're-on'ik go-nad'o-tröp'in) secreted by the trophoblast cells. hCG bypasses hypothalamic-pituitary-ovarian controls at this critical time and prompts the corpus luteum to continue secreting progesterone and estrogen. The *chorion*, the extraembryonic membrane that develops from the trophoblast after implantation, continues this hormonal stimulus. In this way, the developing conceptus takes over the hormonal control of the uterus during this early phase of development. Besides rescuing the corpus luteum, hCG has protease activity and is an autocrine growth factor that promotes placental development. hCG levels are particularly high in areas where the trophoblast faces the endometrium.

Usually detectable in the mother's blood one week after fertilization, blood levels of hCG continue to rise until the end

**Figure 28.4 Cleavage: From zygote to blastocyst.** The zygote begins to divide about 24 hours after fertilization, and continues the more rapid mitotic divisions of cleavage as it travels down the uterine

tube. Three to four days after ovulation, the embryo reaches the uterus and floats freely for two to three days, nourished by secretions of the endometrial glands. Because there is little time for growth between successive

cleavage divisions, the resulting blastocyst is only slightly larger than the zygote. At the late blastocyst stage, the embryo implants into the endometrium; this begins at about day 7 after ovulation.

of the second month. Then, blood levels decline sharply to reach a low value by 4 months, a situation that persists for the remainder of gestation (**Figure 28.6**). Between the second and third month, the placenta (which we describe next) assumes the role of progesterone and estrogen production for the remainder of the pregnancy. The corpus luteum then degenerates and the ovaries remain inactive until after birth. All pregnancy tests used today are antibody tests that detect hCG in a woman's blood or urine.

Initially, the implanted embryo obtains its nutrition by digesting the endometrial cells, but by the second month, the placenta is providing nutrients and oxygen to the embryo and carrying away embryonic metabolic wastes. Since placenta formation is a continuation of the events of implantation, we will consider it next, although we will be getting a little ahead of ourselves as far as embryonic development is concerned.

### ✓ Check Your Understanding

- Which portion of the trophoblast accomplishes implantation?
- Marie, wondering if she is pregnant, buys an over-the-counter pregnancy test to assess this possibility. How will the blastocyst, if present, "make itself known"?

For answers, see Appendix H.

### Placentation

- ✓ Describe placenta formation, and list placental functions.

**Placentation** (plas"en-ta'shun) refers to the formation of a **placenta** ("flat cake"), a temporary organ that originates from both embryonic and maternal (endometrial) tissues. Cells from the original inner cell mass give rise to a layer of extraembryonic mesoderm that

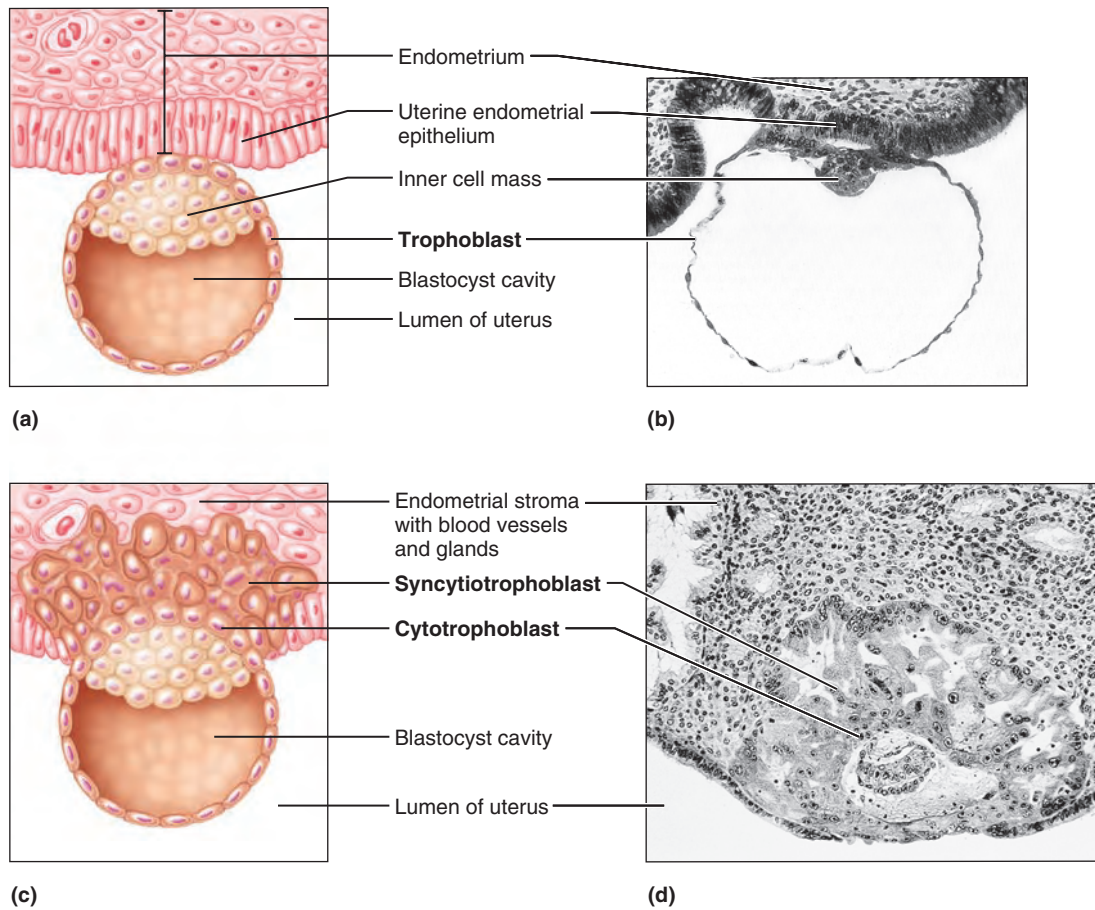

**Figure 28.5** Implantation of the blastocyst.

(c) Slightly later stage of an implanting embryo (approximately seven days after ovulation), depicting the cytotrophoblast and syncytiotrophoblast of the eroding trophoblast. (d) Light micrograph of an implanted blastocyst (approximately 12 days after ovulation).

Source: (b) R. O’Rahilly and R. Muller, *Human Embryology and Teratology*, Wiley-Liss, 3rd Edition, 2001. This material is reproduced with permission of Wiley-Liss, Inc., a subsidiary of John Wiley & Sons, Inc.

**Figure 28.6** Hormonal changes during pregnancy. The relative changes in maternal blood levels of three hormones that maintain pregnancy are depicted, rather than actual blood concentrations.

lines the inner surface of the trophoblast (Figure 28.7b). Together these become the **chorion**. The chorion develops fingerlike **chorionic villi**, which become especially elaborate where they are in contact with maternal blood (Figure 28.7c).

Soon the mesodermal cores of the chorionic villi are invaded by newly forming blood vessels, which extend to the embryo as the umbilical arteries and vein. The continuing erosion produces large, blood-filled **lacunae**, or **intervillous spaces**, in the stratum functionalis of the endometrium (see Figure 27.15, p. 1039). The villi come to lie in these spaces totally immersed in maternal blood, which is continuously refreshed by extravascularized maternal blood (Figure 28.7d). The part of the endometrium that lies beneath the embryo becomes the **decidua basalis** (de-sid’u-ah), and that surrounding the uterine cavity face of the implanted embryo forms the **decidua capsularis** (Figure 28.7d and e). Together, the chorionic villi and the decidua basalis form the disc-shaped placenta.

The placenta detaches and sloughs off after the infant is born, so the name of the maternal portion—**decidua** (“that which falls off”)—is appropriate. During development, the decidua capsularis expands to accommodate the fetus, which eventually fills and stretches the uterine cavity. As the developing fetus grows, the villi in the decidua capsularis are compressed and degenerate, while those in the decidua basalis increase in number and branch even more profusely.

The placenta is usually fully functional as a nutritive, respiratory, excretory, and endocrine organ by the end of the third

(a) **Implanting 7½-day blastocyst.** The syncytiotrophoblast is eroding the endometrium. Cells of the embryonic disc are now separated from the amnion by a fluid-filled space.

(b) **12-day blastocyst.** Implantation is complete. Extraembryonic mesoderm is forming a discrete layer beneath the cytotrophoblast.

(c) **16-day embryo.** Cytotrophoblast and associated mesoderm have become the chorion, and chorionic villi are elaborating. The embryo exhibits all three germ layers, a yolk sac, and an allantois, which forms the basis of the umbilical cord.

(d) **4½-week embryo.** The decidua capsularis, decidua basalis, amnion, and yolk sac are well formed. The chorionic villi lie in blood-filled intervillous spaces within the endometrium. The embryo is nourished via the umbilical vessels that connect it (through the umbilical cord) to the placenta.

(e) **13-week fetus.**

**Figure 28.7** Events of placentation, early embryonic development, and extraembryonic membrane formation.

month of pregnancy. However, well before this time, oxygen and nutrients are diffusing from maternal to embryonic blood, and embryonic metabolic wastes are passing in the opposite direction. The barriers to free passage of substances between the two blood supplies are embryonic barriers—the membranes of the chorionic villi and the endothelium of embryonic capillaries. Although the maternal and embryonic blood supplies are very close, they normally do not intermix (**Figure 28.8**).

The placenta secretes hCG from the beginning, but the ability of its syncytiotrophoblast cells (the “hormone manufacturers”) to produce the estrogens and progesterone of pregnancy matures much more slowly. If, for some reason, placental hormones are inadequate when hCG levels wane, the endometrium degenerates and the pregnancy is aborted. Throughout pregnancy, blood levels of estrogens and progesterone continue to increase (see **Figure 28.6**). They encourage growth and further

**Figure 28.8** Detailed anatomy of the vascular relationships in the mature decidua basalis. This state of development has been accomplished by the end of the third month of development.

differentiation of the mammary glands and ready them for lactation. The placenta also produces other hormones, such as *human placental lactogen* and *relaxin*. Shortly we will describe the effects of these hormones on the mother.

### ✓ Check Your Understanding

7. What is the composition of the chorion?
8. What endometrial decidua cooperates with the chorionic villi to form the placenta?
9. Generally speaking, when does the placenta become fully functional?

For answers, see Appendix H.

## Events of Embryonic Development: Gastrula to Fetus

Having followed placental development into the fetal stage, we will now backtrack and consider development of the embryo during and after implantation, referring again to Figure 28.7. Even while implantation is occurring, the blastocyst is being converted to a **gastrula** (gas'troo-lah), in which the three primary germ layers form, and the extraembryonic membranes develop. Before becoming three-layered, the inner cell mass first subdivides into two layers—the upper *epiblast* and the lower *hypoblast* (Figure 28.7a, b). The subdivided inner cell mass is now called the **embryonic disc**.

## Formation and Roles of the Extraembryonic Membranes

- ✓ Name and describe the formation, location, and function of the extraembryonic membranes.

The **extraembryonic membranes** that form during the first two to three weeks of development include the amnion, yolk sac, allantois, and chorion (Figure 28.7c). The **amnion** (am'ne-on) develops when cells of the epiblast fashion themselves into a transparent membranous sac. This sac, the amnion, becomes filled with **amniotic fluid**. Later, as the embryonic disc curves to form the tubular body, the amnion curves with it. Eventually, the sac extends all the way around the embryo, broken only by the umbilical cord (Figure 28.7d).

Sometimes called the “bag of waters,” the amnion provides a buoyant environment that protects the developing embryo against physical trauma, and helps maintain a constant homeostatic temperature. The fluid also prevents the rapidly growing embryonic parts from adhering and fusing together and allows the embryo considerable freedom of movement. Initially, the fluid is derived from the maternal blood, but as the fetal kidneys become functional later in development, fetal urine contributes to amniotic fluid volume.

The **yolk sac** forms from cells of the primitive gut, which arrange themselves into a sac that hangs from the ventral surface of the embryo (Figure 28.7b–d). The amnion and yolk sac resemble two balloons touching one another with the embryonic disc at the point of contact. In many species, the yolk sac is the main source of nutrition for the embryo, but human

endoderm. Those that follow (g) become mesoderm. The epiblast surface is now called ectoderm.

eggs contain very little yolk and nutritive functions have been taken over by the placenta. Nevertheless, the yolk sac is important in humans because it (1) forms part of the gut (digestive tube), and (2) is the source of the earliest blood cells and blood vessels.

The **allantois** (ah-lan'to-is) forms as a small outpocketing of embryonic tissue at the caudal end of the yolk sac (Figure 28.7c). In animals that develop in shelled eggs, the allantois is a disposal site for solid metabolic wastes (excreta). In humans, the allantois is the structural base for the **umbilical cord** that links the embryo to the placenta, and ultimately it becomes part of the urinary bladder. The fully formed umbilical cord contains a core of embryonic connective tissue (Wharton's jelly), the umbilical arteries and vein, and is covered externally by amniotic membrane.

We have already described the **chorion**, which helps to form the placenta (Figure 28.7c). As the outermost membrane, the chorion encloses the embryonic body and all other membranes.

### ✓ Check Your Understanding

10. What is the function of the amnion?
11. Which extraembryonic membrane provides a path for the embryonic blood vessels to reach the placenta?

For answers, see Appendix H.

### Gastrulation: Germ Layer Formation

✓ Describe gastrulation and its consequence.

During week 3, the two-layered embryonic disc transforms into a three-layered *embryo* in which the **primary germ layers**—*ectoderm*, *mesoderm*, and *endoderm*—are present (Figure 28.7c). This process, called **gastrulation** (gas'troo-la'shun), involves cellular rearrangements and migrations.

**Figure 28.9** focuses on the changes that take place in the days between Figure 28.7b (12-day embryo) and Figure 28.7c

(16-day embryo). Gastrulation begins when a groove with raised edges called the **primitive streak** appears on the dorsal surface of the embryonic disc and establishes the longitudinal axis of the embryo (Figure 28.9e). Surface (epiblast) cells of the embryonic disc then migrate medially across other cells and enter the primitive streak. The first cells to enter the groove displace the hypoblast cells of the yolk sac and form the most inferior germ layer, the **endoderm** (Figure 28.9f). Those that follow push laterally between the cells at the upper and lower surfaces, forming the **mesoderm** (Figure 28.9g). As soon as the mesoderm is formed, the mesodermal cells immediately beneath the early primitive streak aggregate, forming a rod of mesodermal cells called the **notochord** (no'to-kord), the first axial support of the embryo (see Figure 28.12a). The cells that remain on the embryo's dorsal surface are the **ectoderm**. At this point, the embryo is about 2 mm long.

The three primary germ layers serve as the *primitive tissues* from which all body organs derive. Ectoderm (“outer skin”) fashions structures of the nervous system and the skin epidermis. Endoderm (“inner skin”) forms the epithelial linings of the digestive, respiratory, and urogenital systems, and associated glands. Mesoderm (“middle skin”) forms virtually everything else.

Both ectoderm and endoderm consist mostly of cells that are securely joined to each other and are *epithelia*. Mesoderm, by contrast, is a *mesenchyme* [literally, “poured into the middle (of the embryo)”], an embryonic tissue with star-shaped cells that are free to migrate widely within the embryo. Figure 28.13 (p. 1079) lists the germ layer derivatives. Some of the details of the differentiation processes are described next.

### Organogenesis: Differentiation of the Germ Layers

- ✓ Define organogenesis and indicate the important roles of the three primary germ layers in this process.
- ✓ Describe unique features of the fetal circulation.

Gastrulation lays down the basic structural framework of the embryo. It also sets the stage for the rearrangements that occur during **organogenesis** (or'gah-no-jen'ě-sis), formation of body organs and organ systems. By the end of the embryonic period at 8 weeks, when the embryo is about 22 mm (slightly less than 1 inch) long from head to buttocks (referred to as the *crown-rump measurement*), all the adult organ systems are recognizable. It is truly amazing how much organogenesis occurs in such a short time in such a small amount of living matter.

As **Figure 28.10** shows, the embryo starts off as a flat plate, but as it grows, it folds to achieve a cylindrical body shape which lifts off the yolk sac and protrudes into the amniotic cavity. In the simplest sense, this process resembles three stacked sheets of paper folding laterally into a tube (Figure 28.10a, b). At the same time, the folding occurs from both ends (the head and tail regions) and progresses toward the central part of the embryonic body, where the yolk sac and umbilical vessels protrude. As the endoderm undercuts and its edges come together and fuse, it encloses part of the yolk sac (Figure 28.10d).

**Figure 28.10** Folding of the embryonic body, lateral views. **(a)** Model of the flat three-layered embryo as three sheets of paper. **(b, c)** Folding begins with lateral folds, then head and tail folds appear. **(d)** A 24-day embryo in sagittal section. Notice the primitive gut, which derives from the yolk sac, and the notochord and neural tube dorsally.

### Specialization of the Endoderm

The tube of endoderm formed by the folding process described is called the **primitive gut**. It becomes the epithelial lining (mucosa) of the gastrointestinal tract (Figure 28.11). The organs of the GI tract (pharynx, esophagus, etc.) quickly become apparent, and then the oral and anal openings perforate. The mucosal lining of the respiratory tract forms as an outpocketing from the *foregut* (pharyngeal endoderm), and glands arise as endodermal outpocketings at various points further along the tract. For example, the epithelium of the thyroid, parathyroids, and thymus forms from the pharyngeal endoderm.

### Specialization of the Ectoderm

The first major event in organogenesis is **neurulation**, the differentiation of ectoderm that produces the brain and spinal cord (Figure 28.12). This process is *induced* (stimulated to happen) by chemical signals from the *notochord*, the rod of mesoderm that defines the body axis, mentioned earlier. The ectoderm overlying the notochord thickens, forming the **neural plate** (Figure 28.12a). Then the ectoderm starts to fold inward as a **neural groove**. As the neural groove deepens it forms prominent **neural folds** (Figure 28.12b). By day 22, the superior margins of the neural folds fuse, forming a **neural tube**, which soon pinches off from the ectodermal layer and becomes covered by surface ectoderm (Figure 28.12c).

As we described in Chapter 12, the anterior end of the neural tube becomes the brain and the rest becomes the spinal cord. The associated **neural crest cells** (Figure 28.12c) migrate widely and give rise to the cranial, spinal, and sympathetic ganglia (and associated nerves), to the chromaffin cells of the adrenal medulla, to pigment cells of the skin, and contribute to some connective tissues.

By the end of the first month of development, the three primary brain vesicles (fore-, mid-, and hindbrain) are apparent. By the end of the second month, all brain flexures are evident, the cerebral hemispheres cover the top of the brain stem (see Figure 12.2), and brain waves can be recorded. Most of the remaining ectoderm forming the surface layer of the embryonic body differentiates into the epidermis of the skin. Other ectodermal derivatives are indicated in Figure 28.13.

### Specialization of the Mesoderm

The first evidence of mesodermal differentiation is the appearance of the notochord in the embryonic disc (see Figure 28.12a). The notochord is eventually replaced by the vertebral column, but its remnants persist in the springy *nucleus pulposus* of the intervertebral discs. Shortly thereafter, three mesodermal aggregates appear on either side of the notochord (Figure 28.12b, c). The largest of these, the *somites* (so'mīts), are paired mesodermal blocks that hug the notochord on either side. All 40 pairs of somites are present by the end of week 4. Flanking the somites laterally are small clusters of segmented mesoderm called *intermediate mesoderm* and then double sheets of *lateral plate mesoderm*.

Each **somite** has three functional parts—*sclerotome*, *dermatome*, and *myotome* (Figure 28.12d). Cells of the **sclerotome**

**Figure 28.11 Endodermal differentiation.** Endoderm forms the epithelial linings of the digestive and respiratory tracts and associated glands.

(skle'ro-tōm; "hard piece") migrate medially, gather around the notochord and neural tube, and produce the vertebra and rib at the associated level. **Dermatome** ("skin piece") cells help form the dermis of the skin in the dorsal part of the body. The **myotome** (mi'o-tōm; "muscle piece") cells develop in conjunction with the vertebrae. They form the skeletal muscles of the neck, body trunk, and, via their **limb buds**, the muscles of the limbs.

Cells of the **intermediate mesoderm** form the gonads and kidneys. The **lateral plate mesoderm** consists of paired mesodermal plates: the *somatic mesoderm* and the more inferior *splanchnic mesoderm*. Cells of the superior plates help to form (1) the skin dermis; (2) the parietal serosa that lines the ventral body cavity; and (3) most tissues of the limbs. The more inferior plates provide the mesenchymal cells that form the heart and blood vessels and most connective tissues of the body, as well as nearly the entire wall of the digestive and respiratory organs. The lateral mesodermal layers cooperate to form the serosae of the **coelom** (se'lom), or ventral body cavity. The mesodermal derivatives are summarized in Figure 28.13.

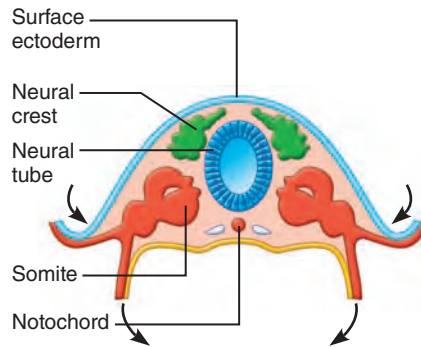

By the end of the embryonic period, the bones have begun to ossify and the skeletal muscles are well formed and contracting spontaneously. Metanephric kidneys are developing, gonads are formed, and the lungs and digestive organs are attaining their final shape and body position. Blood delivery to and from the placenta via the umbilical vessels is constant and efficient. The heart and the liver are competing for space and form a conspicuous bulge on the ventral surface of the embryo's body. All this by the end of eight weeks in an embryo about 2.5 cm (1 inch) long from crown to rump!

(a) 17 days. The flat three-layered embryo has completed gastrulation. Notochord and neural plate are present.

(b) 20 days. The neural folds form by folding of the neural plate, which then deepens, producing the neural groove. Three mesodermal aggregates form on each side of the notochord (somite, intermediate mesoderm, and lateral plate mesoderm).

(c) 22 days. The neural folds have closed, forming the neural tube which has detached from the surface ectoderm and lies between the surface ectoderm and the notochord. Embryonic body is beginning to undercut.

(d) End of week 4. Embryo undercutting is complete. Somites have subdivided into sclerotome, myotome, and dermatome, which form the vertebrae, skeletal muscles, and dermis respectively. Body coelom present.

Figure 28.12 Neurulation and early mesodermal differentiation.

**Figure 28.13** Flowchart showing major derivatives of the embryonic germ layers.

**Development of the Fetal Circulation** Embryonic development of the cardiovascular system lays the groundwork for the fetal circulatory pattern, which is converted to the adult pattern at birth. The first blood cells arise in the yolk sac. Before week 3 of development, tiny spaces appear in the splanchnic mesoderm. These are quickly lined by endothelial cells, covered with mesenchyme, and linked together into rapidly spreading vascular networks, destined to form the heart, blood vessels, and lymphatics. By the end of week 3, the embryo has a system of paired blood vessels, and the two vessels forming the heart have fused and bent into an S shape. By 3½ weeks, the miniature heart is pumping blood for an embryo less than a quarter inch long.

Unique cardiovascular modifications seen only during prenatal development include the **umbilical arteries** and **vein** and three *vascular shunts* (Figure 28.14). All of these structures are occluded at birth. As you read about these vessels, keep in mind that the blood is flowing from and to the fetal heart. The large umbilical vein carries freshly oxygenated blood returning from the placenta into the embryonic body, where it is conveyed to the liver. There, some of the returning blood percolates through the liver sinusoids and out the hepatic veins. Most of the blood coursing through the umbilical vein, however, enters the **ductus venosus** (duk'tus ve-no'sus), a venous shunt

that bypasses the liver sinusoids. Both the hepatic veins and the ductus venosus empty into the inferior vena cava where the placental blood mixes with deoxygenated blood returning from the lower parts of the fetus's body. The vena cava in turn conveys this "mixed load" of blood directly to the right atrium of the heart.

After birth, the liver plays an important role in nutrient processing, but during embryonic life the mother's liver performs these functions. Consequently, blood flow through the fetal liver during development is important only to ensure that the liver cells remain healthy.

Blood entering and leaving the heart encounters two more shunt systems, each serving to bypass the nonfunctional lungs. Some of the blood entering the right atrium flows directly into the left atrium via the **foramen ovale** ("oval hole"), an opening in the interatrial septum loosely closed by a flap of tissue. Blood that enters the right ventricle is pumped out into the pulmonary trunk. However, the second shunt, the **ductus arteriosus**, transfers most of that blood directly into the aorta, again bypassing the pulmonary circuit. (The lungs *do* receive adequate blood to maintain their growth.) Blood enters the two pulmonary bypass shunts because the heart chamber or vessel on the other side of each shunt is a lower-pressure area, owing to the low volume of venous return from the lungs. Blood flowing distally through

**Figure 28.14** Circulation in fetus and newborn. Arrows on blood vessels indicate direction of blood flow. Arrows in color screens go from the fetal structure to what it becomes after birth. **(a)** Special adaptations for embryonic and fetal life. The umbilical

vein carries oxygen- and nutrient-rich blood from the placenta to the fetus. The umbilical arteries carry waste-laden blood from the fetus to the placenta. The ductus arteriosus and foramen ovale bypass the nonfunctional lungs. Note that blood passing through the

foramen ovale comes mostly from the inferior vena cava. The ductus venosus allows blood to partially bypass the liver. **(b)** Changes in the cardiovascular system at birth. The umbilical vessels as well as the liver and lung bypasses are occluded.

(a) Embryo at week 7, about 17 mm long.

(b) Fetus in month 3, about 6 cm long.

(c) Fetus late in month 5, about 19 cm long.

the aorta eventually reaches the umbilical arteries, which are branches of the internal iliac arteries serving the pelvis. From here the largely deoxygenated blood, laden with metabolic wastes, is delivered back to the capillaries in the chorionic villi of the placenta. The changes in the circulatory plan that occur at birth are illustrated in Figure 28.14b.

### ✓ Check Your Understanding

- The early embryo is flat like a three-layered pancake. What event must occur before organogenesis can get going in earnest?
- What germ layer gives rise to essentially all body tissues except nervous tissue, the epidermis, and mucosae?

For answers, see Appendix H

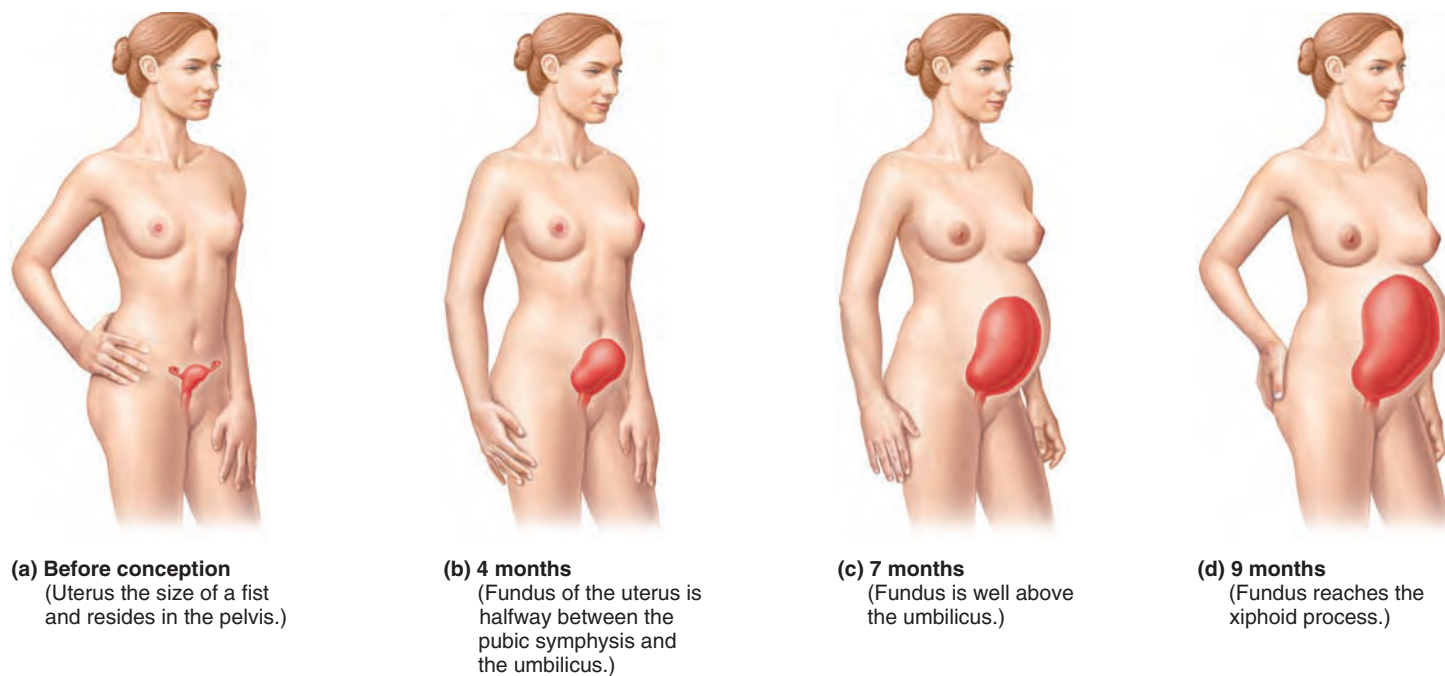

**Figure 28.15** Photographs of a developing fetus. By birth, the fetus is typically 36 cm long from crown to rump.

## Events of Fetal Development

✓ Indicate the duration of the fetal period, and note the major events of fetal development.

During the fetal period, the developing fetus grows from a crown-to-rump length of about 22 mm (slightly less than 1 inch) and a weight of approximately 2 g (0.06 ounce) to about 360 mm (14 inches) and 3.2 kg (7 lb) or more. (Total body length at birth is about 550 mm, or 22 inches.) As you might expect with such tremendous growth, the changes in fetal appearance are quite dramatic (Figure 28.15). The fetal period is a time of

**Figure 28.16** Relative size of the uterus before conception and during pregnancy.

rapid growth of the body structures that were established in the embryo. During the first half of this period, cells are still differentiating into specific cell types to form the body's distinctive tissues and are completing the fine details of body structure. The main events of the fetal period—weeks 9 through 38—are listed chronologically in **Table 28.1** on p. 1084. The greatest amount of growth occurs in the first 8 weeks of life, when the embryo grows from one cell to a fetus of 1 inch.

### ✓ Check Your Understanding

14. When does the fetal period begin?

For answers, see Appendix H.

## Effects of Pregnancy on the Mother

- ✓ Describe functional changes in maternal reproductive organs and in the cardiovascular, respiratory, and urinary systems during pregnancy.
- ✓ Indicate the effects of pregnancy on maternal metabolism and posture.

The mean duration of pregnancy is 38 weeks from the time of ovulation to birth. Pregnancy can be a difficult time for the mother because profound adaptations occur in several body systems. Not only are there anatomical changes, but striking changes in her metabolism and physiology occur to support the pregnancy and prepare her body for delivery and lactation.

## Anatomical Changes

As pregnancy progresses, the female reproductive organs become increasingly vascular and engorged with blood, and the vagina develops a purplish hue (*Chadwick's sign*). The enhanced vascularity increases vaginal sensitivity and sexual intensity, and some women achieve orgasm for the first time when they are pregnant. Prodded by rising levels of estrogen and progesterone, the breasts enlarge and engorge with blood, and their areolae darken. Some women develop increased pigmentation of facial skin of the nose and cheeks, a condition called *chloasma* (klo-az' mah; "to be green") or the "mask of pregnancy."

The degree of uterine enlargement during pregnancy is remarkable. Starting as a fist-sized organ, the uterus fills most of the pelvic cavity by 16 weeks (**Figure 28.16a, b**). Though the fetus is only about 140 mm long (crown-to-rump) at this time, the placenta is fully formed, uterine muscle is hypertrophied, and amniotic fluid volume is increasing.

As pregnancy continues, the uterus pushes higher into the abdominal cavity, exerting pressure on both abdominal and pelvic organs (**Figure 28.16c**). As birth nears, the uterus reaches the level of the xiphoid process and occupies most of the abdominal cavity (**Figure 28.16d**). The crowded abdominal organs press superiorly against the diaphragm, which intrudes on the thoracic cavity. As a result, the ribs flare, causing the thorax to widen.

The increasing bulkiness of the anterior abdomen changes the woman's center of gravity, and many women develop *lordosis* (accentuated lumbar curvature) and backaches during the last few months of pregnancy. Placental production of the hormone **relaxin** causes pelvic ligaments and the pubic symphysis to relax, widen, and become more flexible. This increased flexibility eases birth passage, but it may result in a waddling

gait in the meantime. Considerable weight gain occurs during a normal pregnancy. Because some women are over- or under-weight before pregnancy begins, it is almost impossible to state the ideal or desirable weight gain. However, summing up the weight increases resulting from fetal and placental growth, increased size of the maternal reproductive organs and breasts, and greater blood volume during pregnancy, a weight gain of approximately 13 kg (about 28 lb) usually occurs.

Good nutrition is necessary all through pregnancy if the developing fetus is to have all the building materials (especially proteins, calcium, and iron) needed to form its tissues. Additionally, multivitamins containing folic acid reduce the risk of having a baby with neurological problems, including such birth defects as spina bifida and anencephaly, as well as spontaneous preterm birth. (Indeed, a recent study on preconceptual folic acid supplementation for a year or more resulted in a reduction of spontaneous preterm birth by 50–70%.) However, a pregnant woman needs only 300 additional calories daily to sustain proper fetal growth. The emphasis should be on eating high-quality food, not just more food.

Not surprisingly, effects of the fetal environment may not show up until decades later. Below-normal birth weight, for instance, places females at risk for type 2 diabetes and increases the general risk of cardiovascular disease later in life for both men and women.

## Metabolic Changes

As the placenta enlarges, it secretes increasing amounts of **human placental lactogen (hPL)**, also called **human chorionic somatomammotropin (hCS)**. hPL works cooperatively with estrogens and progesterone to stimulate maturation of the breasts for lactation, promotes growth of the fetus, and exerts a glucose-sparing effect in the mother. Consequently, maternal cells metabolize more fatty acids and less glucose than usual, sparing glucose for use by the fetus. Gestational diabetes mellitus occurs in about 10% of pregnancies, but over half of those women go on to develop type 2 diabetes later in life.

Plasma levels of parathyroid hormone and activated vitamin D rise, so that pregnant women tend to be in positive calcium balance throughout pregnancy. This state ensures that the developing fetus will have adequate calcium to mineralize its bones.

## Physiological Changes

Physiological changes take place in many systems during pregnancy. A few of these changes are described next.

### Gastrointestinal System

The nausea and vomiting (commonly called morning sickness) suffered by many women during the first few months of pregnancy are believed to be related to elevated levels of hCG, estrogens, and progesterone. (Nausea is also a side effect of many birth control pills.) *Heartburn*, due to reflux of stomach acid into the esophagus, is common because the esophagus is displaced and the stomach is crowded by the growing uterus. *Constipation* occurs because motility of the digestive tract declines during pregnancy.

## Homeostatic Imbalance 28.1

Because many potentially harmful substances can cross placental barriers and enter the fetal blood, a pregnant woman should be aware of what she is taking into her body, particularly during the embryonic period when the body's foundations are laid down. **Teratogens** (ter'ah-to-jenz; *terato* = monster), factors that may cause severe congenital abnormalities or even fetal death, include alcohol, nicotine, many drugs (anticoagulants, sedatives, antihypertensives, and some antibiotics), and maternal infections, particularly German measles. For example, when a woman drinks alcohol, her fetus becomes inebriated as well. However, the fetal consequences may be much more lasting and result in the *fetal alcohol syndrome (FAS)* typified by microcephaly (small head), mental retardation, and abnormal growth. Nicotine hinders oxygen delivery to the fetus, impairing normal growth and development. The sedative **thalidomide** (thah-lid'o-mid) was used by thousands of pregnant women in the 1960s to alleviate morning sickness. When taken during the period of limb bud differentiation (days 26–56), it sometimes resulted in tragically deformed infants with short flipperlike legs and arms. +

### Urinary System

The kidneys produce more urine during pregnancy because of the mother's increased metabolic rate and the additional burden of disposing of fetal metabolic wastes. As the growing uterus compresses the bladder, urination becomes more frequent, more urgent, and sometimes uncontrollable (*stress incontinence*).

### Respiratory System

The nasal mucosa responds to estrogens by becoming edematous and congested. Thus, nasal stuffiness and occasional nosebleeds may occur. Tidal volume increases markedly during pregnancy, while respiratory rate is relatively unchanged and residual volume declines. The increase in tidal volume is due to the mother's greater need for oxygen during pregnancy and the fact that progesterone enhances the sensitivity of the medullary respiratory center to CO<sub>2</sub>. Many women exhibit *dyspnea* (disp-ne'ah), or difficult breathing, during the later stages of pregnancy.

### Cardiovascular System

The most dramatic physiological changes occur in the cardiovascular system. Total body water rises, and blood volume may increase as much as 40% by the 32nd week to accommodate the additional needs of the fetus. The rise in blood volume also safeguards against blood loss during birth. Mean blood pressure typically decreases during midpregnancy, but then rises to normal levels during the third trimester. Cardiac output increases by 35–40% at various stages of pregnancy. This helps propel the greater circulatory volume around the body. The uterus presses on the pelvic blood vessels, which may impair venous return from the lower limbs, resulting in *varicose veins* and leg edema.

**Table 28.1** Developmental Events of the Fetal Period

TIME	CHANGES AND ACCOMPLISHMENTS
8 weeks (end of embryonic period)	 <p>Head nearly as large as body; all major brain regions present; first brain waves in brain stem                      Liver disproportionately large and begins to form blood cells                      Limbs present; digits are initially webbed, but fingers and toes are free by the end of this interval                      Ossification just begun; weak, spontaneous muscle contractions occur                      Cardiovascular system fully functional (heart has been pumping blood since the fourth week)                      All body systems present in at least rudimentary form                      Approximate crown-to-rump length: 22 mm (0.9 inch); weight: 2 grams (0.06 ounce)</p>
9–12 weeks (month 3)	 <p>Head still dominant, but body elongating; brain continues to enlarge, shows its general structural features; cervical and lumbar enlargements apparent in spinal cord; retina of eye is present                      Skin epidermis and dermis obvious; facial features present in crude form                      Liver prominent and bile being secreted; palate is fusing; most glands of endodermal origin are developed; walls of hollow visceral organs gaining smooth muscle                      Blood cell formation begins in bone marrow                      Notochord degenerating and ossification accelerating; limbs well molded                      Sex readily detected from the genitals                      Approximate crown-to-rump length at end of interval: 90 mm</p>
13–16 weeks (month 4)	 <p>Cerebellum becoming prominent; general sensory organs differentiated; eyes and ears assume characteristic position and shape; blinking of eyes and sucking motions of lips occur                      Face looks human and growth of the body beginning to outpace that of the head                      Glands developed in GI tract; meconium is collecting                      Kidneys attain typical structure                      Most bones are now distinct and joint cavities are apparent                      Approximate crown-to-rump length at end of interval: 140 mm</p>
17–20 weeks (month 5)	<p>Vernix caseosa (fatty secretions of sebaceous glands) covers body; lanugo (silklime hair) covers skin                      Fetal position (body flexed anteriorly) assumed because of space restrictions                      Limbs reach near-final proportions                      Quickening occurs (mother feels spontaneous muscular activity of fetus)                      Approximate crown-to-rump length at end of interval: 190 mm</p>
21–30 weeks (months 6 and 7)	 <p>Period of substantial increase in weight (may survive if born prematurely at 27–28 weeks, but hypothalamic temperature regulation and lung production of surfactant are still inadequate)                      Myelination of spinal cord begins; eyes are open                      Distal limb bones are beginning to ossify                      Skin is wrinkled and red; fingernails and toenails are present; tooth enamel is forming on deciduous teeth                      Body is lean and well proportioned                      Bone marrow becomes sole site of blood cell formation                      Testes reach scrotum in seventh month (in males)                      Approximate crown-to-rump length at end of interval: 280 mm</p>
30–40 weeks (term) (months 8 and 9)	<p>Skin whitish pink; fat laid down in subcutaneous tissue (hypodermis)                      Approximate crown-to-rump length at end of interval: 360 mm (14 inches); weight: 3.2 kg (7 lb)</p>

### Homeostatic Imbalance 28.2

A dangerous complication of pregnancy called **preeclampsia** results in an insufficient placental blood supply, which can starve a fetus of oxygen. The pregnant woman becomes edematous and hypertensive, and proteinuria occurs. This condition, which affects one in 10 pregnancies, is believed to be due to immunological abnormalities in some cases, because its occurrence seems to be positively correlated with the number of fetal cells that enter the maternal circulation. +

#### Check Your Understanding

15. What causes the difficult breathing that some women experience during pregnancy? What causes the waddling gait seen in some?
16. What is the cause of morning sickness?
17. What is the role of the hormone hPL?

For answers, see Appendix H.

## Parturition (Birth)

- ✓ Explain how labor is initiated, and describe the three stages of labor.

**Parturition** (par"tu-rish'un; "bringing forth young") is the culmination of pregnancy—giving birth to the baby. It usually occurs within 15 days of the calculated due date (280 days from the last menstrual period). The series of events that expel the infant from the uterus are collectively called **labor**.

### Initiation of Labor

Several events and hormones interlock to trigger labor. During the last few weeks of pregnancy, estrogens reach their highest levels in the mother's blood. Studies indicate that the fetus determines its own birth date. Rising levels of fetal adrenocortical hormones (especially cortisol) late in pregnancy are believed to stimulate the placenta to release such large amounts of estrogens. In addition, increased production of *surfactant protein A* (SP-A) by the fetal lungs in the weeks before delivery appears to trigger an inflammatory response in the cervix that stimulates its softening in preparation for labor.

The rise in estrogens has three important consequences. (1) It stimulates the myometrial cells of the uterus to form abundant oxytocin receptors (Figure 28.17). (2) It promotes formation of gap junctions between the uterine smooth muscle cells. (3) It antagonizes progesterone's quieting influence on uterine muscle. As a result, the myometrium becomes increasingly irritable, and weak, irregular uterine contractions begin to occur. These contractions, called *Braxton Hicks contractions*, have caused many women to go to the hospital, only to be told that they were in **false labor** and sent home.

As birth nears, two more chemical signals cooperate to convert these false labor pains into the real thing. Certain fetal cells begin to produce **oxytocin** (ok"sī-to'sin), which causes the placenta to

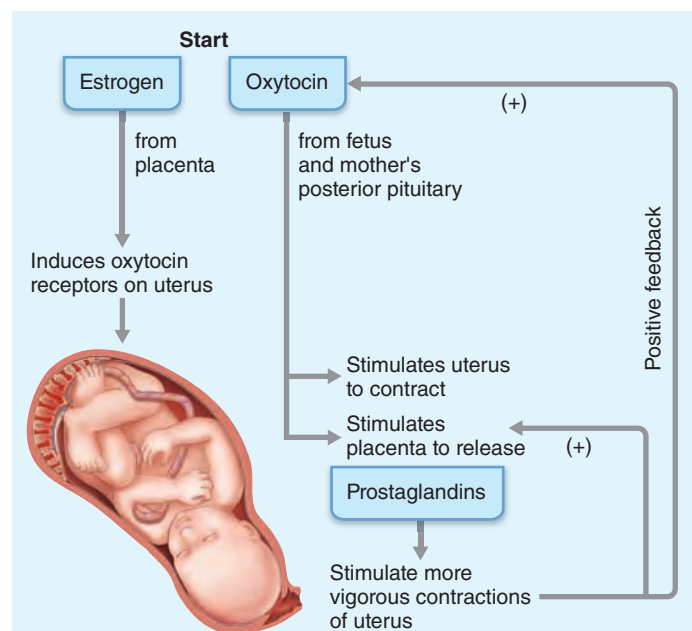

Figure 28.17 Hormonal induction of labor.

release **prostaglandins** (pros"tah-glan'dinz) (Figure 28.17) which, like estrogens, stimulate the synthesis of more gap junctions in uterine smooth muscle. Both hormones are powerful uterine muscle stimulants, and since the myometrium is now highly sensitive to oxytocin, contractions become more frequent and more vigorous. While elevated levels of oxytocin and prostaglandins sustain labor once it begins, many studies indicate that it is the prostaglandins (acting as paracrines) that actually trigger the rhythmic expulsive contractions of true labor, and play a major role in the thinning and softening of the cervix just before and during labor. At this point, the increasing cervical distension activates the mother's hypothalamus, which signals for oxytocin release by the posterior pituitary.

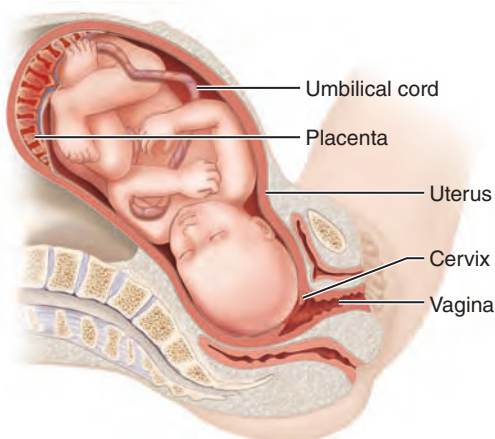

Once the hypothalamus is involved, several *positive feedback mechanisms* involving prostaglandins and oxytocin are propelled into action—greater distension of the cervix causes the release of more oxytocin, which causes greater contractile force, and so on (Figure 28.17). These expulsive contractions are aided by the fact that *fetal fibronectin*, a natural "stickum" (adhesive protein) that binds the fetal and maternal tissues of the placenta together throughout pregnancy, changes to a lubricant just before true labor begins.

As mentioned earlier, prostaglandins are essential for initiating labor in humans, and interfering with their production will hinder onset of labor. For example, antiprostaglandin drugs such as ibuprofen can inhibit the early stages of labor and such drugs are used occasionally to prevent preterm births.

### Stages of Labor

Labor includes the dilation, expulsion, and placental stages illustrated in Figure 28.18.

**1a Early dilation.** Baby's head engaged; widest dimension is along left-right axis.

**1b Late dilation.** Baby's head rotates so widest dimension is in anteroposterior axis (of pelvic outlet). Dilation nearly complete.

**2 Expulsion.** Baby's head extends as it is delivered.

**3 Placental stage.** After baby is delivered, the placenta detaches and is removed.

**1 Dilation stage.** The **dilation stage** is the time from labor's onset until the cervix is fully dilated by the baby's head (about 10 cm in diameter). As labor starts, weak but regular contractions begin in the upper part of the uterus and move toward the vagina. At first, only the superior uterine muscle is active; contractions are 15–30 minutes apart, and last for 10–30 seconds. As labor progresses, the contractions become more vigorous and rapid, and the lower part of the uterus gets involved. As the infant's head is forced against the cervix with each contraction, the cervix softens and thins (*effaces*), and dilates. Eventually the amnion ruptures, releasing the amniotic fluid, an event commonly called “breaking the water.”

The dilation stage is the longest part of labor, lasting 6–12 hours or more. Several events happen during this phase. *Engagement* occurs when the infant's head enters the true pelvis. As descent continues through the birth canal, the baby's head rotates so that its greatest dimension is in the anteroposterior line, which allows it to navigate the narrow dimensions of the pelvic outlet (Figure 28.18 **1b**).

**2 Expulsion stage.** The **expulsion stage** lasts from full dilation to delivery of the infant, or actual childbirth. By the time the cervix is fully dilated, strong contractions occur every 2–3 minutes and last about 1 minute. In this stage, a mother undergoing labor without local anesthesia has an increasing urge to push or bear down with the abdominal muscles. Although this phase may last 2 hours, it is typically 50 minutes in a first birth and around 20 minutes in subsequent births.

*Crowning* occurs when the largest dimension of the baby's head distends the vulva. At this point, an *episiotomy* (e-piz'e-ot'o-me) may be done to reduce tissue tearing. An episiotomy is an incision made to widen the vaginal orifice. The baby's neck extends as the head exits from the perineum, and once the head has been delivered, the rest of the baby's body is delivered much more easily. After birth, the umbilical cord is clamped and cut.

When the infant is in the usual *vertex*, or head-first, *presentation*, the skull (its largest diameter) acts as a wedge to dilate the cervix. The head-first presentation also allows the baby to be suctioned free of mucus and to breathe even before it has completely exited from the birth canal. In *breech* (buttock-first) and other nonvertex presentations, these advantages are lost and delivery is much more difficult, often requiring the use of forceps, or a C-section (see below).

### Homeostatic Imbalance 28.3

If a woman has a deformed or malelike pelvis, labor may be prolonged and difficult. This condition is called *dystocia* (dis-to'se-ah; *dys* = difficult; *toc* = birth). Besides extreme maternal fatigue, another possible consequence of dystocia is fetal brain damage, resulting in cerebral palsy or epilepsy. To prevent these outcomes, a *cesarean (C-) section* (se-sa're-an) is performed in many such cases. A C-section is delivery of the infant through an incision made through the abdominal and uterine walls. +

**Figure 28.18** Parturition.

- ③ **Placental stage.** The **placental stage**, or the delivery of the placenta and its attached fetal membranes, which are collectively called the **afterbirth**, is usually accomplished within 30 minutes after birth of the infant. The strong uterine contractions that continue after birth compress uterine blood vessels, limit bleeding, and shear the placenta off the uterine wall (cause placental detachment). It is very important that all placental fragments be removed to prevent continued uterine bleeding after birth (*postpartum bleeding*).

### ✓ Check Your Understanding

18. What is a breech presentation?
19. What chemical is most responsible for triggering true labor?
20. Why does a baby turn as it travels through the birth canal?

For answers, see Appendix H.

## Adjustments of the Infant to Extrauterine Life

- ✓ Outline the events leading to the first breath of a newborn.
- ✓ Describe changes that occur in the fetal circulation after birth.

The **neonatal period** is the four-week period immediately after birth. Here we will be concerned with the events of just the first few hours after birth in a normal infant. As you might suspect, birth represents quite a shock to the infant. Exposed to physical trauma during the birth process, it is suddenly cast out of its watery, warm environment and its placental life supports are severed. Now it must do for itself all that the mother had been doing for it—respire, obtain nutrients, excrete, and maintain its body temperature.

At 1 and 5 minutes after birth, the infant's physical status is assessed based on five signs: heart rate, respiration, color, muscle tone, and reflexes (tested by response to catheter in nostril). Each observation is given a score of 0 to 2, and the total is called the **Apgar score**. An Apgar score of 8 to 10 indicates a healthy baby. Lower scores reveal problems in one or more of the physiological functions assessed.

### Taking the First Breath and Transition

The crucial first requirement is to breathe. Vasoconstriction of the umbilical arteries, initiated when they are stretched during birth, leads to loss of placental support. Once carbon dioxide is no longer removed by the placenta, it accumulates in the baby's blood, causing central acidosis. This excites respiratory control centers in the baby's brain and triggers the first inspiration. The first breath requires a tremendous effort—the airways are tiny, and the lungs are collapsed. However, once the lungs have been inflated in full-term babies, surfactant in alveolar fluid reduces surface tension in the alveoli, and breathing is easier. The rate of respiration is rapid (about 45 respirations/min) during the first two weeks and then gradually declines.

Keeping the lungs inflated is much more difficult for premature infants (those weighing less than 2500 g, or about 5.5 lb, at birth) because surfactant production occurs during the last months of prenatal life. Consequently, preemies are usually put on respiratory assistance (a ventilator) until their lungs are mature enough to function on their own.

For 6–8 hours after birth, infants pass through an unstable **transitional period** marked by alternating periods of increased activity and sleep. During the activity periods, vital signs are irregular and the baby gags frequently as it regurgitates mucus and debris. After this, the infant stabilizes, with waking periods (dictated by hunger) occurring every 3–4 hours.

### Occlusion of Special Fetal Blood Vessels and Vascular Shunts

After birth the special umbilical blood vessels and fetal shunts are no longer necessary (see Figure 28.14b). The umbilical arteries and vein constrict and become fibrosed. The proximal parts of the umbilical arteries persist as the *superior vesical arteries* that supply the urinary bladder, and their distal parts become the **medial umbilical ligaments**. The remnant of the umbilical vein becomes the **round ligament of the liver**, or **ligamentum teres**, that attaches the umbilicus to the liver. The ductus venosus collapses as blood stops flowing through the umbilical vein and is eventually converted to the **ligamentum venosum** on the liver's undersurface.

As the pulmonary circulation becomes functional, pressure in the left side of the heart increases and that in the right side of the heart decreases, causing the pulmonary shunts to close. The flap of the foramen ovale is pushed to the shut position, and its edges fuse to the septal wall. Ultimately, only a slight depression, the **fossa ovalis**, marks its position. The ductus arteriosus constricts and is converted to the cordlike **ligamentum arteriosum**, connecting the aorta and pulmonary trunk.

Except for the foramen ovale, all of the special circulatory adaptations of the fetus are functionally occluded within 30 minutes after birth. Closure of the foramen ovale is usually complete within the year. As we described in Chapter 18, failure of the ductus arteriosus or foramen ovale to close leads to congenital heart defects.

### ✓ Check Your Understanding

21. What two modifications of the fetal circulation allow most blood to bypass parts of the heart?
22. What happens to the special fetal circulatory modifications after birth?

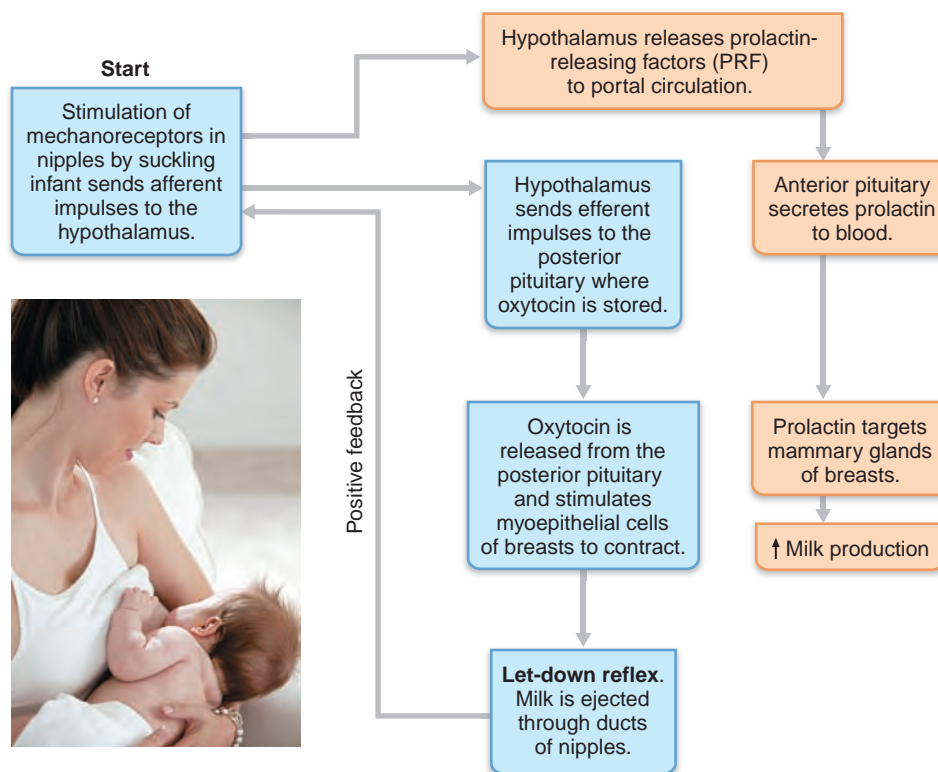

For answers, see Appendix H.

## Lactation

- ✓ Explain how the breasts are prepared for lactation.

**Lactation** is production of milk by the hormone-prepared mammary glands. Rising levels of (placental) estrogens, progesterone, and human placental lactogen toward the end of

**Figure 28.19** Milk production and the positive feedback mechanism of the milk let-down reflex.

pregnancy stimulate the hypothalamus to release prolactin-releasing factors (PRFs). The anterior pituitary gland responds by secreting **prolactin**. (This mechanism is described below.) After a delay of two to three days following birth, true milk production begins.

During the initial delay (and during late gestation), the mammary glands secrete a yellowish fluid called **colostrum** (ko-los'trum). It has less lactose than milk and almost no fat, but it contains more protein, vitamin A, and minerals than true milk. Like milk, colostrum is rich in IgA antibodies. Since these antibodies are resistant to digestion in the stomach, they may help to protect the infant's digestive tract against bacterial infection. Additionally, these IgA antibodies are absorbed by endocytosis and subsequently enter the bloodstream to provide even broader immunity.

After birth, prolactin release gradually wanes, and continual milk production depends on mechanical stimulation of the nipples, normally provided by the suckling infant. Mechanoreceptors in the nipple send afferent nerve impulses to the hypothalamus, stimulating secretion of PRF. This results in a burstlike release of prolactin, which stimulates milk production for the next feeding.

The same afferent impulses also prompt hypothalamic release of oxytocin from the posterior pituitary via a *positive feedback mechanism*. Oxytocin causes the **let-down reflex**, the actual ejection of milk from the alveoli of the mammary glands (**Figure 28.19**). Let-down occurs when oxytocin binds to myoepithelial cells surrounding the glands, after which milk

is ejected from *both* breasts, not just the suckled one. During nursing, oxytocin also stimulates the recently emptied uterus to contract, helping it to return to (nearly) its prepregnant size.

Breast milk has advantages for the infant:

- *Its fats and iron are better absorbed and its amino acids are metabolized more efficiently* than those of cow's milk.
- *It has a host of beneficial chemicals*, including IgA, complement, lysozyme, interferon, and lactoperoxidase, that protect infants from life-threatening infections. Mother's milk also contains interleukins and prostaglandins that prevent overzealous inflammatory responses, and a glycoprotein that deters the ulcer-causing bacterium (*Helicobacter pylori*) from attaching to the stomach mucosa.
- *Its natural laxative effect helps to cleanse the bowels of meconium* (mē-ko'ne-um), a tarry green-black paste containing sloughed-off epithelial cells, bile, and other substances. Since meconium, and later feces, provides the route for eliminating bilirubin from the body, clearing meconium as quickly as possible helps to prevent *physiological jaundice* (see the Related Clinical Terms section). Breast milk also encourages bacteria (the source of vitamin K and some B vitamins) to colonize the large intestine.

When nursing is discontinued, the stimulus for prolactin release and milk production ends, and the mammary glands stop producing milk. Women who nurse their infants for six months or more lose a significant amount of calcium from their bones,

but those on sound diets usually replace lost bone calcium after weaning the infant.

While prolactin levels are high, the normal hypothalamic-pituitary controls of the ovarian cycle are damped, probably because stimulation of the hypothalamus by suckling causes it to release beta endorphin, a peptide hormone that inhibits hypothalamic release of GnRH and, consequently, the release of gonadotropins by the pituitary. Because of this inhibition of ovarian function, nursing has been called natural birth control. Nonetheless, there is a good deal of “slippage” in these controls, and most women begin to ovulate even while continuing to nurse their infants.

### ✓ Check Your Understanding

23. What hormone causes the let-down reflex?

For answers, see Appendix H.

## Assisted Reproductive Technology and Reproductive Cloning

✓ Describe some techniques of ART including IVF, ZIFT, and GIFT.

So far we have been describing how babies are made. But if a couple lacks that capability for some reason, what recourse do they have? Hormone therapy may increase sperm or egg production in cases where that is the problem, and surgery can open blocked uterine tubes. Recently, an artificial ovary, which allows eggs to mature outside the body, has been developed that preserves a woman’s fertility if she needs to undergo treatment for cancer.

Beyond that are *assisted reproductive technology (ART)* procedures that entail surgically removing oocytes from a woman’s ovaries following hormone stimulation, fertilizing the oocytes, and then returning them to the woman’s body. These procedures, now performed worldwide in major medical centers, have produced thousands of infants, but they are expensive, emotionally draining, and painful for the oocyte donor. Unused oocytes, sperm, and embryos can be frozen for later attempts at accomplishing pregnancy.

In the most common ART process, *in vitro fertilization (IVF)*, harvested oocytes are incubated with sperm in culture dishes (*in vitro*) for several days to allow fertilization to occur. In cases where the quality or number of sperm is low, the oocytes are injected with sperm. Embryos reaching the two-cell or blastocyst stage are then carefully transferred into the woman’s uterus in the hope that implantation will occur.

In *zygote intrafallopian transfer (ZIFT)*, oocytes fertilized in vitro are immediately transferred to the woman’s uterine (fallopian) tubes. The goal is to have development to the blastocyst stage occur followed by normal implantation in the uterus.

In *gamete intrafallopian transfer (GIFT)*, no in vitro procedures are used. Instead, sperm and harvested oocytes are transferred together into the woman’s uterine tubes in the hope that fertilization will take place there.

Although there is a great deal of hubbub in the scientific community about using cloning as another possible avenue to produce offspring, humans have proved notoriously difficult to create and sustain past very early (blastocyst) development. Cloning entails insertion of a somatic cell nucleus into an oocyte from which the nucleus is removed and then an incubation period to dedifferentiate the inserted nucleus. This technique has proved more successful in creating stem cells for therapeutic use in treating selected diseases than for reproductive cloning to produce whole and healthy human offspring. Furthermore, human reproductive cloning is currently fraught with legal, moral, ethical, and political roadblocks.

In this chapter, we have focused on changes that occur during human development in utero. But having a baby is not always what the interacting partners have in mind, and we humans have devised a variety of techniques for preventing this outcome (see *A Closer Look* on p. 1090).

We must admit that the description of embryonic development here has fallen short because we have barely touched upon the phenomenon of differentiation. How does an unspecialized cell that can become *anything* in the body develop into a specific *something* (a heart cell, for example)? And what paces the developmental sequence, so that if a particular process fails to occur at a precise time, it never occurs at all? Scientists are beginning to believe that there are master switches in the genes. In Chapter 29, the final chapter of this book, we describe a small part of the “how” as we examine the interaction of genes and other components that determine who we finally become.

## Contraception: To Be or Not To Be

In a society such as ours, where many women opt for professional careers or work for economic reasons, **contraception** (*contra* = against, *cept* = taking), commonly called **birth control**, is often seen as a necessity.

The key to birth control is **dependability**. As the red arrows in the accompanying flowchart show, the birth control techniques currently available have many sites of action for **blocking reproduction**. Generally speaking, birth control methods can be categorized into three groups based on how each prevents pregnancy—behavioral methods, barrier methods, or hormonal methods. Let's examine a few of them more closely.

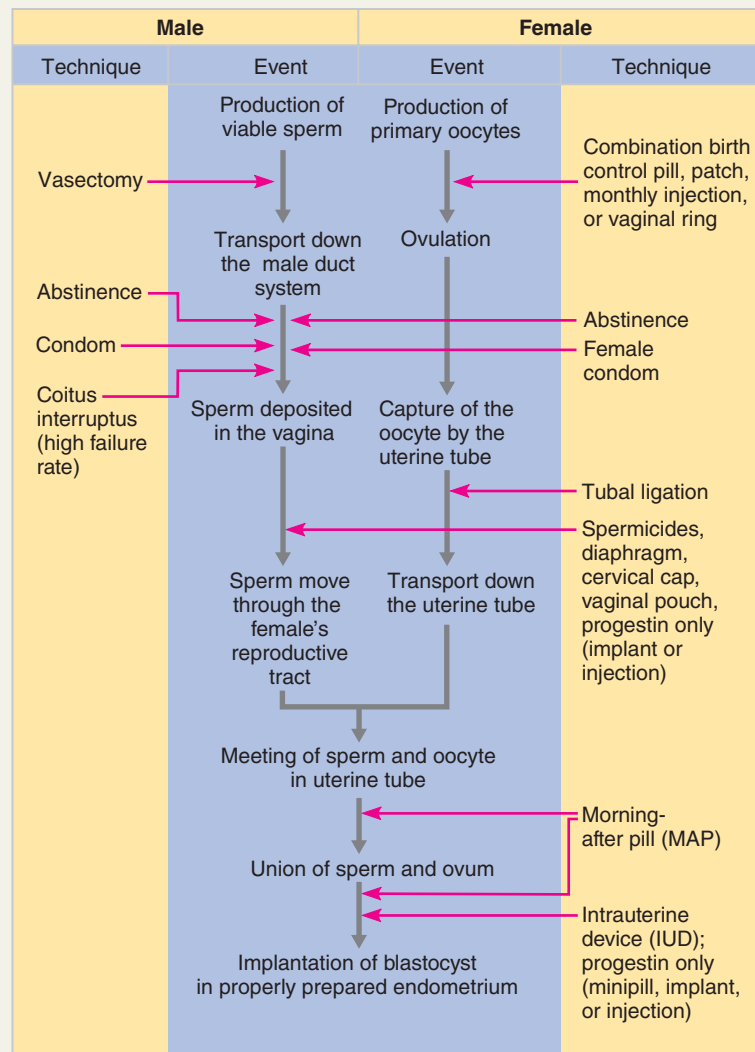

**Behavioral methods** (coitus interruptus, the rhythm method, and abstinence) consist of altering behavior to prevent pregnancy. *Coitus interruptus*, or withdrawal of the penis just before ejaculation, is unreliable because control of ejaculation is never ensured.

*Rhythm or temporary abstinence methods* involve avoiding intercourse during periods of ovulation or fertility. This may be accomplished by recording daily basal body temperatures (body temperature drops slightly immediately prior to ovulation and then rises slightly after ovulation). This technique requires accurate record keeping for several cycles before it can be used with confidence, but has a high success rate for those willing to take the time necessary. With a failure rate of 10–20%, it is obvious that some people are willing and some are not.

**Barrier methods** include diaphragms, cervical caps, male and female condoms, and spermicides. These techniques prevent the sperm and egg from meeting and implanting. They are quite effective, especially when used in combination—for example, condoms and spermicides. But many people avoid them because they can reduce the spontaneity of sexual encounters.

**Hormonal methods** include a broad variety of hormone-containing contraceptive products (the pill, IUD, patches, vaginal ring, and implanted or injected agents). These methods are highly effective, with a failure rate of less than 1%, and have a low risk of adverse effects in most women.

The most-used contraceptive product in the United States is the *oral contraceptive pill (OCP)* or simply "the pill," first

**Mechanisms of contraception.** Techniques or products that interfere with events from production of gametes to implantation are indicated by red arrows at the site of interference and act to prevent the next step from occurring.

marketed in 1960. Supplied in 28-tablet packets, the first 20 or 21 tablets contain minute amounts of estrogens and progestins (progesterone-like hormones) which are taken daily; the hormones contained may be of fixed or of varying combinations. The last seven tablets are hormone free—are placebos or are iron pills. The pill tricks the hypothalamic-pituitary-gonadal axis and "lulls it to sleep," because the relatively constant blood levels of ovarian hormones make it appear that the woman is pregnant (both estrogen and progesterone are produced throughout pregnancy). Ovarian follicles do not develop, ovulation ceases, and menstrual flow is much reduced.

However, since hormonal balance is one of the most precisely controlled body functions, some women cannot tolerate these changes—they become nauseated and/or hypertensive. The pill has adverse cardiovascular effects in a small number of users and there is still debate about whether it increases the risk of uterine, ovarian, or (particularly) breast cancer. Presently, well over 50 million women use the pill.

Other delivery methods using the combination hormone approach include two slow-release products—a flexible ring that is inserted into the vagina, and a transdermal (skin) patch. Failure rates and side effects of the vaginal ring

and skin patch are comparable to those of the pill. Combination birth control pills with substantially higher hormone concentrations used for *postcoital contraception* have a 75% effectiveness. Taken within three days of unprotected intercourse, these *morning-after pills* (MAPs), or *emergency contraceptive pills* (ECPs) as they are also called, “mess up” normal hormonal signals enough to prevent a fertilized egg from implanting or prevent fertilization altogether.

Other hormonal approaches to contraception use progestin-only products that thicken the cervical mucus enough to block sperm entry into the uterus, decrease the frequency of ovulation, and make the endometrium inhospitable to

implantation. These include match-size silicone rods implanted just under the skin that release progestin over a five-year period (Norplant), and an injectable form that lasts for three months (Depo Provera). New intrauterine devices (IUDs) that are inserted into the uterus provide sustained local delivery of synthetic progesterone to the endometrium and are particularly recommended for women who have given birth and are nursing or those in monogamous relationships. The failure rates of progestin treatments are even less than that of the “pill.”

**Sterilization techniques** permanently prevent gamete release. *Tubal ligation* or vasectomy (cutting or cauterizing the uterine tubes or ductus deferentia,

respectively) are nearly foolproof and are the choice of approximately 33% of couples of childbearing age in the United States. Both procedures can be done in the physician’s office. However, these techniques are usually permanent, making them unpopular with individuals who still plan to have children but want to select the time.

This summary doesn’t even begin to touch on the experimental birth control drugs now awaiting clinical trials, and other methods are sure to be developed in the near future. In the final analysis, however, the only 100% effective means of birth control is the age-old one—total abstinence.

1. The gestation period of approximately 280 days extends from the woman’s last menstrual period to birth. The conceptus undergoes embryonic development for 8 weeks after fertilization, and fetal development from week 9 to birth.

### From Egg to Zygote (pp. 1065–1067)

#### Accomplishing Fertilization (pp. 1065–1067)

1. An oocyte is fertilizable for up to 24 hours; most sperm are viable within the female reproductive tract for one to two days.
2. Sperm must survive the hostile environment of the vagina and become capacitated (capable of reaching and fertilizing the oocyte).
3. Hundreds of sperm must release their acrosomal enzymes to break down the egg’s corona radiata and zona pellucida.
4. When one sperm binds to receptors on the egg, it triggers the slow block to polyspermy (release of cortical granules).
5. Following sperm penetration, the secondary oocyte completes meiosis II. Then the ovum and sperm pronuclei fuse (fertilization), forming a zygote.

### Events of Embryonic Development: Zygote to Blastocyst Implantation (pp. 1067–1074)

#### Cleavage and Blastocyst Formation (p. 1067)

1. Early development consists of cleavage, a rapid series of mitotic divisions without intervening growth, that begins with the zygote and ends with a blastocyst. The blastocyst consists of the

trophoblast and an inner cell mass. Cleavage produces a large number of cells with a favorable surface-to-volume ratio.

#### Implantation (pp. 1067, 1070–1071)

2. The trophoblast adheres to, digests, and implants in the endometrium. Implantation is completed when the blastocyst is entirely surrounded by endometrial tissue, about 12 days after ovulation.
3. hCG released by the blastocyst maintains hormone production by the corpus luteum, preventing menses. hCG levels decline after four months.

#### Placentation (pp. 1071–1074)

4. The placenta acts as the respiratory, nutritive, and excretory organ of the fetus and produces the hormones of pregnancy. It is formed from embryonic (chorionic villi) and maternal (endometrial decidua) tissues. The chorion develops when the trophoblast becomes associated with extraembryonic mesoderm. Typically, the placenta is functional as an endocrine organ by the third month.

### Events of Embryonic Development: Gastrula to Fetus (pp. 1074–1081)

#### Formation and Roles of the Extraembryonic Membranes (pp. 1074–1075)

1. The fluid-filled amnion forms from cells of the superior surface (epiblast) of the embryonic disc. It protects the embryo from physical trauma and adhesion formation, provides a constant temperature, and allows fetal movements.
2. The yolk sac forms from the hypoblast of the embryonic disc; it is the source of early blood cells.
3. The allantois, a caudal outpocketing adjacent to the yolk sac, forms the structural basis of the umbilical cord.
4. The chorion is the outermost membrane and takes part in placentation.

#### Gastrulation: Germ Layer Formation (pp. 1075–1076)

5. Gastrulation involves cellular migrations that ultimately transform the inner cell mass into a three-layered embryo

(gastrula) containing ectoderm, mesoderm, and endoderm. Cells that move through the midline primitive streak become endoderm if they form the most inferior layer of the embryonic disc and mesoderm if they ultimately occupy the middle layer. Cells remaining on the superior surface become ectoderm.

### Organogenesis: Differentiation of the Germ Layers (pp. 1076–1081)

- Endoderm forms the mucosa of the digestive and respiratory systems, and the epithelial cells of all associated glands (thyroid, parathyroids, thymus, liver, pancreas). It becomes a continuous tube when the embryonic body undercuts and fuses ventrally.
- Ectoderm forms the nervous system and the epidermis of the skin and its derivatives. The first event of organogenesis is neurulation, which produces the brain and spinal cord. By the eighth week, all major brain regions are formed.
- Mesoderm forms all other organ systems and tissues. It segregates early into (1) a dorsal superior notochord, (2) paired somites that form the vertebrae, skeletal trunk muscles, and part of the dermis, and (3) paired masses of intermediate and lateral plate mesoderm. The intermediate mesoderm forms the kidneys and gonads. The lateral plate mesoderm forms the dermis of skin; parietal serosa; bones and muscles of the limbs; the cardiovascular system; and the visceral serosae.
- The fetal cardiovascular system is formed in the embryonic period. The umbilical vein delivers nutrient- and oxygen-rich blood to the embryo; the paired umbilical arteries return oxygen-poor, waste-laden blood to the placenta. The ductus venosus allows most of the blood to bypass the liver; the foramen ovale and ductus arteriosus are pulmonary shunts.

### Events of Fetal Development (pp. 1081–1082)

- All organ systems are laid down during the embryonic period; growth and tissue/organ specialization are the major events of the fetal period.
- During the fetal period, fetal length increases from about 22 mm to 360 mm, and weight increases from less than an ounce to 7 pounds or more.

### Effects of Pregnancy on the Mother (pp. 1082–1085)

#### Anatomical Changes (pp. 1082–1083)

- Maternal reproductive organs and breasts become increasingly vascularized during pregnancy, and the breasts enlarge.
- The uterus eventually occupies nearly the entire abdominopelvic cavity. Abdominal organs are pushed superiorly and encroach on the thoracic cavity, causing the ribs to flare.
- The increased abdominal mass changes the woman's center of gravity; lordosis and backache are common. A waddling gait occurs as pelvic ligaments and joints are loosened by placental relaxin.
- A typical weight gain during pregnancy in a woman of normal weight is 28 pounds.

#### Metabolic Changes (p. 1083)

- Human placental lactogen has anabolic effects and promotes glucose sparing in the mother.

#### Physiological Changes (pp. 1083–1085)

- Many women suffer morning sickness, heartburn, and constipation during pregnancy.
- The kidneys produce more urine, and pressure on the bladder may cause frequency, urgency, and stress incontinence.

- Respiratory tidal volume increases, but residual volume decreases. The respiratory rate remains relatively unchanged. Dyspnea is common.
- Total body water and blood volume increase dramatically and cardiac output rises. Blood pressure declines in midpregnancy and then rises to normal levels during the third trimester.

### Parturition (Birth) (pp. 1085–1087)

- Parturition encompasses a series of events called labor.

#### Initiation of Labor (p. 1085)

- When estrogen levels are sufficiently high, they induce oxytocin receptors on the myometrial cells and inhibit progesterone's quieting effect on uterine muscle. Weak, irregular contractions begin.
- Fetal cells produce oxytocin, which stimulates prostaglandin production by the placenta. Both hormones stimulate contraction of uterine muscle. Increasing distension of the cervix activates the hypothalamus, causing oxytocin release from the mother's posterior pituitary; this sets up a positive feedback loop resulting in true labor.

#### Stages of Labor (pp. 1085–1087)

- The dilation stage is from the onset of rhythmic, strong contractions until the cervix is fully dilated. The head of the fetus rotates as it descends through the pelvic outlet.
- The expulsion stage extends from full cervical dilation until birth of the infant.
- The placental stage is the delivery of the afterbirth (the placenta and attached fetal membranes).

### Adjustments of the Infant to Extrauterine Life (p. 1087)

- The infant's Apgar score is recorded immediately after birth.

#### Taking the First Breath and Transition (p. 1087)

- After the umbilical cord is clamped, carbon dioxide accumulates in the infant's blood, causing respiratory centers in the brain to trigger the first inspiration.
- Once the lungs are inflated, breathing is eased by the presence of surfactant, which decreases the surface tension of the alveolar fluid.
- During transition, the first 8 hours after birth, the infant is physiologically unstable and adjusting. After stabilizing, the infant wakes approximately every 3–4 hours in response to hunger.

### Occlusion of Special Fetal Blood Vessels and Vascular Shunts (p. 1087)

- Inflation of the lungs causes pressure changes in the circulation; as a result, the umbilical arteries and vein, ductus venosus, and ductus arteriosus collapse, and the foramen ovale closes. The occluded blood vessels are converted to fibrous cords; the site of the foramen ovale becomes the fossa ovalis.

### Lactation (pp. 1087–1089)

- The breasts are prepared for lactation during pregnancy by high blood levels of estrogen, progesterone, and human placental lactogen.
- Colostrum, a premilk fluid, is a fat-poor fluid that contains more protein, vitamin A, and minerals than true milk. It is produced toward the end of pregnancy and for the first two to three days after birth.

- True milk is produced around day 3 in response to suckling, which stimulates the hypothalamus to prompt anterior pituitary release of prolactin and posterior pituitary release of oxytocin. Prolactin stimulates milk production. Oxytocin triggers milk let-down. Continued breast-feeding is required for continued milk production.
- At first, ovulation and menses are absent or irregular during nursing, but in most women the ovarian cycle is eventually reestablished while still nursing.

## Review Questions

### Multiple Choice/Matching

(Some questions have more than one correct answer. Select the best answer or answers from the choices given.)

- Indicate whether each of the following statements is describing (a) cleavage or (b) gastrulation.
  - \_\_\_ (1) period during which a morula forms
  - \_\_\_ (2) period when vast amounts of cell migration occur
  - \_\_\_ (3) period when the three embryonic germ layers appear
  - \_\_\_ (4) period during which the blastocyst is formed
- Most systems are operational in the fetus by four to six months. Which system is the exception to this generalization, affecting premature infants? (a) the circulatory system, (b) the respiratory system, (c) the urinary system, (d) the digestive system.
- The zygote contains chromosomes from (a) the mother only, (b) the father only, (c) both the mother and father, but half from each, (d) each parent and synthesizes others.
- The outer layer of the blastocyst, which later attaches to the uterus, is the (a) decidua, (b) trophoblast, (c) amnion, (d) inner cell mass.
- The fetal membrane that forms the basis of the umbilical cord is the (a) allantois, (b) amnion, (c) chorion, (d) yolk sac.
- In the fetus, the ductus arteriosus carries blood from (a) the pulmonary artery to the pulmonary vein, (b) the liver to the inferior vena cava, (c) the right ventricle to the left ventricle, (d) the pulmonary trunk to the aorta.
- Which of the following changes occur in the baby's cardiovascular system after birth? (a) Umbilical arteries and vein become fibrosed, (b) pulmonary circulation begins to function, and pressure in the left side of the heart increases, (c) the ductus venosus becomes obliterated, as does the ductus arteriosus, (d) all of these.
- Following delivery of the infant, the delivery of the afterbirth includes the (a) placenta only, (b) placenta and decidua, (c) placenta and attached (torn) fetal membranes, (d) chorionic villi.
- The umbilical vein carries (a) waste products to the placenta, (b) oxygen and food to the fetus, (c) oxygen and food to the placenta, (d) oxygen and waste products to the fetus.
- The germ layer from which the skeletal muscles, heart, and skeleton are derived is the (a) ectoderm, (b) endoderm, (c) mesoderm.
- Which of the following cannot pass through placental barriers? (a) blood cells, (b) glucose, (c) amino acids, (d) gases, (e) antibodies.

### Assisted Reproductive Technology and Reproductive Cloning (pp. 1089–1091)

- Assisted reproductive technology (ART) procedures assist infertile couples to bear children. Among the most-used techniques are IVF, ZIFT, and GIFT. IVF and ZIFT attempt to fertilize harvested oocytes in vitro and then return the embryo or zygote to the woman's body. GIFT utilizes in vivo methods—sperm and oocytes are transferred together to the woman's uterine tubes.
- Reproductive cloning in humans has proved difficult to achieve and the practice has met several roadblocks.

- The most important hormone in initiating and maintaining lactation after birth is (a) estrogen, (b) FSH, (c) prolactin, (d) oxytocin.
- The initial stage of labor, during which the neck of the uterus is stretched, is the (a) dilation stage, (b) expulsion stage, (c) placental stage.
- Match each adult structure in column B with the embryonic structure it derives from in column A.

Column A	Column B
___ (1) notochord	(a) kidney
___ (2) ectoderm (not neural tube)	(b) peritoneal cavity
___ (3) intermediate mesoderm	(c) pancreas, liver
___ (4) lateral plate mesoderm	(d) parietal serosa, dermis
___ (5) sclerotome	(e) nucleus pulposus
___ (6) coelom	(f) hair and epidermis
___ (7) neural tube	(g) brain
___ (8) endoderm	(h) ribs and vertebrae

### Short Answer Essay Questions

- What is the function of hCG and why is it not important after the first trimester of pregnancy?
- Fertilization involves much more than a mere restoration of the diploid chromosome number. (a) What does the process of fertilization entail on the part of both the egg and sperm? (b) What are the effects of fertilization?
- Cleavage is an embryonic event that mainly involves mitotic divisions. How does cleavage differ from mitosis occurring during life after birth, and what are its important functions?
- The life span of the ovarian corpus luteum is extended for nearly three months after implantation, but otherwise it deteriorates. (a) Explain why this is so. (b) Explain why it is important that the corpus luteum remain functional following implantation.
- The placenta is a marvelous, but temporary, organ. Starting with a description of its formation, show how it is an intimate part of both fetal and maternal anatomy and physiology during the gestation period.
- Why is it that only one sperm out of the hundreds (or thousands) available enters the oocyte?
- What is the function of gastrulation?
- Cite two problems with a breech presentation.
- What factors are believed to bring about uterine contractions at the termination of pregnancy?
- Explain how the flat embryonic disc takes on the cylindrical shape of a tadpole.

### Critical Thinking and Clinical Application Questions

- Jennie, a freshman in your dormitory, tells you she just discovered that she is three months pregnant. She recently bragged that since she came to college she has been drinking alcohol heavily and experimenting with every kind of recreational drug she could find. From the following, select the advice you would give her, and explain why it is the best choice. (a) She must stop taking drugs, but they could not have affected her fetus during these first few months of her pregnancy. (b) Harmful substances usually cannot pass from mother to embryo, so she can keep using drugs. (c) There could be defects in the fetus, so she should stop using drugs and visit a doctor as soon as possible. (d) If she has not taken any drugs in the last week, she is okay.
- During Mrs. Jones's labor, the obstetrician decided that it was necessary to perform an episiotomy. What is an episiotomy, and why is it done?
- A woman in substantial pain called her doctor and explained (between sobs) that she was about to have her baby "right here." The doctor calmed her and asked how she had come to that conclusion. She said that her water had broken and that her husband could see the baby's head. (a) Was she right? If so, what stage of labor was she in? (b) Do you think that she had time to make it to the hospital 60 miles away? Why or why not?
- Mary is a heavy smoker and has ignored a friend's advice to stop smoking during her pregnancy. On the basis of what you know about the effect of smoking on physiology, describe how Mary's smoking might affect her fetus.
- While Mortimer was cramming for his anatomy test, he read that some parts of the mesoderm become segmented. He suddenly realized that he could not remember what segmentation is. Define segmentation, and give two examples of segmented structures in the embryo.
- Assume a sperm has penetrated a polar body and their nuclei fuse. Why would it be unlikely for the resulting cell to develop into a healthy embryo?

## AT THE CLINIC

### Related Clinical Terms

**Abortion** (*abort* = born prematurely) Termination of a pregnancy that is in progress; may be spontaneous or induced.

**Ectopic pregnancy** (*ek-top'ik; ecto* = outside) A pregnancy in which the embryo implants in any site other than the uterus; most often the site is a uterine tube (tubal pregnancy). Since the uterine tube (as well as most other ectopic sites) is unable to establish a placenta or accommodate growth, the uterine tube ruptures unless the condition is diagnosed early, or the pregnancy spontaneously aborts.

**Hydatid (hydatidiform) mole** (*hi'dah-tid; hydat* = watery) Developmental abnormality of the placenta; the conceptus degenerates and the chorionic villi convert into a mass of vesicles that resemble tapioca. Signs include vaginal bleeding, which contains some of the grapelike vesicles.

**Physiological jaundice** (*jawn'dis*) Jaundice sometimes occurring in normal newborns within three to four days after birth. Fetal

erythrocytes are short-lived, and they break down rapidly after birth; the infant's liver may be unable to process the bilirubin (breakdown product of hemoglobin pigment) fast enough to prevent its accumulation in blood and subsequent deposit in body tissues.

**Abruptio placenta** (*ah-brup'she-o; abrupt* = broken away from) Premature separation of the placenta from the uterine wall; if this occurs before labor, it can result in fetal death due to anoxia.

**Placenta previa** (*pre've-ah*) Placental formation adjacent to or across the internal os of the uterus. Represents a problem because as the uterus and cervix stretch, separation of the placenta may occur. Additionally, the placenta precedes the infant during labor.

**Ultrasonography** (*ul'trah-son-og'rah-fe*) Noninvasive technique that uses sound waves to visualize the position and size of the fetus and placenta (see *A Closer Look*, Chapter 1).

### Case Study Pregnancy

When paramedics arrived on the crash scene on Route 91, they found Maria Rodriguez, a 34-year-old female, lying on the edge of the road. Mrs.

Rodriguez was responsive, but had deep lacerations on both legs and her right arm. Her clothes were heavily stained with blood, despite the efforts of another passenger to slow the bleeding by applying compression. On initial examination, Mrs. Rodriguez's blood pressure was 100/70 with a heart rate of 88. The paramedics started an IV of normal saline, stabilized her, and controlled the bleeding during transport to the hospital. Mrs. Rodriguez was released from the hospital three days later and scheduled for a follow-up visit in one week. At her follow-up appointment, she complained of fatigue and reported that her period was overdue by one week. Hospital blood tests revealed that Mrs. Rodriguez was mildly anemic—and pregnant. While she was excited, she was also very concerned that the blood loss she suffered may have harmed her baby.

- What hormone did the hospital detect in Mrs. Rodriguez's blood to determine that she was pregnant?
- Where is the hormone made that you identified in question 1? What function does it play during the early stages of a pregnancy?
- Mrs. Rodriguez's doctors explained that the blood loss she suffered as a result of the accident occurred approximately 10–12 days after her most recent ovulation. Explain why this may help ease Mrs. Rodriguez's fears about harm to her baby.
- Describe the major developmental events and stages of embryonic development that have occurred during the time prior to Mrs. Rodriguez's accident.
- Mrs. Rodriguez is currently in the third week of pregnancy. Describe the important embryonic developmental event that occurs during this time.

Human Gene Therapy (pp. 1104–1105)

**T**he wondrous growth and development of a new individual is guided by the gene-bearing chromosomes it receives from its parents in egg and sperm. As we described in Chapter 3, individual *genes*, or DNA segments, contain the “recipes” or genetic blueprints for proteins. Many of these proteins are enzymes that dictate the synthesis of virtually all the body’s molecules. Consequently, genes are ultimately expressed in your hair color, sex, blood type, and so on.

Genes, however, do not act as free agents. As you will see, a gene’s ability to prompt the development of a specific trait is enhanced or inhibited by interactions with other genes, as well as by environmental factors.

The science of genetics, which studies the mechanism of heredity (*genes* = give birth to), is relatively young, but our understanding of how human genes act and interact has advanced considerably since Gregor Mendel first proposed the basic principles of heredity in the mid-1800s. Mendel studied characteristics that vary in an either-or fashion, which is easier to understand than the more-or-less fashion in which many human traits vary.

① The slide is viewed with a microscope, and the chromosomes are photographed.

② The photograph is entered into a computer, and the chromosomes are electronically rearranged into homologous pairs according to size and structure.

③ The resulting display is the karyotype, which is examined for chromosome number and structure.

### Figure 29.1 Preparing a karyotype.

After lymphocytes are stimulated to divide and grow in culture for several days, they are treated with a drug that arrests mitosis in metaphase, a stage when the chromosomes

are easily identified. The cells are harvested, treated with a solution that makes their chromosomes spread out, photographed, and then subjected to computer analysis and arrangement of the chromosomes

into homologous pairs. The patterns of stained bands in the karyotype help to identify specific chromosomes and parts of chromosomes.

However, the urge to understand human inheritance is powerful. The *Human Genome Project*, which scanned and determined the human DNA sequence, is enabling geneticists to manipulate and engineer human genes to examine their expression. This research has tremendous promise for more sophisticated genetic screening, and for drug development to treat or cure disease. Although we touch upon some of these newer topics, we will concentrate on the principles of heredity discovered by Mendel more than a century ago.

## The Vocabulary of Genetics

- ✓ Define allele.
- ✓ Differentiate between genotype and phenotype.

The nuclei of all human cells except gametes contain the diploid number of chromosomes (46), consisting of 23 pairs of homologous chromosomes. Recall that *homologous chromosomes* are pairs of chromosomes—one from the father (sperm) and one from the mother (egg)—that look similar and carry genes for the same traits, but do not necessarily bring about the same expressions of those traits. Two of the 46 chromosomes are **sex chromosomes** (X and Y), which determine genetic sex (male = XY; female = XX). The other 44 are the 22 pairs of **autosomes** that guide the expression of most other traits.

The complete human **karyotype** (kar'e-o-tip), or diploid chromosomal complement displayed in homologous pairs, is illustrated in **Figure 29.1** ③. The diploid **genome** (je'nōm), or genetic (DNA) makeup, represents two sets of genetic instructions—one from the egg and the other from the sperm.

### Gene Pairs (Alleles)

Because chromosomes are paired, it follows that the genes in them are paired as well. Consequently, each of us receives *two* genes, one from each parent (for the most part), that interact to dictate each trait. Matched genes, which are at the same *locus* (location) on homologous chromosomes, are called **alleles** (ah-lēlz') of each other. Alleles may code for the same or for alternative forms of a given trait. For example, of the alleles that dictate whether or not you have loose thumb ligaments, one allele might code for tight ligaments and the other for loose ligaments (the double-jointed thumb condition). When the two alleles controlling a trait are the same, a person is said to be **homozygous** (ho-mo-zi'gus) for that trait. When the two alleles are different, the individual is **heterozygous** (het'er-o-zi'gus) for the trait.

Sometimes, one allele masks or suppresses the expression of its partner. Such an allele is said to be **dominant**, whereas the allele that is masked is said to be **recessive**. By convention, a dominant allele is represented by a capital letter (for example, *J*),

**Figure 29.2 Gamete variability resulting from independent assortment.**

During metaphase of meiosis I, the tetrads of homologous chromosomes align

independently of other tetrads. The large circles depict the possible alignments in a mother cell having a diploid number of 6. The small circles show the gametes arising from

each alignment. Some gametes contain all maternal or all paternal chromosomes; others have various combinations of maternal and paternal chromosomes.

and a recessive allele by the lowercase form of the same letter (*j*). Dominant alleles are expressed, or make themselves “known,” when they are present in either single or double dose. For recessive alleles to be expressed, they must be present in double dose, that is, the homozygous condition. Returning to our thumb example, a person whose genetic makeup includes either the gene pair *JJ* (the homozygous dominant condition) or the gene pair *Jj* (the heterozygous condition) will have double-jointed thumbs. The combination *jj* (the homozygous recessive condition) is needed to produce tight thumb ligaments.

## Genotype and Phenotype

A person’s genetic makeup is referred to as his or her **genotype** (jen’o-tip). The way that genotype is expressed in the body is called one’s **phenotype** (fe’no-tip). For example, the double-jointed condition is the phenotype produced by a genotype of *JJ* or *Jj*.

### ✓ Check Your Understanding

1. When a geneticist orders a karyotype, why are cells in metaphase studied instead of those in interphase?
2. What term refers to chromosomes other than our sex chromosomes?
3. Is an allele represented by a capital letter presumed to be dominant or recessive?
4. Harold is homozygous for the dominant alleles *HH*, *CC*, and *LL*, and heterozygous for *Bb* and *Kk*. He is blond and blue-eyed and has a very hairy chest. Which of these descriptions refer to his phenotype?

For answers, see Appendix H.

## Sexual Sources of Genetic Variation

- ✓ Describe events that lead to genetic variability of gametes.

Before we examine how genes interact, let us consider why (with the possible exception of identical siblings) each of us is one of a kind, with a unique genotype and phenotype. This variability reflects three events that occur before we are even a twinkle in our parents’ eyes: independent assortment of chromosomes, crossover of homologues, and random fertilization of eggs by sperm.

## Chromosome Segregation and Independent Assortment

As we described in Chapter 27, each pair of homologous chromosomes synapses during meiosis I, forming a tetrad. This happens during both spermatogenesis and oogenesis. Because chance determines how the tetrads align (line up) on the meiosis I metaphase spindle, maternal and paternal chromosomes are randomly distributed to daughter nuclei.

As illustrated in **Figure 29.2**, this simple event leads to an amazing amount of variation in gametes. The cell in our example has a diploid number of 6, and so three tetrads form. As you can see, the possible combinations of alignments of the three tetrads result in eight gamete possibilities. Because the way each tetrad aligns is random, and because many cells are undergoing meiosis simultaneously, each alignment and each type of gamete occurs with the same frequency as all others.

Two important points about metaphase of meiosis I: (1) The two alleles determining each trait are **segregated**, which

**Figure 29.3 Crossover and genetic recombination.** These meiosis I events increase genetic variability in the gametes formed. For simplicity, only two chromatids are shown taking part in crossover. Multiple crossovers result in more complex patterns.

means that they are distributed to different gametes. Errors in this important process have been linked to cancer progression, infertility, and Down syndrome. (2) Alleles on different pairs of homologous chromosomes are distributed independently of each other. The net result is that each gamete has a single allele for each trait, and that allele represents only one of the four possible parental alleles.

The number of different gamete types resulting from this **independent assortment** of homologues during meiosis I can be calculated for any genome from the formula  $2^n$ , where  $n$  is the number of homologous pairs. In our example,  $2^n = 2^3 (2 \times 2 \times 2)$ , for a total of 8 different gamete types.

Note that the number of gamete types increases dramatically as the chromosome number increases. A cell with six pairs of homologues would produce  $2^6$ , or 64, kinds of gametes. In a man's testes, the number of gamete types that can be produced on the basis of independent assortment alone is  $2^{23}$ , or about 8.5 million—an incredible variety. The number of different gamete types produced simultaneously in a woman's ovaries is substantially less because her ovaries complete at most 500 reduction divisions in her lifetime. Still, each ovulated oocyte will most likely be novel genetically because of independent assortment.

### Crossover of Homologues and Gene Recombination

Additional gamete variation results from the crossing over and exchange of chromosomal parts during meiosis I. Genes are arranged linearly along a chromosome's length, and genes on the same chromosome are said to be **linked** because they are transmitted as a unit to daughter cells during mitosis. However, as we described in Chapter 27, chromosomes can break and precisely exchange gene segments with their homologous counterparts during meiosis. This exchange gives rise to **recombinant chromosomes** that have mixed contributions from each parent.

In the hypothetical example shown in **Figure 29.3**, the genes for hair and eye color are linked. The paternal chromosome contains alleles coding for blond hair and blue eyes, and the maternal alleles code for brown hair and brown eyes. In the **crossover**, or **chiasma**, shown, the break occurs between these linked genes, resulting in one gamete with alleles for blond hair and brown eyes and another with alleles for brown hair and blue eyes. As a result of the crossover, two of the four chromatids present in the tetrad end up with a mixed set of alleles—some maternal and some paternal. This means that when the chromatids segregate, each gamete will receive a unique combination of parental genes.

Because humans have 23 tetrads, with crossovers going on in all of them during meiosis I, the variability resulting from this factor alone is tremendous.

### Random Fertilization

At any point in time, gametogenesis is turning out gametes with all variations possible from independent assortment and random crossovers. Fertilization compounds this variety because a single human egg will be fertilized by a single sperm on a totally hap-hazard, or random, basis. If we consider variation resulting only

from independent assortment and random fertilization, any offspring represents one out of the close to 72 trillion ( $8.5 \text{ million} \times 8.5 \text{ million}$ ) zygotes possible. The additional variation introduced by crossovers increases this number exponentially. Perhaps now you can understand why brothers and sisters are so different, and marvel at how they can also be so alike in many ways.

### ✓ Check Your Understanding

- We said that genetic variability is introduced by independent assortment. Just what is assorting independently?
- How does crossover increase genetic variability?

For answers, see Appendix H.

## Types of Inheritance

A few human phenotypes can be traced to a single gene pair (as we will describe shortly), but most such traits are very limited in nature, or reflect variation in a single enzyme. Most human traits are determined by multiple alleles or by the interaction of several gene pairs.

### Dominant-Recessive Inheritance

- ✓ Compare and contrast dominant-recessive inheritance with incomplete dominance and codominance.

**Dominant-recessive inheritance** reflects the interaction of dominant and recessive alleles. A simple diagram, called the **Punnett square**, is used to figure out, for a single trait, the possible gene combinations that would result from the mating of parents of known genotypes (Figure 29.4). In the example shown, both parents can roll their tongue into a U because both are heterozygous for the dominant allele ( $T$ ) that confers this ability. In other words, each parent has the genotype  $Tt$ . The alleles of one parent are written along one side of the Punnett square, and the alleles for the other parent are shown along an adjacent side. The alleles are then combined down and across to determine the possible gene combinations (genotypes) and their expected frequency in the offspring of these two parents.

As the completed Punnett square shows, the probability of these parents producing a homozygous dominant child ( $TT$ ) is 25% (1 out of 4); of producing a heterozygous child ( $Tt$ ), 50% (2 out of 4); and of producing a homozygous recessive child, 25% (1 out of 4). The  $TT$  and  $Tt$  offspring will be tongue rollers. Only the  $tt$  offspring will not be able to roll their tongues.

The Punnett square predicts only the *probability* of a particular genotype (and phenotype). The larger the number of offspring, the greater the likelihood that the ratios will conform to the predicted values—just as the chances of getting heads half the time and tails half the time increase with the number of tosses of a coin. If we toss only twice, we may well get heads both times. Likewise, if the couple in our example had only two children, it would not be surprising if both children had the genotype  $Tt$ .

What are the chances of having two children of the same genotype? To determine the probability of two events happening in succession, we must multiply the probabilities of the separate

**Figure 29.4** Genotype and phenotype probabilities resulting from a mating of two heterozygous parents. The Punnett square shows all possible combinations of a set of alleles in the zygote. In this example, the  $T$  allele is dominant and determines tongue-rolling ability; the  $t$  allele is recessive.

events happening. The probability of getting heads in one coin toss is  $1/2$ , so the probability of getting two heads in a row is  $1/2 \times 1/2 = 1/4$ . Remember that the production of each child, like each coin toss in a series, is an *independent event* that does not influence the production of any other child by the same couple. If you get heads on the first toss, the chance of getting heads the second time is still  $1/2$ . Likewise, if our couple's first child is a  $tt$ , they still have a  $1/4$  chance of getting a  $tt$  the next time.

### Dominant Traits

Human traits dictated by dominant alleles include widow's peaks, dimples, and freckles.

Disorders caused by dominant genes are uncommon because *lethal dominant genes* are almost always expressed and result in the death of the embryo, fetus, or child. However, in some dominant disorders the person is less impaired or at least survives long enough to reproduce. One example is *Huntington's disease*, a fatal nervous system disease involving degeneration of the basal nuclei. It involves a *delayed-action gene* that is expressed when the affected individual is about 40. Offspring of a parent with Huntington's disease have a 50% chance of inheriting the lethal gene. (The parent is heterozygous, because the dominant homozygous condition is lethal to the fetus.) Many informed offspring of such parents are opting not to become parents themselves.

These and some other dominant gene-determined traits are listed in Table 29.1.

**Table 29.1** Traits Determined by Simple Dominant-Recessive Inheritance

PHENOTYPE DUE TO EXPRESSION OF:	
DOMINANT GENES (ZZ OR Zz)	RECESSIVE GENES (zz)
Tongue roller	Inability to roll tongue into a U shape
Astigmatism	Normal vision
Freckles	Absence of freckles
Dimples in cheeks	Absence of dimples
PTC* taster	PTC nontaster
Widow's peak	Straight hairline
Double-jointed thumb	Tight thumb ligaments
Syndactyly (webbed digits)	Normal digits
Achondroplasia (heterozygous: dwarfism; homozygous: lethal)	Normal endochondral ossification
Huntington's disease	Absence of Huntington's disease
Normal skin pigmentation	Albinism
Absence of Tay-Sachs disease	Tay-Sachs disease
Absence of cystic fibrosis	Cystic fibrosis

\*PTC is phenylthiocarbamide, a harmless bitter chemical.

### Recessive Traits

Some examples of recessive inheritance are the more desirable genetic condition. For example, normal vision is dictated by recessive alleles, whereas astigmatism is prescribed by dominant alleles. However, many if not most genetic disorders are inherited as simple recessive traits. These include conditions as different as *albinism* (lack of skin pigmentation); *cystic fibrosis*, a condition of excessively thick mucus production that impairs lung and pancreatic functioning; and *Tay-Sachs disease*, a disorder of brain lipid metabolism, caused by an enzyme deficit that shows itself a few months after birth.

Recessive genetic disorders are more frequent than those caused by dominant alleles because those who carry a *single* recessive allele for a recessive genetic disorder do not themselves express the disease. However, they can pass the gene on to offspring and so are called carriers of the disorder. Conversely, as we explained above, few individuals with dominant genetic disorders get a chance to pass on the detrimental gene.

### 29 Incomplete Dominance

In dominant-recessive inheritance, one allele variant completely masks the other. Some traits, however, exhibit **incomplete dominance**. In such instances, the heterozygote has a phenotype intermediate between those of homozygous dominant and homozygous recessive individuals. Incomplete dominance is uncommon in humans.

Perhaps the best human example is inheritance of the *sickling gene* (*s*), which causes a substitution of one amino acid in the beta chain of hemoglobin. Hemoglobin molecules containing the abnormal beta chains crystallize when blood

**Table 29.2** ABO Blood Groups

BLOOD GROUP (PHENOTYPE)	GENOTYPE	FREQUENCY (% OF U.S. POPULATION)		
		WHITE	BLACK	ASIAN
O	<i>ii</i>	45	49	40
A	<i>I<sup>A</sup>I<sup>A</sup></i> or <i>I<sup>A</sup>i</i>	40	27	28
B	<i>I<sup>B</sup>I<sup>B</sup></i> or <i>I<sup>B</sup>i</i>	11	20	27
AB	<i>I<sup>A</sup>I<sup>B</sup></i>	4	4	5

oxygen levels are low, causing the erythrocytes to assume a sickle shape (see Figure 17.8b, p. 639). Individuals with a double dose of the sickling allele (*ss*) have **sickle-cell anemia**, and any condition that lowers their blood oxygen level, such as respiratory difficulty or excessive exercise, can precipitate a *sickle-cell crisis*. The deformed erythrocytes jam up and fragment in small capillaries, causing intense pain.

Individuals heterozygous for the sickling gene (*Ss*) have **sickle-cell trait**. They make both normal and sickling hemoglobin, and as a rule, these individuals are healthy. However, they can suffer a crisis if there is prolonged reduction in blood oxygen levels, as might happen when traveling in high-altitude areas, and they can transmit the sickling gene to their offspring.

### Multiple-Allele Inheritance

Although we inherit only two alleles for each gene, some genes exhibit more than two allele forms, leading to a phenomenon called **multiple-allele inheritance**. For example, three alleles determine the ABO blood types in humans: *I<sup>A</sup>*, *I<sup>B</sup>*, and *i*. Each of us receives two of these. The *I<sup>A</sup>* and *I<sup>B</sup>* alleles are *codominant*, and both are expressed when present, resulting in the AB blood type. The *i* allele is recessive to the other two. Genotypes determining the four possible ABO blood groups are shown in **Table 29.2**.

### ✓ Check Your Understanding

- Why are there so few genetic disorders caused by dominant genes?
- How does incomplete dominance differ from codominance?

For answers, see Appendix H.

### Sex-Linked Inheritance

✓ Describe the mechanism of sex-linked inheritance.

Inherited traits determined by genes on the sex chromosomes are said to be **sex-linked**. The X and Y sex chromosomes are not homologous in the true sense. The Y, which contains the gene (or genes) that determines maleness, is much smaller than the X chromosome (**Figure 29.5**). The X bears over 2500 genes, and a disproportionately large number of them code for proteins important to brain function. Because the Y carries only 78 genes as of the last count, it lacks many of the genes present on the X. For example, genes coding for certain clotting factors, cone pigments, and even

**Figure 29.5** Human sex chromosomes (14,100 $\times$ )

testosterone receptors are present on X but not on Y. A gene found only on the X chromosome is said to be **X-linked**.

Only relatively short regions at either end of the Y chromosome (corresponding to about 5% of the Y's DNA) code for nonsexual characteristics corresponding to those on the X. Those regions are the only areas that can participate in crossovers with the X.

When a male inherits an X-linked recessive allele—for example, for hemophilia or for red-green color blindness—its expression is never masked or damped, because there is no corresponding allele on his Y chromosome. Consequently, the recessive gene is always expressed, even when present only in single dose. In contrast, females must have two X-linked recessive alleles to express such a disorder, and as a result, very few females exhibit any X-linked conditions.

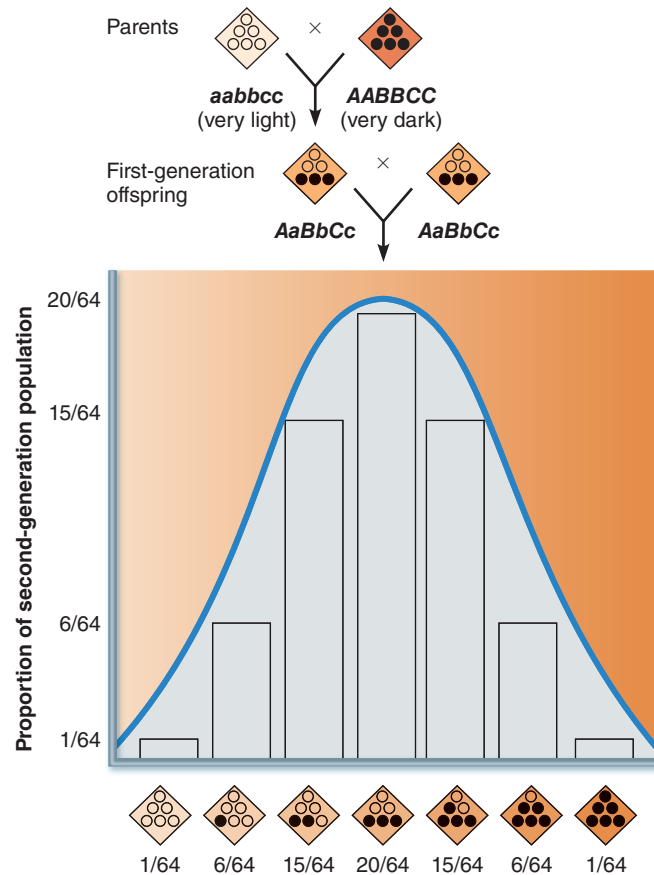

X-linked traits are typically passed from mother to son, never from father to son, because males receive no X chromosome from their father. Of course, the mother can also pass the recessive allele to her daughter, but unless the daughter receives another such allele from her father, she will not express the trait.

## Polygene Inheritance

- ✓ Explain how polygene inheritance differs from that resulting from the action of a single pair of alleles.

So far, we have considered only traits inherited by mechanisms of classical Mendelian genetics, which are fairly easy to understand, and such traits typically have two, or perhaps three, alternate forms. However, many phenotypes depend on several gene pairs at different locations acting in tandem. Such **polygene inheritance** results in *continuous*, or *quantitative*, phenotypic variation between two extremes and explains many human characteristics. Examples of polygene traits in humans include skin color, height, metabolic rate, and intelligence.

Skin color, for instance, is controlled by three separately inherited genes, each existing in two allelic forms: *A*, *a*; *B*, *b*; *C*, *c*. The *A*,

**Figure 29.6** Simplified model for polygene inheritance of skin color based on three gene pairs. Alleles for dark skin are incompletely dominant over those for light skin. Each dominant gene (*A*, *B*, *C*) contributes 1 “unit” of darkness (indicated by a dark dot) to the phenotypes.

Here the parents are homozygotes at opposite ends of the phenotype range. Each child inherits 3 “units” of darkness (is a heterozygote) and has intermediate pigmentation. When they grow up, if they mate with people with the same alleles, their offspring (second generation) may have a wide variation in pigmentation, as shown by the plotted distribution of skin colors.

*B*, and *C* alleles confer dark skin pigment, and their effects are additive. The *a*, *b*, and *c* alleles confer pale skin tone. An individual with an *AABBCC* genotype would be about as dark-skinned as a human can get, while an *aabbcc* person would be very fair. However, when individuals heterozygous for at least one of these gene pairs mate, a broad range of pigmentation is possible in their offspring. Such polygene inheritance results in a distribution of genotypes and phenotypes that, when plotted, yields a bell-shaped curve (**Figure 29.6**).

## ✓ Check Your Understanding

9. Why does a male always express an X-linked recessive allele?
10. How can you explain why parents of average height can produce very tall or very short offspring?

For answers, see Appendix H.

## Environmental Factors in Gene Expression

- ✓ Provide examples illustrating how gene expression may be modified by environmental factors.

In many situations environmental factors override or at least influence gene expression. Our genotype (discounting mutations) is as unchanging as the Rock of Gibraltar, but our phenotype is more like clay. If this were not the case, we would never get a tan, women bodybuilders would never be able to develop bulging muscles, and there would be no hope for treating genetic disorders.

Sometimes, such maternal factors as drugs or pathogens alter normal gene expression during embryonic development. Take, for example, the case of the “thalidomide babies” (discussed on p. 1083). As a result of their mothers taking that sedative, the embryos developed phenotypes (flipperlike appendages) not directed by their genes. Such environmentally produced phenotypes that mimic conditions that may be caused by genetic mutations (permanent transmissible changes in the DNA) are called **phenocopies**.

Equally significant are environmental factors that may influence genetic expression after birth, such as the effect of poor infant nutrition on brain growth, general body development, and height. In this way, a person with “tall genes” can be stunted by insufficient nutrition. Furthermore, part of a gene’s environment consists of the influence of other genes. For example, hormonal deficits during childhood can lead to abnormal skeletal growth and proportions, as in cretinism, a type of dwarfism resulting from hypothyroidism.

### ✓ Check Your Understanding

11. Which of the following factors may alter gene expression?  
Other genes, measles in a pregnant woman, lack of key nutrients in the diet.

For answers, see Appendix H.

## Nontraditional Inheritance

Mendel’s writings underlie mainstream thinking about heredity, but some genetic outcomes do not fit his rules. Among these nontraditional types of inheritance are influences due to RNA-only genes, to chemical groups attached to DNA or histone proteins, and to *extranuclear inheritance* conferred by mitochondrial DNA.

### Beyond DNA: Regulation of Gene Expression

- ✓ Describe how RNA-only genes and epigenetic marks affect gene expression.

Our genome is a biochemical system of awesome complexity, with three basic levels of controls. The protein-coding genes that we have been describing to this point only make up the first level and account for less than 2% of the DNA of a human cell. This is the part of the genome traditionally considered to be a “blueprint” for protein structure.

Since the 1960s, scientists have been finding second and third layers of information important in directing development elsewhere—in the noncoding DNA and even totally outside the DNA sequences. So what are these other regulatory systems?

### Small RNAs

The second layer appears to be the product of the abundant “RNA-only genes,” formerly believed to be “junk,” that are found in the vast oceans of non-protein-coding DNA. They form a parallel regulatory system that generates single-stranded microRNAs (miRNAs) and short interfering RNAs (siRNAs) (see p. 105). These small RNA molecules are “control freaks” that can act directly on DNA, other RNAs, or proteins. They also can tame or inactivate aggressive (jumping) genes, called *transposons*, that tend to replicate themselves and then insert the copies into distant DNA sites, disabling or hyperactivating those genes.

Small RNAs control timing of programmed cell death during development and can also prevent translation of another gene. Mutations in these RNA-only areas have already been linked to several conditions including prostate and lung cancers and schizophrenia.

It takes relatively few genes to build a human being. Our complexity is the result of the small RNAs that control the expression of genes especially during growth and differentiation. Nucleotide sequences of these RNA-specifying DNA areas are now worked out and biochemical companies are investing heavily in gene therapy research. They are especially hot on synthesizing RNA-interfering drugs to silence or shut down particular genes to treat age-related macular degeneration, Parkinson’s disease, cancer, and a host of other disorders.

### Epigenetic Marks

Epigenetic marks form the third layer of gene controls. This continually changing information is stored in the proteins and chemical groups that bind to the DNA and in the way chromatin is packaged in the cell. Within cells, chemical tags such as methyl and acetyl groups bound to DNA segments and to histones determine whether the DNA is available for transcription (acetylation) or silenced (methylation). Epigenetic marks also account for the inactivation (by methylation) of one of the female’s X chromosomes in the early embryo.

Epigenetic marks or lack of them may predispose a cell for transformation from normal to cancerous, and even slight deviations in the epigenetic marks on specific chromosomes can result in devastating human illness.

Epigenetic marks also underlie the phenomenon called genomic imprinting. For most genes, the maternal and paternal genes turn on or off at the same time. This balance is upset during gametogenesis when certain genes in both sperm and eggs are modified by the addition of a methyl ( $-\text{CH}_3$ ) group, a process called **genomic imprinting**. Genomic imprinting somehow tags the genes as paternal or maternal and confers important functional differences in the embryo. The developing embryo “reads” these tags, and then either expresses the mother’s gene while the father’s version remains idle or vice versa. In each generation, the old imprints are “erased” when new gametes are produced and all the chromosomes are newly imprinted according to the sex of the parents.

Mutations of imprinted genes may lead to pathology. For example, victims of Prader-Willi syndrome are mildly to moderately retarded, short, and grossly obese. Children with Angelman syndrome are severely retarded, unable to speak coherently, laugh uncontrollably, and exhibit jerky, lurching movements as if tied to a puppeteer's strings. The symptoms of these two disorders are very different, but the genetic cause is the same—deletion of a particular region of chromosome 15. If the defective chromosome comes from the father, the result is Prader-Willi syndrome; the mother's defective chromosome confers Angelman syndrome. Thus, it seems that the same allele can have different effects depending on which parent it comes from.

In short, protein-coding genes are not the only instructions to which cells refer. RNA matters, and so do the tiny chemical tags that attach to the chromatin.

### Extranuclear (Mitochondrial) Inheritance

- ✓ Describe the basis of extranuclear (mitochondria-based) genetic disorders.

Although we have focused on the chromosomal basis of inheritance, remember that not all genes are in the cell's nucleus. Some 37 genes (referred to as mtDNA) are in mitochondria. Mitochondrial genes are transmitted to the offspring almost exclusively by the mother because the ovum donates essentially all the cytoplasm in the fertilized egg. Additionally, sperm mitochondrial DNA is selectively destroyed by elimination factors in both the sperm and egg.

A growing list of disorders, all rare, is now being linked to errors (mutations) in mitochondrial genes. Most involve problems with oxidative phosphorylation within the mitochondria, but a few lead to unusual degenerative muscle disorders or neurological problems. Some researchers suggest that Alzheimer's and Parkinson's disease may be among them.

### ✓ Check Your Understanding

12. What process labels genes as paternal or maternal?
13. What is the source of the genes that confer extranuclear inheritance?

For answers, see Appendix H.

## Genetic Screening, Counseling, and Therapy

- ✓ List and explain several techniques used to determine or predict genetic diseases.
- ✓ Describe briefly some approaches of gene therapy.

*Genetic screening* and *genetic counseling* provide information and options for prospective parents not even dreamed of 100 years ago. Newborn infants are routinely screened for a number of anatomical disorders (congenital hip dysplasia, imperforate anus, and others), and testing for phenylketonuria (PKU) and other metabolic diseases is mandated by law in many states. These tests

alert the new parents that treatment is necessary to ensure the well-being of their infant. Anatomical defects are usually treated surgically, and PKU is managed by strict dietary measures that exclude most phenylalanine-containing foods.

Adult children of parents with Huntington's disease are obvious candidates for these services, but many other genetic conditions also place babies at risk. For example, a woman pregnant at age 35 may wish to know if her baby has trisomy-21, or Down syndrome (see Related Clinical Terms, p. 1107), a chromosome abnormality with a high incidence in children of older mothers.

Depending on the condition being investigated, screening can occur before conception by carrier recognition, or during fetal testing.

### Carrier Recognition

There are two major avenues for identifying carriers of detrimental genes: pedigrees and blood tests. A **pedigree** traces a genetic trait through several generations and helps predict the future. For prospective parents, a genetic counselor collects phenotype information on as many family members as possible and uses it to construct the pedigree (often called the family tree). By working backward from current individuals and applying the rules of dominant-recessive inheritance, a counselor can deduce the genotypes of the parents and figure out the genotypes of the other individuals in their parents' generation.

Simple blood tests are used to screen for the sickling gene in heterozygotes, and sophisticated *blood chemistry tests* and *DNA probes* can detect the presence of other unexpressed recessive genes. At present, carriers of the Tay-Sachs and cystic fibrosis genes can be identified with such tests.

### Fetal Testing

Fetal testing is used when there is a known risk of a genetic disorder. The most common type of fetal testing is **amniocentesis** (am''ne-o-sen-te'sis), in which a wide-bore needle is inserted into the amniotic sac through the mother's abdominal wall, and about 10 ml of fluid is withdrawn (**Figure 29.7a**). Because there is a chance of injuring the fetus before ample amniotic fluid is present, this procedure is not normally done before the 14th week of pregnancy. Using ultrasound to visualize the position of the fetus and the amniotic sac has dramatically reduced the risk of this procedure.

The fluid is checked for enzymes and other chemicals that serve as markers for specific diseases, but most tests are done on the sloughed-off fetal cells in the fluid. These cells are cultured in laboratory dishes over a period of several weeks. Then the cells are examined for DNA markers of genetic disease and karyotyped to check for chromosomal abnormalities (see Figure 29.1).

**Chorionic villus sampling (CVS)** suctions off bits of the chorionic villi from the placenta for examination (Figure 29.7b). A small tube is inserted through the vagina and cervical canal and guided by ultrasound to an area where a piece of placental tissue can be removed. CVS allows testing at 8 weeks but waiting until after the 10th week is usually recommended. Karyotyping

**Figure 29.7** Fetal testing—amniocentesis and chorionic villus sampling.

can be done almost immediately on the rapidly dividing chorionic cells, much earlier than in amniocentesis.

Both of these procedures are invasive, and they carry with them an inherent risk to both fetus and mother. (For example, increased fetal risk of finger and toe defects is linked to CVS.) These tests are routinely ordered for pregnant women over 35 (because of the higher risk of Down syndrome), but they are performed on younger women when the probability of finding a severe fetal disorder is greater than the probability of doing harm during the procedure. If a serious genetic or congenital defect is detected in the developing fetus, the parents must decide whether or not to continue the pregnancy.

## Human Gene Therapy

As indicated earlier, the Human Genome Project has opened an exciting world to scientists investigating gene expression.

Advances in diagnosing human genetic diseases have been followed quickly by new applications of “gene therapy” to alleviate or even cure the disorders, particularly in cases traced to a single defective gene or protein. Indeed, genetic engineering has the potential to replace a defective gene with a normal version.

One approach (used successfully in treatment of severe combined immunodeficiency disorders) is to “infect” the defective cells with a virus into which a functional gene has been inserted. Another is to inject the “corrected” DNA directly into the patient’s cells. Such therapies have had mixed results in treating cystic fibrosis and muscular dystrophy. However, genetic engineering processes are prohibitively expensive and raise some thorny ethical, religious, and societal questions: Who will pay? Who determines who will be treated with the new therapies? Are we playing God?

### ✓ Check Your Understanding

- Which fetal testing procedure depends on analyzing amniotic fluid?
- What noninvasive imaging procedure is used to determine some aspects of fetal development? (You may want to check *A Closer Look* in Chapter 1, pp. 16–17, for this.)

For answers, see Appendix H.

In this chapter, we have explored some of the basic principles of genetics, the manner in which genes are expressed, and the means by which gene expression can be modified. Considering the precision required to make perfect copies of genes and chromosomes, and the incredible mechanical events of meiotic division, it is amazing that genetic defects are as rare as they are. Perhaps, after reading this chapter, you have a greater sense of wonder that you turned out as well as you did.

## Chapter Summary

For more chapter study tools, go to the Study Area of MasteringA&P at [www.masteringaandp.com](http://www.masteringaandp.com).

There you will find:

- Interactive Physiology **iP**
- A&PFlix **A&PFlix**
- Practice Anatomy Lab **PAL**
- PhysioEx **PEX**
- Videos, Practice Quizzes and Tests, MP3 Tutor Sessions, Case Studies, and much more!

- Genetics is the study of heredity and mechanisms of gene transmission.

### The Vocabulary of Genetics (pp. 1096–1097)

- A complete diploid set of chromosomes is called the karyotype of an organism; the complete genetic complement is the genome. A person's genome consists of two sets of instructions, one from each parent.

### Gene Pairs (Alleles) (pp. 1096–1097)

- Genes coding for the same trait and found at the same locus on homologous chromosomes are called alleles.
- Alleles may be the same or different in expression. When the allele pair is identical, the person is homozygous for that trait; when the alleles differ, the person is heterozygous.

### Genotype and Phenotype (p. 1097)

- The actual genetic makeup of cells is the genotype; phenotype is the manner in which those genes are expressed.

### Sexual Sources of Genetic Variation (pp. 1097–1099)

#### Chromosome Segregation and Independent Assortment (pp. 1097–1098)

- During meiosis I of gametogenesis, tetrads align randomly on the metaphase plate, and chromatids are randomly distributed to the daughter cells. This is called independent assortment of the homologues. Each gamete receives only one allele of each gene pair.
- Each different metaphase I alignment produces a different assortment of parental chromosomes in the gametes, and all combinations of maternal and paternal chromosomes are equally possible.

#### Crossover of Homologues and Gene Recombination (p. 1098)

- During meiosis I, all four chromatids of each tetrad cross over at one or more points and exchange corresponding gene segments. The recombinant chromosomes contain new gene combinations, adding to the variability arising from independent assortment.

### Random Fertilization (pp. 1098–1099)

- The third source of genetic variation is random fertilization of eggs by sperm.

### Types of Inheritance (pp. 1099–1101)

#### Dominant-Recessive Inheritance (pp. 1099–1100)

- Dominant genes are expressed when present in single or double dose; recessive genes must be present in double dose to be expressed.
- For traits following the dominant-recessive pattern, the laws of probability predict the outcome of a large number of matings.
- Genetic disorders more often reflect the homozygous recessive condition than the homozygous dominant or heterozygous condition because dominant genes are expressed and, if they are lethal genes, the pregnancy usually results in miscarriage. Genetic disorders caused by dominant alleles include achondroplasia and Huntington's disease; recessive disorders include cystic fibrosis and Tay-Sachs disease.
- Carriers are heterozygotes who carry a deleterious recessive gene (but do not express the trait) and have the potential of passing it on to offspring.

#### Incomplete Dominance (p. 1100)

- In incomplete dominance, the heterozygote exhibits a phenotype intermediate between those of the homozygous dominant and recessive individuals. Inheritance of sickle-cell trait is an example of incomplete dominance.

#### Multiple-Allele Inheritance (p. 1100)

- Multiple-allele inheritance involves genes that exist in more than two allelic forms in a population. Only two of the alleles are inherited, but on a random basis. Inheritance of ABO blood types is an example of multiple-allele inheritance in which the  $I^A$  and  $I^B$  alleles are codominant.

#### Sex-Linked Inheritance (pp. 1100–1101)

- Traits determined by genes on the X and Y chromosomes are said to be sex-linked. The small Y chromosome lacks most genes present on the X chromosome. Recessive genes located only on the X chromosome are expressed in single dose in males. Examples of such X-linked conditions, passed from mother to son, include hemophilia and red-green color blindness.

#### Polygene Inheritance (p. 1101)

- Polygene inheritance occurs when several gene pairs interact to produce phenotypes that vary quantitatively over a broad range. Height, intelligence, and skin pigmentation are examples.

**Environmental Factors in Gene Expression**

(p. 1102)

1. Environmental factors may influence the expression of genotype.
2. Maternal factors that cross the placenta may alter expression of fetal genes. Environmentally provoked phenotypes that mimic genetically determined ones are called phenocopies. Nutritional deficits or hormonal imbalances may alter anticipated growth and development during childhood.

**Nontraditional Inheritance** (pp. 1102–1103)**Beyond DNA: Regulation of Gene Expression** (pp. 1102–1103)

1. Control of gene expression occurs at three levels: protein-coding genes, RNA-only genes, and epigenetic marks. The latter two account for many cases of inherited disease that fail to follow traditional genetics.
2. The products of the RNA-only genes (siRNA and miRNA) may silence genes or prevent their expression and appear to play a role in directing apoptosis during development.
3. Epigenetic marks involve attachment of small chemical groups (methyl or acetyl) to DNA or histone proteins. In general, methylation prevents access to the DNA whereas acetylation provides access to the DNA. Genomic imprinting, which involves methylation of certain genes during gametogenesis, confers different effects and phenotypes on maternal and paternal genes. It is reversible, and occurs anew each generation.

**Extranuclear (Mitochondrial) Inheritance** (p. 1103)

4. Cytoplasmic (mitochondrial) genes pass to offspring via the ovum and help to determine certain characteristics. Deletions

or mutations in mitochondrial genes are responsible for some problems with oxidative phosphorylation and some rare genetic diseases.

**Genetic Screening, Counseling, and Therapy**

(pp. 1103–1105)

**Carrier Recognition** (p. 1103)

1. The likelihood of an individual carrying a deleterious recessive gene may be assessed by constructing a pedigree. Some of these genes can be deduced by various blood tests and DNA probes.

**Fetal Testing** (pp. 1103–1104)

2. Amniocentesis is fetal testing based on aspirated samples of amniotic fluid. Fetal cells in the fluid are cultured for several weeks, then examined for chromosomal defects (karyotyped) or for DNA markers of genetic disease. Amniocentesis cannot be performed until the 14th week of pregnancy.
3. Chorionic villus sampling is fetal testing based on a sample of the chorion. This tissue is rapidly mitotic, so karyotyping can be done almost immediately. Samples may be obtained by the 8th week.

**Human Gene Therapy** (pp. 1104–1105)

4. The Human Genome Project has allowed research on diagnosis of genetic disease and on its treatment to surge forward. Thus far, gene therapy has been particularly useful for correcting single-gene disorders. The most common approach involves transferring a corrected gene via a virus to the affected cells to restore normal function.

**Review Questions****Multiple Choice/Matching**

(Some questions have more than one correct answer. Select the best answer or answers from the choices given.)

1. Match one of the following terms (a–i) with each of the descriptions below:

Key: (a) alleles (f) homozygote  
 (b) autosomes (g) phenotype  
 (c) dominant allele (h) recessive allele  
 (d) genotype (i) sex chromosomes  
 (e) heterozygote

- \_\_\_ (1) genetic makeup  
 \_\_\_ (2) how genetic makeup is expressed  
 \_\_\_ (3) chromosomes that dictate most body characteristics  
 \_\_\_ (4) alternate forms of the same gene  
 \_\_\_ (5) an individual bearing two alleles that are the same for a particular trait  
 \_\_\_ (6) an allele that is expressed whether in single or double dose  
 \_\_\_ (7) an individual bearing two alleles that differ for a particular trait  
 \_\_\_ (8) an allele that must be present in double dose to be expressed
2. Match the following types of inheritance (a–f) with the descriptions below:
- Key: (a) dominant-recessive (d) polygene  
 (b) incomplete dominance (e) sex-linked  
 (c) multiple-allele (f) extranuclear

- \_\_\_ (1) only sons show the trait  
 \_\_\_ (2) homozygotes and heterozygotes have the same phenotype  
 \_\_\_ (3) heterozygotes exhibit a phenotype intermediate between those of the homozygotes  
 \_\_\_ (4) phenotypes of offspring may be more varied than those of the parents  
 \_\_\_ (5) inheritance of ABO blood types  
 \_\_\_ (6) inheritance of stature  
 \_\_\_ (7) reflects activity of mitochondrial DNA

**Short Answer Essay Questions**

3. Describe the important mechanisms that lead to genetic variations in gametes.
4. The ability to taste PTC (phenylthiocarbamide) depends on the presence of a dominant gene *T*; nontasters are homozygous for the recessive gene *t*. This is a situation of classical dominant-recessive inheritance. (a) Consider a mating between heterozygous parents producing three offspring. What proportion of the offspring are likely to be tasters? What is the chance that all three offspring will be tasters? Nontasters? What is the chance that two will be tasters and one will be a nontaster? (b) Consider a mating between *Tt* and *tt* parents. What is the anticipated percentage of tasters? Nontasters? What proportion can be expected to be homozygous recessive? Heterozygous? Homozygous dominant?
5. Most albino children are born to normally pigmented parents. Albinos are homozygous for the recessive gene (*aa*). What can you conclude about the genotypes of the nonalbino parents?

- A woman with blood type A has two children. One has type O blood and the other has type B blood. What is the genotype of the mother? What are the genotype and phenotype of the father? What is the genotype of each child?
- In skin color inheritance, what will be the relative range of pigmentation in offspring arising from the following parental matches? (a)  $AABBCC \times aabbcc$ , (b)  $AABBCC \times AaBbCc$ , (c)  $Aabbcc \times aabbcc$ .
- Compare and contrast amniocentesis and chorionic villus sampling as to the time at which they can be performed and the techniques used to obtain information on the fetus's genetic status.
- Brian is a college student. His genetics assignment is to do a family pedigree for dimples in the cheeks. Absence of dimples is recessive; presence of dimples reflects a dominant allele. Brian has dimples, as do his three brothers. His mother and maternal grandmother are dimple free, but his father and all other grandparents have dimples. Construct a pedigree spanning three generations for Brian's family. Show the phenotype and genotype for each person.
- Mr. and Mrs. Lehman have sought genetic counseling. Mrs. Lehman is concerned because she is unexpectedly pregnant and her husband's brother died of Tay-Sachs disease. She can recall no incidence of Tay-Sachs disease in her own family. Do you think biochemical testing should be recommended to detect the deleterious gene in Mrs. Lehman? Explain your answer.

### Critical Thinking and Clinical Application Questions

- A color-blind man marries a woman with normal vision. The woman's father was also color-blind. (a) What is the chance that their first child will be a color-blind son? A color-blind daughter? (b) If they have four children, what is the chance that two will be color-blind sons? (Be careful on this one.)
- The Browns are both carriers of the recessive allele that causes the metabolic disorder called phenylketonuria. What is the probability of each of the following occurring? (a) All three children will have the disorder. (b) None of their three children will have the disorder. (c) One or more of their children will have the disorder. (d) At least one of their children will be phenotypically normal.

## AT THE CLINIC

### Related Clinical Terms

**Deletion** Chromosomal aberration in which part of a chromosome is lost.

**Down syndrome** Formerly called mongolism, this condition usually reflects the presence of an extra autosome (trisomy of chromosome 21). The child has slightly slanted eyes, flattened facial features, a large tongue, and a tendency toward short stature and stubby fingers. Some, but not all, affected people are mentally retarded. Down syndrome individuals have mitochondrial defects, which have been associated with neurodegeneration in other disorders. A distinctive feature of Down syndrome is early onset of Alzheimer's disease. The

most important risk factor appears to be advanced maternal (or paternal) age.

**Mutation** (*mutare* = change) A permanent structural change in a gene. The mutation may or may not affect function, depending on the precise site and nature of the alteration.

**Nondisjunction** Abnormal segregation of chromosomes during meiosis, resulting in gametes receiving two or no copies of a particular parental chromosome. It is more common in female meiosis than in male meiosis. If the abnormal gamete participates in fertilization, the resulting zygote will have an abnormal chromosomal complement (monosomy or trisomy) for that particular chromosome (as in Down syndrome).

### Case Study Heredity

We will now return to the case of Maria Rodriguez, whom we met in Chapter 28. Recall that Mrs. Rodriguez had found out that she was pregnant

and was concerned about the health of her baby. Mrs. Rodriguez went on to have a normal pregnancy without complications. During Mrs. Rodriguez's treatment in the hospital, she discovered that her blood is type O. During one of her regular visits to her doctor, Mrs. Rodriguez asked what type of blood her baby will have, given that her husband's blood type is type A. Her doctor explained to Mrs. Rodriguez that she would need to know more about the blood type of Mr. Rodriguez's parents.

- Describe the difference between genotype and phenotype. What are the phenotypes and genotypes of Mr. and Mrs. Rodriguez?
- Describe the type of inheritance that is represented by blood type.
- Mr. Rodriguez's mother has O blood type and his father has A blood type. Explain how this information helps you understand Mr. Rodriguez's genotype.
- What is the probability that Mrs. Rodriguez's baby will have O blood type? A? B? AB?

(Answers in Appendix H)

Lysine (Lys)

Arginine (Arg)

Histidine (His)

① Glucose enters the cell and is phosphorylated by the enzyme hexokinase, which catalyzes the transfer of a phosphate group, indicated as  $P_i$ , from ATP to the number six carbon of the sugar, producing glucose-6-phosphate. The electrical charge of the phosphate group traps the sugar in the cell because the plasma membrane is impermeable to ions. Phosphorylation of glucose also makes the molecule more chemically reactive. Although glycolysis is supposed to produce ATP, ATP is actually consumed in step 1—an energy investment that will be repaid with dividends later in glycolysis.

② Glucose-6-phosphate is rearranged and converted to its isomer, fructose-6-phosphate. Isomers, remember, have the same number and types of atoms but in different structural arrangements.

③ In this step, still another molecule of ATP is used to add a second phosphate group to the sugar, producing fructose-1,6-bisphosphate. So far, the ATP ledger shows a debit of  $-2$ . With phosphate groups on its opposite ends, the sugar is now ready to be split in half.

④ This is the reaction from which glycolysis gets its name. An enzyme cleaves the sugar molecule into two different 3-carbon sugars: glyceraldehyde 3-phosphate and dihydroxyacetone phosphate. These two sugars are isomers of one another.

⑤ An isomerase enzyme interconverts the 3-carbon sugars, and if left alone in a test tube, the reaction reaches equilibrium. This does not happen in the cell, however, because the next enzyme in glycolysis uses only glyceraldehyde phosphate as its substrate and not dihydroxyacetone phosphate. This pulls the equilibrium between the two 3-carbon sugars in the direction of glyceraldehyde phosphate, which is removed as fast as it forms. Thus, the net result of steps 4 and 5 is cleavage of a 6-carbon sugar into two molecules of glyceraldehyde phosphate; each will progress through the remaining steps of glycolysis.

⑥ An enzyme now catalyzes two sequential reactions while it holds glyceraldehyde phosphate in its active site. First, the sugar is oxidized by the transfer of H from the number one carbon of the sugar to  $NAD^+$ , forming  $NADH + H^+$ . Here we see in metabolic context the oxidation-reduction reaction described in Chapter 24. This reaction releases substantial amounts of energy, and the enzyme capitalizes on this by coupling the reaction to the creation of a high-energy phosphate bond at the number one carbon of the oxidized substrate. The source of the phosphate is inorganic phosphate ( $P_i$ ) always present in the cytosol. The enzyme releases  $NADH + H^+$  and 1,3-bisphosphoglyceric acid as products. Notice in the figure that the new phosphate bond is symbolized with a squiggle (~), which indicates that the bond is at least as energetic as the high-energy phosphate bonds of ATP.

**THE TEN STEPS OF GLYCOLYSIS** Each of the ten steps of glycolysis is catalyzed by a specific enzyme found dissolved in the cytoplasm. All steps are reversible. An abbreviated version of the three major phases of glycolysis appears in the lower right-hand corner of the next page.

7 Finally, glycolysis produces ATP. The phosphate group, with its high-energy bond, is transferred from 1,3-bisphosphoglyceric acid to ADP. For each glucose molecule that began glycolysis, step 7 produces two molecules of ATP, because every product after the sugar-splitting step (step 4) is doubled. Of course, two ATPs were invested to get sugar ready for splitting. The ATP ledger now stands at zero. By the end of step 7, glucose has been converted to two molecules of 3-phosphoglyceric acid. This compound is not a sugar. The sugar was oxidized to an organic acid back in step 6, and now the energy made available by that oxidation has been used to make ATP.

8 Next, an enzyme relocates the remaining phosphate group of 3-phosphoglyceric acid to form 2-phosphoglyceric acid. This prepares the substrate for the next reaction.

9 An enzyme forms a double bond in the substrate by removing a water molecule from 2-phosphoglyceric acid to form phosphoenolpyruvic acid, or PEP. This results in the electrons of the substrate being rearranged in such a way that the remaining phosphate bond becomes very unstable; it has been upgraded to high-energy status.

10 The last reaction of glycolysis produces another molecule of ATP by transferring the phosphate group from PEP to ADP. Because this step occurs twice for each glucose molecule, the ATP ledger now shows a net gain of two ATPs. Steps 7 and 10 each produce two ATPs for a total credit of four, but a debt of two ATPs was incurred from steps 1 and 3. Glycolysis has repaid the ATP investment with 100% interest. In the meantime, glucose has been broken down and oxidized to two molecules of pyruvic acid, the compound produced from PEP in step 10.

**Summary**

Phase 1 Sugar activates by phosphorylation

Phase 2 Sugar cleavage

Phase 3 Sugar oxidation and formation of ATP

① Two-carbon acetyl CoA is combined with oxaloacetic acid, a 4-carbon compound. The unstable bond between the acetyl group and CoA is broken as oxaloacetic acid binds and CoA is freed to prime another 2-carbon fragment derived from pyruvic acid. The product is the 6-carbon citric acid, for which the cycle is named.

② A molecule of water is removed, and another is added back. The net result is the conversion of citric acid to its isomer, isocitric acid.

③ The substrate loses a  $\text{CO}_2$  molecule, and the remaining 5-carbon compound is oxidized, forming an  $\alpha$ -ketoglutaric acid and reducing  $\text{NAD}^+$ .

④ This step is catalyzed by a multienzyme complex very similar to the one that converts pyruvic acid to acetyl CoA.  $\text{CO}_2$  is lost; the remaining 4-carbon compound is oxidized by the transfer of electrons to  $\text{NAD}^+$  to form  $\text{NADH}+\text{H}^+$  and is then attached to CoA by an unstable bond. The product is succinyl CoA.

⑤ Substrate-level phosphorylation occurs in this step. CoA is displaced by a phosphate group, which is then transferred to GDP to form guanosine triphosphate (GTP). GTP is similar to ATP, which is formed when GTP donates a phosphate group to ADP. The products of this step are succinic acid and ATP.

⑥ In another oxidative step, two hydrogens are removed from succinic acid (forming fumaric acid) and transferred to FAD to form  $\text{FADH}_2$ . The function of this coenzyme is similar to that of  $\text{NADH}+\text{H}^+$ , but  $\text{FADH}_2$  stores less energy. The enzyme that catalyzes this oxidation-reduction reaction is the only enzyme of the cycle that is embedded in the mitochondrial membrane. All other enzymes of the citric acid cycle are dissolved in the mitochondrial matrix.

⑦ Bonds in the substrate are rearranged in this step by the addition of a water molecule. The product is malic acid.

⑧ The last oxidative step reduces another  $\text{NAD}^+$  and regenerates oxaloacetic acid, which accepts a 2-carbon fragment from acetyl CoA for another turn of the cycle.

**KREBS CYCLE (CITRIC ACID CYCLE)** All but one of the steps (step 6) occur in the mitochondrial matrix. The preparation of pyruvic acid (by oxidation, decarboxylation, and reaction with coenzyme A) to enter the cycle as acetyl CoA is shown above the cycle. Acetyl CoA is picked up by oxaloacetic acid to form citric acid; and as it passes through the cycle, it is oxidized four more times [forming

three molecules of reduced NAD ( $\text{NADH} + \text{H}^+$ ) and one of reduced FAD ( $\text{FADH}_2$ )] and decarboxylated twice (releasing 2  $\text{CO}_2$ ). Energy is captured in the bonds of GTP, which then acts in a coupled reaction with ADP to generate one molecule of ATP by substrate-level phosphorylation.

The periodic table arranges elements according to atomic number and atomic weight into horizontal rows called periods and 18 vertical columns called groups or families. The elements in the groups are classified as being in either A or B classes.

Elements of each group of the A series have similar chemical and physical properties. This reflects the fact that members of a particular group have the same number of valence shell electrons, which is indicated by the roman numeral of the group. For example, group IA elements have one valence shell electron, group IIA elements have two, and group VA elements have five. In contrast, as you progress across a period from left to right, the properties of the elements change in discrete steps, varying gradually from the very metallic properties of groups IA and IIA elements to the nonmetallic properties seen in group VIIA (chlorine and others), and finally to the inert elements (noble gases) in group VIIIA. This change reflects the

continual increase in the number of valence shell electrons seen in elements (from left to right) within a period.

Class B elements are referred to as transition elements. All transition elements are metals, and in most cases they have one or two valence shell electrons. (In these elements, some electrons occupy more distant electron shells before the deeper shells are filled.)

In this periodic table, the colors are used to convey information about the phase (solid, liquid, or gas) in which a pure element exists under standard conditions (25 degrees Celsius and 1 atmosphere of pressure). If the element's symbol is solid black, then the element exists as a solid. If its symbol is red, then it exists as a gas. If its symbol is dark blue, then it is a liquid. If the element's symbol is green, the element does not exist in nature and must be created by some type of nuclear reaction.

\*Atomic weights of the elements per IUPAC Commission on Isotopic Abundances and Atomic Weights, 2007.

The reference values listed for the selected blood and urine studies are common ranges for adults, but specific “normals” are established by the laboratory performing the analysis. The values may be affected by a wide range of circumstances, including testing methods and equipment used, client age, body mass, sex, diet, activity level, medications, and extent of disease processes.

Reference values are identified in both standard or conventional units and in the system of international (SI) units. SI units (given in parentheses) are measurements of amount per volume and are used in most countries and scientific journals. SI units are often given as

moles or millimoles per liter. Most clinical laboratories and textbooks in the United States use conventional or standard units, which measure mass per volume. These values are given as grams, milligrams, or milliequivalents per deciliter or liter. It is anticipated that the United States will eventually use SI units exclusively.

For enzymes, 1 international unit (IU) represents an arbitrary but defined amount of activity, whereas 1 katal (kat) is the amount of enzyme required to consume 1 mol of substrate per second.

Sample types in column 1 are serum (S), plasma (P), arterial whole blood (A), and whole blood (WB).

TEST (SAMPLE)	REFERENCE VALUES: CONVENTIONAL (SI)	PHYSIOLOGICAL INDICATION AND CLINICAL IMPLICATIONS
<b>Blood Chemistry Studies</b>		
Ammonia (P)	15–120 µg/dl (9–70 µmol/L)	Liver and renal function. Increased values in liver disease, renal failure, newborn hemolytic disease, heart failure, cor pulmonale. Decreased values in hypertension.
Amylase (S)	56–190 IU/L (0.4–2.1 µkat/L)	Pancreatic function. Increased values in pancreatitis, mumps, obstruction of pancreatic duct, ketoacidosis. Decreased values in kidney disease, pancreatic damage or cancer, toxemia of pregnancy.
Aspartate aminotransferase (AST, or SGOT) (S)	≤40 IU/L (≤0.7 µkat/L)	Cellular damage. Increased after myocardial infarction, acute liver disease, drug toxicity, muscle trauma. Decreased in pyridoxine (vitamin B <sub>6</sub> ) deficiency.
Bilirubin (S)	Total: 0.1–1.0 mg/dl (1.7–17.1 µmol/L) Direct: <0.4 mg/dl (<6.8 µmol/L) Indirect: 0.1–1.0 mg/dl (1.7–17.1 µmol/L) Newborn: <13.0 mg/dl (<222 µmol/L)	Liver function and red cell breakdown. Increased levels of direct in liver disease and biliary obstruction. Increased levels of indirect in hemolysis of red blood cells.
Blood urea nitrogen (S)	7–26 mg/dl (2.5–9.3 mmol/L)	Kidney function. Increased values in renal disease, dehydration, urinary obstruction, congestive heart failure, myocardial infarction, burns. Decreased values in liver failure, overhydration, impaired protein absorption, pregnancy.
Cholesterol	<200 mg/dl (<5.2 mmol/L)	Metabolism—fat utilization. Increased values in diabetes mellitus, pregnancy, use of oral contraceptives or anabolic steroids.
High-density lipoprotein (HDL) cholesterol (S)	20–30% of total >40 mg/dl (>1.0 mmol/L)	Increased levels in liver disease, aerobic exercise. Decreased levels in atherosclerotic heart disease, malnutrition.
Low-density lipoprotein (LDL) cholesterol (S)	60–70% of total <130 mg/dl (<3.4 mmol/L)	Increased values in hyperlipidemia, atherosclerotic heart disease. Decreased values in fat malabsorption and malnutrition.
Very low density lipoprotein cholesterol (VLDL) (S)	10–15% of total	Same as LDL.
Creatine kinase (CK) (S)	Female: ≤190 U/L (≤3.2 µkat/L) Male: ≤235 U/L (≤3.9 µkat/L)	Cellular damage. Increased values in myocardial infarction, muscular dystrophy, hypothyroidism, pulmonary infarction, cerebrovascular accident (CVA), shock, tissue damage, and trauma.
Creatinine (S)	0.5–1.2 mg/dl (44–106 µmol/L)	Renal function. Increased values in renal disease and acromegaly. Decreased in muscular dystrophy.

**A-10 Appendix F Reference Values for Selected Blood and Urine Studies**

TEST (SAMPLE)	REFERENCE VALUES: CONVENTIONAL (SI)	PHYSIOLOGICAL INDICATION AND CLINICAL IMPLICATIONS
<b>Blood Chemistry Studies</b> (continued)		
Gases (A)		
Bicarbonate	22–26 mEq/L (22–26 mmol/L)	Acid-base balance. Increased values in metabolic alkalosis and respiratory acidosis. Decreased values in metabolic acidosis and respiratory alkalosis.
Carbon dioxide content	Arterial: 19–24 mEq/L (19–24 mmol/L) Venous: 22–30 mEq/L (22–30 mmol/L)	
Carbon dioxide partial pressure (P <sub>CO<sub>2</sub></sub> )	Arterial: 35–45 mm Hg Venous: 45 mm Hg	
Oxygen (O <sub>2</sub> ) saturation	95–98% (same)	
Oxygen partial pressure (P <sub>O<sub>2</sub></sub> )	80–105 mm Hg	Values increased slightly in hyperventilation. Decreased values (hypoxia) in pulmonary disease, hypoventilation, high altitude.
pH	7.35–7.45 (same)	Increased values in metabolic and respiratory alkalosis. Decreased values in metabolic and respiratory acidosis.
Glucose (S)	70–120 mg/dl (3.9–6.7 mmol/L)	Metabolic function. Increased values in diabetes mellitus, Cushing's syndrome, liver disease, acute stress, and acromegaly. Decreased levels in Addison's disease, insulinomas.
Immunoglobulins (S)		
IgG	560–1800 mg/dl (5.6–18 g/L)	Immune response. Increased levels in chronic infections, rheumatic fever, liver disease, rheumatoid arthritis. Decreased levels in amyloidosis, leukemia, and preeclampsia.
IgE	<43.2 µg/dl (<432 µg/L)	Allergic responses. Increased values in allergic responses. Decreased values in agammaglobulinemia.
IgA	85–563 mg/dl (0.85–5.6 g/L)	Immune integrity. Increased values in liver disease, rheumatic fever, chronic infection, inflammatory bowel disease. Decreased values in immunodeficiency disorders and immunosuppression.
IgM	55–375 mg/dl (0.5–3.8 g/L)	Immune integrity. Increased in autoimmune disease (e.g., rheumatoid arthritis), acute infections. Decreased in amyloidosis and leukemia.
IgD	0.5–14 mg/dl (5–140 mg/L)	Immune integrity. Increased values in myelomas.
Ketone bodies (S or P)	Negative Toxic level >20 mg/dl (0.2 g/L)	Fatty acid catabolism. Increased values (ketosis, ketoacidosis) in starvation, low-carbohydrate diet, uncontrolled diabetes mellitus, aspirin overdose.
Lactate dehydrogenase (LDH) (S)	105–333 U/L (1.7–5.6 µkat/L)	Tissue damage of organs or striated muscle. Increased in myocardial infarction, pulmonary infarction, liver disease, cerebrovascular accident, infectious mononucleosis, muscular dystrophy, fractures.
Lactic acid (lactate) (P)	9–16 mg/dl (1.0–1.8 mmol/L)	Anaerobic tissue metabolism. Increased values in congestive heart failure, shock, hemorrhage, strenuous exercise.
Osmolality (S)	280–300 mOsm/kg H <sub>2</sub> O (280–300 mmol/kg H <sub>2</sub> O)	Fluid and electrolyte balance. Increased levels in hypernatremia, dehydration, kidney disease, alcohol ingestion. Decreased levels in hyponatremia, overhydration, and syndrome of inappropriate ADH secretion (SIADH).
Phosphate (S) (phosphorus)	2.5–4.5 mg/dl (0.8–1.5 mmol/L)	Parathyroid function; bone disease. Increased levels in hypoparathyroidism, renal failure, bone metastasis, hypocalcemia. Decreased values in hyperparathyroidism, hypercalcemia, alcoholism, vitamin D deficiency, ketoacidosis, osteomalacia.
Potassium (S)	3.5–5.5 mEq/L (3.5–5.5 mmol/L)	Fluid and electrolyte balance. Increased levels in renal disease, Addison's disease, ketoacidosis, burns, and crush injuries. Decreased levels in vomiting, diarrhea, Cushing's syndrome, alkalosis, diuretics.

TEST (SAMPLE)	REFERENCE VALUES: CONVENTIONAL (SI)	PHYSIOLOGICAL INDICATION AND CLINICAL IMPLICATIONS
<b>Blood Chemistry Studies</b> (continued)		
Protein (S)		
Total	6.0–8.5 g/dl (60–85 g/L)	Osmotic pressure; immune system integrity. Increased values in multiple myeloma, dehydration, myxedema. Decreased values in protein malnutrition, burns, diarrhea, renal failure, liver failure.
Albumin	3.2–5.0 g/dl (32–50 g/L)	Osmotic pressure. Increased levels in dehydration. Decreased levels in liver disease, malnutrition, Crohn's disease, nephrotic syndrome, systemic lupus erythematosus.
Sodium (S)	135–145 mEq/L (135–145 mmol/L)	Fluid and electrolyte balance. Increased values in dehydration, diabetes insipidus, Cushing's syndrome. Decreased values in vomiting, diarrhea, burns, Addison's disease, myxedema, congestive heart failure, overhydration, syndrome of inappropriate ADH secretion (SIADH).
Triglycerides	10–150 mg/dl (0.1–1.5 g/L)	Increased values in diabetes mellitus, liver disease, nephrotic syndrome, pregnancy.
Uric acid (S)	Female: 2.0–7.3 mg/dl (119–434 $\mu$ mol/L) Male: 2.1–8.5 mg/dl (125–506 $\mu$ mol/L)	Renal function. Increased in lead poisoning, impaired renal function, gout, alcoholism, hematologic cancers. Decreased in Wilson's disease.
<b>Hematology Studies</b>		
Hemoglobin (S)	Female: 12–16 g/dl (120–160 g/L) Male: 13–18 g/dl (130–180 g/L)	Oxygenation status. Increased values in dehydration, polycythemia, congestive heart failure, chronic obstructive pulmonary disease, high altitudes. Decreased levels in anemia, hemorrhage, bone marrow cancer, renal disease, systemic lupus erythematosus, nutritional deficiency.
Hematocrit (WB)	Female: 37–47% (same) Male: 42–52% (same)	Oxygenation status. Increased levels in polycythemia, dehydration, congestive heart failure, shock, surgery. Decreased levels in anemia, hemorrhage, bone marrow disease, malnutrition, cirrhosis, rheumatoid arthritis.
Partial thromboplastin time (activated) (PTT or aPTT)	20–36 s (same)	Clotting mechanisms. Increased values in clotting factor deficiencies, cirrhosis, vitamin K deficiency, disseminated intravascular coagulation (DIC). Decreased values in early DIC, extensive cancer.
Platelet count (WB)	150,000–400,000/ $\mu$ l (150–400 $\times 10^9$ /L)	Clotting mechanisms. Increased values in polycythemia, cancers, rheumatoid arthritis, trauma. Decreased values in liver disease, hemolytic uremic syndrome, disseminated intravascular coagulation (DIC), idiopathic thrombocytopenic purpura (ITP), systemic lupus erythematosus (SLE).
Prothrombin time (PT) (WB)	11–12.5 s (same) 1.5–2 $\times$ control (evaluating anticoagulant treatment)	Clotting mechanisms. Increased values in liver disease, vitamin K deficiency, salicylate intoxication. Decreased values in disseminated intravascular coagulation (DIC).
Red blood cell count (RBC) (WB)	Female: 4.2–5.4 million/ $\mu$ l (4.2–5.4 $\times 10^{12}$ /L) Male: 4.7–6.1 million/ $\mu$ l (4.7–6.1 $\times 10^{12}$ /L)	Oxygenation status. Increased values in high altitudes, polycythemia, hemoconcentration, cor pulmonale. Decreased values in hemorrhage, hemolysis, anemias, chronic illness, nutritional deficiencies, leukemia, overhydration.
Reticulocyte count (WB)	0.5–2.0% (same)	Bone marrow function. Increased values in hemolytic anemia, sickle-cell anemia, leukemia, pregnancy. Decreased values in pernicious anemia, folic acid deficiency, cirrhosis, chronic infection, bone marrow depression or failure.
White blood cell count (WBC) (WB)		
Total (males)	4800–10,800/ $\mu$ l (4.8–10.8 $\times 10^9$ /L)	Immune system integrity. Increased values in infection, trauma, stress, tissue necrosis, inflammation. Decreased values in bone marrow depression or failure, drug toxicity, overwhelming infection, malnutrition.

**A-12 Appendix F Reference Values for Selected Blood and Urine Studies**

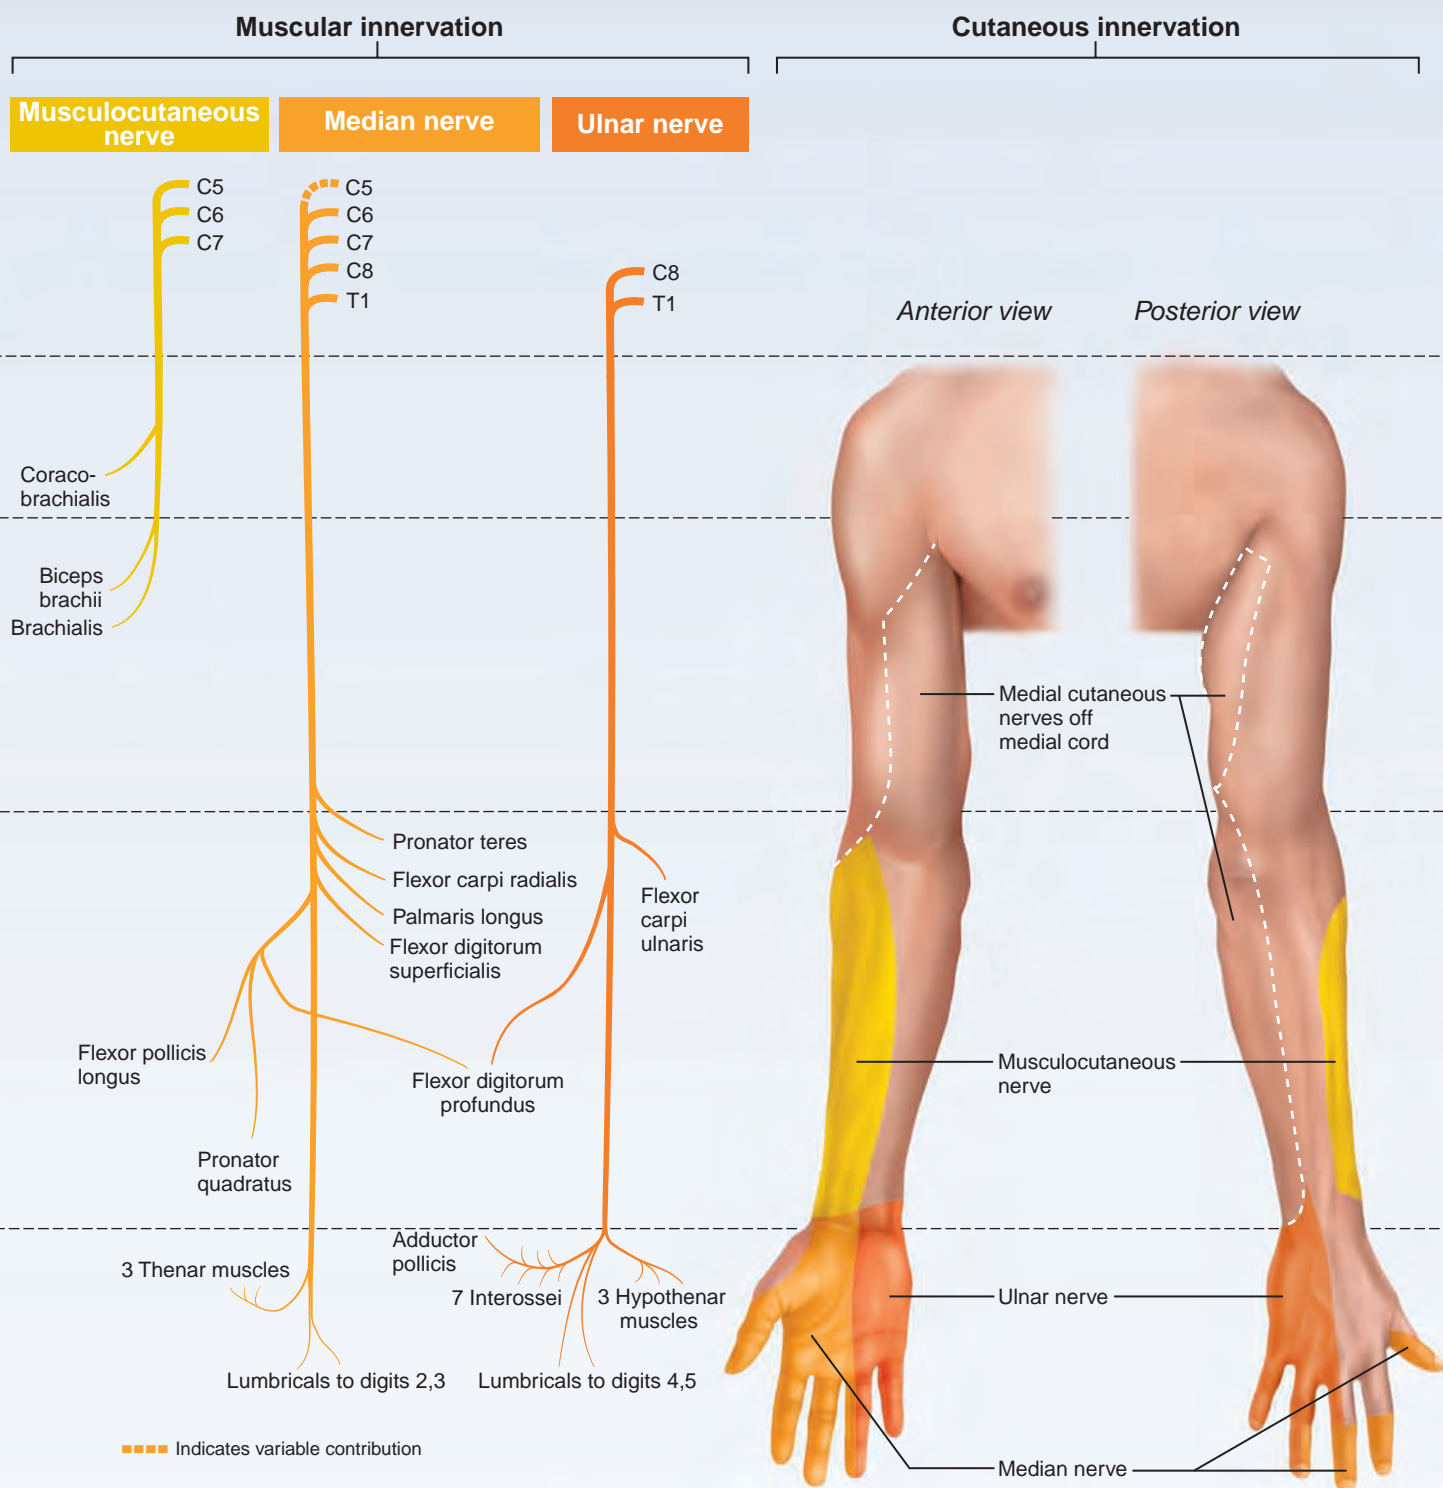

TEST (SAMPLE)	REFERENCE VALUES: CONVENTIONAL (SI)	PHYSIOLOGICAL INDICATION AND CLINICAL IMPLICATIONS
<b>Hematology Studies</b> <i>(continued)</i>		
White blood cell count, differential (WB)		
Neutrophils	50–70% (same)	Immune system integrity. Increased values in acute bacterial infections, stress, Cushing's syndrome, inflammatory disorders, ketoacidosis, gout. Decreased levels in aplastic anemia, bone marrow suppression, and overwhelming bacterial infections.
Lymphocytes	25–40% (same)	Immune system integrity. Increased values in viral infections (e.g., mumps, rubella, infectious mononucleosis, hepatitis), lymphocytic leukemia, certain bacterial infections. Decreased levels in leukemia, immunodeficiency, lupus erythematosus, bone marrow depressive drugs.
Eosinophils	1–4% (same)	Immune system integrity. Increased levels in allergic reactions, parasitic infections, leukemia. Decreased levels in excess adrenocorticosteroid production.
Monocytes	3–8% (same)	Immune system integrity. Increased levels in certain infections (e.g., tuberculosis, malaria), inflammatory disorders.
Basophils	0.5–1.0% (same)	Immune system integrity. Increased levels in myeloproliferative disorders, leukemia. Decreased levels in allergic reactions, hyperthyroidism, stress.
<b>Urine Tests</b>		
Amylase (24 h)	<6000 Somogyi units/24 h 0–500 U/24 h (0–8.3 $\mu$ kat/24 h)	Pancreatic function. Increased values in pancreatic disease or obstruction, inflammation of the salivary glands, and cholecystitis.
Bilirubin (random)	Negative (same)	Liver function. Increased values in liver disease, extrahepatic obstruction (gallstones, tumor, inflammation).
Blood (hemoglobin) (random)	Negative (same)	Urinary system function. Increased values in cystitis, renal disease, hemolytic anemia, transfusion reaction, prostatitis, burns.
Osmolality (random or fasting)	Random: 50–1200 mOsm/kg H <sub>2</sub> O (50–1200 mmol/kg H <sub>2</sub> O) Fluid restriction: $\geq$ 850 mOsm/kg H <sub>2</sub> O ( $\geq$ 850 mmol/kg H <sub>2</sub> O)	Fluid and electrolyte balance, renal function, and endocrine function. Increased levels in hypernatremia, syndrome of inappropriate ADH secretion (SIADH), congestive heart failure, metabolic acidosis. Decreased levels in diabetes insipidus, water intoxication, pyelonephritis, renal tubular necrosis, aldosteronism.
Phosphate (24 h)	0.9–1.3g/24 hr (same)	Parathyroid function. Increased levels in hyperparathyroidism, osteomalacia, certain renal diseases, vitamin D deficiency. Decreased levels in hypoparathyroidism.
Potassium (24 h)	25–120 mEq/24 h (25–120 mmol/24 h)	Fluid and electrolyte balance. Increased values in renal tubular necrosis, metabolic acidosis, dehydration, aldosteronism, Cushing's syndrome. Decreased values in Addison's disease, malabsorption, acute renal failure.
Protein (random)	<8 mg/dl (<80 mg/L)	Renal function. Increased levels in nephrotic syndrome, renal trauma, hyperthyroidism, diabetic nephropathy, systemic lupus erythematosus.
Sodium (24 h)	40–220 mEq/24 h (40–220 mmol/24 h)	Fluid and electrolyte balance. Increased values in dehydration, ketoacidosis, syndrome of inappropriate ADH secretion (SIADH), adrenocortical insufficiency. Decreased levels in congestive heart failure, renal failure, diarrhea, aldosteronism.
Uric acid (24 h)	250–750 mg/24 h (1.5–4.5 mmol/24 h)	Renal function and metabolism. Increased in gout, leukemia, liver disease, ulcerative colitis. Decreased in renal disease, alcoholism, lead toxicity, folic acid deficiency.

TEST (SAMPLE)	REFERENCE VALUES: CONVENTIONAL (SI)	PHYSIOLOGICAL INDICATION AND CLINICAL IMPLICATIONS
<b>Urine Tests</b> ( <i>continued</i> )		
Urinalysis (random)		
Color	Straw, yellow, amber	Fluid balance and renal function. Darker in dehydration. Lighter in overhydration, diabetes insipidus. Color varies with disease states, diet, and medications.
Odor	Aromatic	Metabolic function, infection. Abnormal odors in infection, ketonuria, rectal fistula, hepatic failure, phenylketonuria.
Specific gravity	1.001–1.035	An indirect measurement of urine concentration (osmolality). Same physiological indications and clinical implications as osmolality.
pH	4.5–8.0	A crude indicator of acid-base balance. Decreased by acidic diet (proteins). Increased by a vegetarian diet, prolonged vomiting, and bacterial infection of the urinary tract.
Urobilinogen (24 h)	0.2–1.0 mg/dl (2–10 mg/L)	Liver function. Increased in hemolytic anemias, hepatitis, cirrhosis, biliary disease. Decreased in common bile duct obstruction.
Volume (24 h)	800–2000 ml/24 h (0.8–2.0 L/24 h)	Fluid and electrolyte balance, renal function. Increased values in diabetes insipidus, diabetes mellitus, renal disease. Decreased values in dehydration, syndrome of inappropriate ADH secretion (SIADH), renal disease.

**Figure G.1** Each upper limb is innervated by five major nerves arising from the brachial plexus.

The nerves from the **anterior division of the brachial plexus** innervate the muscles in the anterior compartments: the flexor muscles of the arm, forearm, and hand. These nerves continue distally to supply cutaneous innervation to the forearm and hand.

The nerves from the **posterior division of the brachial plexus** innervate the muscles in the posterior compartments: the extensor muscles of the upper limb. These nerves continue distally to supply cutaneous innervation to much of the posterior arm, forearm, and hand.

**Figure G.2** Each lower limb is innervated by nerves arising from the lumbar and sacral plexuses, together called the lumbosacral plexus.

The nerves from the **lumbar plexus** innervate the muscles in the anterior and medial compartments of the thigh, and supply cutaneous innervation to anterior and medial portions of the thigh and leg.

The nerves from the **sacral plexus** innervate the muscles in the posterior compartments of the thigh and all of the muscles in the leg, and supply cutaneous innervation to the lateral and posterior portions of the leg and to the foot.

**Muscular innervation of posterior thigh and leg**

**Muscular innervation of lateral and anterior leg**

**Cutaneous innervation**

**Tibial nerve**

**Common fibular nerve**

*Anterior view*

*Posterior view*

\*Sciatic nerve formed by tibial and common fibular nerves wrapped by common sheath.

## Chapter 1

**Check Your Understanding 1.** The operation or function of a structure is promoted or prevented by its anatomy. For example, oxygen and carbon dioxide are exchanged across the very thin membranes of the lungs but not across the skin. **2.** Muscle shortening is a topic of physiology. The body location of the lungs is an anatomy topic. **3.** Cytologists study the cellular level of organization. **4.** The order in the structural hierarchy is cell, tissue, organ, and organism. **5.** Bones and cartilages are part of the skeletal system. The nasal cavity, lungs, and trachea are respiratory system organs. **6.** Living organisms can maintain their boundaries, move, respond to environmental changes, digest nutrients, carry out metabolism, dispose of wastes, reproduce, and grow. While inanimate objects may exhibit some of these properties, they do not exhibit all of them. **7.** Metabolism is the term that encompasses all the chemical reactions that occur in body cells. **8.** In flight, the cabin must be pressurized because the atmosphere is thinner at high altitudes and the amount of oxygen entering the blood under such conditions may be insufficient to maintain life. **9.** Negative feedback mechanisms allow us to adjust to conditions outside the normal temperature range by causing heat to be lost from the body (in hot conditions) and retained or generated by the body (in cold conditions). **10.** Thirst is part of a negative feedback control system because it prods us to drink, which ends the thirst stimulus and returns body fluid volume to the normal range. **11.** This is a positive feedback mechanism because it enhances the change (formation of a platelet plug) set into motion by the stimulus (damage to the blood vessel). The response ends when the platelet plug has plugged the hole in the blood vessel. **12.** The position in which a person is standing erect with feet slightly separated and palms facing anteriorly. Knowing the anatomical position is important because directional terms refer to the body as if it is in this position. **13.** Axillary region is the armpit. Acromial area is the tip of the shoulder. **14.** A frontal (coronal) section would separate the brain into anterior and posterior parts. **15.** He may have appendicitis if the pain is in the lower right quadrant of his abdomen. **16.** Of these organs, only the spinal cord is in the dorsal body cavity. **17.** As mobile organs (heart, lungs, digestive organs) work, friction is greatly reduced by the presence of serous fluid. Serous fluid allows the surrounding serous membranes to glide easily over one another.

**Review Questions 1.** c; **2.** a; **3.** e; **4.** a, d; **5.** (a) wrist (b) hip bone (c) nose (d) toes (e) scalp; **6.** neither c nor d would be visible in the median section; **7.** (a) dorsal (b) ventral (c) dorsal (d) ventral; **8.** b; **9.** b; **10.** c

## Chapter 2

**Check Your Understanding 1.** Foods contain chemical energy. **2.** Electrical energy is the energy used by nerve cells to transmit messages in the body. **3.** Potential energy (PE) is available when we are still. PE is converted to kinetic (working) energy when we exercise. **4.** Besides hydrogen and nitrogen, carbon and oxygen help to make up the bulk of living matter. **5.** This element has 82 protons in its nucleus and 82 electrons in its orbitals (electron cloud). **6.** Atomic mass indicates the sum of the protons and neutrons in a given atom's nucleus. Atomic weight indicates the average mass of all the isotopes of a given element. **7.** A molecule is 2 or more atoms held together by chemical bonds. **8.** A compound is formed when two or more different kinds of atoms chemically bond together, as in NaCl. Oxygen gas is 2 oxygen atoms (the same kind of atom) bonded together. **9.** Blood is a mixture because its components are not changed by their combination and they can be separated by physical means. **10.** Hydrogen bonds (linking H of one water molecule to O of another) form between water molecules. **11.** Argon's valence shell is full: )2e )8e )8e. Hence it is nonreactive. **12.** Electrons would spend more time in the vicinity of the more electronegative atom in XY, whereas electrons in XX

would orbit both X atoms to an equal extent. **13.** Fats are digested in the small intestine by decomposition reactions. **14.** Biochemical reactions in the body tend to be irreversible because (a) one or more of the products is removed from the reaction site or (b) the product is needed more than the reactants, so the cell would not provide energy to reverse the reaction. **15.** Decomposition reactions in which foods are broken down for energy are oxidation-reduction (redox) reactions. **16.** Water is an excellent solvent because of its polarity. As a dipole, it can orient itself to the end of other molecules, causing them to dissociate or go into solution. **17.** Electrolytes are substances like salts that will conduct an electrical current in aqueous solution. **18.**  $H^+$  is responsible for acidity. **19.** It is better to add a weak base, which will act to buffer the strong acid. **20.** Monomers of carbohydrates are called monosaccharides or simple sugars. Glucose is blood sugar. **21.** The animal form of stored carbohydrate is glycogen. **22.** Triglycerides, the major source of stored energy in the body, are composed of three fatty acid chains and a glycerol molecule and are found in fat tissue. Phospholipids consist of two fatty acid chains and a charged P-containing group. They are found in all cell membranes and form the basis of those membranes. **23.** Hydrolysis reactions break down polymers or macromolecules to their monomers by adding water to each bond joining monomers. **24.** An "amino acid" has an amine group ( $NH_2$ ) and a COOH group that has acidic properties. **25.** The primary structure of proteins is the stringlike chain of amino acids. **26.** The secondary structures of proteins are the alpha helix and the beta-pleated sheet. **27.** Molecular chaperones prevent inaccurate or inappropriate folding in the 3-D structure of a protein. **28.** Enzymes hold the substrate(s) in a desirable position to interact. **29.** DNA contains deoxyribose sugar and the bases A, T, G, C. RNA contains ribose sugar and the bases A, U, G, C. **30.** DNA dictates protein structure by its base sequence and reproduces itself before a cell divides to ensure that the genetic information in the daughter cells is identical. **31.** ATP stores energy in smaller packets that are more readily released and transferred (during ATP hydrolysis) than the energy stored in glucose. Hence the use of ATP as an energy source keeps energy waste to a minimum. **32.** When ATP releases energy, it loses a phosphate group and becomes ADP (also energy rich).

**Review Questions 1.** d; **2.** d; **3.** b; **4.** a; **5.** b; **6.** a; **7.** a; **8.** b; **9.** d; **10.** a; **11.** b; **12.** a, c; **13.** (1)a, (2)c; **14.** c; **15.** d; **16.** e; **17.** d; **18.** d; **19.** a; **20.** b; **21.** b; **22.** c

## Chapter 3

**Check Your Understanding 1.** The cell is the structural and functional unit of life. The activity of an organism depends on the activities of its cells. The activities of cells depend on their form and relative numbers of subcellular structures. Continuity of life has a cellular basis. **2.** It is the cell concept that includes structures and functions common to all cells. **3.** All cellular membranes consist of a double layer of phospholipids in which proteins are embedded. **4.** Hydrophobic regions (tails of phospholipid molecules) orient toward each other while the hydrophilic regions (phospholipid heads) orient to the aqueous fluid inside and outside the cell. **5.** The sugar residues of the glycocalyx provide recognizable biological markers for cells to recognize each other. **6.** The heart has desmosomes (anchoring junctions) that secure cardiac cells together as the heart works and gap junctions (communicating junctions) that allow ions to flow from cardiac cell to cardiac cell. **7.** Diffusion is driven by kinetic energy of the molecules. **8.** The relative concentration of the substance in different areas determines the direction of diffusion. Diffusion occurs from regions of high concentration to regions of low concentration. **9.** In channel-mediated diffusion, the diffusing substance moves through a membrane channel. In carrier-mediated diffusion, the diffusing substance attaches to a membrane (protein) carrier that moves

it across the membrane. **10.** Phosphorylation of the  $\text{Na}^+\text{-K}^+$  pump causes the pump protein to change shape so that it “pumps”  $\text{Na}^+$  across the membrane.  $\text{K}^+$  binding to the pump protein triggers the release of phosphate and the pump protein returns to its original shape. **11.** The plasma membrane expands as a result of exocytosis. **12.** Phagocytic cells engulf debris, and a smoker’s lungs would be laden with carbon particles and other debris from smoke inhalation. **13.** Cholesterol is taken in by receptor-mediated endocytosis. **14.** Diffusion of ions, mainly the diffusion of  $\text{K}^+$  from the cell through leakage channels, establishes the resting membrane potential. **15.** In a polarized membrane, the inside is negative relative to its outside. **16.** Signaling chemicals that bind to membrane receptors are called ligands. G protein-linked receptors direct intracellular events by promoting formation of second messengers. **17.** Mitochondria are the major sites of ATP synthesis. **18.** Ribosomes are the sites of protein synthesis. The rough ER provides a site for ribosome attachment, and its cisterns package in vesicles the proteins made on the ribosomes for transport to the Golgi apparatus. The Golgi apparatus modifies and packages the proteins it receives for various destinations within or outside the cell. **19.** The lysosomal enzymes digest foreign substances engulfed by the cell, nonuseful or deteriorating organelles, or even the cell itself to prevent the buildup of cellular debris. The enzymes in peroxisomes detoxify harmful chemicals and neutralize free radicals. **20.** Both microfilaments and microtubules are involved in organelle movements within the cell and/or movements of the cell as a whole. **21.** Intermediate filaments are the most important cytoskeletal elements in maintaining cell shape. **22.** The major function of microvilli is to increase the cell’s surface area for absorption of substances. **23.** If a cell loses its nucleus, it is doomed to die because it will be unable to make proteins, which include the enzymes needed for all metabolic reactions. **24.** Nucleoli are the site of synthesis of ribosomal subunits. **25.** Histone proteins provide the means to pack DNA in a compact, orderly way, and they play a role in gene regulation. **26.** The base sequence of the corresponding strand will be GCTTAC. **27.** DNA is synthesized during the S phase. **28.** Nuclear envelope breaks up, spindle forms, nucleoli disappear, and the chromosomes coil and condense. **29.** Codons are three-base sequences in mRNA, each of which specifies an amino acid. Anticodons are three-base sequences in tRNA that are complementary to the codons specifying the amino acid they transport to the ribosome during protein synthesis. **30.** The A site is the entry site for tRNA at the ribosome. The P site is where the tRNA carrying the growing polypeptide is located. The E site is the tRNA exit site from the ribosome. **31.** DNA provides the coded instructions (is the template) for protein synthesis via the mRNA synthesized on it. **32.** Ubiquitin attaches to misfolded, damaged, or unneeded proteins, tagging them for destruction by proteasomes. **33.** Blood plasma is extracellular fluid that transports nutrients, gases, hormones, and other substances throughout the body. Interstitial fluid is an important transport and dissolving medium. **34.** Apoptosis is a process of programmed cell death which rids the body of cells that are stressed, damaged, old, or no longer needed. **35.** The wear-and-tear theory of aging attributes aging to little chemical insults and free radicals, which have cumulative detrimental effects.

**Review Questions 1.** d; **2.** a, c; **3.** b; **4.** b; **5.** e; **6.** c; **7.** d; **8.** a; **9.** d; **10.** a; **11.** b; **12.** d; **13.** c; **14.** b; **15.** d; **16.** a; **17.** b; **18.** d; **19.** c

## Chapter 4

**Check Your Understanding 1.** Fixing tissue preserves it and prevents it from deteriorating. **2.** Heavy metal salts are used to stain tissues viewed by electron microscopes. **3.** Epithelial tissue lines body cavities and covers the body’s external surface; thus polarity with one free (apical) surface is a requirement. **4.** Epithelial tissue can regenerate and its cells are joined by lateral contacts. **5.** Simple epithelia are “built” to provide for efficient absorption and filtration across their thin epithelial barriers. **6.** Pseudo-

stratified epithelia appear to be stratified because their cells’ nuclei lie at different distances from the basement membrane. However, all cells rest on the basement membrane. **7.** Transitional epithelium is found in the urinary bladder and other hollow urinary organs. The ability of this epithelium to thin allows the urinary organs to handle (store or transport) a larger urine volume when necessary. **8.** All unicellular exocrine glands secrete the protein mucin (which becomes mucus on mixing with water). **9.** These exocrine glands are classified by duct structure and secretory mode. **10.** Holocrine glands have the highest rate of cell division. The secretory cells fragment and are lost in the secretion; thus the secretory cells must be continuously replaced. **11.** Connective tissue functions to bind, support, protect, and insulate body organs. In addition, blood acts to transport substances throughout the body. **12.** Reticular, collagen, and elastic fibers are found in the various connective tissues. **13.** Areolar connective tissue, because of its loose weblike nature, is capable of serving as a fluid reservoir. **14.** Dense regular connective tissue is damaged when you lacerate a tendon. **15.** Hyaline cartilage forms the growth plates. **16.** Cardiac muscle cells have striations and are branching cells. **17.** Skeletal muscle tissue is voluntary and is the muscle tissue injured when you “pull a muscle” while exercising. **18.** With extended processes, a neuron can conduct electrical signals a great distance within the body. **19.** A mucous membrane consists of both connective tissue and epithelium. It lines body cavities open to the exterior. **20.** The serous membranes called pleurae line the thorax walls and cover the lungs. **21.** The three main steps of tissue repair are inflammation, organization, and regeneration and fibrosis (which is a permanent repair). **22.** More severe injuries damage and destroy more tissue, requiring greater replacement with scar tissue. **23.** The three embryonic germ layers are the ectoderm, mesoderm, and endoderm. **24.** Ectoderm gives rise to the nervous system. **25.** Epithelium and blood-forming tissue remain highly mitotic all through life.

**Review Questions 1.** (1)a, (2)c, (3)d, (4)b; **2.** c, e; **3.** (1)b, (2)f, (3)a, (4)d, (5)g, (6)d; **4.** b; **5.** c; **6.** b

## Chapter 5

**Check Your Understanding 1.** Since the sole of the foot has thick skin, the layers from most superficial to deepest would be the stratum corneum, stratum lucidum, stratum granulosum, stratum spinosum, and stratum basale. **2.** The stratum basale undergoes almost continuous mitosis to replace cells lost by abrasion. **3.** The skin is subjected to a lot of abrasion and physical trauma. The desmosomes, which are connecting junctions, help to hold the cells together during such stress. **4.** The stratum basale, which abuts the dermis where the blood supply is, has the best nourished cells. **5.** The papillary layer of the dermis gives rise to fingerprint patterns. **6.** Fatty tissue in the hypodermis gives it insulating and shock-absorbing properties. **7.** Because there is no bleeding, the cut has penetrated into the avascular epidermis only. **8.** The third pigment contributing to skin color is hemoglobin, the pigment contained in red blood cells found in blood vessels of the dermis. **9.** Cyanosis is a bluish cast of the skin that indicates that hemoglobin in the red blood cells in the dermal capillaries is poorly oxygenated. **10.** Jaundice or a yellow cast to the skin due to the deposit of yellow bile pigments in body tissues may indicate a liver disorder. **11.** The regions of a hair from outside in are the cuticle, cortex, and medulla. **12.** There are no nerves in a hair, so cutting hair is painless. **13.** The arrector pili muscles pull the hair (normally slanted) to the upright position (when cold or scared). **14.** The hair papilla contains a knot of capillaries that supplies nutrients to cells of the hair bulb. **15.** The lunule of the nail is white because the thick nail matrix that underlies it blocks the rosy color of the dermal blood supply from showing through. **16.** Nails are hard because the keratin they contain is the hard keratin variety. **17.** Sebaceous (oil) glands and apocrine glands are associated with the hair follicles. **18.** His sympathetic nervous system activated his eccrine sweat glands and caused heat-induced sweating

in order to cool the body. **19.** Heat-induced sweating occurs all over the body when we are overheated. A cold sweat is emotionally induced sweating that begins on the palms, soles, and armpits and then spreads to other body areas. Both types of sweating are produced by the eccrine sweat glands, but activity of apocrine sweat glands is also likely during a cold sweat. **20.** The palms of the hands and soles of the feet are thick skin areas. It would be dangerous to have oily soles, and oily palms would decrease the ability of the hands to hang onto things. **21.** The low pH of skin secretions (acid mantle) inhibits division of bacteria, and many bacteria are killed by bactericidal substances in sebum or by natural antibiotics called defensins. Damaged skin secretes cathelicidins that are effective against a certain strain of strep bacteria. **22.** The epidermal dendritic cells play a role in body immunity. **23.** Sunlight causes the skin to produce a precursor of vitamin D from cholesterol. Vitamin D is essential for bone synthesis. **24.** The skin carries out chemical conversions that supplement some of the protective conversions carried out by the liver, convert some chemicals into carcinogens, activate some steroid hormones, and synthesize the vitamin D precursor. **25.** Basal cell carcinoma develops from the youngest epidermal cells. **26.** The ABCD rule helps one to recognize signs of melanoma. **27.** First- and second-degree burns can heal uneventfully by regeneration of epidermal cells as long as infection does not occur. Third-degree burns destroy the entire depth of skin and regeneration is not possible. Infection and loss of body fluid and proteins are problematic. **28.** Burns to the face are serious because damage to the respiratory passageways can occur in such burns. **29.** Vernix caseosa is a product of the sebaceous glands. **30.** Loss of subcutaneous fat, common in the elderly, leads to cold intolerance seen in this group of people. **31.** UV radiation degrades collagen and leads to loss of skin elasticity and water-holding capacity.

**Review Questions** 1. a; 2. c; 3. d; 4. d; 5. b; 6. b; 7. c; 8. c; 9. b; 10. a; 11. d; 12. b

**Case Study 1.** The skin separates and protects the internal environment of the body from potentially dangerous elements in the external environment. Mrs. DeStephano's chart indicates epidermal abrasions, which represent the loss of this barrier. Epidermal loss will also cost Mrs. DeStephano the acid mantle of her skin, protection against UV radiation, and dendritic cells, which protect against invasion by microorganisms. **2.** Macrophages found in the dermis can act as a backup system against bacterial and viral invasion when the epidermis is damaged. **3.** Suturing brings the edges of wounds close together and promotes faster healing because smaller amounts of granulation tissue need to be formed. This is termed healing by first intention. **4.** Cyanosis signals a decrease in the amount of oxygen carried by hemoglobin in the blood. Respiratory system and/or cardiovascular system impairments can lead to cyanosis.

## Chapter 6

**Check Your Understanding** 1. Hyaline cartilage is the most plentiful in the adult body. **2.** The epiglottis and external ear cartilages are flexible elastic cartilage. **3.** Interstitial growth is growth from within. **4.** The components of the axial skeleton are the skull, the vertebral column, and the thoracic cage. **5.** The major function of the axial skeleton is to establish the long axis of the body and to protect structures that it encloses. The general function of the appendicular skeleton is to allow us mobility for propulsion and manipulation of our environment. **6.** The ribs and skull bones are flat bones. **7.** Skeletal muscles use bones as levers to cause movement of the body and its parts. **8.** Bone matrix stores minerals and growth factors. **9.** Bone marrow cavities serve as sites for blood cell formation and fat storage. **10.** Crests, tubercles, and spines are bony projections. **11.** Compact bone looks fairly solid and homogeneous whereas spongy bone has an open network of bone spicules. **12.** Endosteum lines the internal canals and covers the trabeculae. **13.** Bone's inorganic component (bone salts) makes it hard. **14.** The

osteoclast fits this description. **15.** Bones begin as fibrous membranes or hyaline cartilages. **16.** The cartilage model grows, then breaks down and is replaced by bone. **17.** The primary ossification center in a long bone is in the center of the shaft. The secondary ossification centers are in the epiphyses (bone ends). **18.** The chondrocytes are enlarging and their lacunae are breaking down and leaving holes in the cartilage matrix. **19.** If bone-destroying cells (osteoclasts) are more active than bone-forming cells (osteoblasts), bone mass will decrease. **20.** The hormonal stimulus maintains homeostatic blood calcium levels. **21.** In an open fracture, the bone ends are exposed to the external environment. In a closed fracture, the bone ends do not penetrate the external boundary of the skin. **22.** Bone growth increases bone mass, as during childhood or when exceptional stress is placed on the bones. Bone remodeling follows bone growth to maintain the proper proportions of the bone considering stresses placed upon it. **23.** Paget's disease is characterized by excessive deposit of weak, poorly mineralized bone. **24.** Sufficient vitamin D, calcium, and weight-bearing exercise all help to maintain healthy bone density. **25.** Adult rickets is called osteomalacia. **26.** At birth, most bones are well formed and ossified except for their epiphyses. **27.** The skull bones do not appear to lose mass with aging.

**Review Questions** 1. e; 2. b; 3. c; 4. d; 5. e; 6. b; 7. c; 8. b; 9. d, e; 10. c; 11. b; 12. c; 13. a; 14. b

**Case Study 1.** Mrs. DeStephano's broken leg has a transverse fracture of the open variety because the broken ends of the bone are protruding through the skin. **2.** The laceration of the skin caused by the broken end of the bone creates a breach in the protective barrier created by the skin, providing an entry point for bacteria and other microorganisms. In addition, the protruding ends of the bone have now been exposed to the nonsterile external environment. This could result in the development of osteomyelitis, a bacterial infection, which can be treated with antibiotics. **3.** Reduction of a fracture is the clinical term for "setting the bone." Mrs. DeStephano's physician chose internal reduction, in which surgery is performed and the broken ends of the bone are secured together by pins or wires. A cast was applied to keep the aligned ends of the bone immobile until healing of the fracture has occurred. **4.** Healing of Mrs. DeStephano's fracture will begin as bony callus formation fills the break in the bone with bony tissue. This process begins 3–4 weeks after the break occurs and is completed within 2–3 months. **5.** Nutrient arteries supply blood to the bone tissue. In order for Mrs. DeStephano's break to heal normally, the bony tissue must be supplied with oxygen (to generate ATP for energy) and nutrients in order to rebuild the bone. Damage to a nutrient artery will decrease the delivery of these building materials and could slow the process of healing. **6.** For a fracture that is slow to heal, new techniques that promote healing include electrical stimulation, which promotes the deposition of new bone tissue; ultrasound treatments, known to speed healing; and possibly the addition of bone substitutes to the fractured area. **7.** At age 45, Mrs. DeStephano will most likely not regenerate her knee cartilage. (Cartilage growth typically ends during adolescence.) Cartilage damage that occurs during adulthood is slow to heal, due to the avascular nature of cartilage, and is usually irreparable. Surgical removal of cartilage fragments to allow improved movement of the joint is the usual treatment for this type of damage.

## Chapter 7

**Check Your Understanding** 1. The three main parts of the axial skeleton are the skull, vertebral column, and thoracic cage. **2.** The axial skeleton is more important in protecting internal organs. **3.** The frontal, parietal, temporal, sphenoid, and ethmoid bones are all cranial bones. **4.** The ethmoid bone forms the crista galli. **5.** The temporal bones house the external ear canals. **6.** The parietal bones abut each other at the sagittal suture. The occipital bone abuts the parietal bones at the lambdoid suture. **7.** The zygomatic bones are the cheekbones. **8.** Eating or talking,

because the only freely movable joints of the skull are the temporomandibular joints of the jaw. **9.** The maxillae are the keystone bones of the facial skeleton. **10.** The sphenoid, ethmoid, frontal, and maxillary bones contain paranasal sinuses. **11.** The cribriform plates of the ethmoid bone form the roof of the nasal cavity. **12.** The maxillae form the bulk of the orbit floor. The eye is housed in the orbit. **13.** The five major regions of the vertebral column are the cervical, thoracic, lumbar, sacral, and coccygeal regions. **14.** The cervical and lumbar regions are concave posteriorly. **15.** The fibrocartilage discs contribute to the flexibility of the vertebral column. **16.** There are 7 cervical and 12 thoracic vertebrae. **17.** The dens is the axis on which the atlas rotates. If it's broken, movements of the atlas would be less controllable. **18.** A lumbar vertebra is heavier and its massive body is kidney shaped. Its spinous processes are short and project directly back. A thoracic vertebral body is generally heart shaped, its spinous process is long, sharp, and points downward, and its transverse processes have facets for articulating with the ribs. **19.** A true rib connects to the sternum by its own costal cartilage. A false rib connects to the sternum via costal cartilages of other ribs or not at all. **20.** The sternal angle is a ridge across the front of the sternum where the manubrium joins the sternal body. It acts as a hinge allowing the sternum to swing anteriorly when we inhale. Because it is aligned with the second rib, it is a handy cue for finding that rib and then counting the ribs during a physical exam. **21.** The thoracic vertebrae also contribute to the thoracic cage. **22.** Each pectoral girdle is formed by a scapula and a clavicle. **23.** The pectoral girdle attaches to the sternal manubrium of the axial skeleton via the medial end of its clavicle. **24.** A consequence of its flexibility is that it is easily dislocated. **25.** Together the ulna and humerus form the elbow joint. **26.** The ulna and the radius each have a styloid process distally. **27.** Carpals are found in the proximal region of the palm. They are short bones. **28.** The third bone of the os coxae is the ischium. **29.** The pelvic girdle receives the weight of the upper body (trunk, head, and upper limbs) and transmits that weight to the lower limbs. **30.** The female pelvis is wider and has a shorter sacrum and a more movable coccyx. **31.** The tibia is the second largest bone in the body. **32.** The medial malleolus is located on the distalmost medial aspect of the tibia. **33.** The lateral condyles are not sites of muscle attachment, they are articular surfaces. **34.** Because of their springiness, the foot arches save energy during locomotion. **35.** The two largest tarsals are the talus and the calcaneus, which forms the heel. **36.** The enlargement of the facial skeleton between ages 6 and 13 is due to the enlargement of the nose and paranasal sinuses and the development of the permanent teeth. **37.** The lumbar curvature develops when the baby begins to walk.

**Review Questions 1.** (1)b, g; (2)h; (3)d; (4)d, f; (5)e; (6)c; (7)a, b, d, h; (8)i; **2.** (1)g, (2)f, (3)b, (4)a, (5)b, (6)c, (7)d, (8)e; **3.** (1)b, (2)c, (3)e, (4)a, (5)h, (6)e, (7)f

**Case Study 1.** The hemispherical socket at the point where her femur attaches is called the *acetabulum*. **2.** The structure on the femur that forms the “ball” that fits into the “socket” named in question 1 is called the *head* of the femur. **3.** The three bones in the pelvic girdle that fuse together at a point within the structure identified in question 1 are the *ilium*, *ischium*, and *pubis*. **4.** If you were asked to rest your hands on your hips, your hands would be resting on the *iliac crests*. **5.** The structures on the femur where the large muscles of the buttocks and thigh attach are the *greater trochanter* and *lesser trochanter*. **6.** The structure of the pelvis that the sciatic nerve passes through as it travels into the upper thigh is the *greater sciatic notch* of the *ilium*.

## Chapter 8

**Check Your Understanding 1.** Joint and articulation are synonyms. **2.** The synarthroses are the least mobile of the joint types. **3.** Symphyses and synchondroses are cartilaginous joints. **4.** In general, the more stable a joint, the less mobile it is. **5.** The fibrous layer and the synovial membrane

make up the wall of the articular capsule. **6.** Bursae and tendon sheaths help to reduce friction during joint movement. **7.** The muscle tendons that cross the joint are typically the most important factor in stabilizing synovial joints. **8.** Weeping lubrication helps keep the joint cartilages nourished and “lubricates” the joint surfaces. **9.** John’s hip joint was flexed and his knees extended and his thumb was in opposition (to his index finger). **10.** The hinge and pivot joints are uniaxial joints. **11.** The knee and temporomandibular joints have menisci. The elbow and knee act mainly as a uniaxial hinge. The shoulder depends largely on muscle tendons for stability. **12.** Arthritis means inflammation of the joint. **13.** RA typically produces pain, swelling, and joint deformations that tend to be bilateral and crippling. OA patients tend to have pain, particularly on arising, which is relieved by gentle exercise, and enlarged bone ends (due to spurs) in affected joints. Affected joints may exhibit crepitus. **14.** Lyme disease is caused by spirochete bacteria and transmitted by a tick bite. **15.** Regular exercise strengthens joints and keeps them well nourished.

**Review Questions 1.** (1)c, (2)a, (3)a, (4)b, (5)c, (6)b, (7)b, (8)a, (9)c; **2.** b; **3.** d; **4.** d; **5.** b; **6.** d; **7.** d

**Case Study 1.** The hip joint would be structurally classified as a *synovial joint* and functionally classified as a *diarthrotic* (freely movable) joint.

**2.** The six distinguishing features that define a synovial joint are: (1) articular cartilage, (2) joint (synovial) cavity, (3) articular capsule, (4) synovial fluid, (5) reinforcing ligaments, (6) nerves and blood vessels. **3.** The joint space in a synovial joint is normally filled with *synovial fluid*. **4.** The acetabular labrum is a piece of fibrocartilage that attaches to and extends the rim of the acetabulum. The diameter of the labrum is less than the diameter of the head of the femur, and this helps stabilize the joint to prevent it from dislocating. **5.** Mrs. Tanner’s hip was bent (flexed) and her thigh was pulled toward the midline of her body (adducted) and turned in toward this midline (medially rotated). **6.** Mrs. Tanner suffered a posterior dislocation of the hip. When the head of the femur comes away from the acetabulum and then turns posteriorly, it causes the femur to rotate counterclockwise. This can be determined from the fact that her thigh was adducted and medially rotated. **7.** The hip movements include flexion, extension, abduction, adduction, rotation, and circumduction of the thigh.

## Chapter 9

**Check Your Understanding 1.** Striated means “with stripes.” **2.** He should respond “smooth muscle,” which fits the description. **3.** “Epimysium” literally translates to “outside the muscle” and this connective tissue sheath is the outermost muscle sheath, enclosing the entire muscle. **4.** The thin myofilaments have binding sites for calcium on the troponin molecules forming part of those filaments. **5.** In a resting muscle fiber, the SR would have the highest concentration of calcium ions. The mitochondrion provides the ATP needed for muscle activity. **6.** The components of the neuromuscular junction are the axon terminal, the synaptic cleft, and the junctional folds of the sarcolemma. **7.** The final trigger for contraction is a certain concentration of calcium ions in the cytosol. The initial trigger is depolarization of the sarcolemma. **8.** There are always some myosin cross bridges bound to the actin myofilament during the contraction phase. Thus, backward sliding of the actin filaments is prevented. **9.** Without ATP, rigor would occur because the myosin heads could not detach. **10.** A motor unit is an axon of a motor neuron and all the muscle fibers it innervates. **11.** During the latent period, events of excitation-contraction coupling are occurring. **12.** Immediately after Jay grabs the bar, his biceps muscles are contracting isometrically. As his body moves upward toward the bar, they are contracting isotonicly and concentrically. As he lowers his body toward the mat, the biceps are contracting isotonicly and eccentrically. **13.** Eric was breathing heavily because it takes some time for his heart rate and overall metabolism to return to the resting state after exercise. Moreover, he had likely incurred an oxygen debt that required he take in extra oxygen for the

restorative process, the so-called EPOC. Although jogging is primarily an aerobic exercise, there is always some anaerobic respiration that occurs as well—the amount depends on exercise intensity. As fatigue occurs, potassium ions accumulate in the T tubules, and lactic acid and phosphate ions accumulate in the muscle cells. **14.** Factors that influence muscle contractile force include muscle fiber size, the number of muscle fibers stimulated, the frequency of stimulation, and the degree of muscle stretch. Factors that influence velocity of contraction include muscle fiber type, load, and the number of motor units contracting. **15.** Fast glycolytic fibers would provide for short periods of intense strength needed to lift and move furniture. **16.** To increase muscle size and strength, anaerobic exercise is best. Muscle endurance is enhanced by aerobic exercise. **17.** Both skeletal and smooth muscle fibers are elongated cells, but unlike smooth muscle cells, which are spindle shaped, uninucleate, and nonstriated, skeletal muscle cells are very large cigar-shaped, multinucleate, striated cells. **18.** Calcium binds to troponin on the thin filaments in skeletal muscle cells. In smooth muscle cells, it binds to a cytoplasmic protein called calmodulin. **19.** Hollow organs that have smooth muscle cells helping to form their walls often must temporarily store the organ's contents (urine, food residues, etc.), an ability ensured by the stress-relaxation response. **20.** During development of skeletal muscle fibers, the myoblast cells join together, forming multinucleate myotubes. **21.** The connective tissue in muscles increases with age, causing the muscles to get stringier. **22.** Regular exercise and strength training help to defer the loss in strength and muscle wasting that tends to occur with age, and improve neuromuscular function.

**Review Questions** 1. c; 2. b; 3. (1)b, (2)a, (3)b, (4)a, (5)b, (6)a; 4. c; 5. a; 6. a; 7. d; 8. a; 9. (1)a, (2)a, c, (3)b, (4)c, (5)b, (6)b; 10. a; 11. c; 12. c; 13. c; 14. b

**Case Study 1.** The first reaction to tissue injury is the initiation of the inflammatory response. The inflammatory chemicals increase the permeability of the capillaries in the injured area, allowing white blood cells, fluid, and other substances to reach the injured area. The next step in healing involves the formation of granulation tissue, in which the vascular supply for the injured area is regenerated and collagen fibers that knit the torn edges of the tissue together are formed. Skeletal muscle does not regenerate well, so the damaged areas of Mrs. DeStephano's muscle tissue will probably be repaired primarily by the formation of fibrous tissue, creating scar tissue. **2.** Healing is aided by good circulation of blood within the injured area. Vascular damage compromises healing because the supply of oxygen and nutrients to the tissue is reduced. **3.** Under normal circumstances, skeletal muscles receive electrical signals from the nervous system continuously. These signals help to maintain muscle tone and readiness. Severing of the sciatic nerve removes this continuous nervous input to the muscles and will lead to muscle atrophy. Immobility of muscles will lead to a replacement of contractile muscle tissue with noncontractile fibrous connective tissue. Distal to the point of transection, the muscle will begin to decrease in size within 3–7 days of becoming immobile. This process can be delayed by electrically stimulating the tissues. Passive range-of-motion exercises also help prevent loss of muscle tone and joint range, and improve circulation in the injured areas. **4.** Mrs. DeStephano's physician wants to supply her damaged tissues with the necessary building materials to encourage healing. A high-protein diet will provide plenty of amino acids to rebuild or replace damaged proteins, carbohydrates will provide the fuel molecules needed to generate the required ATP, and vitamin C is important for the regeneration of connective tissue.

## Chapter 10

**Check Your Understanding 1.** The term “prime mover” refers to the muscle that bears the most responsibility for causing a particular movement. **2.** The iliacus overlies the iliac bone; the adductor brevis is a small (size) mus-

cle that adducts (movement caused) the thigh; and the quadriceps (4 heads) femoris muscle follows the course of the femur. **3.** Of the muscles illustrated in Figure 10.2, the one with the parallel arrangement (sartorius) could shorten to the greatest degree. The stocky bipennate (rectus femoris) and multipennate (deltoid) muscles would be most powerful because they pack in the most fibers. **4.** Third-class levers are the fastest levers. **5.** A lever that operates at a mechanical advantage allows the muscle to exert less force than the load being moved. **6.** John was using the frontal belly of his epicranium to raise his eyebrows and the orbicularis oculi muscles to wink at Sarah. **7.** To make a sad clown's face you would contract your platysma, depressor anguli oris, and depressor labii inferioris muscles. **8.** The deltoid has a broad origin. When only its anterior fibers contract, it flexes and medially rotates the humerus. When only its posterior fibers contract, it extends and laterally rotates the humerus. **9.** The opponens pollicis does not have an insertion on the bones of the thumb.

**Review Questions** 1. c; 2. c; 3. (1)e, (2)c, (3)g, (4)f, (5)d; 4. a; 5. c; 6. d; 7. c; 8. c; 9. b; 10. d; 11. b; 12. a; 13. c; 14. d; 15. a, b; 16. a

**Case Study 1.** A prime mover is a muscle that has primary or major responsibility for producing a specific movement. A synergist is a muscle that supports or helps the action of a prime mover by adding extra force, or providing stability so that the prime mover can perform its action. **2.** An antagonist is a muscle that opposes, resists, or reverses a particular movement. By mimicking the action of an antagonist, the therapist can test the strength of the agonist muscle and compare it with the same muscle in the other limb. **3.** Ideally, the therapist would assess each muscle individually. In reality, these assessments usually measure the function of a group of muscles because multiple muscles are often involved in similar actions. (a) This assessment focuses on the thigh adductors (magnus, longus, brevis), pectineus, and gracilis. Specifically, the adductor magnus is innervated by the damaged sciatic nerve. (b) This assessment addresses Mrs. Tanner's ability to dorsiflex her foot. Dorsiflexion involves all of the muscles in the anterior compartment of the lower leg: the tibialis anterior, extensor digitorum longus, fibularis (peroneus) tertius, and extensor hallucis longus. (c) This assessment addresses the function of the muscles of the posterior compartment of the thigh. The hamstrings (biceps femoris, semitendinosus, semimembranosus) are the prime movers involved in knee flexion. **4.** To assess these muscles, the therapist would apply resistance to the natural action of these muscles. (a) The extensor hallucis longus inserts on the distal phalanx of the great toe. The therapist can apply resistance to the top of the toe and ask Mrs. Tanner to extend the toe. (b) The fibularis longus is involved in eversion of the foot and plantar flexion. The therapist can apply resistance to the lateral aspect of the foot and ask Mrs. Tanner to evert (turn out) her ankle. In addition, resistance can be applied to the bottom of the foot and Mrs. Tanner asked to push against that resistance. (c) The gastrocnemius, along with the soleus, is a powerful plantar flexor. The therapist can (1) ask Mrs. Tanner to raise her body up on her toes using her right foot, or (2) apply pressure to the bottom of the foot and ask Mrs. Tanner to push against that resistance.

## Chapter 11

**Check Your Understanding 1.** Integration involves processing and interpreting sensory information, and making a decision about motor output. Integration occurs primarily in the CNS. **2.** (a) This “full stomach” feeling would be relayed by the sensory (afferent) division of the PNS (via its visceral afferent fibers). (b) The somatic nervous system, which is part of the motor (efferent) division of the PNS, controls movement of skeletal muscle. (c) The autonomic nervous system, which is part of the motor (efferent) division of the PNS, controls the heart rate. **3.** Astrocytes control the extracellular environment around neuron cell bodies in the CNS, whereas satellite cells perform this function in the PNS. **4.** Oligodendrocytes and Schwann cells form myelin sheaths in the CNS and PNS, respectively.

5. A nerve fiber is a long axon, an extension of the cell. In connective tissue, fibers are extracellular proteins that provide support. In muscle tissue, a muscle fiber is a muscle cell. 6. A nucleus within the brain is a cluster of cell bodies, whereas the nucleus within each neuron is a large organelle that acts as the control center of the cell. 7. In the CNS, a myelin sheath is formed by oligodendrocytes that wrap their plasma membranes around the axon. The myelin sheath protects and electrically insulates axons and increases the speed of transmission of nerve impulses. 8. Burning a finger will first activate unipolar (pseudounipolar) neurons that are sensory (afferent) neurons. The impulse to move your finger away from the heat will be carried by multipolar neurons that are motor (efferent) neurons. 9. The concentration gradient and the electrical gradient—together called the electrochemical gradient—determine the direction in which ions flow through an open membrane channel. 10. There is more leakage of  $K^+$  than of any other cations. 11. Action potentials are larger than graded potentials and travel further. Graded potentials generally initiate action potentials. 12. An action potential is regenerated anew at each membrane patch. 13. Conduction of action potentials is faster in myelinated axons because myelin allows the axon membrane between myelin sheath gaps to change its voltage rapidly, and allows current to flow only at the widely spaced gaps. 14. If a second stimulus occurs before the end of the absolute refractory period, no AP can occur because sodium channels are still inactivated. 15. At an electrical synapse, neurons are joined by gap junctions. 16. Voltage-gated ion ( $Ca^{2+}$ ) channels are found in the presynaptic axon terminal and open when an action potential reaches the axon terminal. Chemically gated ion channels are found in the postsynaptic membrane and open when neurotransmitter binds to the receptor protein. 17. IPSPs result from the flow of either  $K^+$  or  $Cl^-$  through chemically gated channels. EPSPs result from the flow of both  $Na^+$  and  $K^+$  through chemically gated channels. 18. Temporal summation is summation in time of graded potentials occurring in quick succession at the postsynaptic membrane. It can result from EPSPs arising from just one synapse. Spatial summation is summation in space—a postsynaptic neuron is stimulated by a large number of terminals at the same time. 19. ACh interacts with more than one specific receptor type, and this explains how it can excite at some synapses and inhibit at others. 20. cAMP is called a second messenger because it relays the message between the first messenger (the original chemical messenger) outside of the cell and effector molecules that will ultimately bring about the desired response within the cell. 21. Reverberating circuits and parallel after-discharge circuits both result in prolonged output. 22. The pattern of neural processing is serial processing. The response is a reflex arc. 23. The pattern of neural processing is parallel processing. 24. The growing tip of an axon is called a growth cone. Neurotrophins are chemicals that signal the growth cone.

**Review Questions** 1. b; 2. (1)d, (2)b, (3)f, (4)c, (5)a; 3. b; 4. c; 5. a; 6. c; 7. b; 8. d; 9. c; 10. c; 11. a; 12. (1)d, (2)b, (3)a, (4)c

**Case Study 1.** The electrical signals generated by neurons are called *action potentials*. An action potential is a change in membrane potential that involves depolarization and repolarization phases. 2. An inhibitory postsynaptic potential (IPSP) is a signal that makes it less likely that a postsynaptic neuron will be able to generate an action potential. This effect is usually produced when the signal causes the membrane potential of the postsynaptic neuron to become more negative, moving away from the axon's threshold potential. 3. GABA falls into the amino acid class of neurotransmitters. This same class includes glycine, glutamate, and aspartate. 4. To enhance the actions of GABA at a synapse, a drug could either (1) act presynaptically to increase the release of GABA at the synapse, (2) decrease the reuptake of GABA after it has been released, or (3) act postsynaptically to either increase the binding strength of GABA at its receptors, or increase the number of receptors. 5. An influx of  $Cl^-$  into the postsynaptic cell causes the membrane potential to become more

negative (hyperpolarize). When hyperpolarized, the cell is farther from its threshold potential and so is less likely to produce an action potential.

## Chapter 12

**Check Your Understanding 1.** The third ventricle is surrounded by the diencephalon. 2. The cerebral hemispheres and the cerebellum have an outside layer of gray matter in addition to central gray matter and its surrounding white matter. 3. Convolutions increase surface area of the cortex, which allows more neurons to occupy the limited space within the skull. 4. The central sulcus separates primary motor areas from somatosensory areas. 5. Motor functions on the left side of the body are controlled by the right hemisphere of the brain because motor tracts from the right hemisphere cross over (in the medulla oblongata) to the left side of the spinal cord to go to the left side of the body. 6. Commissural fibers (which form commissures) allow the cerebral hemispheres to “talk to each other.” 7. The caudate nucleus, putamen, and globus pallidus together form the basal nuclei. 8. Virtually all inputs ascending to the cerebral cortex synapse in the thalamus en route. 9. The hypothalamus oversees the autonomic nervous system. 10. The pyramids of the medulla are the corticospinal (pyramidal) tracts, the large voluntary motor tracts descending from the motor cortex. The result of decussation (crossing over) is that each side of the motor cortex controls the opposite side of the body. 11. The cerebral peduncles and the colliculi are associated with the mid-brain. 12. There are many possible answers to this question—here are a few: Structurally, the cerebellum and cerebrum are similar in that they both have a thin outer cortex of gray matter, internal white matter, and deep gray matter nuclei. Also, both have body maps (homunculi) and large fiber tracts connecting them to the brain stem. Both receive sensory input and influence motor output. A major difference is that the cerebellum is almost entirely concerned with motor output, whereas the cerebrum has much broader responsibilities. Also, while a cerebral hemisphere controls the opposite side of the body, a cerebellar hemisphere controls the same side of the body. 13. The hypothalamus is part of the limbic system and also an autonomic (visceral) control center. 14. Taylor is increasing the amount of sensory stimuli she receives, which will be relayed to the reticular activating system, which, in turn, will increase activation of the cerebral cortex. 15. Delta waves are typically seen in deep sleep in normal adults. 16. Drowsiness (or lethargy) and stupor are stages of consciousness between alertness and coma. 17. Most skeletal muscles are actively inhibited during REM sleep. 18. Transfer of memory from STM to LTM is enhanced by (1) rehearsal, (2) association (tying “new” information to “old” information), and (3) a heightened emotional state (for example, alert, motivated, surprised, or aroused). 19. The basal nuclei and premotor cortex are involved in procedural (skills) memory, but not in declarative memory. 20. CSF, formed by the choroid plexuses as a filtrate of blood plasma, is a watery “broth” similar in composition to plasma. It protects the brain and spinal cord from blows and other trauma, helps nourish the brain, and carries chemical signals from one part of the brain to another. 21. A TIA is a temporary loss of blood supply to brain tissue, and it differs from a stroke in that the resultant impairment is fully reversible. 22. Mrs. Lee might have Parkinson's disease. 23. The nerves serving the limbs arise in the cervical and lumbar enlargements of the spinal cord. 24. In the spinothalamic pathway, the cell bodies of first-order sensory neurons are outside the spinal cord in a ganglion, cell bodies of second-order sensory neurons are in the dorsal horn of the spinal cord, and cell bodies of third-order sensory neurons are in the thalamus. (See also Figure 12.31b.) 25. A loss of motor function is called paralysis. Lower limb paralysis could be caused by a spinal cord injury in the thoracic region (between  $T_1$  and  $L_1$ ). If the spinal cord is transected, the result is paraplegia. If the cord is only bruised, he may regain function in the limbs. An MRI scan (or CT scan) of the spinal cord would be helpful. 26. Alar plate neuroblasts become interneurons, whereas basal plate neuroblasts become

motor (efferent) neurons. **27.** Premature babies have trouble regulating body temperature because the hypothalamus is immature. **28.** Reversible causes of dementia include prescription drug effects, low blood pressure, poor nutrition, hormone imbalances, depression, and dehydration.

**Review Questions** **1.** a; **2.** d; **3.** c; **4.** a; **5.** (1)d, (2)f, (3)e, (4)g, (5)b, (6)f, (7)i, (8)a; **6.** b; **7.** c; **8.** a; **9.** (1)a, (2)b, (3)a, (4)a, (5)b, (6)a, (7)b, (8)b, (9)a; **10.** d; **11.** (1)d, (2)e, (3)c and d, (4)a; **12.** c

**Case Study 1.** The four regions of the brain are the cerebral hemispheres, diencephalon, brain stem, and cerebellum. A cerebral hemisphere is involved in this case. Motor functions and language are both located in this cerebral hemisphere and have been affected by the injury. **2.** The left side of the brain has been affected in this case. The motor dysfunction on the right side of the body is the primary piece of evidence used to determine this. In addition, the brain areas serving speech are usually located in the left side. **3.** The motor dysfunction on the right side of the body suggests that the injury has affected the primary motor cortex and possibly the premotor cortex of the left cerebral hemisphere. In addition to the problems with motor function, Mrs. Bryans experienced difficulty with language. Two areas of the brain associated with language, Broca's and Wernicke's area, are usually located in the left cerebral cortex. The type of aphasia described suggests damage to Broca's area. **4.** From the surface of the brain to the skull, the three membranes that make up the meninges include the pia mater, arachnoid mater, and dura mater. **5.** The subarachnoid hemorrhage involves bleeding into the region below (*sub* = below) the arachnoid mater. The subdural hematoma involves blood collecting between the dura mater and the arachnoid mater.

## Chapter 13

**Check Your Understanding 1.** In addition to nerves, the PNS also consists of sensory receptors, motor endings, and ganglia. **2.** Nociceptors respond to painful stimuli. They are exteroceptors that are nonencapsulated (free nerve endings). **3.** The three levels of sensory integration are receptor level, circuit level, and perceptual level. **4.** Phasic receptors adapt, whereas tonic receptors exhibit little or no adaptation. Pain receptors are tonic so that we are reminded to protect the injured body part. **5.** Hot and cold are conveyed by different sensory receptors that are parts of separate "labeled lines." Cool and cold are two different intensities of the same stimulus, detected by frequency coding—the frequency of APs would be higher for a cold than a cool stimulus. Action potentials arising in the fingers and foot arrive at different locations in the somatosensory cortex via their own "labeled lines" and in this way the cortex can determine their origin. **6.** Ganglia are collections of neuron cell bodies in the PNS. **7.** Nerves also contain connective tissue, blood vessels, lymphatic vessels, and the myelin surrounding the axons. **8.** Schwann cells, macrophages, and the neurons themselves were all important in healing the nerve. **9.** The oculomotor (III), trochlear (IV), and abducens (VI) nerves control eye movements. Sticking out your tongue involves the hypoglossal nerve (XII). The vagus nerve (X) influences heart rate and digestive activity. The accessory nerve (XI) innervates the trapezius muscle, which is involved in shoulder shrugging. **10.** Roots lie medial to spinal nerves, whereas rami lie lateral to spinal nerves. Dorsal roots are purely sensory, whereas dorsal rami carry both motor and sensory fibers. **11.** The spinal nerve roots were C<sub>3</sub>–C<sub>5</sub>, the spinal nerve was the phrenic nerve, the plexus was the cervical plexus. The phrenic nerve is the sole motor nerve supply to the diaphragm, the primary muscle for respiration. **12.** Varicosities are the series of knoblike swellings that are the axon endings of autonomic motor neurons. You would find them on axon endings serving smooth muscle or glands. **13.** The cerebellum and basal nuclei, which form the precommand level of motor control, plan and coordinate complex motor activities. **14.** The five components of a reflex arc are receptor,

sensory neuron, integration center, motor neuron, and effector. **15.** The stretch reflex is important for maintaining muscle tone and adjusting it reflexively by causing muscle contraction in response to increased muscle length (stretch). It maintains posture. The flexor or withdrawal reflex is initiated by a painful stimulus and causes automatic withdrawal of the painful body part from the stimulus. It is protective. **16.** This response is called Babinski's sign and it indicates damage to the corticospinal tract or primary motor cortex. **17.** The vertebral column, spinal nerves, and dermatomes are all examples of segmentation in the adult.

**Review Questions** **1.** b; **2.** c; **3.** d; **4.** c; **5.** e; **6.** c; **7.** (1)d, (2)c, (3)f, (4)b, (5)e, (6)a; **8.** (1)f, (2)i, (3)b, (4)g, h, (5)e, (6)i, (7)c, (8)k, (9)l, (10)c, d, f, k; **9.** (1)b 6; (2)d 8; (3)c 2; (4)c 5; (5)a 4; (6)a 3, 9; (7)a 7; (8)a 7; (9)d 1; (10)a 3, 4, 7, 9; **10.** (1)a, 1 and 5; (2)a, 3 and 5; (3)a, 4; (4)a, 2; (5)c, 2; (6)b, 2; **11.** c

**Case Study 1.** Cerebrospinal fluid (CSF) is leaking out of Mr. Hancock's right ear. The fracture must have torn both the dura mater and arachnoid mater. In addition, the tympanic membrane must have ruptured. Antibiotics were administered to prevent infection by bacteria that might enter through the ruptured meninges, causing meningitis. Elevating the head of the bed decreases the CSF pressure in the skull. (This allows the torn meninges to heal spontaneously in the majority of cases.) **2.** The observations on Mr. Hancock's chart indicate: (a) Either damage to CN VIII (the vestibulocochlear nerve, which transmits afferent impulses for the sense of hearing) or destruction of the cochlea (the sensory organ for hearing). (b) Damage to CN V<sub>3</sub> (the mandibular division of the trigeminal nerve), which runs through the foramen ovale. This nerve conveys sensory information from the lower part of the face. (c) Damage to CN V<sub>2</sub> (the maxillary division of the trigeminal nerve), which runs through the foramen rotundum. This nerve conveys sensory information from the skin of the upper lip, lower eyelid, and cheek. (d) Damage to CN VI (the abducens nerve), which innervates the lateral rectus muscle of the eye. Because this muscle is responsible for pulling the eye laterally (abduction), loss of tone in this muscle at rest will cause the eye to turn inward. Diplopia will worsen when looking to the right because the eye cannot abduct. **3.** The facial nerve (cranial nerve VII) is the primary motor nerve associated with facial expression. The facial nerve also contains parasympathetic fibers that control secretion of tears from the lacrimal glands. Damage to this nerve explains both the motor symptoms and the dryness of his eye.

## Chapter 14

**Check Your Understanding 1.** The effectors of the autonomic nervous system are cardiac muscle, smooth muscle, and glands. **2.** The somatic motor system relays instructions to muscles more quickly because it involves only one motor neuron, whereas the ANS uses a two-neuron chain. Moreover, axons of somatic motor neurons are typically heavily myelinated, whereas preganglionic autonomic axons are lightly myelinated and postganglionic axons are nonmyelinated. **3.** While you relax in the sun on the beach, the parasympathetic branch of the ANS would probably predominate. When you perceive danger (as in a shark), the sympathetic branch of the ANS predominates. **4.** "Short preganglionic fibers," "origin from thoracolumbar region of spinal cord," "collateral ganglia," and "innervates adrenal medulla" are all characteristic of the sympathetic nervous system. Terminal ganglia are found in the parasympathetic nervous system. **5.** The major differences are (1) the ANS has visceral afferents rather than somatic afferents, (2) the ANS has a two-neuron efferent chain, whereas the somatic nervous system (SNS) has one, and (3) the effectors of the ANS are smooth muscles, cardiac muscle, and glands, whereas the effectors of the SNS are skeletal muscles. **6.** The parasympathetic nervous system increases digestive activity and decreases heart rate. The sympathetic nervous system increases blood pressure, dilates bronchi-

oles, stimulates the adrenal medulla to release its hormones, and causes ejaculation. 7. You would find nicotinic receptors on skeletal muscle and the hormone-producing cells of the adrenal medulla, but not on smooth muscle or glands. Virtually all types of receptors (including nicotinic receptors) are also found in the CNS (see Table 11.3 on p. 415). 8. The main integration center of the ANS is the hypothalamus, although the most direct influence is through the brain stem reticular formation and the reflex centers in the pons and medulla oblongata. 9. Jackson's doctor may have prescribed a beta-blocker because Jackson has hypertension. (Chronic stress is a factor in causing hypertension.) The beta-blocker will decrease blood pressure by blocking beta-adrenergic receptors in the heart, thereby decreasing heart rate and force of contraction, and by decreasing renin release from the kidneys. 10. The neural crest gives rise to both autonomic ganglia and the adrenal medulla.

**Review Questions 1.** d; 2. (1)S, (2)P, (3)P, (4)S, (5)S, (6)P, (7)P, (8)S, (9)P, (10)S, (11)P, (12)S; 3. b; 4. c; 5. a

**Case Study 1.** The location of Jimmy's lacerations and bruises and his inability to rise led the paramedics to suspect a head, neck, or back injury. They immobilized his head and torso to prevent any further damage to the brain and spinal cord. 2. The worsening neurological signs indicate a probable intracranial hemorrhage. The blood escaping from the ruptured blood vessel(s) will begin to compress Jimmy's brain and increase his intracranial pressure. Jimmy's surgery will involve repair of the damaged vessel(s) and removal of the mass of clotted blood pressing on his brain. 3. Loss of motor and sensory function below the level of the nipples indicates a lesion at T<sub>4</sub>. See Figure 13.13. 4. Jimmy is suffering from spinal shock, which occurs as a result of injury to the spinal cord. Spinal shock is a temporary condition in which all reflex and motor activities caudal to the level of spinal cord injury are lost, so Jimmy's muscles are paralyzed. His blood pressure is low due to the loss of sympathetic tone in his vasculature. 5. Jimmy's exaggerated reflexes are caused by damaged upper motor neuron axons in the spinal cord. These upper motor neurons normally inhibit spinal reflexes. He is incontinent because there are no longer pathways to support voluntary control of bowel and bladder emptying. 6. This condition is called autonomic dysreflexia (or autonomic hyperreflexia). This is a condition in which a normal stimulus triggers a massive activation of autonomic neurons. 7. Extremely high arterial blood pressure can cause a rupture of the cerebral blood vessels (as well as other blood vessels in the body) and put Jimmy's life at risk.

## Chapter 15

**Check Your Understanding 1.** Tears (lacrima fluid) are a dilute saline secretion that contains mucus, antibodies, and lysozyme. They are secreted by the lacrimal glands. 2. The blind spot of the eye is the optic disc. It is the part of the retina where the optic nerve exits the eye and it is "blind" because it is a region of the retina that lacks photoreceptors. 3. An increase in intraocular pressure is called glaucoma and is due to an accumulation of aqueous humor, usually because of impaired drainage of the fluid. 4. Light passes through the cornea, aqueous humor, lens, vitreous humor, ganglion cells and bipolar cells before it reaches the photoreceptors. 5. The ciliary muscles and sphincter pupillae relax for distant vision. (If you said the medial rectus muscles also relax, this is true, but remember that the rectus muscles are extrinsic eye muscles, not intrinsic.) 6. The near point moves farther away as you age because the lens becomes less flexible (presbyopia), so that it is unable to assume the more rounded shape required for near vision. 7. The following are characteristics of cones: "vision in bright light," "color vision," and "higher acuity." The following are characteristics of rods: "only one type of visual pigment," "most abundant in the periphery of the retina," "many feed into one ganglion cell," and "higher sensitivity." 8. Breakdown of the retinal-opsin combination is called bleaching of the pigment. It occurs

with exposure to light. 9. A tumor in the right visual cortex would affect the left visual field. A tumor compressing the right optic nerve would affect both the left and right visual fields from the right eye only. 10. The five taste modalities are sweet, sour, bitter, salty, and umami. The fungiform, vallate, and foliate papillae contain taste buds. 11. The cilia and hairs of these receptor cells greatly increase the surface area for sensory receptors. 12. The tympanic membrane separates the external from the middle ear. The oval and round windows separate the middle from the inner ear. 13. The basilar membrane allows us to differentiate sounds of different pitch. 14. You would not be able to locate the origin of a sound if the brain stem did not receive input from both ears. 15. The following apply to a macula: "contains otoliths," "responds to linear acceleration or deceleration," and "inside a saccule." The following apply to a crista ampullaris: "inside a semicircular canal," "has a cupula," "responds to rotational acceleration and deceleration." 16. The "fullness" in Mohammed's ears is likely due to an accumulation of fluid in the middle ear as a result of his upper respiratory infection ("cold") spreading into his ear. He has a form of conduction deafness. 17. With age, the lens discolors and loses its clarity and the dilator pupillae muscles become less efficient, decreasing the amount of light that reaches the retinas at night.

**Review Questions 1.** c; 2. d; 3. a; 4. b; 5. c; 6. c; 7. b; 8. a; 9. b; 10. b; 11. b; 12. d; 13. d; 14. a; 15. d; 16. c; 17. d; 18. b; 19. b; 20. c; 21. d; 22. b; 23. b; 24. e; 25. b; 26. c; 27. c; 28. c; 29. c

**Case Study 1.** The ear is divided into three major areas: external ear, middle ear, and internal ear. The portion of the internal ear, or labyrinth, associated with balance and equilibrium is the part of the ear affected in Mr. Rhen's BPPV. 2. Maintaining balance and equilibrium requires multiple sources of sensory input. The three main sources of sensory input are the vestibular apparatus of the ear, visual input, and input from the proprioceptors of the skin, muscles, and joints. 3. The two functional divisions are the vestibule and semicircular canals. The vestibule's sensory receptors are the maculae, which sense linear (straight line) acceleration and deceleration. The semicircular canals' receptors are the cristae ampullares, which detect rotational acceleration and deceleration. 4. Mr. Rhen's vertigo is brought on by rotational movements of the head, suggesting that the cristae ampullares of the semicircular canals are affected. 5. The added mass of the displaced otoliths pushes on a cupula of a semicircular canal when the head is rotated during the Dix-Hallpike maneuver. The otoliths either stick to the gelatinous cupula, or swirl through the canals during head movement and drift against the cupula like snow. In both cases, the bending of the cupula is prolonged and vertigo persists. As a result, vestibular nystagmus is observed when it would ordinarily be absent.

## Chapter 16

**Check Your Understanding 1.** The endocrine system is more closely associated with growth and development, and its responses tend to be long-lasting, whereas nervous system responses tend to be rapid and discrete. 2. The thyroid and parathyroid glands are found in the neck. 3. Hormones are released into the blood and transported throughout the body, whereas paracrines act locally, generally within the same tissue. 4. The two major chemical classes of hormones are amino acid-based hormones and steroids. Steroids are all lipid soluble. Thyroid hormones are the only amino acid-based hormones that are lipid soluble. 5. Water-soluble hormones act on receptors in the plasma membrane coupled most often via regulatory molecules called G proteins to intracellular second messengers. Lipid-soluble hormones act on intracellular receptors, directly activating genes and stimulating synthesis of specific proteins. 6. Hormone release can be triggered by humoral, neural, or hormonal stimuli. 7. The hypothalamus communicates with the anterior pituitary via hormones released into a special portal system of blood vessels. In contrast, it communicates with the posterior

pituitary via action potentials traveling down axons that connect the hypothalamus to the posterior pituitary. **8.** Drinking alcoholic beverages inhibits ADH secretion from the posterior pituitary and causes copious urine output and dehydration. The dehydration causes the hangover effects. **9.** LH and FSH are tropic hormones that act on the gonads, TSH is a tropic hormone that acts on the thyroid, and ACTH is a tropic hormone that acts on the adrenal cortex. (If you said growth hormone, that's also a good answer, as GH causing the liver to release IGFs might also be considered a tropic effect.) **10.** Thyroid hormone increases basal metabolic rate (and heat production) in the body. Parathyroid hormone increases blood  $\text{Ca}^{2+}$  levels in a variety of ways. Calcitonin at high (pharmacological) levels has a  $\text{Ca}^{2+}$ -lowering, bone-sparing effect. (At normal blood levels its effects in humans are negligible.) **11.** Thyroid follicular cells release thyroid hormone, parathyroid cells in the parathyroid gland release parathyroid hormone, and parafollicular (C) cells in the thyroid gland release calcitonin. **12.** Glucocorticoids are stress hormones that, among many effects, increase blood glucose. Mineralocorticoids increase blood  $\text{Na}^+$  (and blood pressure) and decrease blood  $\text{K}^+$ . Gonadocorticoids are male and female sex hormones that are thought to have a variety of effects (for example, contribute to onset of puberty, sex drive in women, pubic and axillary hair development in women). **13.** Melatonin is used by some individuals as a sleep aid, particularly to counter jet lag. **14.** When we say Sharon is diabetic, this means that she has insufficient insulin action in her body. The most likely explanation for Sharon's behavior is that she has taken too much insulin and is experiencing hypoglycemia. You could help her by making sure she immediately ingests a sugary snack or drink. **15.** Diabetes mellitus is due to a lack of insulin production or action, whereas diabetes insipidus is due to a lack of ADH. Both conditions are characterized by production of copious amounts of urine. You would find glucose in the urine of a patient with diabetes mellitus, but not in the urine of a patient with diabetes insipidus. **16.** The gonadal hormones are steroid hormones. A major endocrine gland that also secretes steroid hormones is the adrenal cortex. **17.** The heart produces atrial natriuretic peptide (ANP). ANP decreases blood volume and blood pressure by increasing the kidneys' production of salty urine. **18.** Vitamin  $\text{D}_3$ , produced in inactive form by the skin, increases intestinal absorption of calcium. **19.** The decline in growth hormone with age contributes to muscle atrophy. The decline in estrogen contributes to osteoporosis in women.

**Review Questions** **1.** b; **2.** a; **3.** c; **4.** d; **5.** (1)c, (2)a and b, (3)f, (4)d, (5)e, (6)g, (7)a, (8)h, (9)b and e, (10)a; **6.** d; **7.** c; **8.** b; **9.** d; **10.** b; **11.** d; **12.** b; **13.** c; **14.** d

**Case Study 1.** Rationale for orders: As Mr. Gutteman is unconscious, the level of damage to his brain is unclear. Monitoring his responses and vital signs every hour will provide information for his care providers about the extent of his injuries. Turning him every 4 hours and providing careful skin care will prevent decubitus ulcers (bedsores) as well as stimulating his proprioceptive pathways. **2.** Mr. Gutteman's condition is termed diabetes insipidus, a condition in which insufficient quantities of antidiuretic hormone (ADH) are produced or released. Diabetes insipidus patients excrete large volumes of urine but do not have glucose or ketones present in the urine. The head trauma could have damaged Mr. Gutteman's hypothalamus, which produces the hormone, or injured his posterior pituitary gland, which releases ADH into the bloodstream. **3.** Diabetes insipidus is not life threatening for most individuals with normal thirst mechanisms, as they will be thirsty and drink to replenish the lost fluid. However, Mr. Gutteman is comatose, so his fluid output must be monitored closely so that the volume lost can be replaced by IV line. His subsequent recovery may be complicated if he has suffered damage to his hypothalamus, which houses the thirst center neurons.

## Chapter 17

**Check Your Understanding 1.** The hematocrit is the percentage of blood that is occupied by erythrocytes. It is normally about 45%. **2.** Blood can prevent blood loss by forming clots when a blood vessel is damaged. Blood can prevent infection because it contains antimicrobial proteins and white blood cells. **3.** Plasma proteins are not used as fuel for body cells because their presence in blood is required to perform many key functions. **4.** Each hemoglobin molecule can transport four  $\text{O}_2$ . The heme portion of the hemoglobin binds the  $\text{O}_2$ . **5.** The kidneys' synthesis of erythropoietin is compromised in advanced kidney disease, so RBC production decreases, causing anemia. **6.** Monocytes become macrophages in tissues. Neutrophils are also voracious phagocytes. **7.** "Thrombopoietin" is derived from the same word as "thrombocyte." It is the hormone that promotes platelet formation. **8.** Amos's red bone marrow is spewing out many abnormal white blood cells, which are crowding out the production of normal bone marrow elements. The lack of normal white blood cells allows the infections, the lack of platelets fails to stop bleeding, and the lack of erythrocytes is anemia. **9.** The three steps of hemostasis are vascular spasm, platelet plug formation, and coagulation. **10.** Fibrinogen is water soluble, whereas fibrin is not. Prothrombin is an inactive precursor, whereas thrombin acts as an enzyme. Most factors are inactive in blood before activation and become enzymes upon activation. (There are exceptions, such as fibrinogen and calcium.) **11.** Thrombocytopenia (platelet deficiency) results in failure to plug the countless small tears in blood vessels, and so manifests as small purple spots. Hemophilia A results from the absence of clotting factor VIII. **12.** Nigel has anti-A antibodies in his blood and type B agglutinogens on his RBCs. He can donate blood to an AB recipient, but he should not receive blood from an AB donor because his anti-A antibodies will cause a transfusion reaction. **13.** If Emily has a bacterial meningitis, a differential WBC count would likely reveal an increase in neutrophils because neutrophils are a major body defense against bacteria. **14.** Hemoglobin F has a higher affinity (binding strength) for oxygen than adult hemoglobin does. It has 2  $\alpha$  and 2  $\gamma$  chains rather than 2  $\alpha$  and 2  $\beta$  chains.

**Review Questions** **1.** c; **2.** c; **3.** d; **4.** b; **5.** d; **6.** a; **7.** a; **8.** b; **9.** c; **10.** d

**Case Study 1.** Saline infusion temporarily replaces the lost blood volume, thereby helping to restore Mr. Malone's circulation. **2.** The PBRCs contain oxygen-carrying hemoglobin. While the saline replaces lost blood volume, it cannot replace the hemoglobin in the lost RBCs. (In acute trauma, the rule of thumb is to use no more than 2 liters of normal saline before starting PRBCs, so that the hematocrit does not drop below 30%.) **3.** O negative blood cells bear neither the A nor the B nor the Rh agglutinogens (antigens). People with O negative blood are sometimes called "universal donors" because their cells lack the antigens responsible for most major transfusion reactions. **4.** Mr. Malone's blood would have anti-B antibodies (agglutinins) so he would not be able to receive B or AB blood. He can safely receive A and O blood. **5.** If doctors had transfused type B or AB blood into Mr. Malone's circulation, his anti-B antibodies would have "attacked" these foreign cells and caused them to agglutinate. This transfusion reaction can be dangerous because the agglutinated cells can clog small vessels. In addition the transfused cells would begin to hemolyze (rupture) or would be destroyed by phagocytes.

## Chapter 18

**Check Your Understanding 1.** The mediastinum is the medial cavity of the thorax within which the heart, great vessels, and trachea are found. **2.** The layers of the heart wall are the endocardium, the myocardium, and the epicardium. The epicardium is also called the visceral layer of the serous pericardium. This is surrounded by the parietal layer of the serous pericardium and the fibrous pericardium. **3.** The serous fluid de-

creases friction caused by movement of the layers against one another. **4.** The papillary muscles and chordae tendineae keep the AV valve flaps from everting into the atria as the ventricles contract. **5.** The right side of the heart acts as the pulmonary pump, whereas the left acts as the systemic pump. **6.** (a) True. The left ventricle wall is thicker than the right. (b) True. The left ventricle pumps blood at much higher pressure than the right ventricle because the left ventricle supplies the whole body, whereas the right ventricle supplies only the lungs. (c) False. Each ventricle pumps the same amount of blood with each beat. If this were not true, blood would back up in either the systemic or pulmonary circulation (because the two ventricles are in series). **7.** The branches of the right coronary artery are the right marginal artery and the posterior interventricular artery. **8.** (a) The refractory period is almost as long as the contraction in cardiac muscle. (b) The source of  $\text{Ca}^{2+}$  for the contraction is only SR in skeletal muscle. (c) The AP exhibits a plateau phase in cardiac muscle. (d) Both skeletal muscle and cardiac muscle have troponin. (e) Only skeletal muscle has triads. **9.** Cardiac muscle cannot go into tetany because the absolute refractory period is almost as long as the contraction. **10.** The subendocardial conducting network excites ventricular muscle fibers. The depolarization wave travels upward from the apex toward the atria, and from endocardium to epicardium. **11.** (a) The QRS wave occurs during ventricular depolarization. (b) The T wave of the ECG occurs during ventricular repolarization. (c) The P-R interval of the ECG occurs during atrial depolarization and the conduction of the action potential through the rest of the intrinsic conduction system. **12.** The second heart sound is associated with the closing of the semilunar valves. **13.** The murmur of mitral insufficiency occurs during ventricular systole (because this is when the valve should be closed, and the murmur is due to blood leaking through the incompletely closed valve into the atrium). **14.** The periods when all four valves are closed are the isovolumetric contraction phase and the isovolumetric relaxation phase. **15.** Exercise activates the sympathetic nervous system. Sympathetic nervous system activity increases heart rate. It also directly increases ventricular contractility, thereby increasing Josh's stroke volume. **16.** If the heart is beating very rapidly, the amount of time for ventricular filling between contractions is decreased. This decreases the end diastolic volume, decreases the stroke volume, and therefore decreases the cardiac output. **17.** The foramen ovale and the ductus arteriosus both allow blood to bypass the fetal lungs. **18.** Elderly athletes may be hampered by sclerosis and thickening of heart valve flaps, a decline in cardiac reserve, fibrosis of cardiac muscle, and atherosclerosis.

**Review Questions 1.** a; 2. c; 3. b; 4. c; 5. b; 6. b; 7. c; 8. d; 9. b

**Case Study 1.** The weak and thready pulse indicates a drop in stroke volume (SV). The pulse is felt as blood is ejected from the heart during ventricular contraction (systole). The weak and thready pulse suggests that less blood is being ejected during each contraction (a lower SV). **2.** An increase in heart rate leads to an increase in cardiac output (recall  $\text{CO} = \text{HR} \times \text{SV}$ ). Mr. Ayers's CO is abnormally low (as shown by his decreasing blood pressure). This is probably due to a decrease in SV. The increase in HR is an attempt to compensate for the decrease in SV in order to maintain CO as close to normal as possible. **3.** In cardiac tamponade, the fluid around the heart compresses the heart and prevents it from fully expanding as it relaxes (diastole). As a result of this restriction, less blood will flow into the heart (ventricular filling). With less blood flowing into the ventricles, the degree of stretch of the heart muscle (preload) will also be reduced. These events lead to a reduction in SV. **4.** Heart sounds are produced by the closing of heart valves during a normal cardiac cycle. When EDV is reduced, there is both reduced SV and reduced force of contraction, leading to slower, quieter valve closure. **5.** The enlarged mediastinum and pericardial effusions suggest that the bleeding is restricted within these compartments. The tear would most likely be located in the

proximal portion of the ascending aorta (the part closest to the heart). This part of the aorta is located within the pericardium. The tear then proceeded distally but was contained within the aortic wall, causing the back pain. An uncontained tear in the aortic arch or descending aorta would lead to bleeding in the thoracic and/or abdominal cavities, which was not observed in this case. **6.** In the face of reduced SV, blood returning to the heart backs up, leading to a rise in venous pressure. This is a key sign of tamponade.

## Chapter 19

**Check Your Understanding 1.** The sympathetic nervous system innervates blood vessels. The sympathetic nerves innervate the tunica media. The effector cells in the tunica media are smooth muscle cells. **2.** When vascular smooth muscle contracts, the diameter of the blood vessel becomes smaller. This is called vasoconstriction. **3.** Elastic arteries play a major role in dampening the pulsatile pressure of heart contractions. Dilation or constriction of arterioles determines blood flow to individual capillary beds. Muscular arteries have the thickest tunica media relative to their lumen size. **4.** If you were doing calf raises, your capillary bed would be in the condition depicted in part (a). The true capillaries would be flushed with blood to ensure that the working calf muscles could receive the needed nutrients and dispose of their metabolic wastes. **5.** Valves prevent blood from flowing backwards in veins. They are formed from folds of the tunica intima. **6.** In the systemic circuit, veins contain more blood than arteries (see Figure 19.5). **7.** The three factors that determine resistance are blood viscosity, vessel length, and vessel diameter. Vessel diameter is physiologically most important. **8.** The rate of flow will decrease 81-fold from its original flow ( $3 \times 3 \times 3 \times 3 = 81$ ). **9.** When you first stand up, mean arterial pressure (MAP) temporarily decreases and this is sensed by aortic and carotid baroreceptors. Medullary cardiac and vasomotor center reflexes increase sympathetic and decrease parasympathetic outflow to the heart. Heart rate and contractility increase, increasing cardiac output, and therefore MAP. Further, sympathetic constriction of arterioles increases peripheral resistance, also increasing MAP. (In addition, increased constriction of veins increases venous return, which increases end diastolic volume, increasing stroke volume, and therefore cardiac output and MAP.) See also Figure 19.9 (bottom). **10.** The kidneys help maintain MAP by influencing blood volume. In renal artery obstruction, the blood pressure in the kidney is lower than in the rest of the body (because it is downstream of the obstruction). Low renal blood pressure triggers both direct and indirect mechanisms to increase blood pressure by increasing blood volume. This can cause hypertension (called "secondary hypertension" because it is secondary to a defined cause—in this case the renal artery obstruction). **11.** In a bicycle race, autoregulation by intrinsic metabolic controls causes arteriolar smooth muscle in your legs to relax, dilating the vessels and supplying more  $\text{O}_2$  and nutrients to the exercising muscles. **12.** Extrinsic mechanisms, primarily the sympathetic nervous system, prevent blood pressure from plummeting by constricting arterioles elsewhere (such as gut, kidneys). In addition, cardiac output increases, which also helps maintain MAP. **13.** (a) An increase in interstitial fluid osmotic pressure ( $\text{OP}_{\text{if}}$ ) would tend to pull more fluid out of capillaries (causing localized swelling, or edema). (b) An increase of  $\text{OP}_{\text{if}}$  to 10 mm Hg would increase the outward pressure on both the arteriole and venule ends of the capillary. The NFP at the venous end would become 1 mm Hg (27 mm Hg – 26 mm Hg). (c) Fluid would flow out of the venous end of the capillary rather than in. **14.** Bob is in vascular shock due to anaphylaxis, a systemic allergic reaction to his medication. His blood pressure is low because of widespread vasodilation triggered by the massive release of histamine. Bob's rapid heart rate is a result of the baroreceptor reflex triggered by his low blood pressure. This activates the sympathetic nervous

system, increasing heart rate, in an attempt to restore blood pressure. **15.** The external carotid arteries supply most of the tissues of the head except for the brain and orbits. **16.** The cerebral arterial circle (circle of Willis) is the arterial anastomosis at the base of the cerebrum. **17.** The four unpaired arteries that emerge from the abdominal aorta are the celiac trunk, the superior and inferior mesenteric arteries, and the median sacral artery. **18.** You would palpate the popliteal artery behind the knee, the posterior tibial artery behind the medial malleolus of the tibia, and the dorsalis pedis artery on the foot. (See also Figure 19.12.) **19.** The vertebral arteries help supply the brain, but the vertebral veins do not drain much blood from the brain. **20.** The internal jugular veins drain the dural venous sinuses. Each internal jugular vein joins a subclavian vein to form a brachiocephalic vein. **21.** A portal system is a system where two capillary beds occur in series. In other words, in a portal system, a capillary bed is drained by a vein that leads into a second capillary bed. The function of the hepatic portal system is to transport venous blood from the digestive organs to the liver for processing before it enters the rest of the systemic circulation. This plays an important role in defense against absorbed toxins or microorganisms and also allows direct delivery of absorbed nutrients to the liver for processing. **22.** The leg veins that often become varicose are the great and small saphenous veins. **23.** Three differences between arteries and veins are (1) arteries run deep while veins are both deep and superficial, (2) venous pathways are more interconnected than arterial pathways, and (3) the brain and digestive systems have unique venous drainage systems, whereas their arterial supply patterns are not substantially different from those of other organs. **24.** The foramen ovale and the ductus arteriosus both bypass the fetal lungs. The ductus venosus bypasses the fetal liver. **25.** Varicose veins, atherosclerosis, and hypertension are associated with aging.

**Review Questions** 1. d; 2. b; 3. d; 4. c; 5. e; 6. d; 7. c; 8. b; 9. b; 10. a; 11. (1)b, e, g; (2)c; (3)i; (4)f, h; (5)d; 12. b; 13. c; 14. d

**Case Study 1.** The tissues in Mr. Hutchinson's right leg were deprived of oxygen and nutrients for at least one-half hour. When tissues are deprived of oxygen, tissue metabolism decreases and eventually ceases, so these tissues may have died due to anoxia. **2.** Mr. Hutchinson's vital signs (low BP; rapid, thready pulse) indicate that he is facing a life-threatening problem that must be stabilized before other, less vital problems can be addressed. As for surgery, he may be scheduled for open reduction of his crushed bone, depending upon the condition of the tissues in his crushed right leg. If tissue death has occurred in his leg, he may undergo amputation of that limb. **3.** Mr. Hutchinson's rapid, thready pulse and falling blood pressure are indications of hypovolemic shock, a type of shock resulting from decreased blood volume. Because his blood volume is low, his heart rate is elevated to increase cardiac output in an effort to maintain the blood supply to his vital organs. Mr. Hutchinson's blood volume must be increased as quickly as possible with blood transfusions or intravenous saline. This will stabilize his condition and allow his physicians to continue with his surgery.

## Chapter 20

**Check Your Understanding 1.** Lymph is the fluid inside lymphatic vessels. It enters lymphatic vessels from interstitial fluid. Interstitial fluid, in turn, is a filtrate of blood plasma. **2.** The right lymphatic duct receives lymph from the right upper arm and the right side of the head and thorax. The thoracic duct drains lymph from the rest of the body. **3.** Lymph movement is driven by the contraction of adjacent skeletal muscles, pressure changes in the thorax during breathing, the pulsations of nearby arteries, and contraction of smooth muscle in the lymphatic vessel walls. (Valves in lymphatic vessels prevent backflow of lymph.) **4.** Lymphoid follicles are solid, spherical bodies consisting of tightly packed reticular fibers and lymphoid cells, often with a lighter-staining central region. They are regions where B cells predominate. **5.** Having fewer efferents

causes lymph to accumulate in lymph nodes, allowing more time for its cleansing. **6.** MALT (mucosa-associated lymphoid tissue) is lymphoid tissue found in the mucosa of the digestive, respiratory, and genitourinary tracts. It includes tonsils, Peyer's patches, and the appendix. **7.** The spleen cleanses the blood, stores breakdown products of RBCs, stores platelets and monocytes, and is thought to be a site of erythrocyte production in the fetus. **8.** The thymus develops first.

**Review Questions** 1. c; 2. c; 3. a, d; 4. c; 5. a; 6. b; 7. a; 8. b; 9. d

**Case Study 1.** The red streaks radiating from Mr. Hutchinson's finger indicate that his lymphatic vessels are inflamed. This inflammation may be caused by a bacterial infection. If Mr. Hutchinson's arm had exhibited edema without any accompanying red streaks, the problem would likely have been impaired lymph transport from his arm back to his trunk, due to injury or blockage of his lymphatic vessels. **2.** Mr. Hutchinson's arm was placed in a sling to immobilize it, slowing the drainage of lymph from the infected area in an attempt to limit the spread of the infection. **3.** Mr. Hutchinson's low lymphocyte count indicates that his body's ability to fight infection by bacteria or viruses is impaired. The antibiotics and additional staff protection will protect Mr. Hutchinson until his lymphocyte count increases again. Gloving and gowning also protect the staff caring for Mr. Hutchinson from any body infection he might have. **4.** Mr. Hutchinson's recovery may be problematic, as he probably already has an ongoing bacterial infection and his ability to raise a defense to this infection is impaired.

## Chapter 21

**Check Your Understanding 1.** The innate defense system is always ready to respond immediately, whereas it takes considerable time to mount the adaptive defense system. The innate defenses consist of surface barriers and internal defenses, whereas the adaptive defenses consist of humoral and cellular immunity, which rely on B and T lymphocytes. **2.** Surface barriers (the skin and mucous membranes) constitute the first line of defense. **3.** Opsonization is the process of making pathogens more susceptible to phagocytosis by decorating their surface with molecules that phagocytes can bind. Antibodies and complement proteins are examples of molecules that act as opsonins. **4.** Our own cells are killed by NK cells when they have been infected by viruses or when they have become cancerous. **5.** Redness, heat, swelling, and pain are the cardinal signs of inflammation. Redness and local heat are both caused by vasodilation of arterioles, which increases the flow of blood (warmed by the body core) to the affected area. The swelling (edema) is due to the release of histamine and other chemical mediators of inflammation, which increase capillary permeability. This increased permeability allows proteins to leak into the interstitial fluid (IF), increasing the IF osmotic pressure and drawing more fluid out of blood vessels and into the tissues, thereby causing swelling. The pain is due to two things: (1) the actions of certain chemical mediators (kinins and prostaglandins) on nerve endings, and (2) the swelling, which can compress free nerve endings. **6.** Three key characteristics of adaptive immunity are that it is specific, it is systemic, and it has memory. **7.** A complete antigen has both immunogenicity and reactivity, whereas a hapten has reactivity but not immunogenicity. **8.** Self-antigens, particularly MHC proteins, mark a cell as self. **9.** Development of immunocompetence of a B or T cell is signaled by the appearance on its surface of specific and unique receptors for an antigen. In the case of a B cell, this receptor is a membrane-bound antibody. (In T cells, it is simply called the T cell receptor.) **10.** The T cell that would survive is (c), one that recognizes MHC but not self-antigen. **11.** Dendritic cells, macrophages, and B cells can all act as APCs. Dendritic cells are most important for T cell activation. **12.** In clonal selection, the antigen does the selecting. What is being selected is a particular clone of B or T cells that has antigen receptors corresponding to that antigen. **13.** The secondary response to an antigen is faster than the primary response because the immune system has

already been “primed” and has memory cells that are specific for that particular antigen. **14.** Vaccinations protect by providing the initial encounter to an antigen—the primary response to that antigen. As a result, when the pathogen for that illness is encountered again, the pathogen elicits the much faster, more powerful secondary response, which is generally effective enough to prevent clinical illness. **15.** IgG antibody is most abundant in blood. IgM is secreted first in a primary immune response. IgA is most abundant in secretions. **16.** Antibodies can bring about destruction of pathogen via “PLAN”—phagocytosis, lysis (via complement), agglutination, or neutralization. **17.** Class II MHC proteins display exogenous antigens. Class II MHC proteins are recognized by CD4 T cells (which usually become helper T cells). APCs display class II MHC proteins. **18.** Binding of antigens in the absence of co-stimulators causes the lymphocyte to develop anergy—a state of permanent unresponsiveness to that antigen. **19.** Helper T cells are central to both humoral and cellular immunity because they are required for activation of both cytotoxic T cells and most B cells. **20.** The cytotoxic T cell releases perforins and granzymes onto the identified target cell. Perforins form a pore in the target cell membrane, and granzymes enter through this pore, activating enzymes that trigger apoptosis (cell suicide). **21.** MHC proteins and blood type antigens (ABO, etc.) are carefully matched before an organ transplant. **22.** HIV is particularly hard for the immune system to defeat because (1) it destroys helper T cells, which are key players in adaptive immunity and (2) it has a high mutation rate and so it rapidly becomes resistant to drugs. **23.** Binding of an allergen onto specific IgE antibodies attached to mast cells triggers the mast cells to release histamine.

**Review Questions** **1.** c; **2.** a; **3.** d; **4.** d, e; **5.** a; **6.** d; **7.** b; **8.** c; **9.** d; **10.** d; **11.** d; **12.** (1)b, g; (2)d, i; (3)a, e; (4)a, e, f, h; (5)e, h; (6)c, f, g

**Case Study 1.** The two kidneys transplanted in this case represent allografts. **2.** A major histocompatibility complex (MHC) protein is a type of cell surface protein that the human body uses to recognize *self* and to help coordinate the recognition of *nonself*, or foreign, antigens. These proteins are involved in the display of antigens to T cells. **3.** Class I MHC proteins are found on virtually all of the body’s cells, while class II MHCs are found only on antigen-presenting cells (APCs). Class I MHCs display antigens for recognition by CD8 T cells (including cytotoxic T cells). Class II MHCs display antigens for recognition by CD4 T cells (including helper T cells). **4.** A foreign MHC protein will provoke an immune response, so the donor’s and recipient’s MHCs must match as closely as possible to minimize such an attack. Tissue typing dramatically reduces the risk of organ rejection due to attack by the recipient’s immune system. **5.** In this case, the donor and recipients were not genetically identical. Even with very careful tissue typing and compatibility testing, there will still be some differences that the recipients’ immune systems will recognize as foreign. To reduce the risk of organ rejection, the recipients are given drugs to suppress their immune systems.

## Chapter 22

**Check Your Understanding 1.** The structures that air passes by are the nasal cavity (nares, nasal vestibule, nasal conchae), nasopharynx (with pharyngeal tonsil), oropharynx (with palatine tonsil), laryngopharynx, and larynx (with epiglottis, vestibular fold, and vocal fold). **2.** The epiglottis seals the larynx when we swallow. **3.** The incomplete, C-shaped cartilage rings of the trachea allow it to expand and contract and yet keep it from collapsing. **4.** The many tiny alveoli together have a large surface area. This and the thinness of their respiratory membranes make them ideal for gas exchange. **5.** The peanut was most likely in the right main bronchus because it is wider and more vertical than the left. **6.** The two circulations of the lungs are the pulmonary circulation, which delivers deoxygenated blood to the lungs for oxygenation and returns oxygenated blood to the heart, and the bronchial circulation, which provides systemic

(oxygenated) blood to lung tissue. **7.** The driving force for pulmonary ventilation is a pressure gradient created by changes in the thoracic volume. **8.** The intrapulmonary pressure decreases during inspiration because of the increase in thoracic cavity volume brought about by the muscles of inspiration. **9.** The partial vacuum (negative pressure) inside the pleural cavity is caused by the opposing forces acting on the visceral and parietal pleurae. The visceral pleurae are pulled inward by the lungs’ natural tendency to recoil and the surface tension of the alveolar fluid. The parietal pleurae are pulled outward by the elasticity of the chest wall. If air enters the pleural cavity, the lung on that side will collapse. This condition is called pneumothorax. **10.** Airway resistance is low because (1) the diameters of most airways are relatively large, (2) for smaller airways there are many in parallel, making their combined diameter large, and (3) air has a low viscosity. **11.** A lack of surfactant increases surface tension in the alveoli and causes them to collapse between breaths. (In other words, it markedly decreases lung compliance.) **12.** Slow, deep breaths ventilate the alveoli more effectively because a smaller fraction of the tidal volume of each breath is spent moving air into and out of the dead space. **13.** In a sealed container, the air and water would be at equilibrium. Therefore, the partial pressures of CO<sub>2</sub> and O<sub>2</sub> (P<sub>CO<sub>2</sub></sub> and P<sub>O<sub>2</sub></sub>) will be the same in the water as in the air: 100 mm Hg each. More CO<sub>2</sub> than O<sub>2</sub> molecules will be dissolved in the water (even though they are at the same partial pressure) because CO<sub>2</sub> is much more soluble than O<sub>2</sub> in water. **14.** The difference in P<sub>O<sub>2</sub></sub> between inspired air and alveolar air can be explained by (1) the gas exchange occurring in the lungs (O<sub>2</sub> continuously diffuses out of the alveoli into the blood), (2) the humidification of inspired air (which adds water molecules that dilute the O<sub>2</sub> molecules), and (3) the mixing of newly inspired air with gases already present in the alveoli. **15.** The arterioles leading into the O<sub>2</sub>-enriched alveoli would be dilated. This response allows matching of blood flow to availability of oxygen. **16.** Both CO<sub>2</sub> and H<sup>+</sup> increase O<sub>2</sub> unloading by binding to Hb. This is called the Bohr effect. **17.** About 70% of CO<sub>2</sub> is transported as bicarbonate ion (HCO<sub>3</sub><sup>-</sup>) in plasma. Just over 20% is transported bound to hemoglobin in the RBCs, and 7–10% is dissolved in plasma. **18.** As blood CO<sub>2</sub> increases, blood pH decreases. This is because CO<sub>2</sub> combines with water to form carbonic acid. (However, the change in pH in blood for a given increase in CO<sub>2</sub> is minimized by other buffer systems.) **19.** The ventral respiratory group of the medulla (VRG) is thought to be the rhythm-generating area. **20.** CO<sub>2</sub> in blood normally provides the most powerful stimulus to breathe. Central chemoreceptors are most important in this response (see Figure 22.25). **21.** The injured soccer player’s P<sub>CO<sub>2</sub></sub> is low. (Recall that normal P<sub>CO<sub>2</sub></sub> = 40 mm Hg.) The low P<sub>CO<sub>2</sub></sub> reveals that this is hyperventilation and not hyperpnea (which is not accompanied by changes in blood CO<sub>2</sub> levels). **22.** Long-term adjustments to altitude include an increase in erythropoiesis, resulting in a higher hematocrit; an increase in BPG, which decreases Hb affinity for oxygen; and an increase in minute respiratory volume. **23.** The obstruction in asthma is reversible, and acute exacerbations are typically followed by symptom-free periods. In contrast, the obstruction in chronic bronchitis is generally not reversible. **24.** The underlying defect in cystic fibrosis is an abnormality in a protein (CFTR protein) that acts as a membrane channel for chloride ions. **25.** Vital capacity declines with age because the thoracic wall becomes more rigid and the lungs lose their elasticity.

**Review Questions** **1.** b; **2.** a and c; **3.** c; **4.** c; **5.** b; **6.** d; **7.** d; **8.** b; **9.** c, d; **10.** c; **11.** b; **12.** b; **13.** b; **14.** c; **15.** b; **16.** b

**Case Study 1.** Spinal cord injury from a fracture at the level of the C<sub>2</sub> vertebra would interrupt the normal transmission of signals from the brain stem down the phrenic nerve to the diaphragm, and Barbara would be unable to breathe due to paralysis of the diaphragm. **2.** Barbara’s head, neck, and torso should have been immobilized to prevent further damage to the spinal cord. In addition, she required assistance to breathe, so her airway was probably intubated to permit ventilation of her lungs. **3.** Cyanosis is a

decrease in the degree of oxygen saturation of hemoglobin. As Barbara's respiratory efforts cease, her alveolar  $P_{O_2}$  will fall, so there is less oxygen to load onto hemoglobin. In her peripheral tissues, what little oxygen hemoglobin carries will be consumed, leaving these tissues with a bluish tinge.

4. Injury to the spinal cord at the level of the  $C_2$  vertebra will cause quadriplegia (paralysis of all four limbs). 5. Atelectasis is the collapse of a lung. Because it is the right thorax that is compressed, only her right lung is affected. Because the lungs are in separate pleural cavities, only the right lung collapsed. 6. Barbara's fractured ribs probably punctured her lung tissue and allowed air within the lung to enter the pleural cavity. 7. The atelectasis will be reversed by inserting a chest tube and removing the air from the pleural cavity. This will allow her lung to heal and reinflate.

## Chapter 23

**Check Your Understanding 1.** The esophagus is found in the thorax. Three alimentary canal organs found in the abdominal cavity include the stomach, small intestine, and large intestine. 2. The usual site of ingestion in a healthy person is the mouth. 3. The process of absorption moves nutrients into the body. 4. Reflexes associated with the GI tract promote muscle contraction and secretion of digestive juices or hormones. 5. The term "gut brain" refers to the enteric nervous system or web of neurons closely associated with the digestive organs. 6. The visceral peritoneum is the outermost layer of the digestive organ; the parietal peritoneum is the serous membrane covering the wall of the abdominal cavity. 7. The pancreas is retroperitoneal. 8. The hepatic portal circulation is the venous portion of the splanchnic circulation. 9. From deep to superficial the layers of the alimentary canal are the mucosa, submucosa, muscularis externa, and serosa. 10. He should temporarily refrain from eating because the parasympathetic nervous system oversees digestive activities. 11. The oral vestibule is the region between the cheek and the teeth. The oral cavity proper is the area enclosed by the teeth. 12. The palate forms the roof of the mouth. The hard palate supported by bone is anterior to the soft palate (no bony support). 13. The tongue is important for speech, particularly for uttering consonants, and taste. 14. The serous portion of saliva is rich in salivary amylase, an enzyme that chemically breaks down starch. Additionally, the serous portion of saliva helps to hydrate the foodstuffs and helps provide protection against microorganisms. 15. Antimicrobial substances found in saliva include lysozyme, defensins, and IgA antibodies. 16. Tina's "show and tell" tooth is a primary tooth, also called a deciduous tooth. 17. Enamel is harder than bone. Pulp consists of nervous tissue and blood vessels. 18. The molars are grinding teeth. 19. The pharynx is part of the digestive and respiratory systems. 20. The esophageal muscularis externa undergoes a transformation along its length from skeletal muscle superiorly to smooth muscle near the stomach. 21. The esophagus is merely a chute for food passage and is subjected to a good deal of abrasion, which a stratified squamous epithelium can withstand. The stomach mucosa is a secretory mucosa served well by a simple columnar epithelium. 22. The tongue mixes the chewed food with saliva, compacts the food into a bolus, and initiates swallowing. 23. During swallowing the larynx rises and the epiglottis covers its lumen so that foodstuffs are diverted into the esophagus posteriorly. 24. The stomach has three layers of smooth muscle—longitudinal, circular, and oblique. Addition of the oblique layer allows the stomach to pummel food in addition to its peristaltic movements. 25. The chief cells produce pepsinogen, which is the inactive enzyme pepsin, and the parietal cells secrete HCl needed to activate pepsinogen. 26. The mucosal barrier consists of the thick alkaline mucus secreted by the mucous cells, the fact that the epithelial cells of the mucosa are joined by tight junctions, and the quick replacement of dead or dying cells by stem cells. 27. The three phases of gastric secretion are the cephalic, gastric, and intestinal phases. 28. The presence of food in the duodenum inhibits gastric activity by triggering the enterogastric reflex and the secretion of enterogastrones (hormones). 29. Venous blood leaving the stomach during a meal becomes more alkaline due to the alkaline tide occurring during HCl secretion. 30. All of these modifications increase the surface area

of the small intestine. The circular folds force the chyme to spiral through the lumen. 31. Brush border enzymes are enzymes associated with the microvilli of the small intestine mucosal cells. 32. A lacteal is a blind-ended lymphatic capillary that picks up lymph (fluid and proteins leaked from the blood stream), which is then returned to the blood. 33. IgA, HCl, defensins, and lysozyme protect the intestinal cells from bacterial damage. 34. A portal triad is a region at the corner of a hepatic lobule that contains a branch of the hepatic portal vein, a branch of the hepatic artery, and a bile duct. 35. The enterohepatic circulation is an important recycling mechanism for retaining bile salts needed for fat absorption. 36. Stellate macrophages rid the blood of bacteria and dead cells. 37. Zymogen granules contain inactive digestive enzymes. 38. Pancreatic acini produce the exocrine products of the pancreas (digestive enzymes and bicarbonate-rich juice). The islets produce pancreatic hormones, most importantly insulin and glucagon. 39. Fluid in the pancreatic duct is bicarbonate-rich, enzyme-rich pancreatic juice. Fluid in the cystic and bile ducts is bile. 40. CCK is secreted in response to the entry of chyme rich in protein and fat into the duodenum. It causes the pancreatic acini to secrete digestive enzymes, stimulates the gallbladder to contract, and relaxes the hepatopancreatic sphincter. 41. Distension of stomach walls enhances stomach secretory activity. Distension of the walls of the small intestine reduces stomach secretory activity (to give the small intestine time to carry out its digestive and absorptive activities). 42. Segmentation is more important for moving food along the small intestine. 43. MMC is the migrating motor complex, a pattern of peristalsis seen in the small intestine that moves the last remnants of a meal plus bacteria and other debris into the large intestine. MMC is important to prevent the overgrowth of bacteria in the small intestine. 44. Mass movements and haustral contractions are unique to the large intestine. Mass movements are long, slow, powerful contractions that move over large areas of the colon three or four times a day, forcing the contents toward the rectum. Haustral contractions are a special type of segmentation. 45. Activation of stretch receptors in the rectal wall initiates the defecation reflex. 46. Enteric bacteria synthesize B vitamins and some of the vitamin K the liver needs to synthesize clotting proteins. 47. All food digestion depends on hydrolysis reactions. 48. Amylase is to starch as lipase is to fats. 49. Bile salts emulsify fats so that they can be acted on efficiently by lipase enzymes, and form micelles that aid fat absorption. 50. The digestive system mucosa develops from the endoderm. 51. The thick viscous mucus produced in cystic fibrosis patients clogs pancreatic ducts and prevents the delivery of pancreatic fluid to the duodenum, thus inhibiting fat digestion and absorption. 52. Colon and stomach cancers are dangerous because they have few early signs and symptoms.

**Review Questions 1.** c; 2. d; 3. d; 4. b; 5. b; 6. a; 7. d; 8. d; 9. b; 10. c; 11. c; 12. a; 13. d; 14. d; 15. b; 16. c; 17. a

**Case Study 1.** Mr. Gutteman's statement about the effects of milk on his digestive tract suggests that he may be deficient in lactase, a brush border enzyme that breaks down lactose (milk sugar). 2. His responses to the questions reduced the possibility that he has gastric ulcers. Mr. Gutteman's diarrhea may be due to gluten-sensitive enteropathy. To verify this diagnosis, Mr. Gutteman should be screened for specific IgA antibodies in his blood. If these screening tests are positive, a biopsy of the intestinal mucosa would be performed. Observation of damaged intestinal villi and microvilli would confirm the diagnosis. A positive diagnosis of gluten-sensitive enteropathy would lead to a lifelong dietary restriction of all grains except rice and corn. Grains should not be restricted prior to the biopsy.

## Chapter 24

**Check Your Understanding 1.** The six major nutrients are carbohydrates, proteins, fats, water, minerals, and vitamins. 2. Cellulose provides fiber, which helps in elimination. 3. Triglycerides are used for ATP synthesis, body insulation and protective padding, and to help the body absorb fat-soluble vitamins. Cholesterol is the basis of our steroid hormones and bile salts, and stabilizes cellular membranes. 4. Beans

(legumes) and grains (wheat) are good sources of protein, but neither is a complete one. However, together they provide all the essential amino acids. **5.** Vitamins serve as the basis for coenzymes, which work with enzymes to accomplish metabolic reactions. **6.** Vitamin B<sub>12</sub> needs intrinsic factor to be absorbed by the intestine. **7.** Iodine is essential for thyroxine synthesis. Calcium in the form of bone salts is needed to make bones hard. Iron is needed to make functional hemoglobin. **8.** A redox reaction is a combination of an oxidation and a reduction reaction. As one substance is oxidized, another is reduced. **9.** Some of the energy released during catabolism is captured in the bonds of ATP, which provides the energy needed to carry out the constructive activities of anabolism. **10.** The energy released during the oxidation of food fuels is used to pump protons across the inner mitochondrial membrane. **11.** In substrate-level phosphorylation, high-energy phosphate groups are transferred directly from phosphorylated intermediates to ADP to form ATP. In oxidative phosphorylation, electron transport proteins forming part of the mitochondrial cristae use energy released during oxidation of glucose to create a steep gradient for protons across the cristae membrane. Then as protons flow back through the membrane, gradient energy is captured to attach phosphate to ADP. **12.** If oxygen is not available, glycolysis will stop because the supply of NAD<sup>+</sup> is limited and glycolysis can continue only if the reduced coenzymes (NADH + H<sup>+</sup>) formed during glycolysis are relieved of their extra hydrogen. **13.** Oxidation (via removal of H) is common in the Krebs cycle; it is indicated by the reduction of a coenzyme (either NAD<sup>+</sup> or FAD). Decarboxylations are also common, and are indicated by the removal of CO<sub>2</sub> from the cycle. **14.** Glycogenolysis is the reaction in which glycogen is broken down to its glucose units. **15.** Carbo loading forces the skeletal muscles to store more glycogen than they ordinarily would. **16.** Glycerol, a breakdown product of fat metabolism, enters the glycolytic pathway. **17.** Acetyl CoA is the central molecule of fat metabolism. **18.** The products of beta oxidation are acetyl CoA (acetic acid + coenzyme A), NADH<sup>+</sup> + H<sup>+</sup>, and FADH<sub>2</sub>. **19.** The liver uses keto acids drained off the Krebs cycle and amino groups (from other nonessential amino acids) as substrates to make the nonessential amino acids that the body needs. **20.** The ammonia removed from amino acids is combined with carbon dioxide to form urea, which is then eliminated by the kidneys. **21.** The three organs or tissues that regulate the directions of interconversions in the nutrient pools are the liver, skeletal muscles, and adipose tissues. **22.** Anabolic reactions and energy storage typify the absorptive state. Catabolic reactions (to increase blood sugar levels) such as lipolysis and glycogenolysis, and glucose sparing occur in the postabsorptive state. **23.** The main antagonist of glucagon is insulin. **24.** A rise in amino acid levels in blood increases both insulin and glucagon release. **25.** High HDLs would be preferable because the cholesterol these particles transport are destined for the liver and elimination from the body. **26.** A total cholesterol level of 200 mg/dl of blood or lower is recommended. **27.** Trans fats are oils that have been hydrogenated (with H atoms). They are unhealthy because they cause LDLs to increase and HDLs to decrease, exactly the opposite of what is desirable. **28.** Among short-term stimuli influencing feeding behavior are neural signals from the digestive tract, nutrient signals related to energy stores, and GI tract hormones (CCK, insulin, glucagon, and ghrelin). **29.** Leptin is the most important long-term regulator of feeding behavior. **30.** Of the factors listed, breathing and kidney function contribute to BMR. **31.** Samantha has a larger relative body surface area and therefore has a higher BMR. **32.** The body's core is the organs within the skull and the thoracic and abdominal cavities. **33.** Cindy's body temperature is rising as heat-promoting mechanisms (shivering, chills) are activated. Something (an infection?) has caused the hypothalamic thermostat to be set to a higher level (fever) temporarily. **34.** In conduction, heat is transferred directly from one object to another (a hot surface to your palm). In convection, air warmed by body heat is continually removed (warm air rises) and replaced by cooler air (cool air falls), which in turn will absorb heat ra-

diating from the body. **35.** Metabolic rate falls in old age because muscle mass declines and physical activity tends to be reduced. **36.** Elderly nutrition can be influenced and impaired by alcohol, certain antibiotics that interfere with food absorption, other drugs that may cause electrolyte imbalances, and use of mineral oil.

**Review Questions** 1. a; 2. c; 3. b; 4. d; 5. b; 6. c; 7. a; 8. d; 9. d; 10. a; 11. b; 12. d; 13. c; 14. d; 15. a

**Case Study 1.** Blood pH: Low (normal: 7.35–7.45); Blood glucose: High (normal: 70–120 mg/dl); Blood ketone bodies: High (normally negative); Urine pH: Low (normal: 4.5–8.0) **2.** Ketone bodies have an acetone smell that can be detected in the urine and the breath. Mr. Boulard is producing abnormal amounts of ketone bodies, which are accumulating in his blood. These substances are being excreted into the urine and diffusing out of the lungs and into the exhaled air. **3.** Ketogenesis, or the production of ketone bodies, is a process that occurs primarily in hepatocytes (liver cells) when carbohydrates are unavailable as an energy source. In this case, the hepatocytes metabolize fats. The fatty acids produced from fat breakdown (lipolysis) are converted to acetyl CoA by beta oxidation. In the absence of glucose, these acetyl CoA molecules cannot enter the Krebs cycle, and hepatocytes convert them into ketone bodies. **4.** Mr. Boulard's elevated blood glucose and his acidotic state indicate diabetes mellitus. In both type 1 and type 2 diabetes, the absence of insulin's actions means that the cells are unable to efficiently take up and utilize glucose from the blood. As a result, blood glucose levels are high, yet the cells are forced to switch to an alternative energy source such as lipids, which results in the production of ketone bodies in a diabetic patient. The stress of alcohol-induced dehydration can trigger ketoacidosis by causing the release of stress hormones that make diabetes worse. **5.** The pH of Mr. Boulard's blood and urine is abnormally low because ketone bodies are acidic (keto acids). As the concentration of ketone bodies in the blood rises, the blood pH falls (acidosis). The kidneys correct the blood pH by moving ketone bodies into the urine, making acidic urine.

## Chapter 25

**Check Your Understanding 1.** The lower part of his rib cage and the perirenal fat capsule protect his kidneys from blows. **2.** The layers of supportive tissue around each kidney are the fibrous capsule, the perirenal fat capsule, and the renal fascia. The parietal peritoneum overlies the anterior renal fascia. **3.** The renal pelvis, which has extensions called calyces, is continuous with the ureter. **4.** Filtrate is formed in the glomerular capsule and then passes through the proximal convoluted tubule (PCT), the descending and ascending limbs of the nephron loop, and the distal convoluted tubule (DCT). **5.** The structural differences are (1) juxtamedullary nephrons have long nephron loops (with long thin segments) and renal corpuscles that are near the cortex-medulla junction, whereas cortical nephrons have short nephron loops and renal corpuscles that lie more superficially in the cortex; (2) efferent arterioles of juxtamedullary nephrons supply vasa recta, while efferent arterioles of cortical nephrons supply peritubular capillaries. **6.** The glomerular capillaries are fenestrated capillaries. (See Figure 19.3 on p. 697 to refresh your memory of capillary types.) Their function is to filter large amounts of plasma into the glomerular capsule. **7.** Intrinsic controls serve to maintain a nearly constant GFR in spite of changes in systemic blood pressure. Extrinsic controls serve to maintain systemic blood pressure. **8.** Net filtration pressure is 5 mm Hg [50 mm Hg – (25 mm Hg + 20 mm Hg)]. **9.** Hydrostatic pressure in the glomerular capillaries (HP<sub>gs</sub>) is regulated by intrinsic and extrinsic controls of GFR. **10.** The majority of reabsorption occurs in the proximal convoluted tubule. **11.** In primary active transport, the energy for the process is provided directly by the cleavage of ATP. In secondary active transport, the energy for the process is provided by the Na<sup>+</sup> concentration gradient. As Na<sup>+</sup> moves down its own concentration gradient established by the active pumping of Na<sup>+</sup> occurring elsewhere in the cell, it drives the movement of another substance (e.g., glucose) against

its concentration gradient. **12.** The reabsorption of  $\text{Na}^+$  by primary active transport drives reabsorption of amino acids and glucose by secondary active transport. It also drives passive reabsorption of chloride, and reabsorption of water by osmosis. The reabsorption of water leaves behind other solutes, which become more concentrated and can therefore be reabsorbed by diffusion. **13.**  $\text{H}^+$ ,  $\text{K}^+$ ,  $\text{NH}_4^+$ , creatinine, urea, and uric acid are all substances that are secreted into the kidney tubules. **14.** The descending limb of the nephron loop is permeable to water and impermeable to  $\text{NaCl}$ . The ascending limb is impermeable to water and permeable to  $\text{NaCl}$ . **15.** ADH is released from the posterior pituitary in response to hyperosmotic extracellular fluid (as sensed by hypothalamic osmoreceptors). ADH causes insertion of aquaporins into the apical membrane of the principal cells of the collecting ducts. **16.** The normal renal clearance value for amino acids is zero. You would expect this because amino acids are valuable as nutrients and as the building blocks for protein synthesis, so it would not be good to lose them in the urine. **17.** The three major nitrogenous wastes excreted in urine are urea, creatinine, and uric acid. **18.** A kidney stone blocking the ureter would interfere with urine flow to the bladder. The pain would occur in waves that coincide with the peristaltic contractions of the smooth muscle of the ureter. **19.** The trigone is a smooth triangular region at the base of the bladder. Its borders are defined by the openings for the ureters and the urethra. **20.** The prostatic urethra, the intermediate part of the urethra, and the spongy urethra are the three regions of the male urethra. **21.** The detrusor contracts in response to increased firing of parasympathetic nerves. The internal urethral sphincter opens. **22.** The three sets of embryonic kidneys in the order that they develop are the pronephros, mesonephros, and metanephros. **23.** Both loss of bladder tone with age and an increase in size of the prostate can contribute to urinary retention in elderly men.

**Review Questions** 1. d; 2. b; 3. c; 4. d; 5. c; 6. b; 7. a; 8. c; 9. a; 10. b

**Case Study 1.** Albumin is the smallest and most abundant plasma protein. More than trace amounts of albumin are not normally found in urine, so its presence indicates damage to the filtration membrane of the nephron. **2.** These medications were prescribed to treat Mr. Boulard's hypertension. Both diabetes and hypertension can cause kidney damage, and hypertension is a major cause of other cardiovascular diseases such as heart failure and stroke. Albuminuria indicates that Mr. Boulard already has damage to his kidneys, so it is important to protect his kidneys from further damage. **3.** Thiazide diuretics increase urine output by inhibiting  $\text{Na}^+$  reabsorption in the DCT. This decreases blood volume, which decreases blood pressure. **4.** While Mr. Boulard still has hypertension, his main problem is that his blood  $\text{K}^+$  is low. He is losing too much  $\text{K}^+$  in his urine. This is the underlying cause of his irregular heartbeat, which could turn into a fatal arrhythmia if his hypokalemia is not corrected. **5.** Thiazide diuretics increase  $\text{Na}^+$  excretion and decrease blood pressure. To compensate for these thiazide effects, Mr. Boulard's renin-angiotensin-aldosterone mechanism is activated. Aldosterone increases  $\text{Na}^+$  reabsorption and  $\text{K}^+$  secretion, resulting in hypokalemia (low blood  $\text{K}^+$ ). **6.** ACE inhibitors decrease blood pressure by blocking the action of angiotensin converting enzyme and so reducing the amount of circulating angiotensin II. Because angiotensin II increases blood pressure in a number of ways, including by increasing aldosterone release and causing vasoconstriction (see Figure 19.10 on p. 708), ACE inhibitors are very effective at lowering blood pressure. (ACE inhibitors also help minimize kidney damage in diabetes.) **7.** Yes. The ACE inhibitors would have prevented the formation of excess angiotensin II and the resulting release of aldosterone. This would have lessened excess secretion of  $\text{K}^+$ .

## Chapter 26

**Check Your Understanding 1.** You have more intracellular than extracellular fluid and more interstitial fluid than plasma. **2.**  $\text{Na}^+$  is the major cation in the ECF and  $\text{K}^+$  is the major cation in the ICF. The intracellular

counterparts to extracellular  $\text{Cl}^-$  are  $\text{HPO}_4^{2-}$  and protein anions. **3.** If you eat salty pretzels, your extracellular fluid volume will expand even if you don't ingest fluids. This is because water will flow by osmosis from the intracellular fluid to the extracellular fluid. **4.** An increase in osmolality of the plasma is most important for triggering thirst. This change is sensed by osmoreceptors in the hypothalamus. **5.** ADH cannot add water—it can only conserve what is already there. In order to reduce an increase in osmolality of body fluids, the thirst mechanism is required. **6.** (a) A loss of plasma proteins causes edema. (b) Copious sweating causes dehydration. (c) Using ecstasy (together with drinking lots of fluids) could cause hypotonic hydration because it promotes ADH secretion, which interferes with the body's ability to get rid of extra water. **7.** Insufficient aldosterone would cause Jacob's plasma  $\text{Na}^+$  to be decreased and his plasma  $\text{K}^+$  to be elevated. The decrease in plasma  $\text{Na}^+$  would cause a decrease in blood pressure, because plasma  $\text{Na}^+$  is directly related to blood volume, which is a major determinant of blood pressure. **8.** The kidneys' handling of  $\text{K}^+$  can be summed up as "The kidneys reabsorb most of the filtered  $\text{K}^+$  in the proximal parts of the kidney's tubules and then secrete just the right amount in the distal parts (collecting duct)." **9.** The major regulator of calcium in the blood is parathyroid hormone. Hypercalcemia decreases excitability of neurons and muscle cells and may cause life-threatening cardiac arrhythmias. Hypocalcemia increases excitability and causes muscle tetany. **10.** Acidemia is an arterial pH below 7.35 and alkalemia is a pH above 7.45. **11.** A weak base would be better at minimizing the shift in pH caused by adding a strong acid to a solution because its ability to loosely tie up  $\text{H}^+$  allows it to act as a buffer. **12.** The three major chemical buffer systems of the body are the bicarbonate buffer system, the phosphate buffer system, and the protein buffer system. The most important intracellular buffer is the protein buffer system. **13.** Joanne's ventilation would be increased. The acidosis caused by the accumulated ketone bodies will stimulate the peripheral chemoreceptors, and this will cause more  $\text{CO}_2$  to be "blown off" in an attempt to restore pH to normal. **14.** Reabsorption of  $\text{HCO}_3^-$  is always linked with secretion of  $\text{H}^+$ . **15.** The most important urine buffer of  $\text{H}^+$  is the phosphate buffer system. **16.** The tubule and collecting duct cells generate new  $\text{HCO}_3^-$  either by excreting ammonium ion ( $\text{NH}_4^+$ ) or by excreting buffered  $\text{H}^+$  ions. **17.** Key features of an uncompensated metabolic alkalosis are an increase in blood pH and an increase in blood  $\text{HCO}_3^-$ . Key features of an uncompensated respiratory acidosis are a decrease in blood pH and an increase in blood  $\text{P}_{\text{CO}_2}$ . **18.** The kidneys compensate for respiratory acidosis by excreting more  $\text{H}^+$  and generating new  $\text{HCO}_3^-$  to buffer the acidosis. **19.** Infants' immature kidneys are not as proficient at concentrating urine. In addition, they have a high metabolic rate, so they produce more metabolic water and also have larger amounts of metabolic wastes and acids that need to be excreted with water.

**Review Questions** 1. a; 2. c; 3. b; 4. a and b; 5. h, i; 6. c, g; 7. a, e; 8. b; 9. a, b; 10. j; 11. b, d; 12. a; 13. c

**Case Study 1.** Mr. Heyden's vital signs suggest that he is in hypovolemic shock, which is probably due to an internal hemorrhage. **2.** The spleen is a highly vascular organ due to its role as a blood-filtering organ. The macrophages in Mr. Heyden's liver and bone marrow will help compensate for the loss of his spleen. **3.** Elevation of renin, aldosterone, and antidiuretic hormone indicate that Mr. Heyden's body is trying to compensate for his falling blood pressure and blood loss. Renin: released when renal blood flow is diminished and blood pressure falls. The angiotensin-aldosterone response is initiated by renin. The formation of angiotensin II leads to vasoconstriction, which will increase blood pressure, and to the release of aldosterone. Aldosterone: increases  $\text{Na}^+$  reabsorption by the kidney. The movement of this reabsorbed  $\text{Na}^+$  into the bloodstream will promote the movement of water from the interstitial fluid, resulting in an increase in blood volume. Antidiuretic hormone (ADH): released when the hypothalamic osmoreceptors sense an increase in osmolality. ADH has two consequences: It is a potent vaso-

constrictor and will increase blood pressure, and it promotes water retention by the kidney, increasing blood volume. **4.** (a) Mr. Heyden's urine production may be decreased for several reasons. The severe drop in his blood pressure would reduce renal blood flow, thus reducing glomerular blood pressure and decreasing his glomerular filtration rate. The elevation in his ADH levels can reduce urine output due to increased water reabsorption by the kidney. He may also have damage to the kidney due to his crush injury in the left lumbar region. (b) The presence of casts and a brownish-red color in his urine are probably due to damaged cells and blood. If he has suffered kidney damage due to being crushed, he may have nephron damage that would include disruption of the filtration membrane, allowing red blood cells to pass into the filtrate and therefore the urine. He may also have damaged renal tubules and peritubular capillaries, allowing entry of blood and damaged renal tubule epithelial cells into the filtrate.

## Chapter 27

**Check Your Understanding 1.** The testes produce the male gametes (sperm) and testosterone. **2.** The sperm factories are the seminiferous tubules. **3.** When the ambient temperature is cold, the associated muscles contract, bringing the testes close to the warm body wall. When body temperature is high, the associated muscles relax, allowing the testes to hang away from the body wall. The pampiniform venous plexus absorbs heat from the arterial blood before it enters the testes. **4.** The erectile tissue of the penis allows the penis to become stiff so that it may more efficiently enter the female vagina to deliver sperm. **5.** The organs of the male duct system in order from the epididymis to the body exterior are the ductus deferens, ejaculatory duct, prostatic urethra, intermediate part of the urethra, and spongy urethra. **6.** These stereocilia pass nutrients to the sperm and absorb excess testicular fluid. **7.** The ductus deferens runs from the scrotum into the abdominal cavity. **8.** Adolph probably has a hypertrophied prostate, a condition which can be felt through the anterior wall of the rectum. **9.** The seminal glands produce the bulk of seminal fluid. **10.** Semen is sperm plus the secretions of the male accessory glands. **11.** Erection is the stiffening of the penis that occurs when blood in the cavernous tissue is prevented from leaving the penis. It is caused by the parasympathetic division of the autonomic nervous system. **12.** Resolution is a period of muscular and psychological relaxation that follows orgasm. It results as the sympathetic nervous system causes constriction of the internal pudendal arteries, reducing blood flow to the penis, and activates small muscles that force blood out of the penis. **13.** Meiosis reduces the chromosomal count from  $2n$  to  $n$  and introduces variability. **14.** The sperm head is the compacted DNA-containing nucleus. The acrosome that caps the head is a lysosome-like sac of enzymes. The midpiece contains the energy-producing mitochondria. The tail, a flagellum fashioned by a centriole, is the propulsive structure. **15.** Sustentocytes provide nutrients and essential development signals to the developing sperm and form the blood testis barrier that prevents sperm antigens from escaping into the blood. Interstitial endocrine cells secrete testosterone. **16.** The HPG axis is the hormonal interrelationship between the hypothalamus, anterior pituitary, and gonads that regulates the production of gametes and sex hormones (e.g., sperm production and testosterone in the male). **17.** Follicle-stimulating hormone indirectly stimulates spermatogenesis by prompting the sustentocytes to secrete androgen-binding protein. Androgen-binding protein keeps the concentration of testosterone high in the vicinity of the spermatogenic cells, which directly stimulates spermatogenesis. **18.** Secondary sex characteristics of males include appearance of pubic, axillary, and facial hair, deepening of the voice, increased oiliness of the skin, and increased size (length and mass) of the bones and skeletal muscles. **19.** The female's internal genitalia include the ovaries and duct system (uterine tubes, uterus, and vagina). **20.** The ovaries produce the female gametes and secrete female sex hormones (estrogens and progesterone). **21.** The antrum is the fluid-filled cavity of a mature follicle. **22.** Women are more at risk for PID than men

because the duct system of women is incomplete—there is no physical connection between the ovary and the uterine tubes, which are open to the pelvic cavity. In men, the duct system is continuous from the testes to the body exterior. **23.** The waving action of the fimbriae and currents created by the beating cilia help to direct the ovulated oocytes into the uterine tube. **24.** The usual site of fertilization is the uterine tube. The uterus serves as the incubator for fetal development. **25.** The greater vestibular glands are the female homologue of the male bulbo-urethral glands. **26.** Both the penis and clitoris are hooded by a skin fold and are largely erectile tissue. However, the clitoris lacks a corpus spongiosum containing a urethra, so the urinary and reproductive systems are completely separate in females. **27.** Developmentally, the mammary glands are modified sweat glands. **28.** Breast cancer usually arises from the epithelial cells of the small ducts. **29.** The products of meiosis in females are 3 polar bodies (tiny haploid cells with essentially no cytoplasm) and 1 haploid ovum (functional gamete). Meiosis in males yields 4 functional gametes, the haploid sperm. **30.** Identical twins develop from separation of a very young embryo (the result of fertilization by a single sperm) into two parts. Fraternal twins develop when different oocytes are fertilized by different sperm. **31.** In the luteal phase, the ovulated follicle develops into a corpus luteum, which then secretes progesterone (and some estrogen). **32.** Leptin is important in advising the brain of the girl's readiness (relative to energy stores) for puberty. **33.** FSH prompts follicle growth and LH prompts ovulation. **34.** Estrogen exerts positive feedback on the anterior pituitary that leads to a burstlike release of LH. **35.** Estrogen is responsible for the secondary sex characteristics of females. **36.** Estrogen promotes epiphyseal closure in both males and females. **37.** The human papillomavirus (HPV) is most associated with cervical cancer. **38.** Chlamydia is the most common bacterial sexually transmitted infection in the U.S. **39.** No. If the sex chromosomes are XY, a male baby will develop. **40.** The sexually indifferent stage of development is the early period when the presumptive reproductive structures can produce either male or female organs. **41.** The gubernaculum guides the descent of the testis into the scrotum. **42.** Early signs of puberty's onset in boys are enlargement of the testes and scrotum. **43.** Menopause has happened when menstruation has not occurred for a year.

**Review Questions 1.** a and b; **2.** d; **3.** a; **4.** d; **5.** b; **6.** d; **7.** d; **8.** c; **9.** a, c, e, f; **10.** (1)c, f; (2)e, h; (3)g; (4)a; (5)b, e, and g; (6)f; **11.** a; **12.** c; **13.** d; **14.** b; **15.** a; **16.** b; **17.** c

**Case Study 1.** Carcinoma is the term for cancer originating from epithelial tissue. The primary source of Mr. Heyden's cancer is likely to be the prostate. **2.** Elevation of PSA levels suggests carcinoma of the prostate. (In addition, Mr. Heyden's age places him in a group that is at relatively higher risk for this type of cancer.) **3.** Digital examination of Mr. Heyden's prostate should detect the presence of carcinoma in this tissue. In addition, transrectal ultrasound imaging may be used in screening, and biopsies of prostate tissue follow positive results of tests. **4.** Mr. Heyden's carcinoma has advanced to the point of metastasis. He will probably undergo a treatment that reduces the levels of androgens in his body, as androgens promote growth of the prostate-derived tissue. These treatments could include castration or administration of drugs that block the production and/or effects of androgens.

## Chapter 28

**Check Your Understanding 1.** Before they can penetrate an oocyte, sperm must be capacitated, and an oocyte's zona pellucida must be eroded by the acrosomal enzymes of many sperm. **2.** The cortical reaction, or slow block to polyspermy, involves the release of enzymes from cortical granules to the oocyte exterior, which accomplishes destruction of the oocyte's sperm receptors and also the detachment of any sperm still bound to receptors. These events ensure monospermy. **3.** The blastocyst is only slightly larger than the zygote because, although cell division has been going on (cleavage divisions), there is essentially no time for

growth between divisions, so the resulting cells get smaller and smaller.

The result is a large number of cells with a high surface-to-volume ratio.

4. The trophoblast cells contribute to the formation of the placenta.

5. The syncytiotrophoblast actually accomplishes implantation. 6. The blastocyst secretes the hormone human chorionic gonadotropin, which is detectable in the urine. 7. The chorion develops from the trophoblast and a layer of extraembryonic mesoderm. 8. The decidua basalis cooperates with the chorionic villi to form the placenta. 9. The placenta is usually fully functional by the end of the third month of pregnancy.

10. The amnion helps to maintain a constant temperature for the developing fetus, protects it from physical trauma, and prevents adhesion of fetal parts. 11. The allantois provides the basis of the umbilical cord, which provides a pathway for the embryonic blood vessels to reach the placenta. 12. Before organogenesis can occur in earnest, the embryonic body must fold and undercut to form a tubular embryo. 13. The mesoderm gives rise to essentially all body tissues except neural and epidermal tissue and mucosae. 14. The fetal period begins at the end of 8 weeks.

15. Difficult breathing during late pregnancy is due to the fact that the uterus is pressing against and crowding the diaphragm (and hence the lungs). The waddling gait is due to the relaxing effect of relaxin on the pelvic ligaments and the pubic symphysis. 16. While the exact cause of morning sickness is unknown, it is thought to be due to the rising levels of female sex hormones and hCG in the mother's blood, which sometimes takes a while to get used to. 17. The hormone hPL works with estrogen and progesterone to stimulate breast maturation in the pregnant woman, promotes fetal growth, and exerts a glucose-sparing effect on the mother. 18. Breech presentation is a buttock-first presentation of the baby during labor. 19. Prostaglandins are most responsible for triggering true labor. 20. The descent of the baby's head (the largest part of its body) follows the widest dimensions of the bony pelvis. 21. The foramen ovale and ductus arteriosus allow most of the blood to bypass the heart. 22. For the most part, the special fetal circulatory modifications are occluded at birth or shortly thereafter. 23. Oxytocin causes the let-down reflex.

**Review Questions** 1. (1)a, (2)b, (3)b, (4)a; 2. b; 3. c; 4. b; 5. a; 6. d; 7. d; 8. c; 9. b; 10. c; 11. a; 12. c; 13. a; 14. (1)e, (2)f, (3)a, (4)d, (5)h, (6)b, (7)g, (8)c

**Case Study 1.** A hospital pregnancy test works by detecting human chorionic gonadotropin (hCG) in the blood. Home pregnancy test kits detect this hormone in urine. 2. Human chorionic gonadotropin is a hormone produced by the trophoblast cells that helps to maintain the viability of the corpus luteum. The corpus luteum is essential during early pregnancy because it is responsible for the production of estrogen and progesterone. These two hormones are required to maintain the uterus during the early stages of a pregnancy. 3. While any amount of trauma can be cause for concern with a pregnancy, Mrs. Rodriguez's accident occurred prior to the formation of the placenta. If her accident had occurred a few weeks later, her blood loss may have had an impact on the oxygenation of her developing fetus. 4. First, the egg that Mrs. Rodriguez released during her most recent ovulation is fertilized to form the zygote. Over the next week, embryonic development features many rapid rounds of cell division as the embryo moves through the uterine tube. Cleavage is the very early period of rapid cell division. By 72 hours after fertilization, the embryo is a ball of 16 or more cells called the morula. Around day 4, a fluid-filled cavity appears, which signals the formation of the blastocyst. Approximately one week after fertilization, the embryo has made its way into the uterus and begins the process of implantation. 5. At this time, Mrs. Rodriguez's embryo transforms into a three-layered structure as the result of a process called gastrulation. This process involves the rearrangement and migration of cells as the three primary germ layers (ectoderm, mesoderm, and endoderm) are formed. These three layers serve as the primitive tissues from which all of the body organs will be formed as development continues.

## Chapter 29

**Check Your Understanding 1.** Chromosomes are not visible during interphase. The DNA-containing material is in the form of dispersed strands of chromatin. As mitosis begins, the chromatin coils and condenses, becoming visible as chromosomes. Chromosomes continue to condense throughout prophase and are most visible during metaphase. 2. Chromosomes other than sex chromosomes are called autosomes. 3. An allele represented by a capital letter is presumed to be a dominant allele. 4. Descriptions of his phenotype are blond, blue-eyed, and hairy chest. 5. The alleles on different pairs of homologous chromosomes are segregated independently of each other to different gametes. 6. It causes separations of linked genes on the same chromosome, producing gametes with variable genomes. 7. Dominant genes are expressed. Thus if the dominant gene is lethal, the carrier will probably not live very long or will die during development. 8. In incomplete dominance, the heterozygote has a phenotype intermediate between that of the dominant and recessive alleles [for example, for the sickling gene, the dominant homozygote (SS) has no evidence of sickling; the heterozygote (Ss) has sickle-cell trait; and the homozygote for the recessive gene (ss) has sickle-cell anemia]. In codominance, both dominant alleles are expressed (as in ABO blood types). 9. A male always expresses an X-linked recessive allele because, unlike a female, he does not have a second X containing homologous alleles to blunt or counteract the effect. The Y chromosome lacks most of the genes carried on the X chromosome. 10. Height is an example of a trait conferred by polygene inheritance in which several genes on different chromosomes contribute to the trait. Such traits show a distribution of phenotypes that yields a bell-shaped curve. 11. Other genes, measles in a pregnant woman, and lack of key dietary nutrients all may alter gene expression. 12. Genomic imprinting labels genes as maternal or paternal. 13. Maternal mitochondrial DNA confers extranuclear inheritance. 14. Amniocentesis analyzes chemicals and cells in amniotic fluid. 15. Ultrasound imaging is used to determine some aspects of fetal development (fetal age for example) and is noninvasive.

**Review Questions 1.** (1)d, (2)g, (3)b, (4)a, (5)f, (6)c, (7)e, (8)h; 2. (1)e, (2)a, (3)b, (4)d, (5)c, (6)d, (7)f

**Case Study 1.** A person's genotype is a description of the alleles that they carry. Phenotype refers to the way that those genes are expressed and show up as traits in the body. Mrs. Rodriguez's genotype is *ii* and her phenotype is O. Mr. Rodriguez's genotype is either  $I^A I^A$  or  $I^A i$ . Either one of these genotypes would result in his phenotype, which is represented by his A blood type. 2. Blood type is determined by multiple-allele inheritance. Three alleles ( $I^A$ ,  $I^B$ ,  $i$ ) represent the three different blood types (A, B, O). The alleles for A and B blood type are codominant, which means that they are both expressed when combined together. The result of this combination would be the AB blood type. The allele for O blood type is recessive to both the A and B blood type alleles. 3. Mr. Rodriguez's genotype can be either  $I^A I^A$  or  $I^A i$ . We now know that Mr. Rodriguez's mother had O blood type, and that means that she carries two copies of the O blood type allele (*ii*). She must have passed on one of these alleles to Mr. Rodriguez. This means that Mr. Rodriguez's father must have passed on the allele for the A blood type. Mr. Rodriguez's genotype *must* be  $I^A i$ . 4. We know that Mrs. Rodriguez's genotype is *ii* and Mr. Rodriguez's genotype is  $I^A i$ . The results of a Punnett square reveal that there is a 50% chance that Mrs. Rodriguez's baby will have the O blood type and a 50% chance that the baby will have the A blood type. The B and AB blood type require that one of the parents is carrying the B allele ( $I^B$ ). Neither Mr. Rodriguez nor Mrs. Rodriguez carries this allele, so there should be a 0% chance of the baby having the B or AB blood type.

# Glossary

## Pronunciation Key

' = Primary accent

" = Secondary accent

Pronounce:

a, fá, át	as in	fate	o, no, ôt	as in	note
ă, hă, at		hat	ö, frö, og		frog
ah		father	oo		soon
ar		tar	or		for
e, stre, ět		street	ow		plow
ě, hě, en		hen	oy		boy
er		her	sh		she
ew		new	u, mu, üt		mute
g		go	ű, sű, un		sun
i, bi, ĩt		bite	z		zebra
ĩ, hĩ, im		him	zh		measure
ng		ring			

**Abduct** (ab-duk't') To move away from the midline of the body.

**Absolute refractory period** Period following stimulation during which no additional action potential can be evoked.

**Absorption** Process by which the products of digestion pass through the alimentary tube mucosa into the blood or lymph.

**Accessory digestive organs** Organs that contribute to the digestive process but are not part of the alimentary canal; include the tongue, teeth, salivary glands, pancreas, liver.

**Accommodation** The process of increasing the refractive power of the lens of the eye; focusing.

**Acetabulum** (as''ĕ-tab'u-lum) Cuplike cavity on lateral surface of the hip bone that receives the femur.

**Acetylcholine (ACh)** (as''ĕ-til-ko'lĕn) Chemical transmitter substance released by some nerve endings.

**Acetylcholinesterase (AChE)** (as''ĕ-til-ko''lin-es'ter-ās) Enzyme present at the neuromuscular junction and synapses that degrades acetylcholine and terminates its action.

**Achilles tendon** See Calcaneal tendon.

**Acid** A substance that releases hydrogen ions when in solution (compare with Base); a proton donor.

**Acid-base balance** Situation in which the pH of the blood is maintained between 7.35 and 7.45.

**Acidosis** (as''i-do'sis) State of abnormally high hydrogen ion concentration in the extracellular fluid.

**Actin** (ak'tin) A contractile protein of muscle.

**Action potential** A large transient depolarization event, including polarity reversal, that is conducted along the membrane of a muscle cell or a nerve fiber.

**Activation energy** The amount of energy required to push a reactant to the level necessary for action.

**Active immunity** Immunity produced by an encounter with an antigen; provides immunological memory.

**Active site** Region on the surface of a functional (globular) protein where it binds and interacts chemically with other molecules of complementary shape and charge.

**Active (transport) processes** (1) Membrane transport processes for which ATP is required, e.g., solute pumping and endocytosis. (2) "Active transport" also refers specifically to solute pumping.

**Adaptation** (1) Any change in structure or response to suit a new environment; (2) decline in the transmission of a sensory nerve when a receptor is stimulated continuously and without change in stimulus strength.

**Adduct** (a-duk't') To move toward the midline of the body.

**Adenine (A)** (ad''ĕ-nĕn) One of the two major purines found in both RNA and DNA; also found in various free nucleotides of importance to the body, such as ATP.

**Adenohypophysis** (ad''ĕ-no-hi-pof''i-sis) Anterior pituitary; the glandular part of the pituitary gland.

**Adenoids** (ad''en-noids) Pharyngeal tonsil.

**Adenosine triphosphate (ATP)** (ah-den'o-sĕn tri''fos'fāt) Organic molecule that stores and releases chemical energy for use in body cells.

**Adipocyte** (ad''i-po-sit) An adipose, or fat, cell.

**Adipose tissue** (ad''i-pōs) Areolar connective tissue modified to store nutrients; a connective tissue consisting chiefly of fat cells.

**Adrenal glands** (uh-drĕ'nul) Hormone-producing glands located superior to the kidneys; each consists of medulla and cortex areas.

**Adrenergic fibers** (ad''ren-er'jik) Nerve fibers that release norepinephrine.

**Adrenocorticotrophic hormone (ACTH)** (ah-dre''no-kor''ti-ko-trop'ik) Anterior pituitary hormone that influences the activity of the adrenal cortex.

**Adventitia** (ad''ven-tish'e-ah) Outermost layer or covering of some organs.

**Aerobic** (a'er-ōb''ik) Oxygen-requiring.

## G-2 Glossary

**Aerobic endurance** The length of time a muscle can continue to contract using aerobic pathways.

**Aerobic respiration** Respiration in which oxygen is consumed and glucose is broken down entirely; water, carbon dioxide, and large amounts of ATP are the final products.

**Afferent** (af'er-ent) Carrying to or toward a center.

**Afferent (sensory) nerve** Nerve that contains processes of sensory neurons and carries nerve impulses to the central nervous system.

**Agglutination** (ah-gloo'ti-na'shun) Clumping of (foreign) cells; induced by cross-linking of antigen-antibody complexes.

**Agonist** (ag'o-nist) Muscle that bears the major responsibility for effecting a particular movement; a prime mover.

**AIDS** Acquired immune deficiency syndrome; caused by human immunodeficiency virus (HIV); symptoms include severe weight loss, night sweats, swollen lymph nodes, opportunistic infections.

**Albumin** (al-bu'min) The most abundant plasma protein.

**Aldosterone** (al-dos'ter-ōn) Hormone produced by the adrenal cortex that regulates Na<sup>+</sup> reabsorption and K<sup>+</sup> secretion by the kidneys.

**Alimentary canal** (al'i-men'tar-e) The continuous hollow tube extending from the mouth to the anus; its walls are constructed by the oral cavity, pharynx, esophagus, stomach, and small and large intestines.

**Alkalosis** (al'kah-lo'sis) State of abnormally low hydrogen ion concentration in the extracellular fluid.

**Allantois** (ah'lan'to-is) Embryonic membrane; its blood vessels develop into blood vessels of the umbilical cord.

**Alleles** Genes coding for the same trait and found at the same locus on homologous chromosomes.

**Allergy** A type of hypersensitivity (overzealous immune response to an otherwise harmless antigen) that involves IgE antibodies and histamine release.

**Alopecia** (al'o-pe'she-ah) Baldness.

**Alpha (α)-helix** The most common type of secondary structure of the amino acid chain in proteins; resembles the coils of a telephone cord.

**Alveolar (acinar) gland** (al-ve'o-lar) A gland whose secretory cells form small, flasklike sacs.

**Alveolar ventilation rate (AVR)** An index of respiratory efficiency; measures volume of fresh air that flows in and out of alveoli.

**Alveolus** (al-ve'o-lus) (1) One of the microscopic air sacs of the lungs; (2) tiny milk-producing glandular sac in the breast; (3) tooth socket.

**Alzheimer's disease (AD)** (altz'hi-merz) Degenerative brain disease resulting in progressive loss of memory and motor control, and increasing dementia.

**Amino acid** (ah-me'no) Organic compound containing nitrogen, carbon, hydrogen, and oxygen; building block of protein.

**Ammonia (NH<sub>3</sub>)** Common waste product of protein breakdown in the body; a colorless volatile gas, very soluble in water and capable of forming a weak base; a proton acceptor.

**Amniocentesis** A common form of fetal testing in which a small sample of fluid is removed from the amniotic cavity.

**Amnion** (am'ne-on) Fetal membrane that forms a fluid-filled sac around the embryo.

**Amoeboid motion** (ah-me'boyd) The flowing movement of the cytoplasm of a phagocyte.

**Amphiarthrosis** (am'fe-ar-thro'sis) A slightly movable joint.

**Ampulla** (am-pul'lah) A localized dilation of a canal or duct.

**Amylase** Digestive system enzyme that breaks down starchy foods.

**Anabolism** (ah-nab'o-lizm) Energy-requiring building phase of metabolism in which simpler substances are combined to form more complex substances.

**Anaerobic** (an-a'er-ōb-ik) Not requiring oxygen.

**Anaerobic glycolysis** (gli-kol'i-sis) Energy-yielding conversion of glucose to lactic acid in various tissues, notably muscle, when sufficient oxygen is not available.

**Anaerobic threshold** The point at which muscle metabolism converts to anaerobic glycolysis.

**Anaphase** Third stage of mitosis, meiosis I, and meiosis II in which daughter chromosomes move toward each pole of a cell.

**Anastomosis** (ah-nas'to-mo'sis) A union or joining of nerves, blood vessels, or lymphatics.

**Anatomy** Study of the structure of living organisms.

**Androgen** (an'dro-jen) A hormone such as testosterone that controls male secondary sex characteristics.

**Anemia** (ah-ne'me-ah) Reduced oxygen-carrying ability of blood resulting from too few erythrocytes or abnormal hemoglobin.

**Aneurysm** (an'u-rizm) Blood-filled sac in an artery wall caused by dilation or weakening of the wall.

**Angina pectoris** (an'ji-nah pek'tor-is) Severe suffocating chest pain caused by brief lack of oxygen supply to heart muscle.

**Angiotensin II** (an'je-o-ten'sin) A potent vasoconstrictor activated by renin; also triggers release of aldosterone.

**Anion** (an'i-on) An ion carrying one or more negative charges and therefore attracted to a positive pole.

**Anoxia** (ah-nōk'se-ah) Deficiency of oxygen.

**Antagonist** (an-tag'o-nist) (1) Muscle that reverses, or opposes, the action of another muscle. (2) Hormone that opposes the action of another hormone.

**Anterior pituitary** See Adenohypophysis.

**Antibody** A protein molecule that is released by a plasma cell (a daughter cell of an activated B lymphocyte) and that binds specifically to an antigen; an immunoglobulin.

**Anticodon** (an'ti-ko'don) The three-base sequence complementary to the messenger RNA (mRNA) codon.

**Antidiuretic hormone** (ADH, also called vasopressin) (an'ti-di'yer-eh'tik) Hormone produced by the hypothalamus and released by the posterior pituitary; stimulates the kidneys to reabsorb more water, reducing urine volume.

**Antigen (Ag)** (an'ti-jen) A substance or part of a substance (living or nonliving) that is recognized as foreign by the immune system, activates the immune system, and reacts with immune cells or their products.

**Antigen-presenting cell (APC)** A specialized cell (dendritic cell, macrophage, or B cell) that captures, processes, and presents antigens on its surface to T lymphocytes.

**Anucleate cell** (a-nu'kle-āt) A cell without a nucleus.

**Anus** (a'nus) Distal end of digestive tract; outlet of rectum.

**Aorta** (a-or'tah) Major systemic artery; arises from the left ventricle of the heart.

**Aortic body** Receptor in the aortic arch sensitive to changing oxygen, carbon dioxide, and pH levels of the blood.

**Apgar score** Evaluation of an infant's physical status at 1 and 5 minutes after birth by assessing five criteria: heart rate, respiration, color, muscle tone, and reflexes.

**Apnea** Breathing cessation.

**Apocrine sweat gland** (ap'ō-krin) The less numerous type of sweat gland; produces a secretion containing water, salts, proteins, and fatty acids.

**Apoenzyme** (ap'ō-en-zīm) The protein portion of an enzyme.

**Aponeurosis** (ap''o-nu-ro'sis) Fibrous or membranous sheet connecting a muscle and the part it moves.

**Apoptosis** A process of controlled cellular suicide; eliminates cells that are unneeded, stressed, or aged.

**Appendicitis** (ă-pen'dī-sī-'tis) Inflammation of the appendix (wormlike sac attached to the cecum of the large intestine).

**Appendicular** Relating to the limbs; one of the two major divisions of the body.

**Appositional growth** Growth accomplished by the addition of new layers onto those previously formed.

**Aquaporins** (ă''kwă-por'ins) Transmembrane proteins that form water channels.

**Aqueous humor** (a'kwe-us) Watery fluid in the anterior segment of the eye.

**Arachnoid** (ah-rak'noid) Weblike; specifically, the weblike arachnoid mater, the middle layer of the three meninges.

**Areola** (ah-re'o-lah) Circular, pigmented area surrounding the nipple; any small space in a tissue.

**Areolar connective tissue** A type of loose connective tissue.

**Arrector pili** (ah-rek'tor pi'li) Tiny, smooth muscles attached to hair follicles; contraction causes the hair to stand upright.

**Arrhythmia** (a-rith'me-ah) Irregular heart rhythm, often caused by defects in the intrinsic conduction system.

**Arteries** Blood vessels that conduct blood away from the heart and into the circulation.

**Arteriole** (ar-tēr'e-ōl) A minute artery.

**Arteriosclerosis** (ar-tēr-r'e-o-skler-o'sis) Any of a number of proliferative and degenerative changes in the arteries leading to their decreased elasticity.

**Arthritis** Inflammation of the joints.

**Arthroscopic surgery** (ar-thro-skop'ik) Procedure enabling a surgeon to repair the interior of a joint through a small incision.

**Articular capsule** Double-layered capsule composed of an outer fibrous layer lined by synovial membrane; encloses the joint cavity of a synovial joint.

**Articular cartilage** Hyaline cartilage covering bone ends at movable joints.

**Articulation (joint)** The junction of two or more bones.

**Association areas** Functional areas of the cerebral cortex that act mainly to integrate diverse information for purposeful action.

**Astigmatism** (ah-stig'mah-tizm) A condition in which unequal curvatures in different parts of the cornea or lens of the eye lead to blurred vision.

**Astrocyte** (as'tro-sit) A type of CNS supporting cell; assists in exchanges between blood capillaries and neurons.

**Atelectasis** (at''ē-lik'tah-sis) Lung collapse.

**Atherosclerosis** (a''ther-o''skler-o'sis) Changes in the walls of large arteries consisting of lipid deposits on the artery walls; one form of arteriosclerosis.

**Atmospheric pressure** Force that air exerts on the surface of the body (760 mm Hg at sea level).

**Atom** Smallest particle of an elemental substance that exhibits the properties of that element; composed of protons, neutrons, and electrons.

**Atomic number** The number of protons in an atom.

**Atomic symbol** The one- or two-letter symbol used to indicate an element; usually the first letter(s) of the element's name.

**Atomic weight** The average of the mass numbers of all the isotopes of an element.

**ATP (adenosine triphosphate)** (ah-den'o-sēn tri''fos'fāt) Organic molecule that stores and releases chemical energy for use in body cells.

**Atria** (a'tre-ah) The two superior receiving chambers of the heart.

**Atrial natriuretic peptide (ANP)** (a'tre-al na''tre-u-ret'ik) A hormone released by certain cells of the heart atria that reduces blood pressure and blood volume by inhibiting nearly all events that promote vasoconstriction and Na<sup>+</sup> and water retention.

**Atrioventricular (AV) bundle** (a''tre-o-ven-trī'kyoo-ler) Bundle of specialized fibers that conduct impulses from the AV node to the right and left ventricles; also called bundle of His.

**Atrioventricular (AV) node** Specialized mass of conducting cells located at the atrioventricular junction in the heart.

**Atrioventricular (AV) valve** Valve that prevents backflow into the atrium when the connected ventricle is contracting.

**Atrophy** (at'ro-fe) Reduction in size or wasting away of an organ or cell resulting from disease or lack of use.

**Auditory ossicles** (ah'sih-kulz) The three tiny bones serving as transmitters of vibrations and located within the middle ear: the malleus, incus, and stapes.

**Auditory tube** *See* Pharyngotympanic tube.

**Autoimmunity** Production of antibodies or effector T cells that attack a person's own tissue.

**Autolysis** (aw'tol'ī-sis) Process of autodigestion (self-digestion) of cells, especially dead or degenerate cells.

**Autonomic ganglion** Collection of sympathetic or parasympathetic postganglionic neuronal cell bodies.

**Autonomic nervous system (ANS)** Efferent division of the peripheral nervous system that innervates cardiac and smooth muscles and glands; also called the involuntary or visceral motor system.

**Autonomic (visceral) reflexes** Reflexes that activate smooth or cardiac muscle and/or glands.

**Autoregulation** The automatic local adjustment of blood flow to a particular body area in response to its current requirements.

**Autosomes** Chromosomes number 1 to 22; do not include the sex chromosomes.

**Avogadro's number** (av''o-gad'rōz) The number of molecules in one mole of any substance,  $6.02 \times 10^{23}$ .

**Axial** Relating to the head, neck, and trunk; one of the two major divisions of the body.

**Axolemma** (ak''so-lem'ah) The plasma membrane of an axon.

**Axon** Neuron process that carries impulses away from the nerve cell body; efferent process; the conducting portion of a nerve cell.

**Axon terminals (terminal boutons)** The bulbous distal endings of the terminal branches of an axon.

**B cells** Also called B lymphocytes; oversee humoral immunity; their descendants differentiate into antibody-producing plasma cells.

**Baroreceptor** (bayr''o-re-sep'tor) A sensory nerve ending in the wall of the carotid sinus or aortic arch sensitive to vessel stretching.

**Basal body** (ba'sal) An organelle structurally identical to a centriole and forming the base of a cilium or flagellum.

**Basal ganglia** *See* Basal nuclei.

**Basal lamina** (lam'i-nah) Noncellular, adhesive supporting sheet consisting largely of glycoproteins secreted by epithelial cells.

**Basal metabolic rate (BMR)** Rate at which energy is expended (heat produced) by the body per unit time under controlled (basal) conditions: 12 hours after a meal, at rest.

**Basal nuclei (basal ganglia)** Specific gray matter areas located deep within the white matter of the cerebral hemispheres.

**Basal surface** The surface near the base or interior of a structure; nearest the lower side or bottom of a structure.

**Base** A substance capable of binding with hydrogen ions; a proton acceptor.

**Basement membrane** Extracellular material consisting of a basal lamina secreted by epithelial cells and a reticular lamina secreted by underlying connective tissue cells.

**Basophil** (ba'zo-fil) White blood cell whose granules stain purplish-black and nucleus purple with basic dye.

**Benign** (be-nin') Not malignant.

**Bile** Greenish-yellow or brownish fluid produced in and secreted by the liver, stored in the gallbladder, and released into the small intestine.

**Bilirubin** (bil'i-roo'bin) Yellow pigment of bile.

**Bipolar neuron** Neuron with axon and dendrite that extend from opposite sides of the cell body.

**Blastocyst** (blas'to-sist) Stage of early embryonic development; the product of cleavage.

**Blood pressure (BP)** Force exerted by blood against a unit area of the blood vessel walls; differences in blood pressure between different areas of the circulation provide the driving force for blood circulation.

**Blood brain barrier** Mechanism that inhibits passage of materials from the blood into brain tissues; reflects relative impermeability of brain capillaries.

**Bolus** (bo'lus) A rounded mass of food prepared by the mouth for swallowing; any soft round mass.

**Bone marrow** Fat- or blood-forming tissue found within bone cavities; called yellow and red bone marrow, respectively.

**Bone (osseous tissue)** (os'e-us) A connective tissue that forms the bony skeleton.

**Bone remodeling** Process involving bone formation and destruction in response to hormonal and mechanical factors.

**Bone resorption** The removal of osseous tissue; part of the continuous bone remodeling process.

**Bowman's capsule** (bo-manz) *See* Glomerular capsule.

**Boyle's law** States that when the temperature is constant, the pressure of a gas varies inversely with its volume.

**Bradycardia** (brad'e-kar'de-ah) A heart rate below 60 beats per minute.

**Brain death** State of irreversible coma, even though life-support measures may have restored other body organs.

**Brain stem** Collectively the midbrain, pons, and medulla of the brain.

**Brain ventricle** Fluid-filled cavity of the brain.

**Branchial groove** (brang'ke-al) An indentation of the surface ectoderm in the embryo; the external acoustic meatus develops from it.

**Bronchioles** Smaller (<1 mm in diameter) branching air passageways inside the lungs.

**Bronchus** (brong'kus) One of the two large branches of the trachea that lead to the lungs.

**Buffer** Chemical substance or system that minimizes changes in pH by releasing or binding hydrogen ions.

**Burn** Tissue damage inflicted by intense heat, electricity, radiation, or certain chemicals, all of which denature cell proteins and kill cells in the affected areas.

**Bursa** (ber'sa) A fibrous sac lined with synovial membrane and containing synovial fluid; occurs between bones and muscle tendons (or other structures), where it acts to decrease friction during movement.

**Bursitis** Inflammation of a bursa.

**Calcaneal tendon** (kal-ka'ne-al) Tendon that attaches the calf muscles to the heelbone (calcaneus); also called the Achilles tendon.

**Calcitonin** (kal'sih-to'nin) Hormone released by the thyroid. Lowers blood calcium levels only when present at high (therapeutic) levels.

**Calculus** (kal'ku-lus) A stone formed within various body parts.

**Callus** (kal'lus) (1) Localized thickening of skin epidermis resulting from physical trauma; (2) repair tissue (fibrous or bony) formed at a fracture site.

**Calorie (cal)** Amount of energy needed to raise the temperature of 1 gram of water 1° Celsius. Energy exchanges associated with biochemical reactions are usually reported in kilocalories (1 kcal = 1000 cal), also called large calories (Cal).

**Calyx** (ka'liks) A cuplike extension of the pelvis of the kidney.

**Canaliculus** (kan'ah-lik'u-lus) Extremely small tubular passage or channel.

**Cancer** A malignant, invasive cellular neoplasm that has the capability of spreading throughout the body or body parts.

**Capillaries** (kap'il-layr'ēs) The smallest of the blood vessels and the sites of exchange between the blood and tissue cells.

**Carbohydrate** (kar'bo-hi'drāt) Organic compound composed of carbon, hydrogen, and oxygen; includes starches, sugars, cellulose.

**Carbonic acid–bicarbonate buffer system** Chemical system that helps maintain pH homeostasis of the blood.

**Carbonic anhydrase** (kar-bon'ik an-hi'drās) Enzyme that facilitates the combination of carbon dioxide with water to form carbonic acid.

**Carcinogen** (kar'si'no-jin) Cancer-causing agent.

**Cardiac cycle** Sequence of events encompassing one complete contraction and relaxation of the atria and ventricles of the heart.

**Cardiac muscle** Specialized muscle of the heart.

**Cardiac output (CO)** Amount of blood pumped out of a ventricle in one minute.

**Cardiac reserve** The difference between resting and maximal cardiac output.

**Cardiogenic shock** Pump failure; the heart is so inefficient that it cannot sustain adequate circulation.

**Cardiovascular system** Organ system that distributes the blood to deliver nutrients and remove wastes.

**Carotene** (kar'o-tēn) Yellow to orange pigment that accumulates in the stratum corneum epidermal layer and in fatty tissue of the hypodermis.

**Carotid body** (kar-rot'id) A receptor in the common carotid artery sensitive to changing oxygen, carbon dioxide, and pH levels of the blood.

**Carotid sinus** (si'nus) A dilation of a common carotid artery; involved in regulation of systemic blood pressure.

**Carrier** A transmembrane protein that changes shape to envelop and transport a polar substance across the cell membrane.

**Cartilage** (kar'ti-lij) White, semiopaque connective tissue.

**Cartilage bone (endochondral bone)** Bone formed by using hyaline cartilage structures as models for ossification.

**Cartilaginous joints** (kar'ti-laj'i-nus) Bones united by cartilage; no joint cavity is present.

**Catabolism** (ka-tab'ō-lizm) Process in which living cells break down substances into simpler substances.

**Catalyst** (kat'ah-list) Substance that increases the rate of a chemical reaction without itself becoming chemically changed or part of the product.

**Cataract** Clouding of the eye's lens; often congenital or age-related.

**Catecholamines** (kat''ē-kol'ah-mēnz) Epinephrine, norepinephrine, and dopamine; a class of amines that act as chemical transmitters.

**Cation** (kat'i-on) An ion with a positive charge.

**Caudal** (kaw'dul) Literally, toward the tail; in humans, the inferior portion of the anatomy.

**Cecum** (se'kum) The blind-ended pouch at the beginning of the large intestine.

**Cell** Structural unit of all living things.

**Cell differentiation** The development of specific and distinctive features in cells, from a single cell (the fertilized egg) to all the specialized cells of adulthood.

**Cell cycle** Series of changes a cell goes through from the time it is formed until it reproduces itself.

**Cell membrane** See Plasma membrane.

**Cellular immunity** Immunity conferred by activated T cells, which directly kill infected or cancerous body cells or cells of foreign grafts and release chemicals that regulate the immune response. Also called cell-mediated immunity.

**Cellular respiration** Metabolic processes in which ATP is produced.

**Cellulose** (sel'u-lōs) A fibrous carbohydrate that is the main structural component of plant tissues.

**Central (Haversian) canal** (hah-ver'zhan) The canal in the center of each osteon that contains minute blood vessels and nerve fibers that serve the needs of the osteocytes.

**Central nervous system (CNS)** Brain and spinal cord.

**Centriole** (sen'tre-ol) Minute body found near the nucleus of the cell; active in cell division.

**Centrosome (cell center)** A region near the nucleus which contains paired organelles called centrioles.

**Cerebellum** (ser''ē-bel'um) Brain region most involved in producing smooth, coordinated skeletal muscle activity.

**Cerebral aqueduct** (ser'ē-bral, sē-re'bral) The slender cavity of the mid-brain that connects the third and fourth ventricles.

**Cerebral arterial circle** (*circle of Willis*) An arterial anastomosis at the base of the brain.

**Cerebral cortex** The outer gray matter region of the cerebral hemispheres.

**Cerebral dominance** Designates the hemisphere that is dominant for language.

**Cerebral palsy** Neuromuscular disability in which voluntary muscles are poorly controlled or paralyzed as a result of brain damage.

**Cerebral white matter** Consists largely of myelinated fibers bundled into large tracts; provides for communication between cerebral areas and lower CNS centers.

**Cerebrospinal fluid (CSF)** (ser''ē-bro-spi'nal) Plasmalike fluid that fills the cavities of the CNS and surrounds the CNS externally; protects the brain and spinal cord.

**Cerebrovascular accident (CVA)** (ser''ē-bro-vas'ku-lar) Condition in which brain tissue is deprived of a blood supply, as in blockage of a cerebral blood vessel; a stroke.

**Cerebrum** (ser'ē-brum) The cerebral hemispheres (including the cerebral cortex, white matter, and basal nuclei).

**Cervical vertebrae** The seven vertebrae of the vertebral column located in the neck.

**Cervix** Lower outlet of the uterus extending into the vagina.

**Channel** A transmembrane protein that forms an aqueous pore, allowing substances to move from one side of the membrane to the other.

**Chemical bond** An energy relationship holding atoms together; involves the interaction of electrons.

**Chemical energy** Energy stored in the bonds of chemical substances.

**Chemical equilibrium** A state of apparent repose created by two reactions proceeding in opposite directions at equal speed.

**Chemical reaction** Process in which molecules are formed, changed, or broken down.

**Chemoreceptor** (ke''mo-re-sep'ter) Receptor sensitive to various chemicals in solution.

**Chemotaxis** (ke''mo-tak'sis) Movement of a cell, organism, or part of an organism toward or away from a chemical substance.

**Cholecystokinin (CCK)** (ko''le-sis'to-ki'nin) An intestinal hormone that stimulates gallbladder contraction and pancreatic juice release.

**Cholesterol** (ko-les'ter-ol'') Steroid found in animal fats as well as in most body tissues; made by the liver.

**Cholinergic fibers** (ko''lin-er'jik) Nerve endings that, upon stimulation, release acetylcholine.

**Chondroblast** (kon'dro-blast) Actively mitotic cell of cartilage.

**Chondrocyte** (kon'dro-sit) Mature cell of cartilage.

**Chorion** (kor'e-on) Outermost fetal membrane; helps form the placenta.

**Chorionic villus sampling** (ko''re-on'ik vil'us) Fetal testing procedure in which bits of the chorionic villi from the placenta are snipped off and the cells karyotyped. This procedure can be done as early as 8 weeks into the pregnancy.

**Choroid** (ko'roid) The vascular middle layer of the eye.

**Choroid plexus** (ko'roid plex'sus) A capillary knot that protrudes into a brain ventricle; produces cerebrospinal fluid.

**Chromatin** (kro'mah-tin) Structures in the nucleus that carry the hereditary factors (genes).

**Chromosomes** (kro'mo-somz) Barlike bodies of tightly coiled chromatin; visible during cell division.

**Chronic obstructive pulmonary disease (COPD)** Collective term for progressive, obstructive respiratory disorders; includes emphysema, chronic bronchitis.

**Chyme** (kim) Semifluid, creamy mass consisting of partially digested food and gastric juice.

**Cilia** (sil'e-ah) Tiny, hairlike projections on cell surfaces that move in a wavelike manner.

**Circumduction** (ser''kum-duk'shun) Movement of a body part so that it outlines a cone in space.

**Cirrhosis** (sī-ro'sis) Chronic disease of the liver, characterized by an overgrowth of connective tissue, or fibrosis.

**Cisterna chyli** (sis-ter'nah ki'li) An enlarged sac at the base of the thoracic duct; the origin of the thoracic duct.

**Cisternae** (sis-ter'ne) Any cavity or enclosed space serving as a reservoir.

**Cleavage** An early embryonic phase consisting of rapid mitotic cell divisions without intervening growth periods; product is a blastocyst.

**Clonal selection** (klo'nul) Process during which a B cell or T cell becomes activated by binding with an antigen.

**Clone** Descendants of a single cell.

**Coagulation** Process in which blood is transformed from a liquid to a gel; blood clotting.

**Cochlea** (kok'le-ah) Snail-shaped chamber of the bony labyrinth that houses the receptor for hearing [the spiral organ (organ of Corti)].

**Codon** (ko'don) The three-base sequence on a messenger RNA molecule that provides the genetic information used in protein synthesis; code for a given amino acid.

**Coenzyme** (ko-en'zim) Nonprotein substance associated with and activating an enzyme, typically a vitamin.

**Cofactor** Metal ion or organic molecule that is required for enzyme activity.

**Collagen fiber** The most abundant of the three fibers found in the matrix of connective tissue.

**Colloid** (kol'oid) (1) A mixture in which the solute particles (usually proteins) do not settle out readily. (2) Substance in the thyroid gland containing thyroglobulin protein.

**Colloid osmotic pressure** (kol'oid ahz-mah'tik) Pressure created in a fluid by large nondiffusible molecules, such as plasma proteins that are prevented from moving through a (capillary) membrane. Such substances tend to draw water to them.

**Colon** Regions of the large intestine; includes ascending, transverse, descending, and sigmoid portions.

**Combination (synthesis) reaction** Chemical reaction in which larger, more complex atoms or molecules are formed from simpler ones.

**Complement** A group of bloodborne proteins, which, when activated, enhance the inflammatory and immune responses and may lead to cell lysis.

**Complementarity of structure and function** The relationship between a structure and its function; i.e., structure determines function.

**Complementary base** Refers to how a given nitrogenous base of DNA or RNA bonds to another nitrogenous base. For example, adenine (A) is the complementary base of thymine (T). The result is base pairing.

**Complete blood count (CBC)** Clinical test that includes counts of all formed elements, a hematocrit, and measurements of erythrocyte size and hemoglobin content.

**Compound** Substance composed of two or more different elements, the atoms of which are chemically united.

**Concentration gradient** The difference in the concentration of a particular substance between two different areas.

**Conducting zone** Includes all respiratory passageways that provide conduits for air to reach the sites of gas exchange (the respiratory zone).

**Conductivity** Ability to transmit an electrical impulse.

**Cones** One of the two types of photoreceptor cells in the retina of the eye; provide for color vision.

**Congenital** (kun-jeh'nih-tul) Existing at birth.

**Congestive heart failure (CHF)** Condition in which the pumping efficiency of the heart is depressed so that circulation is inadequate to meet tissue needs.

**Conjunctiva** (kon'junkt-ti'vah) Thin, protective mucous membrane lining the eyelids and covering the anterior surface of the eye itself.

**Connective tissue** A primary tissue; form and function vary extensively. Functions include support, storage, and protection.

**Consciousness** The ability to perceive, communicate, remember, understand, appreciate, and initiate voluntary movements.

**Contraception** The prevention of conception; birth control.

**Contractility** Muscle cell's ability to move by shortening.

**Contraction** To shorten or develop tension, an ability highly developed in muscle cells.

**Contralateral** Relating to the opposite side.

**Cornea** (kor'ne-ah) Transparent anterior portion of the eyeball; part of the fibrous layer.

**Corona radiata** (kor-o'nah ra-de-ah'tah) (1) Arrangement of elongated follicle cells around a mature ovum; (2) crownlike arrangement of nerve fibers radiating from the internal capsule of the brain to every part of the cerebral cortex.

**Coronary circulation** The functional blood supply of the heart; shortest circulation in the body.

**Cortex** (kor'teks) Outer surface layer of an organ.

**Corticosteroids** (kor'ti-ko-stē'roidz) Steroid hormones released by the adrenal cortex.

**Cortisol (hydrocortisone)** (kor'tih-sol) Glucocorticoid produced by the adrenal cortex.

**Covalent bond** (ko-va'lent) Chemical bond created by electron sharing between atoms.

**Cranial nerves** The 12 nerve pairs that arise from the brain.

**Craniosacral division** Another name for the parasympathetic division of the autonomic nervous system.

**Cranium (cranial bones)** (kra'ne-um) Bony protective encasement of the brain and organs of hearing and equilibrium.

**Creatine kinase** (kre'ah-tin) Enzyme that catalyzes the transfer of phosphate from creatine phosphate to ADP, forming creatine and ATP; important in muscle contraction.

**Creatine phosphate (CP)** (fos-fāt) Compound that serves as an alternative energy source for muscle tissue.

**Creatinine** (kre-at'i-nin) A nitrogenous waste molecule which is not reabsorbed by the kidney; this characteristic makes it useful for measurement of the GFR and glomerular function.

**Crista ampullaris** Sensory receptor organ for rotational acceleration and deceleration housed within the ampulla of each semicircular canal of the inner ear.

**Cross section** A cut running horizontally from right to left, dividing the body or an organ into superior and inferior parts.

**Cutaneous** (ku-ta'ne-us) Pertaining to the skin.

**Cutaneous sensory receptors** Receptors located throughout the skin that respond to stimuli arising outside the body; part of the nervous system.

**Cyclic AMP** Intracellular second messenger that mediates the effects of the first (extracellular) messenger (hormone or neurotransmitter); formed from ATP by a plasma membrane enzyme (adenylate cyclase).

**Cystic fibrosis (CF)** Genetic disorder in which secretion of overly viscous mucus clogs the respiratory passages, predisposes to fatal respiratory infections.

**Cytochromes** (si'to-krōmz) Brightly colored iron-containing proteins that form part of the inner mitochondrial membrane and function as electron carriers in oxidative phosphorylation.

**Cytokines** Small proteins that act as chemical messengers between various parts of the immune system.

**Cytokinesis** (si'to-ki-ne'sis) The division of cytoplasm that occurs after the cell nucleus has divided.

**Cytoplasm** (si'to-plazm) The cellular material surrounding the nucleus and enclosed by the plasma membrane.

**Cytosine (C)** (si'to-sēn) Nitrogen-containing base that is part of a nucleotide structure.

**Cytoskeleton** Literally, cell skeleton. An elaborate series of rods running through the cytosol, supporting cellular structures and providing the machinery to generate various cell movements.

**Cytosol** Viscous, semitransparent fluid substance of cytoplasm in which other elements are suspended.

**Cytotoxic T cell (T<sub>C</sub> cell)** Effector T cell that directly kills foreign cells, cancer cells, or virus-infected body cells by inducing apoptosis (cell suicide).

**Deamination** (de'am-ih-na'shun) Removal of an amine group from an organic compound.

**Decomposition reaction** Chemical reaction in which a molecule is broken down into smaller molecules or its constituent atoms.

**Defecation** (def'ih-ka'shun) Elimination of the contents of the bowels (feces).

**Deglutition** (deg'loo-tish'un) Swallowing.

**Dehydration** (de'hi-dra'shun) Condition of excessive water loss.

**Dehydration synthesis** Process by which a large molecule is synthesized by removing water and covalently bonding smaller molecules together.

**Dendrite** (den'drīt) Branching neuron process that serves as a receptive, or input, region; transmits an electrical signal toward the cell body.

**Dendritic cells** Protective cells that phagocytize antigens, migrate to lymph nodes, and present the antigen to T cells, causing them to activate and mount an immune response; those in the skin are sometimes called Langerhans cells.

**Depolarization** (de-po'ler-ah-za'shun) Loss of a state of polarity; loss or reduction of negative membrane potential.

**Dermatome** (der'mah-tōm) Portion of somite mesoderm that forms the dermis of the skin; also the area of skin innervated by the cutaneous branches of a single spinal nerve.

**Dermis** Layer of skin deep to the epidermis; composed mostly of dense irregular connective tissue.

**Desmosome** (dez'muh-sōm) Cell junction composed of thickened plasma membranes joined by filaments.

**Diabetes insipidus** (di'ah-be'tēz in-sih'pīh-dus) Disease characterized by passage of a large quantity of dilute urine plus intense thirst and dehydration caused by inadequate release of antidiuretic hormone (ADH).

**Diabetes mellitus (DM)** (meh-li'tus) Disease caused by deficient insulin release or by insulin resistance, leading to inability of the body cells to use carbohydrates.

**Dialysis** (di-al'ah-sis) Diffusion of solute(s) through a semipermeable membrane.

**Diapedesis** (di'ah-pē-de'sis) Passage of white blood cells through intact vessel walls into tissue.

**Diaphragm** (di'ah-fram) (1) Any partition or wall separating one area from another; (2) a muscle that separates the thoracic cavity from the lower abdominopelvic cavity.

**Diaphysis** (di-af'i-sis) Elongated shaft of a long bone.

**Diarthrosis** (di'ar-thro'sis) Freely movable joint.

**Diastole** (di-as'to-le) Period of the cardiac cycle when either the ventricles or the atria are relaxing.

**Diastolic pressure** (di-as-tah'lik) Arterial blood pressure reached during or as a result of diastole; lowest level of any given cardiac cycle.

**Diencephalon (interbrain)** (di'en-seh'fuh-lon) That part of the forebrain between the cerebral hemispheres and the midbrain including the thalamus, the epithalamus, and the hypothalamus.

**Differential white blood cell count** Diagnostic test to determine relative proportion of individual leukocyte types.

**Diffusion** (di-fū'zhun) The spreading of particles in a gas or solution with a movement toward uniform distribution of particles; driven by kinetic energy.

**Digestion** A series of catabolic steps in which complex food molecules are broken down to their building blocks by enzymes.

**Digestive system** System that processes food into absorbable units and eliminates indigestible wastes.

**Dipeptide** A combination of two amino acids united by means of a peptide bond.

**Diploë** (dip'lo-ē) The internal layer of spongy bone in flat bones.

**Diploid chromosomal number** The chromosomal number characteristic of an organism, symbolized as  $2n$ ; twice the chromosomal number ( $n$ ) of the gamete; in humans,  $2n = 46$ .

**Diplopia** (dī-plo'pe-ah) Double vision.

**Dipole** (polar molecule) Nonsymmetrical molecules that contain electrically unbalanced atoms.

**Disaccharide** (di-sak'ah-rīd', di-sak'ah-rid) Literally, double sugar; e.g., sucrose, lactose.

**Dislocation (luxation)** Occurs when bones are forced out of their normal alignment at a joint.

**Displacement (exchange) reaction** Chemical reaction in which bonds are both made and broken; atoms become combined with different atoms.

**Distal** (dis'tul) Away from the attached end of a limb or the origin of a structure.

**Diuretics** (di'u-ret'iks) Chemicals that enhance urinary output.

**Diverticulum** (di'ver-tik'u-lum) A pouch or sac in the walls of a hollow organ or structure.

**DNA (deoxyribonucleic acid)** (de-ok'sī-ri'bo-nu-kla'ik) A nucleic acid found in all living cells; it carries the organism's hereditary information.

**DNA replication** Process that occurs before cell division; ensures that all daughter cells have identical genes.

**Dominant traits** Occurs when one allele masks or suppresses the expression of its partner.

**Dominant-recessive inheritance** Reflects the interaction of dominant and recessive alleles.

**Dorsal** (dor'sul) Pertaining to the back; posterior.

**Dorsal root ganglion** Peripheral collection of cell bodies of first-order afferent neurons whose central axons enter the spinal cord.

**Double helix** The secondary structure assumed by two strands of DNA, held together throughout their length by hydrogen bonds between bases on opposite strands.

**Duct (dukt)** A canal or passageway; a tubular structure that provides an exit for the secretions of a gland, or for conducting any fluid.

**Ductus (vas) deferens** Extends from the epididymis to the urethra; propels sperm into the urethra by peristalsis during ejaculation.

**Duodenum** (du'o-de'num) First part of the small intestine.

**Dura mater** (du'rah ma'ter) Outermost and toughest of the three membranes (meninges) covering the brain and spinal cord.

**Dynamic equilibrium** Sense that reports on angular (rotatory) acceleration or deceleration of the head in space.

**Dyskinesia** (dis-kī-ne'ze-ah) Disorders of muscle tone, posture, or involuntary movements.

**Dyspnea** (disp-ne'ah) Difficult or labored breathing; air hunger.

**Eccrine glands** (ek'rin) Sweat glands abundant on the palms, soles of feet, and the forehead.

**Ectoderm** (ek'to-derm) Embryonic germ layer; forms the epidermis of the skin and its derivatives, and nervous tissues.

**Edema** (ë-de'mah) Abnormal increase in the amount of interstitial fluid; causes swelling.

**Effector** (ef-ek'ter) Organ, gland, or muscle capable of being activated by nerve endings.

**Efferent** (ef'er-ent) Carrying away or away from, especially a nerve fiber that carries impulses away from the central nervous system.

**Elastic cartilage** Cartilage with abundant elastic fibers; more flexible than hyaline cartilage.

**Elastic fiber** Fiber formed from the protein elastin, which gives a rubbery and resilient quality to the matrix of connective tissue.

**Electrical energy** Energy formed by the movement of charged particles across cell membranes.

**Electrocardiogram (ECG or EKG)** (e-lek'tro-car'de-o-gram") Graphic record of the electrical activity of the heart.

**Electrochemical gradient** The combined difference in concentration and charge; influences the distribution and direction of diffusion of ions.

**Electroencephalogram (EEG)** (e-lek'tro-en-sef'ah-lo-gram") Graphic record of the electrical activity of nerve cells in the brain.

**Electrolyte** (e-lek'tro-lit) Chemical substances, such as salts, acids, and bases, that ionize and dissociate in water and are capable of conducting an electrical current.

**Electrolyte balance** Refers to the balance between input and output of salts (sodium, potassium, calcium, magnesium) in the body.

**Electromagnetic radiation** Emitted photons (wave packets) of energy, e.g., light, X ray, infrared.

**Electron** Negatively charged subatomic particle; orbits the atom's nucleus.

**Electron shells (energy levels)** Regions of space that consecutively surround the nucleus of an atom.

**Element** One of a limited number of unique varieties of matter that composes substances of all kinds; e.g., carbon, hydrogen, oxygen.

**Embolism** (em'bo-lizm) Obstruction of a blood vessel by an embolus (blood clot, fatty mass, bubble of air, or other debris) floating in the blood.

**Embryo** (em'bre-o) Developmental stage extending from fertilization to the end of the eighth week.

**Emesis** Reflexive emptying of the stomach through the esophagus and pharynx; also known as vomiting.

**Encephalitis** (en'seh-fuh-li-'tis) Inflammation of the brain.

**Endergonic reaction** Chemical reaction that absorbs energy, e.g., an anabolic reaction.

**Endocardium** (en'do-kar'de-um) Endothelial membrane that lines the interior of the heart.

**Endochondral ossification** (en'do-kon'dral) Embryonic formation of bone by the replacement of calcified cartilage; most skeletal bones are formed by this process.

**Endocrine glands** (en'do-krin) Ductless glands that empty their hormonal products directly into the blood.

**Endocrine system** Body system that includes internal organs that secrete hormones.

**Endocytosis** (en'do-si-to'sis) Means by which fairly large extracellular molecules or particles enter cells, e.g., phagocytosis, pinocytosis, receptor-mediated endocytosis.

**Endoderm** (en'do-derm) Embryonic germ layer; forms the lining of the digestive tube and its associated structures.

**Endogenous** (en-doj'ë-nüs) Originating or produced within the organism or one of its parts.

**Endometrium** (en'do-me'tre-um) Mucous membrane lining of the uterus.

**Endomysium** (en'do-mis'e-um) Thin connective tissue surrounding each muscle cell.

**Endoplasmic reticulum (ER)** (en'do-plaz'mik rë-tik'u-lum) Membranous network of tubular or saclike channels in the cytoplasm of a cell.

**Endosteum** (en-dos'te-um) Connective tissue membrane covering internal bone surfaces.

**Endothelium** (en'do-the'le-um) Single layer of simple squamous cells that line the walls of the heart, blood vessels, and lymphatic vessels.

**Energy** The capacity to do work; may be stored (potential energy) or in action (kinetic energy).

**Energy intake** Energy liberated during food oxidation.

**Energy output** Sum of energy lost as heat, as work, and as fat or glycogen storage.

**Enzyme** (en'zim) A protein that acts as a biological catalyst to speed up a chemical reaction.

**Eosinophil** (e'o-sin'o-fil) Granular white blood cell whose granules readily take up an acid stain called eosin.

**Ependymal cell** (ë-pen'di-mul) A type of CNS supporting cell; lines the central cavities of the brain and spinal cord.

**Epidermis** (ep'i-der'mis) Superficial layer of the skin; composed of keratinized stratified squamous epithelium.

**Epидidymis** (ep'i-dī'di-mis) That portion of the male duct system in which sperm mature. Empties into the ductus (or vas) deferens.

**Epidural space** Area between the bony vertebrae and the dura mater of the spinal cord.

**Epiglottis** (ep'i-glot'is) Elastic cartilage at the back of the throat; covers the opening of the larynx during swallowing.

**Epileptic seizures** Abnormal electrical discharges of groups of brain neurons, during which no other messages can get through.

**Epimysium** (ep'i-mis'e-um) Sheath of fibrous connective tissue surrounding a muscle.

**Epinephrine** (ep'i-nef'rin) Chief hormone produced by the adrenal medulla. Also called adrenaline.

**Epiphyseal plate** (e'pi-fis'e-ul) Plate of hyaline cartilage at the junction of the diaphysis and epiphysis that provides for growth in length of a long bone.

**Epiphysis** (e-pif'i-sis) The end of a long bone, attached to the shaft.

**Epithalamus** Most dorsal portion of the diencephalon; forms the roof of the third ventricle with the pineal gland extending from its posterior border.

**Epithelium (epithelial tissue)** (ep'i-the'le-ul) Pertaining to a primary tissue that covers the body surface, lines its internal cavities, and forms glands.

**Erythrocytes** (e-rith'ro-sits) Red blood cells.

**Erythropoiesis** (ë-rith'ro-poi-e'sis) Process of erythrocyte formation.

**Erythropoietin (EPO)** (ë-rith'ro-poi'ë-tin) Hormone that stimulates production of red blood cells.

**Esophagus** (ë-sof'ah-gus) Muscular tube extending from the laryngopharynx through the diaphragm to join the stomach; collapses when not involved in food propulsion.

**Estrogens** (es'tro-jenz) Hormones that stimulate female secondary sex characteristics; female sex hormones.

**Eupnea** (ūp-ne'ah) Normal respiratory rate and rhythm.

**Excess postexercise oxygen consumption (EPOC)** The volume of oxygen required after exercise to replenish stores of O<sub>2</sub>, ATP, creatine phosphate, and glycogen and oxidize the lactic acid formed during exercise. Also called oxygen debt.

**Exchange (displacement) reaction** Chemical reaction in which bonds are both made and broken; atoms become combined with different atoms.

**Excitability (responsiveness)** Ability to respond to stimuli.

**Excitation-contraction (E-C) coupling** Sequence of events by which transmission of an action potential along the sarcolemma leads to the sliding of myofilaments.

**Excitatory postsynaptic potential (EPSP)** Depolarizing graded potential in a postsynaptic neuron.

**Excretion** (ek-skre'shun) Elimination of waste products from the body.

**Exergonic reaction** Chemical reaction that releases energy, e.g., a catabolic or oxidative reaction.

**Exocrine glands** (ek'so-krin) Glands that have ducts through which their secretions are carried to a particular site.

**Exocytosis** (ek'so-si-to'sis) Mechanism by which substances are moved from the cell interior to the extracellular space as a secretory vesicle fuses with the plasma membrane.

**Exons** Amino acid-specifying informational sequences (separated by introns) in the genes of higher organisms.

**Extension** Movement that increases the angle of a joint, e.g., straightening a flexed knee.

**Exteroceptor** (ek'ster-o-sep'tor) Sensory receptor that responds to stimuli from the external world.

**Extracellular fluid (ECF)** Internal fluid located outside cells; includes interstitial fluid, blood plasma, and cerebrospinal fluid.

**Extracellular matrix** Nonliving material in connective tissue consisting of ground substance and fibers that separates the living cells.

**Extrasystole** (ek'strah-sis'to-le) Premature heart contraction.

**Extrinsic** (ek-strin'sik) Of external origin.

**Extrinsic eye muscles** The six skeletal muscles that attach to and move each eye.

**Facilitated diffusion** Passive transport process used by certain large or charged molecules (e.g., glucose, Na<sup>+</sup>) that are unable to pass through the plasma membrane unaided. Involves movement through channels or movement facilitated by a membrane carrier.

**Fallopian tube** (fah-lō'pe-un) *See* Uterine tube.

**Fascia** (fash'e-ah) Layers of fibrous tissue covering and separating muscle.

**Fascicle** (fas'i-kl) Bundle of nerve or muscle fibers bound together by connective tissue.

**Fatty acids** Linear chains of carbon and hydrogen atoms (hydrocarbon chains) with an organic acid group at one end. A constituent of fat.

**Feces** (fe'sēz) Material discharged from the bowel; composed of food residue, secretions, bacteria.

**Fenestrated** (fen'es-tra-tid) Pierced with one or more small openings.

**Fertilization** Fusion of the sperm and egg nuclei.

**Fetus** Developmental stage extending from the ninth week of development to birth.

**Fiber** A slender threadlike structure or filament. *See also* Nerve fiber, Muscle fiber.

**Fibrillation** Condition of rapid and irregular or out-of-phase heart contractions.

**Fibrin** (fi'brin) Fibrous insoluble protein formed during blood clotting.

**Fibrinogen** (fi-brin'o-jin) A soluble blood protein that is converted to insoluble fibrin during blood clotting.

**Fibrinolysis** Process that removes unneeded blood clots when healing has occurred.

**Fibroblast** (fi'bro-blast) Young, actively mitotic cell that forms the fibers of connective tissue.

**Fibrocarrilage** The most compressible type of cartilage; resistant to stretch. Forms vertebral discs and knee joint cartilages.

**Fibrocyte** (fi'bro-sīt) Mature fibroblast; maintains the matrix of fibrous types of connective tissue.

**Fibrosis** Proliferation of fibrous connective tissue called scar tissue.

**Fibrous joints** Bones joined by fibrous tissue; no joint cavity is present.

**Filtrate** A plasma-derived fluid that is processed by the renal tubules to form urine.

**Filtration** Passage of a solvent and dissolved substances through a membrane or filter.

**First-degree burn** A burn in which only the epidermis is damaged.

**Fissure** (fi'h'sher) (1) A groove or cleft; (2) the deepest depressions or inward folds on the brain.

**Fixator** (fix'a-ter) Muscle that immobilizes one or more bones, allowing other muscles to act from a stable base.

**Flagellum** (flah-jel'lum) Long, whiplike cellular extension containing microtubules; propels sperm and some single-celled eukaryotes.

**Flexion** (flek'shun) Movement that decreases the angle of the joint, e.g., bending the knee from a straight to an angled position.

**Flexor (withdrawal) reflex** Reflex initiated by a painful stimulus (actual or perceived); causes automatic withdrawal of the threatened body part from the stimulus.

**Fluid mosaic model** A depiction of the structure of the membranes of a cell as phospholipid bilayers in which proteins are dispersed.

**Follicle** (fah'lih-kul) (1) Ovarian structure consisting of a developing egg surrounded by one or more layers of follicle cells; (2) colloid-containing structure of the thyroid gland; (3) B cell-rich region in lymphoid tissue.

**Follicle-stimulating hormone (FSH)** Hormone produced by the anterior pituitary that stimulates ovarian follicle production in females and sperm production in males.

**Fontanelles** (fon'tah-nelz') Fibrous membranes at the angles of cranial bones that accommodate brain growth in the fetus and infant.

**Foramen** (fo-ra'men) Hole or opening in a bone or between body cavities.

**Forebrain (prosencephalon)** Anterior portion of the brain consisting of the telencephalon and the diencephalon.

**Formed elements** Cellular portion of blood.

**Fossa** (fos'ah) A depression, often an articular surface.

**Fovea** (fo've-ah) A pit.

**Fracture** A break in a bone.

**Free radicals** Highly reactive chemicals with unpaired electrons that can scramble the structure of proteins, lipids, and nucleic acids.

**Frontal (coronal) plane** Longitudinal (vertical) plane that divides the body or an organ into anterior and posterior parts.

**Fulcrum** The fixed point on which a lever moves when a force is applied.

**Fundus** (fun'dus) Base of an organ; part farthest from the opening of the organ. For example, the posterior wall of the eye.

**G protein** Protein that relays signals between extracellular first messengers (hormones or neurotransmitters) and intracellular second messengers (such as cyclic AMP) via an effector enzyme.

**Gallbladder** Sac beneath the right lobe of the liver used for bile storage.

**Gallstones (biliary calculi)** Crystallized cholesterol that obstructs the flow of bile from the gallbladder.

**Gamete** (gam'ēt) Sex or germ cell.

**Gametogenesis** (gam'eh-to-jen'eh-sis) Formation of *gametes*.

**Ganglion** (gang'gle-on) Collection of nerve cell bodies outside the CNS.

**Gap junction** A passageway between two adjacent cells; formed by transmembrane proteins called connexons.

**Gastrin** Hormone secreted in the stomach; regulates gastric juice secretion by stimulating HCl production.

**Gastroenteritis** Inflammation of the gastrointestinal tract.

**Gastrulation** (gas'troo-la'shun) Developmental process that produces the three primary germ layers (ectoderm, mesoderm, and endoderm).

**Gene** One of the biological units of heredity located in chromatin; transmits hereditary information.

**Genetic code** Refers to the rules by which the base sequence of a DNA gene is translated into protein structures (amino acid sequences).

**Genitalia** (jen'i-ta'le-ă) The internal and external reproductive organs.

**Genome** The complete set of chromosomes derived from one parent (the haploid genome); or the two sets of chromosomes, i.e., one set from the egg, the other from the sperm (the diploid genome).

**Genotype** (jen'o-tip) One's genetic makeup or genes.

**Germ layers** Three cellular layers (ectoderm, mesoderm, and endoderm) that represent the initial specialization of cells in the embryonic body and from which all body tissues arise.

**Gestation period** (jes-ta'shun) The period of pregnancy; about 280 days for humans.

**Gland** Organ specialized to secrete or excrete substances for further use in the body or for elimination.

**Glaucoma** (glaw-ko'mah) Condition in which intraocular pressure increases to levels that cause compression of the retina and optic nerve; results in blindness unless detected early.

**Glial cells** (gle'al) *See* Neuroglia.

**Glomerular capsule** (glo-mer'yoo-ler) Double-walled cup at end of a renal tubule; encloses a glomerulus. Also called Bowman's capsule.

**Glomerular filtration rate (GFR)** Rate of filtrate formation by the kidneys.

**Glomerulus** (glo-mer'u-lus) (1) Cluster of capillaries forming part of the nephron; forms filtrate; (2) odor-specific processing unit in olfactory bulb.

**Glottis** (glah'tis) Opening between the vocal cords in the larynx.

**Glucagon** (gloo'kah-gon) Hormone formed by alpha cells of pancreatic islets; raises the glucose level of blood.

**Glucocorticoids** (gloo'ko-kor'ti-koidz) Adrenal cortex hormones that increase blood glucose levels and aid the body in resisting long-term stressors.

**Gluconeogenesis** (gloo'ko-ne'o-jen'ě-sis) Formation of glucose from noncarbohydrate molecules.

**Glucose** (gloo'kōs) Principal blood sugar; a hexose.

**Glycerol** (glis'er-ol) A modified simple sugar (a sugar alcohol); a building block of fats.

**Glycocalyx (cell coat)** (gli'ko-kal'iks) A layer of externally facing glycoproteins on a cell's plasma membrane; its components determine blood

type and are involved in the cellular interactions of fertilization, embryonic development, and immunity, and act as an adhesive between cells.

**Glycogen** (gli'ko-jin) Main carbohydrate stored in animal cells; a polysaccharide.

**Glycogenesis** (gli'ko-jen'ě-sis) Formation of glycogen from glucose.

**Glycogenolysis** (gli'ko-jě-nol'i-sis) Breakdown of glycogen to glucose.

**Glycolipid** (gli'ko-lip'id) A lipid with one or more covalently attached sugars.

**Glycolysis** (gli-kol'i-sis) Breakdown of glucose to pyruvic acid—an anaerobic process.

**Goblet cells** Individual cells (unicellular glands) that produce mucus.

**Golgi apparatus** (gol'je) Membranous system close to the cell nucleus that packages protein secretions for export, packages enzymes into lysosomes for cellular use, and modifies proteins destined to become part of cellular membranes.

**Gonad** (go'nad) Primary reproductive organ; i.e., the testis of the male or the ovary of the female.

**Gonadocorticoids** (gon'ah-do-kor'ti-koidz) Sex hormones, primarily androgens, secreted by the adrenal cortex.

**Gonadotropins** (gon'ah-do-trōp'inz) Gonad-stimulating hormones produced by the anterior pituitary.

**Graded muscle responses** Variations in the degree of muscle contraction by changing either the frequency or strength of the stimulus.

**Graded potential** A local change in membrane potential that varies directly with the strength of the stimulus, declines with distance.

**Graves' disease** Disorder resulting from hyperactive thyroid gland.

**Gray matter** Gray area of the central nervous system; contains neuronal cell bodies and their dendrites.

**Growth hormone (GH)** Hormone that stimulates growth in general; produced in the anterior pituitary; also called somatotropin.

**Guanine (G)** (gwan'ēn) One of two major purines occurring in all nucleic acids.

**Gustation** (gus-ta'shun) Taste.

**Gyrus** (ji'rus) An outward fold of the surface of the cerebral cortex.

**Hair follicle** Structure with outer and inner root sheaths extending from the epidermal surface into the dermis and from which new hair develops.

**Hapten** (hap'ten) An incomplete antigen; has reactivity but not immunogenicity.

**Haversian system** (hah-ver'zhen) *See* Osteon.

**Heart attack (coronary)** *See* Myocardial infarction.

**Heart block** Impaired transmission of impulses from atrium to ventricle resulting in abnormally slow heart rhythms.

**Heart murmur** Abnormal heart sound (usually resulting from valve problems).

**Heimlich maneuver** Procedure in which the air in a person's own lungs is used to expel an obstructing piece of food.

**Helper T cell (T<sub>H</sub> cell)** Type of T lymphocyte that orchestrates cellular immunity by direct contact with other immune cells and by releasing chemicals called cytokines; also helps to mediate the humoral response by interacting with B cells.

**Hematocrit** (he-mat'o-krit) The percentage of total blood volume occupied by erythrocytes.

**Hematoma** (he'mah-to'mah) Mass of clotted blood that forms at an injured site.

- Hematopoiesis** (hem"ah-to-poi-e'sis) Blood cell formation; hemopoiesis.
- Hematopoietic stem cell** (hem"ah-to-poi-et'ik) Bone marrow cell that gives rise to all the formed elements of blood; hemocytoblast.
- Heme** (hēm) Iron-containing pigment that is essential to oxygen transport by hemoglobin.
- Hemoglobin** (he'muh-glo-bin) Oxygen-transporting protein of erythrocytes.
- Hemolysis** (he-mah'lē-sis) Rupture of erythrocytes.
- Hemophilia** (he"mo-fil'e-ah) A term loosely applied to several different hereditary bleeding disorders that exhibit similar signs and symptoms.
- Hemopoiesis** (he"mo-poi-e'sis) *See* Hematopoiesis.
- Hemorrhage** (hem'or-ij) Loss of blood from the vessels by flow through ruptured walls; bleeding.
- Hemostasis** (he"mo-sta'sis) Stoppage of bleeding.
- Heparin** Natural anticoagulant secreted into blood plasma.
- Hepatic portal system** (hē-pat'ik) Circulation in which the hepatic portal vein carries dissolved nutrients to the liver tissues for processing.
- Hepatitis** (hep"ah-ti'tis) Inflammation of the liver.
- Hernia** (her'ne-ah) Abnormal protrusion of an organ or a body part through the containing wall of its cavity.
- Heterozygous** (het'er-o-zi'gus) Having different allelic genes at a given locus or (by extension) many loci.
- Hilton's law** Any nerve serving a muscle that produces movement at a joint also innervates the joint and the skin over the joint.
- Hilum** (hi'lum) The indented region of an organ from which blood and/or lymphatic vessels and nerves enter and exit.
- Hippocampus** Limbic system structure that plays a role in converting new information into long-term memories.
- Histamine** (his'tuh-mēn) A chemical messenger (neurotransmitter or paracrine); causes vasodilation and increased capillary permeability; in stomach causes acid secretion.
- Histology** (his-tol'o-je) Branch of anatomy dealing with the microscopic structure of tissues.
- HIV (human immunodeficiency virus)** Virus that destroys helper T cells, thus depressing adaptive immunity; symptomatic AIDS gradually appears when lymph nodes can no longer contain the virus.
- Holocrine glands** (hol'o-krin) Glands that accumulate their secretions within their cells; secretions are discharged only upon rupture and death of the cell.
- Homeostasis** (ho"me-o-sta'sis) A state of body equilibrium or stable internal environment of the body.
- Homologous** (ho-mol'ō-gus) Parts or organs corresponding in structure but not necessarily in function.
- Homozygous** (ho-mo-zi'gus) Having identical genes at one or more loci.
- Hormones** Steroidal or amino acid-based molecules released to the blood that act as chemical messengers to regulate specific body functions.
- Humoral immunity** (hu'mer-ul) Immunity conferred by antibodies present in blood plasma and other body fluids.
- Huntington's disease** Hereditary disorder leading to degeneration of the basal nuclei and the cerebral cortex.
- Hyaline cartilage** (hi'ah-lin) The most abundant cartilage type in the body; provides firm support with some pliability.
- Hydrochloric acid (HCl)** (hi"dro-klor'ik) Acid that aids protein digestion in the stomach; produced by parietal cells.
- Hydrogen bond** Weak bond in which a hydrogen atom forms a bridge between two electron-hungry atoms. An important intramolecular bond.
- Hydrogen ion (H<sup>+</sup>)** A hydrogen atom minus its electron and therefore carrying a positive charge (i.e., a proton).
- Hydrolysis** (hi"drah'lā-sis) Process in which water is used to split a substance into smaller particles.
- Hydrophilic** (hi"dro-fil'ik) Refers to molecules, or portions of molecules, that interact with water and charged particles.
- Hydrophobic** (hi"dro-fo'bik) Refers to molecules, or portions of molecules, that interact only with nonpolar molecules.
- Hydrostatic pressure** (hi"dro-stā'tic) Pressure of fluid in a system.
- Hydroxyl ion (OH<sup>-</sup>)** (hi-drok'sil) An ion liberated when a hydroxide (a common inorganic base) is dissolved in water.
- Hyperalgesia** Pain amplification.
- Hypercapnia** (hi"per-kap'ne-ah) High carbon dioxide levels in the blood.
- Hyperemia** An increase in blood flow into a tissue or organ; congested with blood.
- Hyperglycemic** (hi"per-gli-se'mik) Term used to describe hormones such as glucagon that elevate blood glucose level.
- Hyperopia** (hi"per-o'pe-ah) A condition in which visual images are routinely focused behind rather than on the retina; commonly known as farsightedness.
- Hyperplasia** (hi"per-pla'ze-ah) Accelerated growth, e.g., in anemia, the bone marrow produces red blood cells at a faster rate.
- Hyperpnea** (hi"perp-ne'ah) An increase in ventilation in response to metabolic need (e.g., during exercise).
- Hyperpolarization** An increase in membrane potential in which the membrane becomes more negative than resting membrane potential.
- Hypersensitivity** Overzealous immune response to an otherwise harmless antigen.
- Hypertension** (hi"per-ten'shun) High blood pressure.
- Hypertonic** (hi"per-ton'ik) Excessive, above normal, tone or tension.
- Hypertonic solution** A solution that has a higher concentration of non-penetrating solutes than the reference cell; having greater osmotic pressure than the reference solution (blood plasma or interstitial fluid).
- Hypertrophy** (hi-per'trah-fe) Increase in size of a tissue or organ independent of the body's general growth.
- Hyperventilation** An increase in the depth and rate of breathing that is in excess of the body's need for removal of carbon dioxide.
- Hypocapnia** Low carbon dioxide levels in the blood.
- Hypodermis** (superficial fascia) Subcutaneous tissue just deep to the skin; consists of adipose plus some areolar connective tissue.
- Hypoglycemic** (hi"po-gli-se'mik) Term used to describe hormones such as insulin that decrease blood glucose level.
- Hyponatremia** Abnormally low concentrations of sodium ions in extracellular fluid.
- Hypoproteinemia** (hi"po-pro'te-i-ne'me-ah) A condition of unusually low levels of plasma proteins causing a reduction in colloid osmotic pressure; results in tissue edema.
- Hypotension** Low blood pressure.
- Hypothalamic-hypophyseal tract** (hi"po-thah-lam'ik hi"po-fiz'-e-al) Nerve bundles that run through the infundibulum and connect the posterior pituitary to the hypothalamus.
- Hypothalamus** (hi"po-thal'ah-mus) Region of the diencephalon forming the floor of the third ventricle of the brain.

**Hypotonic** (hi"po-ton'ik) Below normal tone or tension.

**Hypotonic solution** A solution that is more dilute (containing fewer nonpenetrating solutes) than the reference cell. Cells placed in hypotonic solutions plump up rapidly as water rushes into them.

**Hypoventilation** A decrease in the depth and rate of breathing; characterized by an increase in blood carbon dioxide.

**Hypovolemic shock** (hi"po-vo-le'mik) Most common form of shock; results from extreme blood loss.

**Hypoxia** (hi-pok'se-ah) Condition in which inadequate oxygen is available to tissues.

**Ileocecal valve** (il'e-o-se'kal) Site where the small intestine joins the large intestine.

**Ileum** (il'e-um) Terminal part of the small intestine; between the jejunum and the cecum of the large intestine.

**Immune system** A functional system whose components attack foreign substances or prevent their entry into the body.

**Immunity** (im'un'i-te) Ability of the body to resist many agents (both living and nonliving) that can cause disease; resistance to disease.

**Immunocompetence** Ability of the body's immune cells to recognize (by binding) specific antigens; reflects the presence of plasma membrane-bound receptors.

**Immunodeficiency** Any congenital or acquired condition causing a deficiency in the production or function of immune cells or certain molecules (complement, antibodies, etc.) required for normal immunity.

**In vitro** (in ve'tro) In a test tube, glass, or artificial environment.

**In vivo** (in ve'vo) In the living body.

**Incompetent valve** Valve which does not close properly.

**Incontinence** Inability to control micturition or defecation voluntarily.

**Infarct** (in'farkt) Region of dead, deteriorating tissue resulting from a lack of blood supply.

**Infectious mononucleosis** Highly contagious viral disease; marked by excessive agranulocytes.

**Inferior (caudal)** Pertaining to a position toward the lower or tail end of the long axis of the body.

**Inferior vena cava** Vein that returns blood from body areas below the diaphragm.

**Inflammation** (in'flah-ma'shun) An innate (nonspecific) defensive response of the body to tissue injury; includes dilation of blood vessels and an increase in vessel permeability; indicated by redness, heat, swelling, and pain.

**Infundibulum** (in'fun-dib'u-lum) (1) A stalk of tissue that connects the pituitary gland to the hypothalamus; (2) the distal end of the uterine (fallopian) tube.

**Inguinal** (ing'wi-nal) Pertaining to the groin region.

**Inhibitory postsynaptic potential (IPSP)** A graded potential in a postsynaptic neuron that inhibits action potential generation; usually hyperpolarizing.

**Inner cell mass** Accumulation of cells in the blastocyst from which the embryo develops.

**Innervation** (in'er-va'shun) Supply of nerves to a body part.

**Inorganic compound** Chemical substances that do not contain carbon, including water, salts, and many acids and bases.

**Insertion** Movable attachment of a muscle.

**Insula** Lobe of the cerebral cortex that is buried in the lateral sulcus beneath portions of the parietal, frontal, and temporal lobes.

**Insulin** A hormone that enhances the carrier-mediated diffusion of glucose into tissue cells, thus lowering blood glucose levels.

**Insulin resistance** State in which a greater than normal amount of insulin is required to maintain normal glucose blood levels.

**Integration** The process by which the nervous system processes and interprets sensory input and makes decisions about what should be done at each moment.

**Integumentary system** (in-teg'u-men'tar-e) Skin and its derivatives; provides the external protective covering of the body.

**Intercalated discs** (in-ter'kah-la'ted) Specialized connections between myocardial cells containing gap junctions and desmosomes.

**Interferons (IFNs)** (in-ter-fēr'ons) Proteins released from virus-infected (and other) cells that protect uninfected cells from viral takeover. Also inhibit some cancers.

**Internal capsule** Band of projection fibers that runs between the basal nuclei and the thalamus.

**Internal respiration** Exchange of gases between blood and tissue fluid and between tissue fluid and cells.

**Interneuron (association neuron)** Nerve cell located between motor and sensory neurons that shuttles signals through CNS pathways where integration occurs.

**Interoceptor** (in'ter-o-sep'tor) Sensory receptor in the viscera that is sensitive to changes and stimuli within the body's internal environment; also called visceroreceptor.

**Interphase** One of two major periods in the cell life cycle; includes the period from cell formation to cell division.

**Interstitial endocrine cells** Cells located in the loose connective tissue surrounding the seminiferous tubules; they produce androgens (most importantly testosterone), which are secreted into the surrounding interstitial fluid.

**Interstitial fluid (IF)** (in'ter-stish'al) Fluid between the cells.

**Interstitial lamellae** Incomplete lamellae that lie between intact osteons, filling the gaps between forming osteons, or representing the remnants of an osteon that has been cut through by bone remodeling.

**Intervertebral discs** (in'ter-ver'teh-brul) Discs of fibrocartilage between vertebrae.

**Intracapsular ligament** Ligament located within and separate from the articular capsule of a synovial joint.

**Intracellular fluid (ICF)** (in'trah-sel'u-ler) Fluid within a cell.

**Intrinsic factor** Substance produced by the stomach that is required for vitamin B<sub>12</sub> absorption.

**Intron** Noncoding segment or portion of DNA that ranges from 60 to 100,000 nucleotides long.

**Involuntary muscle** Muscle that cannot ordinarily be controlled voluntarily (e.g., smooth and cardiac muscle).

**Involuntary nervous system** The autonomic nervous system.

**Ion** (i'on) Atom or molecule with a positive or negative electric charge.

**Ionic bond** (i-ah'nik) Chemical bond formed by electron transfer between atoms.

**Ipsilateral** (ip'sih-lā'ter-ul) Situated on the same side.

**Ischemia** (is-ke'me-ah) Local decrease in blood supply.

**Isograft** Tissue graft donated by an identical twin.

**Isomer** (i'so-mer) One of two or more substances that has the same molecular formula but with its atoms arranged differently.

**Isometric contraction** (i'so-mē'trik) Contraction in which the muscle does not shorten (the load is too heavy) but its internal tension increases.

**Isotonic contraction** (i'so-tah'nik) Contraction in which muscle tension remains constant at a given load, and the muscle shortens.

**Isotonic solution** A solution with a concentration of nonpenetrating solutes equal to that found in the reference cell.

**Isotopes** (i'so-tōps) Different atomic forms of the same element, which vary only in the number of neutrons they contain; the heavier species tend to be radioactive.

**Jejunum** (jě-joo'num) The part of the small intestine between the duodenum and the ileum.

**Joint (articulation)** The junction of two or more bones.

**Joint kinesthetic receptor** (kin'es-thet'ik) Receptor that provides information on joint position and motion.

**Juxtaglomerular complex (JGC)** (juks'tah-glo-mer'u-lar) Cells of the distal part of the ascending limb of the nephron loop and afferent arteriole located close to the glomerulus; involved in blood pressure regulation (via release of the hormone renin) and autoregulation of GFR.

**Karyotype** (kar'e-o-tip) The diploid chromosomal complement, typically shown as homologous chromosome pairs arranged from longest to shortest (X and Y are arranged by size rather than paired).

**Keratin** (ker'ah-tin) Fibrous protein found in the epidermis, hair, and nails that makes those structures hard and water resistant; precursor is keratohyaline.

**Ketones (ketone bodies)** (ke'tōnz) Fatty acid metabolites; strong organic acids.

**Ketosis** (kē-tō'sis) Excess levels of ketone bodies in blood. Called ketoacidosis if blood pH is low.

**Killer T cell** See Cytotoxic T cell.

**Kilocalories (kcal)** See Calorie.

**Kinetic energy** (ki-net'ik) The energy of motion or movement, e.g., the constant movement of atoms, or the push given to a swinging door that sets it into motion.

**Krebs cycle** Aerobic metabolic pathway occurring within mitochondria, in which food metabolites are oxidized and CO<sub>2</sub> is liberated, and coenzymes are reduced. Also called the citric acid cycle.

**Labia** (la'be-ah) Lips; singular: labium.

**Labor** Collective term for the series of events that expel the fetus from the uterus.

**Labyrinth** (lab'i-rinth") Bony cavities and membranes of the inner ear.

**Lacrimal** (lak'ri-mal) Pertaining to tears.

**Lactation** (lak-ta'shun) Production and secretion of milk.

**Lacteal** (lak'te-al) Special lymphatic capillaries of the small intestine that take up lipids.

**Lactic acid** (lak'tik) Product of anaerobic metabolism, especially in muscle.

**Lacuna** (lah-ku'nah) A small space, cavity, or depression; lacunae in bone or cartilage are occupied by cells.

**Lamella** (lah-mel'ah) A layer, such as of bone matrix in an osteon of compact bone.

**Lamina** (lam'i-nah) (1) A thin layer or flat plate; (2) the portion of a vertebra between the transverse process and the spinous process.

**Large intestine** Portion of the digestive tract extending from the ileocecal valve to the anus; includes the cecum, appendix, colon, rectum, and anal canal.

**Larynx** (lar'ingks) Cartilaginous organ located between the trachea and the pharynx; voice box.

**Latent period** Period of time between stimulation and the onset of muscle contraction.

**Lateral** Away from the midline of the body.

**Leptin** Hormone released by fat cells that signals satiety.

**Leukemia** Refers to a group of cancerous conditions of white blood cells.

**Leukocytes** (loo'ko-sits) White blood cells; formed elements involved in body protection that take part in inflammatory and immune responses.

**Leukocytosis** An increase in the number of leukocytes (white blood cells); usually the result of a microbiological attack on the body.

**Leukopenia** (loo'ko-pe'ne-ah) Abnormally low white blood cell count.

**Leukopoiesis** The production of white blood cells.

**Lever system** Consists of a lever (bone), effort (muscle action), resistance (weight of object to be moved), and fulcrum (joint).

**Ligament** (lig'ah-ment) Band of regular fibrous tissue that connects bones.

**Ligands** Signaling chemicals that bind specifically to membrane receptors.

**Limbic system** (lim'bik) Functional brain system involved in emotional response and memory formation.

**Lipid** (lih'pid) Organic compound formed of carbon, hydrogen, and oxygen; examples are fats and cholesterol.

**Lipolysis** (li-pol'i-sis) The breakdown of stored fats into glycerol and fatty acids.

**Liver** Lobed accessory organ that overlies the stomach; produces bile to help digest fat, and serves other metabolic and regulatory functions.

**Lumbar** (lum'bar) Portion of the back between the thorax and the pelvis.

**Lumbar vertebrae** The five vertebrae of the lumbar region of the vertebral column, commonly called the small of the back.

**Lumen** (loo'min) Cavity inside a tube, blood vessel, or hollow organ.

**Luteinizing hormone (LH)** (lu'te-in-iz'ing) Anterior pituitary hormone that aids maturation of cells in the ovary and triggers ovulation in females. In males, causes the interstitial endocrine cells of the testis to produce testosterone.

**Lymph** (limf) Protein-containing fluid transported by lymphatic vessels.

**Lymph node** Small lymphoid organ that filters lymph; contains macrophages and lymphocytes.

**Lymphatic system** (lim-fat'ik) System consisting of lymphatic vessels, lymph nodes, and lymph; drains excess tissue fluid from the extracellular space. The nodes provide sites for immune surveillance.

**Lymphatics** General term used to designate the lymphatic vessels that collect and transport lymph.

**Lymphocyte** Agranular white blood cell that arises from bone marrow and becomes functionally mature in the lymphoid organs of the body.

**Lysosomes** (li'so-sōmz) Organelles that originate from the Golgi apparatus and contain strong digestive enzymes.

**Lysozyme** (li'so-zim) Enzyme in sweat, saliva, and tears that is capable of destroying certain kinds of bacteria.

**Macromolecules** Large, complex molecules containing from 100 to over 10,000 subunits.

**Macrophage** (mak'ro-fāj") Protective cell type common in connective tissue, lymphoid tissue, and many body organs; phagocytizes tissue cells, bacteria, and other foreign debris; presents antigens to T cells in the immune response.

**Macula** (mak'u-lah) (1) Receptor for linear acceleration, deceleration, and gravity, located within the vestibule of the inner ear; (2) a colored area or spot.

**Malignant** (muh-lig'nent) Life threatening; pertains to neoplasms that spread and lead to death, such as cancer.

**Malignant melanoma** (mel'ah-no'mah) Cancer of the melanocytes; can begin wherever there is pigment.

**Mammary glands** (mam'mer-e) Milk-producing glands of the breast.

**Mandible** (man'di-bl) Lower jawbone; U shaped, largest bone of the face.

**Mass number** Sum of the number of protons and neutrons in the nucleus of an atom.

**Mast cells** Immune cells that function to detect foreign substances in the tissue spaces and initiate local inflammatory responses against them; typically found clustered deep to an epithelium or along blood vessels.

**Mastication** (mas'ti-ka'shun) Chewing.

**Meatus** (me-a'tus) External opening of a canal.

**Mechanical advantage (power lever)** Condition that occurs when the load is close to the fulcrum and the effort is applied far from the fulcrum; allows a small effort exerted over a relatively large distance to move a large load over a small distance.

**Mechanical disadvantage (speed lever)** Condition that occurs when the load is far from the fulcrum and the effort is applied near the fulcrum; the effort applied must be greater than the load to be moved.

**Mechanical energy** The energy directly involved in moving matter; e.g., in bicycle riding, the legs provide the mechanical energy that moves the pedals.

**Mechanoreceptor** (meh'kē-no-re-sep'tor) Receptor sensitive to mechanical pressure such as touch, sound, or exerted by muscle contraction.

**Medial** (me'de-ahl) Toward the midline of the body.

**Median (midsagittal) plane** Specific sagittal plane that lies exactly in the midline.

**Mediastinum** (me'de-ah-sti'num) The medial cavity of the thorax containing the heart, great vessels, and trachea.

**Medulla** (mē-dul'ah) Central portion of certain organs.

**Medulla oblongata** (mē-dul'ah ob'long-gah'tah) Inferiormost part of the brain stem.

**Medullary cavity** Central cavity of a long bone. Contains yellow or red (bone) marrow.

**Meiosis** (mi-o'sis) Nuclear division process that reduces the chromosomal number by half and results in the formation of four haploid (*n*) cells; occurs only in certain reproductive organs.

**Melanin** (mel'ah-nin) Dark pigment formed by cells called melanocytes; imparts color to skin and hair.

**Melatonin** (mel'ah-to'nin) A hormone secreted by the pineal gland; secretion peaks at night and helps set sleep-wake cycles; also a powerful antioxidant.

**Membrane potential** Voltage across the plasma membrane.

**Membrane receptors** A large, diverse group of integral proteins and glycoproteins that serve as binding sites for signaling molecules.

**Memory cells** Members of T cell and B cell clones that provide for immunological memory.

**Menarche** (mē-nar'ke) Establishment of menstrual function; the first menstrual period.

**Meninges** (mē-nin'jēz) Protective coverings of the central nervous system; from the most external to the most internal, the dura mater, arachnoid mater, and pia mater.

**Meningitis** (mē-nin-ji'tis) Inflammation of the meninges.

**Menopause** Period of life when, prompted by hormonal changes, ovulation and menstruation cease.

**Menstruation** (men'stroo-a'shun) The periodic, cyclic discharge of blood, secretions, tissue, and mucus from the mature female uterus in the absence of pregnancy.

**Merocrine glands** (mer'o-krin) Glands that produce secretions intermittently; secretions do not accumulate in the gland.

**Mesencephalon** (mes'en-sef'ah-lon) One of the three primary vesicles of the developing brain; becomes the midbrain.

**Mesenchyme** (meh'zin-kīm) Common embryonic tissue from which all connective tissues arise.

**Mesenteries** (mes'en-ter'ēz) Double-layered extensions of the peritoneum that support most organs in the abdominal cavity.

**Mesoderm** (mez'o-derm) Primary germ layer that forms the skeleton and muscles of the body.

**Mesothelium** (mez'o-the'le-um) The epithelium found in serous membranes lining the ventral body cavity and covering its organs.

**Messenger RNA (mRNA)** Long nucleotide strands that reflect the exact nucleotide sequences of the genetically active DNA and carry the DNA's message.

**Metabolic rate** (mēt'ah-bol'ik) Energy expended by the body per unit time.

**Metabolic water (water of oxidation)** Water produced from cellular metabolism (about 10% of our body's water).

**Metabolism** (mē-tab'o-lizm) Sum total of the chemical reactions occurring in the body cells.

**Metaphase** Second stage of mitosis.

**Metastasis** (mē-tas'tah-sis) The spread of cancer from one body part or organ into another not directly connected to it.

**Metencephalon (afterbrain)** A secondary brain vesicle; anterior portion of the rhombencephalon of the developing brain; becomes the pons and the cerebellum.

**MHC (major histocompatibility complex) proteins** Molecules on the outer surface of the plasma membrane of all cells; help the immune system distinguish self from nonself. T cells recognize antigens only when combined with these proteins.

**Microfilaments** (mi'kro-fil'ah-ments) Thin strands of the contractile protein actin.

**Microglial cells** (mi-kro'gle-al) A type of CNS supporting cell; can transform into phagocytes in areas of neural damage or inflammation.

**Microtubules** (mi'kro-tu'būlz) One of three types of rods in the cytoskeleton of a cell; hollow tubes made of spherical protein that determine the cell shape as well as the distribution of cellular organelles.

**Microvilli** (mi'kro-vil'i) Tiny projections on the free surfaces of some epithelial cells; increase surface area for absorption.

**Micturition** (mik'tu-rish'un) Urination, or voiding; emptying the bladder.

**Midbrain (mesencephalon)** Region of the brain stem between the diencephalon and the pons.

**Midsagittal (median) plane** Specific sagittal plane that lies exactly in the midline.

**Milliequivalents per liter (mEq/L)** The units used to measure electrolyte concentrations of body fluids; a measure of the number of electrical charges in 1 liter of solution.

**Mineralocorticoid** (min'er-al'ō-kor'tih-koyd) Steroid hormone of the adrenal cortex that regulates Na<sup>+</sup> and K<sup>+</sup> metabolism and fluid balance.

**Minerals** Inorganic chemical compounds found in nature; salts.

**Mitochondria** (mi'to-kon'dre-ah) Cytoplasmic organelles responsible for ATP generation for cellular activities.

**Mitosis** Process during which the chromosomes are redistributed to two daughter nuclei; nuclear division. Consists of prophase, metaphase, anaphase, and telophase.

**Mitotic (M) phase** One of two major periods in the cell life cycle; involves the division of the nucleus (mitosis) and the division of the cytoplasm (cytokinesis).

**Mitral (bicuspid) valve** (mi'tral) The left atrioventricular valve.

**Mixed nerves** Nerves containing the processes of motor and sensory neurons; their impulses travel to and from the central nervous system.

**Molar** (mo'lar) (1) A solution concentration determined by mass of solute—1 liter of solution contains an amount of solute equal to its molecular weight in grams. (2) Broad back teeth that grind and crush.

**Molarity** (mo-lar'i-te) A way to express the concentration of a solution; moles per liter of solution.

**Mole** (mól) A mole of any element or compound is equal to its atomic weight or its molecular weight (sum of atomic weights) measured in grams.

**Molecule** Particle consisting of two or more atoms joined together by chemical bonds.

**Monoclonal antibodies** (mon'o-klo'nal) Pure preparations of identical antibodies that exhibit specificity for a single antigen.

**Monocyte** (mon'o-sit) Large single-nucleus white blood cell; agranular leukocyte.

**Monosaccharide** (mon'o-sak'ah-ríd) Literally, one sugar; building block of carbohydrates; e.g., glucose.

**Morula** (mor'u-lah) The mulberry-like solid mass of blastomeres resulting from cleavage in the early conceptus.

**Motor areas** Functional areas in the cerebral cortex that control voluntary motor functions.

**Motor (efferent) nerves** Nerves that carry impulses leaving the brain and spinal cord, and destined for effectors.

**Motor unit** A motor neuron and all the muscle cells it stimulates.

**Mucous membranes (mucosae)** Membranes that form the linings of body cavities open to the exterior (digestive, respiratory, urinary, and reproductive tracts).

**Mucus** (myoo'kus) A sticky, thick fluid secreted by mucous glands and mucous membranes; keeps the free surface of membranes moist.

**Multinucleate cell** (mul'ti-nu'kle-át) Cell with more than one nucleus, e.g., skeletal muscle cells, osteoclasts.

**Multiple sclerosis (MS)** Demyelinating disorder of the CNS; causes hardened patches (sclerosis) in the brain and spinal cord.

**Multipolar neurons** Neurons with three or more processes; most common neuron type in the CNS.

**Muscarinic receptors** (mus'kah-rin'ik) Acetylcholine-binding receptors of the autonomic nervous system's target organs; named for activation by the mushroom poison muscarine.

**Muscle fiber** A muscle cell.

**Muscle spindle** Encapsulated receptor found in skeletal muscle that is sensitive to stretch.

**Muscle tension** The force exerted by a contracting muscle on some object.

**Muscle tone** Low levels of contractile activity in relaxed muscle; keeps the muscle healthy and ready to act.

**Muscle twitch** The response of a muscle to a single brief threshold stimulus.

**Muscular dystrophy** A group of inherited muscle-destroying diseases.

**Muscular system** The organ system consisting of the skeletal muscles of the body and their connective tissue attachments.

**Myelencephalon (spinal brain)** A secondary brain vesicle; lower part of the developing hindbrain, especially the medulla oblongata.

**Myelin sheath** (mi'è-lin) Fatty insulating sheath that surrounds all but the smallest nerve fibers.

**Myoblasts** Embryonic mesoderm cells from which all muscle fibers develop.

**Myocardial infarction (MI)** (mi'o-kar'de-al in-fark'shun) Condition characterized by dead tissue areas in the myocardium; caused by interruption of blood supply to the area. Commonly called heart attack.

**Myocardium** (mi'o-kar'de-um) Layer of the heart wall composed of cardiac muscle.

**Myofibril** (mi'o-fi'bril) Rodlike bundle of contractile filaments (myofilaments) found in muscle fibers (cells).

**Myofilament** (mi'o-fil'ah-ment) Filament that constitutes myofibrils. Of two types: actin and myosin.

**Myoglobin** (mi'o-glo'bin) Oxygen-binding pigment in muscle.

**Myogram** A graphic recording of mechanical contractile activity produced by an apparatus that measures muscle contraction.

**Myometrium** (mi'o-me'tre-um) Thick uterine musculature.

**Myopia** (mi-o'pe-ah) A condition in which visual images are focused in front of rather than on the retina; nearsightedness.

**Myosin** (mi'o-sin) One of the principal contractile proteins found in muscle.

**Myxedema** (mik'sè-de'mah) Condition resulting from underactive thyroid gland.

**Nares** (na'rez) Nostrils.

**Natural killer (NK) cell** Defensive cell (a type of lymphocyte) that can kill cancer cells and virus-infected body cells before the adaptive immune system is activated.

**Necrosis** (ně-kro'sis) Death or disintegration of a cell or tissues caused by disease or injury.

**Negative feedback mechanisms** The most common homeostatic control mechanism. The net effect is that the output of the system shuts off the original stimulus or reduces its intensity.

**Neonatal period** The four-week period immediately after birth.

**Neoplasm** (ne'o-plazm) An abnormal mass of proliferating cells. Benign neoplasms remain localized; malignant neoplasms are cancers, which can spread to other organs.

**Nephron** (nef'ron) Structural and functional unit of the kidney; consists of the renal corpuscle and renal tubule.

**Nerve** A bundle of axons in the peripheral nervous system.

**Nerve fiber** Axon of a neuron.

**Nerve growth factor (NGF)** Protein that promotes survival and development of neurons; secreted by their target cells and many other cell types.

**Nerve impulse** A self-propagating wave of depolarization; also called an action potential.

**Nerve plexuses** Interlacing nerve networks that occur in the cervical, brachial, lumbar, and sacral regions and primarily serve the limbs.

**Nervous system** Fast-acting control system that triggers muscle contraction or gland secretion.

**Neural tube** Fetal structure that gives rise to the brain, spinal cord, and associated neural structures; formed from ectoderm by day 23 of embryonic development.

**Neuroglia** (nu-rog'le-ah) Nonexcitable cells of neural tissue that support, protect, and insulate the neurons; glial cells.

**Neurohypophysis** (nu'ro-hi-pof'i-sis) Posterior pituitary plus infundibulum; portion of the pituitary gland derived from the brain.

**Neuromuscular junction** Region where a motor neuron comes into close contact with a skeletal muscle cell.

**Neuron (nerve cell)** (nu'ron) Cell of the nervous system specialized to generate and transmit electrical signals (action potentials and graded potentials).

**Neuron cell body** The biosynthetic center of a neuron; also called the perikaryon, or soma.

**Neuronal pools** Functional groups of neurons that process and integrate information.

**Neuropeptides** (nu'ro-pep'tids) A class of neurotransmitters including beta endorphins and enkephalins (which act as euphorics and reduce perception of pain) and gut-brain peptides.

**Neurotransmitter** Chemical messenger released by neurons that may, upon binding to receptors of neurons or effector cells, stimulate or inhibit those neurons or effector cells.

**Neutral fats** Consist of fatty acid chains and glycerol; also called triglycerides or triacylglycerols. Commonly known as oils when liquid.

**Neutralization reaction** Displacement reaction in which mixing an acid and a base forms water and a salt.

**Neutron** (nu'tron) Uncharged subatomic particle; found in the atomic nucleus.

**Neutrophil** (nu'tro-fil) Most abundant type of white blood cell.

**Nicotinic receptors** (nik'o-tin'ik) Acetylcholine-binding receptors of all autonomic ganglionic neurons and skeletal muscle neuromuscular junctions; named for activation by nicotine.

**Nitric oxide (NO)** A gaseous chemical messenger; diverse functions include participation in memory formation in the brain, and causing vasodilation throughout the body.

**Nociceptor** (no'se-sep'tor) Receptor sensitive to potentially damaging stimuli that result in pain.

**Nondisjunction** Failure of sister chromatids to separate during mitosis or failure of homologous pairs to separate during meiosis; results in abnormal numbers of chromosomes in the resulting daughter cells.

**Nonmyelinated fibers** (non-mi'e-li-nat'ed) Axons lacking a myelin sheath and therefore conducting impulses quite slowly.

**Nonpolar molecules** Electrically balanced molecules.

**Nonvolatile (fixed) acid** Acid generated by cellular metabolism that must be eliminated by the kidneys.

**Norepinephrine (NE)** (nor'ep-i-nef'rin) A catecholamine neurotransmitter and adrenal medullary hormone, associated with sympathetic nervous system activation.

**Nuclear envelope** The double membrane barrier of a cell nucleus.

**Nucleic acid** (nu-kle'ik) Class of organic molecules that includes DNA and RNA.

**Nucleoli** (nu-kle'o-li) Dense spherical bodies in the cell nucleus involved with ribosomal RNA (rRNA) synthesis and ribosomal subunit assembly.

**Nucleosome** (nu'kle-o-som) Fundamental unit of chromatin; consists of a strand of DNA wound around a cluster of eight histone proteins.

**Nucleotide** (nu'kle-o-tid) Building block of nucleic acids; consists of a sugar, a nitrogen-containing base, and a phosphate group.

**Nucleus** (nu'kle-is) (1) Control center of a cell; contains genetic material; (2) clusters of nerve cell bodies in the CNS.

**Nutrients** Chemical substances taken in via the diet that are used for energy and cell building.

**Oblique section** A cut made diagonally between the horizontal and vertical plane of the body or an organ.

**Occlusion** (ah-kloo'zhun) Closure or obstruction.

**Octet rule (rule of eights)** (ok-tet') The tendency of atoms to interact in such a way that they have eight electrons in their valence shell.

**Olfaction** (ol-fak'shun) Smell.

**Oligodendrocyte** (ol'i-go-den'dro-sit) A type of CNS supporting cell that composes myelin sheaths.

**Oocyte** (o'o-sit) Immature female gamete.

**Oogenesis** (o'o-jen'e-sis) Process of ovum (female gamete) formation.

**Ophthalmic** (of-thal'mik) Pertaining to the eye.

**Optic** (op'tik) Pertaining to the eye or vision.

**Optic chiasma** (op'tik ki-az'muh) The partial crossover of fibers of the optic nerves.

**Organ** A part of the body formed of two or more tissues and adapted to carry out a specific function; e.g., the stomach.

**Organ system** A group of organs that work together to perform a vital body function; e.g., the nervous system.

**Organelles** (or'gah-nelz') Small cellular structures (ribosomes, mitochondria, and others) that perform specific metabolic functions for the cell as a whole.

**Organic compound** Any compound composed of atoms (some of which are carbon) held together by covalent (shared electron) bonds.

**Organic** Pertaining to carbon-containing molecules, such as proteins, fats, and carbohydrates.

**Organism** The living animal (or plant), which represents the sum total of all its organ systems working together to maintain life.

**Origin** Attachment of a muscle that remains relatively fixed during muscular contraction.

**Osmolality** The number of solute particles dissolved in 1 kilogram (1000 g) of water; reflects the solution's ability to cause osmosis.

**Osmolarity** (oz'mo-lar'i-te) The number of solute particles present in 1 liter of a solution.

**Osmoreceptor** (oz'mo-re-sep'tor) Structure sensitive to osmotic pressure or concentration of a solution.

**Osmosis** (oz-mo'sis) Diffusion of a solvent through a membrane from a dilute solution into a more concentrated one.

**Osmotic pressure** A measure of the tendency of water to move into a more concentrated solution.

**Ossicles** See Auditory ossicles.

**Ossification** (os'i-fi-ka'shun) See Osteogenesis.

**Osteoblasts** (os'te-o-blasts) Bone-forming cells.

**Osteoclasts** (os'te-o-klasts) Large cells that resorb or break down bone matrix.

**Osteocyte** (os'te-o-sit) Mature bone cell.

**Osteogenesis** (os'te-o-jen'e-sis) The process of bone formation; also called ossification.

- Osteoid** (os'te-oid) Unmineralized bone matrix.
- Osteomalacia** (os'te-o-mah-la'she-ah) Disorder in which bones are inadequately mineralized; soft bones.
- Osteon** (os'te-on) System of interconnecting canals in the microscopic structure of adult compact bone; unit of bone; also called Haversian system.
- Osteoporosis** (os'te-o-po-ro'sis) Decreased density and strength of bone resulting from a gradual decrease in rate of bone formation.
- Ovarian cycle** (o-vayr'e-an) Monthly cycle of follicle development, ovulation, and corpus luteum formation in an ovary.
- Ovary** (o'var-e) Female reproductive organ in which ova (eggs) are produced; female gonad.
- Ovulation** (ov'u-la'shun) Ejection of an immature egg (oocyte) from the ovary.
- Ovum** (o'vum) Female gamete; egg.
- Oxidases** Enzymes that catalyze the transfer of oxygen in oxidation-reduction reactions.
- Oxidation** (oks'i-da'shun) Process of substances combining with oxygen or the removal of hydrogen.
- Oxidation-reduction (redox) reaction** A reaction that couples the oxidation (loss of electrons) of one substance with the reduction (gain of electrons) of another substance.
- Oxidative phosphorylation** (ok'si-da'tiv fos'for-i-la'shun) Process of ATP synthesis during which an inorganic phosphate group is attached to ADP; occurs via the electron transport chain within the mitochondria.
- Oxyhemoglobin** (ok'si-he'mo-glo'bin) Oxygen-bound form of hemoglobin.
- Oxytocin** (ok'si-to'sin) Hormone synthesized in the hypothalamus and secreted by the posterior pituitary; stimulates contraction of the uterus during childbirth and the ejection of milk during nursing.
- Paget's disease** (paj'ets) Disorder characterized by excessive bone breakdown and abnormal bone formation.
- Palate** (pal'at) Roof of the mouth.
- Pancreas** (pan'kre-us) Gland located behind the stomach, between the spleen and the duodenum; produces both endocrine and exocrine secretions.
- Pancreatic juice** (pan'kre-at'ik) Bicarbonate-rich secretion of the pancreas containing enzymes for digestion of all food categories.
- Papilla** (pah-pil'ah) Small, nipple-like projection; e.g., dermal papillae are projections of dermal tissue into the epidermis.
- Paracrine** (par'ah-krin) A chemical messenger that acts locally within the same tissue and is rapidly destroyed. Examples are prostaglandins and nitric oxide.
- Parasagittal planes** All sagittal planes offset from the midline.
- Parasympathetic division** The division of the autonomic nervous system that oversees digestion, elimination, and glandular function; the resting and digesting subdivision.
- Parasympathetic tone** Normal (background) level of parasympathetic output; sustains normal gastrointestinal and urinary tract activity, lowers heart rate.
- Parathyroid glands** (par'ah-thi'roid) Small endocrine glands located on the posterior aspect of the thyroid gland.
- Parathyroid hormone (PTH)** Hormone released by the parathyroid glands that regulates blood calcium level.
- Parietal** (pah-ri'e-tal) Pertaining to the walls of a cavity.
- Parietal serosa** The part of the double-layered membrane that lines the walls of the ventral body cavity.
- Parkinson's disease** Neurodegenerative disorder of the basal nuclei due to insufficient secretion of the neurotransmitter dopamine; symptoms include tremor and rigid movement.
- Partial pressure** The pressure exerted by a single component of a mixture of gases.
- Parturition** (par'tu-rish'un) Culmination of pregnancy; giving birth.
- Passive immunity** Short-lived immunity resulting from the introduction of "borrowed antibodies" obtained from an immune animal or human donor; immunological memory is not established.
- Passive (transport) processes** Membrane transport processes that do not require cellular energy (ATP), e.g., diffusion, which is driven by kinetic energy.
- Pathogen** (path'o-jen) Disease-causing organism.
- Pectoral** (pek'tor-al) Pertaining to the chest.
- Pectoral (shoulder) girdle** Bones that attach the upper limbs to the axial skeleton; includes the clavicle and scapula.
- Pedigree** Traces a particular genetic trait through several generations and helps predict the genotype of future offspring.
- Pelvic girdle (hip girdle)** Consists of the paired coxal bones and sacrum that attach the lower limbs to the axial skeleton.
- Pelvis** (pel'vis) (1) Basin-shaped bony structure composed of the pelvic girdle, sacrum, and coccyx; (2) funnel-shaped tube within the kidney continuous with the ureter.
- Penis** (pe'nis) Male organ of copulation and urination.
- Pepsin** Enzyme capable of digesting proteins in an acid pH.
- Peptide bond** (pep'tid) Bond joining the amine group of one amino acid to the acid carboxyl group of a second amino acid with the loss of a water molecule.
- Perforating canals** Canals that run at right angles to the long axis of the bone, connecting the vascular and nerve supplies of the periosteum to those of the central canals and medullary cavity; also called Volkmann's canals.
- Pericardium** (per'i-kar'de-um) Double-layered sac enclosing the heart and forming its superficial layer; has fibrous and serous layers.
- Perichondrium** (per'i-kon'dre-um) Fibrous, connective-tissue membrane covering the external surface of cartilaginous structures.
- Perimysium** (per'i-mis'e-um) Connective tissue that bundles muscle fibers into fascicles.
- Perineum** (per'i-ne'um) That region of the body spanning the region between the ischial tuberosities and extending from the pubic arch to the coccyx.
- Periosteum** (per'e-os'te-um) Double-layered connective tissue that covers and nourishes the bone.
- Peripheral congestion** Condition caused by failure of the right side of the heart; results in edema in the extremities.
- Peripheral nervous system (PNS)** Portion of the nervous system consisting of nerves and ganglia that lie outside of the brain and spinal cord.
- Peripheral resistance** A measure of the amount of friction encountered by blood as it flows through the blood vessels.
- Peristalsis** (per'i-stal'sis) Progressive, wavelike contractions that move foodstuffs through the alimentary tube organs (or that move other substances through other hollow body organs).
- Peritoneum** (per'i-to-ne'um) Serous membrane lining the interior of the abdominal cavity and covering the surfaces of abdominal organs.
- Peritonitis** (per'i-to-ni'tis) Inflammation of the peritoneum.

**Permeability** That property of membranes that permits passage of molecules and ions.

**Peroxisomes** (pě-roks'ī-sōmz) Membranous sacs in cytoplasm containing powerful oxidase enzymes that use molecular oxygen to detoxify harmful or toxic substances, such as free radicals.

**Peyer's patches** (pi'erz) Lymphoid organs located in the small intestine; also called aggregated lymphoid nodules.

**pH unit** (pe-äch) The measure of the relative acidity or alkalinity of a solution.

**Phagocytosis** (fag'o-si-to'sis) Engulfing of foreign solids by (phagocytic) cells.

**Phagosome** (fag'o-sōm) Vesicle formed as a result of phagocytosis.

**Pharmacological dose** A drug dose that is dramatically higher than normal levels of that substance (e.g., hormone) in the body.

**Pharyngotympanic tube** Tube that connects the middle ear and the pharynx. Also called auditory tube, eustachian tube.

**Pharynx** (fay'rinks) Muscular tube extending from the region posterior to the nasal cavities to the esophagus.

**Phenotype** (fe'no-tīp) Observable expression of the genotype.

**Phospholipid** (fos'fo-lip'id) Modified lipid, contains phosphorus.

**Phosphorylation** A chemical reaction in which a phosphate molecule is added to a molecule; for example, phosphorylation of ADP yields ATP.

**Photoreceptor** (fo'to-re-sep'tor) Specialized receptor cells that respond to light energy; rods and cones.

**Physiological acidosis** (as'i-do'sis) Arterial pH lower than 7.35 resulting from any cause.

**Physiological dose** A drug dose that replicates normal levels of that substance (e.g., hormone) in the body. (*Compare with* Pharmacological dose.)

**Physiology** (fiz'e-ol'o-je) Study of the function of living organisms.

**Pineal gland (body)** (pin'e-al) A hormone-secreting part of the diencephalon of the brain thought to be involved in setting the biological clock and influencing reproductive function.

**Pinocytosis** (pe'no-si-to'sis) Engulfing of extracellular fluid by cells.

**Pituitary gland** (pī-tu'ih-tayr'e) Neuroendocrine gland located beneath the brain that serves a variety of functions including regulation of gonads, thyroid, adrenal cortex, lactation, and water balance.

**Placenta** (plah-sen'tah) Temporary organ formed from both fetal and maternal tissues that provides nutrients and oxygen to the developing fetus, carries away fetal metabolic wastes, and produces the hormones of pregnancy.

**Plasma** (plaz'mah) The nonliving fluid component of blood within which formed elements and various solutes are suspended and circulated.

**Plasma cells** Members of a B cell clone; effector B cells specialized to produce and release antibodies.

**Plasma membrane** Membrane, composed of phospholipids, cholesterol, and proteins, that encloses cell contents; outer limiting cell membrane.

**Platelet** (plāt'let) Cell fragment found in blood; involved in clotting.

**Pleurae** (ploo're) Two layers of serous membrane that line the thoracic cavity and cover the external surface of the lung.

**Pleural cavity** (ploo'ral) A potential space between the two layers of pleura; contains a thin film of serous fluid.

**Plexus** (plek'sus) A network of converging and diverging nerve fibers, blood vessels, or lymphatics.

**Polar molecules** Nonsymmetrical molecules that contain electrically unbalanced atoms.

**Polarized** State of a plasma membrane of an unstimulated neuron or muscle cell in which the inside of the cell is relatively negative in comparison to the outside; the resting state.

**Polycythemia** (pol'e-si-the'me-ah) An abnormally high number of erythrocytes.

**Polymer** A substance of high molecular weight with long, chainlike molecules consisting of many similar (repeated) units.

**Polypeptide** (pol'e-pep'tid) A chain of amino acids.

**Polyps** Benign mucosal tumors.

**Polysaccharide** (pol'e-sak'ah-rīd) Literally, many sugars, a polymer of linked monosaccharides; e.g., starch, glycogen.

**Pons** (1) Any bridgelike structure or part; (2) the part of the brain stem connecting the medulla with the midbrain, providing linkage between upper and lower levels of the central nervous system.

**Pore** The surface opening of the duct of a sweat gland.

**Positive feedback mechanisms** Feedback that tends to cause the level of a variable to change in the same direction as an initial change.

**Posterior pituitary** Neural part of pituitary gland; part of the neurohypophysis.

**Postganglionic neuron** (post'gan'gle-ah'nik) Autonomic motor neuron that has its cell body in a peripheral ganglion and projects its axon to an effector.

**Potential energy** Stored or inactive energy.

**Preganglionic neuron** Autonomic motor neuron that has its cell body in the central nervous system and projects its axon to a peripheral ganglion.

**Presbyopia** (pres'be-o'pe-ah) A condition that results in the loss of near focusing ability; typical onset is around age 40.

**Pressure gradient** Difference in pressure (hydrostatic or osmotic) that drives movement of fluid.

**Primary active transport** A type of active transport in which the energy needed to drive the transport process is provided directly by hydrolysis of ATP.

**Prime mover** Muscle that bears the major responsibility for effecting a particular movement; an agonist.

**Process** (1) Prominence or projection; (2) series of actions for a specific purpose.

**Progesterone** (pro-jes'ter-ōn) Hormone partly responsible for preparing the uterus for the fertilized ovum.

**Prolactin (PRL)** (pro-lak'tin) Adenohypophyseal hormone that stimulates the breasts to produce milk.

**Pronation** (pro-na'shun) Inward rotation of the forearm causing the radius to cross diagonally over the ulna—palms face posteriorly.

**Prophase** The first stage of mitosis, consisting of coiling of the chromosomes accompanied by migration of the two daughter centrioles toward the poles of the cell, and nuclear membrane breakdown.

**Proprioceptor** (pro'pre-o-sep'tor) Receptor located in a joint, muscle, or tendon; concerned with locomotion, posture, and muscle tone.

**Prostaglandin** (pros'tah-glan'din) A lipid-based chemical messenger synthesized by most tissue cells; acts locally as a paracrine.

**Prostate** Accessory reproductive gland; produces one-third of semen volume, including fluids that activate sperm.

**Protein** (pro'tēn) Organic compound composed of carbon, oxygen, hydrogen, and nitrogen; types include enzymes, structural components; 10–30% of cell mass.

- Prothrombin time** Diagnostic test to determine status of hemostasis system.
- Proton** (pro' ton) Subatomic particle that bears a positive charge; located in the atomic nucleus.
- Proton acceptor** A substance that takes up hydrogen ions in detectable amounts. Commonly referred to as a base.
- Proton donor** A substance that releases hydrogen ions in detectable amounts; an acid.
- Proximal** (prok' si-mul) Toward the attached end of a limb or the origin of a structure.
- Pseudounipolar neuron** (soo'do-u'ni-po'lar) Another term for unipolar neuron.
- Puberty** Period of life when reproductive maturity is achieved.
- Pulmonary** (pul' muh-nayr-e) Pertaining to the lungs.
- Pulmonary arteries** Vessels that deliver blood to the lungs to be oxygenated.
- Pulmonary circuit** System of blood vessels that serves gas exchange in the lungs; i.e., pulmonary arteries, capillaries, and veins.
- Pulmonary edema** (ë-de'muh) Leakage of fluid into the air sacs and tissue of the lungs.
- Pulmonary veins** Vessels that deliver freshly oxygenated blood from the respiratory zones of the lungs to the heart.
- Pulmonary ventilation** Breathing; consists of inspiration and expiration.
- Pulse** Rhythmic expansion and recoil of arteries resulting from heart contraction; can be felt from outside the body.
- Pupil** Opening in the center of the iris through which light enters the eye.
- Pus** Fluid product of inflammation composed of white blood cells, the debris of dead cells, and a thin fluid.
- Pyloric sphincter** (pi-lor'ik sfink'ter) Valve of the distal end of the stomach that controls food entry into the duodenum.
- Pyramidal (corticospinal) tracts** Major motor pathways concerned with voluntary movement; descend from pyramidal cells in the frontal lobes of each cerebral hemisphere.
- Pyruvic acid** An intermediate compound in the metabolism of carbohydrates.
- Radioactivity** The process of spontaneous decay seen in some of the heavier isotopes, during which particles or energy is emitted from the atomic nucleus; results in the atom becoming more stable.
- Radioisotope** (ra'de-o-i'so-töp) Isotope that exhibits radioactive behavior.
- Ramus** (ra'mus) Branch of a nerve, artery, vein, or bone.
- Rapid eye movement (REM) sleep** Stage of sleep in which rapid eye movements, an alert EEG pattern, and dreaming occur.
- Reactant** A substance taking part in a chemical reaction.
- Receptor** (re-sep'tor) (1) A cell or nerve ending of a sensory neuron specialized to respond to particular types of stimuli; (2) protein that binds specifically with other molecules, e.g., neurotransmitters, hormones, paracrines, antigens.
- Receptor-mediated endocytosis** The type of endocytosis in which engulfed particles attach to receptors before endocytosis occurs.
- Receptor potential** A graded potential that occurs at a sensory receptor membrane.
- Recessive traits** A trait due to a particular allele that does not manifest itself in the presence of other alleles that generate traits dominant to it; must be present in double dose to be expressed.
- Reduction** Chemical reaction in which electrons and energy are gained by a molecule (often accompanied by gain of hydrogen ions) or oxygen is lost.
- Referred pain** Pain felt at a site other than the area of origin.
- Reflex** Automatic reaction to stimuli.
- Refraction** The bending of a light ray when it meets a different surface at an oblique rather than right angle.
- Regeneration** Replacement of destroyed tissue with the same kind of tissue.
- Regulatory T cells (T<sub>Reg</sub> cells)** Population of T cells (usually expressing CD4) that suppress the immune response.
- Relative refractory period** Follows the absolute refractory period; interval when a threshold for action potential stimulation is markedly elevated.
- Renal** (re'nal) Pertaining to the kidney.
- Renal autoregulation** Process the kidney uses to maintain a nearly constant glomerular filtration rate despite fluctuations in systemic blood pressure.
- Renal clearance** The volume of plasma from which a particular substance is completely removed in a given time, usually 1 minute; provides information about renal function.
- Renin** (re'nin) Enzyme released by the kidneys that raises blood pressure by initiating the renin-angiotensin-aldosterone mechanism.
- Rennin** Stomach-secreted enzyme that acts on milk protein; not produced in adults.
- Repolarization** Movement of the membrane potential to the initial resting (polarized) state.
- Reproductive system** Organ system that functions to produce offspring.
- Resistance exercise** High-intensity exercise in which the muscles are pitted against high resistance or immovable forces and, as a result, muscle cells increase in size.
- Respiration** The processes involved in supplying the body with oxygen and disposing of carbon dioxide.
- Respiratory system** Organ system that carries out gas exchange; includes the nose, pharynx, larynx, trachea, bronchi, lungs.
- Resting membrane potential** The voltage that exists across the plasma membrane during the resting state of an excitable cell; ranges from  $-90$  to  $-20$  millivolts depending on cell type.
- Reticular activating system (RAS)** (re-tik'u-lar) Diffuse brain stem neural network that receives a wide variety of sensory input and maintains wakefulness of the cerebral cortex.
- Reticular connective tissue** Connective tissue with a fine network of reticular fibers that form the internal supporting framework of lymphoid organs.
- Reticular formation** Functional system that spans the brain stem; involved in regulating sensory input to the cerebral cortex, cortical arousal, and control of motor behavior.
- Reticular lamina** A layer of extracellular material containing a fine network of collagen protein fibers; together with the basal lamina it is a major component of the basement membrane.
- Reticulocyte** (rë-tik'u-lo-sit) Immature erythrocyte.
- Retina** (ret'i-nah) Inner layer of the eyeball; contains photoreceptors (rods, cones).
- Rhombencephalon (hindbrain)** (romb'en-sef'ah-lon) Caudal portion of the developing brain; constricts to form the metencephalon and myelencephalon; includes the pons, cerebellum, and medulla oblongata.
- Ribosomal RNA (rRNA)** A constituent of ribosome; exists within the ribosomes of cytoplasm and assists in protein synthesis.
- Ribosomes** (ri'bo-sômz) Cytoplasmic organelles at which proteins are synthesized.

**RNA (ribonucleic acid)** (ri'bo-nu-kle'ik) Nucleic acid that contains ribose and the bases A, G, C, and U. Carries out DNA's instructions for protein synthesis.

**Rods** One of the two types of photosensitive cells in the retina.

**Rotation** The turning of a bone around its own long axis.

**Rugae** (ru'ge) Elevations or ridges, as in stomach mucosa.

**Rule of nines** Method of computing the extent of burns by dividing the body into a number of areas, each accounting for 9% (or a multiple thereof) of the total body area.

**S (synthetic) phase** The part of the interphase period of the cell cycle in which DNA replicates itself, ensuring that the two future cells will receive identical copies of genetic material.

**Sagittal plane** (saj'i-tal) A longitudinal (vertical) plane that divides the body or any of its parts into right and left portions.

**Saliva** Secretion of the salivary glands; cleanses and moistens the mouth and begins chemical digestion of starchy foods.

**Saltatory conduction** Transmission of an action potential along a myelinated fiber in which the nerve impulse appears to leap from gap to gap.

**Sarcolemma** The plasma membrane of a muscle fiber.

**Sarcomere** (sar'ko-mēr) The smallest contractile unit of muscle; extends from one Z disc to the next.

**Sarcoplasm** The nonfibrillar cytoplasm of a muscle fiber.

**Sarcoplasmic reticulum (SR)** (sar'ko-plaz'mik rě-tik'u-lum) Specialized endoplasmic reticulum of muscle cells.

**Schwann cell** A type of supporting cell in the PNS; forms myelin sheaths and is vital to peripheral nerve fiber regeneration.

**Sclera** (skle'rah) White opaque portion of the fibrous layer of the eyeball.

**Scrotum** (skro'tum) External sac enclosing the testes.

**Sebaceous glands (oil glands)** (se-ba'shus) Epidermal glands that produce an oily secretion called sebum.

**Sebum** (se'bum) Oily secretion of sebaceous glands.

**Second-degree burn** A burn in which the epidermis and the upper region of the dermis are damaged.

**Second messenger** Intracellular molecule generated by the binding of a chemical (hormone or neurotransmitter) to a receptor protein; mediates intracellular responses to the chemical messenger.

**Secondary sex characteristics** Anatomical features, not directly involved in the reproductive process, that develop under the influence of sex hormones, e.g., male or female pattern of muscle development, bone growth, body hair distribution.

**Secretion** (se-kre'shun) (1) The passage of material formed by a cell to its exterior; (2) cell product that is transported to the exterior of a cell.

**Secretory vesicles (granules)** Vesicles that migrate to the plasma membrane of a cell and discharge their contents from the cell by exocytosis.

**Section** A cut through the body (or an organ) that is made along a particular plane; a thin slice of tissue prepared for microscopic study.

**Segregation** During meiosis, the distribution of the members of the allele pair to different gametes.

**Selectively permeable membrane** A membrane that allows certain substances to pass while restricting the movement of others; also called differentially permeable membrane.

**Semen** (se'men) Fluid mixture containing sperm and secretions of the male accessory reproductive glands.

**Semilunar valves** (sě'me-loo'ner) Valves that prevent blood return to the ventricles after contraction; aortic and pulmonary valves.

**Seminiferous tubules** (sem'i-nif'er-us) Highly convoluted tubes within the testes; form sperm.

**Sense organs** Localized collections of many types of cells working together to accomplish a specific receptive process.

**Sensory (afferent) nerves** Nerves that contain processes of sensory neurons and carry impulses to the central nervous system.

**Sensory areas** Functional areas of the cerebral cortex that provide for conscious awareness of sensation.

**Sensory receptor** A cell or part of a cell (e.g., receptive endings of sensory neurons) specialized to respond to a stimulus.

**Serosa (serous membrane)** (se-ro'sah) The moist membrane found in closed ventral body cavities.

**Serous fluid** (sēr'us) Clear, watery fluid secreted by cells of a serous membrane.

**Serum** (sēr'um) Amber-colored fluid that exudes from clotted blood as the clot shrinks; plasma without clotting factors.

**Sesamoid bones** (ses'ah-moid) Short bones embedded in tendons, variable in size and number, many of which influence the action of muscles; largest is the patella (kneecap).

**Severe combined immunodeficiency syndromes (SCIDs)** Congenital conditions resulting in little or no protection against disease-causing organisms of any type.

**Sex chromosomes** The chromosomes, X and Y, that determine genetic sex (XX = female; XY = male); the 23rd pair of chromosomes.

**Sex-linked inheritance** Inherited traits determined by genes on the sex chromosomes, e.g., X-linked genes are passed from mother to son, Y-linked genes are passed from father to son.

**Sexually transmitted infection (STI)** Any infectious disease spread through sexual contact.

**Signal sequence** A short peptide segment present in a protein being synthesized that causes the associated ribosome to attach to the membrane of rough ER.

**Simple diffusion** The unassisted transport across a plasma membrane of a lipid-soluble or very small particle.

**Sinoatrial (SA) node** (si'no-a'tre-al) Specialized myocardial cells in the wall of the right atrium; pacemaker of the heart.

**Sinus** (si'nus) (1) Mucous-membrane-lined, air-filled cavity in certain cranial bones; (2) dilated channel for the passage of blood or lymph.

**Skeletal muscle** Muscle composed of cylindrical multinucleate cells with obvious striations; the muscle(s) attached to the body's skeleton; voluntary muscle.

**Skeletal system** System of protection and support composed primarily of bone and cartilage.

**Skull** Bony protective encasement of the brain and the organs of hearing and equilibrium; includes cranial and facial bones.

**Small intestine** Convoluted tube extending from the pyloric sphincter to the ileocecal valve where it joins the large intestine; the site where digestion is completed and virtually all absorption occurs.

**Smooth muscle** Spindle-shaped cells with one centrally located nucleus and no externally visible striations (bands). Found mainly in the walls of hollow organs.

**Sodium-potassium (Na<sup>+</sup>-K<sup>+</sup>) pump** A primary active transport system that simultaneously drives Na<sup>+</sup> out of the cell against a steep gradient and pumps K<sup>+</sup> back in. Also called Na<sup>+</sup>-K<sup>+</sup> ATPase.

**Sol-gel transformation** Reversible change of a colloid from a fluid (sol) to a more solid (gel) state.

**Solute** (sol'yoot) The substance that is dissolved in a solution.

**Solute pump** Enzyme-like protein carrier that mediates active transport of solutes such as amino acids and ions uphill against their concentration gradients.

**Somatic nervous system** (so-mă'tik) Division of the peripheral nervous system that provides the motor innervation of skeletal muscles; also called the voluntary nervous system.

**Somatic reflexes** Reflexes that activate skeletal muscle.

**Somatosensory system** That part of the sensory system dealing with reception in the body wall and limbs; receives inputs from exteroceptors, proprioceptors, and interoceptors.

**Somite** (so'mit) A mesodermal segment of the body of an embryo that contributes to the formation of skeletal muscles, vertebrae, and dermis of skin.

**Spatial discrimination** The ability of neurons to identify the site or pattern of stimulation.

**Special senses** The senses of taste, smell, vision, hearing, and equilibrium.

**Specific gravity** Term used to compare the weight of a substance to the weight of an equal volume of distilled water.

**Sperm (spermatozoon)** Male gamete.

**Spermatogenesis** (sper'mah-to-jen'ě-sis) The process of sperm (male gamete) formation; involves meiosis.

**Sphincter** (sfink'ter) A circular muscle surrounding an opening; acts as a valve.

**Spinal cord** The bundle of nervous tissue that runs from the brain to the first to third lumbar vertebrae and provides a conduction pathway to and from the brain.

**Spinal nerves** The 31 nerve pairs that arise from the spinal cord.

**Splanchnic circulation** (splangk'nik) The blood vessels serving the digestive system.

**Spleen** Largest lymphoid organ; provides for lymphocyte proliferation, immune surveillance and response, and blood-cleansing functions.

**Spongy bone** Internal layer of skeletal bone. Also called cancellous bone.

**Sprain** Ligaments reinforcing a joint are stretched or torn.

**Static equilibrium** Sense of head position in space with respect to gravity.

**Stenosis** (stě-no'sis) Abnormal constriction or narrowing.

**Steroids** (stě'roidz) Group of chemical substances including certain hormones and cholesterol; they are fat soluble and contain little oxygen.

**Stimulus** (stim'u-lus) An excitant or irritant; a change in the environment that evokes a response.

**Stomach** Temporary reservoir in the gastrointestinal tract where chemical breakdown of proteins begins and food is converted into chyme.

**Stressor** Any stimulus that directly or indirectly causes the hypothalamus to initiate stress-reducing responses, such as the fight-or-flight response.

**Stroke** See Cerebrovascular accident.

**Stroke volume (SV)** Amount of blood pumped out of a ventricle during one contraction.

**Stroma** (stro'mah) The basic internal structural framework of an organ.

**Structural (fibrous) proteins** Consist of extended, strandlike polypeptide chains forming a strong, ropelike structure that is linear, insoluble in water, and very stable; e.g., collagen.

**Subcutaneous** (sub'kyu-ta'ne-us) Beneath the skin.

**Subendocardial conducting network** Modified ventricular muscle fibers of the conduction system of the heart. Also called Purkinje fibers.

**Substrate** A reactant on which an enzyme acts to cause a chemical action to proceed.

**Sudoriferous gland** (su'do-rif'er-us) Epidermal gland that produces sweat.

**Sulcus** (sul'kus) A furrow on the brain, less deep than a fissure.

**Summation** Accumulation of effects, especially those of muscular, sensory, or mental stimuli.

**Superficial** Located close to or on the body surface.

**Superior** Toward the head or upper body regions.

**Superior vena cava** Vein that returns blood from body regions superior to the diaphragm.

**Supination** (soo'pī-na'shun) The outward rotation of the forearm causing palms to face anteriorly.

**Surfactant** (ser-fak'tant) Secretion produced by certain cells of the alveoli that reduces the surface tension of water molecules, thus preventing the collapse of the alveoli after each expiration.

**Suspension** Heterogeneous mixtures with large, often visible solutes that tend to settle out.

**Suture** (soo'cher) An immovable fibrous joint; with one exception, all bones of the skull are united by sutures.

**Sweat gland** See Sudoriferous gland.

**Sympathetic division** The division of the autonomic nervous system that prepares the body for activity or to cope with some stressor (danger, excitement, etc.); the fight, fright, and flight subdivision.

**Sympathetic (vasomotor) tone** State of partial vasoconstriction of the blood vessels maintained by sympathetic fibers.

**Symphysis** (sim'fih-sis) A joint in which the bones are connected by fibrocartilage.

**Synapse** (sin'aps) Functional junction or point of close contact between two neurons or between a neuron and an effector cell.

**Synapsis** (sī-nap'sis) Pairing of homologous chromosomes during the first meiotic division.

**Synaptic cleft** (sī-nap'tik) Fluid-filled space at a synapse.

**Synaptic delay** Time required for a signal to cross a synapse between two neurons.

**Synaptic vesicles** Small membranous sacs containing neurotransmitter.

**Synarthrosis** (sin'ar-thro'sis) Immovable joint.

**Synchondrosis** (sin'kon-dro'sis) A joint in which the bones are united by hyaline cartilage.

**Syndesmosis** (sin'des-mo'sis) A joint in which the bones are united by a ligament or a sheet of fibrous tissue.

**Synergist** (sin'er-jist) (1) Muscle that aids the action of a prime mover by effecting the same movement or by stabilizing joints across which the prime mover acts, preventing undesirable movements. (2) Hormone that amplifies the effect of another hormone at a target cell.

**Synostosis** (sin'os-to'sis) A completely ossified joint; a fused joint.

**Synovial fluid** Fluid secreted by the synovial membrane; lubricates joint surfaces and nourishes articular cartilages.

**Synovial joint** Freely movable joint exhibiting a joint cavity; also called a diarthrosis.

**Synthesis (combination) reaction** A chemical reaction in which larger, more complex atoms or molecules are formed from simpler ones.

**Systemic** (sis-tem'ik) Pertaining to the whole body.

**Systemic circuit** System of blood vessels that serves gas exchange in the body tissues.

**Systole** (sis'to-le) Period when either the ventricles or the atria are contracting.

**Systolic pressure** (sis-tah'lik) Pressure exerted by blood on the blood vessel walls during ventricular contractions.

**T cells** Lymphocytes that mediate cellular immunity; include helper, cytotoxic, regulatory, and memory cells. Also called T lymphocytes.

**T tubule (transverse tubule)** Extension of the muscle cell plasma membrane (sarcolemma) that protrudes deeply into the muscle cell.

**Tachycardia** (tak'e-kar'de-ah) A heart rate over 100 beats per minute.

**Taste buds** Sensory receptor organs that house gustatory cells, which respond to dissolved food chemicals.

**Telencephalon (endbrain)** (tel'en-seh'fuh-lon) Anterior subdivision of the primary forebrain that develops into olfactory lobes, cerebral cortex, and basal nuclei.

**Telophase** The final phase of mitosis; begins when migration of chromosomes to the poles of the cell has been completed and ends with the formation of two daughter nuclei.

**Tendon** (ten'dun) Cord of dense fibrous tissue attaching muscle to bone.

**Tendon organ** Proprioceptor located in tendon; monitors muscle tension to prevent tearing and help smooth onset and termination of muscle contraction.

**Tendonitis** Inflammation of tendon sheaths, typically caused by overuse.

**Terminal branches** Branching ends of an axon that allow it to form many axon terminals; terminal arborization.

**Testis** (tes'tis) Male primary reproductive organ that produces sperm; male gonad.

**Testosterone** (tes-tos'tě-rōn) Male sex hormone produced by the testes; during puberty promotes virilization, and is necessary for normal sperm production.

**Tetanus** (tet'ah-nus) (1) A smooth, sustained muscle contraction resulting from high-frequency stimulation; (2) an infectious disease caused by an anaerobic bacterium.

**Thalamus** (thal'ah-mus) A mass of gray matter in the diencephalon of the brain.

**Thermogenesis** (ther'mo-jen'ě-sis) Heat production.

**Thermoreceptor** (ther'mo-re-sep'ter) Receptor sensitive to temperature changes.

**Third-degree burn** A burn that involves the entire thickness of the skin; also called a full-thickness burn. Usually requires skin grafting.

**Thoracic cage (bony thorax)** Bones and costal cartilages that form the framework of the thorax; includes sternum, ribs, and thoracic vertebrae.

**Thoracic duct** Large duct that receives lymph drained from the entire lower body, the left upper extremity, and the left side of the head and thorax.

**Thoracic vertebrae** The 12 vertebrae that are in the middle part of the vertebral column and articulate with the ribs.

**Thorax** (tho'raks) That portion of the body trunk above the diaphragm and below the neck.

**Threshold stimulus** Weakest stimulus capable of producing a response in an excitable tissue.

**Thrombin** (throm'bin) Enzyme that induces clotting by converting fibrinogen to fibrin.

**Thrombocyte** (throm'bo-sīt) Platelet; cell fragment that participates in blood coagulation.

**Thrombocytopenia** (throm'bo-si'to-pe'ne-ah) A reduction in the number of platelets circulating in the blood.

**Thrombus** (throm'bus) A clot that develops and persists in an unbroken blood vessel.

**Thymine (T)** (thi'mēn) Single-ring base (a pyrimidine) in DNA.

**Thymus** (thi'mus) Lymphoid organ and endocrine gland active in immune response; site of maturation of T lymphocytes.

**Thyroid gland** (thi'roid) One of the largest of the body's endocrine glands; straddles the anterior trachea.

**Thyroid hormone (TH)** The major hormone secreted by thyroid follicles; stimulates enzymes concerned with glucose oxidation.

**Thyroid-stimulating hormone (TSH)** Anterior pituitary hormone that regulates secretion of thyroid hormones.

**Thyroxine (T<sub>4</sub>)** (thi-rok'sin) Iodine-containing hormone secreted by the thyroid gland; accelerates cellular metabolic rate in most body tissues.

**Tight junction** Area where plasma membranes of adjacent cells are tightly bound together, forming an impermeable barrier.

**Tissue** A group of similar cells and their intercellular substance specialized to perform a specific function; primary tissue types of the body are epithelial, connective, muscle, and nervous tissue.

**Tissue perfusion** Blood flow through body tissues or organs.

**Tonicity** (to-nis'i-te) A measure of the ability of a solution to cause a change in cell shape or tone by promoting osmotic flows of water.

**Tonsils** A ring of lymphoid tissue around the entrance to the pharynx. *See also* Adenoids.

**Trabecula** (trah-bek'u-lah) (1) Any of the fibrous bands extending from the capsule into the interior of an organ; (2) strut or thin plate of bone in spongy bone.

**Trachea** (tra'ke-ah) Windpipe; cartilage-reinforced tube extending from larynx to bronchi.

**Tract** A collection of axons in the central nervous system having the same origin, termination, and function.

**Transcription** One of the two major steps in the transfer of genetic code information from a DNA base sequence to the complementary base sequence of an mRNA molecule.

**Transduction** (trans-duk'shun) The conversion of the energy of a stimulus into an electrical event.

**Transepithelial transport** (trans-ep'i-the'le-al) Movement of substances through, rather than between, adjacent epithelial cells connected by tight junctions, such as absorption of nutrients in the small intestine.

**Transfer RNA (tRNA)** Short-chain RNA molecules that transfer amino acids to the ribosome.

**Transfusion reaction** Agglutination and destruction of red blood cells following transfusion of incompatible blood.

**Translation** One of the two major steps in the transfer of genetic code information, in which the information carried by mRNA is decoded and used to assemble polypeptides.

**Transverse (horizontal) plane** A plane running from right to left, dividing the body or an organ into superior and inferior parts.

**Tricuspid valve** (tri-kus'pid) The right atrioventricular valve.

**Triglycerides** (tri-glis'er-idz) Fats and oils composed of fatty acids and glycerol; are the body's most concentrated source of energy fuel; also known as neutral fats.

**Triiodothyronine (T<sub>3</sub>)** (tri'i-o'do-thi'ro-nēn) Thyroid hormone; secretion and function similar to those of thyroxine (T<sub>4</sub>).

**Trophoblast** (tro'fo-blast) Outer sphere of cells of the blastocyst.

**Tropic hormone (tropin)** (trōp'ik) A hormone that regulates the secretory action of another endocrine organ.

**Trypsin** Proteolytic enzyme secreted by the pancreas.

**Tubular reabsorption** The movement of filtrate components from the renal tubules into the blood.

**Tubular secretion** The movement of substances (such as drugs, urea, excess ions) from blood into filtrate.

**Tumor** An abnormal growth of cells; a swelling; may be cancerous.

**Tunica** (too'ni-kah) A covering or tissue coat; membrane layer.

**Tympanic membrane** (tim-pan'ik) Eardrum.

**Ulcer** (ul'ser) Lesion or erosion of the mucous membrane, such as gastric ulcer of stomach.

**Umbilical cord** (um-bi'li-kul) Structure bearing arteries and veins connecting the placenta and the fetus.

**Umbilicus** (um-bi'li-kus) Navel; marks site where umbilical cord was attached in fetal stage.

**Unipolar neuron** Neuron in which embryological fusion of the two processes leaves only one process extending from the cell body.

**Uracil (U)** (u'rah-sil) A smaller, single-ring base (a pyrimidine) found in RNA.

**Urea** (u-re'ah) Main nitrogen-containing waste excreted in urine.

**Ureter** (u-re'ter) Tube that carries urine from kidney to bladder.

**Urethra** (u-re'thrah) Canal through which urine passes from the bladder to outside the body.

**Uric acid** The nitrogenous waste product of nucleic acid metabolism; component of urine.

**Urinary bladder** A smooth, collapsible, muscular sac that stores urine temporarily.

**Urinary system** System primarily responsible for water, electrolyte, and acid-base balance and removal of nitrogenous wastes.

**Uterine tube** (u'ter-in) Tube through which the ovum is transported to the uterus. Also called fallopian tube.

**Uterus** (u'ter-us) Hollow, thick-walled organ that receives, retains, and nourishes fertilized egg; site where embryo/fetus develops.

**Uvula** (u'vu-lah) Tissue tag hanging from soft palate.

**Vaccine** Preparation that provides artificially acquired active immunity.

**Vagina** Thin-walled tube extending from the cervix to the body exterior; often called the birth canal.

**Valence shell** (va'lens) Outermost electron shell (energy level) of an atom that contains electrons.

**Varicosities** Knoblike swellings of certain autonomic axons containing mitochondria and synaptic vesicles.

**Vas** (vaz') A duct; vessel.

**Vasa recta** (va'sah rek'tah) Capillary branches that supply nephron loops in the medulla region of the kidney.

**Vascular** Pertaining to blood vessels or richly supplied with blood vessels.

**Vascular spasm** Immediate response to blood vessel injury; results in constriction.

**Vasoconstriction** (vas'o-kon-strik'shun) Narrowing of blood vessels.

**Vasodilation** (vas'o-di-la'shun) Relaxation of the smooth muscles of the blood vessels, producing dilation.

**Vasomotion** (vas'o-mo'shun) Intermittent contraction or relaxation of the precapillary sphincters, resulting in a staggered blood flow when tissue needs are not extreme.

**Vasomotor center** (vas'o-mo'ter) Brain area concerned with regulation of blood vessel resistance.

**Vasomotor fibers** Sympathetic nerve fibers that cause the contraction of smooth muscle in the walls of blood vessels, thereby regulating blood vessel diameter.

**Veins** (vānz") Blood vessels that return blood toward the heart from the circulation.

**Ventral** Pertaining to the front; anterior.

**Ventricles** (1) Paired, inferiorly located heart chambers that function as the major blood pumps; (2) cavities in the brain.

**Venule** (ven'ül) A small vein.

**Vertebral column (spine)** (ver'tē-brul) Formed of a number of individual bones called vertebrae and two composite bones (sacrum and coccyx).

**Vesicle** (vē'si-kul) A small liquid-filled sac or bladder.

**Vesicular transport** Transport of large particles and macromolecules into or out of a cell or between its compartments in membrane-bound sacs.

**Vesicular follicle** Mature ovarian follicle.

**Vestibule** An enlarged area at the beginning of a canal, i.e., inner ear, nose, larynx.

**Villus** (vil'us) One of the fingerlike projections of the small intestinal mucosa that tremendously increase its surface area for absorption.

**Visceral** (vis'er-al) Pertaining to an internal organ of the body or the inner part of a structure.

**Visceral muscle** Type of smooth muscle; its cells contract as a unit and rhythmically, are electrically coupled by gap junctions, and often exhibit spontaneous action potentials. Also called unitary smooth muscle.

**Visceral organs (viscera)** A group of internal organs housed in the ventral body cavity.

**Visceral serosa** (se-ro'sah) The part of the double-layered membrane that lines the outer surfaces of organs within the ventral body cavity.

**Viscosity** (vis'kos'i-te) A measurement of thickness (stickiness) of a fluid.

**Visual field** The field of view seen when the head is still.

**Vital capacity (VC)** The volume of air that can be expelled from the lungs by forcible expiration after the deepest inspiration; total exchangeable air.

**Vital signs** Includes pulse, blood pressure, respiratory rate, and body temperature measurements.

**Vitamins** Organic compounds required by the body in minute amounts.

**Vocal folds** Mucosal folds that function in voice production (speech); also called the true vocal cords.

**Volatile acid** An acid that can be eliminated by the lungs; carbonic acid is converted to CO<sub>2</sub>, which diffuses into the alveoli.

**Volkmann's canals** *See* Perforating canals.

**Voluntary muscle** Muscle under strict nervous control; skeletal muscle.

**Voluntary nervous system** The somatic nervous system.

**Vulva** (vul'vuh) Female external genitalia.

**Wallerian degeneration** (wal-er'ē-an) A process of disintegration of an axon that occurs when it is crushed or severed and cannot receive nutrients from the cell body.

**White matter** White substance of the central nervous system; myelinated nerve fibers.

**Xenograft** Tissue graft taken from another animal species.

**Yolk sac** (yōk) One of the extraembryonic membranes; involved in early blood cell formation.

**Zygote** (zi'gōt) Fertilized egg.

 Lateral compartment of leg, muscles of, **370t, 372f, 373t, 380t, 381f**  
 Lateral condyle  
   of femur, **238, 239f**  
   of tibia, **239–241, 240f**  
 Lateral cords, brachial plexus, **504f, 505, 505t**  
 Lateral corticospinal tract, **469f, 472f, 473t**  
 Lateral cuneiform bone, **241f, 242, 243t**  
 Lateral cutaneous branch of intercostal nerve, **502f**  
 Lateral epicondyle  
   of femur, **238, 239f**  
   of humerus, **230, 230f**  
 Lateral excursion, **268–269, 268f**  
 Lateral femoral cutaneous nerve, **507f, 507t**  
 Lateral fornx, **1037f, 1040**  
 Lateral funiculi, **467f, 468**  
 Lateral geniculate bodies/nuclei, **441, 442f, 563, 564f, 565**  
 Lateral horns, **466, 467f, 529, 530f**  
 Lateral hypothalamic area, **442f**  
   food intake regulation and, **939, 940, 940f**  
 Lateral inhibition, **565**  
 Lateralization, **433, 437**  
 Lateral lemniscus, **579, 579f**  
 Lateral ligaments, of temporomandibular joint, **267, 268f**  
 Lateral longitudinal arch of foot, **242, 242f**  
 Lateral malleolus, **240f, 241**  
 Lateral mass  
   of atlas, **221, 221f**  
   of ethmoid bone, **210, 210f**  
 Lateral meniscus of knee, **262–263f**  
 Lateral (small cell) nuclear group, **450**  
 Lateral patellar retinaculum, **262f, 263**  
 Lateral plantar artery, **734–735f, 735t**  
 Lateral plantar nerve, **509, 509t**  
 Lateral plantar vein, **744t**  
 Lateral plate mesoderm, **1077, 1078f, 1079f**  
 Lateral pterygoid muscle, **332t, 333f**  
 Lateral rectus muscle, **547, 547f**  
 Lateral reticulospinal tract, **469f, 473t**  
 Lateral rotation, **257f, 258**  
   of lower limb, **380t, 381f**  
   of upper limb, **358t, 359f**  
 Lateral sacral crest, **224, 224f**  
 Lateral semicircular canal, **573, 573f**  
 Lateral spinothalamic tract, **469, 469f, 470f, 471t**  
 Lateral sulcus, **431, 432f**  
 Lateral supracondylar line, **238, 239f**
- Lateral supracondylar ridge, **230, 230f**  
 Lateral thoracic artery, **728f, 728t, 729f**  
 Lateral ventricles, **429f, 430, 431f**  
 Late secondary follicle, **1045, 1046f**  
 Latissimus dorsi muscle, **327f, 346t, 348–349f, 350t, 351f, 351t, 358t**  
 Laughing, **824t**  
 LDLs. *See* Low-density lipoproteins  
 L-dopa, for Parkinson's disease, **464**  
 Leader sequence, **105, 108f**  
 Leading strand, **97, 98f**  
 Lead salts, skin penetrated by, **162, 163**  
 Leakage channels, **69, 396**  
 Learned (acquired) reflex, **513**  
 Lecithin, **896, 908**  
 Lectin(s), **772**  
 Lectin pathway, of complement activation, **772, 772f**  
 Left anterior descending artery (anterior interventricular artery), **663f, 668, 670f**  
 Left ascending lumbar vein, **741t, 742–743f**  
 Left atrium, **659, 662, 663–665f, 669f**  
 Left brachiocephalic vein, **736–737f, 736t**  
 Left bundle branch, **676**  
 Left colic artery, **730f, 732t, 733f**  
 Left colic (splenic) flexure, **887, 888f**  
 Left common carotid artery, **724f, 724t, 726f, 728f**  
 Left common iliac artery, **724f, 724t, 732t**  
 Left coronary artery, **663f, 668, 670f, 724f, 724t**  
 Left gastric artery, **730f, 731f, 731t**  
 Left gastroepiploic artery, **730f, 731f, 731t**  
 Left hypochondriac region, **19, 20f**  
 Left iliac (inguinal) region, **19, 20f**  
 Left lobe, of liver, **878, 879f**  
 Left lower quadrant (LLQ), **19, 19f**  
 Left lumbar region, **19, 20f**  
 Left main (primary) bronchus, **802f, 810, 811f**  
 Left marginal artery, **670**  
 Left pulmonary artery, **663–665f, 722f, 722t, 814f**  
 Left pulmonary vein, **663–665f, 722f, 722t, 814f**  
 Left subclavian artery, **724f, 724t, 726f, 728f, 729f**  
 Left suprarenal vein, **736f, 743f**  
 Left upper quadrant (LUQ), **19, 19f**  
 Left ventricle, **659, 662, 663–665f, 668, 669f, 670f**
- Leg  
   bones of, **239–241, 240f, 243t**  
   muscles of/muscles controlling movement of, **326f, 327f, 363–369t, 364f, 367–368f, 370–373t, 371f, 372f, 374–375f, 380t, 381f**

- Zygomatic process, 204*f*, 206*f*, **208, 208*f*, 211*f*, 212, 216*t*, 217*t***
- Zygomaticus muscles, 326*f*, **330*t*, 331*f***
- Zygote, 1019, **1065, 1067**  
 cleavage of, **1067, 1071*f***
- Zygote intrafallopian transfer (ZIFT), 1089
- Zymogen granules, **882–883, 882*f***

# Word Roots, Prefixes, Suffixes, and Combining Forms

## Prefixes and Combining Forms

- a-, an-** *absence, lack* acardia, lack of a heart; anaerobic, in the absence of oxygen
- ab-** *departing from, away from* abnormal, departing from normal
- acou-** *hearing* acoustics, the science of sound
- ac-, acro-** *extreme or extremity, peak* acrodermatitis, inflammation of the skin of the extremities
- ad-** *to, toward* adorbital, toward the orbit
- aden-, adeno-** *gland* adeniform, resembling a gland in shape
- adren-** *toward the kidney* adrenal gland, adjacent to the kidney
- aero-** *air* aerobic respiration, oxygen-requiring metabolism
- af-** *toward* afferent neurons, which carry impulses to the central nervous system
- agon-** *contest* agonistic and antagonistic muscles, which oppose each other
- alb-** *white* corpus albicans of the ovary, a white scar tissue
- aliment-** *nourish* alimentary canal, or digestive tract
- allel-** *of one another* alleles, alternative expressions of a gene
- amphi-** *on both sides, of both kinds* amphibian, an organism capable of living in water and on land
- ana-** *apart, up, again* anaphase of mitosis, when the chromosomes separate
- anastomos-** *come together* arteriovenous anastomosis, a connection between an artery and a vein
- aneurysm** *a widening* aortic aneurysm, a weak spot that causes enlargement of the blood vessel
- angi-** *vessel* angiitis, inflammation of a lymph vessel or blood vessel
- angin-** *choked* angina pectoris, a choked feeling in the chest due to dysfunction of the heart
- ant-, anti-** *opposed to, preventing, inhibiting* anticoagulant, a substance that prevents blood coagulation
- ante-** *preceding, before* antecubital, in front of the elbow
- aort-** *great artery* aorta
- ap-, api-** *tip, extremity* apex of the heart
- append-** *hang to* appendicular skeleton
- aqua-, aque-** *water* aqueous solutions
- arbor** *tree* arbor vitae of the cerebellum, the treelike pattern of white matter
- areola-** *open space* areolar connective tissue, a loose connective tissue
- arrect-** *upright* arrector pili muscles of the skin, which make the hairs stand erect
- arthr-, arthro-** *joint* arthropathy, any joint disease
- artic-** *joint* articular surfaces of bones, the points of connection
- atri-** *vestibule* atria, upper chambers of the heart
- auscult-** *listen* auscultatory method for measuring blood pressure
- aut-, auto-** *self* autogenous, self-generated
- ax-, axi-, axo-** *axis, axle* axial skeleton, axis of vertebral column
- azyg-** *unpaired* azygous vein, an unpaired vessel
- baro-** *pressure* baroreceptors for monitoring blood pressure
- basal** *base* basal lamina of epithelial basement membrane
- bi-** *two* bicuspid, having two cusps
- bili-** *bile* bilirubin, a bile pigment
- bio-** *life* biology, the study of life and living organisms
- blast-** *bud, germ* blastocyte, undifferentiated embryonic cell
- brachi-** *arm* brachial plexus of peripheral nervous system supplies the arm
- brady-** *slow* bradycardia, abnormally slow heart rate
- brev-** *short* fibularis brevis, a short leg muscle
- broncho-** *bronchus* bronchospasm, spasmodic contraction of bronchial muscle
- bucco-** *cheek* buccolabial, pertaining to the cheek and lip
- calor-** *heat* calories, a measure of energy
- capill-** *hair* blood and lymph capillaries
- caput-** *head* decapitate, remove the head
- carcin-** *cancer* carcinogen, a cancer-causing agent
- cardi-, cardio-** *heart* cardiotoxic, harmful to the heart
- carneo-** *flesh* trabeculae carneae, ridges of muscle in the ventricles of the heart
- carot-** (1) *carrot*, (2) *stupor* (1) carotene, an orange pigment, (2) carotid arteries in the neck, blockage of which causes fainting
- cata-** *down* catabolism, chemical breakdown
- caud-** *tail* caudal (directional term)
- cec-** *blind* cecum of large intestine, a blind-ended pouch
- cele-** *abdominal* celiac artery, in the abdomen
- cephal-** *head* cephalometer, an instrument for measuring the head
- cerebro-** *brain, especially the cerebrum* cerebrospinal, pertaining to the brain and spinal cord
- cervic-, cervix** *neck* cervix of the uterus
- chiasm-** *crossing* optic chiasma, where optic nerves cross
- chole-** *bile* cholesterol, cholecystokinin, a bile-secreting hormone
- chondr-** *cartilage* chondrogenic, giving rise to cartilage
- chrom-** *colored* chromosome, so named because they stain darkly
- cili-** *small hair* ciliated epithelium
- circum-** *around* circumnuclear, surrounding the nucleus
- clavic-** *key* clavicle, a "skeleton key"
- co-, con-** *together* concentric, common center, together in the center
- coccy-** *cuckoo* coccyx, which is beak-shaped
- cochlea** *snail shell* the cochlea of the inner ear, which is coiled like a snail shell
- coel-** *hollow* coelom, the ventral body cavity
- commis-** *united* gray commissure of the spinal cord connects the two columns of gray matter
- concha** *shell* nasal conchae, coiled shelves of bone in the nasal cavity
- contra-** *against, opposite* contraceptive, agent preventing conception

**corn-, cornu-** *horn* stratum corneum, outer layer of the skin composed of (horny) cells  
**corona** *crown* coronal suture of the skull  
**corp-** *body* corpse; corpus luteum, hormone-secreting body in the ovary  
**cort-** *bark* cortex, the outer layer of the brain, kidney, adrenal glands, and lymph nodes  
**cost-** *rib* intercostal, between the ribs  
**crani-** *skull* craniotomy, a skull operation  
**crypt-** *hidden* cryptomenorrhea, a condition in which menstrual symptoms are experienced but no external loss of blood occurs  
**cusp-** *pointed* bicuspid, tricuspid valves of the heart  
**cutic-** *skin* cuticle of the nail  
**cyan-** *blue* cyanosis, blue color of the skin due to lack of oxygen  
**cyst-** *sac, bladder* cystitis, inflammation of the urinary bladder  
**cyt-** *cell* cytology, the study of cells  
**de-** *undoing, reversal, loss, removal* deactivation, becoming inactive  
**decid-** *falling off* deciduous (milk) teeth  
**delta** *triangular* deltoid muscle, roughly triangular in shape  
**den-, dent-** *tooth* dentin of the tooth  
**dendr-** *tree, branch* dendrites, branches of a neuron  
**derm-** *skin* dermis, deep layer of the skin  
**desm-** *bond* desmosome, which binds adjacent epithelial cells  
**di-** *twice, double* dimorphism, having two forms  
**dia-** *through, between* diaphragm, the wall through or between two areas  
**dialys-** *separate, break apart* kidney dialysis, in which waste products are removed from the blood  
**diastol-** *stand apart* cardiac diastole, between successive contractions of the heart  
**diure-** *urinate* diuretic, a drug that increases urine output  
**dors-** *the back* dorsal, dorsum, dorsiflexion  
**duc-, duct** *lead, draw* ductus deferens, tube which carries sperm from the epididymis into the urethra during ejaculation  
**dura** *hard* dura mater, tough outer meninx  
**dys-** *difficult, faulty, painful* dyspepsia, disturbed digestion  
**ec-, ex-, ecto-** *out, outside, away from* excrete, to remove materials from the body  
**ectop-** *displaced* ectopic pregnancy; ectopic focus for initiation of heart contraction  
**edem-** *swelling* edema, accumulation of water in body tissues  
**ef-** *away* efferent nerve fibers, which carry impulses away from the central nervous system  
**ejac-** *to shoot forth* ejaculation of semen  
**embol-** *wedge* embolus, an obstructive object traveling in the bloodstream  
**en-, em-** *in, inside* encysted, enclosed in a cyst or capsule  
**enceph-** *brain* encephalitis, inflammation of the brain  
**endo-** *within, inner* endocytosis, taking particles into a cell  
**entero-** *intestine* enterologist, one who specializes in the study of intestinal disorders  
**epi-** *over, above* epidermis, outer layer of skin  
**erythr-** *red* erythema, redness of the skin; erythrocyte, red blood cell  
**eso-** *within* esophagus  
**eu-** *well* eusthesia, a normal state of the senses  
**excret-** *separate* excretory system  
**exo-** *outside, outer layer* exophthalmos, an abnormal protrusion of the eye from the orbit  
**extra-** *outside, beyond* extracellular, outside the body cells of an organism  
**extrins-** *from the outside* extrinsic regulation of the heart  
**fasci-, fascia-** *bundle, band* superficial and deep fascia  
**fenestr-** *window* fenestrated capillaries  
**ferr-** *iron* transferrin, ferritin, both iron-storage proteins  
**flagell-** *whip* flagellum, the tail of a sperm cell  
**flat-** *blow, blown* flatulence

**folli-** *bag, bellows* hair follicle  
**fontan-** *fountain* fontanelles of the fetal skull  
**foram-** *opening* foramen magnum of the skull  
**foss-** *ditch* fossa ovalis of the heart; mandibular fossa of the skull  
**gam-, gamet-** *married, spouse* gametes, the sex cells  
**gangli-** *swelling, or knot* dorsal root ganglia of the spinal nerves  
**gastr-** *stomach* gastrin, a hormone that influences gastric acid secretion  
**gene** *beginning, origin* genetics  
**germin-** *grow* germinal epithelium of the gonads  
**gero-, geront-** *old man* gerontology, the study of aging  
**gest-** *carried* gestation, the period from conception to birth  
**glauc-** *gray* glaucoma, which causes gradual blindness  
**glom-** *ball* glomeruli, clusters of capillaries in the kidneys  
**glosso-** *tongue* glossopathy, any disease of the tongue  
**gluco-, glyco-** *gluconeogenesis*, the production of glucose from noncarbohydrate molecules  
**glute-** *buttock* gluteus maximus, largest muscle of the buttock  
**gnost-** *knowing* the gnostic sense, a sense of awareness of self  
**gompho-** *nail* gomphosis, the term applied to the joint between tooth and jaw  
**gon-, gono-** *seed, offspring* gonads, the sex organs  
**gust-** *taste* gustatory sense, the sense of taste  
**hapt-** *fasten, grasp* hapten, a partial antigen  
**hema-, hemato-, hemo-** *blood* hematocyst, a cyst containing blood  
**hemi-** *half* hemiglossal, pertaining to one-half of the tongue  
**hepat-** *liver* hepatitis, inflammation of the liver  
**hetero-** *different or other* heterosexuality, sexual desire for a person of the opposite sex  
**hiat-** *gap* the hiatus of the diaphragm, the opening through which the esophagus passes  
**hippo-** *horse* hippocampus of the brain, shaped like a seahorse  
**hirsut-** *hairy* hirsutism, excessive body hair  
**hist-** *tissue* histology, the study of tissues  
**holo-** *whole* holocrine glands, whose secretions are whole cells  
**hom-, homo-** *same* homeoplasia, formation of tissue similar to normal tissue; homocentric, having the same center  
**hormon-** *to excite* hormones  
**humor-** *a fluid* humoral immunity, which involves antibodies circulating in the blood  
**hyal-** *glass, clear* hyaline cartilage, which has no visible fibers  
**hydr-, hydro-** *water* dehydration, loss of body water  
**hyper-** *excess* hypertension, excessive tension  
**hypno-** *sleep* hypnosis, a sleeplike state  
**hypo-** *below, deficient* hypodermic, beneath the skin; hypokalemia, deficiency of potassium  
**hyster-, hystero-** *uterus, womb* hysterectomy, removal of the uterus; hysterodynia, pain in the womb  
**ile-** *intestine* ileum, the last portion of the small intestine  
**im-** *not impermeable, not permitting passage, not permeable*  
**inter-** *between* intercellular, between the cells  
**intercal-** *insert* intercalated discs, the end membranes between adjacent cardiac muscle cells  
**intra-** *within, inside* intracellular, inside the cell  
**iso-** *equal, same* isothermal, equal, or same, temperature  
**jugul-** *throat* jugular veins, prominent vessels in the neck  
**juxta-** *near, close to* juxtaglomerular complex, a cell cluster next to a glomerulus in the kidneys  
**karyo-** *kernel, nucleus* karyotype, the assemblage of the nuclear chromosomes  
**kera-** *horn* keratin, the water-repellent protein of the skin  
**kilo-** *thousand* kilocalories, equal to 1000 calories  
**kin-, kines-** *move* kinetic energy, the energy of motion

**labi-, labri-** *lip* labial frenulum, the membrane which joins the lip to the gum

**lact-** *milk* lactose, milk sugar

**lacun-** *space, cavity, lake* lacunae, the spaces occupied by cells of cartilage and bone tissue

**lamell-** *small plate* concentric lamellae, rings of bone matrix in compact bone

**lamina** *layer, sheet* basal lamina, part of the epithelial basement membrane

**lat-** *wide* latissimus dorsi, a broad muscle of the back

**laten-** *hidden* latent period of a muscle twitch

**later-** *side* lateral (directional term)

**leuko-** *white* leukocyte, white blood cell

**leva-** *raise, elevate* levator labii superioris, muscle that elevates upper lip

**lingua-** *tongue* lingual tonsil, adjacent to the tongue

**lip-, lipo-** *fat, lipid* lipophagy, a cell that has taken up fat in its cytoplasm

**lith-** *stone* cholelithiasis, gallstones

**luci-** *clear* stratum lucidum, clear layer of the epidermis

**lumen** *light* lumen, center of a hollow structure

**lut-** *yellow* corpus luteum, a yellow, hormone-secreting structure in the ovary

**lymph** *water* lymphatic circulation, return of clear fluid to the bloodstream

**macro-** *large* macromolecule, large molecule

**macula** *spot* macula lutea, yellow spot on the retina

**magn-** *large* foramen magnum, largest opening of the skull

**mal-** *bad, abnormal* malfunction, abnormal functioning of an organ

**mamm-** *breast* mammary gland, breast

**mast-** *breast* mastectomy, removal of a mammary gland

**mater** *mother* dura mater, pia mater, membranes that envelop the brain

**meat-** *passage* external acoustic meatus, the ear canal

**medi-** *middle* medial (directional term)

**medull-** *marrow* medulla, the middle portion of the kidney, adrenal gland, and lymph node

**mega-** *large* megakaryocyte, large precursor cell of platelets

**meio-** *less* meiosis, nuclear division that halves the chromosome number

**melan-** *black* melanocytes, which secrete the black pigment melanin

**men-, menstru-** *month* menses, the cyclic menstrual flow

**meningo-** *membrane* meningitis, inflammation of the membranes of the brain

**mer-, mero-,** *a part* merocrine glands, the secretions of which do not include the cell

**meso-** *middle* mesoderm, middle germ layer

**meta-** *beyond, between, transition* metatarsus, the part of the foot between the tarsus and the phalanges

**metro-** *uterus* endometrium, the lining of the uterus

**micro-** *small* microscope, an instrument used to make small objects appear larger

**mictur-** *urinate* micturition, the act of voiding the bladder

**mito-** *thread, filament* mitochondria, small, filament-like structures located in cells

**mnem-** *memory* amnesia

**mono-** *single* monospasm, spasm of a single limb

**morpho-** *form* morphology, the study of form and structure of organisms

**multi-** *many* multinuclear, having several nuclei

**mur-** *wall* intramural ganglion, a nerve junction within an organ

**muta-** *change* mutation, change in the base sequence of DNA

**myelo-** *spinal cord, marrow* myeloblasts, cells of the bone marrow

**myo-** *muscle* myocardium, heart muscle

**nano-** *dwarf* nanometer, one-billionth of a meter

**narco-** *numbness* narcotic, a drug producing stupor or numbed sensations

**natri-** *sodium* atrial natriuretic peptide, a sodium-regulating hormone

**necro-** *death* necrosis, tissue death

**neo-** *new* neoplasm, an abnormal growth

**nepbro-** *kidney* nephritis, inflammation of the kidney

**neuro-** *nerve* neurophysiology, the physiology of the nervous system

**noci-** *harmful* nociceptors, receptors for pain

**nom-** *name* innominate artery; innominate bone

**noto-** *back* notochord, the embryonic structure that precedes the vertebral column

**nucle-** *pit, kernel, little nut* nucleus

**nutri-** *feed, nourish* nutrition

**ob-** *before, against* obstruction, impeding or blocking up

**oculo-** *eye* monocular, pertaining to one eye

**odonto-** *teeth* orthodontist, one who specializes in proper positioning of the teeth in relation to each other

**olfact-** *smell* olfactory nerves

**oligo-** *few* oligodendrocytes, neuroglial cells with few branches

**onco-** *a mass* oncology, study of cancer

**oo-** *egg* oocyte, precursor of female gamete

**ophthalmo-** *eye* ophthalmology, the study of the eyes and related disease

**orb-** *circular* orbicularis oculi, muscle that encircles the eye

**orchi-** *testis* cryptorchidism, failure of the testes to descend into the scrotum

**org-** *living* organism

**ortho-** *straight, direct* orthopedic, correction of deformities of the musculoskeletal system

**osm-** *smell* anosmia, loss of sense of smell

**osmo-** *pushing* osmosis

**osteo-** *bone* osteoderma, bony formations in the skin

**oto-** *ear* otoscope, a device for examining the ear

**ov-, ovi-** *egg* ovum; oviduct

**oxy-** *oxygen* oxygenation, the saturation of a substance with oxygen

**pan-** *all, universal* panacea, a cure-all

**papill-** *nipple* dermal papillae, projections of the dermis into the epidermal area

**para-** *beside, near* paranuclear, beside the nucleus

**pect-, pectus** *breast* pectoralis major, a large chest muscle

**pelv-** *a basin* pelvic girdle, which cradles the pelvic organs

**peni-** *a tail* penis; penile arteriole

**penna-** *feather* unipennate, bipennate muscles, whose fascicles have a feathered appearance

**pent-** *five* pentose, a 5-carbon sugar

**pep-, peps-, pept-** *digest* pepsin, a digestive enzyme of the stomach; peptic ulcer

**per-, permea-** *through* permeate; permeable

**peri-** *around* perianal, situated around the anus

**phago-** *eat* phagocyte, a cell that engulfs and digests particles or cells

**pheno-** *show, appear* phenotype, the physical appearance of an individual

**phleb-** *vein* phlebitis, inflammation of the veins

**pia** *tender* pia mater, delicate inner membrane around the brain and spinal cord

**pili** *hair* arrector pili muscles of the skin, which make the hairs stand erect

**pin-, pino-** *drink* pinocytosis, the engulfing of small particles by a cell

**platy-** *flat, broad* platysma, broad, flat muscle of the neck

**pleur-** *side, rib* pleural serosa, the membrane that lines the thoracic cavity and covers the lungs

**plex-, plexus** *net, network* brachial plexus, the network of nerves that supplies the arm

**pneumo-** *air, wind* pneumothorax, air in the thoracic cavity

**pod-** *foot* podiatry, the treatment of foot disorders

**poly-** *multiple* polymorphism, multiple forms

**post-** *after, behind* posterior, places behind (a specific) part

**pre-, pro-** *before, ahead of* prenatal, before birth

**procto-** *rectum, anus* proctoscope, an instrument for examining the rectum

**pron-** *bent forward* prone, pronate

**propri-** *one's own* proprioception, awareness of body parts and movement  
**pseudo-** *false* pseudotumor, a false tumor  
**psycho-** *mind, psyche* psychogram, a chart of personality traits  
**ptos-** *fall* renal ptosis, a condition in which the kidneys drift below their normal position  
**pub-** *of the pubis* puberty  
**pulmo-** *lung* pulmonary artery, which brings blood to the lungs  
**pyo-** *pus* pyocyst, a cyst that contains pus  
**pyro-** *fire* pyrogen, a substance that induces fever  
**quad-, quadr-** *four-sided* quadratus lumborum, a muscle with a square shape  
**re-** *back, again* reinfect  
**rect-** *straight* rectus abdominis, rectum  
**ren-** *kidney* renal; renin, an enzyme secreted by the kidney  
**retin-, retic-** *net, network* endoplasmic reticulum, a network of membranous sacs within a cell  
**retro-** *backward, behind* retrogression, to move backward in development  
**rheum-** *watery flow, change, flux* rheumatoid arthritis; rheumatic fever  
**rhin-, rhino-** *nose* rhinitis, inflammation of the nose  
**rug-** *fold, wrinkle* rugae, the folds of the stomach, gallbladder, and urinary bladder  
**sagitt-** *arrow* sagittal (directional term)  
**salta-** *leap* saltatory conduction, the rapid conduction of impulses along myelinated neurons  
**sanguin-** *blood* consanguineous, indicative of a genetic relationship between individuals  
**sarco-** *flesh* sarcomere, unit of contraction in skeletal muscle  
**saphen-** *visible, clear* great saphenous vein, superficial vein of the thigh and leg  
**sclero-** *hard* sclerodermitis, inflammatory thickening and hardening of the skin  
**seb-** *grease* sebum, the oil of the skin  
**semen** *seed, sperm* semen, the discharge of the male reproductive system  
**semi-** *half* semicircular, having the form of half a circle  
**sens-** *feeling* sensation, sensory  
**septi-** *rotten* sepsis, infection; antiseptic  
**septum** *fence* nasal septum  
**sero-** *serum* serological tests, which assess blood conditions  
**serrat-** *saw* serratus anterior, a muscle of the chest wall that has a jagged edge  
**sin-, sino-** *a hollow* sinuses of the skull  
**soma-** *body* somatic nervous system  
**somn-** *sleep* insomnia, inability to sleep  
**sphin-** *squeeze* sphincter  
**splanchn-** *organ* splanchnic nerve, autonomic supply to abdominal viscera  
**spondyl-** *vertebra* ankylosing spondylitis, rheumatoid arthritis affecting the spine  
**squam-** *scale, flat* squamous epithelium, squamous suture of the skull  
**steno-** *narrow* stenocoriasis, narrowing of the pupil  
**strat-** *layer* strata of the epidermis; stratified epithelium  
**stria-** *furrow, streak* striations of skeletal and cardiac muscle tissue  
**stroma** *spread out* stroma, the connective tissue framework of some organs  
**sub-** *beneath, under* sublingual, beneath the tongue  
**sucr-** *sweet* sucrose, table sugar  
**sudor-** *sweat* sudoriferous glands, the sweat glands  
**super-** *above, upon* superior, quality or state of being above other parts  
**supra-** *above, upon* supracondylar, above a condyle  
**sym-, syn-** *together, with* synapse, the region of communication between two neurons  
**synerg-** *work together* synergism  
**systol-** *contraction* systole, contraction of the heart  
**tachy-** *rapid* tachycardia, abnormally rapid heartbeat

**tact-** *touch* tactile sense  
**telo-** *the end* telophase, the end of mitosis  
**templ-, tempo-** *time* temporal summation of nerve impulses  
**tens-** *stretched* muscle tension  
**terti-** *third* fibularis tertius, one of three fibularis muscles  
**tetan-** *rigid, tense* tetanus of muscles  
**therm-** *heat* thermometer, an instrument used to measure heat  
**thromb-** *clot* thrombocyte, thrombus  
**thyro-** *a shield* thyroid gland  
**tissu-** *woven* tissue  
**tono-** *tension* tonicity, hypertonic  
**tox-** *poison* toxicology, study of poisons  
**trab-** *beam, timber* trabeculae, spicules of bone in spongy bone tissue  
**trans-** *across, through* transpleural, through the pleura  
**trapez-** *table* trapezius, the four-sided muscle of the upper back  
**tri-** *three* trifurcation, division into three branches  
**trop-** *turn, change* tropic hormones, whose targets are endocrine glands  
**troph-** *nourish* trophoblast, from which develops the fetal portion of the placenta  
**tuber-** *swelling* tuberosity, a bump on a bone  
**tunic-** *covering* tunica albuginea, the covering of the testis  
**tympan-** *drum* tympanic membrane, the eardrum  
**ultra-** *beyond* ultraviolet radiation, beyond the band of visible light  
**vacc-** *cow* vaccine  
**vagin-** *a sheath* vagina  
**vagus** *wanderer* the vagus nerve, which starts at the brain and travels into the abdominopelvic cavity  
**valen-** *strength* valence shells of atoms  
**venter, ventr-** *abdomen, belly* ventral (directional term), ventricle  
**vent-** *the wind* pulmonary ventilation  
**vert-** *turn* vertebral column  
**vestibul-** *a porch* vestibule, the anterior entryway to the mouth and nose  
**vibr-** *shake, quiver* vibrissae, hairs of the nasal vestibule  
**villus** *shaggy hair* microvilli, which have the appearance of hair in light microscopy  
**viscero-** *organ, viscera* visceroinhibitory, inhibiting the movements of the viscera  
**viscos-** *sticky* viscosity, resistance to flow  
**vita-** *life* vitamin  
**vitre-** *glass* vitreous humor, the clear jelly of the eye  
**viv-** *live* in vivo  
**vulv-** *a covering* vulva, the female external genitalia  
**zyg-** *a yoke, twin* zygote

## Suffixes

**-able** *able to, capable of* viable, ability to live or exist  
**-ac** *referring to* cardiac, referring to the heart  
**-algia** *pain in a certain part* neuralgia, pain along the course of a nerve  
**-apsi** *junction* synapse, where two neurons communicate  
**-ary** *associated with, relating to* coronary, associated with the heart  
**-asthen** *weakness* myasthenia gravis, a disease involving paralysis  
**-bryo** *swollen* embryo  
**-cide** *destroy or kill* germicide, an agent that kills germs  
**-cipit** *head* occipital  
**-clast** *break* osteoclast, a cell that dissolves bone matrix  
**-crine** *separate* endocrine organs, which secrete hormones into the blood  
**-dips** *thirst, dry* polydipsia, excessive thirst associated with diabetes  
**-ectomy** *cutting out, surgical removal* appendectomy, cutting out of the appendix  
**-ell, -elle** *small* organelle  
**-emia** *condition of the blood* anemia, deficiency of red blood cells  
**-esthesi** *sensation* anesthesia, lack of sensation

**-ferent** *carry* efferent nerves, nerves carrying impulses away from the CNS  
**-form, -forma** *shape* cribriform plate of the ethmoid bone  
**-fuge** *driving out* vermifuge, a substance that expels worms of the intestine  
**-gen** *an agent that initiates* pathogen, any agent that produces disease  
**-glea, -glia** *glue* neuroglia, the connective tissue of the nervous system  
**-gram** *data that are systematically recorded, a record* electrocardiogram, a recording showing action of the heart  
**-graph** *an instrument used for recording data or writing* electrocardiograph, an instrument used to make an electrocardiogram  
**-ia** *condition* insomnia, condition of not being able to sleep  
**-iatrics** *medical specialty* geriatrics, the branch of medicine dealing with disease associated with old age
