  - Contrast administration shows delayed enhancement with delayed excretion
- Radionuclide scan: Cortical agents (eg, DMSA) reveal decreased activity in the affected kidney; Useful to identify areas of scarring

Diagnostic Procedures/Surgery

Determine postvoid residual if indicated.

Pathologic Findings

- Gross: Edematous kidney with multiple foci of inflammation
- Microscopic: Focal areas of destruction of renal architecture with lymphocytic infiltrations

DIFFERENTIAL DIAGNOSIS

- Any intra-abdominal inflammatory process
  - Appendicitis, cholecystitis, diverticulitis, pancreatitis, peptic ulcer disease
- Gynecologic conditions:
  - Pelvic inflammatory disease, ectopic pregnancy, ruptured ovarian cysts
- Urologic conditions:
  - Renal colic with fever
  - Renal and perinephric abscesses
- Lower lobe pneumonia
- Musculoskelet al pain

TREATMENT

GENERAL MEASURES

- Supportive care consists of hydration, antipyretics, and analgesics
- Empiric antibiotics that are active against the possible causative organisms and achieve adequate levels in the renal parenchyma and urine are used

MEDICATION

First Line

- Outpatient therapy: In uncomplicated acute pyelonephritis, those who are reliable, tolerate oral intake, and do not have signs of sepsis do not require hospitalization (4,5)
  - Oral fluoroquinolones (ciprofloxacin 500 mg PO BID, or levofloxacin 750 mg/d PO) are adequate for empiric treatment. Levofloxacin is approved for a 5-day regimen
  - An alternative: Trimethoprim–sulfamethoxazole
  - Traditionally, continue therapy for 10–14 days. Recent data shows a 7-day course of ciprofloxacin is not inferior to a 14-day 1 in women with uncomplicated acute pyelonephritis
  - Recent data suggests increased quinolone resistance as well as susceptibility to TMP-SMZ
- Inpatient therapy: If signs of sepsis, bacteremia, or cannot tolerate oral medications
  - Also recommended for children, the elderly, pregnant patients, diabetics, and the immunocompromised and with complicated pyelonephritis
  - Parenteral antibiotic therapy uncomplicated
    - Ampicillin (2 g IV q6h) and gentamicin (1.5 mg/kg IV q8h) is traditional treatment; *OR*
    - Ceftriaxone (1 g/d IV) empirically; *OR*
    - IV fluoroquinolones ciprofloxacin 400 mg q12h or levofloxacin 750 mg q24h; aztreonam is also an acceptable alternative
  - Most patients continue to have fever or flank pain for several days after appropriate therapy has been started.
  - IV therapy continued until the patient is afebrile or cultures indicate another appropriate antibiotic.
  - When able to tolerate oral intake, switch to an oral antibiotic as for oral therapy above.
  - Pregnant patients: Place on suppression therapy (eg, nitrofurantoin 100 mg/d PO, cephalexin 250 mg/d PO) after treatment until delivery, due to a relapse rate of up to 60% in nonsuppressed patients.
  - Patients with a delayed response to therapy should be treated with a longer course of antibiotics (14–21 days), even without evidence of complicated disease.
- Complicated pyelonephritis: Assess for underlying urologic abnormalities (obstruction, stones, etc.) (6)
  - Parenteral antibiotic therapy in complicated cases:
    - Piperacillin–tazobactam 3.375 g q6h, ticarcillin–clavulanate 3.1 g q6h, cefepime 1 g q12h
    - Alternates include meropenem, and imipenem. Dose-adjust with renal failure.
  - After transitioning to species-specific antibiotics, PO continued for 14–21 days
- Pregnancy considerations:
  - Ampicillin, amoxicillin and, PO cephalosporins have proven to be safe;

amoxicillin/clavulanic acid (Augmentin) is recommended for resistant organisms; nitrofurantoin is safe for the fetus but potentially toxic to the mother; fluoroquinolones should be avoided in pregnancy

SURGERY/OTHER PROCEDURES

- Diversion with indwelling stent or percutaneous drain may be necessary in patients with urinary obstruction.
- If a renal abscess forms:
  - 3–5 cm in size then place percutaneous drain
  - >5 cm may require more than 1 percutaneous drain or surgical drainage

ONGOING CARE

PROGNOSIS

With 1st episode of acute pyelonephritis, 1-yr risk of a 2nd episode was 9.2% in females and 5.7% in males. With a 4th episode, the risk of a 5th infection was 50% for females and males.

COMPLICATIONS

- Short term:
  - Septic shock
  - Abscess formation (corticomedullary, perinephric)
  - Papillary necrosis
- Long term: Renal scarring (20%)
- Children with developing kidneys are at significant risk of scarring from even 1 episode of acute pyelonephritis
- Diabetics are at significant risk of developing emphysematous pyelonephritis, a more fulminant process with a high mortality:
  - Characterized by renal intraparenchymal gas and detectable on KUB
- Patients with calculi or urinary tract obstruction who have recurrent episodes of pyelonephritis may develop xanthogranulomatous pyelonephritis:
  - Characterized by large nonfunctioning renal mass
  - Stones are present in 80% of cases
- Pregnant patients are at high risk because of the physiologic changes of pregnancy to the urinary tract:
  - Sepsis
  - Adult respiratory distress syndrome
  - Preterm delivery with low–birth-weight infants

FOLLOW-UP

Patient Monitoring

- Urine cultures 4–6 wk after completion of antibiotics to verify infection cleared
- 10–30% suffer a relapse and may be treated with a 2nd 14-day course of antibiotics
- Occasionally, a 6-wk course needed for cure
- Confirm hematuria clears if initially present

CLINICAL/SURGICAL PEARLS

- Urine cultures may be negative in patients especially if started on recent antibiotics.
- If fevers last for more than 72 hr after antibiotics, obtain at CT scan to rule obstruction, soft

tissue infection, or abscess formation.

PYELONEPHRITIS, ACUTE, PEDIATRIC

Ross M. Decter, MD, FRCS
Paul H. Smith III, MD

BASICS

DESCRIPTION

- Infectious process involving the renal parenchyma and collecting system
- Retrograde ascent of uropathogenic bacteria is most common cause

EPIDEMIOLOGY

Incidence

- 18,000–20,000 children per year hospitalized for diagnosis of pyelonephritis
- Risk of childhood UTI 2% for boys and 8% for girls
- UTI more common in males during 1st yr of life
  - Gender predilection reversed thereafter

Prevalence

Low, given the acuity of illness and prompt treatment

RISK FACTORS

- Circumcision reduces risk of UTI during 1st yr of life
  - 10× greater risk of UTI in uncircumcised boys
- Dysfunctional voiding
- Anatomic urinary tract anomalies
  - Ureteropelvic junction obstruction
  - Vesicoureteral reflux (VUR)
  - Ureterocele/ectopic ureter
- Neurogenic bladder dysfunction

Genetics

P1 blood group antigen associated with recurrent pyelonephritis

PATHOPHYSIOLOGY

- Periurethral and fecal flora are the source of most uropathogens
  - *Escherichia coli* is the most common organism
  - Other common organisms are *Klebsiella, Enterococcus, Pseudomonas, Staphylococcus saprophyticus, Enterobacter*
- Bacterial virulence factors promote upper tract infection
  - P fimbriae: *E. coli* virulence factor promotes adherence and subsequent invasion of bacteria into the urothelium (1)
- Inflammatory response initiated by interaction between bacterial endotoxin and toll-like receptor (TLR) 4 (1)

ASSOCIATED CONDITIONS

- Lobar nephronia: Pyelonephritis affecting only an isolated focus within the kidney

- Pyonephrosis: Purulent material within the collecting system
- Renal abscess

GENERAL PREVENTION
- Prophylactic antibiotics in patients with recurrent episodes of UTI or with VUR
- Surgical correction of anatomic urinary tract anomalies
- Optimization of bladder/bowel management in patients with neurogenic and nonneurogenic bladder dysfunction
- Antibiotic prophylaxis if major GU instrumentation

DIAGNOSIS

HISTORY
- Nonspecific symptoms or failure to thrive in young children
  - High degree of suspicion required in young children
- Fever, nausea, vomiting
- Flank or abdominal pain
- Hematuria, dysuria, foul smelling urine, frequency, urgency
- History of UTIs
- Functional or anatomic urinary tract anomalies

PHYSICAL EXAM
- Fever
- Sepsis
- CVA tenderness
- Exam findings nonspecific in young children

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis
  - WBCs: >5 per HPF
  - Presence of any bacteria
  - Positive leukocyte esterase
  - Positive nitrites: ~4 hr of dwell time in the bladder required for nitrites to become positive
- Urine culture: Specimen collected by clean catch, catheterization or suprapubic aspiration (SPA)
  - >50,000 C FU signifies positive culture (2)
- CBC: Leukocytosis with left shift
- Blood cultures
- Elevated CRP, ESR, procalcitonin

Imaging
- Renal and bladder ultrasonography (RBUS)
  - Failure to improve clinically within 1st 2 days of antibiotic treatment should prompt evaluation with RBUS to evaluate for complications
    - Renal abscess

- Pyonephrosis
  - Used to identify structural abnormalities contributing to the development of pyelonephritis
- Voiding cystourethrogram (VCUG)
  - Identifies VUR
  - Requirement for VCUG after 1st febrile UTI controversial
  - Invasive study (requires catheterization)
- Nuclear cystogram
  - More sensitive for low-grade VUR than VCUG but less anatomic detail
- Nuclear renography (DMSA)
  - Gold standard for diagnosis of pyelonephritis
    - Rarely necessary in acute setting
  - Delayed study identifies renal scarring (3)
  - Invasive study (IV injection of radionuclide)
  - Radiation exposure

Diagnostic Procedures/Surgery

SPA for urine culture if clean catch or catheterization not feasible

Pathologic Findings

- Renal scarring
  - Inflammatory reaction to renal parenchymal infection can cause irreversible renal scarring

DIFFERENTIAL DIAGNOSIS

- Renal abscess
- Pyonephrosis
- Other intra-abdominal process

TREATMENT

GENERAL MEASURES

- Prompt initiation of empiric antibiotics after acquisition of urine specimen suitable for culture (clean catch, catheterization, SPA)
- General supportive measures
  - Volume resuscitation, antipyretics, analgesics
- Need for hospitalization based on severity of illness, however admission generally indicated for infants (< 2–3 mo)

MEDICATION

First Line

- Empiric coverage
  - Tailor to local antimicrobial resistance patterns (2)[A]
  - Ampicillin (25–50 mg/kg/d) + gentamicin (2–2.5 mg/kg TID)
    - 3rd-generation cephalosporin an alternative to ampicillin if low risk for *enterococcus* UTI
- Oral culture-directed antibiotics once clinically improving and tolerating oral intake
  - Avoid nitrofurantoin due to minimal tissue penetration
  - Parenteral antibiotics (daily ceftriaxone, IM) also an option for outpatient therapy

- 7–14 days total duration of therapy (2)[B]

Second Line
- Vancomycin if penicillin allergic
- Aztreonam an alternate to aminoglycoside if renal insufficiency

SURGERY/OTHER PROCEDURES
- Urethral catheter if critically ill or poor bladder emptying
- Surgery generally not indicated in acute treatment
- Ureteral stent or nephrostomy tube if obstruction
- Percutaneous aspiration/drainage if progression to renal abscess

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
Probiotics (experimental)

ONGOING CARE

PROGNOSIS
Related to degree of renal injury from pyelonephritic scarring

COMPLICATIONS
- Pyelonephritic scarring, especially with recurrent episodes and delayed treatment
- Pyonephrosis
- Renal abscess
- Xanthogranulomatous pyelonephritis
- Hypertension

FOLLOW-UP
Patient Monitoring
- Current American Academy of Pediatrics guidelines recommends RUS in children with febrile UTI
  - Selective VCUG in patients with abnormal RUS or recurrent episodes (2)[C]
  - Indications for radiographic imaging in children with 1st episode of febrile UTI remain controversial
- Delayed DMSA scan to detect renal scarring

Patient Resources
- National Kidney and Urologic Diseases Information Clearinghouse (NKUDIC)

CODES

ICD9

- 041.49 Other and unspecified Escherichia coli [E. coli]
- 590.10 Acute pyelonephritis without lesion of renal medullary necrosis
- 593.73 Other vesicoureteral reflux with reflux nephropathy NOS

ICD10

- B96.20 Unsp Escherichia coli as the cause of diseases classd elswhr
- N10 Acute tubulo-interstitial nephritis
- N13.729 Vesicoureter-reflux w reflux nephropathy w/o hydrourt, unsp

CLINICAL/SURGICAL PEARLS

- Signs and symptoms are often nonspecific in infants and young children with pyelonephritis.
- Culture of appropriately collected urine specimen mandatory in patients with suspected UTI and in infants with fever and no obvious source.
- Acute imaging (RUS) recommended if critically ill or failure to respond to treatment.

PYELONEPHRITIS, CHRONIC

Debra L. Fromer, MD
Drew A. Freilich, MD

BASICS

DESCRIPTION

- Injury to the kidney with inflammation and fibrosis of the renal parenchyma, pelvis, and calyces. It is most often caused by recurrent or chronic renal infection
- Not usually diagnosed based on clinical presentation, chronic pyelonephritis is usually a radiologic or pathologic diagnosis
- Clinical signs and symptoms are often vague but can be related to the infection and the severity and location of injury within the kidney:
  - Often an incidental finding, it may present as asymptomatic bacteriuria, dysuria and frequency (lower urinary tract symptoms), vague complaints of flank or abdominal discomfort, and intermittent low-grade fevers.
  - Synonym(s): Chronic interstitial nephritis

EPIDEMIOLOGY

Incidence

- Occurs in males and females of all ages:
  - More common in childhood, especially with congenital anomalies such as vesicoureteral reflux (VUR) (1)[B]
- Chronic pyelonephritis accounts for 15–20% of cases of chronic renal failure
- Less common in patients having no underlying functional or structural urinary tract abnormalities

Prevalence

4:1,000 asymptomatic adults

RISK FACTORS

- Female sex
- In 50% of cases, history of a previous episode of acute pyelonephritis
- VUR/reflux nephropathy
- Congenital urinary tract anomalies
- Neurogenic bladder dysfunction
- Pregnancy
- Urinary tract obstruction with complicated UTI can result in renal insufficiency:
  - Mechanical obstruction includes prostatic hyperplasia, calculi, retroperitoneal fibrosis, neoplasms, and congenital anomalies

Genetics

Susceptibility to acute pyelonephritis may have a familial component and may be associated with decreased CXCR1 expression.

PATHOPHYSIOLOGY

- Progressive localized immune response to bacterial infection
- Hyaline casts in tubule may cause resemblance to thyroid colloid known as *renal thyroidization*
- Fibrosis around the glomeruli replaces kidney parenchyma in patches:
  – Calyceal clubbing with nonuniform localized scarring

ASSOCIATED CONDITIONS
- VUR
- Spinal cord injury
- Xanthogranulomatous pyelonephritis (XGP) is a form of chronic pyelonephritis
  – Presents with foamy lipid laden macrophages
  – Often unilateral and associated with longstanding obstructing nephrolithiasis

GENERAL PREVENTION
- Upper urinary tract evaluation in patients with recurrent bacteriuria or recurrent acute pyelonephritis
- Early detection, evaluation, and treatment of childhood UTIs
- Prompt detection and management of VUR
- Detection and treatment of obstructive uropathy

Geriatric Considerations
- Chronic pyelonephritis can present with atypical symptoms and signs (ie, failure to thrive, low-grade fevers). Diagnosis requires a high level of suspicion.

Pregnancy Considerations
- Antibiotic prophylaxis during pregnancy in patients with risk factors including:
  – History of acute pyelonephritis during pregnancy
  – Recurrent bacteriuria after treatment during pregnancy
  – History of recurrent UTIs on previous antibiotic prophylaxis before being pregnant

Pediatric Considerations
- Assess UTI with:
  – Voiding cystourethrogram (VCUG) (to check for VUR or anatomical abnormality)
  – DMSA (to detect scar formation/progression)
  – Renal US (to assess for hydronephrosis)

DIAGNOSIS

HISTORY
- Frequently asymptomatic and discovered incidentally
- UTIs in childhood and during pregnancy
- Presence of HTN, especially in children with known reflux nephropathy
- Proteinuria, polyuria, nocturia, frequency
- Patients with spinal cord injury present with cloudy or malodorous urine, vague abdominal discomfort, malaise, lethargy, leakage between catheterizations, or increased spasticity or autonomic dysreflexia.
- Fever of unknown origin
- Failure to thrive in infant or child

PHYSICAL EXAM

- HTN may be present
- Nonspecific, unless associated with an episode of acute pyelonephritis
- May be mild flank pain or CVA tenderness

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis may be normal or indicate pyuria or proteinuria. WBC casts can be seen.
- Urine culture is usually only positive with an active, symptomatic infection. Culture is often negative.
- Microalbuminuria/proteinuria is an adverse prognostic sign.

Imaging

- CT reveals the typical findings of chronic pyelonephritis
  - Small or atrophic kidney, unilaterally or bilaterally
  - Compensatory hypertrophy with unilateral atrophy
  - Blunted and dilated calyces
  - Renal cortical scarring and thinning of the cortex
- Renal US to evaluate for hydronephrosis, renal anatomy, or stones. Not a good test to identify active reflux, but dilated ureters suggest obstruction or reflux
- VCUG for the evaluation of reflux
- CT is more sensitive than US for nephrolithiasis; also to rule out obstruction, hydronephrosis, stone disease, urinary tract abnormality. Pyonephrosis or abscesses are usually identified if present
- Technetium-99m DMSA is the best study to evaluate for renal scarring

Diagnostic Procedures/Surgery

- Cystoscopy in selected cases
- Renal biopsy

Pathologic Findings

- Gross kidney is often diffusely contracted, scarred at periphery with thin cortex
- Microscopically, an interstitial infiltrate of lymphocytes, plasma cells, and occasional neutrophils is present
- Scarring is often polar with underlying calyceal blunting. Histologic changes are patchy:
  - Periglomerular fibrosis is often seen
  - Leukocytes and hyaline casts can be present in tubules, and the hyaline casts may resemble thyroid colloid, hence the description renal thyroidization

DIFFERENTIAL DIAGNOSIS

- Analgesic nephropathy
- Diabetic nephropathy
- Gouty nephritis
- Hypertensive renal disease
- Psoas and subdiaphragmatic abscess
- Renal artery stenosis
- Renal malakoplakia
- Renal tuberculosis

- Urolithiasis
- Xanthogranulomatous pyelonephritis (XGP) (2)[B]

TREATMENT

GENERAL MEASURES

- Chronic pyelonephritis is difficult to manage as it is an irreversible process
- With mild VUR, suppressive antibiotics are used until resolution or puberty in children
- Severe reflux may require reimplantation
- Correct anatomic anomalies or stones if possible

MEDICATION

First Line

- Acute episodes of pyelonephritis should be treated (See Section I: "Pyelonephritis, Acute") (3)[B]
- Suppressive antibiotics VUR in children has become controversial:
  - In children < 3–6 mo, use low-dose amoxicillin or cephalexin, cefazolin, or other 1st-generation cephalosporin can be considered
  - In children > 6 mo, switch to nitrofurantoin, trimethoprim-sulfamethoxazole, or trimethoprim alone can be considered
- Hypertension is best treated by ACE inhibitors (lisinopril, enalapril, ramipril) that may also protect the kidney from progressive renal failure
  - ACE inhibitors are contraindicated in pregnancy

Second Line

Based upon urine culture sensitivities, prior treatment attempts and patient presenting symptoms

SURGERY/OTHER PROCEDURES

- Correction of reflux may be necessary in children with high-grade reflux (Grade 4–5). Low-grade reflux (Grade 1–3) often resolves with time
- Nephrectomy for persistent/recurrent infection unresponsive to systemic treatment, markedly decreased function (ie, 10%), pain, or refractory HTN, XGP

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

Little data to support

ONGOING CARE

PROGNOSIS

- 24-hr protein excretion may be an important prognostic indicator of progressive

deterioration of renal function due to focal and segmental glomerulosclerosis superimposed on tubulointerstitial disease
- Radionuclide renal scan can assess renal function and scarring

COMPLICATIONS
- Emphysematous pyelonephritis
- End-stage renal disease (rare)
- Focal segmental glomerulosclerosis
- HTN
- Perinephric abscess: Requires surgical drainage
- Polyuria, nocturia from loss of tubular concentrating ability
- Pregnancy-related miscarriages in women with chronic reflux
- Proteinuria
- Pyonephrosis
- XGP

FOLLOW-UP
Patient Monitoring
- Annual serum creatinine to monitor chronic kidney disease
- Blood pressure monitoring (good control of BP may limit renal damage over time)
  – 15% of patients with reflux nephropathy who reach adulthood have HTN
  – Some advocate screening renal scan or VCUG of siblings who have reflux
- Urine analysis to monitor for proteinuria and bacteruria (4)[A]
- Selective long-term antibiotics to limit infection (5)[A]

Patient Resources
National Kidney and Urologic Diseases Information Clearinghouse (NIH).

CODES

ICD9

590.00 Chronic pyelonephritis without lesion of renal medullary necrosis

ICD10

- N11.1 Chronic obstructive pyelonephritis
- N11.8 Other chronic tubulo-interstitial nephritis
- N11.9 Chronic tubulo-interstitial nephritis, unspecified

CLINICAL/SURGICAL PEARLS

For best determination of renal function the bladder should be empty and kidneys unobstructed (ie, ureteral stent if large stones).

PYELONEPHRITIS, EMPHYSEMATOUS

Jennifer E. Heckman, MD, MPH
Stephen Y. Nakada, MD, FACS

BASICS

DESCRIPTION

- Acute necrotizing infection of the renal parenchyma and perirenal tissues caused by gas-forming organisms
  - Onset may be acute or insidious
  - Course is potentially life threatening (mortality: 11–42%)
- 1st report in 1898
- >200 reported cases

EPIDEMIOLOGY

Incidence

- All documented cases in adults
  - Most patients >60 yr old
- Female predominance (6:1)
- Bilateral cases, unusual but reported (L > R)

Prevalence

N/A

RISK FACTORS

- Diabetes mellitus (DM) (up to 95%)
  - Especially with poor glycemic control
- Urinary tract obstruction
  - Urinary calculi
  - Papillary necrosis
  - Neoplasm
- Immunosuppression

Genetics

N/A

PATHOPHYSIOLOGY

- Poorly understood
- Impaired host response allows microorganism proliferation
- Hypothesized that elevated tissue glucose levels provide substrate for microorganisms
  - Bacterial fermentation of sugar produces carbon dioxide
  - Low oxygen tension allows urinary tract infection to ascend
- *E. coli* is primary causative organism (70–90%)
  - *Klebsiella*, *Proteus*, *Streptococcus*, and coagulase-negative *Staphylococcus* less common
  - *Candida*, *Entamoeba histolytica*, and *Aspergillus fumigatus* are rare causes

ASSOCIATED CONDITIONS
- Alcohol abuse
- Diabetic ketoacidosis
- Immunocompromised states, including transplant patients
- Impaired renal function
- Malnutrition
- Urinary tract obstruction, including urinary calculi, papillary necrosis, or neoplasm

GENERAL PREVENTION
- Strict glycemic control in diabetes mellitus (DM)
- Adequate treatment of pre-existing pyelonephritis
- Prompt relief of urinary tract obstruction, if present

DIAGNOSIS
HISTORY
- Classic triad:
  - Fever, chills
  - Nausea, vomiting
  - Flank pain and/or abdominal pain
- Urinary frequency/urgency, dysuria
- Malaise
- Altered mental status
- History of DM, urinary calculi, and/or immunocompromise
- Pneumaturia absent unless infection involves collecting system

PHYSICAL EXAM
- Pyrexia
- Abdominal or flank tenderness
- Crepitus over flank (rare)
- Lethargy, confusion, altered mental status
- Sepsis/shock (tachycardia, hypotension)

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Complete blood count (CBC)
  - Leukocytosis
  - Thrombocytopenia
- Basic metabolic panel (BMP)
  - Hyperglycemia
  - Elevated serum creatinine
- Urinalysis +/− urine culture
  - Pyuria, bacteriuria, positive urine culture
- Blood cultures
  - Bacteremia (isolated organism same as that in urine)

Imaging

- Abdominal radiograph may show tissue gas in parenchyma (nonspecific, low sensitivity)
- Renal ultrasound may show highly echogenic area with dirty shadowing
- Computed tomography (CT) is imaging modality of choice (most sensitive and specific)
  - May see:
    - Absence of fluid or presence of streaky or mottled gas +/− bubbly and loculated gas in renal parenchyma, collecting system, and/or perirenal tissue
    - Rim-like or crescent-shaped gas distribution surrounding kidney
    - Gas in renal vein, inferior vena cava, or retroperitoneum
    - Urinary tract obstruction (seen in ~25% of cases)
  - Contrast not necessary for diagnosis (and may be contraindicated in renal impairment)
- Classification system (1)[B]:
  - Class 1: Gas confined to collecting system
  - Class 2: Gas confined to renal parenchyma without extension to extrarenal space
  - Class 3A: Perinephric extension of gas or abscess
  - Class 3B: Pararenal extension of gas or abscess (beyond Gerota's fascia and/or extension to adjacent tissues)
  - Class 4: Bilateral emphysematous pyelonephritis or emphysematous pyelonephritis in a solitary kidney
  - Therapeutic and prognostic implications:
    - Class 1 and 2: Percutaneous drainage successful, low mortality
    - Class 3 and 4: Percutaneous drainage less successful, increased mortality

Diagnostic Procedures/Surgery

None, diagnosis is radiographic

Pathologic Findings

- Gross
  - Multiple renal parenchymal abscesses with central, gas-filled region
  - Foci of micro- and macroinfarctions
- Microscopic
  - Glomerulosclerosis, arteriosclerosis, intrarenal vascular thrombi, or papillary necrosis

DIFFERENTIAL DIAGNOSIS

- Acute pyelonephritis
- Emphysematous cystitis
- Fistulous communication with gastrointestinal or respiratory tracts
- Iatrogenic (instrumentation of urinary tract)
- Necrotic renal tumor
- Pyonephrosis with urinary tract obstruction
- Renal abscess
- Xanthogranulomatous pyelonephritis

TREATMENT

ALERT

Emphysematous pyelonephritis is urologic emergency that requires prompt diagnosis and

intervention to prevent morbidity and mortality.

GENERAL MEASURES

- Rapid supportive measures:
  - Fluid resuscitation
  - Correction of electrolyte imbalances
  - Vasopressors as needed
  - Usually requires ICU status
- Indwelling urethral catheter to maximize urinary tract drainage and monitor urine output.

MEDICATION

First Line

- Antimicrobial agents
  - Broad-spectrum parenteral antibiotics initially (dosages assume normal renal function):
    - Ampicillin–sulbactam (1.5 g q6h)
    - Ticarcillin–clavulanate (3.1 g q6h)
    - Piperacillin–tazobactam (3.375 g q6h)
    - Meropenem (500 mg q8h)
    - Imipenem (500 mg q6h)
    - Doripenem (500 mg q8h)
  - Narrow to culture-directed antibiotics
  - At least 14 days of therapy
- Hyperglycemia management
  - Insulin (intravenous or subcutaneous)

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Percutaneous drainage
  - Indicated if:
    - Affected kidney is functioning
    - Affected kidney is obstructed
    - Localized area of gas identified
  - $\geq$14Fr catheter (may benefit from more than one catheter)
  - CT guidance preferred
  - In combination with antibiotic therapy reduces mortality rate
  - Helps preserve renal function in affected kidney
- If clinical improvement with medical management and percutaneous drainage, may delay or avoid nephrectomy
- Nephrectomy
  - Requires adequate resuscitation and stabilization preoperatively
  - Immediate vs. delayed (elective) based on clinical course
  - Indicated if:
    - Affected kidney is nonfunctioning and nonobstructed
    - Lack of clinical improvement with medical management and percutaneous drainage
  - Consider if:

- Presence of risk factors, including acute renal failure, thrombocytopenia, altered mental status, or shock
- Gas limited to renal parenchyma (dry-type emphysematous pyelonephritis)

– Flank approach preferred

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Dependent on:
  – Time to diagnosis and treatment
  – Local extent of the infection
- Mortality greatest in those presenting with (2)[B], (3)[B]:
  – Acute renal failure
  – Thrombocytopenia
  – Mental status changes
  – Shock
- Recent meta-analysis demonstrated treatment-based mortality (4)[B]:
  – Medical management alone: 50%
  – Medical management + emergency nephrectomy: 25%
  – Medical management + percutaneous drainage: 13.5%

COMPLICATIONS

- Perinephric abscess
- Renal insufficiency or failure
- Loss of renal unit
- Sepsis/shock
- Death
- Following procedural intervention:
  – Bowel or vascular injury
  – Wound infection

FOLLOW-UP

Patient Monitoring

- Follow urine and blood cultures for growth and sensitivities for directed antibiotic therapy
- Follow-up CT (4–7 days postpercutaneous drainage) (5)[C]
  – Look for other noncommunicating air/fluid collections (insert additional catheters as needed)
  – Maintain all drainage catheters until imaging demonstration of resolution

- Nuclear renal scan to assess degree of renal functional impairment and determine necessity of elective nephrectomy when patient stabilized

CODES

ICD9

- 250.40 Diabetes with renal manifestations, type II or unspecified type, not stated as uncontrolled
- 590.10 Acute pyelonephritis without lesion of renal medullary necrosis
- 599.60 Urinary obstruction, unspecified

ICD10

- E11.21 Type 2 diabetes mellitus with diabetic nephropathy
- N10 Acute tubulo-interstitial nephritis
- N13.9 Obstructive and reflux uropathy, unspecified

CLINICAL/SURGICAL PEARLS

- Must have high index of suspicion to diagnose this rare, potentially life-threatening condition promptly.
- Diagnosis made radiographically (CT most sensitive and specific).
- Outcomes most optimal with combination of fluid resuscitation, systemic antibiotics, and percutaneous drainage (with nephrectomy when indicated).

PYELONEPHRITIS, XANTHOGRANULOMATOUS

Demetrius H. Bagley, MD, FACS
Kelly A. Healy, MD

BASICS

DESCRIPTION

- Xanthogranulomatous pyelonephritis (XGP) is an uncommon chronic destructive granulomatous process of renal parenchyma in association with long-term urinary tract obstruction and infection
- Associated obstruction, stones
- Diffuse renal destruction with nonfunctioning kidney
- Local mass formation sometimes confused with malignancy

EPIDEMIOLOGY

Incidence

- Rare, occurring in 0.5–1.4% of patients with renal inflammatory disorders (1, 2)
- Female to male (3:1)
- Peak incidence in 5th–7th decade
- Reported in children as young as 6 mo
- Left = right

Prevalence

N/A

RISK FACTORS

- Diabetes
- History of stones
- History of UTIs

Genetics

N/A

PATHOPHYSIOLOGY

- Stones
- Obstruction
- Infection
- Proteus mirabilis is most common organism with *Escherichia coli* secondary.

ASSOCIATED CONDITIONS

- Diabetes (3)
- Renal calculi, including staghorn (35%)
- Immunosuppression

GENERAL PREVENTION

Adequate treatment and follow-up of known UTIs

DIAGNOSIS

HISTORY

- Nonspecific signs
- Fever, chills, flank pain, fatigue, anorexia
- Persistent bacteriuria even after antibiotic therapy
- ~1/3 of XGP patients have a history of stones
- 100% found to have stones at treatment
- Diabetes common

PHYSICAL EXAM

- Fever
- Flank tenderness
- Palpable flank mass
- Rarely elevated BP
- Weight loss
- Less commonly hematuria

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Anemia 71%
- Leukocytosis 62%
- Pyuria 81%
- Urine culture: Proteus and *E. coli* are most common
  - Mixed urine cultures occur in 10% of XGP patients
- Liver enzymes abnormal in as many as ½ of XGP patients

Imaging

- CT is the 1st-choice imaging study (4,5)
  - Demonstrates stones and hydronephrosis
  - Seen multiple renal calculi or staghorn calculi
  - Shows enlarged kidney with mass, usually diffused
  - Renal parenchyma replaced with multiple fluid-filled cavities and extension of inflammatory mass to perinephric spaces
- IV urogram shows nonvisualization in 30–80% of patients
  - Stone visible in 30–80%
  - Cannot distinguish renal mass from neoplasm
- Renal ultrasound demonstrates enlargement of the kidney
  - Hydronephrosis
  - Echogenic focus of the calculus
  - Multiple anechoic areas of parenchyma
- MRI provides little additional information
- Functional renal scans can evaluate differential renal function and may confirm nonfunction of the involved kidney

ALERT

XGP may not be distinguished clinically or radiographically from renal cell carcinoma.

Diagnostic Procedures/Surgery

Diagnosis is made on the basis of clinical suspicion and radiographic imaging studies

Pathologic Findings

- Diffuse involvement of the entire kidney occurs in 80 + % of cases
- Segmental involvement is much less common
- XGP commonly extends beyond the kidney and mass
  - Fistulae, pyelocutaneous and ureterocutaneous have been noted
- Gross findings:
  - Massively enlarged kidney
  - Hydronephrosis
  - Obstructing stones
  - Pus-filled calyces and parenchymal abscesses
  - Yellow nodules surrounding the calyces
- Microscopic findings:
  - Thin cortex with extension of inflammatory response beyond kidney
  - Lipid-laden macrophages (xanthoma cells) mixed with lymphocytes, plasma cells, and giant cells form sheets around the calyces and parenchymal abscesses, show grossly as yellow nodules
  - Mass may resemble a renal cell carcinoma with hemorrhage, necrosis and yellow appearance in gross sectioning
  - Associated rare neoplasms have been reported with XGP

DIFFERENTIAL DIAGNOSIS

- Renal tumor
- Pyelonephrosis
- Renal abscess
- Renal lymphoma
- TB

TREATMENT

GENERAL MEASURES

- Antibiotics, culture specific if possible continued until urine cultures are negative
- Usually managed by nephrectomy
- Partial nephrectomy with rare segmental cases
- Even less, reports of endoscopic treatment with stone removal, drainage continued antibiotics
- In cases of nephrectomy or partial nephrectomy, tissue culture should be used to guide antibiotic therapy

MEDICATION

First Line

- Broad-spectrum antibiotics pending urine culture, such as ampicillin 1 g q8h and an aminoglycoside (ie, gentamicin 5 mg/kg q24h) are usually effective until culture-specific antibiotics can be initiated.

- Negative urine cultures are common, and tissue cultures taken at the time of surgery may be necessary to identify the offending organism.
- Some recommend continuing oral antibiotics for up to 1 wk following nephrectomy.

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Nephrectomy is the most common treatment
  – Diffuse inflammatory process
  – Nonfunctioning kidney
  – Concern for malignancy
  – Inflammatory reaction, nephrectomy can be technically difficult
- Partial nephrectomy in rare cases of segmental XGP
- Mechanical and antibiotic bowel prep is performed since XGP may involve any adjacent organs or tissues
  – Drains should be placed in renal bed
- Laparoscopic nephrectomy has been shown to be safe without increasing complications but, again difficult (6)

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
Percutaneous drainage with antibiotics (7)

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Preservation of renal function related to the function of the contralateral kidney
- Recurrence in the contralateral kidney is very rare
- Chance of recurrent stones is high

COMPLICATIONS
- Postoperative respiratory complications
- Wound infection
- An injury to adjacent organs can occur during nephrectomy
- Major vascular injury related to the inflammatory process
- Fistulas or abscesses postoperatively require drainage and antibiotic therapy
- Renal insufficiency related to the function of the contralateral kidney
- Recurrent stone formation

FOLLOW-UP
Patient Monitoring
- Urinalysis and urine culture

- Serum creatinine, CBC, liver enzymes repeated to follow for normalization
- Further radiographic studies depending upon the histopathology of the kidney specimen

Patient Resources
N/A

CODES

ICD9
- 041.6 Proteus (mirabilis) (morganii) infection in conditions classified elsewhere and of unspecified site
- 590.00 Chronic pyelonephritis without lesion of renal medullary necrosis
- 599.60 Urinary obstruction, unspecified

ICD10
- B96.4 Proteus (mirabilis) (morganii) causing dis classd elswhr
- N11.8 Other chronic tubulo-interstitial nephritis

- N13.9 Obstructive and reflux uropathy, unspecified

CLINICAL/SURGICAL PEARLS

- Be suspicious in patients with fever, flank pain, and weight loss.
- Persistent UTI with adequate treatment is a warning.
- CT scan for diagnosis and extent of disease.
- XGP is primarily a surgically managed disease usually by nephrectomy with antibiotics critical to the management of this condition.
- Usually unilateral and frequently confused clinically and radiographically with renal cell carcinoma.

PYONEPHROSIS

Anthony J. Tracey, MD, MPH
Raju Thomas, MD, MHA, FACS

BASICS

DESCRIPTION

- Pyonephrosis is a collection of purulent material in the renal collection system
- Typically resulting from an underlying obstruction within the upper urinary tract (2)
  - With concomitant urinary tract infection
- Considered a surgical emergency with drainage of obstructed collecting system necessary (1)

EPIDEMIOLOGY

Incidence

- True incidence is unknown
- Increased in patients with upper urinary tract obstruction

Prevalence

See above

RISK FACTORS

- Upper urinary tract obstruction
- History of prior urologic instrumentation
- Immunocompromised patient
- Diabetes mellitus
- Chronic UTIs

Genetics

None

PATHOPHYSIOLOGY

- Etiologies of obstruction (1)
  - Stones and staghorn calculi: In as many as 75% of patients
  - Mucinous adenocarcinoma of the renal pelvis
  - Pregnancy
  - Fungus balls
  - Metastatic retroperitoneal fibrosis—eg, renal tumors, testicular cancer, colon cancer
  - Obstructing transitional cell carcinoma
  - Ureteropelvic junction obstruction (UPJO)
  - Obstructing ureterocele
  - Ureterovesical junction obstruction
  - Chronic stasis of urine and hydronephrosis secondary to neurogenic bladder
  - Ureteral strictures
  - Papillary necrosis
  - Tuberculosis
  - Duplicated kidneys with obstructive components

  – Ectopic ureter with ureterocele
  – Neurogenic bladder
• Infectious agents (in decreasing order of incidence) (1)
  – *Escherichia coli*
  – *Enterococcus* species
  – *Candida* species and other fungal infections
  – *Enterobacter* species
  – *Klebsiella* species
  – *Proteus* species
  – *Pseudomonas* species
  – *Bacteroides* species
  – *Staphylococcus* species
  – Methicillin-resistant *Staphylococcus aureus (MRSA)*
  – *Salmonella* species
  – Tuberculosis (causes both infection and strictures) (2)

ASSOCIATED CONDITIONS
• Nephrolithiasis (most common) (1)
• UPJO
• Urothelial carcinoma (UC) of the upper tracts
• Pyelonephritis
• Emphysematous pyelonephritis/pyelitis
• Xanthogranulomatous pyelonephritis (XGP)
• Ureteral stricture (2)

GENERAL PREVENTION
• Relief of underlying urologic obstruction
• Proper medical management of immunosuppression
• Identification of any anatomic urologic abnormality (ie, horseshoe kidney)

ALERT
Patients may rapidly decline clinically and become septic.

DIAGNOSIS
HISTORY
• Fever
• Flank pain
• Clinical evidence of UTI

PHYSICAL EXAM
CVA tenderness with or without palpable abdominal mass (hydronephrotic kidney)

DIAGNOSTIC TESTS & INTERPRETATION
Lab
• Pyuria
• Elevated white count (less specific)
• Bacteriuria (less specific)

- Urine culture of obstructed system
- Elevated C-reactive protein
  - 1 study showed CRP levels >28 mg/L with flank pain a reliable indication for emergent decompression (1)

Imaging

- CT scan with IV contrast (2)
  - Diagnostic criteria for pyonephrosis
    - Increased wall thickness of the renal pelvis ≥2 mm
    - The presence of renal pelvic contents and debris
    - Parenchymal and perirenal findings, such as perirenal fat stranding (3)
- Ultrasonography (US)
  - Sensitivity of renal US for differentiating hydronephrosis from pyonephrosis is 90%, and the specificity is 97% (1)
    - Debris
    - Low-level echogenic foci
    - Hydronephrosis
- MRI
  - Use increasing for inflammatory disorders of the GU tract
    - Diffusion MRI shows hyperintense collecting system for pyonephrosis and hypointense signal for simple hydronephrosis
    - May be useful for patients with impaired renal function (3)
- Renal nuclear scan
  - Useful in assessing renal function after decompression and to evaluate if involved renal unit is salvageable
  - Not helpful in the immediate diagnostic period

Diagnostic Procedures/Surgery

- Once pyonephrosis has been diagnosed, there are two possible initial interventions:
  - Antegrade nephrostomy tube placement
  - Retrograde ureteral stent placement

Pathologic Findings

- Aspiration of obstructed system will usually show:
  - WBCs
  - Bacteria or fungus
  - Sloughed urothelial cells

DIFFERENTIAL DIAGNOSIS

- Nephrolithiasis/urolithiasis
- Xanthogranulomatous pyelonephritis
- Ureteropelvic junction obstruction (UPJO)
- Urothelial carcinoma (UC) of upper tracts
- Ureteral stricture
- Extrinsic obstruction with hydronephrosis (malignancy, retroperitoneal fibrosis)

TREATMENT

GENERAL MEASURES

- Drainage of obstructed collecting system is the mainstay of treatment
  - Antegrade nephrostomy tube placement
    - Indicated in the clinically unstable patient
    - Best for maximal decompression
  - Retrograde ureteral stent placement
    - Indicated in the stable patient able to tolerate general anesthesia
    - Relatively contraindicated in setting of a large upper tract stone that will eventually need percutaneous therapy or fungus ball
- Treatment of source obstruction:
  - Once collecting system has been decompressed and appropriate antibiotic/antifungal therapy has been given for 2 wk
  - May include endoscopic, percutaneous, transurethral, laparoscopic, robotic, extracorporeal, or open approaches
  - Depends on the nature of obstruction (ie, stone, stricture) (1)
  - Clinical feasibility of intervention

MEDICATION

First Line

- Broad spectrum intravenous antibiotics (ie, piperacillin and tazobactam, gentamicin, and ampicillin) and antifungals if clinically indicated for funguria
  - Antibiotics can be focused once cultures result

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Indication for nephrectomy is controversial
  - May be indicated if source of infection is not found
  - Help to exclude malignant etiology of obstruction
  - Lack of response to percutaneous drainage and IV antibiotics/antifungals
  - Poorly functioning kidney

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Good in patients who receive prompt diagnosis and therapy

- Most patients will improve 24–48 hr after drainage of obstructed renal collecting system
- Recovery of renal function is rapid

COMPLICATIONS

- Sepsis is the most common complication of delayed treatment
- Other complications of delayed treatment include:
  - Rupture of pyonephrotic kidney resulting in:
    - Generalized peritonitis
    - Renocolic fistula
    - Renoduodenal fistula
    - Renocutaneous fistula
    - Splenic rupture
  - Rare complications:
    - Pneumoperitoneum
    - Renal vein thrombosis
    - Psoas abscess
    - Perinephric abscess
    - Rhabdomyolysis
  - Loss of renal function
- Complications from nephrostomy tube:
  - Blood transfusions
  - Hematoma
  - Nephrostomy tube replacement/revision
- Increased risk of infection if nephrectomy is not performed when indicated.

FOLLOW-UP

Patient Monitoring

- Treatment of underlying obstruction (ie, calculus, stricture, malignancy)
- Treatment and control of any predisposition to infection (ie, DM, HIV/AIDS, neurogenic bladder)

Patient Resources

CODES

ICD9
- 590.80 Pyelonephritis, unspecified
- 593.89 Other specified disorders of kidney and ureter
- 599.0 Urinary tract infection, site not specified

ICD10
- N13.6 Pyonephrosis
- N28.89 Other specified disorders of kidney and ureter
- N39.0 Urinary tract infection, site not specified

CLINICAL/SURGICAL PEARLS
- Patients with pyonephrosis may be asymptomatic or present with a picture of an abscess with fever and chills.
- Urolithiasis, staghorn calculi, and fungus balls are the most common clinical causes of pyonephrosis.

PYURIA

Christina Carpenter, MD
Mark L. Jordan, MD, FACS

BASICS

DESCRIPTION

- Presence of WBCs in the urine
- Normal #WBCs in a urine specimen
  - Men ≤ 2 WBC/hpf
  - Women ≤ 5 WBC/hpf
- When seen with bacteriuria, suggests inflammatory response of urothelium (ie, infection)
- When seen without bacteriuria (sterile pyuria), raises suspicion for tuberculosis, partially treated UTI, stones, and/or malignancy

EPIDEMIOLOGY

When seen in a voided urine specimen, has an 80–95% sensitivity for detecting patients with a urinary tract infection (UTI)

RISK FACTORS

- Urolithiasis
- Previous UTI
- Sexually transmitted disease
- Malignancy

PATHOPHYSIOLOGY

- Clean-catch midstream urine may contain contaminants (bacteria, squamous epithelial cells)
- Significant pyuria (at least 10 WBCs/mm^3) is uncommonly seen in patients without true infection

ALERT

60% of elderly women have significant pyuria without associated bacteriuria (1)[A].

- Can be caused by bacteria in the urinary tract provoking an inflammatory response
- Bacteria can colonize the genitourinary system in a retrograde fashion
- Certain bacteria are more frequently the cause of UTIs as they are more efficient at adhering to the mucosal cells of the urinary tract (eg, *Escherichia coli*)

ASSOCIATED CONDITIONS

- Bacteriuria
- UTI
- Pyelonephritis
- Nephrolithiasis

GENERAL PREVENTION

- Proper toileting habits
- Complete bladder emptying

- Adequate fluid intake (stone prevention)

DIAGNOSIS

HISTORY

- Common symptoms: Dysuria, frequency, urgency, malaise
- Fever (more common with upper tract infection)
- Hematuria (gross)
  - Occasional
  - More common in females
  - Rare in children
- Atypical presentations
  - Young patients
    - Difficulty with toilet training, urgency, incontinence
    - Abdominal discomfort, failure to thrive, fever, vomiting, jaundice
  - Elderly
    - Incontinence, fevers, frequency, urgency
    - May be asymptomatic
- History of recurrent childhood fevers—may imply frequent UTIs and potential congenital anomalies
- History of UTIs among female family members

PHYSICAL EXAM

- Suprapubic tenderness
- Costovertebral angle tenderness
- Fever
- Children—may have abdominal discomfort, tenderness, and/or distention

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Dipstick
  - Best screening tool
  - Leukocyte esterase (LE)
    - Produced by granulocytes that catalyze the hydrolysis of an indoxylcarbonic acid ester to indoxyl, which reacts with a diazonium salt to produce a purple color on the reagent strip
    - 75–96% sensitive for a culture-positive UTI (2)[A]
    - Sterile pyuria
      - Produces positive LE test with negative culture
      - Disease process without bacteriuria
    - Causes of false negatives
      - RBC >10 K/μL
      - Glucose >1 g/dL
      - Albumin >500 mg/dL
      - Formaldehyde
      - Medications: Cephalexin, gentamicin, tetracycline

    - Causes of false positives
        - Specimen contamination
        - Recent instrumentation of GU tract
        - Medications: Imipenem, meropenem, clavulanic acid
  - Presence of nitrites, blood, or protein suggests UTI
- Microscopic analysis—can see crystals and/or bacteria
- Gram stain—can identify type of bacteria
- Culture
  - Clean-catch midstream specimen = most common
  - Catheterized urine—required in situations in which patients are unable to collect specimen (children, incontinent adults, obese population, patients in urinary retention)
  - Segmented urine specimen
    - Sequential voided urine samples aimed to localize infection/inflammation source
    - Stamey test (see Stamey test [Three-glass test, Four-glass tests, Meares-Stamey Test])
- AFB culture—if patient has history of and/or possible exposure to TB
- Rapid in-office microbiology testing
  - 80% accurate for detecting, quantifying, and identifying specific bacteria in urine
  - Usually performed on a fresh unspun sample
- Urine cytology—if malignancy is suspected

Imaging

- Children: Ultrasound, VCUG, radionuclide cystogram, IV pyelogram
- Adult: Indicated only in the setting of suspected pathology, obstruction, stone disease, and/or hematuria
- Sterile pyuria: Imaging to identify source/evaluate cause

Diagnostic Procedures/Surgery

- Localization of bacteria
  - Segmented urine specimen
  - Ureteral catheterization in OR
  - Immunologic/antibody studies
- Isotopic function studies
- Cystogram
- CT: Localization of nidus/abnormality responsible for bacteriuria/pyuria (ie, abscess)
- Cystoscopy—indicated for symptomatic patients with persistent pyuria and negative urine cultures (3)[A]

DIFFERENTIAL DIAGNOSIS

- Specimen contamination
- Cystitis
- Epididymitis
- Pyelonephritis—acute, chronic, emphysematous, tuberculous, xanthogranulomatous
- Genitourinary TB
- Interstitial cystitis
- Interstitial nephritis
- Neoplasm

  – Urothelial carcinoma
  – Renal cell carcinoma
- Prostatitis
- Renal abscess
- Periurethral abscess
- STI/STD
- Renal transplant rejection
- Urethral diverticulum
- Urethritis
- Foreign bodies in GU tract (stents, catheters)
- Urinary tract fistula
- Vulvovaginitis
- Kawasaki disease

TREATMENT

GENERAL MEASURES
- Identify cause of inflammatory response
- Direct treatment at cause of pyuria
- UTI is most commonly the origin

MEDICATION
First Line
- In infection, should be empiric until targeted therapy can be initiated based on culture results (4)
- See “Urinary tract infection (UTI), adult female,” “Urinary tract infection (UTI), adult male” and “Urinary tract infection (UTI), pediatric”

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Correct underlying abnormality
- Treat calculus
- Remove foreign body (eg, ureteral stent)

ADDITIONAL TREATMENT
- Bacteriuria with pyuria is treated as a UTI in children and premenopausal women
- Persistent or recurrent bacteriuria may require prolonged antibiotic treatment followed by chronic low-dose prophylactic antibiosis
- High-risk patients (children with congenital abnormalities, immunocompromised adults) may need chronic suppressive antibiotic treatment
- Postmenopausal women
  – May have chronic pyuria with mild bacteriuria
    - Require treatment only if symptomatic or if associated with complicating factors
- Diabetics, patients with obstructive uropathy, and immunocompromised patients may have additional requirements to address ongoing pyuria adequately

ONGOING CARE

PROGNOSIS

Dependent upon etiology

COMPLICATIONS

- Ascending bacterial infections
- Urosepsis
- Renal failure
- Death

FOLLOW-UP

Patient Monitoring

- Repeat exam 2-wk post-UTI treatment
  - Urinalysis, urine culture
  - Reassess symptoms
- Routine periodic evaluation to check for recurrence of pyuria

Patient Resources

www.UrologyHealth.org

CODES

ICD9

791.9 Other nonspecific findings on examination of urine

ICD10

N39.0 Urinary tract infection, site not specified

CLINICAL/SURGICAL PEARLS

- Absence of pyuria should lead the clinician to question a diagnosis of UTI.
- Sterile pyuria does not suggest a benign process.
- Persistent symptomatic pyuria requires further workup, ie, cystoscopy, imaging.
- Atypical presentations in children, the elderly, and the immunocompromised require the clinician to maintain a high index of suspicion.

RECTAL INJURY DURING RADICAL PROSTATECTOMY OR RADICAL CYSTECTOMY

Debasish Sundi, MD
Misop Han, MD

BASICS

DESCRIPTION

- Rectal injury is a rare, potential complication of radical prostatectomy or radical cystoprostatectomy, with a reported incidence ranging from 0.1–1.7%
  - Reported for radical prostatectomy: Retropubic perineal, laparoscopic, and robotically assisted laparoscopic approaches
  - Reported for radical cystectomy: Open and robotically assisted approaches
- Intraoperative recognition of the rectal injury is paramount; this will allow primary repair in layers and minimize the chance of subsequent rectourethral fistula
- Occasionally the problem will not be identified until the postoperative period

EPIDEMIOLOGY

Incidence

- The rate of rectal injury during urologic pelvic procedures varies by procedure and approach
- For radical prostatectomy, rectal injury rates are quite low, ranging from 0.1–0.5% (open retropubic, pure laparoscopic, or robot assisted) (1,2)[C]
  - Rectal injury rates are higher for radical cystoprostatectomy (up to 1.7%) (3)[C], and highest for perineal prostatectomy (8–11%) (4)[C]

Prevalence

Extrapolating from the number of procedures performed annually in US, the prevalence of rectal injury for radical prostatectomy ranges from 80–400 cases per yr, and for radical cystectomy, up to 150 cases per yr

RISK FACTORS

History of pelvic radiation therapy or prior pelvic surgery

Genetics

N/A

PATHOPHYSIOLOGY

N/A

ASSOCIATED CONDITIONS

- Prior pelvic radiation or surgical procedures may increase the risk of rectal injury
- Extensive transurethral resection of bladder floor for urothelial carcinoma
- Inflammatory bowel disease
- Locally advanced malignancy

GENERAL PREVENTION

- Adequate intraoperative hemostasis to aid visualization

- Bowel preparation has not been proven to reduce the risk of intraoperative bowel injury but may limit contamination in the event of an injury
- Placement of a rectal tube at the start of the procedure may aid in the identification of the rectal wall in difficult cases (ie, salvage prostatectomy following radiation)
- Careful identification of the anterior and posterior layers of Denonvilliers fascia will aid in avoiding rectal injury

DIAGNOSIS

HISTORY

- After removal of the specimen (open surgery), inspection of the surgical bed using posterior traction to efface folds of tissue will typically reveal a rectal injury by direct visualization
  - Obtaining good hemostasis will aid visualization
  - Copious irrigation of the pelvis with sterile saline may also reveal air bubbles emanating from the rectal vault (2)[C]
- Symptoms may include abdominal or pelvic pain; nausea and vomiting may also be present

PHYSICAL EXAM

Postoperative manifestations may include exam findings that may include tenderness to palpation, fever, tachycardia, hypotension, ileus (2)[C]

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Acute injury may not manifest any lab abnormalities
- An unrecognized postoperative injury may demonstrate leukocytosis

Imaging

- Postoperatively CT ± cystourethrography
  - Free air in pelvis and/or peritoneum
  - Contrast communicating between rectum and bladder/urethra

Diagnostic Procedures/Surgery

- After removal of the specimen (laparoscopic or robotic surgery) from the prostatic fossa, a suspected rectal injury can be confirmed by flooding the pelvis with saline irrigant and gently insufflating the rectum with air injected via a Foley catheter
  - A rectal enterotomy will be evident by air bubbling through the irrigant

Pathologic Findings

A through-and-through injury will involve both the rectal serosa and mucosa

DIFFERENTIAL DIAGNOSIS

- Intraoperative differential diagnosis is limited
- Postoperative differential includes:
  - Small bowel or large perforation (iatrogenic)
  - Colonic perforation secondary to pathologic distension such as in colonic pseudoobstruction, or Ogilvie syndrome
  - Pelvic abscess

TREATMENT

GENERAL MEASURES

- When a rectal injury is diagnosed postoperatively, management depends on the patient's clinical picture
- Patients who are minimally symptomatic and have a small injury radiographically may be initially managed conservatively by indwelling urethral catheter, with reassessment by cystogram after 2–3 mo (5)[C]
- The GI tracts of patients who are symptomatic, septic, or have a history of prior pelvic radiation should be diverted with an end colostomy (5)[C]
  - These patients' GI tracts can be brought back in continuity if a cystogram and/or Gastrografin enema are negative in 2–3 mo. If these patients have persistent fistulas, they should be surgically repaired with a transrectal advancement flap (2)[C].

MEDICATION

First Line

- 7–14 days of antimicrobial therapy (4)[C]
  - Antibiotic regimen should cover both gram-negatives and anaerobes (such as ciprofloxacin and metronidazole)

Second Line

N/A

SURGERY/OTHER PROCEDURES

- When a rectal injury is diagnosed intraoperatively, it should be repaired immediately, closing the rectal mucosa and serosa in separate layers
  - Suture choice includes mucosal layer with 3-0 chromic and the serosa with 3-0 silk or other suitable alternatives (2)
  - An additional flap of vascularized tissue (omentum or peritoneum) should be interposed between the rectal repair and the bladder/urethra. Immediate repair minimizes the risk of subsequent rectourethral fistula.
    - If a rectourethral fistula does form in spite of immediate repair, management options are conservative treatment via Foley catheterization or surgical repair via diverting colostomy and, if necessary, a transrectal advancement flap (6)[C]

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Among patients undergoing immediate intraoperative repair, there is a 12.5% incidence of

subsequent rectourethral fistula (6)[C]
  – Rectal injuries of increasing length are associated with a higher risk of rectourethral fistulae, as are those recognized and repaired in delayed fashion

COMPLICATIONS

- Need for temporary colostomy diversion
- Rectourethral fistula
- With delayed rectoanastomotic fistula after radical prostatectomy: incontinence (7)
- Sepsis

FOLLOW-UP

Patient Monitoring

- After repair, routine monitoring on a regular surgical floor with daily labs is appropriate
  – Prior to routine Foley catheter removal after radical prostatectomy, perform cystogram to rule out fistula at 14 days after surgery
    - If rectourethral fistula is demonstrated, continue Foley catheter, as resolution of fistula with period of catheterization up to 9 wk has been demonstrated

Patient Resources

None

CODES

ICD9

- 599.1 Urethral fistula
- 863.45 Injury to rectum, without mention of open wound into cavity
- 998.2 Accidental puncture or laceration during a procedure, not elsewhere classified

ICD10

- K91.72 Acc pnctr & lac of a dgstv sys org during oth procedure
- N36.0 Urethral fistula
- S36.60XA Unspecified injury of rectum, initial encounter

CLINICAL/SURGICAL PEARLS

- Rectal injury during radical urologic pelvic surgery is a rare but serious complication.
- This injury can occur during open, laparoscopic and robotically assisted laparoscopic pelvic surgery.
- When recognized intraoperatively, immediate primary repair assures the best outcomes.
- When immediate repair is not possible or contraindicated, the patient may be temporized with a diverting colostomy until the rectal injury heals and the GI tract can be brought back into continuity.
- Rectourethral fistula is a delayed complication of rectal injury repair, the chance of which can be minimized with immediate recognition and repair of rectal injury.

RENAL AND PERIRENAL ABSCESS

Mary K. Powers, MD
Raju Thomas, MD, MHA, FACS

BASICS

DESCRIPTION

- Renal abscess/carbuncle:
  - Collection of purulent material confined to the renal parenchyma
- Perirenal abscess:
  - Results from extension of an acute cortical abscess into the perinephric space; confined by Gerota fascia
- Pararenal/perinephric abscess:
  - Results from the rupture of a perinephric abscess through Gerota fascia into the pararenal space

EPIDEMIOLOGY

Incidence

Perinephric and renal abscesses are uncommon but potentially lethal complications of UTI

Prevalence

- 2/3 of gram-negative abscesses are associated with renal calculi or kidneys with poor function
- Pregnant women with untreated bacteriuria are associated with a higher incidence of pyelonephritis and subsequent diagnosis of abscess
- Renal infection is among the most common sites for extrapulmonary disease in patients with TB

RISK FACTORS

Diabetes mellitus, polycystic kidney disease, hemodialysis, neurogenic bladder, IV drug users, tuberculosis, recurrent urinary tract infection and/or pyelonephritis, nephrolithiasis, vesicoureteral reflux, ureteropelvic junction obstruction or other source of obstruction, any immunocompromised state

Genetics

N/A

PATHOPHYSIOLOGY

- Gram-negative organisms have been implicated in the majority of adults with renal abscesses (*Escherichia coli*, *Proteus mirabilis*, and *Staphylococcus aureus*) account for the majority of infections (in descending order of occurrence) (1)
- Hematogenous renal seeding by gram-negative organisms may occur, but this is not likely to be the primary pathway for gram-negative abscess formation
- Hematogenous renal seeding: Skin infection with gram-positive organisms, IV drug abuse, immunocompromised status
- Ascending infection associated with tubular obstruction from prior infections, vesicoureteral

reflux, or calculi appears to be the primary pathway for the establishment of gram-negative abscesses

ASSOCIATED CONDITIONS
See “Risk Factors" above

GENERAL PREVENTION
Increased clinical suspicion, prompt recognition, and treatment of infection, especially in the face of obstruction in high-risk patients

DIAGNOSIS

HISTORY
- Significant chronic or acute illnesses including diabetes, neurogenic bladder dysfunction, chronic renal failure, hemodialysis, and polycystic renal disease
- Renal calculi
- IV drug abuse
  - Gram-positive source of infection 1–8 wk before the onset of urinary tract symptoms
    - Preceding infection can occur in any area of the body (eg, skin lesions, dental infections)
- Patients with UTI and abdominal or flank mass
- Persistent fever with suspected genitourinary source after 3–5 days of antimicrobial therapy

PHYSICAL EXAM
- Elevated temperature
- CVA or flank tenderness
- Abdominal and/or flank mass
- Distended or palpable bladder
- Look for skin carbuncles or dermatologic evidence of IV drug abuse
- Heart murmurs

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum creatinine:
  - Variable findings, dependent on concurrent obstruction and underlying renal dysfunction
- CBC:
  - Patients typically have marked leukocytosis
- Urine analysis:
  - Pyuria and bacteria often present, although pyuria/bacteriuria may not be evident unless the abscess communicates with the collecting system
  - Sterile pyuria often seen with TB
- Urine culture:
  - When abscesses contain gram-negative organisms, urine culture often demonstrates the same organism isolated from the abscess
  - Since gram-positive organisms are most commonly blood borne, urine cultures in these cases typically show no growth or a microorganism different from that isolated from the abscess
  - Catheterized urine collection recommended for female patients

- Blood cultures:
  - Gram-negative organisms are most commonly cultured
  - Gram-positive organisms are not routinely similar to those cultured from abscess

Imaging

- Differentiation between early renal abscess and acute pyelonephritis is difficult due to small size
- Abdominal CT:
  - Diagnostic procedure of choice
  - Can often delineate the route of spread of infection into surrounding tissues
  - Abscesses are characteristically well defined both before and after contrast agent enhancement
  - Acute findings include renal enlargement and focal, rounded areas of decreased attenuation
  - Chronic findings include obliteration of adjacent tissue planes, thickening of Gerota (perinephric) fascia, a round or oval parenchymal mass of low attenuation, and a surrounding inflammatory wall of slightly higher attenuation that forms a ring when the scan is enhanced with contrast material (ring sign)
  - See Figure 1, Renal Abscess
- IV urography (if performed)
  - Abnormal in up to 80% of patients, although findings often are nonspecific
  - Generalized enlargement of involved renal unit with distortion of renal contour and collecting system
  - Absence of psoas shadow on affected side
  - Bubbles of extraluminal gas can be seen surrounding the kidney in large perinephric abscesses
- Abdominal US:
  - Quickest and least expensive diagnostic imaging study
  - Common findings include an echo-free or low-echodensity space-occupying lesion with increased transmission, which is poorly marginated during the acute phase
  - Well-defined discrete lesion during chronic stages, which is difficult to distinguish from a renal mass

ALERT
Evidence of air within renal parenchyma tissue is diagnostic for emphysematous pyelonephritis which may require urgent surgical intervention. See Section I: Emphysematous pyelonephritis.

Diagnostic Procedures/Surgery

CT- or US-guided needle aspiration may be necessary to differentiate an abscess from a hypervascular tumor; aspirated material can be collected for culture to guide appropriate antimicrobial therapy. A percutaneous drain may be left in place and clinical course can be evaluated.

Pathologic Findings

Abscess fluid will demonstrate neutrophils and gram stain will reveal bacteria

DIFFERENTIAL DIAGNOSIS

- Pyelonephritis (2)
- Pyonephrosis
- Xanthogranulomatous pyelonephritis
- Emphysematous pyelonephritis
- Renal TB
- Bowel perforation with retroperitoneal spread of infection

TREATMENT

GENERAL MEASURES (3,4)

- Hospitalization with initiation of IV antibiotics and fluid resuscitation.
- Suspected pyelonephritis treated with antibiotics for 48–72 hr without significant improvement requires radiographic evaluation to rule out obstruction and/or abscess formation.
- Recent evidence indicates that for very small (< 3-cm abscesses), careful observation and IV-tailored antimicrobial agents may obviate surgical procedures.
- Abscesses 3–5 cm in diameter and smaller abscesses in immunocompromised hosts or those that do not respond to antimicrobial therapy should be drained percutaneously.
- Surgical drainage, however, currently remains the procedure of choice for most renal abscesses > 5 cm in diameter or if perirenal extension of abscess occurs.
- Obstruction, if present, must be relieved.

MEDICATION

First Line

- Antibiotic therapy: May prevent surgical intervention unless abscess involves perinephric space.
- Initiate empiric treatment with fluid resuscitation and broad-spectrum IV antibiotics.
  - 3rd-generation cephalosporins
    - Cefotaxime—1–2 mg IV/Q8–12h
    - Ceftriaxone—1–2 mg IV/Q24h
    - Ceftazidime—1 g IV/Q8–12h
  - Aminoglycosides
    - Gentamicin—1–1.7 mg/kg IV/Q8h
    - Amikacin—7.5 mg/kg IV/Q12h
    - Tobramycin—1–1.7 mg/kg IV/Q8h
  - Antipseudomonal penicillins
    - Piperacillin/Tazobactam—3.375 g IV/Q6h
    - Ticarcillin/Clavulanate—3.1 g IV/Q4–6h
- IV antibiotics until afebrile for 24–48 hr, switch to PO for at least 2 wk based on culture.
- Adjust dose for renal function.

Second Line

- For a suspected hematogenous source, expand coverage to include penicillin-resistant Staphylococcus.
  - Vancomycin—1 g IV/Q12h

SURGERY/OTHER PROCEDURES

- Standard treatment for renal abscesses >5 cm or those that fail to respond to percutaneous drainage and IV antibiotic therapy has been rapid incision and drainage.
- Relief of coexisting obstruction is mandatory.
- Primary treatment remains drainage for all perinephric abscesses.
- Nephrectomy may be required for adequate treatment if medical therapy/incision and drainage fails.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

CT- or US-guided placement of percutaneous drains with concurrent IV antibiotic therapy is currently an accepted method of treatment for abscesses 3–5 cm in size and smaller abscesses in immunocompromised patients who fail to respond to medical therapy.

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Perinephric abscess is historically associated with mortality rates approaching 39–50%.
- Recent series with prompt implementation of IV antibiotics and subsequent percutaneous or surgical drainage report mortality rates of 5–12%.

COMPLICATIONS

- Delay in diagnosis is associated with higher mortality rate.
- Delay in diagnosis and treatment is associated with loss of renal function and, in rare circumstances, genitourinary fistulas to the pleura, colon, skin, etc.

FOLLOW-UP

Patient Monitoring

- Address the underlying medical conditions to prevent recurrent infections.
- Repeat radiographic studies to confirm complete resolution.
- Extended antibiotic therapy is often required.

• N15.1 Renal and perinephric abscess
• N20.0 Calculus of kidney

CLINICAL/SURGICAL PEARLS

• Abscesses <3 cm can be managed with medical treatment initially.
• Continued fevers require surgical drainage of abscess.
• Include gram-positive antibiotic coverage if suspect hematogenous spread (IV drug use).

RENAL ANGIOMYOLIPOMA

Casey Allison Seideman, MD
Ganesh V. Raj, MD, PhD, FACS

BASICS

DESCRIPTION

- Angiomyolipoma (AML): Benign renal tumor composed of vascular tissue (angio), muscle (myo), and adipose (lipoma) tissue elements
- Tumors < 4 cm are less likely to be symptomatic
- Tumors > 4 cm have increased risk of spontaneous bleeding
- Can be sporadic, but is associated with tuberous sclerosis (TS) and lymphangioleiomyomatosis (LAM)
- Can be a cause of Wunderlich syndrome:
  - Spontaneous, nontraumatic renal hemorrhage
  - Bleeding usually confined to renal capsule

EPIDEMIOLOGY

Incidence

- 20–30% of cases are seen in patients with tuberous sclerosis (TS)
- Mean age:
  - Sporadic AML: 5th or 6th decade
  - Tuberous sclerosis complex (TSC) patients: Age 30
- Female > male (4:1) overall; 2:1 in TS patients
- Right side more common

Prevalence

Prevalence 0.13%, 2–3% of all renal tumors

RISK FACTORS

- TSC (50% develop AML)
- LAM (40% develop AML)
- Patients with TC tend to develop larger, bilateral, multicentric, tumors which grow more rapidly, and tend to have more spontaneous bleeds

Genetics

- TSC, AD with variable expression
- 2/3 result from sporadic mutations
- 2 genes: TSC1 (9q34), TSC2 (16p13)

PATHOPHYSIOLOGY

In rare cases, can cause: Renal failure (large volume of tumor, or solitary kidney)

ASSOCIATED CONDITIONS

- TS (1)
  - 50–80% of patients with TS develop AML

- TS: Autosomal dominant condition, comprised of mental retardation, epilepsy, angiofibromas of the face (adenoma sebaceum), hamartomas in the kidney, brain (subependymal giant-cell astrocytomas [SEGAs]), eye (retinal phakomas), heart, lung, and bone

• LAM—rare lung disease, associated with TS
- Characterized by smooth muscle growth in the lungs, resulting in obstruction of small airways. Also occurs with TS

DIAGNOSIS

HISTORY
• Most asymptomatic, discovered incidentally
• Occasionally diagnosed by flank pain, hypotension, and spontaneous hemorrhage
• History of LAM, TSC
• GI complaints due to mass effect
• Hematuria, hypertension, anemia

PHYSICAL EXAM
• Hypertension, or hypotension (in the setting of hemorrhage)
• TSC: Mental retardation, adenoma sebaceum, ungula/subungual fibromas, lung disease
• Flank pain/mass
- Up to 50% of patients who are symptomatic may have a palpable mass

DIAGNOSTIC TESTS & INTERPRETATION
Lab
• Anemia
• Gross/micro hematuria
• Renal insufficiency
• Genetic testing if TS is suspected

Imaging
• CT: AML is commonly diagnosed on CT scans that reveal solid masses with areas of fat density (Hounsfield units below −20); most reliable imaging modality; IV contrast not necessary
• Fat density is not identified on CT in some cases with reduced fat content (1)[C]
• Rare reported cases of RCC containing fat densities (finding of calcification in mass is suspicious for RCC) (2)[C]
- US: Well-circumscribed, hyperechoic mass with shadowing (other RCTs may also be echogenic)
- IVP: Similar appearance to other RCTs
- Angiogram: Increased vascularity (also seen in many malignant renal lesions); 50% of AMLs are found to have aneurysmal dilation
- MRI: Adipose tissue has high signal intensity on T1-weighted images and lower on T2-weighted images

Pathologic Findings
• Pathology findings:

  – Thick-walled vessels, smooth muscle, and adipose tissue with spindle and epithelioid cells
  – The amount of each component varies
- Epithelioid AMLs
  – Variant of AML characterized by epithelioid cells that are cytokeratin negative and HMB-45 positive. More aggressive clinical course

DIFFERENTIAL DIAGNOSIS (2)
- Renal masses:
  – Oncocytoma
  – Renal and retroperitoneal liposarcoma
  – Renal cell carcinoma
  – Renal cysts
  – Renal lipoma
  – Sarcoma (including fibrosarcoma, leiomyosarcoma, and liposarcoma)
  – Teratoma
  – Upper-tract urothelial carcinoma
  – Wilms tumor
  – Xanthogranulomatous pyelonephritis
- Renal/retroperitoneal hemorrhage:
  – Arteriovenous malformation
  – Coagulopathy
  – Hemorrhage of other renal mass such as renal cell carcinoma
  – Iatrogenic
  – Ruptured aneurysm
  – Traumatic injury
  – Vasculitis

TREATMENT

GENERAL MEASURES (3)
- Benign renal masses, rarely transform to malignant entities
- Observation unless large, or symptomatic

MEDICATION

First Line
- Medical management is not currently standard
- Everolimus (4)
  – Approved in adults with renal AML and TSC not requiring immediate surgery
  – May benefit other TSC-associated disease manifestations, such as skin manifestations, pulmonary LAM, cardiac rhabdomyomas, and epilepsy
  – An inhibitor of mammalian target of rapamycin (mTOR), a serine-threonine kinase, downstream of the PI3K/AKT pathway
  – 10 mg once daily with or without food

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Indications: Diagnostic uncertainty, hemorrhage causing significant symptoms, pain, hematuria, risk of rupture
- Asymptomatic AML < 4 cm:
  - Observation with serial imaging at 12-mo intervals
- Asymptomatic AML > 4 cm:
  - Treatment should be considered; observation with serial imaging
  - The risk of spontaneous hemorrhage appears greatest in masses > 4 cm
  - Women of childbearing age may consider proactive treatment
- Symptomatic AML/lesion > 4 cm:
  - Selective arterial embolization or nephron-sparing surgery
- Acute hemorrhage:
  - Initially treated with embolization (stabilizes patient and often eliminates need for more intervention)
  - If explored emergently, total nephrectomy usually necessary

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Limited reports of treatment using cryoablation and radiofrequency ablation
- In patients with LAM or TS, mTOR inhibitors such as sirolimus/temsirolimus have been shown to decrease mass size by 30%

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Local recurrence rare after removal.
- Extrarenal lesions are multicentric and not metastatic.
- Extended follow-up is necessary after selective embolization due to complications and recurrence risk.
- Extremely rare case reports of malignant transformation.

COMPLICATIONS

- Flank/abdominal pain
- Hematuria
- Hemorrhage (may cause anemia or shock)
- Mass effect on surrounding organs

FOLLOW-UP

Patient Monitoring

- Controversial in patients with newly diagnosed AML; screen for TS
- Conservative management: Serial imaging (usually with CT or US) every 6–12 mo
- Growth rate typically 5% per yr for solitary AML

- TSC patients and those with multicentric AMLs have growth rate of 20% per yr

Patient Resources

- TS alliance www.tsalliance.com
- LAM Foundation www.theLAMfoundation.com

- Renal Mass
- Retroperitoneal Hematoma
- Tuberous sclerosis

CODES

ICD9

- 223.0 Benign neoplasm of kidney, except pelvis
- 593.81 Vascular disorders of kidney
- 759.5 Tuberous sclerosis

ICD10

- D17.71 Benign lipomatous neoplasm of kidney

- N28.89 Other specified disorders of kidney and ureter
- Q85.1 Tuberous sclerosis

CLINICAL/SURGICAL PEARLS

- Benign renal tumor characterized by presence of vascular, muscle, and adipose components.
- Larger lesions have increased risk of spontaneous hemorrhage.
- Diagnosis is usually made by imaging.
- Observation for small masses, consider embolization for larger masses.
- Everolimus (mTOR inhibitor) can shrink large multifocal lesions in patients with tuberous sclerosis (TS) and lymphangioleiomyomatosis (LAM).

RENAL ARTERY STENOSIS/RENOVASCULAR HYPERTENSION

Brian M. Benway, MD
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION

- Renal artery stenosis (RAS) refers to anatomic vascular lesion that causes decreased blood flow to the kidney
- May not be associated with hypertension (HTN)
- May be atherosclerotic in nature (athersclerotic renal artery stenosis or ARAS)
- Rarely caused by fibromuscular dysplasia (FMD)
- Renovascular HTN (RVH) refers to HTN that is caused by renal hypoperfusion and is reversed by correction of the lesion or nephrectomy

EPIDEMIOLOGY

Incidence

- RAS often found incidentally
  - 33% of patients with aorto-occlusive disease
  - 20% of patients with coronary artery disease (CAD)
  - 43% of patients with diabetes
  - 7% of asymptomatic normotensive adults >65 yr (1)

Prevalence

RVH <1% of hypertensive patients

RISK FACTORS

- Atherosclerosis
- Diabetes
- CAD
- Advanced age

Genetics

N/A

PATHOPHYSIOLOGY

- Atherosclerosis
  - Accounts for 70% of all RAS
  - Nearly half of patients will have progressive obstruction within 2 yr of diagnosis
  - Usually located at the ostium or proximal renal artery
  - 10% caused by FMD, which causes primarily distal lesions
- RVH
  - Results from significant vascular stenosis which produces renal hypoperfusion
  - Hypoperfusion results in increased renin levels, which in turn increases angiotensin II levels
  - Angiotensin elevates blood pressure through several mechanisms

- Generalized vasoconstriction
- Increased aldosterone production, promoting sodium absorption and excretion of potassium and hydrogen
- Causes efferent arteriolar vasoconstriction to maintain glomerular filtration

- FMD is a nonatherosclerotic, noninflammatory process of the renal vessels
  - Intimal fibroplasia occurs in children and young adults
    - Accounts for 10% of FMD
    - Can be associated with dissection and hematoma
    - Involves proximal or midportion of artery, appears smooth on angiography
    - Invariably progressive if untreated
  - Medial fibroplasia
    - 70–80% of FMD
    - More common in women aged 25–50
    - Usually bilateral
    - "String of beads" appearance on angiography
    - Rarely associated with functional loss and may be managed medically
  - Perimedial fibroplasia
    - Women aged 15–30
    - Dense collar of collagen constricting the artery
    - Length is variable
    - Frequently associated with development of collaterals
    - Invariably progressive if not treated
  - Fibromuscular hyperplasia
    - Extremely rare (2–3% of all renal artery lesions)
    - Most commonly affects children and young adults
    - Progressive if untreated

ASSOCIATED CONDITIONS

- High-grade retinopathy
- Atherosclerosis
- Diabetes
- CAD
- Peripheral vascular disease

GENERAL PREVENTION

Reduction of risk factors for cardiovascular disease and diabetes

DIAGNOSIS

HISTORY

- Onset of HTN after age 50
- No family history of HTN
- Difficult-to-control HTN, on multiple antihypertensives
- Increase in serum creatinine with use of ACE inhibitors or angiotensin receptor blockers (ARBs)

PHYSICAL EXAM

- Blood pressure measurement
- Abdominal exam with auscultation for bruit
- Retinal exam

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Plasma renin activity (PRA)
  - By itself, not diagnostic of RAS or RVH
- Captopril test
  - Useful for excluding RVH
  - Diuretics and ACE inhibitors stopped 1 wk prior
  - PRA measured before and 1 hr after 25-mg dose of captopril
  - Positive test if postdose PRA >12 ng/mL/h, absolute increase of PRA >10 ng/mL/h, 4-fold increase in PRA over baseline
  - Not appropriate in children or in patients with azotemia

Imaging

- Arteriography is gold standard
  - Highly sensitive and specific (99%)
  - Provides detailed anatomy, and allows for discrimination between FMD subtypes
  - Allows for simultaneous endovascular treatment
  - Invasive
  - Recommended as initial diagnostic intervention in patients with high suspicion for RVH
- Captopril renography
  - Keep well hydrated on a liberal salt diet
  - Off ACE inhibitors for 3–5 days prior to exam
  - ^{99m}Technetium-MAG3 renal scan generally used before and 1 hr after captopril dose
  - Diagnostic criteria for RVH: Delay in maximal activity >11 min, asymmetrical peak activity, cortical retention of radionuclide, significant decrease in glomerular filtration rate
  - Recommended as initial diagnostic intervention in patients with low-to-moderate suspicion for RVH
- Duplex ultrasonography
  - Positive diagnostic criteria: Peak systolic velocity of renal artery >80 cm/s, ratio of diameter of renal artery to aorta >3.5
  - Inexpensive, noninvasive, but quality of study is operator dependent
- Magnetic resonance angiography (MRA)
  - May be more sensitive than ultrasound or renography, but inferior to conventional arteriography
  - Poorly visualizes distal arteries
  - Contraindicated in patients with met al or claustrophobia
  - Contrast must be used with caution in patients with renal insufficiency (2)
- Computed tomography angiography (CTA)
  - Uses potentially nephrotoxic contrast agents
  - More widely available and cost-effective compared to MRA

Diagnostic Procedures/Surgery

- Renal angiography
- Renal vein renin sampling
  - Useful in determining which kidney is primary contributor to RVH in patients with bilateral lesions

Pathologic Findings

- Renal biopsy indicated in patients with creatinine >4 mg/dL
  - Tubular atrophy, interstitial fibrosis, arteriosclerosis indicate functional recovery may be possible
  - Widespread glomerular hyalinization indicates irreversible injury

DIFFERENTIAL DIAGNOSIS

- Aortic aneurysm
- Essential HTN
- Functional adrenal adenoma
- Intrinsic renal disease
- Renal artery aneurysm

TREATMENT

GENERAL MEASURES

- Recognition of underlying cause is critical in guiding management
- Smoking cessation
- Weight loss
- Reduction of risk factors for cardiovascular disease and diabetes

MEDICATION

First Line

- ACE inhibitors/ARBs: Improves HTN in 96% of patients with RVH. May not prevent progression of atherosclerotic lesions.
  - Captopril: 25–50 mg PO BID-TID
  - Enalapril: 10–40 mg PO QD
  - Losartan: 25–100 mg PO divided QD-BID
  - Telmisartan: 20–80 mg PO QD
- Aspirin 81 mg PO QD
- Statins

Second Line

- Thiazide diuretics
- Loop diuretics
- Calcium channel blockers
- β-blockers

SURGERY/OTHER PROCEDURES

- Surgical intervention recommended for patients with high-grade stenosis, bilateral disease, solitary kidney, declining renal function, pulmonary edema, congestive heart failure (3)
- Angioplasty with or without endovascular stenting

  – Percutaneous access through common femoral artery
  – Selective angiography performed
  – ≥70% stenosis treated with angioplasty and deployment of balloon-mounted stent
  – Angioplasty without stenting is associated with increased risk of restenosis
- One recent clinical trial suggests that the addition of renal artery stenting to comprehensive, multifactorial medical therapy did not confer a significant benefit (4)
- Aortorenal bypass (hypogastric or saphenous vein)
- Nephrectomy (especially in patients with a poorly functioning ipsilateral renal unit)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Treatment of concomitant disease
  – Antiplatelet agents
  – Statins
  – Smoking cessation
  – Weight loss

Complementary & Alternative Therapies

Sympathetic renal denervation using radiofrequency ablation is investigational at the present time, but shows promise (5)

ONGOING CARE

PROGNOSIS

Untreated disease, except for medial fibroplasia, is often progressive and can result in renal functional loss

COMPLICATIONS

- Functional loss, worsening HTN, pulmonary edema, congestive heart failure in untreated patients
- Endovascular interventions: Access site hematoma, renal artery dissection, thrombosis, contrast-induced nephropathy
- Surgical interventions: Hemorrhage, wound infection, hematoma, anesthesia complications

FOLLOW-UP

Patient Monitoring

High-risk patients and those on medical therapy should be observed with serial metabolic and renal function studies in addition to Doppler ultrasonography

Patient Resources

CODES

ICD9

- 250.40 Diabetes with renal manifestations, type II or unspecified type, not stated as uncontrolled
- 405.91 Unspecified renovascular hypertension
- 440.1 Atherosclerosis of renal artery

ICD10

- E11.21 Type 2 diabetes mellitus with diabetic nephropathy
- I15.0 Renovascular hypertension
- I70.1 Atherosclerosis of renal artery

CLINICAL/SURGICAL PEARLS

- RVH HTN is caused by significant stenosis of the renal artery and is reversed by correction of stenosis or nephrectomy.
- Renal angiography remains gold standard for diagnosis.
- With the exception of medial fibroplasia, untreated RVH disease often leads to progressive renal functional loss.

RENAL CAPSULAR NEOPLASMS

Mathew C. Raynor, MD
Raj S. Pruthi, MD, FACS

BASICS

DESCRIPTION

- Predominantly mesenchymal neoplasms arising from the renal capsule encompassing a wide variety of cell progenitors
  - Tumors can be composed of fibrous, smooth muscle, vascular, adipose, nerve, or other tissue differentiation
    - Encompasses benign and malignant neoplasms

EPIDEMIOLOGY

Incidence

- Very rare tumors
- Represent up to ~1.5% of all surgically treated benign renal masses (1)
- Incidentally found at autopsy in up to ~5% of cases (1)
- Similar gender preference

Prevalence

Unknown, due to rarity of tumor

RISK FACTORS

- None known
  - Increased cross-sectional imaging use may identify incidental mass

Genetics

- No recognized genetic predisposition
- Some common genetic alterations seen in soft tissue sarcomas
  - No current clinical application for genetic alterations

PATHOPHYSIOLOGY

- Benign
  - Leiomyoma, hemangiopericytoma, hemangioma, lymphangioma, myxoma, schwannoma, solitary fibrous tumor, paraganglioma, lipoma, fibroma, myolipoma
- Malignant
  - Leiomyosarcoma, malignant fibrous histiocytoma, fibromyxoid sarcoma, hemangiosarcoma, liposarcoma, fibrosarcoma

ASSOCIATED CONDITIONS

Some renal hemangiomas may be associated with Sturge–Weber or Klippel–Trénaunay syndromes (1)

GENERAL PREVENTION

No preventive strategies identified

DIAGNOSIS

HISTORY

- Usually asymptomatic or discovered incidentally
- May present with hematuria or flank pain
- Weight loss, anorexia, malaise, or bone pain may signify metastatic disease

PHYSICAL EXAM

- Usually normal
  - Rarely, flank mass may be palpable

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis
  - Microscopic hematuria may be identified, but usually normal
- CBC
  - Anemia may be present with advanced disease or bleeding mass
- Serum chemistries usually normal

Imaging

- CT or MRI with and without contrast
  - May show enhancing mass arising from the kidney
    - Indistinguishable from renal cell carcinoma in most cases
    - Presence of fat may signify angiomyolipoma, lipoma, or liposarcoma
- Chest x-ray
  - Evaluate for metastatic disease

Diagnostic Procedures/Surgery

- Core needle biopsy
  - May be used in cases of suspected renal malignancy or if active surveillance considered
- Angiography
  - May be utilized for bleeding lesions
  - Benign lesions usually hypovascular
    - Except hemangiopericytoma, which is highly vascular

Pathologic Findings

- Leiomyoma
  - Firm, well-circumscribed, exophytic mass
  - Microscopically, composed of spindle cells arranged in fascicles typical of smooth muscle
  - Immunostaining positive for desmin, smooth muscle actin, and usually HMB-45 (1)[C]
- Hemangiopericytoma
  - Solid, encapsulated mass
  - Microscopically, varied cell shapes and sizes with morphologic variability
  - Immunostaining positive for vimentin, BCL2, CD99 and negative for S100, cytokeratins, and HMB-45 (2)[C]
- Lymphangioma
  - Well-encapsulated, multilocular cystic mass
  - Microscopically, communicating cysts seen with flattened endothelial cells

  - Immunostaining positive for D2-40
    - Labels lymphatic endothelium (1,3)[C]
- Solitary fibrous tumor
  - Well-encapsulated firm mass without necrosis, cysts, or hemorrhage
  - Microscopically, usually shows areas of spindle cells intermixed with hypocellular areas of fibrous tissue
  - Immunostaining strongly positive for CD34
    - May also stain positive for CD99 and BCL2 and can be misclassified as hemangiopericytoma (1,2)[C]
- Leiomyosarcoma
  - Usually large circumscribed mass with areas of necrosis
  - Microscopically, spindle cells with haphazard growth pattern, nuclear pleomorphism, mitoses, and necrosis
  - Immunostaining positive for SMA, desmin, and calponin (1)[C]
- Fibrosarcoma
  - Large encapsulated mass
  - Microscopically, elongated spindle cells
    - "Herringbone" pattern
  - Immunostaining positive for vimentin
    - Differentiates fibrosarcoma from sarcomatoid RCC and leiomyosarcoma (1)[C]
- Malignant fibrous histiocytoma
  - Solid, well-encapsulated mass
  - Microscopically, proliferation of fibrohistiocytes
  - Immunostaining positive for α1-antitrypsin and vimentin

DIFFERENTIAL DIAGNOSIS
- Angiomyolipoma
- Renal cysts
- Cystic nephroma
- Hemorrhagic/proteinaceous cysts
- Juxtaglomerular cell tumor
- Metastasis to kidney
- Oncocytoma
- Renal cell carcinoma
- Renal pseudotumor/scar
- Splenule (ectopic or traumatic)
- Urothelial carcinoma
- Wilms tumor
- Xanthogranulomatous pyelonephritis

TREATMENT

GENERAL MEASURES
- Surgical excision is both diagnostic and therapeutic
- Multimodal therapy generally recommended for malignancies such as sarcoma

MEDICATION

First Line

- Chemotherapy may be beneficial for certain advanced renal capsular malignancies (sarcoma) and metastatic lesions (4)[C].
  - Usually given in the adjuvant setting.
- Targeted therapies may be beneficial in certain cases.
  - Sunitinib, sorafenib, bevacizumab active in angiosarcoma, solitary fibrous tumor, and hemangiopericytoma.

SURGERY/OTHER PROCEDURES

- Surgical excision remains gold standard
  - Radical nephrectomy
    - Open or minimally invasive
  - Partial nephrectomy
    - Open or minimally invasive
    - Renal capsule margin should be excised with mass
    - Should be procedure of choice for patients with chronic kidney disease, when feasible
- Active surveillance
  - Similar surveillance protocol for patients with small renal masses

ADDITIONAL TREATMENT

Radiation Therapy

- May be beneficial in cases of renal capsular sarcoma
  - Usually given in adjuvant setting

Additional Therapies

Angioembolization for bleeding masses

Complementary & Alternative Therapies

None known

ONGOING CARE

PROGNOSIS

- Surgical excision usually curative
- Renal capsular sarcoma has poor prognosis
  - Locally advanced disease is common
  - Recurrence and metastases common
  - Overall prognosis is poor, despite adjuvant chemoradiation
    - 5-yr overall survival ~15%
    - Median survival 28 mo (4)[C]

COMPLICATIONS

- Injury to adjacent organs
- Thromboembolic event
- Delayed bleed
  - AV fistula
  - Pseudoaneurysm

• Development of metastatic disease

FOLLOW-UP

Patient Monitoring

• Periodic surveillance imaging
• Serum chemistry panel and liver function tests

Patient Resources

None due to rarity of disease

CODES

ICD9

• 189.0 Malignant neoplasm of kidney, except pelvis
• 223.0 Benign neoplasm of kidney, except pelvis
• 239.5 Neoplasm of unspecified nature of other genitourinary organs

ICD10

• C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
• D30.00 Benign neoplasm of unspecified kidney
• D49.5 Neoplasm of unspecified behavior of other genitourinary organs

CLINICAL/SURGICAL PEARLS

• Renal capsular neoplasms difficult to distinguish from RCC by imaging alone.

- Surgical excision (partial or radical nephrectomy) can be diagnostic and curative in most cases.
- Renal capsular sarcomas carry generally poor prognosis, despite adjuvant therapy.

RENAL CELL CARCINOMA WITH TUMOR THROMBUS

Chandy Ellimoottil, MD
Marcus L. Quek, MD, FACS

BASICS

DESCRIPTION

- Patients with renal cell carcinoma (RCC) are at risk for developing intravenous tumor thrombus (IVTT) with tumor extending into the renal vein (RV) and inferior vena cava (IVC).
- RCC is the most common malignancy to extend into IVC.
- Tumor growth follows the path of least resistance into the venous system extending into the RV and IVC (and into the right atrium) or it can invade into the vein wall.
- Multiple staging systems exist for RCC with venous extension. 3 common staging systems include:
  - TNM
    - pT3a—RV extension
    - pT3b—IVC below diaphragm
    - pT3c—IVC above diaphragm
  - Anatomic (Hinman system)
    - Level I—RV/infrahepatic IVC
    - Level II—Intrahepatic IVC
    - Level III—Supradiaphragmatic IVC/right atrium
- Anatomic (Neves/Novick system)
  - Level 0—RV
  - Level I—IVC <2 cm above RV
  - Level II—IVC >2 cm above RV and below hepatic veins
  - Level III—IVC above hepatic veins and below diaphragm
  - Level IV—IVC above diaphragm

EPIDEMIOLOGY

Incidence

There are approximately 63,920 cases of RCC diagnosed each year; about 10% have IVTT.

Prevalence (1)

- RCC with IVTT is seen in 4–15% of cases.
  - In 50% of these cases, IVTT only extends to the RV.
  - IVTT extends into the right atrium in 1% of cases.
- Among patients that have IVTT, 29–55% will have concomitant metastatic disease.

RISK FACTORS

Risk factors for RCC with IVTT are the same for RCC and include smoking, obesity, hypertension, family history.

Genetics

No known genetic factors exist that predict IVTT.

PATHOPHYSIOLOGY

- RCC with IVTT can occur with all histologic subtypes including clear cell, papillary, and chromophobe
- RCC can occur sporadically or in a hereditary form (although there is no known genetic predisposition to IVTT)
- IVTT can cause occlusion of the IVC, which can cause lower-extremity edema, varicocele in males
- IVTT can also cause a pulmonary embolism
- Acute caval obstruction may rarely lead to disseminated intravascular coagulation, though more commonly IVTT may cause chronic venous obstruction leading to the development of collateral venous drainage

ASSOCIATED CONDITIONS

- Pulmonary embolus
- Bilateral lower-extremity edema
- Lower-extremity DVT
- Varicocele
- Caput medusa

GENERAL PREVENTION

Modification of above risk factors for RCC

DIAGNOSIS

HISTORY

- Presentation of patients with RCC with IVTT is similar to RCC without tumor thrombus, but those with tumor thrombus are more likely to be symptomatic
- Up to 95% of patients with intracaval extension present with symptoms it is an incidental finding in 23%
- Symptoms include:
  - Hematuria (35%)
  - Flank/abdominal pain (17%)
  - Constitutional symptoms including fatigue, weight loss, or paraneoplastic syndrome (9%)
  - Flank/abdominal mass (2%)

PHYSICAL EXAM

- Physical exam findings can include:
  - Bilateral lower-extremity edema
  - Varicocele (right side)
  - Dilated superficial abdominal wall veins
  - Caput medusa

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Basic lab work is necessary for preoperative workup including
  - Liver function tests

– Complete blood count
– Basic metabolic panel
– Urinalysis

Imaging

- Chest imaging (preferably CT) and bone scan should be ordered as part of staging workup
- Assessment of IVTT cephalad extension should be performed 7–14 days before surgery because it can affect the surgical approach and the need for bypass procedures
- Ultrasonography and standard CT can be used to detect the presence of IVTT, but may not be sufficient for surgical planning
- MRI (T1-weighted images) is the gold standard imaging technique used to assess the cephalad extent of the IVTT, the degree of occlusion, and its relationship to liver, diaphragm, and atrium
- Multidetector CT (MDCT) can also be used in patients who are not candidates for MRI
- Studies comparing MRI to MDCT for staging IVTT have shown comparable results
- Transesophageal echocardiography can be used intraoperatively for real-time monitoring of thrombus
- Size of tumor thrombus on imaging studies may predict vein wall invasion and need for vein reconstruction

Diagnostic Procedures/Surgery

Biopsy can be performed if urothelial cell carcinoma is suspected or patient is poor surgical candidate

Pathologic Findings

- All subtypes of RCC have been associated with IVTT
- Clear cell is the most common histologic subtype associated with IVTT

DIFFERENTIAL DIAGNOSIS

Other tumors associated (rarely) with IVTT include urothelial cell carcinoma, adrenocortical carcinoma, and angiomyolipoma

TREATMENT

GENERAL MEASURES

- For those with no evidence of distant metastatic disease, surgical resection is the gold standard for RCC with IVTT
- For patients who present with metastatic disease, biopsy may be indicated for consideration of systemic therapy
- For select patients with metastatic disease, cytoreductive nephrectomy with tumor thrombectomy may be considered, although the outcomes in this setting are usually poor

MEDICATION

First Line

- Anticoagulation (preoperatively) should be considered for patients with IVTT to prevent bland thrombus development and propagation below the tumor
- Preoperative tyrosine kinase inhibitors (TKIs)
  – Controversial

- May be utilized in the metastatic setting or when tumor felt not to be surgically resectable
- Most common TKIs used preoperatively are sorafenib and sunitinib; may decrease tumor size before surgical resection; may reduce level of IVTT, potentially altering surgical approach

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Surgery is the gold standard for the treatment of RCC with IVTT (2,3,4)
- Accurate assessment of the cephalad extent of the tumor thrombus is critical in determining the surgical approach and need for adjunctive procedures
- While there are some reports of robotic and laparoscopic approaches to RCC with IVTT, the mainstay is open surgery
- Midline, subcostal (chevron), or thoracoabdominal incisions can be used
- Median sternotomy or thoracoabdominal approaches can be used for IVTT above the diaphragm
- For all levels, IVC should be resected if tumor is invading into the wall and reconstruction can be performed with graft (if lumen diameter compromised >50%)
- Resection of retroperitoneal lymph nodes and/or metastasectomy can be performed as needed
- Surgical steps include:
  - Expose renal hilum, ligate renal artery
  - Expose the RV and IVC
  - Isolate venous inflow into IVC
  - Cavotomy, tumor extraction
  - Caval repair/reconstruction/ligation
- Level I Thrombus Specifics
  - Milk the thrombus into the RV and take a side bite of the IVC using a vascular clamp making sure not to occlude IVC flow
  - Incise the IVC and remove the thrombus and kidney under direct vision
  - Oversew the caval defect
- Level II Thrombus Specifics
  - Mobilize the liver and divide minor hepatic veins to expose the intrahepatic IVC
  - Place Rummel tourniquets or vascular clamps sequentially on the infrarenal vena cava, contralateral RV, and suprarenal vena cava above the thrombus
  - Incise IVC, remove the thrombus and kidney
  - Flush-exposed IVC with heparinized saline
  - Suture cavotomy; release vascular clamps
- Level III–IV Thrombus Specifics
  - A wide variety of surgical approaches have been described
  - Clamping of the IVC at the this level can compromise hemodynamic stability
  - Cardiopulmonary bypass: Used for IVTT above the diaphragm, maintains continuous arterial/venous blood flow during IVC occlusion
  - Deep hypothermic circulatory arrest (DHCA) cools the body and create a bloodless field
  - Venovenous bypass can be used for level II–IV tumors. Venovenous bypass allows for

continuous venous return to the heart while IVC is clamped.
  – Pringle maneuver (clamping of the hepatic pedicle) can be used to avoid hepatic congestion and/or IVC bleeding that may occur when IVC is clamped above the hepatic veins (limit warm hepatic ischemia to 20 min)
  – Cephalad IVC control can be obtained by exposing the intrapericardial IVC via pericardiotomy
  – Langenbuch maneuver (medial mobilization of liver) to expose retrohepatic IVC
  – Transesophageal echocardiography should be used for real-time intraoperative monitoring to identify tumor emboli
  – A multidisciplinary approach, including the involvement of cardiac, vascular, hepatic surgeons as well as a specialized anesthesia team, is highly encouraged for these complex tumors

ADDITIONAL TREATMENT

Radiation Therapy

No role, except for palliation

Additional Therapies

- IVC filter can be used to prevent pulmonary embolus, however its use is controversial
  – IVTT may become incorporated into IVC filter causing a surgical challenge
  – When IVC is chronically occluded, simple ligation of IVC below hepatic veins may be performed
- Preoperative renal artery embolization
  – Allows for early venous clamping when renal artery control may be difficult; may cause pain and complications (angioinfarction syndrome)
  – Can be used as a palliative procedure

Complementary & Alternative Therapies

None

ONGOING CARE

PROGNOSIS

- Prognostic factors include TNM stage, nuclear grade, presence of necrosis, histologic type (worse for unclassified RCC and collecting duct carcinomas), sarcomatoid features, invasion into adjacent structures (renal sinus, perinephric fat, hepatic veins, collecting system, RV ostium), ECOG performance status, presence of lymph nodes, and distant metastasis
- Prognostic significance of tumor thrombus level remains controversial
- Median survival for nonmetastatic disease: 38–116 mo; 5-yr disease specific survival 40–60% when all gross disease is resected
- Median survival for metastatic disease: 11–20 mo and 5-yr disease specific survival is 4–30%. Patients that present with metastatic disease: 5-yr survival 0–10%.

COMPLICATIONS

- Overall complication rate is 12.5%, however, the complication rates vary greatly with level of tumor thrombus.
- Perioperative death varies from 0.8–10%. There has been a reported rate of mortality up to

40% for level IV IVTT.
- Most common complications are hemorrhage, pulmonary embolism, wound infection, acute renal failure, ileus, and need for additional surgery.
- The incidence of intraoperative tumor thrombus embolization is 1.5% and is associated with 75% mortality rate.
- Cardiopulmonary bypass is a risk factor for stroke (6% of cases) during nephrectomy for RCC with IVTT.

FOLLOW-UP

Patient Monitoring

- Surveillance based on TNM staging
- Surveillance labs include metabolic panel, liver function tests
- Surveillance imaging includes abdominal and thoracic imaging

Patient Resources

- American Cancer Society

CLINICAL/SURGICAL PEARLS

Preoperative assessment of cephalad extent of thrombus is critical for surgical planning.

RENAL CELL CARCINOMA, GENERAL

Matthew A. Meissner, MD
Ganesh V. Raj, MD, PhD, FACS

BASICS

DESCRIPTION

- Renal cell carcinomas (RCC's) are malignant tumors of the kidney arising from different parts of the nephron
- Majority of renal neoplasms are RCC (80%)
- RCC is typically resistant to conventional chemotherapy and radiation, making it primarily a surgical disease

EPIDEMIOLOGY

Incidence

- 65,150 estimated new cases of RCC in 2014 in USA (39,140 in men and 24,780 in women); 12 new cases per 100,000/yr (1)[B]
- Male > Female, 3:2
- Increase in incidence since the 1970s of 3–4%/yr due to increased use of abdominal CT
- Estimated 13,860 deaths will occur in 2014 from RCC in USA (1)[B]
- Primarily occurs in 6th–7th decade of life
- 2–3% are familial; majority are sporadic

Prevalence

- 3rd most common GU malignancy in men (prostate, bladder); most common urinary tract malignancy in women
- RCC represents 2.3–6.6% of all pediatric renal tumors

RISK FACTORS

- Tobacco exposure: 1.4–2.5 times increased risk, this increases with duration, decreases after cessation (2)[C]
- Obesity
- Hypertension (HTN) has a 1.4–2-fold increase of RCC
- Family history in a 1st- or 2nd-degree relative associated with a relative risk of 2.9 of developing RCC
- Other potential environmental factors include viruses, lead compounds, and aromatic hydrocarbons

Genetics

- Clear-cell RCC is associated with chromosomal 3p deletion and/or mutations of VHL gene
- Alterations of chromosome 3p25–26 lead to clear-cell RCC in VHL syndrome (3)[A]
- Nonhereditary papillary RCC is linked to changes in chromosomes 7 and 17
- Hereditary pRCC typically involves type 1 pRCC and is due to missense mutations of the c-met proto-oncogene
- Chromophobe RCC is a result of allelic loss of chromosome 17

- Birt–Hogg–Dubé syndrome (BHD) includes cutaneous manifestations, spontaneous pneumothoraces, and chromophobe RCC, renal oncocytomas, or hybrid tumors consisting of both due to mutations in BHD gene on chromosome 17
- Translocation Xp11.2 Translocation carcinoma; predominantly younger patients

PATHOPHYSIOLOGY

- Clear cell and papillary RCC develop from the proximal convoluted tubules.
- Chromophobe and collecting-duct RCC develop from the distal convoluted tubule and collecting duct, respectively.
- VEGF and TNF-α are growth factors altered in development and progression of RCC.
- Local invasion is common; 20% of cases have invasion of the capsule or collecting system, and 10% have a tumor thrombus.
- Bilateral tumors occur 2–4% of the time with sporadic RCC, either at diagnosis or metachronously.

ASSOCIATED CONDITIONS

- For ESRD patients there is a 5–20-fold increase in risk of developing RCC, most commonly papillary subtype.
- Acquired renal cystic disease in conjunction with ESRD has a 1–2% risk of developing RCC.
- VHL-related RCC is associated with retinal angioma, pancreatic cysts, cerebellar and spinal hemangioblastomas, and neuroendocrine tumors.
- BHD-related RCC is associated with facial fibrofolliculomas in addition to lung cysts and spontaneous pneumothoraces.

GENERAL PREVENTION

- Smoking cessation reduces the relative risk of developing RCC by 20–50%
- Weight reduction: It is estimated that 40% of the cases of RCC in USA may be linked to obesity

DIAGNOSIS

HISTORY

- Most cases of localized RCC are asymptomatic and >50% of cases are detected incidentally during abdominal imaging for other reasons.
- Classic Triad: Flank pain, palpable flank mass, and hematuria. This is rarely seen except in advanced disease.
- Paraneoplastic symptoms found in 20% of patients. These include hypercalcemia (due to paraneoplastic phenomena or osteolytic bone involvement), HTN, polycythemia.
- Constitutional symptoms such as fever, weight loss, and anemia are thought to be due to paraneoplastic syndromes.

PHYSICAL EXAM

- Physical exam findings are usually absent, except in cases of advanced disease.
- Deep palpation for upper quadrant masses and auscultation for a renal artery bruit should be included in the abdominal exam.
- Assess for a varicocele with a careful testicular exam as venous outflow obstruction can occur due to a renal vein tumor thrombus. An epididymal mass may be seen in VHL-related

disease.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Initial evaluation includes CBC, electrolytes, creatinine, LFTs, and UA
- Elevated ESR is present in 56% of patients
- Stauffer syndrome found in 14.4% of patients
  - Characterized by abnormal LFTs from a paraneoplastic syndrome and not from liver metastases
  - Also find elevated alkaline phosphatase, PTT, low albumin, elevated bilirubin, or transaminases
- Hypercalcemia seen in 13% overall, and in 4.9% resulting from paraneoplastic syndromes
- Anemia may be due to blood loss

Imaging

- Thin-slice renal CT scan with and without IV contrast is the best test for diagnosing renal masses
- Any enhancing lesion on CT or MRI is RCC until proven otherwise
  - Enhancement generally defined as $\geq$20 HU increase between contrast and noncontrast phases
- R.E.N.A.L. Nephrometry score may provide a standardized system for radiologic comparison of renal masses (See RENAL Nephrometry in Section II)
- Any renal mass with a negative CT attenuation (< -20 HU) consistent with fat density is an AML
- Metastatic evaluation may include CT or MRI of the abdomen, chest x-ray for pulmonary lesions, and a bone scan in patients with elevated alkaline phosphatase or bone pain

Diagnostic Procedures/Surgery

- Biopsy of a renal mass is typically not included in the workup due to high false-negative rate, risk of bleeding, and remote possibility of seeding the biopsy tract
  - Difficult to distinguish between oncocytoma and RCC on biopsy
  - 83–90% of solid renal masses thought to be RCC are confirmed on final pathology
  - Sensitivity and specificity of FNA biopsy is 80% and 95%, which is no better than imaging alone
- Biopsy helps differentiate primary renal neoplasms from metastasis or renal lymphoma
- Biopsy is now considered more frequently in patients being considered candidates for observation vs. surgical extirpation
  - Biopsy is being used for surveillance in small RCC with $>$90% accuracy with adequate specimens

Pathologic Findings

- RCCs are adenocarcinomas, arising from renal tubular epithelial cells
- Clear cell RCC (formerly known as “conventional RCC”) 70–80% of RCC
- Papillary RCC accounts for 10–15%
  - Type 1: Associated with *Hereditary papillary renal cell carcinoma* (*HPRCC*)
  - Type 2: Aggressive, associated with *Hereditary leiomyomatosis and renal cell cancer* (*HLRCC*)
- Chromophobe 3–5% of solid renal masses, associated with a good prognosis

- Collecting duct (Bellini) RCC is rare (< 1%), but associated with a very poor prognosis. Occurs in younger patients (3rd–5th decades of life).
- Renal medullary RCC found in African Americans with sickle cell trait, and is often metastatic at the time of diagnosis
- Furhman nuclear grading: Graded 1–4 according to nuclear aberrations in RCC. Independent prognostic indicator with higher grades portending worse outcomes (4)[B]
- Sarcomatoid differentiation: Reported as presence and extent found in the primary histologic subtype; not a distinct category. Associated with a worse prognosis

DIFFERENTIAL DIAGNOSIS

- Adrenal mass
- Angiomyolipoma (fat poor)
- Collecting duct tumor (Bellini)
- Cystic nephromas (multilocular cystic nephroma)
- Cysts (hemorrhagic, infected)
- Focal pyelonephritis
- Hemangioma
- Inflammatory masses (xanthogranulomatous pyelonephritis, abscess, infected calyceal diverticulum)
- Leiomyoma
- Metanephric adenoma
- Metastasis from other primary tumor
- Oncocytoma
- Pseudotumors (hypertrophied column of Bertin, or fet al lobulations: Can mimic a central tumor, particularly in congenitally solitary kidneys)
- Renal cell carcinoma
- Renal lymphoma
- Renal medullary carcinoma (sickle cell trait)
- Renal sarcomas
- Reninoma (JG apparatus tumors)
- Urothelial carcinoma
- Wilms tumor (nephroblastoma)

TREATMENT

GENERAL MEASURES

- Surgical extirpation (radical or partial nephrectomy) is the primary treatment for solid renal masses
- Radical nephrectomy: Removal of the entire kidney, perinephric fascia, lymph nodes, and ipsilateral adrenal gland in upper pole tumors

MEDICATION

First Line

Systemic immunotherapy and targeted molecular therapies have no role in clinically localized RCC

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Partial nephrectomy is now the standard of care for clinical T1 renal masses (≤7 cm) in patients with a normal contralateral kidney who are surgical candidates. Oncologic outcomes equal to radical nephrectomy in selected patients. Renal function is preserved.
- Radical nephrectomy is the standard of care for large tumors, and for patients with metastases undergoing cytoreductive nephrectomy.
- Radiofrequency ablation/cryoablation minimally invasive; considered in selected small masses.

ADDITIONAL TREATMENT
Radiation Therapy
Radiation is limited to palliation of systemic metastases; no role in the management of clinically localized RCC

Additional Therapies
- Resection of solitary metastatic lesions (ie, lung) may be useful in selected cases
- No role for adjuvant systemic therapy in localized RCC

Complementary & Alternative Therapies
Renal masses <2 cm can be observed in many patients including those who are poor surgical candidates (~30% benign).

ONGOING CARE

PROGNOSIS
- The single most important prognostic factor for RCC is pathologic stage (5):
  - pT1a: 90–100% 5-yr survival
  - pT1b: 80–90% 5-yr survival
  - pT2: 70–80% 5-yr survival
  - pT3: 45–69% 5-yr survival in the absence of nodal or systemic metastases
  - pT4: 0–20% 5-yr survival in the absence of nodal or systemic metastases
- Direct invasion ipsilateral adrenal: 0–30% 5-yr survival; node-positive RCC: 0–20% 5-yr survival; metastatic RCC: 0–10% 5-yr survival
- Paraneoplastic syndromes, poor performance status, weight loss >10% worse outcome
- Other important prognostic factors include Fuhrman nuclear grade, histologic subtype, sarcomatoid features. Nomograms exist to predict risk of recurrence based on the above features.

COMPLICATIONS
- Surgical complications include bleeding, infection, urine leak, damage to surrounding structures including bowel, liver, spleen
- Large or locally invasive tumors may compromise GI or pulmonary function
- Bone metastases may result in pain and pathologic fractures
- Paraneoplastic syndromes causing cachexia, bleeding, HTN

FOLLOW-UP

Patient Monitoring

- See follow-up recommendations in "Renal Cell Carcinoma, Localized (T1–T2)"
- Incidence of local recurrence and the development of systemic metastases are directly associated with tumor stage (6)[B]:
  - T1: 0% local; 4% metastatic
  - T2: 2% local; 5.3% metastatic
- Surveillance is tailored to tumor stage

CODES

ICD9

- 189.0 Malignant neoplasm of kidney, except pelvis
- 599.70 Hematuria, unspecified
- 789.09 Abdominal pain, other specified site

ICD10
- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- R10.9 Unspecified abdominal pain
- R31.9 Hematuria, unspecified

CLINICAL/SURGICAL PEARLS
- Most common solid renal mass is clear cell RCC.
- Most renal masses are detected incidentally.
- VHL syndrome is associated with chromosome 3p deletion and RCC, as well as other tumors.
- Surgical removal is the mainstay of treatment for RCC.
- Partial nephrectomy is increasingly utilized for larger, clinically localized tumors.

RENAL CELL CARCINOMA, LOCALIZED (T1–T2)

Reza Mehrazin, MD
Robert G. Uzzo, MD

BASICS

DESCRIPTION

- Renal cell carcinoma (RCC) refers to an adenocarcinoma and is the most common type of renal neoplasm. Stage T1 and T2 differ by size and are localized to the parenchyma with no extension outside the capsule.
- Stage T1 is further classified as T1a (tumor <4 cm) or T1b tumor (4–7 cm). Stage T2 is confined to the kidney and further classified as T2a (tumor 7–10 cm) and T2b (>10 cm).

EPIDEMIOLOGY

Incidence

- 63,920 new cases; 13,570 deaths in USA in 2014
  - Most lethal of all GU neoplasms (21% of those diagnosed will ultimately die of disease)
- Male > Female ($\sim$1.7:1)
  - 7th most frequent tumor in men (lifetime risk 1:61 in men and 1:103 in women)
- Peak incidence: 6th and 7th decades of life
- 10–20% higher incidence in African Americans
- 96% of cases are sporadic, whereas 4% are associated with familial syndromes

RISK FACTORS

- Only accepted environmental risk factor is tobacco exposure: Increases relative risk by 1.4–2.5. All forms of tobacco implicated; Risk increases with cumulative exposure
- Family history, obesity, hypertension, end stage renal disease (ESRD), autosomal dominant polycystic kideny disease (ADPCKD) and horseshoe kidney have all been implicated but not proven to be genetic or acquired risk factors

Genetics

- 3p25 (VHL gene) (tumor suppressor) implicated in $>70\%$ of all acquired (somatic mutations) cases of clear cell RCC. In cases of germ line *Von Hippel-Lindau syndrome* (VHL) mutation, additional manifestations include retinal angiomas, CNS hemangioblastomas, epididymal cystadenomas, endolymphatic sac tumors, pancreatic cysts, islet cell tumors, and pheochromocytomas.
- 7q31 (cMet gene) (oncogene) implicated in papillary type I RCC. With germ line mutations there are no known extrarenal manifestations.
- 17p11 (Birt–Hogg–Dubé/folliculin gene) (tumor suppressor) implicated in cases of chromophobe/oncocytoma. With germ line mutations can see: Cutaneous fibrofolliculomas, nevus, PTH adenomas, colonic polyps/tumors and pneumothorax.
- 1q42 (HLRCC gene) (Tumor suppressor) HLRCC syndrome (type II papillary RCC) manifestations include painful cutaneous leiomyomas, and uterine fibroids

PATHOPHYSIOLOGY

- RCC arises from the proximal convoluted tubule. Chromophobe, oncocytoma, and papillary tumors, believed to arise from the distal tubule.
- Tumors may grow locally and/or systemically concurrently. Local symptoms occur late and renal insufficiency is rare even with large tumors.
- Histology, grade, and stage are independent factors that correlate with survival
  - Lower risk: Low-grade (type I) papillary, chromophobe, and oncocytic carcinomas
  - Intermediate risk: Clear cell tumors
  - High risk: Collecting duct carcinomas, sarcomatoid clear cell carcinomas, renal medullary carcinomas associated with sickle cell
- Lesions < 4 cm: Up to 20–30% can be benign. Progression to metastasis appears to be a late event although up to 3–5% of small renal masses can present with synchronous metastases.
- In highly selected series, median radiographic growth rate during a period of active surveillance for a small renal mass is 0.08–0.58 cm/yr with mean growth rate of ~0.28 cm/yr (1)

ASSOCIATED CONDITIONS
- Extrarenal manifestations associated with RCC typically part of hereditary syndromes (such as *Von Hippel-Lindau syndrome* [VHL], *Hereditary leiomyomatosis and renal cell cancer* [*HLRCC*], Birt–Hogg–Dubé [BHD])
- Renal medullary carcinomas associated with sickle cell trait are highly aggressive (mean survival: 12–15 mo) and present during 3rd decade of life

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Most stage T1/T2 lesions are asymptomatic, incidentally discovered on cross-sectional imaging for unrelated reasons
- Symptoms of more advanced disease include hematuria, flank pain, fever, weight loss (> 10% of total body weight), bone pain

PHYSICAL EXAM
- In stage T1/T2 disease, typically few physical findings. Larger tumors may be palpable or symptomatically compressing on adjacent organs.
- Palpable abdominal mass, lymphadenopathy, nonreducing or rapid onset of varicocele may suggest advanced disease (renal vein or IVC involvement)
- Absence of symptoms or findings on physical exam does not rule out advanced disease

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CBC: Anemia may suggest worse prognosis, polycythemia may suggest paraneoplastic state
- Serum creatinine: eGFR clearance better estimate of renal function. Calculate CKD stage.
- Liver function tests: If abnormal consider Stauffer syndrome (reversible hepatitis), metastasis, or biliary duct obstruction
- Calcium: Elevated in paraneoplastic syndromes due to PTH-like substances

- Alkaline phosphatase: Elevation suggests bone or liver involvement

Imaging

- Pre- and postcontrast-based CT or MRI is essential (>20 Hounsfield units enhancement on CT of >20% increase in postcontrast region of interest (ROI) on MR)
- US can usually distinguish cystic from solid masses. Hyperdense cyst which may look solid and exhibit pseudoenhancement. CT or MRI (not US) is used to assign Bosniak grade.
- Extent of disease evaluation includes CXR or CT chest. Bone scan and CNS imaging performed if symptoms/signs mandate.
- FDG-PET not useful in evaluation of T1/T2 RCC due to low sensitivity and specificity

Pathologic Findings

- Staging (see "TNM Staging" section)
- Needle biopsy:
  - Appropriate if wide range of options are under consideration (focal therapy vs. observation)
  - Needle-tract seeding very uncommon
  - Good at distinguishing cancer and histologic type. Unreliable for tumor grade.

DIFFERENTIAL DIAGNOSIS

- Adrenal mass
- Angiomyolipoma (fat poor)
- Collecting duct tumor (Bellini)
- Cystic nephromas (multilocular cystic nephroma)
- Cysts (hemorrhagic, infected)
- Focal pyelonephritis
- Hemangioma
- Inflammatory masses (xanthogranulomatous pyelonephritis, abscess, infected calyceal diverticulum)
- Leiomyoma
- Metanephric adenoma
- Metastasis from other primary tumor
- Oncocytoma
- Pseudotumors (hypertrophied column of Bertin, or fet al lobulations: Can mimic a central tumor, particularly in congenitally solitary kidneys)
- RCC
- Renal lymphoma
- Renal medullary carcinoma (sickle cell trait)
- Renal sarcomas
- Reninoma (JG apparatus tumors)
- Urothelial carcinoma
- Wilms tumor (nephroblastoma)

TREATMENT

GENERAL MEASURES

- To avoid future renal insufficiency and metabolic disturbances, assess global renal function (eGFR) and consider nephron-sparing approaches, especially in those patients with low-to-intermediate complex renal masses and reasonable life expectancy
- For T1/T2 lesions, depending on pathology, surgery by radical or partial nephrectomy is highly likely to result in a long-term cure
- For T1 tumors radical and partial nephrectomy appear cancer equivalent. For T2 tumors partial is emerging as oncologically equivalent option (2).

MEDICATION

First Line

- Localized RCC is a surgical disease. Limited role for tyrosine kinase inhibitors and antiangiogenic therapy in localized RCC.
- Control of blood pressure, diabetes, lipids and minimization of atherosclerotic risk factors (smoking) are all important to subsequent renal function mandating physician involvement and patient counseling
- Use of ACE inhibitors or angiotensin receptor blockers may slow hyperfiltration injury

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Approach is dictated by many factors (3) including patient risks (comorbidities, underlying renal function, prior surgeries, trade-offs), tumor risk (size/location of the tumor, complexity of the mass [ie, nephrometry score—www.nephrometry.com], number of lesions), hospital and physician factors
- Excision: Partial or radical nephrectomy via open, laparoscopic, or robotic techniques
- Nephron-sparing surgery:
  - Partial nephrectomy is the standard of care for masses T1 in young otherwise healthy individuals for absolute, relative, and elective indications. Removal of mass with a small rim of normal parenchyma.
  - Other indications for partial nephrectomy: Absolute indications (patients with bilateral renal masses, a tumor in a solitary kidney) and relative indications (existing or comorbidities with potential for future renal insufficiency)
  - Enucleation (removal of mass by dissection between normal parenchyma and pseudocapsule of the tumor) is acceptable for small and/or multiple renal masses as long as negative margins are achieved
- Bilateral (synchronous) RCC: ~1–6%. Stage surgeries (Nephron sparing surgery (NSS) on easier side 1st as it provides more options for the difficult side). Can alter if there is a large discrepancy between complexity, size, and risks of the two sides.
- Ablation: Cryoablation or radio frequency ablation (RFA) by minimally invasive surgery (MIS) or percutaneous (preferred) technique:
  - Best with advanced age, significant comorbidities, and potentially amenable recurrence after prior NSS
  - Best: <3.5 cm, peripheral, solid, exophytic, remote from vessels/collecting system
  - Survival data are short term and there are no definitive data to date proving that ablation impacts tumor biologic potential

- Active surveillance: Elderly or with significant medical risks. Serial radiographic surveillance with assessment of the growth kinetics of the untreated mass and continued reassessment.

ADDITIONAL TREATMENT

Radiation Therapy

- No role in localized RCC outside of clinical trials of focal radiotherapy (CyberKnife) or HIFU
- Used for painful bony metastases and CNS metastasis in advanced RCC

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Related to stage, grade, histology. Nomograms available to calculate risk at www.cancernomograms.com.
- Local recurrence after resection is ~2–3% after radical nephrectomy and 4–6% after partial depending on pathology
- 5-yr risks of recurrence for local or regional RCC fully excised are approximately:
  - 5–9% low-risk disease
  - 20–25% intermediate-risk disease
  - 60–80% high-risk disease
- Prognosis for partial nephrectomy with a positive margin is less clear. Related to pathology and biology. Every attempt should be made intraoperatively to avoid a positive surgical margin; with focal positive margin, close observation is often indicated.

COMPLICATIONS

- Acute surgical/medical risks depend on treatments, techniques, comorbidities, and complexity of the mass. Overall perioperative death rate <0.5%. Risk of major Clavien grade 3–5 complications: 6.4%, 11.1%, 21.9% for low-, intermediate-, and high-complexity lesions (4).
- Risks after partial nephrectomy: Urinary leak/fistulas, AVF, bleeding, transient or permanent decline in renal function (5)
- Increased risk of *Nephrogenic systemic fibrosis* (*NSF*), with gadolinium (eGFR <30 mL/min per 1.73 m^2) and/or risk of contrast-induced nephropathy following use of iodinated contrast for radiographic surveillance

FOLLOW-UP

Patient Monitoring

- Periodic history, physical (including BP monitoring), and selected lab studies (calcium, hemoglobin, liver, renal profiles, urine analysis) at least yearly
- Radiographic stage/grade/histology-specific surveillance mandatory based on clinical stage and mode of treatment. Surveillance may be adjusted for other risk factors (grade/histology).

- Following ablation, initial radiographic follow-up requires lack of enhancement on pre-/postcontrast-based CT or MRI at 3–6 mo after procedure. Biopsy confirmation of successful ablation is recommended. Occasionally after cryotherapy, an area of rim enhancement can be seen that should resolve within 1st 3 mo.
- NCCN (National Comprehensive Cacner Network) guidelines (level of evidence 2B—lower level but consensus recommended)
  – Every 6 mo for 2 yr, then annually for 5 yr: History, physical, metabolic panel
  – At 2 yr (based on recurrence risk) chest and abdominal ± pelvic imaging then risk based

- Always review the images and carefully assess the presence of the contralateral kidney and the adrenal glands.
- Do not overtreat or undertreat renal mass.

RENAL CELL CARCINOMA, LOCALLY ADVANCED (T3–T4)

Ahmad Shabsigh, MD, FACS

BASICS

DESCRIPTION

- T3 renal cell carcinoma (RCC) extends into major veins or perinephric tissues but not into the ipsilateral adrenal gland and not beyond Gerota fascia.
  - T3a tumor grossly extends into the renal vein or its segmental (muscle containing) branches, or tumor invades perirenal and/or renal sinus fat but not beyond Gerota fascia.
  - T3b tumor grossly extends into the vena cava below the diaphragm.
  - T3c tumor grossly extends into the vena cava above the diaphragm or invades the wall of the vena cava.
- T4 RCC invades beyond Gerota fascia (including contiguous extension into the ipsilateral adrenal gland).

EPIDEMIOLOGY

Incidence

- 63,920 new cases in USA in 2014 (39,140 in men and 24,780 in women)
- 13,860 deaths in USA in 2014
- 20% of patients present with locally advanced or node-positive RCC
- RCC with IVC involvement is seen in 4–10% of patients

Prevalence

8.3–12 new cases per 100,000 per year

RISK FACTORS

- Cigarette smoking results in a 1.4–2.5 increased risk of RCC; risk increases with higher pack/yr consumption, may not be as much of a factor for women as men.
- Obesity: 40% of RCC may be attributed to overweight or obesity.
- A positive family history of RCC in a 1st- or 2nd-degree relative carries a relative risk of 2.9 of developing RCC.
- HTN has a 1.4–2-fold increase in risk of RCC.
- Low socioeconomic status, urban background, and parity have been associated with an increased risk of RCC.

Genetics

- Nonhereditary clear cell RCC is associated with deletion of chromosome 3p and/or mutations of the VHL gene.
- VHL manifests clear cell RCC due to alterations of the VHL gene on chromosome 3p25–26.
- Nonhereditary papillary RCC has been linked with changes in both chromosome 7 and 17.
- *Hereditary papillary renal cell carcinoma* (*HPRCC*) arises from mutation of the MET protooncogene on chromosome 7p34.
- Chromophobe RCC: Loss of chromosome 17.
- Birt–Hogg–Dubé syndrome develops from changes in the BHD1 gene on chromosome

17p11.2.
- FH (fumarate hydratase) mutations on chromosome 1q42 in hereditary leiomyomatosis: Predispose to papillary Type 2 RCC.
- Mutations in the TSC1/2 genes predispose to tuberous sclerosis.

PATHOPHYSIOLOGY
- 20% of cases will have frank invasion of the capsule or collecting system.
- 10% will demonstrate venous involvement with tumor thrombus.
- Adjacent organs are usually compressed by growing tumor, whereas direct invasion of liver, spleen, colon, pancreas, diaphragm, and duodenum are rare but associated with very poor prognosis.

ASSOCIATED CONDITIONS
- Acquired renal cystic disease in conjunction with ESRD has a 1–2% risk of developing RCC, an overall 5–20-fold increase in risk of RCC for ESRD patients
- VHL-related RCC:
  - Retinal angioma
  - Cerebellar and spinal hemangioblastoma
  - Pancreatic cysts
  - Neuroendocrine tumors
- Facial fibrofolliculomas in the malar region, lung cysts, and spontaneous pneumothoraces are associated with BHD-related RCC
- Familial leiomyomatosis and RCC:
  - Type 2 papillary RCC
  - Cutaneous leiomyomas
  - Uterine leiomyomas
- Birt–Hogg–Dubé syndrome:
  - Chromophobe RCC
  - Oncocytoma
  - Occasional clear cell RCC
  - Cutaneous fibrofolliculomas
  - Lung cysts
  - Spontaneous pneumothorax
- Possibly an increased risk of RCC in individuals with TS

GENERAL PREVENTION
- Smoking cessation
- Physical activity
- Weight loss
- Questionable association with certain foods and alcohol consumption

DIAGNOSIS

HISTORY
- The classic triad of symptoms: Flank pain, palpable flank mass, and hematuria are rarely seen since the advent of CT scanning.
- Associated symptoms are due to local tumor growth, hemorrhage, paraneoplastic syndromes

(hypercalcemia, hypertension, polycythemia, Stauffer's syndrome), or metastatic disease and generally indicate advanced disease.
- Locally invasive RCC causes pain from invasion of posterior abdominal wall, nerve roots, or paraspinous muscles.
- History of pulmonary embolism should increase index of suspicion for venous thrombus in patient with kidney mass.
- Caput medusa
- Early satiety or emesis
- Varicocele, lower-extremity edema
- Lower-extremities edema

PHYSICAL EXAM
- Palpable abdominal mass
- Flank or abdominal tenderness
- Bilateral lower-extremity edema
- Isolated right-sided varicocele, or one that does not decompress
- Caput medusa (dilated abdominal veins)

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- LFTs, creatinine, electrolytes, CBC, and urine analysis are standard initial evaluation, serum calcium
- Elevated ESR is present in 55.6%
- Abnormal liver function tests (LFT's) are found in 14.4%, which is called Stauffer syndrome if elevation is due to paraneoplastic syndrome and not due to liver metastases
  - Stauffer syndrome:
    - Elevated alkaline phosphatase
    - Increased PTT
    - Low albumin, and sometimes elevated bilirubin or transaminases
- Elevated serum calcium is seen in up to 13% overall and in 4.9% as a result of paraneoplastic syndromes
- Polycythemia can be detected in 3.5%
- Elevated C-reactive protein

Imaging
- CT scan with IV contrast if renal function is acceptable.
- MRI is generally considered best for IVC tumor thrombus evaluation, although multiplanar CT with contrast is similar in accuracy.
- Transabdominal US with color Duplex imaging can be used but may not be as accurate in evaluation of the extent of thrombus (85% accuracy).
- Transesophageal echocardiography (TEE) can be helpful pre-op and intraoperatively (1).
- Venacavography is only for those who cannot have an MRI or have an indeterminate MRI.
- Nonfunction of affected kidney may indicate extensive venous thrombus formation.
- Chest CT: Evaluate for pulmonary metastasis.
- CT or MRI of the brain if symptomatic.

Diagnostic Procedures/Surgery

Biopsy or FNA has a role in differentiating RCC from a renal metastasis of another primary and from renal lymphoma; rarely used for routine diagnosis except in cases of percutaneous ablation

Pathologic Findings

- Tumors with histologic necrosis are almost twice as likely to have lymph node metastases as those without necrosis.
- All RCC are adenocarcinomas, arising from renal tubular epithelial cells.
- Clear cell RCC is 70–80%.
- Higher Fuhrman nuclear grading is linked to worse outcome and more aggressive disease.
- Papillary RCC makes up 10–15% and has 2 subtypes:
  - Type 1 associated with HPRCC: Basophilic cells with low-grade nuclei
  - Type 2 very aggressive and associated with HLRCC: Eosinophilic cells with high-grade nuclei
  - Immunohistochemistry (IHC): Low molecular weight cytokeratins (LMWCKs), CK7 (type 1 > type 2), alpha-methylacyl-CoA racemase (AMACR) positive in over 75%
- Chromophobe RCC is 3–5% of solid renal masses and may be less aggressive.
- Collecting duct RCC is rare (<1%) but very lethal.
- Medullary carcinoma associated with sickle cell trait in young African Americans, is often advanced and metastatic at the time of diagnosis; death occurs within a few months of diagnosis.
- Sarcomatoid variants of all subtypes have been described and are associated with a worse prognosis.

DIFFERENTIAL DIAGNOSIS

- Adrenal mass
- Angiomyolipoma (fat poor)
- Collecting duct tumor (Bellini)
- Cystic nephromas (multilocular cystic nephroma)
- Cysts (hemorrhagic, infected)
- Focal pyelonephritis
- Hemangioma
- Inflammatory masses (xanthogranulomatous pyelonephritis, abscess)
- Leiomyoma
- Metanephric adenoma
- Metastasis from other primary tumor
- Oncocytoma
- Renal lymphoma
- Urothelial carcinoma
- Wilms tumor (nephroblastoma)

TREATMENT

GENERAL MEASURES

- Preoperative renal artery embolization may cause the tumor thrombus to regress and reduce the morbidity of surgery as a result.

- Avoid IVC filter placement.

MEDICATION

The role of neoadjuvant targeted therapies (eg, sunitinib, sorafenib, others) for downsizing the primary tumor and the IVC thrombus is controversial: 5–10% reduction in primary site.

SURGERY/OTHER PROCEDURES

- Radical nephrectomy is standard of care.
- Nephron-sparing surgery is possible in selected patients with locally advanced RCC, with equivalent oncologic efficacy to radical nephrectomy (2).
- 45–70% of T3b patients can be cured with aggressive surgery.
- No clear survival benefit of extended lymph node dissection, except in HLRCC patients (3).
- In patients with single lymph node metastasis or micrometastasis, a regional lymphadenectomy may be beneficial.
- Open or minimally invasive surgery is acceptable.

ADDITIONAL TREATMENT

Radiation Therapy

- Role is limited; no survival benefit to preoperative treatment
- May slow growth if residual tumor left after surgery; rarely used
- May palliate symptomatic local recurrences in nonsurgical candidates

Additional Therapies

Targeted agents to growth factors are being evaluated in both an adjuvant and neoadjuvant setting for patients at high risk for recurrence (4).

Complementary & Alternative Therapies

None proven

ONGOING CARE

PROGNOSIS

- T3a: 60–80% 5-yr survival
- T3b/c: 40–60% 5-yr survival
- T4: 0–20% 5-yr survival
- Ipsilateral adrenal involvement has 0–40% 5-yr survival
- Node-positive RCC has 0–20% 5-yr survival
- For T4 tumors, the median time to recurrence is only 9.5 mo

COMPLICATIONS

- Surgical complications are bleeding, infection, injury to surrounding organs (liver, spleen, bowel, pancreas). Urine leak in partial nephrectomy.
- Pulmonary embolism from tumor thrombus
- Advanced tumors can bleed spontaneously either locally causing flank pain or into the urine resulting in hematuria and/or clot-induced urinary obstruction.
- Venous congestion resulting in bilateral lower-extremity edema, varicoceles, or portal HTN from tumor thrombi into the renal, caval, or hepatic vasculature.

FOLLOW-UP

Patient Monitoring

- T3: Every 6 mo for 2 yr then annually for 5 yr: H + P, comprehensive metabolic panel, LDH. Chest and abdomen imaging at 2–6 mo then as indicated.
- T4: Every 3 mo history and physical exam, CXR, labs; every 6 mo abdominal CT for 3 yr

Patient Resources

CODES

ICD9

- 189.0 Malignant neoplasm of kidney, except pelvis
- 198.89 Secondary malignant neoplasm of other specified sites

ICD10

- C64.1 Malignant neoplasm of right kidney, except renal pelvis

- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- C79.89 Secondary malignant neoplasm of other specified sites

CLINICAL/SURGICAL PEARLS

- Detailed evaluation of extent of the disease is critical.
- Consult vascular and/or cardiothoracic surgeon if needed.

RENAL CELL CARCINOMA, METASTATIC (N+, M+)

Jianqing Lin, MD
Wm. Kevin Kelly, DO

BASICS

DESCRIPTION

- Advanced stage of renal cell carcinoma (RCC)
  - N1: Metastasis in regional lymph node(s)
  - M1: Distant metastasis
  - Nodal involvement is now simplified to N0 vs. N1
- Other changes for staging from the *AJCC Cancer Staging Manual* (7th edition):
  - Ipsilateral adrenal involvement is reclassified as T4 if contiguous invasion and M1 if not contiguous
  - Renal vein involvement is reclassified as T3a

EPIDEMIOLOGY

Incidence

- Renal cancer increased by 2% per year for the past 65 yr. Increased by 3.1% per year from 2005–2009 primarily due to an increase in early-stage disease. Renal cancer accounts for 2–3% of all malignancies. Median age of diagnosis is 65 yr, median age of death is 70 yr.
  - 1/3 of patients with RCC present M+/N+
- 40–50% will develop metastatic disease after initial diagnosis. Male > Female (ratio is 3:2).
- Death rates for kidney cancer decreased by 0.5% per year from 2005–2009

Prevalence

N/A

RISK FACTORS

- Smoking
- Obesity
- Hypertension and chronic renal failure
  Chemicals or radiation exposure slightly increases risk.
- Rare hereditary conditions
  - Von Hippel–Lindau (VHL) disease
  - Hereditary papillary RCC

Genetics

- Majority of cases are sporadic
- VHL tumor suppressor gene (on 3p25–26) associated with clear cell RCC
- Chromosome 7q31 is associated with papillary RCC, type 1 associated with mutations in c-MET
- Fumarate hydratase (FH) associated with papillary RCC type 2
- Birt–Hogg–Dubé (BHD) syndrome associated with chromophobic RCC
- Xp11.2 translocation: Patients under 45 yr

- BRCA1-associated protein-1 (BAP1) loss associated with high tumor grade

PATHOPHYSIOLOGY
- RCCs derived from renal tubular epithelium
- Mode of spread is via direct extension, propagation into renal vein, or hematogenous
- Rare reports of spontaneous regressions, usually pulmonary, following nephrectomy

ASSOCIATED CONDITIONS
- VHL syndrome
- Chronic renal failure
- Lymphoma

GENERAL PREVENTION
Smoking cessation helps prevent primary tumor

DIAGNOSIS
HISTORY
- Usually no symptoms in early stage but incidental diagnosis of kidney mass. Metastasis may or may not cause symptoms.
- Gross hematuria
- Flank or abdominal pain
- Symptoms related to involved organ(s)
- Constitutional symptoms:
  - Fatigue, weight loss, fever, or lower-extremity edema

PHYSICAL EXAM
- With attention to abdominal mass, adenopathy, lower-extremity edema
- Varicocele (classically on left)

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CBC: Anemia of chronic disease in up to 30%
- Urinalysis: Hematuria
- Complete metabolic panel
- Paraneoplastic syndromes (found in 20% of patients):
  - Hypercalcemia
  - Hypertension
  - Erythrocytosis
  - Elevated erythrocyte sedimentation rate (ESR)
  - Nonmetastatic hepatic dysfunction (Stauffer syndrome)
- Urine cytology: R/O urothelial carcinoma

Imaging
- MRI or CT of abdomen and pelvis (~85% of enhancing renal masses are RCC)
  - Most enlarged lymph nodes by imaging are inflammatory rather than neoplastic
- CNS imaging: In patients with symptoms or radiographic evidence of advanced disease
- Positron emission tomography (PET) has poor sensitivity and not commonly used

Diagnostic Procedures/Surgery

- Needle biopsy to the metastatic site or metastasectomy usually required to establish diagnosis
- Needle biopsy is generally safe and warranted if any uncertainty for M1 disease

Pathologic Findings

- Histologic subtypes:
  - Clear cell: 70–80%
  - Papillary: 10–15%
  - Chromophobe: 3–5%
  - Collecting duct/medullary cancer $<1\%$
  - Translocation Xp11.2: Clear and/or eosinophilic, voluminous cytoplasm
- Sarcomatoid variants all histologic subtypes:
  - Represent poorly differentiated regions
  - Portends a much more aggressive biology with recurrence/resistance to therapy

DIFFERENTIAL DIAGNOSIS

- Renal masses:
  - Angiomyolipoma (fat-poor)
  - Collecting-duct tumors
  - Cystic nephromas
  - Cysts (hemorrhagic, infected)
  - Focal pyelonephritis
  - Hemangioma
  - Inflammatory masses (xanthogranulomatous pyelonephritis, abscess)
  - Leiomyoma
  - Metanephric adenoma
  - Metastasis from other primary tumor
  - Oncocytoma
  - Pseudotumors (column of Bertin, others)
  - RCC
  - Renal lymphoma
  - Renal medullary carcinoma
  - Sarcomas
  - Reninoma (Juxtaglomerular tumors)
  - Urothelial carcinoma
  - Wilms tumor (nephroblastoma)
- Lymphadenopathy:
  - Inflammatory related to RCC
  - RCC
  - Infectious/inflammatory:
    - Granulomatous: TB, sarcoidosis, histoplasmosis, lymphogranuloma venereum, Castleman disease, etc.
    - Nongranulomatous: Viral, bacterial (if abscess in local areas), sinus histiocytosis
  - Primary lymphatic malignancy: Lymphoma (non-Hodgkin and Hodgkin, others)
  - Other metastatic malignancies:

- Gastrointestinal (GI) (carcinoid, colorectal, lymphoma), urothelial, prostate, melanoma, penile, germ cell, cervical, ovarian, uterine
- Pulmonary nodules:
  - Benign hamartoma/AVM, nonspecific granuloma, infectious granuloma (aspergillosis, coccidioidomycosis, cryptococcosis, histoplasmosis, tuberculosis, atypical mycobacterial infections), septic emboli, abscesses
  - Malignancy: Lung primary, metastasis (choriocarcinoma, RCC, melanoma, thyroid carcinoma, Kaposi's sarcoma), non-Hodgkin lymphoma

TREATMENT

GENERAL MEASURES

- Stage IV disease may also benefit from cytoreductive surgery
- Minimal regional adenopathy does not preclude surgery
- Potential candidate for nephrectomy and/or surgical metastasectomy:
  - Resectable primary RCC and a solitary resectable metastasis
  - A solitary recurrence after prolonged disease-free interval from nephrectomy
- Tends to be resistant to both traditional chemotherapy and radiation therapy
- Antiangiogenesis via targeting vascular endothelial growth factor (VEGF) pathway is the mainstay of treatment; improve survival for M1
- Multityrosine kinase inhibitors (TKI) or mTOR inhibitors or monoclonal antibody
- Data for nonclear cell RCC therapy limited
- Sarcomatoid RCC: Gemcitabine- or capecitabine- or floxuridine- or 5-FU- or doxorubicin-based chemotherapy (category 3 and limited data)
- Other immunotherapy is under development

MEDICATION

First Line

- High-dose (bolus) interleukin-2 (IL-2) (Aldesleukin, Proleukin) (1)
  - IL-2: Only agent shown to produce durable and complete responses (CR) in 6–8% of patients; Partial response 10–15%
  - 1st line. Selected patients: Mostly clear cell, <65 yr old, good cardiac, pulmonary, liver and renal function, no brain mets
  - Typical regimen 600,000–720,000 IU/kg IV Q8h for 5 days. One course as 2 cycles on days 1–5 and 15–19 of 28-day cycle. If no progression, repeat approximately every 3 mo to a max of 3 courses.
  - Systemic inflammatory response syndrome (SIRS), "capillary leak syndrome" side effects
  - "Treat as tolerated" significantly reduces treatment-related mortality
- Sunitinib: Targets VEGF receptor tyrosine kinase and other pathways (2)
  - 1st line
  - 50 mg/d PO for 4 wk of 6-wk cycle (4 wk on, 2 wk off)
- Pazopanib: Targets VEGF receptors and other pathways
  - 1st line or postcytokine: 800 mg PO daily
- Bevacizumab: VEGF antibody
  - 1st line with interferon-α 10 mg/kg IV Q2wk

- Interferon-α: Stimulates immune function
  - 1st line, only combination with bevacizumab
  - SubQ a start of 9 MU on 3 nonconsecutive days per week, with dose reduction to 6 MU and to 3 MU if toxicity
- Temsirolimus: mTOR inhibitor (3)
  - 1st line for poor-risk patients or nonclear cell histology: 25 mg IV weekly
- Sorafenib: Targets VEGF receptor and other pathways: 1st or 2nd line: 400 mg PO BID (4)

Second Line

- Agents as noted above after failure of 1st targeted therapy
- Axitinib: Potent, selective, 2nd-generation inhibitor of VEGFR 1, 2, and 3 (5):
  - 2nd line: 5 mg PO BID,10 mg PO BID max
- Everolimus: mTOR inhibitor
  - 2nd line: 10 mg PO daily

SURGERY/OTHER PROCEDURES

- Cytoreductive nephrectomy in patients with metastatic disease is generally considered standard of care (6):
  - SWOG 8949: Improved overall survival for debulking nephrectomy in interferon-treated patients with advanced RCC. However, no similar data is available in TKI era.
- Strongly consider metastasectomy for amendable and isolated solitary metastasis (synchronous or metachronous)
  - Lymphadenectomy should be performed in radiographically suspicious cases; however, ultimate role and benefit is yet to be defined.

ADDITIONAL TREATMENT

Radiation Therapy

Palliative role for osseous or CNS metastasis or pain control

Additional Therapies

- Many other agents under study and reported:
  - Nonmyeloablative allogeneic hematopoietic cell transplantation
  - Interferon-γ, vaccines, other interleukins alone and in combination
- Multiple studies under way addressing sequencing and combination of targeted therapies along with immunotherapy

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- 5-yr survival: Improving (7)
  - Stage III: 15–35%
  - Stage IV: 0–10%
  - Enhanced survival with the following characteristics: Long interval between nephrectomy and the appearance of distant metastases, a single metastatic site, and the absence of retroperitoneal adenopathy

COMPLICATIONS

- Related to treatment
  - High-dose IL-2: Vascular leak syndrome
  - TKIs: Fatigue, HTN, hand and foot syndrome, GI toxicity, hypothyroidism
  - mTOR inhibitors: Fatigue, rash, hyperglycemia, dyslipidemia
- Others related to disease progression

FOLLOW-UP

Patient Monitoring

- Depends on stage of disease and treatment
  - Usually chest and abdominal imaging every 3–6 mo if not being treated
  - Imaging every 3–4 cycles if underactive systemic treatment
  - Serum chemistries and liver function tests as routine

Patient Resources

- Kidney Cancer Association www.kidneycancer.org
- National Cancer Institute, Kidney Cancer www.cancer.gov/cancertopics/types/kidney

CODES

ICD9

- 189.0 Malignant neoplasm of kidney, except pelvis
- 196.2 Secondary and unspecified malignant neoplasm of intra-abdominal lymph nodes

ICD10

- C64.1 Malignant neoplasm of right kidney, except renal pelvis
- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- C77.2 Secondary and unsp malignant neoplasm of intra-abd nodes

CLINICAL/SURGICAL PEARLS

- Cytoreductive surgery should be considered for M1 disease.
- Only high-dose IL-2 provide durable complete response (CR).
- No targeted agents show significant complete response (CR).
- Patients achieving response with targeted agents such as TKI have a response duration of ~8–10 mo (medium <12 mo) with continuous therapy treatment.
- Combination therapies are being explored.

RENAL CELL CARCINOMA, PEDIATRIC

Sarah M. Lambert, MD
Pasquale Casale, MD, FACS

BASICS

DESCRIPTION
Renal cell carcinoma (RCC) is a very rare tumor in childhood arising from the renal tubular epithelium

EPIDEMIOLOGY
Incidence
- 2–6% of all pediatric renal tumors
- Only ~4 cases of pediatric RCC per year
- Estimated at <0.3% of all pediatric tumors
- Just over 350 cases reported in the literature
- Mean age of presentation between 8 and 10 yr vs. <3 yr for Wilms tumor
- Equal male:female

Prevalence
N/A

RISK FACTORS
- Von Hippel–Lindau syndrome
- Tuberous sclerosis

Genetics
- Translocation type of RCC, which forms a distinct category has recently emerged as the predominant type of RCC in children and adolescents, whereas it is rarely diagnosed in adults.
- Chromosomal translocations in Xp11.3 region involving TFE3 gene (1).
- Less frequently, 6p21 translocation.
- If seen with Von Hippel–Lindau, more likely to be bilateral.

PATHOPHYSIOLOGY
- Thought to arise from renal tubular epithelium
- Most frequently papillary subtype with Xp11 translocation
  – Role of translocation at Xp11.2 region involving TFE3 gene unknown (1)
- Lung and bone are the most common distant metastases.

ASSOCIATED CONDITIONS
- Tuberous sclerosis, chronic renal failure, neuroblastoma, and teratoma with chemotherapy
- Rarely associated with adult familial RCC

GENERAL PREVENTION
N/A

DIAGNOSIS

HISTORY

- Gross hematuria (~40%), flank pain, abdominal distension (2)
- Nausea, vomiting, malaise common
- Pain in up to 50%
- 30% found incidentally (2)

PHYSICAL EXAM

- Palpable abdominal mass (~40%) (2)
- Triad of hematuria, flank pain, and palpable mass found in <6% of children (3)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis: Hematuria found in >40% of patients (3)
- CBC: Polycythemia is rare
- Liver and renal function tests: Baseline prior to treatment

Imaging

- Abdominal x-ray may show tumor calcifications (~25%) vs. Wilms tumor (~5%) (3)
- US demonstrates solid or cystic renal mass.
- CT or MRI with and without contrast reveal enhancing renal mass.
- Pediatric RCCs typically present as large, heterogeneous masses, commonly hemorrhage and contain internal calcifications.
- IVP can demonstrate renal mass by displacement of the collecting system.
- Chest x-ray or chest CT scan for workup of metastatic disease.
- Radionuclide bone scan is indicated based on concern for mets.

Diagnostic Procedures/Surgery

Biopsy is not indicated

Pathologic Findings

- Predominately papillary histologic features in children vs. clear cell features in adults
- Pathologic staging based on modified Robson staging system
- Up to 25% pediatric RCC cannot be clearly classified due to atypical features
- Pathologic parameters typically associated with poor outcome in adults (metastasis/high tumor stage, high Fuhrman nuclear grade, angiolymphatic invasion, tumor necrosis), do not appear to have similar implications in pediatric patients

DIFFERENTIAL DIAGNOSIS

- Benign renal mass in children:
  - Choledochal cyst, intestinal duplication cyst
  - Congenital mesoblastic nephroma
  - Hydronephrosis
  - Mesenteric cyst
  - Multicystic dysplastic kidney
  - Polycystic kidney
  - Renal abscess
  - Splenomegaly

- Malignant renal masses in children:
  - Hepatoblastoma
  - Lymphoma
  - Lymphosarcoma
  - Neuroblastoma
  - RCC
  - Rhabdomyosarcoma
  - Wilms tumor

TREATMENT

GENERAL MEASURES

Management is primarily surgical excision by either radical nephrectomy or partial nephrectomy

MEDICATION

First Line

- The use of chemotherapy, immunotherapy, or tyrosine kinase inhibitors is not adequately described in pediatric population.
- The use of tyrosine kinase inhibitors should be considered in the pediatric patient with unresectable, metastatic, or advanced-stage RCC.
- Small series of patients treated with neoadjuvant chemotherapy according to Wilms tumor protocol.

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Radical nephrectomy (4)
  - Removal of entire kidney and portion of the ureter
  - Common approaches in children include flank and abdominal incisions
- Partial nephrectomy (5)
- Laparoscopic and robotic-assisted radical or partial nephrectomy for RCC in children are described in select cases (6,7)

ADDITIONAL TREATMENT

Radiation Therapy

Has been used for both initial treatment and recurrence but not well studied in pediatric populations

Additional Therapies

- Adjuvant chemotherapy for metastatic disease has been tried in the pediatric population but not well characterized.
- Tyrosine inhibitors have been used in children with metastatic disease but data are limited (9).

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Overall survival similar to adult RCC and depends on (Robson) stage:
  - Rest prognosis stage with stage I (>90%) and II (>80%)
  - Stage III ~75%, stage IV ~15% (2)

COMPLICATIONS

- Surgical complications (bleeding, infection, diathesis, bowel injury)
- Metastasis to lung and bone, multiple other sites

FOLLOW-UP

Patient Monitoring

- Adult protocols followed as there are no pediatric protocols
- No long-term follow-up guidelines:
  - Physical exam, chest x-ray, chemistry panel, CBC, and urinalysis every 6 mo for 5 yr
  - CT on yearly basis for 5 yr
- Risk of chronic kidney disease likely attributed to reduced renal reserve capacity should be recognized and treated with nephrologic evaluation (8)

CODES

ICD9

- 189.0 Malignant neoplasm of kidney, except pelvis
- 197.0 Secondary malignant neoplasm of lung
- 198.5 Secondary malignant neoplasm of bone and bone marrow

ICD10

- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- C78.00 Secondary malignant neoplasm of unspecified lung
- C79.51 Secondary malignant neoplasm of bone

CLINICAL/SURGICAL PEARLS

The most common subtypes of RCC in children are the translocation-associated tumors, papillary RCC, renal medullary carcinoma, and oncocytic RCC.

RENAL COLIC

Scott G. Hubosky, MD

BASICS

DESCRIPTION

- Renal colic is a constellation of symptoms that usually accompanies upper urinary tract obstruction (1)[C]
  - Pain
    - Involves the flank and/or groin, with radiation to the ipsilateral scrotum or labia majora
    - Pain character is colicky with patients demonstrating a restless nature, unable to stay still
    - Pain is abrupt in onset and not associated with physical activity or positions
  - Nausea/vomiting
    - Simultaneously presents with flank pain but not in all cases
  - Irritative or obstructive voiding complaints which are not present at baseline
    - Urinary frequency, feeling of incomplete emptying, hesitancy
  - Hematuria
    - Gross or microscopic
    - Presence of hematuria strongly suggests underlying urologic etiology over gastrointestinal origin

EPIDEMIOLOGY

Incidence

Renal colic accounts for about 1% of all emergency department visits (2,3)[C] representing over 1 million cases per year

Prevalence

- Renal colic caused by nephrolithiasis has an estimated prevalence of 6.3% in men and 4.1% in women over a study period of 1988–1994 (4)[C]
  - Prevalence seems to be increasing compared to past estimates

RISK FACTORS

- History of nephrolithiasis
- Recent urologic surgery
- History of ureteral stricture
  - Pelvic radiation history

Genetics

N/A

PATHOPHYSIOLOGY

- Presence of obstruction anywhere along the course of the ureter results in stretching of involuntary smooth muscle lining the ureter and renal pelvis
- This stretching of the ureteral smooth muscle is exacerbated by baseline ureteral peristalsis
- Stretching of hollow viscera, such as the ureter/renal pelvis, is a well-known stimulus for

pain as transmitted by the autonomic nervous system (1)[C]
- The kidneys, proximal ureters, and stomach are all served by the celiac ganglion thus explaining why nausea and vomiting frequently accompany renal colic

ASSOCIATED CONDITIONS
- Any process causing obstruction of the upper urinary tract
  - Ureteral stone
  - Ureteral stricture
  - Upper tract urothelial neoplasm
  - Extrinsic ureteral obstruction
  - Iatrogenic ureteral injury
    - Ureteral ligation during hysterectomy or colectomy
- Upper urinary tract infection
  - Pyelonephritis
  - Renal abscess
- Recent urologic surgery
  - Obstructing blood clots from upper tract
  - Ureteral stent in poor position
  - Presence of poorly draining percutaneous nephrostomy tube
  - Residual ureteral stone fragments after lithotripsy
- Miscellaneous
  - Renal artery embolus/infarction
  - Renal vein thrombosis

GENERAL PREVENTION
- Empiric advice for nephrolithiasis prevention
  - Adequate hydration
    - Enough fluid consumption to generate 2.5 L of urine output per day
  - Low-sodium diet
    - Daily sodium intake should be $<$2,500 mg
    - Diets high in sodium result in hypercalciuria
    - About 82% of renal stones produced have calcium as a constituent
  - Normal calcium diet
    - Daily calcium intake should range between 800 and 1,200 mg
    - Vitamins, supplements, and antacids should be considered

DIAGNOSIS

HISTORY
- Sudden onset of colicky flank pain
  - May be associated with simultaneous nausea or vomiting
  - May have associated gross or microhematuria
  - May have radiation to ipsilateral groin or scrotum/labia majora
  - Pain is colicky and intermittent
- The location and characteristics of renal colic pain relating to urolithiasis (5):
  - Stones obstructing UPJ: Mild to severe deep flank pain without radiation to the groin;

irritative voiding symptoms (eg, frequency, dysuria); suprapubic pain, urinary frequency/urgency, dysuria, stranguria, bowel symptoms
  - Stones within ureter: Abrupt, severe, colicky pain in the flank and ipsilateral lower abdomen; radiation to testicles or vulvar area; intense nausea with or without vomiting
  - Upper ureteral stones: Radiate to flank or lumbar areas
  - Midureteral calculi: Radiate anteriorly and caudally
  - Distal ureteral stones: Radiate into groin or testicle (men) or labia majora (women)
  - An objective clinical prediction rule for uncomplicated ureteral stones that uses 5 patient factors—sex, timing, origin (ie, race), nausea, and erythrocytes(STONE)—to create a score between 0 and 13 (the STONE score). With a high STONE score, patients are likely to have a kidney stone.

PHYSICAL EXAM

- General appearance is that of a restless patient unable to be still
- Usually unilateral flank pain with radiation to ipsilateral lower quadrant

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum creatinine/BUN and electrolytes
- Complete blood count
- Urinalysis
  - Look for signs of blood or infection
- Urine culture

Imaging

- CT scan of abdomen and pelvis without any contrast
  - Most sensitive way to detect urinary tract calculi (99% sensitivity to detect ureteral stones)
  - Relatively expensive and subjects patients to radiation exposure
    - Low-dose radiation stone protocol still gives 95% sensitivity for ureteral stone detection with 60% less radiation exposure
- CT urogram
  - CT scan of abdomen/pelvis with IV contrast which is useful to expand diagnostic capability when no ureteral stones are found
    - Can diagnose causes of colic not caused by stones such as UPJ obstructions or intraluminal filling defects such as neoplasms, fungus balls, or blood clots
- Renal/bladder ultrasound
  - No radiation exposure/safe in pregnancy and in pediatric patients
  - Ask for Doppler assessment of ureteral jets
    - Presence of ureteral jets rules out complete ureteral obstruction (although partial obstruction may exist)
    - Absence of ureteral jet may indicate obstruction or dehydration
  - Relies on indirect evidence to diagnosis obstruction
    - Hydronephrosis
    - Presence or absence of ureteral jets
  - Not very sensitive for detecting small ureteral stones

- KUB x-ray
  - May detect calcification along the expected course of the ureter
  - Not very sensitive or specific
  - Benefits are low-radiation dose and is inexpensive

Diagnostic Procedures/Surgery
- Relief of obstruction may be necessary
  - Ureteral stent placement
  - Percutaneous nephrostomy
- Culture-specific antibiotics
  - If infection is present
- Definitive surgical procedure as dictated by underlying condition

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Ureteral calculus
- Ureteral stricture
- UPJ obstruction
- Upper tract urothelial neoplasm
  - Upper tract urothelial carcinoma
  - Fibroepithelial polyps
- Iatrogenic ureteral obstruction
  - Ureteral ligation after hysterectomy or colon resection
  - Obstructing residual stone fragments after lithotripsy
  - Obstructing blood clots following upper tract urologic procedure
- Upper urinary tract infection
  - Pyelonephritis
  - Pyonephrosis
  - Renal abscess
  - Obstructing fungus ball
- Renal vascular etiology
  - Renal artery embolus/renal infarction
  - Renal vein thrombosis

TREATMENT

GENERAL MEASURES
- Rule out sepsis
- Treat infection
- Control pain
- Alleviate obstruction, if present

MEDICATION
First Line
- Analgesia based on degree of discomfort

  - Narcotic analgesics for more severe pain
    - Given PO or IV
    - Morphine sulfate, oxycodone/APAP, hydrocodone/APAP, meperidine, nalbuphine
  - Ketorolac
  - IV acetaminophen
    - Less dizziness and hypotension than morphine in one study
- Antiemetics (metoclopramide, ondansetron)

Second Line
- α-blockers: Tamsulosin, alfuzosin, silodosin
  - Given to relieve ureteral smooth muscle spasm patients with ureteral stones
  - Off-label use in cases of urolithiasis
    - Alfuzosin (10 mg/d)
    - Silodosin (8 mg/d)
    - Tamsulosin (start 0.4 mg to max 0.8 mg); most reported data

SURGERY/OTHER PROCEDURES
- Initial stent placement for significant obstruction
- Lithotripsy for nephrolithiasis
  - Ureteroscopy with laser lithotripsy
  - ESWL (extracorporeal shock wave lithotripsy)
  - PCNL (Percutaneous nephrolithotomy)
- Ureteral stricture treatment
  - Balloon dilation, laser incision
  - Open or laparoscopic reconstruction
- UPJ obstruction
  - Pyeloplasty (open, laparoscopic, robotic)
  - Endopyelotomy (retrograde, antegrade)
- Upper tract neoplasm
  - Ureteroscopic ablation
  - Nephroureterectomy (open or laparoscopic)

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
- Obtain adequate drainage if necessary, especially if the patient appears septic
  - Ureteral stenting is usually a good 1st choice
    - Chronically obstructed patients often have significant ureteral tortuosity making retrograde access challenging
  - Percutaneous drainage
    - Can be performed with conscious sedation
    - Optimal in cases of significant extrinsic ureteral compression

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS

Depends on underlying etiology but usually good once obstruction is relieved and infection treated, if present

COMPLICATIONS

- Persistent obstruction if left untreated
  - Renal cortical loss
    - Could lead to nonfunctioning kidney
  - Serious infection

FOLLOW-UP

Patient Monitoring

Renal/bladder ultrasound after treatment to ensure no evidence of silent hydronephrosis or recurrent obstruction

Patient Resources

Urology Care Foundation http://www.urologyhealth.org/urology/index.cfm?article=148

CODES

ICD9

- 599.69 Urinary obstruction, not elsewhere classified
- 787.01 Nausea with vomiting
- 788.0 Renal colic

ICD10

- N13.8 Other obstructive and reflux uropathy
- N23 Unspecified renal colic
- R11.2 Nausea with vomiting, unspecified

CLINICAL/SURGICAL PEARLS

- Vast majority of patients with renal colic will have calculi.
- Young patients with hydronephrosis and no evidence of calculus likely have congenital UPJ obstruction or other upper tract narrowing.
- Support patient with medicines to alleviate the acute pain of renal colic.
- Treat infection if present.

RENAL CYSTS (INTRARENAL, PERIPELVIC, AND PARAPELVIC)

Jeffrey J. Tomaszewski, MD
Robert G. Uzzo, MD

BASICS

DESCRIPTION

- Renal cycts are fluid-filled renal structures not continuous with the nephron or collecting system
- Simple cyst
  - Arise from the renal parenchyma
  - Size varies, often <2 cm but may be significantly larger
  - Typically asymptomatic incidentally detected on CT or US
  - Can be single, multiple, and/or bilateral
  - If large, may impinge on the renal pelvis causing obstruction
  - Diagnostic US findings include a mass that is free of internal echos (anechoic), through transmission with posterior acoustic enhancement
- Complex cyst
  - Features not consistent with simple cyst; raise the possibility of malignancy
    - Increased fluid density, internal thick-walled septations, thickened wall, nodular projections into the lumen, calcifications, and contrast enhancement
- Pyogenic cysts are infected cysts
- Parapelvic cyst (aka peripelvic, parapelvic lymphatic, parapelvic lymphangiectasia, and renal sinus cysts); arise from the renal sinus

ALERT
Parapelvic cysts may be confused with hydronephrosis given their central location.

- Acquired cyst
  - Associated with chronic hemodialysis
  - Occasionally regress spontaneously
- Bosniak classification used to classify cysts based on CT complexity and likelihood of malignancy

EPIDEMIOLOGY

Incidence

- 0.22% from birth to 18 yr
- 20% by age 40
- 33% by age 60
- In autopsy series, 50% of patients >50 have ≥ 1 simple renal cysts
- Acquired cystic renal disease is more common among men
- Bilateral simple cysts infrequent <50 yr

Prevalence

N/A

RISK FACTORS

- Age, a known risk factor for simple renal cysts
- Increasing age (7-fold increase from 4th–8th decade or an increased incidence from 5–36%)
- Polycystic kidney disease (autosomal dominant and recessive types)
- Hemodialysis
  - In ESRD, cysts in 8–13% prior to hemodialysis (HD)
  - 10–20% have acquired cystic renal disease after 3 yr of dialysis, 40–60% after 5 yr, and >90% after 10 yr

Genetics

- ARPKD: PKHD1 gene, chromosome 6, protein product fibrocystin
- ADPKD: PKD1 & PKD2 genes, chromosome 16, protein products polycystin-1,-2

Other genetic cystic diseases: Juvenile nephronoph-thisis, medullary cystic kidney disease, glomerulo-cystic kidney disease, Von Hippel–Lindau syndrome (VHL), tuberous sclerosis, Birt–Hogg–Dubé syndrome

PATHOPHYSIOLOGY

- Simple cysts
  - Development of discrete fibrous saccules of clear fluid lined with cuboidal epithelium
  - Estimated growth rate: 2.18 mm/yr
  - Some will involute and disappear over time although most will not
  - It is controversial if renal cysts are causative agents of HTN
- Parapelvic cysts
  - Found on <2% of kidneys at autopsy
  - Can be confused with hydronephrosis

ASSOCIATED CONDITIONS

- ADPKD (Autosomal dominant polycystic kidney disease)
- ARPKD (Autosomal recessive polycystic kidney disease)
- Birt–Hogg–Dubé syndrome
- ESRD (end stage renal disease)
- Tuberous sclerosis
  - 50% have multiple renal angiomyolipomas
  - 20–25% of have renal cysts
- VHL disease
  - Individuals develop cysts in multiple organs (kidney, pancreas, liver, epididymis)
  - Increased risk of clear cell renal cell carcinoma (RCC) in cyst wall

GENERAL PREVENTION

Family members of patients with ADPKD and VHL should be screened

DIAGNOSIS

HISTORY

- Patients may present with an abdominal mass, pain, hematuria, or HTN but most are radiographically incidental
- Family member with polycystic kidney disease or other inherited cystic disease

PHYSICAL EXAM

- Abdominal/flank mass (rare)
- Often a benign exam

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis most often normal unless concurrent medical renal disease present
- Renal function tests—calculate eGFR and stage chronic kidney disease (CKD)

Imaging

- Ultrasound
  - Simple cyst
    - No internal echoes, distinct walls with defined margins, spherical shape with no internal echoes

ALERT
Complex renal cysts including hyperdense cysts may mimic solid renal masses. Doppler US is helpful.

- CT
  - Simple cysts
    - Have sharp walls with smooth margins, spherical shape, homogenous throughout (Hounsfield units (HU) ranging from −10 to +20); no enhancement with IV contrast
    - CT diagnosis of a simple cyst is almost 100% if study performed properly (bi- or triphasic)
    - Enhancement is defined as an increase in HU by at least 15–20
    - If cyst does not meet criteria for being simple, further workup of the lesion is necessary
  - Parapelvic cyst
    - Appears on US as a medially located cystic mass with surrounding echogenic walls (located within the fatty renal sinus)
    - On US or even CT can be confused with hydronephrosis. An excretory phase CT is most helpful in distinguishing a parapelvic cyst from a simple parcehncymal renal cyst.
- MRI:
  - Bosniak criteria can be applied to MRI (exception: Calcifications may not be well seen)
  - Low signal T1, high signal T2 is consistent with benign simple cyst
  - Hyperdense cysts can be high signal on T1 and low on T2 but appearance depends on hemoglobin breakdown
  - MRI may have a role in a subset of patients (VHL, multiple renal masses) if concern exists regarding excessive radiation due to multiple long-term imaging studies
  - May be superior in characterization of internal cyst contents (blood, mucin)
- Bi- or triphasic CT represents the gold standard for distinguishing renal cysts:
  - Discriminate between cysts and collecting system on excretory phase
  - Particularly important in assessing hydronephrotic systems
    - US may be misleading/difficult to interpret
- Bosniak classification system of cystic renal masses originally based on CT (image) (1):
  - Category I: Benign simple cysts; thin wall without septa, calcifications, or solid components, water density, and no contrast enhancement; No further imaging needed

    - Nearly all are benign
  - Category II: Benign cysts with a few thin septae; the wall or septa may contain fine calcification, sharp margins, nonenhancing
  - Category IIF: Well marginated and may have thin septae or minimal smooth thickening of the septa or wall, which may contain calcification that may also be thick and nodular; no contrast enhancement; includes totally intrarenal nonenhancing complex lesions >3 cm
    - These require follow-up (designated by the F designation)
    - 5–20% of Bosniak II/IIF cysts contain malignancy in wall
  - Category III: Indeterminate cysts with thickened irregular or smooth walls or septae; enhancement present
    - 40–60% of these are malignant (cystic RCC and multiloculated cystic RCC)
    - Other class III lesions are benign (infected cysts and multiloculated cystic nephroma)
  - Category IV: Characteristics of category III cysts plus they contain contrast-enhancing soft tissue components that are adjacent to and independent of the wall or septum
    - Risk of malignancy is 85–100%

Diagnostic Procedures/Surgery

- Cyst aspiration is rarely curative as fluid reaccumulates. Infected cysts may require aspiration and catheter placement.
  - Infected cysts often represent calyceal diverticula
- Cyst biopsy is difficult and frequently results in indeterminate pathology
- Cytologic evaluation of fluid for malignancy or culture based on the indication and characteristics of the cyst

Pathologic Findings

- Simple renal cyst
  - Single layer of cuboidal epithelium
- Not continuous with the collecting system

DIFFERENTIAL DIAGNOSIS (2)

- ADPKD (Autosomal dominant polycystic kidney disease)
- ARPKD (Autosomal recessive polycystic kidney disease)
- Calyceal diverticulum (evaluate for connection to the collecting system)
- Cystic degeneration (necrosis) of RCC
- Cystic malignancy (cystic RCC; sometimes called papillary cystadenocarcinoma)
- Hydronephrosis (parapelvic cysts)
- Juvenile nephronophthisis
- Medullary sponge kidney
- Multicystic dysplastic kidney
- Renal abscess
- Urinoma
- Pararenal (retroperitoneal or adjacent mesenteric/liver/splenic/adrenal cyst)
- Xanthogranulomatous pyelonephritis

TREATMENT

GENERAL MEASURES

- The major issue with renal cysts is differentiating a simple cyst from more serious diseases: Malignancy (RCC), polycystic kidney disease, complex cysts, and solid masses (such as a renal carcinoma or abscess)
- Risk of RCC with Bosniak III and IV lesions
- Bosniak I (benign cyst)
  - No action necessary
- Bosniak II (septae and/or wall calcifications)
  - Some clinicians consider 1 follow-up study (US) to confirm stability or if unable to differentiate from IIF cyst
- Bosniak IIF (increased, thicker walls and calcifications compared to type I)
  - Require follow-up studies for 2–3 yr
- Bosniak III (irregular thick walls with calcification)
  - Excision vs. alternative diagnostic evaluation (needle biopsy, MRI). May be observed in elderly and infirmed.
- Bosniak IV (enhancement with contrast, malignancy likely); surgical management

MEDICATION

First Line

Specific to those cystic diseases noted that cause HTN or renal insufficiency

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Radical or partial nephrectomy for complex or suspicious cysts
- Cyst decortication with marsupialization should be reserved for very select cases
  - Laparoscopic, open, and percutaneous approaches

ADDITIONAL TREATMENT

Additional Therapies

- Cyst aspiration and sclerotherapy (3)
  - Rarely employed for large simple symptomatic renal cysts
  - Pain often does not resolve with surgical management of renal cysts
  - Not for parapelvic/peripelvic cysts
  - Many consider this approach as primary therapy for large symptomatic cysts before surgical management; others support laparoscopic management initially
  - Simple aspiration rarely leads to resolution; reaccumulation common
  - Negative cyst fluid cytology required
  - Sclerosing agents increase success but associated with pain and infection
  - Multiple sessions are usually required, and use of indwelling percutaneous catheter may increase success rates
  - Sclerosing agents: Ethanol, bismuth phosphate, n-butyl cyanoacrylate, povidone-iodine, and tetracycline; No agent superior

ONGOING CARE

PROGNOSIS

- Up to 15% of ADPKD will require hemodialysis
- Benign simple cysts demonstrate little risk of progressing to malignancy
- Bosniak classification and risk of malignancy
  - Bosniak I: No risk
  - Bosniak II/IIF: 5–20% risk depending on imaging characteristics
  - Bosniak III: 50% risk
  - Bosniak IV: 75–90% risk

COMPLICATIONS

- Rupture and hemorrhage with simple renal cyst; usually associated with flank pain and hematuria
- Infected renal cyst
- ADPKD

ALERT

- Associated with cerebral berry aneurysms.
  - In up to 40% of patients.
  - 9% mortality (subarachnoid hemorrhage).

FOLLOW-UP

Patient Monitoring

- Follow-up imaging of Bosniak type IIF cysts
- Multicystic dysplastic kidney/VHL
  - Periodic sonography to monitor for neoplastic changes
- Acquired renal cystic disease
  - Periodic imaging (US) on dialysis

Patient Resources

http://kidney.niddk.nih.gov/kudiseases/pubs/cysts/

RENAL DYSPLASIA, HYPODYSPLASIA, AND HYPOPLASIA

Kymora Scotland, MD, PhD
T. Ernesto Figueroa, MD, FAAP, FACS

BASICS

DESCRIPTION

- Renal dysplasia, hypoplasia, and hypodysplasia are forms of renal dysgenesis; namely, maldevelopment of kidney size, shape, or structure
- Renal dysplasia: Chiefly a histologic diagnosis based on the presence of primitive renal components (ie, ducts) and embryonic mesenchymal cells (ie, cartilage):
  - Classification of renal dysplasia:
    - Total dysplasia: Involves both cortex and medulla; spectrum ranging from aplastic (small and solid) to multicystic (enlarged) kidneys (eg, Multicystic dysplastic kidney [MCDK])
    - Subtotal dysplasia: Segmental distribution in cortex and medulla
    - Hereditary: Zellweger and Meckel syndromes
- Renal hypoplasia: Small kidneys that have a normal nephron density with less than normal number of calyces and nephrons and are not dysplastic (1):
  - Classification:
    - With urethral obstruction
    - Prune-belly syndrome
    - True oligonephronia
    - With normal ureteral orifice
    - With abnormal ureteral orifice
    - Oligomeganephronia
    - Segmental (Ask-Upmark kidney)
- Renal hypodysplasia: Small kidneys that have normal nephron density with less than normal number of calyces and nephrons and are dysplastic:
  - Classification:
    - Normal ureteral orifice: With and without obstruction
    - Ectopic ureteral orifice with or without ureterocele: Lateral, medial, or caudal
    - With urethral obstruction
    - Prune-belly syndrome
- Renal development is dependent on the interaction between the ureteric bud and the metanephric mesenchyme

EPIDEMIOLOGY

Incidence

N/A

Prevalence

- Renal dysplasia:
  - Unilateral or bilateral in 2–4 per 1,000 births
  - Male > Female (1.3:1)

  - Male > Female (1.9:1)
- Renal hypoplasia
  - Oligomeganephronia:
    - Male > Female (3:1)
    - Increased with low birth weight, often present by age 2
  - Ask-Upmark kidney:
    - Male < Female (1:2)
    - Commonly present ≤10 yr of age

RISK FACTORS

- Vesicoureteral reflux (VUR)
- Posterior urethral valves
- Ureteral abnormalities: Primary megaureter, Ureteropelvic junction obstruction (UPJO), ureterocele
- Prune-belly syndrome

Genetics

- A majority of dysplastic and hypoplastic kidney disorders are sporadic and nonheritable
- Genetic pathways can affect ureteric bud formation, branching morphogenesis within the metanephric blastema, and normal nephrogenesis
- Familial renal adysplasia: Heterogenous autosomal dominant inheritance of renal agenesis, renal dysplasia, MCDK, etc., within 1 family

PATHOPHYSIOLOGY

- Normal metanephric differentiation requires induction via the ureteric bud (1)
- The branching of the collecting system, as well as nephron formation, are determined by the ureteric bud
- Epithelial–mesenchymal interactions and peptide growth factors play a central role in nephrogenesis
- Dysplasia: Histologically manifests as distortion of renal architecture, immature or primitive glomeruli, cartilage, and tubules encircled by fibromuscular cells (primitive ducts):
  - Aplastic dysplasia: Region of nonfunctioning parenchyma
    - Inhibition of nephron development
    - Increased TGF-β
    - S-shaped bodies and cysts
    - Dedifferentiation of renal cells
- Hypoplasia: Normal nephron density despite smaller size, bilateral or unilateral; can be associated with reflux:
  - Oligomeganephronia:
    - Reduction in nephron number and hypertrophy of each nephron
    - Usually bilateral, but contralateral renal agenesis has been reported
    - No clear distinction between cortex and medulla, reduced number of renal segments, small renal artery, elongated nephrons
  - Ask-Upmark kidney:
    - Likely secondary to reflux nephropathy
    - Deep groove(s) on lateral convexity with underlying tubules resembling thyroid tissue

    - Underdeveloped medulla
    - Arteriosclerosis and juxtaglomerular hyperplasia
- Hypodysplasia: Most often seen in conjunction with an ectopic ureteral orifice or obstruction; extent of dysplasia correlates with degree of ureteral ectopia:
  - Normal ureteral orifice:
    - With obstruction: Primary obstructive megaureter and UPJO
    - Without obstruction: Dwarf kidney; according to bud theory is the result of deficient metanephric blastema
  - Abnormal ureteral orifice:
    - Pan-bud anomaly; abnormal budding leads to an ectopic ureteral orifice with thin renal parenchyma and ectatic calyces
    - Lateral ectopia: Often associated with reflux; rounded calyces are a result of premature termination of calyceal development
    - Medial or caudal ectopia and ureteroceles: Dilated ureter is the norm with thin renal cortex
  - Urethral obstruction:
    - Position of ureteral orifices correlates with degree of renal dysgenesis in posterior urethral valves (PUV): Orthotopic has normal histology; lateral orifice has hypoplasia; extremely lateral has hypodysplasia
    - Prune-belly syndrome: Large laterally displaced ureteral orifices with dysplastic kidneys explained by abnormal budding theory

ASSOCIATED CONDITIONS

- Branchio-oto-renal syndrome
- Ectopic ureteral orifice
- Fraser syndrome
- Jeune syndrome
- Kallmann syndrome
- Meckel–Gruber syndrome
- Oral–facial–digital syndromes
- Posterior urethral valves
- Potter syndrome
- Primary obstructing megaureter
- Prune-belly syndrome
- Pulmonary hypoplasia
- Renal coloboma syndrome
- Simpson–Golabi–Behmel syndrome
- Townes–Brocks syndrome
- Uretero pelvic junction obstruction (UPJO)
- Vesico ureteral reflux (VUR)
- Zellweger syndrome

GENERAL PREVENTION

N/A

DIAGNOSIS

HISTORY

- Systemic:
  - Failure to thrive, abnormal growth, headache, fever, chills, shortness of breath, nausea, emesis, anorexia, skin pallor, vision change, mental status change
- Renal disease:
  - Polyuria, polydipsia, abdominal pain or mass, flank pain, hematuria
- Bladder disease:
  - Lower urinary tract symptoms (LUTS), dysuria, nocturia, incontinence

PHYSICAL EXAM

- Abnormal weight or height
- Vital signs: Hypertensive
- Mental status: Encephalopathic
- HEENT: Retinopathy, papillary edema, dehydration
- Lungs: Crackles
- Abdomen: Distention, palpable mass, guarding, CVA tenderness, ascites
- Extremities: Pallor, peripheral edema

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis: Proteinuria, hematuria, low specific gravity, bacteria
- Urine culture
- Electrolytes, BUN, Cr, K^+
  - Elevated Cr, hyperkalemia, uremia

Imaging

- Renal bladder ultrasound
  - Kidney number and size, pelvicaliectasis, ureteral dilation, presence of cysts or mass, hyperechoic or hypoechoic parenchyma
  - Bladder volume, ureterocele
- CT abdomen and pelvis
  - Anomalous GU anatomy, presence of dilation, calculus disease
- Static fluid and excretory MR urography
  - GU anatomy, renal function, obstruction
- Renal scan
  - Split function or obstruction
- Voiding cystourethrogram
- Retrograde pyelography:
  - Defines anatomy

Diagnostic Procedures/Surgery

- Cystoscopy may help define anatomic abnormalities
- Renal biopsy

Pathologic Findings

- Gross findings (2)

  - Smaller renal size, mass, and contour
  - Renal lobulations and cysts
  - Pale and firm kidneys
  - Duplicated kidney or ureter
  - Dilated collecting system
  - Ectopic ureteral orifice
  - Ureterocele
  - Thickened bladder wall
- Histologic findings
  - Dysplasia
    - Always with decreased nephron number
    - Embryonic mesenchyme
    - Primitive renal components
    - Distortion of renal architecture
    - Primitive glomeruli
    - Nephron precursors: Comma and S-bodies
    - Primitive ducts: Cartilage and tubules encircled by collars of fibromuscular cells
  - Hypoplasia
    - May have a normal nephron density
    - Oligomeganephronia: Reduction in nephron number with corresponding hypertrophy of the nephrons, nephron diverticula
    - Ask-Upmark kidney: Arteriosclerosis, juxtaglomerular hyperplasia, tubules resembling thyroid tissue
  - Hypodysplasia
    - Both dysplastic and hypoplastic

DIFFERENTIAL DIAGNOSIS

- Polycystic kidney disease, autosomal dominant (ADPKD)
- Polycystic kidney disease, autosomal recessive (ARPKD)
- Juvenile nephronophthisis
- Medullary sponge kidney
- Reflux nephropathy
- Renal vein thrombosis
- Simple cysts
- Sporadic glomerulocystic kidney disease
- Tuberous sclerosis
- UPJO
- Von Hippel–Lindau disease
- VUR
- Wilms tumor

TREATMENT

GENERAL MEASURES

Consultation with nephrology and multimodality management

MEDICATION

First Line

Antibiotics for UTI or as prophylaxis for VUR

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Indications for nephrectomy: Pain, chronic infection, HTN, or increasing size (3)
- Renal transplantation for end-stage renal disease
- Ureteral reimplantation: Reflux, primary megaureter
- Pyeloplasty for UPJO
- Valve ablation for posterior urethral valves

ADDITIONAL TREATMENT

Peritoneal or hemodialysis for ESRD

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Varies with degree of renal insufficiency and degree of comorbid conditions

COMPLICATIONS

Renal failure, anemia, UTI, failure to thrive

FOLLOW-UP

Patient Monitoring

- BP and growth chart annually
- Electrolytes, Cr, BUN annually
- Urinalysis and urine culture as indicated
- Bilateral disease: Renal US annually
- MCDK: Renal US every 2 yr to observe for involution

Patient Resources

National Kidney and Urologic Diseases Information Clearinghouse (NKUDIC)

CLINICAL/SURGICAL PEARLS

Prognosis varies; however, most patients have renal insufficiency and its sequelae.

RENAL ECTOPIA

Vani S. Menon, MD
Derek Matoka, MD

BASICS

DESCRIPTION

- Renal ectopia describes a kidney that is located outside of the normal orthotopic position within the renal fossa
- Positions for ectopia:
  - Pelvic kidney: Below aortic bifurcation; this is the most common ectopic position
  - Lumbar: Near sacral promontory
  - Abdominal: Above iliac crest
  - Cephalad: Seen in conjuncture with omphalocele when intra-abdominal organs herniate into the defect and cranial ascent of kidney is limited by the diaphragm
  - Thoracic: Above the diaphragm with vasculature arising from a cranial source
- Crossed fused renal ectopia
  - Fusion occurs in up to 90% of cases
  - Left to right crossing and more common in males
  - Solitary and bilateral crossed varieties less common
  - Type of anomaly is descriptive of the fusion anomaly
    - (inferior, lump, S-shaped [aka sigmoid], L-shaped, disc, or pancake)
  - Fused unit usually caudal to the orthotopic renal moiety
- Horseshoe kidney is a noncross-fused ectopia

EPIDEMIOLOGY

Incidence

- 1 in 500 to 1 in 1,290 in postmortem studies
  - Incidence is higher in autopsy series than in clinical studies, suggesting many clinically insignificant and not recognized
  - Left side favored over right
- Pelvic kidney 1 in 2,200 and 1 in 3,000
- Crossed renal ectopia: Extremely rare

Prevalence

N/A

RISK FACTORS

Potential relationship with maternal illnesses/teratogenic exposure

Genetics

N/A

PATHOPHYSIOLOGY

- Failure of ascent
  - Anomalous vasculature impeding ascent; possibly and abnormally situated umbilical

artery
  – Thought to occur at the 4th–8th wk of gestation
  – Normal kidney ascent to the level of L2 at the end of the 8th wk of gestation
• Abnormality of the ureteric bud or metanephric blastema
• Fusion abnormalities occur early in embryogenesis
  – Horseshoe kidney is the most common fusion anomaly
  – Two renal moieties joined at lower pole in 90% of cases
• Anatomic considerations:
  – Orthotopically located adrenal gland
  – Ureter inserts into bladder in orthotopic position
  – Renal pelvis of ectopic kidney is usually anterior to the parenchyma secondary to malrotation
  – Failure of development of fascial layers in the flanks on the side not occupied by renal tissue
• Malrotation of the ectopic kidney almost always occurs

ASSOCIATED CONDITIONS
• Vesicoureteral reflux: Estimated incidence between 20 and 30%
  – Contralateral kidney demonstrates reflux in approximately 50% of cases
  – Bilateral renal ectopia carries highest risk for reflux—>70% (1)[C]
• Hydronephrosis: Seen in over 50%
  – Half of these cases are due to either ureteropelvic junction obstruction (UPJO) or ureterovesical junction obstruction (UVJO)
  – 25% of the hydronephrotic cases are secondary to reflux and the remaining 25% due to malrotation (2)[C]
• Genital anomalies: Estimated incidence between 15 and 45%
  – 10–20% of males will have cryptorchidism, hypospadias, or duplicated urethras
  – 20–66% of females will have uterine or vaginal anomalies
• Cloacal anomalies: 14% of these patients will have an ectopic kidney
• Nephrolithiasis
• Recurrent urinary tract infections (UTIs)

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
• UTIs (30%), vague abdominal pain or renal colic
• Incidentally during pre- or postnatal screening
• Abdominal mass, hypertension, hematuria, incontinence, renal insufficiency

PHYSICAL EXAM
• Usually normal
• May find abdominal mass or flank tenderness
• Genitourinary abnormalities

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine analysis and culture
- BUN/Cr

Imaging

- If kidney absent on ultrasound (US), radionucleotide imaging should be performed to evaluate for an ectopic kidney
  - Average differential function of ectopic kidney is 35% (1)[C]
- Diuretic renography if moderate-to-severe pelvicalyceal dilation or progressive dilation found to evaluate for obstructive process
- Voiding cystourethrogram for febrile UTI and/or pelvicalyceal dilation
- If kidney is nonfunctional, computed tomography scan or abdominal US for localization
- Recent use of magnetic resonance urogram for small, poorly functioning kidneys can be utilized

Diagnostic Procedures/Surgery

N/A

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Horseshoe kidney
- Malrotated kidney
- Ptosis of orthotopically located kidney
- Supernumerary kidney:
  - Usually caudad to orthotopic kidney

TREATMENT

GENERAL MEASURES

Specific treatment for renal ectopia itself is not indicated. However, special considerations for associated conditions may be necessary.

MEDICATION

First Line

Antibiotic prophylaxis for reflux based on clinical need

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Nephrolithiasis
  - Shock-wave lithotripsy, ureteroscopy, percutaneous nephrolithotomy, laparoscopic nephrolithotomy (3)[C]
- UPJO
  - $<$15% are due to an aberrant crossing vessel
  - Goal of management is to achieve dependent pelvic drainage

  - Dismembered pyeloplasty: Open and minimally invasive
  - Ureterocalicostomy
  - Endopylotomy could be a consideration for failed pyeloplasty but is rarely indicated as the initial surgical intervention
- Vesicoureteral reflux
  - Open vs. endoscopic repair for clinically significant reflux

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Outcomes for treatment of nephrolithiasis and UPJO are comparable to management of these entities in the orthotopic-positioned kidney
- Current literature suggests no adverse effects on blood pressure or kidney function (4)[B]
- No evidence for increased risk of malignancy

COMPLICATIONS

- Vesicoureteral reflux
- Nephrolithiasis
  - Most likely due to urinary stasis
- UPJO/UVJO
- UTIs
- Bowel laxity in the region of the empty renal fossa
- Traumatic injury to renal unit due to poor protection in ectopic location

FOLLOW-UP

Patient Monitoring

- Nephrolithiasis
  - Imaging by renal US and/or CT scans
- Vesicoureteral reflux
  - VCUG and/or DMSA
- Hydronephrosis
  - Renal US and/or nuclear scans
- Yearly blood pressure measurements
- Yearly BUN/Cr measurements

CODES

ICD9
753.3 Other specified anomalies of kidney

ICD10
- Q63.2 Ectopic kidney
- Q63.1 Lobulated, fused and horseshoe kidney

CLINICAL/SURGICAL PEARLS

- Renal ectopia carries an increased risk of urologic abnormalities such as reflux, hydronephrosis, and genital abnormalities.
- Over half the cases of reflux occur in the orthotopic kidney.
- >80% of ectopic kidneys will have differential function of approximately 35%.
- An anterior renal pelvis and anomalous vasculature must be a consideration prior to surgical intervention.
- Surgical interventions for nephrolithiasis have similar success rates as for orthotopic kidneys.

RENAL FUSION ANOMALIES

Ross M. Decter, MD, FRCS
Paul H. Smith III, MD

BASICS

DESCRIPTION

- Reanl fusion is a congenital condition in which the renal units are joined
- Horseshoe kidney and crossed-fused ectopia are the most common variants
  - Horseshoe kidney:
    - Most common renal fusion anomaly
    - Poles of the kidney are fused by the isthmus
    - Fusion occurs at the lower poles in 95%
- Crossed-fused ectopia:
  - 2nd most common renal fusion anomaly
    - Kidney is on opposite side of where ureter inserts (ureter crosses midline)
    - The ectopic renal unit is fused to its companion in 90% of cases
  - Crossing from left to right is the most common morphology

EPIDEMIOLOGY

Incidence

- Male > Female
- Horseshoe kidney occurs in 1 in every 400–500 live births
- Crossed-fused ectopia occurs in 1 in every 1,000–2,000 live births (1)

Prevalence

- Horseshoe Kidney: ~1:400–500
- Crossed-fused ectopia: ~1:3,000

RISK FACTORS

- Crossed-fused ectopia is frequently seen with vertebral anomalies such as myelomeningocele and sacral agenesis (1)
- Horseshoe kidney is present in 60% of female patients with Turner syndrome and 20% of patients with trisomy 18

Genetics

Specific genetic causes unknown, but renal fusion anomalies commonly seen in association with a variety of chromosomal and congenital abnormalities (Turner syndrome, trisomy 18)

PATHOPHYSIOLOGY

- Metanephric blastema is the embryologic precursor to the adult kidney
- Development of the kidney begins in the 4th–5th wk with ingrowth of the ureteric bud, an outpouching of the mesonephric duct, into the surrounding metanephric blastema
- Proper renal development is coordinated through interactions between the metanephric blastema and ureteric bud
- The developing kidney ascends and rotates medially to reach its usual anatomic position by

the 9th wk of gestation
- Several theories have been offered to explain crossed ectopia
  - One theory proposes that an aberrantly oriented ureteric bud induces renal development in the contralateral mesonephric blastema
  - An alternate theory suggests that the developing kidney is channeled/displaced to the contralateral side during its ascent by the presence of an aberrant umbilical or common iliac artery or other pelvic structures
- The developing left and right metanephric blastemas are in close proximity to each other within the pelvis and, if abutting, may merge to form a horseshoe kidney or other fusion anomaly (2)

ASSOCIATED CONDITIONS
- Other congenital anomalies are present in up to a one-third of patients with horseshoe kidney
  - Skelet al, cardiovascular, neural tube, and anorectal anomalies are the most common
- Other GU anomalies associated with horseshoe kidney
  - Cryptorchidism or hypospadias in 4% of males
  - Vesicoureteral reflux (VUR) in >50% of patients
    - Voiding cystourethrogram (VCUG) is routine part of evaluation
- 2–8 times increased risk of Wilms tumor
- 2–4 times increased risk of TCC
- Imperforate anus in 4% with crossed ectopia
- Horseshoe kidney associated with imperforate anus and Meckel's diverticulum
- Increased risk of urolithiasis due to both anatomic and metabolic factors

GENERAL PREVENTION
- Preventative measures aim to minimize risk factors for future renal deterioration:
  - Prophylactic antibiotics or surgical correction if VUR present
  - Decompression of obstructed moieties (pyeloplasty)

DIAGNOSIS
HISTORY
- Most are asymptomatic and are incidentally discovered
- May be diagnosed on prenatal ultrasound (US)
- Symptoms are usually the result of infection, stones, or obstruction of the abnormally positioned collecting system (UPJO)
  - Nonspecific abdominal pain, nausea, vomiting, hematuria

PHYSICAL EXAM
- Palpable abdominal mass (hydronephrosis)
- CVA tenderness (stone or pyelonephritis)

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis (hematuria)
- Serum creatinine (elevated with obstruction)

- Metabolic evaluation for urolithiasis
  - Metabolic etiologies for stone disease common in patients with horseshoe kidney
    - Serum chemistries
    - 24-hr urinalysis

Imaging
- Renal US: Hydronephrosis
- VCUG:
  - High incidence of VUR
- Diuretic renography (MAG3):
  - If clinical or radiographic concern for obstruction
- Contrast-enhanced CT or gadolinium-enhanced MRI with delayed images can accurately characterize the renal, collecting system, and vascular anatomy for surgical planning

Diagnostic Procedures/Surgery
Karyotype in females with horseshoe kidney if dysmorphic features suggestive of Turner syndrome

Pathologic Findings
- Wilms tumor in children and TCC in adults are more common in horseshoe kidneys:
  - Unclear if carcinoma related to embryologic mechanisms, urinary sepsis, or infection

DIFFERENTIAL DIAGNOSIS
- Renal mass
- Supernumerary kidney:
  - An accessory organ with its own blood supply and collecting system
  - It may not be reniform, but possesses a distinct capsule surrounding a parenchymal mass
- Malrotated kidneys: Can look like a horseshoe kidney on radiographic imaging

TREATMENT

GENERAL MEASURES
No treatment if asymptomatic. Specific management dictated by complicating features.

MEDICATION
First Line
- Antibiotics:
  - VUR treated the same as in those without fusion anomalies
  - Antibiotic prophylaxis may be used until resolution for low-grade reflux

Second Line
N/A

SURGERY/OTHER PROCEDURES
- General operative considerations:
  - Horseshoe and ectopic kidneys often have abnormal and complex renal vasculature
    - Renal vessels may arise from the aorta, common iliac artery, or both, and typically enter the kidney anteriorly
    - Angiography (including CT and MR angiogram) may be useful to delineate renal

vascular anatomy for operative planning
  - The renal pelvis and ureteropelvic junction of the horseshoe kidney often have an abnormal configuration, which can result in urinary stasis or obstruction. This anatomic abnormality contributes to the majority of the symptoms associated with horseshoe kidney, including stone formation, infection, hydronephrosis, and frank UPJO.
  - In the horseshoe kidney, the lower poles are joined by an isthmus, which is typically situated just caudal to the inferior mesenteric artery. The isthmus may be divided if necessary during nephrectomy.
- UPJO, best managed with dismembered pyeloplasty:
  - Endoscopic management of UPJO is feasible (3)[B]
- Stone procedures:
  - PCNL:
    - Provides the highest stone-free rates for larger renal stones and is typically the primary procedure for renal calculi in the horseshoe kidney. Access to the collecting is usually best achieved through a posterior upper pole calyx. (4)[B]
  - ESWL:
    - It may be difficult to target stones for ESWL due to the abnormal location of the kidney. ESWL is most appropriate for stones <1.5 cm associated with unobstructed collecting systems. Repeat treatments may be required in order to achieve a stone-free status (4)[B].
  - Ureteroscopy:
    - Safe and effective approach for calculi associated with horseshoe or ectopic renal moieties; however, the smaller ureteroscopic instruments generally limit this approach to smaller stone burdens

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Related to complicating features. Outcomes comparable to those for anatomically normally positioned kidneys.

COMPLICATIONS

- Possible increased risk of malignancy
- UTI
- Urolithiasis
- UPJO

- VUR

FOLLOW-UP

Patient Monitoring

- Due to slight increase in incidence of Wilms tumor in children, some advocate imaging every 6 mo once the diagnosis is made
- The abnormalities and conditions for crossed-fused ectopia are similar to horseshoe kidneys, and treatment often follows similar lines

Patient Resources

- Vesicoureteral Reflux, Pediatric

CODES

ICD9

753.3 Other specified anomalies of kidney

ICD10

- Q63.1 Lobulated, fused and horseshoe kidney
- Q63.2 Ectopic kidney

CLINICAL/SURGICAL PEARLS

- Renal fusion anomalies often associated with other congenital anomalies.
- Ureteropelvic junction obstruction (UPJO) in up to 1/3 of patients with horseshoe kidney.
- Renal vasculature usually aberrant.
- Increased risk of urolithiasis due to medical and anatomic abnormalities.

RENAL INFARCTION

Matthew A. Meissner, MD
Ganesh V. Raj, MD, PhD, FACS

BASICS

DESCRIPTION

- Renal infarction is a rare condition that occurs secondary to any process that interrupts or halts blood flow to the kidney causing necrosis and cessation of function
- Most commonly caused by thromboembolic phenomenon in conditions such as atrial fibrillation (a-fib), bacterial endocarditis, or cardiac mural thrombi

EPIDEMIOLOGY

Autopsy data reveal an estimated prevalence of 0.48–1.4%

RISK FACTORS

- Acute tubular necrosis
- Antiphospholipid antibody syndrome
- Atherosclerosis
- A-fib
- Chagas disease
- Cocaine abuse
- Collagen vascular disease
- Congestive heart failure
- Diabetes mellitus
- Dilated cardiomyopathy
- Endocarditis
- Hypercoagulable states (factor V Leiden)
- Hypertension
- Iatrogenic (surgical manipulation of renal vasculature)
- Intimal dissection
- Long bone fractures (fat emboli)
- Myocardial infarction
- Patent foramen ovale (paradoxical embolism)
- Pyelonephritis
- Renal artery aneurysm and stenosis
- Renal artery or vein thrombosis
- Sickle cell disease causing papillary necrosis
- Trauma: Blunt or iatrogenic
- Valvular heart disease

Genetics

- Patients with inherited hypercoagulable disorders such as factor V Leiden mutation, protein C or S deficiency, lupus, antiphospholipid antibody syndrome, neurofibromatosis, Ehler–Danlos, and other collagen vascular disorders are at increased risk

- Familial history of coronary artery disease, diabetes, or metabolic syndrome portends an increased risk for these diseases, and consequently, renal infarction

PATHOPHYSIOLOGY

- The main mechanism is embolization of the renal vasculature:
  - Clot emboli are the most common (a-fib)
  - Atherosclerotic emboli
  - Vegetative emboli (endocarditis)
  - Fat emboli
- Renal arterial occlusion is more common on the left side, due to the more acute angle of the left renal artery with the aorta (1)
- Acute infarction due to trauma may show a hematoma in the vessel wall (intimal flap); infarction due to clot emboli will reveal a clot, blocking the renal artery or its branches (2) [C]
- Renal vasoconstriction from sepsis, α-adrenergics, cocaine, others

ASSOCIATED CONDITIONS

- Aneurysms of the aorta or renal artery
- Angina
- Atrial fibrillation
- Claudication
- Collagen vascular disease (Ehlers–Danlos)
- Congestive heart failure
- Mesenteric ischemia
- Patent foramen ovale
- Prosthetic heart valve
- Sub acute bacterial endocarditis (SBE)
- Polyarteritis nodosa with vasculitis
- Sickle cell disease (papillary necrosis)

GENERAL PREVENTION

- Reduce risk factors for coronary artery disease (CAD), hypertension, and diabetes
- Appropriate anticoagulation for a-fib, deep vein thrombosis, and valvular heart disease
- Treatment of hypercholesterolemia with statins
- Measures to reduce the risk of trauma (seat belts)

DIAGNOSIS

HISTORY

- A high suspicion is mandated in patients with underlying heart disease, hypercholesterolemia, or recent trauma who present with abdominal or flank pain
- Suspect a ventricular thrombus in patients with a recent myocardial infarction
- Acute flank pain: ~75%
- Nausea/vomiting: ~50%
- Gross hematuria may be seen

ALERT

The symptoms associated with acute renal infarction closely mimic those of an acute episode of urolithiasis or pyelonephritis resulting in delayed diagnosis. This detrimentally impacts long-term renal function and potential for recovery.

PHYSICAL EXAM

- Diffuse abdominal pain without peritonitis
- CVA tenderness
- Fever
- Acute hypertension
- Flank ecchymosis in trauma patients
- Heart murmur
- Peripheral vascular disease
- Decreased urine output
- Abdominal bruit from an aneurysm

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Leukocytosis: 70% of patients
- Elevated or normal creatinine
- Microscopic hematuria: 80% of patients
- Proteinuria: 90% of patients
- Elevated LDH: 100% of patients. If LDH is elevated with normal transaminases, this is highly suggestive of renal infarction in the presence of appropriate symptoms.
- Elevated ALT: 83% of patients
- Elevated AST: 66% of patients

Imaging

- The best study is abdominal CT with and without IV contrast
- Classic CT findings of renal infarction:
  - Lack of IV contrast uptake in affected kidney
  - Areas of low attenuation secondary to local edema
  - Sharply demarcated, wedge-shaped area of devascularized infarct
  - Cortically based, hypodense areas triangular in shape, widest part at the cortex (base of infarct)
  - Cortical rim sign: Perfusion to infarcted aspect of cortex is maintained by collateral branches, showing a thin rim of enhanced cortex (3)[C]
- IVP reveals poorly or nonvisualized kidney on the affected side
- Renal ultrasound with Doppler flow

ALERT

A noncontrast CT, often obtained due to suspicion for renal colic, will fail to show a renal infarct.

Diagnostic Procedures/Surgery

- Renal angiography will diagnose any renal vascular occlusion and allow for intervention
- ECG to diagnose arrhythmias
- Echocardiography for diagnosis of mural thrombi and valvular vegetations

Pathologic Findings

- Acutely, histology demonstrates apoptosis of glomerular and renal tubular epithelial cells
- Chronic changes include necrosis and nuclear loss in glomeruli and tubules

DIFFERENTIAL DIAGNOSIS

- Acute abdominal processes (acute mesenteric ischemia, appendicitis, bowel obstruction)
- Cystic renal disease
- Pyelonephritis
- Renal artery stenosis
- Renal calculi
- Renal tumor
- Renal vein thrombosis

TREATMENT

GENERAL MEASURES

- The optimal therapy for renal infarction is not clear
- Initial therapy includes supportive measures with IV fluids and pain control
- Since thromboembolic disease is the most common cause of renal infarction, primary anticoagulation is considered 1st line
- Other acute treatment options include thrombolysis, endovascular stenting, and thrombectomy

MEDICATION

First Line

- Antihypertensives to control hypertension
- Anticoagulation therapy:
  - Heparin: Start with a bolus of 80 U/kg followed by a continuous infusion titrated to a therapeutic PTT
  - Begin warfarin therapy concurrently, goal INR of 2–3
  - Continue in patients with known causes of thromboembolic disease

Second Line

- Thrombolytic therapy may be used, especially in unstable patients
  - Direct intra-arterial infusion to limit systemic side effects
  - Many contraindications: Cerebral malignancy or AVM, history of cerebral hemorrhage, GI bleed, active hemorrhage, or aortic dissection
  - Relative contraindications: Pregnancy, major surgery within the last 3 wk, uncontrolled hypertension

SURGERY/OTHER PROCEDURES

- Surgical intervention is not considered a primary treatment for thromboembolic renal infarction. Exceptions include:
  - Young patients diagnosed within 6 hr of the infarct.
  - Bilateral infarcts or infarcts in a solitary kidney.
- For traumatic injuries leading to renal infarction (avulsion of the renal pedicle), open surgical repair may be attempted during exploration for other injuries.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Percutaneous angioplasty of the renal artery or thrombectomy

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- The duration of renal ischemia is the critical factor in determining prognosis
- Prognosis also depends on the cause of the infarct and the amount of parenchyma affected
- Patients often die of illness related to the comorbid medical conditions causing the infarct

COMPLICATIONS

- Chronic renal insufficiency
- Renal atrophy
- Hypertension

FOLLOW-UP

Patient Monitoring

- Regular blood pressure monitoring to assess for new-onset hypertension following infarct
- Follow-up imaging to monitor the progression or remission of an infarct
- Medical therapy for underlying condition that led to the infarct
- Monitoring of serum creatinine

Patient Resources

N/A

CODES

ICD9

- 440.1 Atherosclerosis of renal artery
- 584.5 Acute kidney failure with lesion of tubular necrosis
- 593.81 Vascular disorders of kidney

ICD10

- I70.1 Atherosclerosis of renal artery
- N17.0 Acute kidney failure with tubular necrosis
- N28.0 Ischemia and infarction of kidney

CLINICAL/SURGICAL PEARLS

- Renal infarction is most commonly due to thromboembolic disease from underlying medical conditions.
- Prompt diagnosis is paramount for preserving renal parenchyma and function.
- Signs and symptoms may mimic more common GU or intra-abdominal pathology.
- Renal infarction should be in the initial differential diagnosis of nephrolithiasis and pyelonephritis.
- Anticoagulation therapy is the primary form of treatment for renal infarction.

BASICS

DESCRIPTION

- Masses in kidney can be benign or malignant, cystic (simple or complex) or solid, unilateral or bilateral, single or multifocal, primary or metastatic
- Most common renal mass on imaging: Benign cysts (60–70%)
- Most renal cell carcinoma (RCC) are now detected incidentally (up to 70%)
- Most common malignant renal mass is RCC (90%), urothelial (~5%), mets to kidney (~4%)
- Asymptomatic patients (CT screening for colon cancer) may have incidental renal masses 15% of time (90% determined to be benign, 10% indeterminate requiring follow-up)
- Most common renal masses in children: Hydronephrosis (a "pseudomass"), multicystic dysplastic kidney (MCDK), and Wilms tumor (WT)
- Angiomyolipoma (AML) most common benign renal tumor in addition to oncocytoma

EPIDEMIOLOGY

Incidence

- Rates of "kidney cancer" are highest in Europe, North America, and Australia, whereas low in India, Japan, Africa, and China
- 2% worldwide kidney cancer incidence increase per year stabilized in 2008
- Kidney cancer in USA incidence 63,920 with 13,860 deaths in 2014; most lethal GU malignancy
- Antenatal hydronephrosis 0.15% of all pregnancies (50% of GU abnormalities)
- AML 40–80% in tuberous sclerosis (TSC) patients; 0.13–0.03% of general population; ~80% are sporadic & ~20% are in TSC patients
- WT: 6% of all pediatric tumors, 95% of all urologic tumors, ~500 diagnosed annually

Prevalence

- On autopsy 50% of people over 50 yr old have at least one renal cyst
- Kidney cancer: 340,000 in USA

RISK FACTORS

- Kidney cancer: Male 2:1; median age 64 yr old; genetic factors; ¼ of kidney cancer occurs under age of 55; smoking increases risk by 40%; smoking cessation >10 yr almost reverses risk completely; diet effects inconsistent, occupational also conflicting but PCE (perchloroethylene also called tetrachloroethylene), solvents, wool and glass fibers, brick dust, and lead have up to 2-fold increase for RCC, end-stage renal disease (ESRD) debated
- Renal cysts: Genetic factors, age, risk factors for medical renal disease, hemodialysis

Genetics

- RCC 2–3% familial: Von Hippel–Lindau (clear cell RCC)—chromosome 3p25–26 (*VHL gene*); Hereditary papillary RCC (papillary type 1)— chromosome 7q31 (C-*met*); familial leiomyomatosis (papillary type 2)—chromosome 1q42 (*fumarate hydratase*); Birt–Hogg–Dubé (chromophobe RCC, oncocytoma)—chromosome 17p11.2 (*Folliculin*); TSC same risk for RCC as general population based on meta-analysis.
- AML: TSC—*TSC1/TSC2 (50:50),* chromosome 16 & 9 respectively, tumor suppressor genes
- Renal cysts: Autosomal dominant polycystic kidney disease (ADPKD)—PKD1 (85%)/PKD2

(polycystins-cilia, Ca^{2+} channel); autosomal recessive polycystic kidney disease (ARPKD) PKD1 (chromosomal locus 6p12.2) expressed via Potter's sequence; VHL (75%); TSC (50%) *TSC2* gene lies next to PKD1; medullary cystic kidney disease *MCKD1* (chromosome 1q21), *MCKD2* (chromosome 16p12)
- WT: *WT1 (11p13)/WT2 (11p15),* tumor suppressor gene; associated with WAGR, Denys–Drash, Beckwith–Wiedemann (BWS), mixed gonadal dysgenesis (MGD), Trisomy 18, Perlman syndrome

PATHOPHYSIOLOGY
- Renal cysts: Structural abnormalities in the nephron causing fluid to accumulate
- WT1 encodes a zinc-finger transcription factor that is expressed in the kidney and gonads and is necessary for ureteric bud outgrowth and nephrogenesis. Considered tumor suppressor gene but only 20% of Wilms have identifiable WT1 mutation. Undifferentiated blastema, epithelial, or stroma leads to cancer.
- VHL: HIF-1–mediated VEGF angiogenesis upregulated because normal VHL protein-mediated degradation of HIF-1 decreased due to mutation
- AML: Vascular component does not have normal wall, and prone to bleeding when mass size >3 cm (prophylactic intervention at 3.5–4 cm)
- RCC: Clear cell 80% (proximal tubule), papillary 15% (proximal tubule), chromophobe 5% (collecting duct), collecting duct carcinoma <1%, medullary renal carcinoma <1% (sickle cell)
- Untreated small renal masses (SRM), <4 cm, are unlikely to metastasize (~1%) at 3 yr but size and growth rates are variable and not predictive
- RCC size at diagnosis can predict synchronous mets
  - <3 cm, 0.2%
  - 3–5 cm, 2%
  - 5–7 cm, 7%
  - >7 cm ~20%

ASSOCIATED CONDITIONS
- Kidney failure (APKD, papillary RCC)
- Congenital diseases (Wilms, ARPKD, TSC, BWS, BHD, Li–Fraumeni, Cowden syndrome)
- Von Hippel–Lindau (clear cell RCC)
- Cerebral bleeds (ADPKD)
- Sickle cell disease (medullary RCC)
- Hereditary leiomyomatosis (RCC)

GENERAL PREVENTION
- Early screening if genetic predisposition high
- Eliminate modifiable risk factors
- In VHL remove only tumors >3 cm

DIAGNOSIS
HISTORY
- Most RCC patients asymptomatic (why was imaging done that detected incidental mass?)
- Cough or bone pain (mets)

- Flank pain, hematuria (2 of RCC triad of flank pain/hematuria/mass) <10% of patients with RCC

PHYSICAL EXAM

- Eye exam (TSC hamartomas; VHL angiomas)
- Skin (With TSC adenoma sebaceum & ash leaf spot & shagreen patches & finger nail fibromas); With BHD fibrofolliculomas
- Lung exam (BHD associated with pneumothorax)
- Neurologic exam (may be abnormal in TSC, VHL)
- Leg lymphedema (might suggest retroperitoneal LN mets)
- Supraclavicular lymph nodes (possibly distant mets)
- Genital exam (RCC nonreducing varicocele with renal vein thombosis due to RCC; TSC/VHL epididymal cysts/masses)
- Flank mass (part of RCC triad) <10%; more common in Wilms tumor
- Signs of comorbid conditions that will increase peri-op surgical risk (CVA, CAD, HTN, DM, COPD)
- Paraneoplastic signs:
  - Hypertension (RCC and Pheo too)
  - Cachexia, weight loss (check albumin)
  - Neuromyopathy (also part of TSC & VHL)
  - Signs of anemia

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine analysis: Hematuria keeps RCC, UTUC, AML in the differential diagnosis; nitrite and leukocyte esterase positive suggests infection (renal abscess, etc.)
- Voided urine cytology: May detect TCC of urinary tract (not useful if "atypical")
- CBC (anemia or polycythemia in RCC), renal function tests (BUN and creatinine)
- Increased LFTs (Stauffer syndrome: Reversible hepatic dysfunction not due to liver mets)
- Serum calcium: May be elevated in RCC secondary to paraneoplastic syndrome

Imaging

- CT scan w/ and w/o contrast gold standard for renal masses (>10 Hounsfield unit (HU) increase = enhancement = 90% neoplasm) (25–35 mSv effective radiation)
- CT scan with above plus delayed excretory phase for upper-tract neoplasms
- Bosniak cyst CT classification (**1** and **2** benign, no follow-up; **2F** indeterminate, CT 6 mo [5% malignant]; **3** [50% malignant: Surgery or close obs]; **4** ~100% malignant [surgery])
- GFR for contrast-induced nephropathy (CIN)
  - CIN leading to dialysis high if GFR <30
  - CIN risk increases if GFR <60
  - CIN risk 0.6% if GFR >40 and 8% if <40 in one study (GFR 45 may be threshold)
  - 15% of patients can have normal Cr but GFR <50 so GFR better indicator of CIN risk
- If GFR between 30 and 60 gadolinium is safe so consider MRI for these renal masses
  - Gadolinium not safe if GFR <30 (nephrogenic systemic fibrosis—NSF)
- MRI optimal for assessing IVC thrombus and anomalous renal hilar vessels (no radiation)
- Patients on dialysis can get CT contrast without need for immediate dialysis

- Consider CT chest no contrast in patients at risk for mets (CXR misses 10%)
- Nuclear medicine for split functional differentiation rarely needed if Cr <1.5 and kidney size and shape similar to contralateral side
- Brain/bone imaging for mets if symptomatic

Diagnostic Procedures/Surgery

Biopsy necessary for metastatic disease prior to initiation of systemic therapy and if concern for mets *to* the kidney. Indeterminate biopsy occurs 10–20%. Biopsy not routinely needed due to high positive predictive value of enhanced imaging but has role in ablation.

DIFFERENTIAL DIAGNOSIS

- Adults: A solid primary renal mass in adult is most likely to be a RCC, although UCC or metastatic disease is an important consideration
  - AML: Fat in a renal mass strongly suggests AML; fat-poor AML may resemble RCC
  - Carcinoid tumors
  - Collecting duct tumor (Bellini)
  - Cystic nephromas
  - Cysts (simple, hemorrhagic, infected)
  - Focal pyelonephritis
  - Hemangioma
  - Inflammatory masses (xanthogranulomatous pyelonephritis, abscess)
  - Leiomyoma: Usually in renal capsule
  - Metanephric adenoma
  - Metastasis: Lung, gastric, breast cancers most common; melanoma and others
  - Oncocytoma: Benign; cannot be reliably differentiated from RCC on imaging studies
  - Pseudotumors (column of Bertin, others)
  - Renal capsule neoplasm
  - RCC
  - Renal cortical adenoma: Controversial entity; cannot be distinguished from RCC on imaging: <2 cm, metastasis exceedingly rare
  - Renal lymphoma
  - Renal medullary carcinoma
  - Renal sarcomas: 1–2% of all renal masses (leiomyosarcomas, fibrosarcomas, malignant fibrous histiocytomas, anaplastic sarcoma)
  - Reninoma (JG apparatus tumors)
  - Urothelial carcinoma upper tract (UTUC)
- Benign renal mass in children:
  - Choledochal cyst, intestinal duplication cyst
  - Congenital mesoblastic nephroma
  - Crossed-fused ectopia
  - Cystic nephroma (multiloculated cystic nephroma)
  - Hydronephrosis
  - Mesenteric cyst
  - MCDK—involuted nonfunctional kidney
  - Polycystic kidney disease
  - Renal abscess

  – Splenomegaly
- Malignant renal masses in children:
  – Lymphoma, lymphosarcoma
  – Neuroblastoma (actually adrenal origin)
  – Ossifying renal tumor of infancy
  – RCC (rare in children)
  – Sarcomas (clear cell, rhabdomyosarcoma)
  – WT (nephroblastoma): Renal mass in a child is WT until proven otherwise

TREATMENT

GENERAL MEASURES

- Renal lesions suspicious for RCC are treated surgically (laparoscopically or open) usually with radical nephrectomy or partial nephrectomy (PNx). PNx use dependent on surgeon experience and location of tumor to hilum; most <3–4 cm (1).
- PNx decreases long-term risk of CVD mortality and ESRD vs. nephrectomy
- Most recommend surgery for Bosniak III (50% malignant) and IV cysts ($\sim$100%)
- TCC of the renal pelvis: By endoscopic ablation for small superficial lesions (low-grade Ta), or radical nephroureterectomy
- Asymptomatic AML >3.5 cm or small symptomatic lesions are treated by embolization, partial nephrectomy, or nephrectomy
- Painful simple renal cysts and infected cysts: Percutaneous aspiration and sclerotherapy
- Although cytoreductive nephrectomy is debated in post-IL-2 era, FDA approval of TKI & mTOR inhibitors based on studies where almost half patients had received a nephrectomy

MEDICATION

First Line

- Usually used for advanced mRCC
- Sunitinib or bevacizumab + IFN-α: 1st line in low/intermediate risk
- Temsirolimus: 1st line in high risk
- Pazopanib: 1st line and after cytokine failure
- Interleukin-2 has more side effects than INF-α. High-dose IL-2 gives durable complete responders in a limited number of patients. IL-2 can be monotherapy in selected good prognosis.

Second Line

- Sorafenib: 2nd line after cytokine failure
- Everolimus: 2nd line after TKI

ADDITIONAL TREATMENT

Radiation Therapy

- Radiation used in pediatric tumors: Wilms stage 3–4, all clear cell and rhabdoid stages
- Metastatic RCC for pain/CNS mets in adults

Additional Therapies

- RCC: Embolization prior to nephrectomy not beneficial but can be palliative for pain and bleeding if nonsurgical candidate

- Ablation (cryotherapy or radio frequency) of smaller renal masses (<3 cm) may be considered in selected cases (elderly, poor surgical risk) (1)

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- MSKCC (Motzer) criteria to predict survival of patients with advanced RCC; for RCC, Kattan and UCLA nomograms popular (based on 2002 TNM)
- RCC 5-yr cancer-specific survival (2010) is 88–100% stage T1–T2, T3 45–75%, T4 <5–30%; +LN 0–30%, or +mets 0–10%
- Wilms: 4-yr survival stage 1–4 favorable histology (FH): 90–98%, stage 5 FH ~56–87%; stage 1–5 unfavorable histology ~66%; clear cell RCC any stage ~75%; rhabdoid sarcoma any stage ~25%

COMPLICATIONS

Surgical complications include hematoma, pneumothorax, infection, adjacent organ injury (liver, spleen, pancreas, duodenum, and bowel), urinary leak, myocardial infarction, thromboembolism, positive surgical margins

FOLLOW-UP

Patient Monitoring

- AML: Renal US every 6–12 mo
- Poor surgical candidate with SRM imaging every 6 mo alternating with renal US and CT scan with yearly CXR or chest CT
- Stage 1–3 RCC, 20–30% relapse, lung most common (50–60%), median relapse 1–2 yr, evaluate every 6 mo for 2 yr, then annually. Stage 4 RCC f/u dependent on primary treatment and provider dependent.

CODES

ICD9

- 189.0 Malignant neoplasm of kidney, except pelvis
- 593.9 Unspecified disorder of kidney and ureter

ICD10

- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- N28.89 Other specified disorders of kidney and ureter

CLINICAL/SURGICAL PEARLS

- Much less than 10% of patients with RCC present with the “classic triad” of hematuria, flank pain, and a renal mass.
- A solid renal mass in childhood is WT until proven otherwise.

RENAL MASS, INTRAOPERATIVE CONSULTATION

Mark R. Anderson, MD, MSc
Anthony T. Corcoran, MD
Robert G. Uzzo, MD

BASICS

DESCRIPTION

- Most renal masses are incidentally found preoperatively on routine axial imaging (eg, CT or MRI of the abdomen)
- Although rare today, some renal masses are 1st identified intraoperatively
  - Typically associated with trauma or urgent cases where preoperative imaging was either not done or inadequate for renal visualization

EPIDEMIOLOGY

Incidence

- Renal cell carcinoma (RCC)
  - 63,920 estimated new cases in 2014 (NCI data)
  - Primarily occurs in 6th or 7th decade
  - Male > Female (3:2)
  - 4% of RCC are familial; majority are sporadic
  - 10–20% higher incidence in African Americans

Prevalence

N/A

RISK FACTORS

- RCC
  - Family history, smoking, obesity, hypertension, end stage renal disease (ESRD)
- For intraoperative renal mass consult, risk factors include:
  - Pre-existing nonrenal primary cancer
    - Possible metastatic lesion on kidney
  - Inheritable tumor syndrome
    - Associated renal tumor component
  - Renal insufficiency preventing use of contrast during imaging
  - Centrally located or small tumors initially missed on imaging

PATHOPHYSIOLOGY

N/A

ASSOCIATED CONDITIONS

- Polycystic kidney disease
  - Autosomal dominant (autosomal dominant polycystic kidney disease) or recessive (autosomal recessive polycystic kidney disease)
- Inheritable tumor syndromes with renal and extrarenal manifestations
  - Birt–Hogg–Dubé (BHD gene; 17p11)

- Cutaneous lesions, lung cysts, spontaneous pneumothorax, colonic polyps, or cancer
- Hereditary leiomyomatosis and renal cell cancer syndrome (HLRCC gene; 1q42) (aka: Reed's syndrome)
  - Uterine leiomyoma and leiomyosarcoma, cutaneous leiomyoma and leiomyosarcoma
- Hereditary hyperparathyroidism-jaw tumor syndrome (CDC23 gene; 1q24–32)
  - Parathyroid tumor, fibroosseous mandibular and maxillary tumor, uterine tumor
- Papillary thyroid carcinoma with associated papillary renal neoplasia (1q21)
  - Papillary thyroid cancer, nodular thyroid disease
- Tuberous sclerosis complex (TSC1, 9q34)
  - Facial angiofibroma, subungual fibroma, hypopigmentation and café au lait spots, cardiac rhabdomyoma, seizure, mental retardation, CNS tubers, lymphangioleiomyomatosis
- VHL (VHL gene; 3p25)
  - Retinal and CNS hemangioblastomas, pheochromocytoma, pancreatic cyst and endocrine tumor, endolymphatic sac tumor, epididymal and broad ligament cystadenomas

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Obtain history from operative team and review available medical and radiographic records
  - Prior or current cancers
  - Inheritable tumor syndromes
  - History of renal or abdominal trauma

PHYSICAL EXAM
- Intraoperative evaluation—location of mass
  - Check adrenal
  - Intrarenal
  - Extrarenal within Gerota fascia
  - Perirenal
  - Renal pelvis

DIAGNOSTIC TESTS & INTERPRETATION
Lab
Serum creatinine and eGFR

Imaging
- Review all preoperative ultrasound (US), contrast-enhanced CT, and/or MR if available
  - If serial images available, determine growth rate to help define risk (1)[B]
    - Average yearly linear growth rate of 0.3 cm for all masses vs. 0.8 cm found in patients with progression
    - Masses with no growth under surveillance unlikely to metastasize
- Intraoperative US with color Doppler (use laparoscopic or finger probe in open surgery)
  - Features suggesting malignant pathology

- Purely cystic lesions without septation can be observed
- Remove lesions with solid elements

– Color Doppler also useful to:
- Assess flow to ipsilateral and contralateral kidney
- Differentiate an isoechoic lesion with renal parenchyma since vessels are displaced around solid renal masses
- Identifies deep vessels near the wall of the lesion that may be encountered during excision

ALERT

Obtain all available informatIon on renal function.

• Calculate overall renal function (GFR—Cockcroft–Gault equation; calculators available online) and classify CKD status.
• Status of contralateral renal unit presence, flow, and function.
• Enhancement characteristics on imaging.

Objectify risk:

• Overall survival vs. competing risks of death.
– Competing risks nomogram operationalized online at www.cancernomograms.com (2) [B].
• Remaining renal function.
– Can estimate percent functional volume preservation if partial nephrectomy planned as volume loss correlates well with ultimate renal function after partial nephrectomy (3)[B].

Diagnostic Procedures/Surgery

• Diagnostic procedures
– Consider intraoperative renal mass biopsy and frozen section analysis
- Obtain core biopsy with biopsy gun
- ~20% of intraoperative frozen sections of renal lesions nondiagnostic (4)[B]
- Management options include active surveillance, ablation, or extirpation (Note: Renal biopsy and frozen section analysis yield poor tumor grade information)

Pathologic Findings

• Approximately 14% of incidentally found renal masses are benign depending on size (5)[B]
– 68% clear cell RCC
– Positive association between tumor size and:
- Rates of clear cell RCC
- Fuhrman grade for clear cell RCC
- Tumor stage

DIFFERENTIAL DIAGNOSIS

• Renal masses (see Section I “Renal Mass” for more information)
– Abscess (acute or chronic)—consider history and available labs
– Angiomyolipoma (AML)—check for fat on imaging
– Adrenal lesion—check for presence of contralateral gland prior to removal—if unable beware of postoperative insufficiency
– Benign lesion—oncocytoma, etc.

- Calyceal diverticulum (chronic and infected can cause mass-like appearance with heavy perinephric reaction)
- Hemorrhagic cyst—may appear solid and pseudoenhance
- Lymphoma—may cause renomegaly
- Metastatic lesion from other primary tumor
- Pseudotumor (column of Bertin)
- Renal lobulations
- RCC, Wilms tumor
- Renal cysts
- Sarcoma (renal or retroperitoneal—including leiomyosarcoma and liposarcoma)
- Subcapsular hematoma—may be chronic especially with old trauma or extracorporeal shock wave lithotripsy
- Upper-tract urothelial carcinoma
- Vascular—hemangioma, renal artery aneurysm, malformation

• Perirenal
- Adrenal lesion or adrenocortical carcinoma
- Mesothelial cyst
- Teratoma

TREATMENT

GENERAL MEASURES

• What to do if called to the operating room emergen-tly to evaluate a renal mass (See Section III: Renal Mass, Intraoperative Consultation Algorithm)
• If patient unstable and involved kidney uninjured, defer to later date
• If films unavailable, safely defer if possible
• If unable to defer treatment—assess presence, function, and anatomy of both kidneys and consider biopsy
• Look at available films to see if pre-/postcontrast phases available
- If preoperative imaging suggests a solid, enhancing mass amenable to partial nephrectomy
  - Consider intraoperative biopsy and frozen section analysis
  - Reasonable to perform partial nephrectomy after family discussion (if present)
- Do not get fooled by hyperdense cyst or pseudotumor—see clinical pearls

• If no films, and cannot postpone intervention, consider biopsy
- If solid elements with flow on Doppler US, normal contralateral kidney and amenable to partial nephrectomy, then intervene
- If radical required for technical reasons, perform biopsy with frozen section pathologic analysis and possibly deferring intervention until permanent section results obtained
  - Unless absolute indication for radical nephrectomy (≥cT3, adjacent organ involvement, vascular compromise)

• Avoid the following:
- Rely on US as only test for radical nephrectomy (get biopsy)
- Rely solely on intraoperative single shot IVP to evaluate contralateral kidney
- Perform a radical nephrectomy because technically easier
- Assume presence, flow, or function of contralateral kidney

MEDICATION

First Line

N/A

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Extirpative procedures
  - Partial nephrectomy
    - Tumor enucleation may yield equivalent oncologic outcomes. Best used when mass locally confined on preoperative imaging, easily delineated intraoperatively, and do not appear to grossly invade beyond the pseudocapsule.
    - Frozen section analysis on margin if in question
  - Radical nephrectomy
  - Resection of mass adjacent to kidney ± partial or radical nephrectomy, if only way to get specimen out safely
- Surgical approach
  - Attempt to use existing approach (laparoscopic/robotic) or incision
    - Convert from laparoscopic to open if needed for imperative indications only, otherwise may defer if oncologic risk low
    - If nephron sparing requires conversion for technical reasons, consider performing at later date with patient consent
- Remember to place perirenal closed suction drain for most nephron-sparing procedures

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Investigate adjuvant therapies or eligibility for adjuvant clinical trials based on pathology
- Follow functional (nephrologic) results
- If adrenalectomy was performed—beware of postoperative adrenal insufficiency

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Influenced by stage, grade, histology
- Margin status appears not to portend an adverse prognosis or increased local recurrence
- Local recurrence after resection is ~2–3% after partial or radical nephrectomy
- 5-yr risks of recurrence for local or regional RCC fully excised are approximately:
  - >95% for pT1, ~85% for pT2, range from 40–60% for pT3b

COMPLICATIONS

- For partial and radical nephrectomy: Acute renal failure, need for dialysis

- Long-term risk of chronic renal insufficiency after radical nephrectomy associated with increased cardio- and cerebrovascular morbidity
- For partial nephrectomy: Urinary fistulas, and bleeding
- Major complications, including urine leak, increase with increasing tumor complexity
  - Low complexity—6%
  - Moderate complexity—11%
  - High complexity—22%

FOLLOW-UP

Patient Monitoring

- NCCN guidelines (level of evidence 2B—lower level but consensus recommended)
  - Every 6 mo for 2 yr, then annually for 5 yr
    - History and physical exam
    - Comprehensive metabolic panel
  - At 2 yr as indicated based on recurrence risk
    - Chest and abdominal ± pelvic imaging
    - Risk-based follow-up clinical practice guidelines operationalized at www.cancernomograms.com

Patient Resources

CODES

ICD9

- 189.0 Malignant neoplasm of kidney, except pelvis
- 593.9 Unspecified disorder of kidney and ureter
- 753.10 Cystic kidney disease, unspecified

ICD10

- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- N28.89 Other specified disorders of kidney and ureter
- Q61.9 Cystic kidney disease, unspecified

CLINICAL/SURGICAL PEARLS

- Traumatic hemorrhage into a cyst can mimic a hypoechoic, solid renal mass. Color Doppler can establish blood flow ruling out hemorrhagic cysts.
- Failing to check preoperative films if available as AML can often be distinguished by macroscopic fat on CT/MR.
- Avoid getting fooled by renal pseudotumor or adrenal lesion.
- Avoid expanding the goals of planned operation without consent or clearly thought out plan.

RENAL ONCOCYTOMA

Gillian Stearns, MD
Oleg Shapiro, MD, FACS

BASICS

DESCRIPTION
- Renal oncocytoma is the most common benign solid renal tumor in adults
- Usually asymptomatic at time of presentation
- Frequently detected incidentally at time of CT scan

EPIDEMIOLOGY
Incidence
- 3–7% of all renal masses
- Epidemiology similar to renal cell carcinoma (RCC)
- Male > female (2:1)
- Median age of diagnosis 62 yr
- 6% occur bilaterally
- 17% multifocal

Prevalence
N/A

RISK FACTORS
- Familial renal oncocytoma syndrome
  - Described rarely to date
- Birt–Hogg–Dubé (BHD)

Genetics
- Most frequent abnormalities (1,2):
  - Loss of chromosome 1p
  - Loss of chromosome Y (males)
- Less frequent translocations
  - Breakpoint region on 11q13
  - Region encoding mDNA
  - Loss of heterozygosity at chromosomes 1,14,21
    - May reflect progression of oncocytoma to chromophobe RCC

PATHOPHYSIOLOGY
- Arise from intercalated cells in collecting duct of kidney (like chromophobe RCC)
- Occasionally oncocytoma and RCC may be found in the same kidney

ASSOCIATED CONDITIONS
- Most usually sporadic
- BHD
  - Autosomal dominant

- Mutation in gene for folliculin
- Renal tumors
  - Chromophobe/oncocytoma
- Spontaneous pneumothorax, lung cysts
- Fibrofolliculomas, especially on face

GENERAL PREVENTION

No preventative strategies have been described. Relatives of those with genetic syndromes may be screened.

DIAGNOSIS

HISTORY

- Most patients asymptomatic
- Incidentally detected
- Gross hematuria/flank pain/flank mass rare
- Family history of renal tumors, fibrofolliculomas, lung cysts/pneumothorax—rule out BHD

PHYSICAL EXAM

- No specific findings for sporadic oncocytoma
- Palpable flank mass rare
- Dermatologic exam if suspected BHD

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- No lab test can identify renal tumor as oncocytoma
- Lab panel as with any newly diagnosed renal mass
  - CBC, chemistry panel, LFTs

Imaging

- Cannot be used to reliably distinguish oncocytoma from RCC
- CT with and without IV contrast
  - Diagnostic test of choice for solid renal mass
  - Central scar within mass often seen in oncocytoma, but this can be confused with necrosis, commonly seen with RCC
- MRI
  - Solid enhancing renal mass ± central scar
  - Test of choice with IV contrast allergy, renal insufficiency
- Renal US
  - Not typically helpful for identification of mass as oncocytoma
- Renal angiogram
  - Spoke wheel pattern of feeding vessels
    - Not definitive for diagnosis
  - Usually not helpful in evaluation of renal mass
- Metastatic evaluation for solid renal mass
  - Chest x-ray vs. chest CT
- Additional studies may be indicated clinically

Diagnostic Procedures/Surgery

- Percutaneous biopsy
  - May be useful to exclude metastasis to kidney based on patient history
  - May guide management of poor surgical candidates
- Pitfalls of biopsy
  - Difficult to distinguish oncocytoma from chromophobe RCC
  - Coexistence of RCC and oncocytoma in up to 10% cases

Pathological-Findings (3,4)

- The term "oncocytoma" is a general descriptor of an epithelial tumor that consists of oncocytes. Oncocytes are large eosinophilic cells with small, round, benign-appearing nuclei without nucleoli.
  - Oncocytomas can arise in a number of different organs
- Renal oncocytoma: Gross findings
  - Well-circumscribed mass, mahogany brown, often with pseudocapsule
  - Average size 6–7 cm
  - 33% with central stellate scar
  - 20% demonstrate extension into perinephric fat
  - Calcifications and necrosis rarely seen
- Renal oncocytoma: Microscopic findings
  - Round to polygonal eosinophilic cells
  - Abundance of mitochondria seen on electron microscopy
  - Mitotic figures rare
  - Regular nuclei
  - Cells arranged in distinct nests
  - May be difficult to distinguish from chromophobe RCC
    - Colloidal iron stain positive in chromophobe RCC but not oncocytoma
    - Chromophobe RCC is vimentin, cytokeratin 7 positive
    - CD82 and epithelial-related antigen (MOC31) may be helpful in the distinction between chromophobe RCC and renal oncocytoma
    - Gene expression differences are being explored
    - The World Health Organization (2004) renal tumor classification indicates renal oncocytomas are benign neoplasms. In the past some renal oncocytomas were classified as malignant.
    - This may have resulted from confusion with clear cell renal carcinomas with eosinophilic component or due to eosinophilic chromophobe RCC (low metastatic potential)

ALERT

Although oncocytoma has "Classic Findings" on imaging, no radiographic studies exist to differentiate benign oncocytoma from malignant RCC.

DIFFERENTIAL DIAGNOSIS

- Adrenal mass
- Angiomyolipoma
- Carcinoid tumor

- Collecting duct tumor
- Cystic nephroma
- Cysts
- Focal pyelonephritis
- Hemangioma
- Inflammatory masses (xanthogranulomatous pyelonephritis (XGP), abscess)
- Leiomyoma
- Metanephric adenoma
- Metastasis
- Pseudotumor (column of Bertin)
- RCC
- Renal cortical adenoma
- Renal lymphoma
- Renal medullary carcinoma
- Renal sarcoma
- Reninoma
- Urothelial carcinoma
- Wilms tumor

TREATMENT

GENERAL MEASURES
Mainstay of treatment is surgical

MEDICATION
First Line
No medical treatment exists

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Establishes diagnosis of oncocytoma
- Partial nephrectomy whenever feasible based on size and location
- Radical nephrectomy rarely indicated unless very large, uncertain diagnosis or partial not possible

ADDITIONAL TREATMENT
Radiation Therapy
No role

Additional Therapies
N/A

Complementary & Alternative Therapies
- Renal cryotherapy and radiofrequency ablation (5)
  - Being studied as treatment option
  - Unable to differentiate between oncocytoma and RCC due to lack of tissue for histology

  - Primarily for smaller lesions (< 3 cm)
  - May be done laparoscopically or percutaneously
  - No long-term follow-up exists
  - Usually considered for poor surgical candidates
- Active surveillance
  - Good for select patients with solid renal masses, but no size can reliably differentiate between benign and malignant processes
    - 3 cm usually used as cutoff in BHD

ONGOING CARE

PROGNOSIS

- Oncocytoma is uniformly considered a benign tumor and surgical removal is curative
- Multiple series report no metastases or death from oncocytoma on long-term follow-up
- Older, rare reports of metastases may represent unrecognized, low-grade RCC (6,7)
- Risk of metachronous oncocytoma 4–6%

COMPLICATIONS

- Perioperative for partial/radical nephrectomy
  - Bleeding, infection, urine leak
- Long term after nephrectomy depends on renal reserve
  - Chronic renal insufficiency/dialysis

FOLLOW-UP

Patient Monitoring

- Patient monitoring
  - Long-term surveillance of renal units recommended annually to semiannually
  - Metachronous ipsilateral and bilateral oncocytomas have been reported
- Renal US preferred modality
  - Minimizes radiation exposure
  - No need for IV contrast
- Urinalysis
  - Hematuria/proteinuria
- Serum creatinine

CODES

ICD9

223.0 Benign neoplasm of kidney, except pelvis

ICD10

- D30.00 Benign neoplasm of unspecified kidney
- D30.01 Benign neoplasm of right kidney
- D30.02 Benign neoplasm of left kidney

CLINICAL/SURGICAL PEARLS

- Oncocytoma is a benign solid renal lesion.
- No imaging study reliably differentiates oncocytoma from RCC. The CT finding of a central

scar, previously felt to be specific for oncocytoma, has been found with RCCs, and this finding is not specific.

RENAL SARCOMA, ADULT AND PEDIATRIC

Adam O. Kadlec, MD
Robert C. Flanigan, MD, FACS

BASICS

DESCRIPTION

- Sarcomas of the kidney are rare solid tumors that arise from the embryonic mesoderm
  - Sarcomas of the renal parenchyma itself are very rare. More commonly, "renal sarcomas" represent a soft tissue sarcoma that either invades or abuts the kidney.
  - In large case series of adult patients, leiomyosarcoma and liposarcoma are the most common histologic subtypes
- Renal sarcomas are more likely to be seen in childhood than adulthood
- Childhood sarcomas
  - Represented almost exclusively (approximately 95%) by Wilms tumor (historically called nephroblastoma) (1)[A]
  - Other sarcomas of childhood include clear cell sarcoma, rhabdomyosarcoma, congenital mesoblastic nephroma, and fibrosarcoma

EPIDEMIOLOGY

Incidence

- Adults: 1–2% of genitourinary cancer with peak incidence in 5th decade
- Children: 6–7% of childhood cancers represented mainly by Wilms tumor
- Wilms tumor occurs equally in boys and girls, with a median age of onset of 3.5 yr

Prevalence

N/A

RISK FACTORS

- Specific etiologies are not known
- HIV is associated with Kaposi sarcoma of the kidney
- Wilms tumor does have a small component of family history

Genetics

- Adult renal sarcomas unknown; suggestion of familial tendency with angiosarcoma
  - Possible role of DNA mismatch repair pathway
- 1–2% of Wilms tumor patients have an inherited genetic predisposition
  - Most common loss or inactivation of a tumor suppressor gene called WT1 on chromosome 11
  - WT1 located at 11p13 and is associated with renal and gonadal development
  - WT2 located at 11p15 and is associated with Beckwith–Wiedemann syndrome
  - 90% of Wilms tumors arise from somatic mutations with overall genetic paradigm remaining unknown

PATHOPHYSIOLOGY

- Most common adult renal sarcomas are leiomyosarcomas, representing as many as 50–60%

of such tumors. A wide variety of other types, such as liposarcoma and fibrosarcoma, are also found (2)[B].

- Sarcomas exhibit aggressive local growth with high rate of local recurrence, even in the event of negative surgical margins, due to a tendency for "skip lesions."
- RCC with sarcomatoid features is an increasingly recognized variant of RCC (<5% of all cases) that contains regions of mesenchymal-appearing malignant cells adjacent to or within another typical RCC histology
- Later metastasis to the lung and liver can occur
- Wilms tumor is categorized into favorable or unfavorable histology; this has important implications regarding treatment (1)[A]

ASSOCIATED CONDITIONS

Wilms tumor is associated with aniridia, hemihypertrophy, Beckwith–Wiedemann syndrome, Denys–Drash, and GU abnormalities (hypospadias and cryptorchidism)

GENERAL PREVENTION

N/A

DIAGNOSIS

HISTORY

- Age and sex of patient
- Family history
- History of mental retardation or GU anomalies
- Noticeable abdominal mass (esp. Wilms)
- Shortness of breath, lethargy, abd pain, weight loss, and other systemic symptoms may be present

PHYSICAL EXAM

- Abdominal exam for mass
  – In children, a palpable mass will be seen with Wilms tumor in >80% of cases
- Assess for associated lymphadenopathy
- GU exam to assess for GU anomalies such as hypospadias or undescended testis, which may alert to syndromes such as Denys–Drash

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Comprehensive metabolic panel to include liver function tests
- CBC
- UA (microhematuria, pyuria)
- No reliable tumor markers for sarcoma

Imaging

- CXR or CT to evaluate for metastatic disease in the chest or abdomen
- CT/MRI to assess local extent of tumor may aid surgical planning
- On MRA, sarcomas tend to be avascular
- Renal US may be helpful in evaluation of cystic renal mass

Diagnostic Procedures/Surgery
Biopsy of limited utility

Pathologic Findings
- Morphologically, renal sarcomas are similar to their extrarenal counterparts
- In adults they can arise from both the parenchyma and the renal capsule
- Wilms tumor
  - Generally soft and friable with hemorrhage and necrosis
  - Classic: Coexistence of blastemal, epithelial, and stromal cells
  - Unfavorable histology is associated with nuclear enlargement, hyperchromasia, and abnormal mitotic figures
- Leiomyosarcoma (most common)
  - Cell origin is smooth muscle of capsule or the perinephric structures
  - Displaces rather than invade parenchyma
- Fibrosarcoma, malignant fibrous histiocytomas, anaplastic sarcoma of the kidney are other histologic types

DIFFERENTIAL DIAGNOSIS
- Adults: A solid primary renal mass in adult is most likely to be a RCC, although urothelial carcinoma or metastatic diseases are other considerations
  - AML: Fat in a renal mass strongly suggests AML; fat-poor AML may resemble RCC
  - Carcinoid tumors
  - Collecting duct tumor (Bellini)
  - Cystic nephromas
  - Cysts (simple, hemorrhagic, infected)
  - Focal pyelonephritis
  - Hemangioma
  - Inflammatory masses (xanthogranulomatous pyelonephritis, abscess)
  - Leiomyoma: Usually in renal capsule
  - Metanephric adenoma
  - Metastasis: Lung, gastric, breast cancers most common; melanoma and others
  - Oncocytoma: Benign; cannot be reliably differentiated from RCC on imaging studies
  - Pseudotumors (column of Bertin, others)
  - Renal capsule neoplasm
  - Renal cell carcinoma (RCC)
  - Renal cortical adenoma: Controversial; cannot be distinguished from RCC on imaging: <2 cm
  - Renal lymphoma
  - Renal medullary carcinoma
  - Renal sarcomas
    - Angiosarcoma
    - Chondrosarcoma
    - Clear cell sarcoma
    - Ewing sarcoma/primitive neuroectodermal tumor
    - Fibrosarcoma
    - Kaposi sarcoma

- Leiomyosarcoma (including the myxoid types)
- Liposarcoma
- Malignant fibrous histiocytoma
- Malignant hemangiopericytoma
- Malignant mesenchymoma
- Malignant schwannoma
- Osteogenic sarcoma
- Rhabdomyosarcoma
- Sarcomatoid renal cell carcinoma
- Synovial sarcoma
- Wilms tumor

– Reninoma (JG apparatus tumors)
– Urothelial carcinoma upper tract (UTUC)

• Benign renal mass in children:
– Choledochal cyst, intestinal duplication cyst
– Congenital mesoblastic nephroma
– Crossed-fused ectopia
– Cystic nephroma (multiloculated cystic nephroma)
– Hydronephrosis
– Mesenteric cyst
– Multicystic dysplastic kidney (MCDK): involuted nonfunctional kidney
– Polycystic kidney disease
– Renal abscess
– Splenomegaly

• Malignant renal masses in children:
– Lymphoma, lymphosarcoma
– Neuroblastoma (actually adrenal origin)
– Ossifying renal tumor of infancy
– RCC (rare in children)
– Sarcomas (clear cell, rhabdomyosarcoma)
– Wilms tumor (nephroblastoma): A renal mass in childhood is Wilms until proven otherwise

ALERT
Primary renal sarcoma is extremely rare. Primary retroperitoneal soft tissue sarcoma (such as leiomyosarcoma or liposarcoma) with secondary renal invasion is the more common clinical presentation.

TREATMENT

GENERAL MEASURES

• In adults, the lesions are usually approached as for RCC, with surgical excision being 1st-line therapy, as the histology of lesion is rarely known preoperatively (3)[B]
• Masses tend to be quite large, presumably due to rapid growth pattern
• The primary treatment of renal sarcomas is surgical excision. Local recurrences should be

resected when feasible.
- The role of adjuvant and neoadjuvant therapy in the adult population is poorly understood

MEDICATION

First Line

- Dactinomycin and vincristine are used for more favorable stages of Wilms, with the addition of doxorubicin and abdominal radiation for more advanced stages
- Doxorubicin for clear cell sarcoma in children
- Doxorubicin, dacarbazine, and ifosfamide have been used with adult sarcomas; however, response rates at best are poor

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Mainstay of treatment for all sarcomas involving the kidney is radical nephrectomy with excision of entire tumor mass, which may require resection of adjacent organs. In some cases, partial nephrectomy may be possible (2)[B].
- Wide excision is the preferred approach due to sarcomas' tendencies toward skip lesions
- Sarcomas tend to surround the renal vasculature as well as surrounding vascular structures
- No defined role for lymphadenectomy
- Preoperative chemotherapy is given in advanced cases of Wilms to downstage prior to surgery, usually with external radiation therapy. In bilateral disease, nephron sparing is indicated.

ADDITIONAL TREATMENT

Radiation Therapy

- Sometimes employed in management of Wilms tumor postoperatively. Radiation of the tumor bed is indicated if the tumor extended beyond the renal capsule to involve adjacent organs or lymph nodes or with intraoperative tumor spillage.
- Radiation therapy after surgery in adult sarcomas may reduce local recurrence.

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Adult sarcomas, especially high grade, have a generally poor prognosis, with 5-yr survival rates of approximately 50%
  - Poor prognostic variables include high-grade histology, metastases at presentation, large tumor size, and incomplete resection/margin positivity
- Local recurrence alone is associated with a better survival rate than local recurrence with concomitant metastasis
- Pediatric patients with Wilms tumors can expect a >90% cure rate, but prognosis for clear

cell sarcoma and especially rhabdoid tumors is much worse

COMPLICATIONS

Children should be monitored for long-term effects of radiation and/or chemotherapy (such as cardiac dysfunction, HTN, secondary malignancies, endocrinologic abnormalities, and ovarian or testicular failure)

FOLLOW-UP

- Careful patient monitoring is essential due to the high recurrence rate
  - Adults: Close follow-up for 2–5 yr
    - CXR every 3–6 months
    - Abd MRI or CT screening every 3–6 min
    - No specific tumor markers to follow
  - Children: Same as adults. Try to limit studies such as CT due to long-term ionizing radiation risks.

CODES

ICD9

- 171.5 Malignant neoplasm of connective and other soft tissue of abdomen
- 236.91 Neoplasm of uncertain behavior of kidney and ureter

ICD10

- C49.4 Malignant neoplasm of connective and soft tissue of abdomen
- D41.00 Neoplasm of uncertain behavior of unspecified kidney
- D41.01 Neoplasm of uncertain behavior of right kidney

CLINICAL/SURGICAL PEARLS

- Primary renal sarcomas are very rare. Soft tissue sarcomas that involve the kidney are the more common presentation.
- Renal sarcomas are more likely to be seen in childhood than adulthood. Wilms tumor is the most common pediatric renal sarcoma and has a distinct treatment algorithm.
- The primary treatment of renal sarcomas is surgical excision. Wide excision is the preferred approach due to sarcomas' tendencies toward skip lesions. Local recurrences should be resected when feasible.
- It is important to differentiate renal or soft tissue sarcomas from RCC with sarcomatoid features, which is an aggressive variant of RCC, *not* a primary sarcoma.

RENAL TRAUMA, ADULT

Lee C. Zhao, MD, MS
Allen F. Morey, MD, FACS

BASICS

DESCRIPTION

- Renal injuries can occur by either blunt or penetrating trauma
  - Renal contusions, renal laceration, and renal vascular injury are the general categories
- Renal injury classification: Based on American Association for the Surgery of Trauma (AAST) renal injury grading system (1)
  - Grade I: Subcapsular hematoma
  - Grade II: Laceration <1 cm deep into cortex, small hematoma with Gerota's fascia
  - Grade III: Laceration >1 cm into medulla, no collecting system injury
  - Grade IV: Laceration into collecting system, vascular segmental vein or artery injury, renal pelvis laceration and/or complete ureteral pelvic disruption
  - Grade V: Main renal artery or vein injury or thrombosis
  - Substratification of grade IV injuries (2)[B]
    - Grade IVb: Higher risk of intervention (angioembolization or exploration) if 2 or more
      - Active vascular extravasation
      - Perinephric hematoma >3.5 cm
      - Medial/complex laceration

EPIDEMIOLOGY

Incidence

- 1–3% of all traumatic injuries
- Most commonly injured GU organ

Prevalence

Estimated 245,000 cases of traumatic renal injuries per year, world wide

RISK FACTORS

- Blunt trauma
  - Rapid deceleration
    - Motor vehicle
    - Falls
    - Direct strike to abdomen or flank (sports injury related, bicycle accident, pedestrian in motor vehicle accident [MVA])
- Penetrating trauma
  - Upper abdominal
    - Stab, gunshot, or industrial injury
- Iatrogenic injury
  - Laparoscopic, endourologic, renal biopsy, percutaneous procedures

PATHOPHYSIOLOGY

- Kidneys are well protected in the retroperitoneum
  - Deceleration can lead to intimal tearing of renal artery and thrombosis

ASSOCIATED CONDITIONS
- Rib fractures
- Injury to other organ systems

GENERAL PREVENTION
- General trauma preventative measures
  - Restraints in motor vehicles

DIAGNOSIS
HISTORY
- Ample trauma history:
  - Allergies
  - Medications
  - Past medical history
  - Last meal
  - Event
- Contrast allergy, previous renal surgeries, stones, trauma, cancer

PHYSICAL EXAM
- Tachycardia and hypotension suggest major bleeding
- Primary survey
  - Flank contusion
  - Abdominal tenderness

ALERT
Degree of hematuria does not correlate with degree of injury.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis
  - Hematuria >90% of renal injuries
  - Hematuria absent in 36% renal vasculature injuries
  - Hematuria with hypotension predictor for major renal injury
- Basic labs: Hgb, Hct, Cr, electrolytes

Imaging
- Indications for imaging
  - Blunt trauma
    - Hypotension (SBP < 90) and hematuria
    - Gross hematuria
    - Clinical indicators of renal injury from mechanism or associated injury
  - Penetrating trauma
    - Any degree of hematuria
- US

- Focused abdominal sonography for trauma (FAST) used in some centers for detection of hemoperitoneum
- CT
  - Contrast enhanced is best
  - Delayed films to evaluate urine leak and collecting system
  - Medial urine extravasation
- IV urography (IVP)
  - While mostly replaced by CT scan, single shot intraoperative IVP when pre-op imaging is not available before abdominal exploration in the OR with a film under patient on OR table
    - Single plain film 10 min after 2 mL/kg of IV contrast (max 150 mL)

Diagnostic Procedures/Surgery

Angiography may be performed if embolization is being considered

DIFFERENTIAL DIAGNOSIS

- Spontaneous hemorrhage in patients with renal mass: Traumatic or atraumatic
  - Renal angiomyolipoma
  - Renal cell carcinoma
  - Wunderlich syndrome: Atraumatic renal hemorrhage
- Injury to other organs

TREATMENT

GENERAL MEASURES

- Supportive care
- Assessment of associated injuries
- Decision for nonoperative or operative management of renal injuries (for operative management see “Surgery/Other Procedures” below)
- Nonoperative management: Blunt trauma
  - Hemodynamically stable patients with well-staged renal injury may be managed nonoperatively
  - 97% blunt renal injuries can be managed nonoperatively (1)[B]
  - Monitor with serial Hct and imaging
  - Consider angiography and embolization as alternative to renal exploration
    - Large perinephric hematoma and extravasation of contrast predictive for need of angiographic embolization (3)[B]
  - Isolated renal injuries
    - Most managed nonoperatively except for grade V pedicle avulsion
    - Consider placement of ureteral stent for persistent urine extravasation
- Nonoperative management: Penetrating trauma
  - 55% of stab wounds and 24% of GSW can be managed nonoperatively
  - If laparotomy is required for other reasons explore the retroperitoneum for pulsatile, expanding hematoma

MEDICATION

First Line
- Basic fluid and transfusion management
- Broad-spectrum antibiotics for penetrating injury and blunt trauma with urinary extravasation or large retroperitoneal hematoma

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Indications for operative management
  - Absolute: Persistent bleeding, expanding and pulsatile retroperitoneal hematoma
  - Relative: Urine extravasation, urinoma, nonviable parenchyma, delayed diagnosis, segmental arterial injury
  - Isolated urine extravasation can be managed nonoperatively with expectation of >90% resolution (4)[B]
    - Stent placement if no resolution after 3–7 days
  - Nonviable tissue >20%, then complications are greater
- Renal exploration: Transperitoneal approach
  - Early isolation of vessels
  - Retroperitoneal exploration for expanding and pulsatile hematoma
- Renal reconstruction
  - Debridement of nonviable tissue, closure of collecting system, coverage of parenchymal defect
  - For polar injury, consider partial nephrectomy with removal of devitalized tissue

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
Bed rest for nonoperative management

Complementary & Alternative Therapies
N/A

ONGOING CARE
PROGNOSIS
Most blunt trauma does not require surgical intervention and prognosis is excellent

COMPLICATIONS
- Urinoma/urinary extravasation
  - May require internal stent or external drainage
- Urinary fistula
- Delayed bleeding
- Perinephric abscess
- Sepsis
- Calculus formation

- Hydronephrosis
- Hypertension
  - Due to renal vessel injury
  - Compression of kidney
  - Posttraumatic AV fistula
- Pseudoaneurysm

FOLLOW-UP

Patient Monitoring

- Bed rest for continued hematuria
- Repeat CT scan
- Serial Hct

CODES

ICD9

- 866.00 Injury to kidney without mention of open wound into cavity, unspecified injury
- 866.01 Injury to kidney without mention of open wound into cavity, hematoma without rupture of capsule
- 866.02 Injury to kidney without mention of open wound into cavity, laceration

ICD10

- S37.009A Unspecified injury of unspecified kidney, initial encounter
- S37.019A Minor contusion of unspecified kidney, initial encounter
- S37.039A Laceration of unsp kidney, unspecified degree, init encntr

CLINICAL/SURGICAL PEARLS

- CT with IV contrast is single best study.
- Most blunt renal trauma is managed nonoperatively.
- Angioembolization should be considered for stable patients with isolated renal laceration and renal vascular laceration.
- Renal vascular avulsions should be explored.
- Grade IV renal injuries may be substratified by additional findings of active vascular extravasation, perinephric hematoma, medial/complex laceration.

RENAL TRAUMA, PEDIATRIC

Kymora Scotland, MD, PhD
T. Ernesto Figueroa, MD, FAAP, FACS

BASICS

DESCRIPTION

- Traumatic injury overall is the leading cause of childhood death in the United States.
- Pediatric renal trauma is subdivided into blunt and penetrating mechanisms of injury.
- The pediatric kidney is believed to be more susceptible to trauma vs. the adult kidney.
- Over the past 2 decades, the management of pediatric renal trauma has shifted from operative intervention to conservative management.

EPIDEMIOLOGY

Incidence

- 10–20% of all abdominal blunt trauma involves a renal injury.
- 90% of GU injuries are from blunt trauma.
- Nearly 90% of patients with GU injuries have coexisting injuries to the thorax, spine, pelvis, or intra-abdominal organs.

Prevalence

N/A

RISK FACTORS

- Pre-existing GU abnormalities (ie, ureteropelvic junction obstruction horseshoe kidney vs. pelvic kidney):
  - 3–5-fold more common in pediatric patients undergoing CT for trauma
  - Classically presents with a history of hematuria disproportionate to the severity of trauma
- Decrease in physical renal protective mechanisms:
  - More pliable thoracic cage and weaker abdominal muscles
  - Less renal fat
  - Position of the kidney within the abdomen

Genetics

Disorders that lead to an increase in GU anomalies have a greater risk for traumatic injury

PATHOPHYSIOLOGY

- Tissue or organ injury from external source of energy
- Grading system:
  - Grade I: Subcapsular hematoma, microscopic or gross hematuria, normal radiographic studies
  - Grade II: Nonexpanding perirenal hematoma or cortical laceration <1 cm deep
  - Grade III: Laceration >1 cm in parenchyma without collecting system rupture or urine extravasation
  - Grade IV: Parenchymal laceration through renal cortex, medulla, collecting system; contained main renal artery or vein hemorrhage

– Grade V (shattered kidney): Renal pedicle avulsion, multiple parenchymal lacerations, major injury to the renal vessels, urinary extravasation

ASSOCIATED CONDITIONS
Injury to other organ systems

GENERAL PREVENTION
Measures that decrease traumatic injury in general, such as seat belts, air bags

DIAGNOSIS

HISTORY
- Mechanism of injury: Degree of actual traumatic injury may not correlate with the mechanism
  – Blunt: Falls, automobile collision, sporting injuries, etc.
  – Penetrating: Gunshot wound, stabbing, etc.
- Vital signs in the field:
  – Hypotension: Children will often have a normal BP despite a significant blood loss.
- Hematuria: Unlike adults, an unreliable indicator of underlying renal injury in children:
  – Up to 70% of children with grade II or higher renal injury may have neither gross nor microscopic hematuria.
- Medical history: Any acute or chronic medical conditions and any previous GU abnormality
- Surgical history: Previous urologic procedure for reflux, stone, hypospadias, etc.
- Iodine or latex allergy
- Loss of consciousness

PHYSICAL EXAM
- Vital signs and ABCD of resuscitation to stabilize patient
- BP is often normal in severely hypovolemic children
- Exposure: Observe for obvious signs of abdominal/flank/thoracic trauma, abdominal/flank tenderness, flank ecchymosis, gross hematuria, pelvic instability
- DRE: Observe for perineal ecchymosis
- If blood at the urethral meatus, do not insert catheter

ALERT
Degree of hematuria does not correlate with degree of injury.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CBC, basic metabolic profile, coagulation profile
- Urinalysis
  – Unreliable in determining the extent of GU trauma
  – Up to 70% of children with grade II renal trauma will have neither gross nor microscopic hematuria.

ALERT
The patient's hemodynamic status determines when and what type of imaging modality is indicated.

Imaging

- Indications for radiographic imaging: All penetrating abdominal trauma or blunt trauma victims with 1 of the following criteria (1):
  - Significant deceleration or high-velocity injury: MVA, fall from >15 ft
  - Trauma resulting in fracture of the thoracic cage, spine, pelvis, or femur, or bruising of the torso/perineum
  - Acute peritonitis
  - Gross hematuria
  - Microscopic hematuria (>50 RBC/HPF) associated with shock (SBP <90 mm Hg)
  - Delayed hemorrhage following renal trauma
- CT:
  - Currently the most commonly used imaging modality in these patients
  - Triphasic abdominal and pelvic CT (ideally): Clinically stable patients; most sensitive method for diagnosing and classifying GU trauma, precontrast phase, nephrogram phase after injection of contrast, and delayed images at 15 min. The downside of this is radiation exposure.
  - Single-phase CT: Clinically labile patients; allows for determination of renal perfusion and major renal fractures. This can be followed by a KUB to assess renal integrity.
  - Delayed CT: Obtained postoperatively after patient is stabilized or after patient is resuscitated in the ICU for full trauma evaluation; used to assess grade 3–5 renal injuries 2–3 days posttrauma to assess for baseline hematoma or urinoma
- Focused assessment with sonography for trauma (FAST):
  - Often combined with serial physical exams as a screening modality after blunt trauma
  - Sensitivity ranges from 70–85% and specificity ranges from 93–100%; operator dependent
  - Option in areas with limited radiologic resources
- Arteriography:
  - Used for diagnosis of arteriovenous fistula in the setting of delayed hemorrhage following renal trauma
- Retrograde pyelography:
  - Rule out presence of partial/total ureteral disruption
  - Management of symptomatic urinoma with placement of ureteral stent
- Single-shot IVP:
  - Increasingly limited role
  - Done after patient is hemodynamically stable following trauma-exploratory laparotomy; allows for visualization of functioning contralateral kidney when considering unilateral nephrectomy
- DMSA scan:
  - Allows for quantification of renal function for grade 3–5 injuries; obtain at least 1 wk after traumatic injury, also indicated
- Follow-up imaging:
  - Triphasic CT is indicated for patients with persistent fever, worsening flank pain, or gross hematuria >72 hr after injury

Diagnostic Procedures/Surgery

N/A

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
Injury to other major abdominal viscera in the setting of acute trauma

TREATMENT

GENERAL MEASURES
- The major challenge facing the urologist in evaluating pediatric renal trauma is in determining when to surgically intervene.
- The decision to intervene operatively is based on 3 clinical indicators: Hemodynamic stability, accurate radiographic staging, presence of associated organ injuries (2).
- In general:
  - Irrespective of the mechanism of injury and provided there are no absolute indications for abdominal exploration then all renal trauma can be observed.
  - Renal exploration and renorrhaphy for grade III or higher renal injuries should be carried out if laparotomy is necessary for coexisting intra-abdominal injuries.
  - Renal exploration may be excluded in patients with concurrent intra-abdominal injuries if the urinary tract is separated from the enteric tract by omentum or other tissue, and adequate drains are left in place.
- Renal injury classification: Based on American Association for the Surgery of Trauma (AAST) renal injury grading system (see “Renal Trauma, Adult”)

MEDICATION
First Line
- Basic fluid and transfusion management
- Broad-spectrum antibiotics for penetrating injury and blunt trauma with urinary extravasation or large retroperitoneal hematoma

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Absolute indications for renal exploration:
  - Hemodynamic instability from a renal source
  - Expanding or pulsatile retroperitoneal hematoma
  - Inability to stop persistent or delayed hemorrhage via selective vascular embolization
- Relative indications for renal exploration:
  - Patients with vascular instability resulting in an inability to obtain adequate preoperative radiographic studies
  - Retroperitoneal hematoma found at the time of surgical exploration
  - Known grade III or higher renal injury during concomitant abdominal exploration: Either perform renal exploration with renorrhaphy or separation of GI from GU tract and drain placement
- Renal salvage via renorrhaphy or partial nephrectomy requires complete exposure of the injured kidney, debridement of nonviable tissue, repair of the collecting system, and ligation

of all bleeding vessels.
  – Renal pelvic or ureteral injuries should be closed watertight; if not, then ureteral stents or nephrostomy tube may be necessary.
  – Nephrectomy should be considered in the setting of irreparable grade IV–V injures and in cases where nephrectomy would help control bleeding in the coagulopathic or hypothermic patient.
  – Renal vascular injuries: The kidney is an end organ; segmental renal vessel repair should not be attempted, main renal artery reconstruction should only be considered if patients are hemodynamically stable and have either a solitary kidney or bilateral renal injuries.
  – Endoscopic stent placement and/or percutaneous placement of perirenal drain or nephrostomy tube in cases of expanding urinoma

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Nonoperative management (3)
  – Initially only for if hemodynamically stable
  – Admission to ICU for monitoring is warranted:
    - Bed rest, monitor urine output, serial abdominal exams, serial hemoglobin/HCT, resuscitate and transfuse as necessary
- Ideal candidate will have grade I–II injury
- Patients with isolated grade III, IV, and V renal injuries are candidates for nonoperative treatment:
  – Conservative management of isolated grade III–IV renal injuries will prevent 95% of patients from requiring operative intervention
  – Angiographic, endoscopic, or percutaneous intervention will be required in up to 55% of patients

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Based on the overall renal function following the traumatic injury
- Renal vascular HTN
  – Usually develops within 36 mo after injury
  – DMSA scan is indicated to determine differential renal function
  – CT angiogram may be necessary to rule out arteriovenous fistula as the source of HTN
- End-stage renal disease
  – Bilateral renal injury
  – May require peritoneal or hemodialysis

FOLLOW-UP

Patient Monitoring

- Repeat CT of the kidney 2–3 days after trauma for grade III or higher renal injuries.
  - Have low threshold for repeat CT if patient has decreasing hemoglobin/HCT despite blood transfusion or if child is hemodynamically unstable.
- Ambulation should resume when gross hematuria resolves.
  - Strenuous physical activity should be avoided for 6 wk.

CLINICAL/SURGICAL PEARLS

Hemodynamically stable patients can be managed conservatively.

RENAL TUBULAR ACIDOSIS

Steve Dong, MD

BASICS

DESCRIPTION

- Renal tubular acidosis (RTA) is a metabolic condition characterized by abnormal urinary acidification due to a defect in renal tubules, resulting in hyperchloremic nonanion gap metabolic acidosis, increased pH of the urine
- 4 major types of RTA are now considered to be only 3:
  - Type I (distal): Defective distal tubular H+ secretion
  - Type II (proximal): Defective proximal tubular bicarbonate reabsorption
  - Type III (mixed): No longer considered as a distinct entity
  - Type IV: Aldosterone deficiency/resistance

EPIDEMIOLOGY

Incidence

- RTA I: More common in adults (2/3 adults, 1/3 children) and women; endemic in certain regions of Thailand
- RTA II: Usually more predominant in males associated with Fanconi syndrome; urinary loss of glucose, amino acids, uric acid, phosphate, and bicarbonates
- Most RTAs are sporadic occurring at any age. Familial RTA are rare and usually occurs in childhood.

RISK FACTORS

- Genetic disorders
- Secondary to systemic disease. See "Commonly Associated Conditions."

Genetics

- Familial RTA I (1):
  - Autosomal dominant (AD) form is associated with mutation in anion exchanger 1 gene
  - Autosomal recessive (AR) form is due to a mutation in the B1 or H^+-ATPase (V-ATPase) gene and associated with sensorineural deafness
- Familial RTA II:
  - AD form is rare
  - AR form associated with ocular abnormalities and mental retardation
  - AR form associated with osteopetrosis and cerebral calcification
  - AR form associated with Fanconi syndrome
- Familial RTA IV: Associated with pseudohypoaldosteronism type 1

PATHOPHYSIOLOGY

- Type I (distal) tubular acidosis: Secondary to impaired ability to secrete hydrogen ions into the distal tubule or collecting duct. Urine pH $>$ 5.5.
- Type II (proximal) tubular acidosis: Impaired bicarbonate absorption in the proximal tubule. Urine pH may be $<$5.5.

- Type IV: Presence of aldosterone resistance or deficiency leading to hyperkalemia (not seen in type I and II) along with acidosis. Urine pH may be <5.5.

ASSOCIATED CONDITIONS

- Acquired RTA type I:
  - Autoimmune disease: Systemic lupus erythematosus (SLE), Sjögren syndrome, primary biliary cirrhosis, chronic active hepatitis
  - Chronic pyelonephritis
  - Diseases causing nephrocalcinosis
  - Drugs (amphotericin B, lithium, analgesics)
  - Ehlers–Danlos syndrome
  - Fabry disease
  - Glycogenosis type III
  - Hepatic cirrhosis
  - Hypercalciuria
  - Hypergammaglobulinemic syndrome
  - Leprosy
  - Malnutrition
  - Medullary cystic disease
  - Obstructive uropathy
  - Sickle cell disease, hereditary elliptocytosis
  - Toxins (toluene, glue)
  - Vitamin D intoxication
  - Wilson disease
- Acquired RTA type II:
  - Fanconi syndrome due to toxin-related or immunologic nephrotoxic damage
  - Tubular toxicity causing acute tubular necrosis:
    - Sepsis
    - Rhabdomyolysis
    - Hypotension
    - Nephrotoxins: Intravenous (IV) contrast, aminoglycoside antibiotics
  - Interstitial renal disease:
    - Multiple myeloma
    - Heavy met al poisoning (cadmium, lead, mercury)
    - Medications (methicillin, cisplatin, adefovir, tenofovir, COX-2 inhibitors, cimetidine, acetazolamide, sulfanilamide, ifosfamide, tetracycline, Topamax)
    - Infections: Leptospirosis, corynebacterium, diptheria, polyomavirus, cytomegalovirus
    - Autoimmune disease: SLE, Sjögren's syndrome, sarcoidosis
  - Amyloidosis
- Acquired RTA type IV:
  - Addison disease
  - Diabetic nephropathy
  - Hypertension
  - Lupus nephropathy
  - Obstructive nephropathy

– Tubulointerstitial nephropathies
• Gordon syndrome
• Sickle cell nephropathy

GENERAL PREVENTION
N/A

DIAGNOSIS

HISTORY
• Failure to thrive, rickets, and osteomalacia in children
• Anorexia, nausea, vomiting
• Weakness and polyuria due to potassium loss
• Constipation
• Polydipsia
• History of hematuria, urinary tract infections (UTIs), passage of stones in urine
• History of recurrent, familial, or childhood renal stone disease
• Ask about systemic diseases causing RTA

PHYSICAL EXAM
• Urologic exam of genitalia, suprapubic area for swelling and tenderness
• Exam for osteomalacia, hypokalemic muscle weakness, and growth retardation
• Exam for other systemic diseases

DIAGNOSTIC TESTS & INTERPRETATION
Lab
• Renal function test usually normal
• Electrolytes and blood gas reveal hyperchloremic, nonanion gap metabolic acidosis:
– Hypokalemia or normokalemia in type I and II
– Hyperkalemia in type IV
• Urine pH (fasting, under oil, pH meter):
– pH > 5.5: Complete type I RTA
– pH > 5.5, but systemic acidosis mild or absent: Ammonium chloride loading test and measure urinary bicarbonates; failure of urine pH to go below 5.5 is diagnostic of RTA (1) [C]
• RTA II is diagnosed by bicarbonate loading test: After IV bicarbonate infusion, fractional excretion of bicarbonate >15% is diagnostic (1)[C]
• Urine calcium: High in type I, normal in type II
• Phosphaturia, glycosuria, and aminoaciduria in Fanconi's syndrome

Imaging
• Plain x-ray and computed tomography (CT) urogram:
– Likely to demonstrate nephrocalcinosis and nephrolithiasis

Pathologic Findings
• Nephrocalcinosis
• Nephrolithiasis
• Osteomalacia

DIFFERENTIAL DIAGNOSIS

- Other causes of metabolic acidosis (2)[C]
  - Lactic and ketoacidosis, chronic renal failure, chronic diarrhea, etc.
- Azotemia
- Bilateral stones
- Calcium phosphate stones
- Chronic pyelonephritis
- Hypocitraturia < 0.5 mmol/24 h
- Hypokalemia
- Medullary nephrocalcinosis
- Medullary sponge kidney
- Recurrent stones: >2/yr

TREATMENT

GENERAL MEASURES

- Identifiable causes, such as obstructive uropathy or drug-induced RTA, should be corrected or eliminated
- If there is no identifiable etiology, then direct treatment to correction of acidosis

MEDICATION

First Line

- Alkali therapy decreases stone formation and growth, prevents nephrocalcinosis, normalizes growth retardation in children, and corrects hypokalemia in most cases:
  - Oral alkali therapy: In both type I and type II RTA with the goal of treatment to restore urinary citrate to high-normal levels, and not simply correct the metabolic acidosis (3)[C]
    - Sodium bicarbonate (7.7 mEq HCO_3/tab)
    - Bicitra (1 mEq Na, 1 mEq citrate/mL)
    - Polycitra (1 mEq Na, 1 mEq K, 2 mEq citrate/mL)
  - Type I RTA generally requires lifelong treatment:
    - 1–4 mEq/kg/d of oral bicarbonate or citrate in 2–3 divided doses in adults (4)[C]
    - May require potassium supplementation for hypokalemia
- Type II (proximal) RTA:
  - 5–20 mEq/kg/d in 4–6 doses/d due to the severe bicarbonate wasting.
  - Adults with bicarbonate levels >10 mEq/mL and no evidence of bone disease may not require treatment.
  - Supplemental potassium, calcium, vitamin D, and phosphate may become necessary.
- Type IV RTA treatment is directed toward correction of hyperkalemia rather than acidosis:
  - Dietary potassium restriction
  - Thiazide or loop diuretics
  - Mineralocorticoid replacement in cases of adrenal disease or hyporeninemia (fludrocortisone 0.1 mg/d)

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Management of stone by shock wave lithotripsy, ureteroscopy, percutaneous nephrolithotomy, and rarely, open surgery
- Management of obstructive uropathy

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Monitor osteoporosis

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Primary RTA I: Although a permanent disease, prognosis is excellent if diagnosis and treatment initiated early.
- Prognosis of other RTAs depends on associated disease

COMPLICATIONS

- Hypercalciuria
- Hyperkalemia or hypokalemia
- Nephrocalcinosis
- Nephrolithiasis
- Osteomalacia/osteoporosis

FOLLOW-UP

Patient Monitoring

- Spot urine testing for NAG (N-acetyl-β-D-glucosaminidase) has eliminated the need for 24-hr urine collection. Levels increased secondary to renal tubular cell damage and hypercalciuria.
- Urinary calcium excretion should be kept <0.05 mmol/kg/d in infants and children
- Potassium levels should be monitored during alkali therapy and replaced appropriately
- Monitor underlying disease as indicated

CODES

ICD9

- 255.42 Mineralocorticoid deficiency
- 276.7 Hyperpotassemia
- 588.89 Other specified disorders resulting from impaired renal function

ICD10

- E27.40 Unspecified adrenocortical insufficiency
- E87.5 Hyperkalemia
- N25.89 Oth disorders resulting from impaired renal tubular function

CLINICAL/SURGICAL PEARLS

- Type I RTA is the only type associated with increased stone formation, nephrocalcinosis.
- Potassium levels should be monitored during alkali therapy for RTA and replaced appropriately.
- A young person with multiple stones with systemic acidosis and high urine pH, a diagnosis of type I RTA should be considered.

RENAL VEIN THROMBOSIS, ADULT AND PEDIATRIC

Adonteng A. Kwakye, MD

BASICS

DESCRIPTION

- Renal vein thrombosis (RVT) is an acute or chronic thrombosis in the renal vein leading to a reduction in venous drainage of the kidney.
- In infants, RVT typically presents as a severe illness, occasionally with colicky pain:
  - 60% have enlarged kidneys on physical exam; gross hematuria and microangiopathic hemolytic anemia and thrombocytopenia can also be present
- In the adult, RVT presentation depends on onset of RVT:
  - Acute RVT: Triad of sudden flank pain
  - Costovertebral angle tenderness and gross hematuria only present in minority of cases.
  - Chronic RVT: Generally asymptomatic;
    - Can have proteinuria and microscopic or gross hematuria.

EPIDEMIOLOGY

Incidence

- Newborns and infants:
  - Commonly associated with hypoxia, dehydration, shock, and/or sepsis
  - Usually acute and unilateral (more common on the left side); although 30% bilateral
  - Male-to-female ratio 2:1 in the neonate, with no sex predilection beyond age 1
  - Accounts for approximately 10% of venous thrombosis in newborns
  - Most common form of thrombosis not associated with a vascular catheter (1)
- Adults:
  - Associated with nephrotic syndrome (reported incidence of RVT in patients with nephrotic syndrome ranges from 5–62%), renal cell carcinoma, or renal transplantation
  - More often chronic and unilateral

Prevalence

N/A

RISK FACTORS

- Newborn/infant:
  - Acute hypoxia
  - Birth trauma
  - Cyanotic congenital heart disease with polycythemia
  - Cytomegalovirus infection
  - Dehydration from diarrhea/vomiting
  - Maternal diabetes, polyhydramnios
  - Hyperosmolar state form angiocardiography
  - Preterm (<36 wk) infants at greater risk
  - Sickle cell disease
- Adult:

- Abdominal tumors, especially renal cell carcinoma
- Endothelial damage
- Intrinsic hypercoagulability (eg, Factor V Leiden deficiency)
- Nephrotic syndrome:
- Membranous nephropathy: Lesion most frequently associated with nephrotic syndrome–related RVT; also reported in many other nephropathies.
- Use of oral contraceptives, steroids
- Renal transplantation, particularly in those taking OKT-3 and cyclosporine for immunosupression
- Shock, sepsis, dehydration
- Trauma
- Use of IV contrast agents
- Vasculitis
- Compression from aortic aneurysm, lymphadenopathy, retroperitoneal fibrosis (2)

Genetics

Unknown

PATHOPHYSIOLOGY

- Newborn/infant:
  - Diminished intrarenal blood flow due to hypovolemia (sepsis, dehydration, diarrhea)
  - Creates prothrombotic state
  - Clot can then propagate in antegrade and/or retrograde manner, resulting in RVT
  - May become bilateral, produce vena caval occlusion and/or renal artery thrombosis
  - 65% in neonates, 30% beyond 1 yr age
  - Associated with adrenal hemorrhage in 15% of cases
- Adults: Most often unilateral; acute and chronic forms described:
  - Acute RVT: Severe dehydration, sudden hypercoagulability, renal vein obstruction from tumor or transplant rejection
  - Chronic RVT:
    - Nephrotic syndrome leads to alterations in coagulation pathway that creates prothrombotic conditions (3)
    - RVT is a result of nephrotic syndrome and not the cause
    - Slow onset allows the development of collateral venous kidney drainage

ASSOCIATED CONDITIONS

- DVT in patients with nephrotic syndrome
- Pulmonary embolus

GENERAL PREVENTION

- Adults: Long-term anticoagulation is appropriate if RVT has recurred when patients discontinued anticoagulation
- Treatment of underlying cause

DIAGNOSIS

HISTORY

- Newborn/infant:
  - Risk factors: Mother's history, birth, and early postnatal course
  - Gross hematuria
- Adult:
  - Sudden onset of hematuria and flank pain should raise the question of RVT, as should a history of nephrotic syndrome in the presence of hematuria

PHYSICAL EXAM

- Newborn/infant:
  - Unilateral, or often bilateral, flank masses
  - Evidence of dehydration
  - Evidence of cyanotic heart disease
  - If the thrombosis is bilateral, oliguria may be present; urine output may be normal with a unilateral thrombus (4)
- Adult:
  - Evidence of blunt trauma, abdominal mass
  - Edema or anasarca suggestive of nephrotic syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Newborn/infant:
  - Thrombocytopenia, leukocytosis, hemolytic anemia
  - Consumptive coagulopathy (prolonged clotting time, elevated fibrinogen and fibrin split products)
  - Proteinuria
  - Elevated BUN and creatinine
- Adult:
  - Proteinuria and microscopic hematuria
  - Hemolytic anemia, consumptive coagulopathy, and thrombocytopenia may be present
  - Elevated BUN and creatinine
  - Hypoalbuminemia
  - Marked elevation in LDH with normal transaminases

Imaging

- Newborn/infant:
  - The extent of thrombus may be assessed by duplex ultrasonography, and only rarely will CT, MRI, or renal venography be required for confirmation of the diagnosis or determination of the extent of thrombus
  - Ultrasonography: Enlarged and echogenic kidneys (90%) with attenuation or loss of corticomedullary differentiation
    - Doppler studies may detect increased resistance or absence of flow in renal venous branches; increased resistance in the renal artery may be present
    - Doppler ultrasonography is the primary modality for the detection of RVT; however, its utility is operator specific (3)
  - IVP: Delayed opacification and renomegaly
  - A renal scan may be obtained to assess the function of the involved kidney.

  - MRI is more expensive and requires sedation in pediatric patients (6)
- Adult:
  - Inferior vena cavography with selective catheterization of the renal vein is the gold standard for the diagnosis.
  - CT findings are similar in noninvasive evaluation of acute RVT.
    - Sensitivity of CT angiography approaches 100%; considered current imaging modality of choice
    - Low attenuation within the renal vein; proximal venous enlargement
    - Capsular venous collaterals, thickened Gerota's fascia and pericapsular stranding
  - Doppler ultrasonography is helpful, especially in a transplanted kidney.
  - MRI: Excellent imaging; avoids iodinated contrast, but concerns with gadolinium in patients with renal insufficiency
  - IVP
    - Faint or absent excretion of contrast
    - Enlarged kidney due to congestion
    - Collateral circulation may cause collecting system opacification and/or notching of ureter
    - Renal pelvis is often distorted

Diagnostic Procedures/Surgery

Renal biopsy in the setting of nephrotic syndrome and RVT confirms etiology and may guide therapy

Pathologic Findings

- Membranous nephropathy is the most common finding in the setting of nephrotic syndrome and RVT.
- In infants the condition is pathologically more correctly described as "renal venous thrombosis" as the interlobular and arcuate renal veins are primarily affected rather than the main renal vein in adults.

DIFFERENTIAL DIAGNOSIS

- Other causes of flank pain (eg, urolithiasis, pyelonephritis, renal infarction)
- Renal cell carcinoma with direct compression or tumor thrombus
- Renal vein leiomyosarcoma (filling defect)

TREATMENT

GENERAL MEASURES

- Evaluate and treat all underlying causes
- Aggressive rehydration and treatment of sepsis, diarrhea, and electrolyte abnormalities

MEDICATION

First Line

- Newborn/infant:
  - Use of thrombolytic agents is reported, but controversial
  - Systemic heparinization:
    - Prevents thrombus propagation into vena cava (risk of propagation low with fluid and

electrolyte repletion).
  - Used in neonates with bilateral RVT
  - Equivocal results regarding long-term preservation of renal function
- Adult:
  – Unilateral RVT: Heparin anticoagulation and long-term anticoagulation with warfarin:
  – Optimum duration of anti-coagulation unknown
  – Most experts feel that warfarin should be continued for as long as nephrotic syndrome persists (3).

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Infants: No role for surgical thrombectomy
- Thrombectomy in adults:
  – Rarely used, because neither renal preservation nor improvement in survival demonstrated
  – Surgical thrombectomy (either open or percutaneous) in patients with acute bilateral RVT with poor prognosis
  – Postoperative posttransplant RVT
- Nephrectomy in highly selected patients for lifesaving measures
- Radical nephrectomy and thrombectomy in renal cell carcinoma

ADDITIONAL TREATMENT
- Infants with renal failure—dialysis if needed
- IVC filters are indicated in high-risk adult patients for pulmonary embolism.

Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Neonates: Mortality rate of 3%
- The kidney may recover completely, atrophy, or recover partially, resulting in renovascular hypertension or chronic tubular dysfunction.
- Nephrectomy may be required if renovascular hypertension or chronic infection develops.
- ACE inhibitors and/or angiotensin II receptor blockers may decrease proteinuria from nephrotic syndrome as decreased urinary protein loss decreases hypercoagulability.

COMPLICATIONS (5)
- Consumptive coagulopathy
- Pulmonary embolism

- Renal failure
- Loss of graft in transplant patient

FOLLOW-UP

Patient Monitoring

- Newborn/infant:
  - Renal function may be followed using nuclear scanning. Atrophy is often detected long term. About 5% of affected neonates progress to dialysis or transplantation.
  - Monitor blood pressure, as renovascular hypertension may occur after RVT in ~20%, even with normal renal function.
- Adult:
  - Treat cause of nephrotic syndrome
  - Long-term anticoagulation as preventive measure in nephrotic syndrome not supported
  - Because RVT may be asymptomatic, all patients with nephrotic syndrome should be monitored for symptoms of RVT

CODES

ICD9

• 453.3 Other venous embolism and thrombosis of renal vein
• 581.9 Nephrotic syndrome with unspecified pathological lesion in kidney
• 788.0 Renal colic

ICD10

• I82.3 Embolism and thrombosis of renal vein
• N04.9 Nephrotic syndrome with unspecified morphologic changes
• N23 Unspecified renal colic

CLINICAL/SURGICAL PEARLS

• Renal vein thrombosis (RVT) is associated with nephrotic syndrome in adults.
• Membranous nephropathy is most common pathology in RVT with nephrotic syndrome.
• Newborns and infants more likely than adults to have bilateral RVT.

RETROGRADE EJACULATION

Pravin K. Rao, MD

BASICS

DESCRIPTION

- Expulsion of semen from posterior urethra into bladder with low- or zero-volume antegrade ejaculate.
- Suspected in men with symptoms or semen analysis findings suggesting low or absent ejaculate volume.
- Primary implications are for infertility.
  - Also: Sexual function/satisfaction.
- No other known medical health effects.
- Men with failure of emissions are often labeled as having "retrograde ejaculation."
  - Failed deposition of ejaculate contents into posterior urethra before expulsion.

EPIDEMIOLOGY

Incidence

- 74–78% incidence after transurethral prostate surgery (1)[B]
- 4–26% incidence with α-blocker tamsulosin (2,3)[A]
- As low as 14% incidence after bilateral nerve-sparing retroperitoneal lymph node dissection (RPLND) (4)[B]

Prevalence

N/A

RISK FACTORS

- Bladder neck/prostate procedures
  - Transurethral resection of the prostate
  - Transurethral incision of the prostate (TUIP)
  - Bladder neck incision (BNI)
- Surgical/traumatic/congenital neuropathy
  - Retroperitoneal surgery
    - eg, RPLND
  - Pelvic surgery
    - eg, abdominoperineal resection
  - Spinal cord injury (SCI)/surgery
  - Spina bifida/myelomeningocele
- Medical neuropathy
  - Diabetes mellitus (DM)
  - Multiple sclerosis (MS)
- Iatrogenic from medications
  - α-blockers
    - Reduce bladder neck muscle tone

- Reduce seminal emissions
- Tamsulosin, terazosin, doxazosin

– Antipsychotic and psychotropic medications
- Risperidone

– Antidepressants
- Selective serotonin reuptake inhibitors

Genetics

N/A

PATHOPHYSIOLOGY

- Normal ejaculation requires:
  – Seminal emission
  – Bladder neck closure
  – Antegrade expulsion from urethra
- Neurologic control:
  – Central control in multiple brain regions
    - Can promote or inhibit ejaculation
  – Sympathetic (T12–L3):
    - Hypogastric nerve (thoracolumbar)
    - Seminal "emission" into posterior urethra by contraction of epididymis, vas deferens/ampulla, seminal vesicle (SV), and prostate smooth muscle
    - Bladder neck closure preventing retrograde ejaculation
  – Parasympathetic (S2–S4):
    - Pelvic nerve
    - Gland secretions of prostate SV
  – Somatic (S2–S4):
    - Pudendal nerve
    - Efferents from sacral cord
    - Contraction of bulbocavernosal and ischiocavernosal muscles
    - Relaxation of external urethral sphincter
    - Projectile expulsion of ejaculate
  – Sensory
    - Pudendal nerve
    - Tactile stimulation of penis can activate ejaculatory reflex
- Retrograde ejaculation occurs from impaired bladder neck closure due to various causes
  – Poor coaptation of bladder neck
    - Medication side effect
    - Prostate surgery
    - Idiopathic
  – Neural disruption
    - Spinal cord injury (SCI)
    - Diabetes mellitus (DM)
    - Retroperitoneal lymphnode dissection (RPLND)
    - Pelvic surgery

ASSOCIATED CONDITIONS
- See risks factors
- Benign prostatic hyperplasia (BPH)
- Bladder neck dysfunction
- Diabetes mellitus (DM)
- Multiple sclerosis (MS)
- Rectal cancer
- Testicular cancer

GENERAL PREVENTION
- Avoidance of iatrogenic causes
- Nerve sparing during RPLND

DIAGNOSIS
HISTORY
- Absence or presence of orgasm
- Presence of erectile dysfunction
- Cloudy urine after sex/orgasm
- Symptoms of hypogonadism
- Medical history (see risk factors)
- Surgical history (see risk factors)
- Medications (see risk factors)
- Accuracy of semen analysis findings:
  - Low measured volume may be due to spillage
  - Some patients report subjective low volume only at time of sample collection
    - Anxiety due to lab/atmosphere
    - Anxiety related to medical condition

PHYSICAL EXAM
- Usually normal physical exam findings
- Absent vasa suggests congenital absence of the vas deferens
- Small testes may suggest hypogonadism
- Seminal vesical (SV) dilation may suggest ejaculatory duct obstruction (EDO)
- Muscle weakness or focal neurologic deficit may suggest primary neurologic cause

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- If ejaculate volume <1.5 cc, consider postejaculatory urinalysis (PEU)
- PEU
  - >10–15 sperm/HPF is diagnostic for retrograde ejaculation
  - Small number of sperm may be normal
  - Technique:
    - Abstain from ejaculation 2–3 days
    - Empty bladder
    - Collect/attempt antegrade ejaculate
    - Collect urine by void or catheter

- Endocrine evaluation if clinical suspicion for hypogonadism

Imaging

Only performed for concurrent medical conditions

Diagnostic Procedures/Surgery

N/A

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Anejaculation
- Anorgasmia (inability to reach orgasm)
- Aspermia due to failure of emission
- Congenital bilateral/unilateral absence of the vas deferens
- EDO
- Erectile dysfunction
  - Failure to reach orgasm
  - Poor expulsion of ejaculate through flaccid penile urethra
- Hypogonadism
- Semen spillage in lab
- Poor semen collection technique

TREATMENT

GENERAL MEASURES

- Treatment typically reserved for fertility purposes
- Treat reversible causes
- Modify causative medications
  - Change or discontinue causative medications
  - Some clinicians favor alfuzosin for BPH (possibly less RE than other α-blockers)

MEDICATION

First Line

- α-adrenergic agents
  - Dosing structure highly variable:
    - Pseudoephedrine 60 mg
    - Ephedrine 25–50 mg
    - Imipramine 25–50 mg (may cause dizziness and nausea)
    - Frequency ranges from QD to QID
    - Duration ranges from 2–14 days
    - Side effects: HTN, tachycardia
- Author recommendation: Pseudoephedrine 60 mg QID × 2–7 days prior to ejaculation (titrate to effectiveness)
- Medical therapy less likely to be effective after bladder neck injury or surgery

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Sperm retrieval
  - For use with assisted reproductive techniques
    - IUI (intrauterine insemination)
    - IVF In vitro fertilization
    - ICSI Intracytoplasmic sperm injection
- Sperm retrieval technique
  - Prior to collection, alkalinize urine to pH 7
    - Sodium bicarbonate 650 mg QID or 1–3 tablespoons of baking soda, 12–48 hr before collection
  - Catheterize or void for collection
- Sperm retrieval from the testis and epididymis, an option for unsuccessful retrograde collection
  - Adoption and use of donor sperm can prevent the need for IVF/ICSI

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Success rates with assisted reproductive techniques largely dependent on female factors
- 44% pregnancy rates with intrauterine insemination (5)[C]

COMPLICATIONS

- Main issue is infertility
- Emotional distress

FOLLOW-UP

Patient Monitoring

Follow up semen analysis to determine effectiveness of medical therapy

Patient Resources

CODES

ICD9

- 355.9 Mononeuritis of unspecified site
- 608.87 Retrograde ejaculation
- 606.9 Male infertility, unspecified

ICD10

- G62.9 Polyneuropathy, unspecified
- N46.8 Other male infertility
- N53.14 Retrograde ejaculation

CLINICAL/SURGICAL PEARLS

In men with spinal cord injury (SCI) or history of retroperitoneal surgery, men may have failure of seminal emission, so sperm retrieval from the bladder may not be feasible.

RETROPERITONEAL ABSCESS

Jessica H. Hannick, MD
Ahmer V. Farooq, DO

BASICS

DESCRIPTION

- A retroperitoneal abscess is an infectious process that involves the retroperitoneum.
- The retroperitoneum spans anteroposteriorly from the peritoneum to posterior pariet al wall of the abdominal cavity and craniocaudally from the diaphragm to the pelvic floor.
- Most common source of infection is from renal diseases.

EPIDEMIOLOGY

Incidence

Reported highest incidence in 3rd–6th decades.

Prevalence

N/A

RISK FACTORS

- Appendicitis
- Diabetes
- Diverticulitis
- Existing osteomyelitis or epidural infection
- GU tract obstruction
- Immunosuppression
- Inflammatory bowel disease (Crohn's disease)
- Malignancy
- Osteomyelitis
- Pyelonephritis
- Recent instrumentation or surgery of the GU or GI tract
- Systemic infection (ie, hematogenous spread from remote infection)
- Trauma
- Tuberculosis

PATHOPHYSIOLOGY

- Retroperitoneal abscess is an infectious process that can be found in 1 of 4 retroperitoneal compartments (1):
  - Anterior retroperitoneum:
    - Esophagus, duodenum, pancreas, bile duct, portal and splenic veins, appendix, ascending/descending colon, rectosigmoid
  - Posterior retroperitoneum (aka perinephric/perirenal):
    - Kidneys, ureters, gonadal vessels, aorta, inferior vena cava, lymphatics
    - See "Renal and Perirenal Abscess"
  - Retrofascial (aka iliopsoas):

    - 12th rib, spine, paraspinous muscles
  - Pelvic retroperitoneal:
    - Prevesical, retrovesical, presacral, perirectal spaces
- Primary infection if spread is hematogenous (75–90% *Staphylococcus aureus*)
- Secondary infection if spread is from infected adjacent organs (78% enteric bacteria).
- Most common source is from renal diseases accounting for 47% of retroperitoneal abscesses.
- Infection seeds a contained space in retroperitoneum:
  - Depending on the source, anaerobic and aerobic organisms may be present.
  - Usual source is normal flora from a nearby organ site (eg, GI, GU, female reproductive tract).
  - Multimicrobial infections are common.
  - Malignancy frequently violates fascial barriers, whereas abscesses tend to be contained by the fascia.
  - Hypoxia and lack of appropriate blood supply limit effective immune response.
  - If untreated, bacteremia, followed by shock ensues.
- TB and *Staphylococcus* (skin source) were previously major pathogens, but are less common today.
- *Proteus* and *Escherichia coli* are the most commonly cultured bacteria in retroperitoneal abscesses.
- Common pathogens (aerobic and anaerobic) (2,3):
  - Enterobacteriaceae:
    - *E. coli*
    - *Klebsiella pneumonia*
    - *Proteus* sp.
    - *Pseudomonas aeruginosa*
  - Anaerobes:
    - *Peptostreptococcus* sp.
    - *Bacteroides fragilis*
    - *Prevotella* sp.
    - *Clostridium* sp.
  - *Enterococcus* sp.
  - *Streptococcus* sp.
  - *S. aureus*
- Site-specific pathogens:
  - Pancreatic abscess:
    - *S. aureus*
    - *K. pneumoniae*
    - *P. aeruginosa*
  - Pelvic retroperitoneal:
    - *Neisseria gonorrhoeae*
    - Streptococcus B
  - Anterior retroperitoneal:
    - *Clostridium* sp.
    - *Fusobacterium nucleatum*

ASSOCIATED CONDITIONS
- Diabetes, liver disease, renal insufficiency, immunosuppression, retroperitoneal hematoma
- GU specific: Urinary tract infection (UTI), urolithiasis, instrumentation/surgery, malignancy
- GI specific: Malignancy, surgery, pancreatic pathology

GENERAL PREVENTION
Perioperative antibiotic prophylaxis

DIAGNOSIS
HISTORY
- Abdominal or flank pain (60–75%)
- Sweats, fever, and chills (30–90%)
- Malaise (10–22%)
- Nausea/vomiting
- Altered bowel habits
- Dysuria
- Weight loss (12%)
- Duration of symptoms is typically longer than 1 wk
- Recent instrumentation/surgery/trauma
- Recent treatment for UTI
- History of urolithiasis, inflammatory bowel disease, pancreatitis, diverticulitis, appendicitis, osteomyelitis, malignancy, TB
- Medical comorbidities: Diabetes, renal insufficiency, immunosuppression (ie, HIV)

PHYSICAL EXAM
- General vital signs:
  - Fever
  - Tachycardia
  - Tachypnea
- Unlike peritoneal cavity, retroperitoneum is relatively concealed on exam.
- Assess for:
  - Tenderness: Usually localized, dull, and mild
  - Costovertebral angle tenderness
  - Palpable flank/abdominal mass
  - Lower abdominal, groin, and/or upper thigh referred pain due to irritation of retroperitoneal nerves
  - Psoas sign: Increased pain when flexing patient's thigh against examiner's hand; suggests involvement of psoas muscle

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Lab findings often nonspecific (ie, elevated ESR)
- Obtain CBC (leukocytosis)
- BMP: Serum glucose often elevated
- Urinalysis
  - Approximately 30% will have microscopic hematuria.

  – Pyuria is also very common.
• Urine/blood/abscess cultures

Imaging
• Cross-sectional CT or MRI is most helpful:
  – CT (100% sensitivity, 77% specificity):
    ○ Low-density mass in retroperitoneum with surrounding inflammation
    ○ Gas may be present in approximately 33% of cases
    ○ Evaluates surrounding organs (ie, possible sources)
• MRI:
  – Thick purulent collections have high-intensity signal on T1-weighted images
  – Edema in surrounding fat seen as high signal on T2-weighted images
  – High soft tissue contrast resolution sensitive for detecting psoas muscle pathology and intervertebral disc involvement
  – May not show calcifications or gas collections
• US: Can reveal gas/fluid collections
• KUB: May show psoas shadow, loss of renal outline, displacement of organs, gas, or urolithiasis
• Gallium^{67} citrate and indium^{111} chloride scanning can be helpful:
  – False positives: Pyelonephritis, acute tubular necrosis, vasculitis, and neoplasms
• Chest x-ray may show elevation of hemidiaphragm, pleural effusions, secondary pneumonia

Diagnostic Procedures/Surgery
• CT, MRI, or US-guided aspiration and drainage of abscess cavity
• Specimens must be sent for both aerobic and anaerobic cultures
• Consider sending for AFB culture

Pathologic Findings
Coagulation necrosis

DIFFERENTIAL DIAGNOSIS
• Malignancy
• Necrotizing fasciitis
• Osteomyelitis
• Pancreatitis
• Perforated viscus (ie, duodenal ulcer)
• Perinephric aneurysm/pseudoaneurysm
• Perinephric/perirenal abscess
• Psoas abscess
• Pyelonephritis
• Ruptured aortic aneurysm
• TB
• Trauma/retroperitoneal hematoma
• Urinoma

TREATMENT

GENERAL MEASURES

- Supportive care
- DVT prophylaxis

MEDICATION

First Line

- Broad-spectrum antibiotics to empirically cover most likely pathogens (ampicillin, gentamicin, and metronidazole) (4)
  - Refine antibiotic coverage based on culture results
  - Tailor duration of treatment to clinical progress

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Early percutaneous drainage (5)
  - Essential in lesions >3 cm
  - May consider antibiotics only in abscesses <3 cm
- Surgical drainage must be considered if:
  - Safe percutaneous drainage not possible
  - Percutaneous drainage has failed
  - Multiple abscesses
  - Multiloculated abscesses
  - Purulent material too thick to be drained
  - If patient is persistently febrile after 48–72 hr of appropriate antibiotics
  - If primary cause must be addressed surgically (ie, xanthogranulomatous pyelonephritis (XGP), malignancy, urolithiasis)
- Surgical approach should be retroperitoneal unless pancreatic pathology is present:
  - Obtain cultures
  - Irrigate abscess cavity aggressively
  - Use drains liberally

ADDITIONAL TREATMENT

Radiation Therapy

No role

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Mortality is considerable (5–50%) despite modern management that combines antibiotics, drainage, and intensive care support.
- High success with antibiotics and percutaneous drainage (>80%):

- Only 1–4% recurrence with percutaneous drainage
- If abscess is not drained and only antibiotics are used, mortality approaches 100%

COMPLICATIONS
- Abscess crossing the midline to opposite side or tracking into the ipsilateral thigh
- DVT
- GI bleed
- Organ failure
- Pneumonia
- Secondary infections: Osteomyelitis, involvement of psoas muscle, fistulization to the skin

FOLLOW-UP

Patient Monitoring
- Reimaging necessary
  - CT or MRI (MRI avoids radiation)
  - Timing depends on clinical progress
- Drains:
  - Must be monitored carefully and irrigated appropriately
- Can be removed when:
  - Patient is clinically improved
  - Drainage stops (<10 mL/d) or becomes serous
  - Abscess cavity involution is documented on imaging

CLINICAL/SURGICAL PEARLS

• Nonspecific signs and symptoms frequently lead to a delay in diagnosis and treatment.
• Early percutaneous drainage is essential in lesions >3 cm.

RETROPERITONEAL FIBROSIS (RPF, ORMOND DISEASE)

Steve Dong, MD
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION

- Retroperitoneal fibrosis (RPF) also refered to as Ormond disease, is characterized by sclerotic tissue from inflammatory processes causing encasement of the retroperitoneal structures including the ureters, aorta, and inferior vena cava. The main manifestation is obstructive uropathy.
- Exhibits a perivascular distribution, typically including the periaortic, pericaval, and peri-iliac retroperitoneum.
- Generally classified as either primary (idiopathic) or secondary RPF.
- Hallmark is medial deviation of the ureters on imaging with or without hydronephrosis.

EPIDEMIOLOGY

Incidence

- In Finland, incidence is 0.1:100,000/yr
- Unknown, but estimated at 1:200,000–1:500,000/yr

Prevalence

1–38 per 100,000

RISK FACTORS

- Asbestos exposure
- Associated with autoimmune disorders
- Abdominal aortic aneurysm
- Male > Female (2–3:1)
- RPF most common in the 5th–6th decades, but can occur at any age
- Use of implicated medications (see below)
- Malignancy

Genetics

- Evidence suggests an immunogenetic role with certain HLA haplotypes:
  – HLA-DRB1*03 and HLA-B*08

PATHOPHYSIOLOGY

- Idiopathic RPF recently identified as a immunoglobulin G4-related disease (IgG4-RD) and is a multisystem, fibroinflammatory condition (1)
- Most commonly, the retroperitoneal thickening is located between L5 and S1, close to the aortic bifurcation
- Mechanical obstruction of the ureters is usual presentation; may also cause venous or arterial occlusion
- Primary RPF:
  – 70% of cases are idiopathic, and the exact pathogenesis is unclear

- Mitchinson and Parums classify idiopathic RPF in a range of diseases collectively termed chronic periaortitis
  - Immune-mediated reaction to antigens (ceroid and low-density lipoprotein) within atherosclerotic plaques
  - Often have autoantibodies, and thus overlap with many autoimmune disorders
  - IgG4-bearing plasma cells may also be involved in the pathogenesis of RPF
- Secondary RPF: 30% of patients with RPF have an identifiable cause of their RPF:
  - Medications:
    - Prolonged therapy with ergot alkaloids such as methylsergide (Sansert, once widely used for migraine headaches)
    - Others include LSD, methyldopa, phenacetin, β-blockers, amphetamines, hydralazine, and analgesics
  - Malignancy:
    - Lymphoma (most common), multiple myeloma, carcinoid, pancreatic tumors, prostate cancer, testicular cancer, and sarcoma
  - Radiotherapy for malignancies such as seminoma, colon, or pancreatic cancer
  - Infections: Tuberculosis, actinomycosis, histoplasmosis
  - Others: Trauma (hemorrhage, urinary extravasation), surgical injury, Crohn disease, inflammatory bowel disease, asbestos exposure, fat necrosis, collagen vascular disease, perianeurysmal inflammation

ASSOCIATED CONDITIONS

- Atherosclerotic disease (abdominal aortic aneurysm)
- Autoimmune diseases: Ankylosing spondylitis and Wegener granulomatosis
- Membranous glomerulonephritis
- Multifocal fibrosclerosis: RPF may present as part of a systemic sclerosis
  - Presentation may include sclerosing mediastinitis, sclerosing cholangitis, orbital pseudotumor, and Riedel thyroiditis

GENERAL PREVENTION

Avoid medication implicated in RPF (see above)

DIAGNOSIS

HISTORY

- Constitutional symptoms (fatigue, weight loss, anorexia, low-grade fever)
- Pain (back, flank, abdominal) and duration
- Signs of vascular obstruction:
  - Testicular pain, varicocele, hydrocele, leg edema, deep vein thrombosis, claudication
- GI symptoms such as weight loss, nausea, anorexia, constipation, or vomiting
- Urinary symptoms, including frequency, and dysuria, also oliguria if severe
- Medication history especially ergot alkaloids
- History of malignancies, other autoimmune or collagen vascular diseases, fibrotic processes, inflammatory bowel diseases, asbestos exposure, radiation exposure
- Surgical history:
  - Abdominal, vascular, or endoscopic procedures

PHYSICAL EXAM

- Patient can appear pale, ill, and has malaise if significant azotemia is present
- Low-grade fevers and hypertension
- Abdominal exam: Mass, abdominal bruit, costovertebral angle tenderness
- Testicular masses
- Lower-extremity edema, varicosities

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- No tests are diagnostic
- Metabolic profile: Electrolyte abnormalities will depend upon the degree of ureteral obstruction
- Erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) are usually elevated
- Ferritin and other acute phase reactants are often high
- Polyclonal hypergammaglobulinemia
- ANA is positive in 60% of patients along with other autoantibodies including antismooth muscle antibodies and rheumatoid factor

Imaging

- Excretory Urography (2):
  - Medial deviation of the ureters with tapering of the middle 1/3 of the ureter beginning at the 3rd or 4th lumbar vertebra
  - Varying degrees of hydronephrosis; may see a nonfunctioning kidney
  - Encasement of ureters may prevent dilation of middle and distal ureteral segments
- Ultrasound (US)
  - More useful for following the response to therapy
- Computed tomography (CT)
  - Imaging modality of choice
  - Typically shows a symmetric, geometrically shaped mass encasing the retroperitoneal structures
  - Demonstrates the medial deviation of the ureters and extrinsic compression with hydronephrosis
  - Mass is often isodense to muscle with contrast enhancement
- Magnetic resonance imaging (MRI)
  - Hypodensity on T1 images but high intensity on T2-weighted images
- Positron emission tomography (PET):
  - Investigational; may visualize other disease sites
  - May reveal neoplastic or infectious processes to which the RPF may be secondary

Diagnostic Procedures/Surgery

- Retrograde pyelography may be indicated in patients with severe azotemia prohibiting the use of contrast-enhanced imaging. Usually shows medial deviation of ureters.
- CT-guided biopsy may be necessary to rule out a malignant process.

Pathologic Findings

- Gross findings secondary RPF:
  - Smooth, flat, firm, grayish/tan-colored mass

– Extends from the origin of the renal vessels to the distal extent of the common iliac vessels
– May also involve the thoracic aorta and other atypical areas
• Microscopic findings
– Early findings: Collagen bundles with capillary proliferation and inflammatory cells
– Later acellular and avascular mass with sheets of hypocellular collagen
– Vasculitis of small retroperitoneal vessels with plasma cells staining for IgG4 (rarest IgG subclass)

DIFFERENTIAL DIAGNOSIS
• Medial deviation of the ureters
– Malignancies, aneurysms, bladder diverticulum, and prior surgery
– 20% of normal individuals have medial deviation of the ureters, especially on the right
• Retroperitoneal mass: See also Section I "Retroperitoneal masses, fluid, and cysts"
– Malignant processes; inflammatory myofibroblastic tumors
– Desmoid-type fibromatosis; associated with Gardner syndrome; presents as soft tissue mass with mass effect

TREATMENT

• Discontinue any offending medications
• Relieve urinary obstruction:
– Monitor for postobstructive diuresis after the urinary system is decompressed
• Biopsy to rule out malignancy
• Unclear if trial of steroids or immediate ureterolysis is optimal therapy

MEDICATION
First Line
• After ureteral obstruction has been relieved, 1st-line therapy is generally glucocorticoids (prednisone). No consensus as to duration of therapy:
– Prednisone 60 mg every other day for 2 mo, then tapered over 5 mo to 5 mg/d
– Alternate regimen: 60 mg/d for 6 wk, and tapered over the next 2–3 mo to 10 mg/d for a total of 1 yr

Second Line
• In patients with glucocorticoid-resistant RPF or who have recurrent disease, immunosuppressive agents may also be helpful:
– Prednisone in combination with cyclophosphamide or azathioprine for 6–12 mo
– Mycophenolate mofetil has also been used in combination with glucocorticoids

SURGERY/OTHER PROCEDURES
• Relief of ureteral obstruction:
– Ureteral stents may be helpful during subsequent ureterolysis
– Usually not difficult; often elect to stent both sides even if not bilaterally obstructed to prevent obstruction or provide guide for surgery
• Percutaneous nephrostomy undertaken only in acutely ill patients; rarely necessary
• Ureterolysis:
– May be performed via an open approach (transabdominal) or laparoscopically (hand-

assisted or standard) (3)
  – Ureters are often wrapped in omentum or intraperitonealized to prevent further fibrous entrapment
- Other procedures: May require ileal interposition graft, autotransplantation, nephrectomy, or urinary diversion in complicated or severe cases

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Observation:
  – There may be a role in patients on methylsergide after discontinuation of the medication if normal renal function.
  – These patients should be monitored for resolution of hydronephrosis. If the hydronephrosis does not resolve, then the standard combination of medical and surgical therapy should be administered.
- Tamoxifen has been used
- Low-protein, sodium-restricted diet for patients with renal insufficiency

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Prognosis is excellent with combined medical and surgical therapy

COMPLICATIONS

- Recurrence of RPF: Typically in 1st yr; usually limited to those treated with medical therapy
- Ureteral injury, requiring further surgical management
- Vascular injury
- Postoperative adhesions due to intraperitoneal procedure

FOLLOW-UP

Patient Monitoring

- Patients can be monitored at regular intervals with symptom check, ESR/CRP levels, creatinine, and degree of hydronephrosis on US
- CT/MRI is usually performed 2–4 mo after the beginning of the steroid treatment (1)
- Patients treated with definitive surgical intervention require less frequent follow-up

CODES

ICD9

• 590.80 Pyelonephritis, unspecified
• 593.4 Other ureteric obstruction
• 599.60 Urinary obstruction, unspecified

ICD10

• N13.5 Crossing vessel and stricture of ureter w/o hydronephrosis.
• N13.6 Pyonephrosis.
• N13.9 Obstructive and reflux uropathy, unspecified.

CLINICAL/SURGICAL PEARLS

• Although no tests are diagnostic of RPF, most will present with medial deviation of the ureters on imaging.
• CT is the image modality of choice.
• Stents are often placed for relief of obstruction.
• Patients who fail steroid treatment without evidence of malignancy should undergo ureterolysis.

RETROPERITONEAL MASSES, FLUID, AND CYSTS

Mark R. Anderson, MD, MSc
Judd W. Moul, MD, FACS

BASICS

DESCRIPTION

- Retroperitoneal masses and cysts can originate from retroperitoneal organs or nonorgan tissue. The latter are relatively rare.
- 70–80% of primary retroperitoneal neoplasms are malignant in nature, and these account for 0.1–0.2% of all malignancies in the body.
- Most cystic lesions within the retroperitoneum are benign; unless the lesion is mostly solid then suspect malignancy.
- Metastatic disease is the most common etiology of a solid retroperitoneal mass.
- Liposarcomas are among the most common of primary retroperitoneal tumors and are distinguished by their often large dimensions and range of subtypes.
  - Peak incidence: Ages 40–60.
  - 10–15% of sarcomas, and approximately 20% of these lesions arise in the retroperitoneum.
  - Often recur usually within the 1st 6 mo after surgery.

EPIDEMIOLOGY

Incidence

Retroperitoneal sarcoma: Accounts for $<1\%$ of all adult malignancy, or 9,500 new diagnoses per year, ~ 2.7 cases per million per year of retroperitoneal sarcoma

Prevalence

N/A

RISK FACTORS

- Primary, solid/cystic retroperitoneal mass: Previous radiotherapy (dose dependant), chemical exposure (vinyl chloride, arsenic), HIV/AIDS
- Primary, cystic retroperitoneal mass: Parasitic infection, embryonic remnants, prior lymphadenectomy

Genetics

- Tuberous sclerosis (TS1, TS2 mutation, tumor suppressor loss)
- Werner syndrome (chromosome 8 alteration, premature aging)
- Li–Fraumeni syndrome (p53 mutation, tumor suppressor loss)
- Neurofibromatosis (NF1, NF2 mutation)
- Liposarcomas are being reclassified based on a molecular basis. Well-differentiated and dedifferentiated lesions are a continuum of lesions based on the genetic abnormality of giant and ring chromosomes usually involving chromosome 12.
- Gene amplification, particularly of *MDM2,* drives their pathology.
- Myxoid and round-cell lesions are another continuum that have fusion transcripts caused by

translocations in chromosomes 16 and 12.
- Alveolar rhabdomyosarcoma t(2;13) (q35;q14) PAX3-FKHR, and t(1;13) (p36;q14) PAX7-FKHR
- Sporadic gastrointestinal stromal tumor activating kinase mutations KIT or PDGFRA

PATHOPHYSIOLOGY
- The retroperitoneum extends from the diaphragm superiorly to the pelvis inferiorly and is situated between the posterior pariet al peritoneum anteriorly and the transversalis fascia posteriorly (1).
- The anterior pararenal space is bordered anteriorly by the posterior pariet al peritoneum, posteriorly by the anterior renal fascia (Gerota fascia), and laterally by the lateroconal fascia.
- The anterior pararenal space is subdivided into the pancreaticoduodenal space (contains the pancreas and duodenum) and the pericolonic space (contains ascending and descending colon).
- The posterior pararenal space is situated between the posterior renal fascia (Zuckerkandl fascia) and the transversalis fascia.
- The perirenal space is located between the anterior renal fascia and the posterior renal fascia.
- The great vessel space is the fat-containing region that surrounds the aorta and the inferior vena cava (IVC) and lies anterior to the vertebral bodies and psoas muscles.
- Below the kidneys, the anterior and posterior pararenal spaces merge to form the infrarenal retroperitoneal space, which communicates inferiorly with the prevesical space and extraperitoneal compartments of the pelvis.
- Due to the loose connective tissue in the retroperitoneum, tumors can have widespread growth and extension before clinical presentation.

ASSOCIATED CONDITIONS
N/A

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Headaches, palpitations, etc. for hypertension secondary to pheochromocytoma
- Unexplained weight loss
- Constitutional symptoms
- Night sweats
- History of chemotherapy, radiation therapy
- Back or bone pain
- Medications: Methysergide, methyldopa, LSD
- GI complaints: Nausea, vomiting, pain, constipation, increasing abdominal girth

PHYSICAL EXAM
- Vitals for hypertension

- Cachexia
- Lymphadenopathy
- Neurologic deficits from paraneoplastic syndrome
- Lower-extremity lymphedema
- Breast exam
- Testicular exam
- Abdominal mass
- Signs of virilization

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC: Leukocytosis (infection or lymphoma), leukopenia, anemia
- Serum chemistry: Elevated serum creatinine, azotemia (obstructive uropathy), transaminitis (biliary obstruction), and elevated alkaline phosphatase (bone involvement).
- AFP, LDH, and β-HCG: Testicular tumor markers
- ESR: Elevated in retroperitoneal fibrosis
- Urinalysis: Hematuria, pyuria
- Urine cytology: Evidence of a malignant urothelial source
- Blood and urine culture
- Adrenal mass: Pheochromocytoma screen
  - Plasma metanephrines
    - 96–100% sensitivity, 85–89% specificity
  - 24-hr urine-fractionated metanephrines
    - 91–98% sensitivity and specificity

Imaging

- Adrenal: CT washout for adenoma, MRI “light bulb” sign/T2 bright for carcinoma and pheochromocytoma, MIBG scan for pheochromocytoma (2)
- CT urogram for RCC and urothelial carcinoma
- CT can show enhancement, fat density, water density to help characterize underlying components
- MRI better at defining local invasion
- Ultrasound can differentiate between solid and fluid-filled masses but not good at determining malignant potential or regional mets.
- CT with contrast has relative contraindication if GFR <60, MRI has relative contraindication if GFR <30.
- MAG-3 diuretic renal scan can determine relative differential function between each kidney and urine obstruction.
- Testicular sonogram for mass
- Bone scan, mammogram if needed
- Cystogram if pelvic lipomatosis

Diagnostic Procedures/Surgery

- Image-guided biopsy: CT- or US-guided fine-needle aspiration is usually feasible, but core-needle biopsy improves diagnostic capability
- Open surgical biopsy: Best option if the mass is small and inconveniently located for needle

biopsy
- Be prepared to complete the resection if sarcoma identified
- Aspiration of cyst: Fluid for cytology, culture, creatinine
- Angiogram: To delineate relationship of tumor to vascular anatomy or to determine extent of aneurysm

Pathologic Findings
- Metastasis pathology is consistent with primary tumor pathology.
- Determination of benign vs. malignant tissue is not always possible, leaving final determination to the surgical pathology.
- Well-differentiated liposarcomas mostly resemble lipomas and are typically low grade.
- Pleomorphic liposarcomas comprise 10–15% defined as high-grade malignant variants with very bizarre nuclei and huge lipoblasts and carry poor prognosis.
- Liposarcoma is most common (35%), followed by leiomyosarcoma (30%), malignant fibrous histiocytoma (20%), rhabdomyosarcoma, and peripheral nerve neoplasm.
- Lymphoma: Diffuse, monomorphous proliferation of lymphocytes.
- Fibrosis: Cellular and acellular variants coexist; fibroblast and collagen proliferation.

DIFFERENTIAL DIAGNOSIS
- Solid masses—Benign (malignant variant in parenthesis)
  - Lipoma (liposarcoma)
  - Leiomyoma (leiomyosarcoma)
  - Fibroma (chondro-, synovial cell-, fibrosarcoma)
  - Rhabdomyoma (rhabdomyosarcoma)
  - Hemangioma (angiosarcoma)
  - Perivascular epithelioid cell tumor (PECT): Angiomyolipoma, lymphangioleiomyomatosis, clear cell "sugar" tumor, clear cell myomelanocytic tumor, pigmented melanotic tumor (sarcoma variants)
  - Gastrointestinal stromal tumor, aka GIST
  - Myxoma (myxosarcoma)
  - Chordoma
  - Schwannoma, neurofibroma
  - Ganglioneuroma, ganglioneuroblastoma (neuroblastoma)
  - Paraganglioma, pheochromocytoma (pheochromocytoma)
  - Mature teratoma (seminoma, nonseminoma germ cell tumors; choriocarcinoma, malignant teratoma, yolk sac, embryonal, mixed)
  - Sex cord: Granulose, thecoma, Sertoli–Leydig (rarely malignant)
  - Malignant lymphoma, extramedullary plasmacytoma, fibrous histiocytoma
- Cystic malignant masses
  - Mucinous cystadenoma or cystadenocarcinoma
  - Mesothelioma
  - Cystic teratoma
  - Paraganglioma, neurilemmoma, sarcoma
- Cystic nonmalignant mass
  - Hematoma
  - Urinoma

– Lymphocele
– Pancreatic cyst and pseudocyst
– Lymphangioma
– Postoperative seroma

TREATMENT

GENERAL MEASURES

- Need tissue diagnosis via primary excision or needle biopsy
- Core biopsy better than fine needle if possible

MEDICATION

First Line

- Metastatic lesions and lymphoproliferative cancers are best treated with systemic, tumor-specific chemotherapy (in most cases).
- Sarcomas respond variably to chemotherapy, depending on the histology, and generally do not influence survival.
- Pheochromocytoma needs α-blocking blood pressure control, followed by β-blockade. Some advocate single agent calcium channel blockade.
- May need stress steroids if functional adrenal tumor suppresses contralateral function.
- Infected retroperitoneal cysts are treated with broad-spectrum (gram positive and negative) antibiotics until culture sensitivities are known:
  – Ampicillin 1 g IV q6h (gram positive)
  – Gentamicin 5–7 mg/kg/d (gram negative)

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Metastatic site resection may be beneficial for prognosis and/or symptoms for RCC and testicular tumors
- Liposarcoma needs primary excision
- Extensive lymph node resection commonly needed in liposarcoma and testicular cancer (modified templates used in some instances)
- Benign cysts can be aspirated and sclerosed

ADDITIONAL TREATMENT

Radiation Therapy

- Retroperitoneal sarcoma is typically radiation resistant.
- Intraoperative radiotherapy for sarcoma has been shown to improve local control rates, but does not improve survival.

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- 5- and 10-yr survival following surgical resection of retroperitoneal sarcoma is 45% and 29%.
- Poorly differentiated liposarcoma metastasize.
- Completely resected, nonmetastatic, and low-grade sarcomas are associated with improved survival.
- Leiomyosarcoma is an independent predictor of poor outcome.
- Adrenal carcinoma typically presents late stage and has poor prognosis even with complete resection.
- Pheochromocytoma has good prognosis.
- RCC has good prognosis though is most lethal GU cancer and present with mets ~25% of time.

COMPLICATIONS

- Bowel injury
- Adjacent organ injury (liver, spleen, pancreas)
- Lymphocele
- Deep vein thrombosis
- Wound infection
- Transfusion-dependent anemia

FOLLOW-UP

Patient Monitoring

Schedule imaging that is intensive during 1st 2 yr (q3–6mo) followed by biannual, migrating to annual by year 5 is generally recommended for most retroperitoneal masses.

Patient Resources

- 789.39 Abdominal or pelvic swelling, mass, or lump, other specified site

ICD10

- C48.0 Malignant neoplasm of retroperitoneum
- K68.9 Other disorders of retroperitoneum
- R19.09 Other intra-abdominal and pelvic swelling, mass and lump

CLINICAL/SURGICAL PEARLS

Most solid retroperitoneal masses are malignant.

RHABDOMYOLYSIS

Sanjay S. Kasturi, MD
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION

- Rhabdomyolysis is muscle necrosis resulting in the egress of cellular muscle particles (namely myoglobin, potassium, creatine kinase [CK], and lactic acid dehydrogenase [LDH]) into the blood stream.
- In particular myoglobin is harmful to the kidney and often causes acute kidney injury.
  – Up to 15% of patients who have rhabdomyolysis can have renal failure.
- There are many causes for rhabdomyolysis; this section primarily focuses on operative causes.

EPIDEMIOLOGY

Incidence

- 2,600 cases per year (likely underreported)
- Overall incidence of 0–4.9% in the laparoscopic nephrectomy data

RISK FACTORS

- Trauma and immobilization (1)
  – Lying unconscious on hard surface under the influence of alcohol or drugs
  – Crush injury
  – Prolonged compression as seen in excessive operating times (esp. males)
    - Laparoscopic, robotic, and open
    - Dorsal lithotomy positioning
- Elevated BMI (esp. muscle mass)
- Sepsis and shock
- Toxins (spider and snake venom [mostly in South America, Asia, Africa])
- Medications (cocaine, Ecstasy [MDMA] LSD, amphetamines, statins [especially in combination with fibrate-derived lipid-lowering agents such as niacin], cyclosporin, itraconazole, colchicine, steroids)
- Infections (HIV, influenza)
- Excessive muscle use (status epilepticus, prolonged exercise)
- Electrolyte and endocrine abnormalities (hyponatremia, hyperthyroidism, ketoacidosis)
- Electrical shock injury, lightning strike
- 3rd-degree burns
- High body temperature, heat stroke, malignant hyperthermia
- Myopathy (eg, Duchenne muscular dystrophy)

Genetics

- Suspect a genetic disorder with recurrent rhabdomyolysis after minimal to moderate exertion or after viral infections starting in childhood
  – Glycogen and lipid disorders (McArdle disease, carnitine deficiency, others)

- Duchenne muscular dystrophy

PATHOPHYSIOLOGY

- Muscle cell destruction
  - Pressure or crush
  - Cellular hypoxia
- Reperfusion injury results in large quantities of potassium, phosphate, myoglobin, CK, and urate leak into the circulation
  - Electrolyte alterations further impact cellular integrity
- Normal plasma myoglobin is very low (0–0.003 mg/dL)
  - With >100 g of skelet al muscle damaged, serum haptoglobin binding capacity becomes saturated
  - At this point circulating myoglobin becomes "free" and is filtered by the glomeruli
  - Myoglobin precipitates in the kidney and cause renal tubular obstruction, potentially leading to acute kidney injury
- Myoglobin levels return to normal values in 1–6 hr after injury due to hepatic metabolism and renal excretion
- Up to 12 L of fluid may be sequestered in the necrotic muscle tissues
  - This relative hypovolemia is an additional cause of renal failure in rhabdomyolysis
  - Free iron, which catalyses free radical production further enhances ischemic renal tubule damage
- Compartment syndrome
  - Caused by insufficient blood supply to muscles due to increased pressure within a body compartment (arm, leg, any enclosed space within the body)
  - 6 "Ps" associated with compartment syndrome: Pain out of proportion based on exam, paresthesia, pallor, paralysis, pulselessness, and pressure
  - For most prolonged operative cases the paraspinous muscles and the extremities are at risk for compartment syndrome

ASSOCIATED CONDITIONS

- Acidosis
- Cardiac arrest (hyperkalemia)
- Compartment syndrome
- Disseminated intravascular coagulation (DIC)
  - Activation of the coagulation cascade by the substances released from damaged muscle cells
- Hepatic dysfunction
- Myoglobinuric acute renal failure

GENERAL PREVENTION

- Avoid immobilization or prolonged operating times
- Appropriate patient padding in the operating room
- Some reports of using pulse oximetry monitoring of lower extremity to monitor for compartment syndrome
- Monitor for malignant hyperthermia

DIAGNOSIS

HISTORY

- Trauma
- Sepsis
- New medication
- Toxin exposure, drug use or infection
- Excessive muscle use
- Electrolyte or endocrine disorder
- Prolonged operating room time—most common reason in urology (2,3,4)
  - Most commonly reported in the laparoscopic nephrectomy data when patients are in flank or modified flank position for >6 hr but also seen in exaggerated lithotomy and steep Trendelenburg
  - Male sex predominates
  - Elevated BMI, reported mean BMI of 33.2 in review of the laparoscopic nephrectomy data

PHYSICAL EXAM

- Generalized fatigue, nausea, fevers
- Mental status changes
- Skin discoloration
- Muscular pain and swelling (symptoms may be out of proportion with exam)
- Muscle weakness
- Symptoms may be absent in 50% of patients
- Reddish-brown urine
- Classic triad of muscle pain, weakness, and dark urine

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Myoglobinuria:
  - Myoglobin only appears in the urine when serum level >1.5 mg/dL
    - Red-brown urine when urine levels >100 mg/dL
  - Positive for blood on urine dipstick but no RBCs suggests myoglobinuria (5)
  - Short half-life only 2–3 hr, so it may return to normal if muscle damage is limited
- Elevated CK levels (5× upper limit of normal which is about >1,000 U/L)
  - CK half-life of 26 hr and remains elevated longer than myoglobin, peaks at 1–3 days and declines at 3–5 days after all muscle injury has stopped
- Basic metabolic panel
  - Monitor for acute renal failure and hyperkalemia
- Calcium level:
  - Can be hypocalcemic early, then hypercalcemic later
- Uric acid:
  - Conversion of purines from lysed muscle cells
- CBC/clotting studies (for DIC)
- LFTs, ABG
- Microscopic urine: Pigmented casts, dysmorphic red cells

Imaging

- Often unnecessary
- MRI with gadolinium best modality for muscle injury
  - Sensitivity of 100% vs. 42% for US and 62% for CT scan

Diagnostic Procedures/Surgery
- Muscle biopsy is unnecessary
- Forearm ischemic test to differentiate genetic causes of rhabdomyolysis (6)
  - Relies on forearm compression with exercise and determination of ammonia and lactate levels

Pathologic Findings
- Though muscle biopsy is not needed, one would see noninflammatory loss of the nucleus and muscular stria.
- Renal biopsy: Myoglobin precipitates and forms obstructive casts.

DIFFERENTIAL DIAGNOSIS
- Acidotic states
- Compartment syndrome
- DIC
- Nephritic syndromes
- Rhabdomyolysis can be the result of another process (ie, sepsis) and result in other complications (ie, compartment syndrome, DIC)

TREATMENT

GENERAL MEASURES
- Prevention of acute renal failure (ARF)
- Recognition of compartment syndrome
- Elderly patients and those with comorbidities should be treated in an intensive care unit

MEDICATION

First Line (6,7)
- Aggressive hydration initially with normal saline
  - Urine output should be maintained at (goal of 2 mg/kg/h of urine output) until myoglobinuria has ceased
  - High rates of IV fluid administration should be used at least until the CK level decreases to or below 1,000 U/L
- Consider mannitol for osmotic diuresis to purge nephrotoxic agents
- Diuretics should not be used as they may worsen the condition
- Alkalinize urine to prevent ARF:
  - Bicarbonate: 1 ampule in 1 L of normal saline
    - Goal: Urine pH >6.5 and serum pH 7.4–7.45
- There are retrospective data to suggest aggressive hydration is sufficient for treatment and that mannitol and bicarbonate are not needed
- Avoid correction of early hypocalcemia as hypercalcemia can develop later

Second Line

May need to correct acidosis, DIC, and hyperkalemia, if present

SURGERY/OTHER PROCEDURES

- Fasciotomy for compartment syndrome.
  - For the extremity such as the leg recommendations for fasciotomy vary. In general an intracompartmental pressure of >30 mmHg or a >30 mm Hg difference between diastolic blood pressure and the compartment pressure.
- Dialysis for hyperkalemia, acidosis, and/or fluid overload.
  - In general, only 4% of patients require dialysis, but up to 55% in the laparoscopic nephrectomy data

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Monitor osteoporosis

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Overall survival rate of 78.6% at 14 yr
- Initial mortality rate as high as 8%
- ARF develops in 33% of patients
  - In review of the laparoscopic nephrectomy data, patients who developed ARF had a higher peak CK than those who did not (46,780 U/L vs. 25,650 U/L)

COMPLICATIONS

- Long-term weakness, pain, and numbness; may have permanent disability
- Morbidity associated with dialysis and fasciotomy

FOLLOW-UP

Patient Monitoring

- Check for return of renal function
- Physical therapy as needed

- 929.9 Crushing injury of unspecified site
- 958.5 Traumatic anuria

ICD10

- M62.82 Rhabdomyolysis
- T79.5XXA Traumatic anuria, initial encounter
- T79.6XXA Traumatic ischemia of muscle, initial encounter

CLINICAL/SURGICAL PEARLS

- The classic triad of muscle pain, weakness, and dark urine suggests rhabdomyolysis.
- Limit operative times especially in obese and muscular patients. Consider high BMI as a risk factor for intraoperative rhabdomyolysis.
- Some advocate not using a kidney rest/bar during laparoscopic surgery to help prevent rhabdomyolysis.
- Appropriately pad all pressure points in the operating room.
- Early recognition and aggressive hydration (better outcomes within the 1st 6 hr of presentation).

RHABDOMYOSARCOMA, PEDIATRIC (SARCOMA BOTRYOIDES)

Nicholas G. Cost, MD
Paul H. Noh, MD, FACS, FAAP

BASICS

DESCRIPTION

- Rhabdomyosarcoma (RMS) (sarcoma botryoides) is a malignancy arising from embryonal mesenchyme that tends to occur mostlyin children (Sometimes also called Embryonal Rhabdomyosarcoma)
- Most common soft tissue sarcoma in children
- Sarcoma botryoides describes a polypoid variant of RMS originating in a hollow viscus (vagina, bladder)
- Of all types of pediatric RMS15–20% involve GU system:
  - Paratesticular
  - Bladder
  - Prostate
  - Uterus
  - Vagina

EPIDEMIOLOGY

Incidence

- 0.5–0.7 cases per million children <15 yr
- Bimodal age distribution:
  - 1st peak: 2–4 yr
  - 2nd peak: 15–19 yr
- 3rd most common solid tumor in children (behind neuroblastoma and Wilms tumor)

Prevalence

N/A

RISK FACTORS

See genetics

Genetics

- Li–Fraumeni syndrome:
  - Mutation of p53 tumor suppressor gene
  - Higher incidence of RMS
- Neurofibromatosis:
  - Higher incidence of RMS
- Cytogenetic abnormalities:
  - Alveolar histology subtype:
    - 1;13 translocation (favorable prognosis)
    - 2;13 translocation (unfavorable prognosis)

  - Embryonal histology subtype:
    - Loss of heterozygosity on chromosome 11

PATHOPHYSIOLOGY

- The Latin word “botryoides” refers to the polypoid or “grape-like lesion” appearance of the tumor beneath the mucosa
  - Some sources refer to this as “embryonal RMS”
- Rapid growth with local invasion
- Can spread by lymphatic and hematogenous routes
- Thought to arise from immature cells that are destined to form striated skelet al muscle:
  - However, may arise in locations where skelet al muscle is not typically found, such as the bladder
- Defect in regulatory mechanism that controls proliferation and differentiation of skelet al muscle
- Prognosis and pattern of spread depends on histologic subtype and clinical staging
- Lymph nodes (LNs) and lungs are the most common sites of distant metastasis

ASSOCIATED CONDITIONS

See Genetics

GENERAL PREVENTION

None

DIAGNOSIS

HISTORY

- Family history of malignancy or genetic syndromes (Li–Fraumeni, neurofibromatosis)
- Bladder/prostate:
  - Urinary frequency
  - Stranguria
  - Urinary retention
  - Hematuria
- Paratesticular:
  - Scrotal swelling or pain
  - Back pain
- Vaginal/uterine:
  - Vaginal discharge/bleeding

PHYSICAL EXAM

- Bladder/prostate
  - Abdominal mass
  - Bladder distention
  - Firm prostate or mass on rectal exam
- Paratesticular
  - Scrotal mass
- Vagina/uterine
  - Vaginal mass (may be prolapsing)

- Abdominal mass

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Basic metabolic panel: BUN/Cr may be elevated with ureteral obstruction
- Complete blood count: May see anemia due to vaginal bleeding or hematuria
- β-HCG or AFP: Evaluate for testicular tumors

Imaging

- CT/MRI of abdomen/pelvis: Evaluate local extent of tumor, pelvic or retroperitoneal LN involvement, distant metastasis
- Chest x-ray/CT: Evaluate for pulmonary metastases
- PET scan: Evaluate the metabolic activity of the primary for future comparison after therapy, as well as assess for metastasis
- Bone scan: Evaluate for osseous metastasis
- Scrotal US: Characterize paratesticular mass

Diagnostic Procedures/Surgery

- Bone marrow aspirate/biopsy: Evaluate for metastases for all primary sites of RMS
- Bladder/prostate
  - Cystoscopy: Transurethral resection/biopsy for pathologic diagnosis
  - Image-guided needle biopsy: Pathologic diagnosis
- Paratesticular
  - Radical inguinal orchiectomy: Diagnostic and therapeutic
- Vagina/uterine
  - Cystoscopy/vaginoscopy: Evaluate extent of tumor, biopsy for pathologic diagnosis

Pathologic Findings

- Embryonal:
  - Most common subtype
  - Accounts for majority of GU RMS
  - Embryonal variants associated with excellent prognosis:
    - Sarcoma botryoides
    - Spindle cell/leiomyomatous
- Alveolar:
  - Less common in GU RMS
  - More common in trunk/extremity RMS
  - Higher rates of local recurrence, LN spread, and distant metastasis
- Pleomorphic:
  - Undifferentiated/anaplastic variant
  - Poor prognosis

DIFFERENTIAL DIAGNOSIS

- Bladder/prostate
  - TCC of bladder
  - Inflammatory pseudotumor of bladder
  - Nephrogenic adenoma of bladder

  - Fibroepithelial polyps of prostatic urethra
- Testis
  - Primary testicular tumor
  - Benign adnexal mass
- Vagina/uterine
  - Prolapse of ureterocele, urethra, vagina

TREATMENT

GENERAL MEASURES

- Pre- and post-op staging and risk classification are critical in evaluation and treatment planning
  - Preoperative staging: Intergroup Rhabdomyosarcoma Study Group (IRSG) staging/classification system based on TNM and primary location
  - Postoperative grouping: IRSG grouping based on primary resection
  - Risk classification: Combines stage, group, and histology—helps determine therapy and prognosis
- Preoperative staging: TNM system
  - T1: Confined to organ of origin
    - (a) ≤5 cm in diameter
    - (b) >5 cm in diameter
  - T2: Extension or fixed to surrounding tissue
    - (a) ≤5 cm in diameter
    - (b) >5cm in diameter
  - N0: Regional LNs clinically negative
  - N1: Regional LNs clinically positive
  - Nx: Unknown
  - M0: No distant metastasis
  - M1: Metastasis present
- Preoperative staging: IRSG
  - Stage 1: Vaginal and paratesticular, any T, any N, M0
  - Stage 2: Bladder/prostate, T1/T2a, N0/Nx, M0
  - Stage 3 Bladder/prostate, T1/T2a and N1, *OR* T1b/T2b, any N, M0
  - Stage 4: Any T, M1
- Postoperative grouping
  - Group I: Localized disease, completely excised, no microscopic residual
    - (a) Confined to site of origin, completely resected
    - (b) Infiltrating beyond site of origin, completely resected
  - Group II: Total gross resection
    - (a) Gross resection with microscopic local residual
    - (b) Regional disease with involved LNs, completely resected, no microscopic residual
    - (c) Microscopic local or nodal residual
  - Group III: Incomplete resection with gross residual disease or biopsy only for diagnosis
  - Group IV: Distant metastasis
- Risk grouping

  - Low risk
    - Embryonal histology, Stage 1, all groups
    - Embryonal histology, Stage 2/3, Group I/II
  - Intermediate risk
    - Embryonal histology, Stage 2/3, Group III
    - Alveolar histology, Stage 1/2/3, Group I/II/III
  - High risk
    - Any histology, Stage 4, Group IV
- All sites of GU RMS require a multidisciplinary approach to curative therapy including appropriate surgical excision, chemotherapy, and radiation (1)
- For bladder/prostate and vaginal/uterine RMS, chemotherapy is 1st-line therapy after biopsy and before radiation or extirpative surgery in all cases except rare instances amenable to immediate partial cystectomy with negative margins
- For paratesticular RMS, retroperitoneal staging is critical. Any boys <10 yr with radiologic evidence of enlargedretroperitoneal LNs, and all patients >10 yr should have an ipsilateral retroperitoneal LN dissection (RPLND). Thisshould be done to complete staging and must be done before chemotherapy or radiation (1).

MEDICATION

First Line

- Bladder/prostate
  - Low risk: Vincristine, actinomycin-D (VA)
  - Low-risk N1, intermediate risk, high-risk: VA + Cyclophosphamide (VAC)
- Paratesticular
  - VA: Stage 1, <10 yr, no evidence of LN involvement on imaging (1)
  - VAC: Positive LNs on RPLND
- Vagina/uterine (1)
  - VAC: Chemotherapy followed by repeat biopsy to assess residual disease

Second Line

- 2nd-line chemotherapy with addition of carboplatin, etoposide, irinotecan, or topotecan
- Phase I studies

SURGERY/OTHER PROCEDURES

- Bladder/prostate:
  - Partial cystectomy: Primary treatment in rare cases at dome/lateral wall where adequate margins can be obtained
  - Radical cystectomy: Performed after chemotherapy or chemoradiation if tumor not amenable to bladder-sparing options
  - Urinary diversion: Both temporary and permanent reconstructive options
  - Radical prostatectomy: Performed for isolated prostatic tumors after chemoradiotherapy
- Paratesticular:
  - Radical inguinal orchiectomy: All cases should be approached inguinally with radical resection
  - RPLND (2):
    - All >10 yr regardless of imaging

- <10 yr if evidence of LN involvement on imaging, prior to chemotherapy
- Vagina/uterine:
  - Vaginectomy: If evidence of residual disease on postchemotherapy biopsy

ADDITIONAL TREATMENT

Radiation Therapy

- Bladder/prostate:
  - Postdiagnostic biopsy, in addition to chemotherapy: Most cases (Group III)
  - Following initial attempted resection initial resection with residual margins, in addition to chemotherapy: Group II
- Paratesticular:
  - Positive LNs on RPLND
- Vagina/uterus:
  - After chemotherapy or surgical resection unless an initial upfront resection (Group I)

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Bladder/prostate:
  - 3-yr disease-free survival (3)
    - Embryonal: 83% (Botryoid variant: 92%) (4)
    - Alveolar: 40%
- Paratesticular:
  - 3-yr disease-free survival: 81% (3)
  - Overall survival: 96%
- Vagina/uterine:
  - 5-yr disease-free survival: 69% (3)
  - Overall survival: 82% (94%in those <10 yr, 76% in those >10 yr) (5)

COMPLICATIONS

- Bladder/prostate
  - Bladder dysfunction
  - Hematuria/dysuria
  - Secondary malignancy
  - Incontinence
- Paratesticular
  - Complications of RPLND
    - Bowel obstruction
    - Ejaculatory dysfunction
- Vaginal/uterine
  - Infertility

  – Sexual dysfunction
- Chemotherapy-related toxicity
  – Neurotoxicity
  – Secondary malignancy

FOLLOW-UP

Patient Monitoring

- Follow up imaging to assess for recurrent disease
- Assessment of residual bladder/vaginal function (exam, labs, urodynamics)

Patient Resources

http://www.curesearch.org/

CODES

ICD9

- 171.6 Malignant neoplasm of connective and other soft tissue of pelvis
- 171.9 Malignant neoplasm of connective and other soft tissue, site unspecified
- 184.9 Malignant neoplasm of female genital organ, site unspecified

ICD10

- C49.5 Malignant neoplasm of connective and soft tissue of pelvis
- C49.9 Malignant neoplasm of connective and soft tissue, unsp
- C57.9 Malignant neoplasm of female genital organ, unspecified

CLINICAL/SURGICAL PEARLS

- Radical upfront surgery should be avoided with the goal of organ preservation.
- Small residual masses may not require resection if such surgery would lead to morbidity.

SACRAL AGENESIS, UROLOGIC CONSIDERATION

Nicholas G. Cost, MD
Paul H. Noh, MD, FACS, FAAP

BASICS

DESCRIPTION

- The partial or complete absence of 2 or more lower vertebral bodies
- May be occult or associated with voiding dysfunction

EPIDEMIOLOGY

Incidence

- 1 in 25,000 live births
- 16% of children with sacral agenesis (SA) have a diabetic mother (1)
- 80% of cases are detected during infancy
- 20% of cases go undetected until difficulty with toilet training (at 3–4 yr of age) (1)

Prevalence

None

RISK FACTORS

- Maternal insulin-dependent diabetes
- Maternal drug exposure (Minoxidil noted in case reports) (2)
- Genetic predispositions, see "Genetics"

Genetics

- Mutations in HLXB9 gene on chromosome 7 involved in neural plate infolding (3)
- Deletion of chromosome 7q
- Currarino syndrome (4)
  - Autosomal dominant
  - Mutation in HLXB9 on chromosome 7
  - Presacral mass, sacral agenesis, anorectal malformation

PATHOPHYSIOLOGY

- Failure of fusion or formation of lower vertebral bodies—ie, caudal regression syndrome
- Spectrum of anomalies including meningocele and anorectal malformations
- Urologic manifestations (5):
  - Upper motor neuron (UMN) lesions (35%)
    - Detrusor hyperreflexia
    - Detrusor sphincter dyssynergia (DSD)
  - Lower motor neuron (LMN) lesions (40%)
  - No neurologic deficit (25%)

ASSOCIATED CONDITIONS

- Maternal diabetes
- Tethered cord/tethered cord syndrome

- VACTERL/VATER Association
- Currarino syndrome
  - Form of caudal regression syndrome
  - Hemisacrum, anorectal malformations, and a presacral mass

GENERAL PREVENTION
Avoid maternal exposures to potentially causative agents

DIAGNOSIS
HISTORY
- Urinary tract infections (UTIs) in 75% of affected children
- Gestational/birth history
- Maternal drug exposure
- Gestational diabetes
- Toilet training history
- Bowel function/constipation

PHYSICAL EXAM
- Sacral dermatome sensation is usually intact
- Lower extremity strength is usually normal
- High arched feet, claw/hammer toes are possible findings
- Flat buttocks
- Low-riding, short gluteal cleft
- Palpation of coccyx and sacrum for abnormalities
- Assess for anal location and reflex
  - Bulbocavernosal reflex: Gently squeeze head of penis or clitoris and observe for anal wink
    - Present in most UMN lesion, absent in most LMN lesions

DIAGNOSTIC TESTS & INTERPRETATION
Lab
Assess metabolic panel

Imaging
- Lateral x-ray of lower spine
  - Confirms absence of lower vertebral bodies
  - Eliminates obscured image due to bowel gas on an anterior–posterior view
- Prenatal/postnatal ultrasound (US)
  - Can detect defect after ossification is complete at 18-wk gestation
  - Can be used to evaluate kidneys and bladder once diagnosis is confirmed
- Magnetic resonance imaging (fet al or postnatal)
  - Confirms diagnosis, often shows sharp cutoff of conus medullaris at T12

Diagnostic Procedures/Surgery
- Video urodynamics/voiding cystourethrogram
  - UMN lesion: Detrusor overactivity, exaggerated sacral reflexes, no voluntary sphincter control, detrusor sphincter dyssnergia (DSD), no evidence of sphincter denervation (5)
    - Bladder may appear thick walled with closed bladder neck (1)

- LMN lesion: Detrusor acontractility, diminished sacral reflexes, denervation of sphincter
  - Bladder appears smoothed walls with open bladder neck
- Vesicoureteral reflux (VUR) in 37% (1)

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Spectrum of anomalies that include myelomeningocele and other spinal dysraphisms
- Anorectal malformations
- Sacrococcygeal teratoma
- Presacral mass

TREATMENT

GENERAL MEASURES

- Bladder management
  - Consideration for clean intermittent catheterization regimen depending on status of ability to empty bladder and low pressure, state of the upper urinary tracts, and renal function status
  - Potentially utilizing anticholinergics in the setting of high-pressure neurogenic bladder
- Bowel management
  - Identify and treat constipation
  - Anorectal manometry
- Orthopedics consultation

MEDICATION

First Line

- UMN Lesions: Anticholinergics
  - Oxybutynin (Ditropan)
    - 1 yr: No dose established
    - 1–5 yr: 0.2 mg/kg PO BID–QID
    - 5–12 yr: 5 mg PO BID–TID (15 mg/d max)
    - >12 yr: Adult dose: 5 mg PO BID–QID
    - XL form: 5–20 mg/d

Second Line

- UMN lesions
  - Alternate anticholinergics, many not approved for children but used “off-label”

SURGERY/OTHER PROCEDURES

- UMN lesions
  - Augmentation cystoplasty may be necessary depending on bladder capacity and compliance
  - Done in conjunction with continent catheterizable channel (ie, Mitrofanoff)
  - May require reconstructive surgery for the bladder outlet if there is concomitant incontinence from an open bladder neck.
- LMN Lesions

  - Endoscopic injections of bulking agents to help with bladder neck continence
  - May require reconstructive surgery for the bladder outlet if there is concomitant incontinence from an open bladder neck
  - May require continent catheterizable channel (ie, Mitrofanoff) to reliably empty the bladder
- Ureteral reimplantation or endoscopic bulking agent at the ureteral orifices for persistent VUR
- Bowel management may require enemas and even include the creation of a continent catheterizable channel for antegrade enemas (MACE [Malone antegrade continence enema])

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Best prognosis for successful toilet training and management of sequelae is when defect is detected early and when the child has normal lowerextremity function.

COMPLICATIONS

- Renal function deterioration
  - Potential for high-pressure urinary storage transmitted to the kidneys which is deleterious for renal function
  - Scarring from VUR and recurrent UTI
- Social and developmental difficulties associated with fecal/urinary incontinence

FOLLOW-UP

Patient Monitoring

- Renal/bladder US at regular intervals
  - Monitor status of upper urinary tracts
- Basic metabolic panel
  - Monitor renal function by a calculated glomerular filtration rate using serum creatinine
- Voiding cystourethrogram to follow status of VUR as needed
- Urodynamics every year or every other year to ensure bladder is of a safe capacity and compliance to avoid a setup detrimental to renal health

Patient Resources

- The International Sacral Agenesis Caudal Regression Association (iSACRA)
  - https://sites.google.com/site/caudalregressionsyndrome/

CODES

ICD9

- 344.61 Cauda equina syndrome with neurogenic bladder
- 596.55 Detrusor sphincter dyssynergia
- 756.13 Absence of vertebra, congenital

ICD10

- N32.81 Overactive bladder
- N32.89 Other specified disorders of bladder
- Q76.49 Other congenital malformations of spine, not associated with scoliosis

CLINICAL/SURGICAL PEARLS

- There is variability in the level of neurologic insult and resulting in bladder dysfunction. This ranges from a UMN lesion with bladderhyperreflexia to an LMN lesion with areflexia.
- Aggressive medical management with anticholinergics and CIC may prevent renal damage and the need for major reconstructive surgery.

SARCOIDOSIS, UROLOGIC CONSIDERATIONS

Jay Simhan, MD
Michael A. Pontari, MD

BASICS

DESCRIPTION

- Sarcoidosis is a systemic granulomatous disease with unknown etiology; it is characterized by the formation of noncaseating granulomas, primarily in the lungs, but also throughout the rest of the body.
- Hypercalcuria is more common than hypercalcemia.
  - Renal stones secondary to hypercalcuria can be associated in up to 14% of patients. Occasionally, this can be the presenting complaint that leads to the diagnosis of sarcoidosis.
- Other urologic manifestations of sarcoidosis are rare. These include acute interstitial nephritis, neurogenic bladder dysfunction secondary to neurosarcoidosis, renal pseudotumors, bladder sarcoidosis with gross hematuria, and ureteral obstruction due to retroperitoneal adenopathy or fibrosis.

EPIDEMIOLOGY

Incidence

- In US, sarcoidosis is 10 times more common in African Americans than in whites (AA: 35–64/100,000; whites: 10–14/100,000)
  - African Americans have a 2.4% lifetime risk of developing the disease, whereas in Caucasian Americans and Europeans, the incidence is lower
- Female > Male
- Onset is most often before age 50. Peak is age 20–39 (1)[A]
- Sarcoidosis affects both men and women, but it seems to be most prevalent among African American women

Prevalence

1–40 cases per 100,000 population

RISK FACTORS

- Many organisms have been linked, including *Mycoplasma* sp., fungi, *Histoplasma* and *Cryptococcus* spp.; viruses, and Propionibacterium (2)[B].
- Environmental exposures to noninfectious agents, such as aluminum, zirconium, talc, pine tree pollen, and clay, have also been implicated.

Genetics

- Familial clustering of cases has been reported. Monozygotic twins who have sarcoidosis are 2–4 times as likely to have the disease as dizygotic twins.
- Most common allele found in sarcoidosis is HLA-B8. Other associated alleles include HLA-A1 and HLA-DR3.

PATHOPHYSIOLOGY

- The cause of sarcoidosis is unknown. Symptoms are extensive and can involve pulmonary, arthritic, skin lesions, and manifestations relative to specific organ involvement.
- It is suspected that the granulomas of sarcoidosis are caused by an abnormal immunologic response to a stimulus.
- The most common presentation is pulmonary: Bilateral hilar adenopathy (50%). Less common is bilateral hilar adenopathy and pulmonary infiltrate (25%) and pulmonary infiltrate alone (15%). Other presenting manifestations include cough, wheezing, fever, malaise, fatigue, hepatomegaly, splenomegaly, night sweats, and uveitis.
- Hypercalcemia:
  - Present in at least 20–30% of patients with sarcoidosis.
  - Sarcoidosis may cause resorptive hypercalciuria and urolithiasis.
  - The sarcoid granuloma produces 1,25 $(OH)_2D_3$ (calcitriol), causing increased intestinal absorption of calcium, hypercalcemia. 60% develop hypercalciuria (3)[A].
  - Pulmonary alveolar cells and lymph node in patients with sarcoidosis are capable of synthesizing vitamin D; this is usually a function limited to the kidney.
  - Most patients with sarcoidosis have a suppressed level of PTH secondary to hypercalcemia.
  - Secondary hyperoxaluria can be seen.
  - Most sarcoidosis stones are calcium oxalate.
- Glomerular involvement is very rare and may include:
  - Membranous nephropathy, IgA nephropathy, minimal-change disease, proliferative or crescentic glomerulonephritis, and focal glomerulosclerosis.
  - Interstitial nephritis with granuloma formation is relatively common in sarcoidosis.
- Tubulointerstitial nephritis and uveitis (TINU) syndrome is idiopathic; these patients should be evaluated for sarcoidosis and Sjögren syndrome.
- Prostatic involvement has been reported.

ALERT
A diagnosis of sarcoidosis should always be considered when patients present with renal calculi of unknown origin.

ASSOCIATED CONDITIONS

Erythema nodosum

GENERAL PREVENTION

N/A

DIAGNOSIS

HISTORY

- Sarcoidosis can involve any organ system; the clinical presentation is variable and insidious.
- Patients most commonly present in winter and early spring, which suggests a possible environmental trigger.
- Cutaneous involvement is seen in 25% of patients with sarcoidosis. It may accompany systemic involvement.

- Fever, anorexia, and polyarthralgias.
- Dyspnea on exertion, cough, chest pain, and occasionally hemoptysis.

PHYSICAL EXAM
- Cutaneous involvement may be present (lupus pernio, erythema nodosum)
  - Most common sites are face, upper back, trunk, or extremities (3)[A]
- Wheezing
- Adenopathy
- Some cases of involvement of testis and epididymis, range from induration to painless mass
- Neurologic symptoms

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Sterile pyuria and mild proteinuria
- Leukopenia and/or thrombocytopenia are common.
- Eosinophilia: 24%
- Anemia: 5%
- Hypercalciuria: 49%
- Hypercalcemia: 13%
- Elevated calcitriol levels
- Serum ACE level is elevated in 60% of patients; therefore, this test is not sensitive in diagnosing sarcoidosis.
- BUN and Cr may be elevated if there is renal involvement.

Imaging
- Chest imaging may demonstrate hilar adenopathy or pulmonary infiltrate present in 90% of sarcoidosis patients.
- Abdominal imaging may show hepatomegaly, retroperitoneal adenopathy, and retroperitoneal fibrosis.
- Stones and nephrocalcinosis secondary to hypercalcemia can be seen on CT.
- Sarcoid renal pseudotumors can mimic renal cell carcinoma, and more diffuse enlargement may mimic lymphoma. Retroperitoneal lymph nodes may enlarge sufficiently in sarcoidosis to cause obstruction.
- In rare cases of urinary involvement, ureterohydronephrosis may be seen from urolithiasis or obstruction.

Diagnostic Procedures/Surgery
- Many physicians prefer a biopsy to confirm the diagnosis of sarcoidosis.
  - Mediastinoscopy is utilized to assess hilar adenopathy.
  - Fiberoptic bronchoscopy with transbronchial biopsy is used for biopsy documentation of pulmonary sarcoidosis.
  - Biopsy of renal mass (especially atypical in appearance) in patient with sarcoid to distinguish from RCC.
- Bladder involvement confirmation requires transurethral bladder resection.
- Sarcoidosis can also be differentiated from other diagnoses by the rapid resolution of hypercalcemia with initiation of corticosteroid therapy.
- In cases of bilateral testicular masses in man with sarcoid and negative markers, consider

testes sparing approach (3)[C].

Pathologic Findings

Typical sarcoid lesions are characterized by the presence of circumscribed granulomas of epithelioid cells with little or no necrosis (noncaseating granuloma).

DIFFERENTIAL DIAGNOSIS

- Interstitial lung diseases:
  - Medications (nitrofurantoin, methotrexate), idiopathic pulmonary fibrosis, collagen vascular diseases, amyloidosis, hypersensitivity pneumonitis, granulomatous vasculitis, collagen vascular diseases
  - Other granulomatous diseases: TB, brucellosis, Q fever, biliary cirrhosis, Wegener granulomatosis, Hodgkin disease
- Other skin and arthritic disorders
- Other causes of hypercalcemia/hypercalcuria:
  - PTH-related malignancy, vitamin D-related mediations (eg, lithium), endocrine disorders, immobilization
- Causes of interstitial nephritis:
  - Sjögren syndrome
  - Systemic lupus erythematosus
  - Wegener granulomatosis
  - Behçet disease

TREATMENT

GENERAL MEASURES

- Sarcoidosis remains a diagnosis of exclusion. Before a definitive diagnosis can be made, multiple other conditions that can share similar symptomatology and pathologic findings must be ruled out (See “Differential diagnosis” above).
- Coordination of care is suggested with experts in the management of the systemic and pulmonary manifestations of the disease.
- Corticosteroids are the mainstay of therapy for most manifestations of sarcoidosis.
- For sarcoidosis-related renal disease, the primary management is steroid therapy. Although many have poor renal function on presentation, patients may respond dramatically to steroid therapy. The steroids are given at high dose for 1–2 mo then reduced for the remainder of the course, which should be at least 1 yr.
- Hydration and limiting sodium intake can reduce hypercalcuria.

MEDICATION

First Line

- Oral corticosteroids are the treatment of choice for patients with hypercalcemia and systemic involvement.
  - Initial prednisone 40 mg/d, PO which is tapered to every other day over several weeks for long-term therapy; typically 10–15 mg PO every other day
- Nephropathy due to sarcoidosis appears to respond to steroid therapy.

Second Line

- Inhaled steroids
- Methotrexate
- Chloroquine

SURGERY/OTHER PROCEDURES
- Biopsy is necessary for diagnosis.
- Obstruction may require diversion.
- Surgical management of urolithiasis

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE
PROGNOSIS
- The course of the disease is variable.
- Spontaneous remission occurs in 50% of patients.
- 1/3 of patients have eventual improvement.
- 10–30% of patients have chronic or progressive disease.

COMPLICATIONS
- Renal lithiasis, gross hematuria, ureteral obstruction, neurogenic bladder dysfunction
- Renal failure is rare and is due to hypercalcemic nephropathy.

FOLLOW-UP
Patient Monitoring
History, physical exam, chest x-ray, pulmonary function tests, and serum chemistry

Patient Resources
- National Heart Lung and Blood Institute. http://www.nhlbi.nih.gov/health/health-topics/topics/sarc/
- UpToDate. http://www.uptodate.com/contents/sarcoidosis-beyond-the-basics

See Also (Topic, Algorithm, Media)
- Hypercalcemia, Urologic Considerations
- Urolithiasis, Adult, General

CODES

ICD9
- 135 Sarcoidosis
- 275.40 Unspecified disorder of calcium metabolism
- 592.0 Calculus of kidney

ICD10
- D86.9 Sarcoidosis, unspecified
- E83.52 Hypercalcemia
- N20.0 Calculus of kidney

CLINICAL/SURGICAL PEARLS
- Sarcoidosis may cause resorptive hypercalciuria and urolithiasis.
- Retroperitoneal lymph nodes may enlarge sufficiently in sarcoidosis to cause obstruction..
- Consider a diagnosis of sarcoidosis in patients presenting with nephrolithiasis of unknown etiology, especially in an African American female.
- For sarcoidosis-related renal disease, oral corticosteroids is the mainstay of treatment.

SCROTUM AND TESTICLE, MASS

Jay Simhan, MD
Jack H. Mydlo, MD

BASICS

DESCRIPTION
- A mass in the scrotum or testicle can be noted by the patient or during physical exam
- Lesions can be in scrotal wall, testicle, or paratesticular tissues
- Testicular masses can be distinguished from other common intrascrotal masses (hydrocele, varicocele, spermatocele, epididymal cyst, hernia) based on exam or imaging studies
- Most palpable testicular tumors in adults are malignant; 80% nonpalpable lesions are benign.
- Children with testicular tumors are more likely to have benign lesions (20–40% benign).

EPIDEMIOLOGY
Incidence
8,820 cases of testicular cancer in the US in 2014 with 380 deaths

Prevalence
- Testicular tumors: 0.05–2/100,000 children
- Lifetime risk 1/270

RISK FACTORS
- Malignancy: Cryptorchidism, prior testicular neoplasm or hematopoietic malignancy, HIV, family history of testicular cancer, marijuana use
- Benign mass: Recent trauma, UTI, STDs, viral illness, urethral instrumentation, congenital anomalies, previous history of scrotal surgery

Genetics
- Chromosome 12 alterations in testicular cancer:
  – Genetics associated in 33% of cases
  – 2.2% incidence in brothers of patients with testicular cancer

PATHOPHYSIOLOGY
- Depends upon the etiology of the mass
- Differential diagnosis can be narrowed based on patient's age and history

ASSOCIATED CONDITIONS
Inguinal hernia in pediatric hydrocele

GENERAL PREVENTION
None (testicular self-exam may help diagnose)

DIAGNOSIS

HISTORY
- Age of the patient

  - Tumor types are age-specific
  - Torsion usually in prepubertal age group
- Description of the mass
  - Small, discrete mass commonly neoplastic
  - Diffuse enlargement with tenderness seen with infection, torsion, or trauma
- Associated pain
  - Torsion: Sudden, severe, unilateral pain with nausea and vomiting. If torsion intermittent, pain may wax and wane; may have pain during sleep
  - Neoplasms rarely cause severe pain, usually described as dull ache or fullness
  - Orchitis pain may gradually increase as infection causes increased inflammation
- Referred pain to the scrotum without a mass can be due to renal colic, or nerve root irritation
- Prior scrotal surgery: Orchidopexy for cryptorchidism; increased risk of cancer; malignancy; postvasectomy granuloma
- History of trauma, surgery, any radiation
- Previous UTI or current lower UTI complaints suggests orchitis ± epididymitis
- Urethral discharge suggests STD-concurrent *epididymo-orchitis* (*Chlamydia* and gonorrhea are most common in men < 35 yr of age).
- Urethral instrumentation: Ascending infection
- Current illnesses: Mumps, UTI
- Medical problems: Diabetes mellitus, immunodeficiency, neurologic disorders, autoimmune disorders, others
- Fever, weight loss, nausea, vomiting, hemoptysis, shortness of breath, and back pain can all be clues to possible metastatic testicular neoplasm.
- Nausea and vomiting in torsion or orchitis

ALERT
- Evaluate scrotal swelling and testicular masses urgently.
- Solid, firm testicular mass must be considered testicular cancer until proven otherwise.
- Patients may present with complaint of testicular mass when they have paratesticular mass instead.

PHYSICAL EXAM
- Fever can be marker for infection, tumor necrosis, or testicular necrosis
- Mumps orchitis: 30% with mumps parotitis, onset 3–7 days following the parotitis
- Gynecomastia: Germ cell or Leydig cell tumor
- Abdomen:
  - Retroperitoneal lymphadenopathy from metastatic tumors can sometimes be palpated
  - Palpate for signs of hernia
- Testes:
  - Evaluate if testicular vs. paratesticular mass
  - Evaluate for associated pain on palpation
  - Neoplastic/cystic processes usually painless
  - Torsion or epididymoorchitis is exquisitely tender
  - Phren sign: Scrotal elevation relieves pain in epididymitis, but worsens pain or no effect

with torsion; not reliable
- Discrete lesion vs. diffuse swelling:
  – Most early-stage neoplasms or cysts are palpable discrete masses
  – Orchitis and torsion lead to generalized testicular enlargement
- Position of mass in testicle:
  – May be high riding or in altered position in torsion
  – Bell clapper deformity: In torsion, occurs when the testicle is situated in a horizontal lie with the long axis in the anteroposterior direction
- Scrotum:
  – Evaluate if the mass is within testicle, epididymis, spermatic cord, or scrotal wall
  – Edema and erythema: Torsion or orchitis
  – Evaluate for prior scrotal scars/past surgery
  – Transilluminate to evaluate for hydrocele
  – Valsalva maneuver to elicit varicocele
  – Cremasteric reflex: Stroke upper thigh and observe ipsilateral testicle/scrotum for contraction (absent in torsion)
- Penis: Ulcers, induration, or discharge can be seen in epididymoorchitis (STD)
- Epididymis:
  – Normally located posterior to testicle
  – Pain or swelling helps make diagnosis of *epididymo-orchitis.* If severe, difficult to demarcate epididymis from testicle
- Extremities:
  – Swelling due to malignant retroperitoneal lymphadenopathy or venous thrombosis
- Neurologic exam
- Lymphatics:
  – Testicular tumor metastasizes to pelvic and retroperitoneal nodes, not inguinal nodes; tender or enlarged inguinal nodes are associated with infection
- Rectal exam: Evidence of prostatitis
- Skin: Signs of cellulitis, swelling, discoloration, or breaks in skin:
  – Blue dot sign: Torsion of the appendix testes

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- WBC count to evaluate for infection or leukemia/lymphoma
- HCT to evaluate for anemia associated with malignancy
- Urine analysis and urine culture: May suggest the diagnosis of orchitis or epididymitis
- Hematuria and proteinuria: Viral infection
- Pyuria and bacteriuria: Bacterial infection
- Tumor markers:
  – AFP: Elevated in embryonal cell carcinomas, teratocarcinoma, yolk sac tumors, or combined tumors, but never increased in pure seminomas
  – β-hCG: Elevated in all choriocarcinomas and some embryonal cell carcinomas, yolk sac carcinomas, and seminomas
  – LDH: Nonspecific; elevated in metastatic disease
- Urethral swab to rule out gonorrhea/Chlamydia

Imaging (1)

- Ultrasound, US (diagnostic procedure of choice):
  - 95% sensitivity for testicular tumor diagnosis
  - Specificity for malignancies is lower since US detects benign lesions as well
  - Most testicular tumors have hypoechoic areas, but overall heterogeneity of the lesion is common
  - Color flow Doppler is essential for the differentiation of torsion from *epididymo-orchitis:*
    - Decreased blood flow with torsion
    - Increased blood flow with *epididymo-orchitis*
    - Will also sometimes show increased vascularity in testicular neoplasms
- MRI: Minor role in testicular masses; can help evaluate intratesticular masses that are difficult to visualize or characterize on US
- Nuclear scintigraphy is most useful for testicular torsion, but is less convenient than US

Diagnostic Procedures/Surgery

Biopsy is avoided if there is suspicion for testicular neoplasm.

Pathologic Findings

See specific Section I and II topics.

DIFFERENTIAL DIAGNOSIS

- Adult/pediatric painful mass:
  - *Epididymo-orchitis:* bacterial, STD, mumps, TB
  - Fournier gangrene
  - Henoch–Schönlein purpura (usually no mass)
  - Incarcerated/strangulated hernia
  - Post-vasectomy syndrome (usually no mass)
  - Testicular trauma: Usually blunt; contusion, rupture; usually associated hematocele
  - Torsion (testicle, testicular, or epididymal appendage)
  - Tumor (infrequent unless traumatized or rapidly growing; see differential diagnosis below)
- Adult painless mass:
  - Adenomatoid tumor of testis or epididymis
  - Adrenal rest tumors
  - Adenocarcinoma of the rete testis
  - Chylocele: Usually associated with filariasis
  - Fibrous pseudotumor of the tunica albuginea
  - Hydrocele, primary or due to trauma, torsion, tumor, epididymitis; hydrocele of the cord
  - Lipoma of the cord
  - Mesothelioma of tunica vaginalis
  - Polyorchidism
  - Paratesticular sarcomas: Rhabdomyosarcoma, fibrosarcoma, leiomyosarcoma, liposarcoma
  - Scrotal edema (insect bite, nephrotic syndrome, acute idiopathic scrotal edema)
  - Scrotal wall: Sebaceous and inclusion cysts, idiopathic calcinosis, fat necrosis, malignancy
  - Sperm granuloma following vasectomy
  - Spermatocele (epididymal cyst)

- Testicular cysts (simple, tunica albuginea, epidermoid)
- Testicular tumor:
  - Germ cell tumors (95% of testicular malignancies): Seminoma, embryonal cell carcinoma, choriocarcinoma, yolk sac carcinoma teratoma (1–5%), teratocarcinoma
  - Gonadal stromal tumors: Leydig tumor, Sertoli cell, granulosa cell tumors
  - Metastatic tumors: Prostate, lung, and GI tract; rare kidney, malignant melanoma, pancreas, bladder, and thyroid
  - Mixed germ cell and stromal tumor (gonadoblastoma)
  - Angioma, fibroma, leiomyoma, hamartoma, carcinoid, mesothelioma, and neurofibroma
  - Malignant fibrous histiocytoma (most common soft tissue sarcoma in late adult life)
  - Leukemia or lymphoma
- Varicocele

• Pediatric painless mass:
- Similar to adult list; most common are: Hydrocele, hernia, varicocele, testicular teratoma, adrenal rest tumors, rhabdomyosarcoma

TREATMENT

GENERAL MEASURES

• Scrotal ultrasound is indicated in most cases of scrotal mass
• Testicular torsion is an emergency and requires immediate evaluation

MEDICATION

First Line

• Cause-specific treatment, as well as supportive care, should be applied to cases of orchitis: Bed rest, scrotal support, ice bags, and analgesics.
• Broad-spectrum antibiotics should be administered if a bacterial source is suspected.
• A patient's sexual partners should be treated if STD is the cause.

Second Line

N/A

SURGERY/OTHER PROCEDURES

• Testicular neoplasms: Radical orchiectomy with high ligation of the spermatic cord; inguinal incision:
- Testicular biopsy or orchiectomy through a scrotal approach is contraindicated if there is the possibility of neoplasm.

• Cystic lesions are difficult to differentiate from neoplastic lesions and are usually removed as above for testicular neoplasms.
• In children, testis-sparing surgery for benign lesions such as teratoma, Leydig cell tumor, and epidermoid cyst based on frozen biopsy findings.

ADDITIONAL TREATMENT

Radiation Therapy

Seminoma or some sarcomas

Additional Therapies

Chemotherapy for advanced testicular tumors

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS

- Neoplasms: See tumor types in Section I or II.
- Cystic lesions: Simple periodic exam.
- Torsion: Evaluation in 6–12 mo to check for testicular atrophy and presence of new masses:
  – Infertility noted as a long-term problem.
- Orchitis: If primary cause resolved, no follow-up needed.
  – In prepubertal patients, *epididymo-orchitis* may be due to underlying urinary tract anomaly. These patients need structural evaluation of their urinary tracts.
- Trauma: After documentation of adequate healing, no follow-up is required.

COMPLICATIONS

Infertility; complications secondary to radiation or chemotherapy

FOLLOW-UP

Patient Monitoring

- Patients should be advised to perform monthly testicular self-exams.
- Patients diagnosed with cancer should have disease-specific follow-up.

Patient Resources

CODES

ICD9

- 186.9 Malignant neoplasm of other and unspecified testis
- 222.0 Benign neoplasm of testis
- 608.89 Other specified disorders of male genital organs

ICD10

- C62.90 Malig neoplasm of unsp testis, unsp descended or undescended
- D29.20 Benign neoplasm of unspecified testis
- N50.8 Other specified disorders of male genital organs

CLINICAL/SURGICAL PEARLS

- Evaluate acute scrotal swelling or testicular masses urgently.
- A solid, firm testicular mass in an adult is cancer until proven otherwise.

SCROTUM AND TESTICLE, TRAUMA

Lee C. Zhao, MD, MS
Allen F. Morey, MD, FACS

BASICS

DESCRIPTION

- Injury to the scrotum and testicle can occur through a variety of mechanisms—blunt, penetrating, avulsion, ischemic, burn
- American Association for the Surgery of Trauma (AAST) injury severity scale for the scrotum
  - Grade 1 contusion
  - Grade 2 laceration < 25% of scrotal diameter
  - Grade 3 laceration > 25% of scrotal diameter
  - Grade 4 avulsion < 50%
  - Grade 5 avulsion > 50%
- AAST injury severity scale for the testis (with bilateral testicular injury advance 1 grade up to Grade 5)
  - Grade 1 contusion or hematoma
  - Grade 2 subclinical laceration of tunica albuginea
  - Grade 3 laceration of tunica albuginea with < 50% parenchymal loss
  - Grade 4 major laceration of tunica albuginea with > 50% parenchymal loss
  - Grade 5 total testicular destruction or avulsion

EPIDEMIOLOGY

Incidence/Prevalence

- < 1% of all civilian traumas
- < 5% of battlefield injuries
  - More frequently caused by fragmentation devices
- < 5% of all burn victims

RISK FACTORS

- High-speed trauma
- Contact or "extreme" sports
- Industrial workers
- Bicycling recently recognized as leading sport associated with injury to the external genitalia

PATHOPHYSIOLOGY

- Blunt injury
- Penetrating injury
  - Gunshot wound (GSW), stab wound, human or animal bite
- Avulsion or ischemic injury
  - Industrial injury, self-mutilation
- Burn injury
  - Flame, electrical, chemical

ASSOCIATED CONDITIONS
- Associated injuries
  - Urethra, corpora spongiosum
  - Corpora cavernosa
- Testicular torsion
- Testicular tumor

GENERAL PREVENTION
- Protective equipment during contact sports
- Proper safety training for industrial machinery
- Military services are developing devices for ballistic protection of the external genitalia

DIAGNOSIS
HISTORY
- Trauma
  - Determine type of injury and magnitude of force infected
  - Investigate contamination of objects used in stab injuries
  - Determine species of animal in bite injuries
- Timing, severity, progression of pain, swelling, discoloration
  - Testicular rupture is usually immediately painful followed by acute onset of swelling
  - Minor trauma is associated with delayed onset of pain, swelling, and discoloration
  - Tumors typically have more insidious progression of symptoms
- Associated abdominal pain, nausea, emesis

PHYSICAL EXAM
- Evaluate for other trauma, including penile injury
- Document size of laceration or percentage of degloving injury
- Transilluminate any palpable scrotal mass
  - Hydrocele will transilluminate
  - Hematocele or tumor will not transilluminate
- Blood at meatus: Rule out urethral injury
- Absence of cremasteric reflex is a possible sign of testicular torsion
- Assess for inguinal hernia

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis
- Urine culture if infection suspected
- CBC
- For delayed presentation with abscess formation, culture abscess contents

Imaging
- Scrotal ultrasound
  - Highly sensitive and specific for hematocele, avulsion, and rupture (1)[B]
  - Evaluate integrity of tunica albuginea
  - Heterogeneous areas within testicular parenchyma is suggestive of testicular rupture

– Doppler US may rule out torsion

DIFFERENTIAL DIAGNOSIS

- Torsion of the testicle or one of its appendages
- Infection (epididymitis, orchitis)
- Ruptured varicocele resulting in discoloration or tenderness
- Pelvic fracture resulting in scrotal swelling

TREATMENT

GENERAL MEASURES

- Select cases of blunt injury can be managed conservatively
  – Intact scrotal skin and nonruptured, viable testis on US
  – Small hematoceles
- Tetanus and/or rabies immunization for penetrating injuries
- For bilateral testicular injury, or injury to solitary testis, consider sperm extraction for cryopreservation, if available

MEDICATION

First Line

- Narcotics as needed: Oral and IV
- Avoid NSAIDs and aspirin

SURGERY/OTHER PROCEDURES

- Blunt trauma: Ruptured testis, expanding hematocele
- Irrigation, debridement of devascularized skin
  – Noninfected wound: Primary closure
  – Infected wound: Wet-to-dry dressing changes, broad-spectrum antibiotic
- Scrotal exploration and early repair is better for testicular rupture
- Penetrating trauma
  – Surgical exploration recommended for penetrating scrotal injuries
  – For testicular injury
    - Most are salvageable (2)[B]
    - Debride nonviable tissue
    - Primary closure with fine absorbable suture
    - Free graft of tunica vaginalis may be used (3)[B]
    - Drain placement may reduce postoperative hematoma
    - Layered closure of deep fascia and skin
- Burn
  – Flame or electrical:
    - Debridement of eschar and devascularized tissue
    - Split-thickness skin graft
    - Silver sulfadiazine cream for partial thickness
  – Chemical
    - Do not irrigate a chemical burn with water as this can exacerbate damage
    - Irrigate with saline if chemical is unknown

- Alkaline burns: Irrigate with dilute acetic acid
- Acidic burns: Irrigate with sodium bicarbonate

- Avulsion injury:
  - Small injuries may be managed with irrigation, debridement, and primary closure
  - Complex injuries: Debridement, delayed rotational scrotal flaps and/or split-thickness skin graft
- Animal or human bite
  - Treat as penetrating trauma with addition of antibiotics
  - Dicloxacillin or cephalexin (500 mg PO QID)
  - Dog bites: Add penicillin V 500 mg PO QID for coverage of Pasteurella multocida

ADDITIONAL TREATMENT

Additional Therapies

- Scrotal elevation
- Ice packs

ONGOING CARE

PROGNOSIS

- Early exploration and repair of testicular injury results in >90% testicular salvage
- Fertility is not compromised by repair (4)[C]
- Antisperm antibodies are not prevalent after trauma
- Nonoperative management of testicular rupture will result in 45% chance of delayed exploration and orchiectomy

COMPLICATIONS

- Abscess
- Fistula
- Fournier gangrene
- Hematoma
- Infertility and hormonal dysfunction
- Ischemic injury to testicle

FOLLOW-UP

Patient Monitoring

- Repeat US for conservatively managed patients
- Serum testosterone and fertility testing for patients with bilateral testicular injuries

- Penis, Trauma
- Scrotum and Testicle, Trauma Algorithm
- Scrotum and Testicle, Trauma Images
- Testis Pain
- Torsion, Testis, and Testicular Appendages
- Urethra, Trauma (Anterior and Posterior)

CODES

ICD9

- 878.2 Open wound of scrotum and testes, without mention of complication
- 922.4 Contusion of genital organs
- 959.14 Other injury of external genitals

ICD10

- S30.22XA Contusion of scrotum and testes, initial encounter
- S31.31XA Laceration w/o foreign body of scrotum and testes, init
- S39.94XA Unspecified injury of external genitals, initial encounter

CLINICAL/SURGICAL PEARLS

- Sonogram is the best technique to evaluate for testicular rupture.
- Heterogeneous areas within testicular parenchyma are more often suggestive of testicular rupture than defect in tunica albuginea on ultrasound.
- Repair testicular rupture whenever possible.
- Early exploration and repair of testicular injury is highly efficacious. Rupture of tunica albuginea of testicle in as many of 50% of blunt scrotal trauma presenting for evaluation. Prompt exploration and repair leads to improved salvage rates.
- In pediatric patients, painless hematocele after abdominal injury is a concern for ruptured viscera (especially spleen).

SCROTUM, SQUAMOUS CELL CARCINOMA

Lydia T. Laboccetta, MD
James S. Rosoff, MD

BASICS

DESCRIPTION

- Squamous cell carcinoma (SCC) of the scrotum is a very rare, environmentally induced cancer with high metastatic potential
- The first reported occupational cancer
  – Initially described in 1775 by Sir Percivall Pott in chimney sweeps
- Synonyms: Chimney sweeps cancer, Mule-spinners' disease, Pott cancer

EPIDEMIOLOGY

Incidence

- 1.5–3/10 million men in US(1); similar rates noted in Dutch series (2)
- Increasing incidence in US may be related to increases in HPV infection, Psoralen plus ultraviolet light A (*PUVA*) treatment for psoriasis, and also due to improved reporting
- Lower incidence among black men in older series, though increased risk in black men in more recent SEER database analysis (1)
- Most reported in men >50 yr; median age in SEER series: 68

Prevalence

N/A

RISK FACTORS

- Chemical/mechanical irritation
- Classically described in chimney sweeps: Related to soot or chemical exposure, poor hygiene
- Oil/petroleum: Machine workers (lathe workers, mule-spinners [men and boys who worked on cotton spinning machines])
- Poor hygiene
- Repeated trauma
- Rarely in patients with prior scrotal incision/scar
- PUVA: Ultraviolet A radiation for psoriasis. Effect is dose dependent.
- Associated with HPV 16, 18 in limited case reports
- Chronic immunosuppression

Genetics

N/A

PATHOPHYSIOLOGY

- SCC is a malignant tumor of epidermal keratinocytes thought to occur mainly from chronic irritation from a mechanical or chemical source.
- 3,4-benzpyrene, a polycyclic aromatic hydrocarbon, is a common occupational carcinogen in these men
- Associations with many other carcinogens have been described

ASSOCIATED CONDITIONS
- Psoriasis
- HPV/condylomata
- Sexually transmitted infections

GENERAL PREVENTION
- Decrease exposure to carcinogenic agents:
  - Protective clothing for those with occupational risk
  - Prevention of HPV transmission
  - Shielding of area during PUVA treatment
- Improve hygiene

DIAGNOSIS

HISTORY
- Occupational exposure to chemical and/or mechanical irritants
- History of treatment for psoriasis
- History of HPV, HIV
- History of scrotal trauma, scrotal surgery
- Inflammatory conditions involving the scrotum
- Change in size of lesion or ulceration
- Fever
- Nonhealing nodule or ulcer

PHYSICAL EXAM
- Exam of external genitalia, inguinal and distant lymph nodes:
  - Usually a solitary, slow-growing nodule with or without ulceration usually on the anterolateral aspect of the scrotum
  - Starts as a small pimple or nodule which gradually develops ulceration, raised or rolled edges, purulent discharge
  - Lesion may persist for 6 mo before ulcerating
  - May have associated condylomata of penis, scrotum, perianal region
- May lead to lymphadenopathy due to malignancy or infection
  - 30–60% have palpable lymphadenopathy at presentation
  - 25% have inguinal metastases at presentation

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- WBC count to rule out acute infection
- Urinalysis and urine culture if indicated

Imaging
- CT may help to assess size, extent of lymphadenopathy but cannot differentiate inflammation vs. malignancy
- MRI
  - Improved accuracy in diagnosis and staging
  - Can assess infiltrative vs. inflammatory process

- Lymphangiography is accurate in delineating metastatic vs. inflammatory nodes, but cannot detect micrometastases

Diagnostic Procedures/Surgery

Excisional biopsy of primary lesion

Pathologic Findings

- SCC:
  - Most are well or moderately differentiated and contain focal areas of keratosis
  - Surrounding epidermis demonstrates hyperkeratosis, acanthosis, dyskeratosis
  - Diffuse lymphocytic infiltrate may be present
- Staging (staging for all scrotal carcinoma, not only SCC, no TNM classification exists) (3)
  - Stage A1: Localized to scrotal wall
  - Stage A2: Locally invasive involving adjacent structures (testis, spermatic cord, penis, pubis, and perineum)
  - Stage B: Metastatic disease to the inguinal lymph nodes only
  - Stage C: Metastatic disease to the pelvic lymph nodes without evidence of distant spread
  - Stage D: Metastatic disease beyond the pelvis involving distant organs
  - In SEER series, 76% presented with localized disease, 20% with regional metastases, and 4% with distant metastases (4)

DIFFERENTIAL DIAGNOSIS

- Benign scrotal lesions:
  - Condyloma
  - Eczema
  - Hidradenitis suppurativa
  - Folliculitis
  - Nevus
  - Periurethral abscess
  - Psoriasis
  - Sebaceous cysts/epidermal inclusion cyst
  - Syphilis
  - Tuberculous epididymitis with a draining sinus
- Malignant scrotal lesions:
  - Basal cell carcinoma
  - Malignant melanoma
  - Paget disease
  - Marjolin ulcer: Cancer arising from site of prior inflammation
  - Kaposi sarcoma: A purple, papular, plaque-like, or ulcerated lesion on the penis or scrotum
  - Sarcoma: Leiomyosarcoma from the Dartos layer of the scrotum is most common, though still very rare
  - Metastatic lesion

TREATMENT

GENERAL MEASURES

- Management is primarily surgical.
- Local wide excision is diagnostic and therapeutic.

MEDICATION

First Line

- Broad-spectrum antibiotics for 4–6 wk in patients with lymphadenopathy
- Chemotherapy has not demonstrated success for primary treatment (single agent or combination therapy)
  - Methotrexate, bleomycin, and cisplatin have been used with radiotherapy in 1 case report, but the patient later required surgical resection
  - Bleomycin has been reported as successful in 2 cases
  - Multiple case reports exist in the literature of combined adjuvant chemotherapy and radiotherapy
- Topical 5-FU has not been successful in treating carcinoma in situ of the scrotum

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Primary lesion:
  - Wide local excision of lesion with a 2-cm margin of skin and dartos fascia.
  - Small lesions may be closed primarily.
  - Large lesions may require split-thickness skin grafting or local flaps.
  - If hemiscrotectomy is performed, the ipsilateral testis may be placed in a thigh pouch or moved to the contralateral hemiscrotum.
  - Excision of all scrotal contents is required only when structures are directly involved by tumor.
- Regional lymph nodes
  - If palpable adenopathy resolves after antibiotics or was never present, then a superficial inguinal lymph node biopsy should be performed:
    - Ipsilaterally if lesion is lateral.
    - Bilaterally if lesion at the median raphe
  - If palpable lymphadenopathy persists after antibiotics, then a bilateral superficial lymph node biopsy should be performed.
  - Full ilioinguinal lymphadenectomy should be performed only on the side of the positive biopsy:
    - If performing a unilateral ilioinguinal lymphadenectomy, a contralateral superficial inguinal lymph node biopsy should also be performed.
    - If there is a positive frozen section, then perform a bilateral ilioinguinal lymphadenectomy.
- Laser vaporization of the primary lesion has been used in poor surgical candidates or those who refused surgery.
- Mohs micrographic surgery has also been used for primary lesions.

ADDITIONAL TREATMENT

Radiation Therapy

- Has not been effective and is reserved for recurrences and poor surgical candidates.
- Has been described in multiple case reports as adjuvant therapy.

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Scrotal cancer survival is worse for SCC histology than all other histologies except melanoma (4)
- Survival at 5 yr (1):
  - Stage A: 70–80%
  - Stage B: 40–50%
  - Stage C: Rare
  - Stage D: Rare
- Local recurrence rates:
  - 21–40%
  - May require additional excision
  - Patients with industrial exposure may be at higher risk for recurrence

COMPLICATIONS
- Femoral hernias after ilioinguinal lymphadenectomy
- Lymphedema
- Lymphoceles
- Wound infections

FOLLOW-UP
Patient Monitoring
- Patient Monitoring
  - Self-exams for local recurrence of lesion or lymphadenopathy
  - Periodic follow-up by physician for monitoring of local recurrence or lymphadenopathy
- Follow-up is required for life

Patient Resources
N/A

CODES

ICD9

187.7 Malignant neoplasm of scrotum

ICD10

C63.2 Malignant neoplasm of scrotum

CLINICAL/SURGICAL PEARLS

A nonhealing ulcer or nodule on the scrotum should raise suspicion for squamous cell carcinoma.

SEMINAL VESICLE, CYSTS AND MASSES

Mark W. Ball, MD
Arthur L. Burnett, II, MD, MBA, FACS

BASICS

DESCRIPTION

- The most common seminal vesicle (SV) masses are secondary malignancies
- Cystic masses are the 2nd most common, followed by primary seminal vesical malignancies.
- Cysts
  - Rare; either congenital or acquired
  - Age at diagnosis, 20–50 yr
  - Usually unilateral; size varies considerably from small (5 mm) to huge cysts that fill the pelvis.
- Neoplasms
  - Primary malignant neoplasms of the seminal vesicles are exceedingly rare
  - SV solid mass is more likely from local invasion by another malignancy such as prostate cancer

EPIDEMIOLOGY

Incidence

- Cysts: Incidence peaks at age 20–30 yr.
- Primary SV malignancy: Exceedingly rare. Only case reports and small series reported.

Prevalence

N/A

RISK FACTORS

- Secondary malignancies
- Prior transurethral surgery causing scarring at the ejaculatory duct

Genetics

- SV formation occurs at the 12th wk of gestation. Abnormal branching of the ureteral bud from the mesonephric duct can disrupt SV formation and result in an ectopic ureteral orifice:
  - The abnormal ureter and metanephrogenic blastema results in a dysplastic kidney.
- A basement membrane defect that is seen in multiple organs (as in autosomal dominant polycystic kidney disease [ADPKD]) is believed to also affect SV cysts.

PATHOPHYSIOLOGY

- Normal anatomy:
  - SVs are elongated, flat, paired structures that lie between the rectum and bladder, superior to the prostate.
  - Mean normal length is 3.1 cm and width is 1.5 cm; contributes 50–80% of total seminal ejaculatory volume
  - Blood supply: Vesiculodeferential artery, a branch of the umbilical artery

- Cystic disease of the SVs can be either congenital or acquired; congenital cysts are associated with anomalies of the ipsilateral mesonephric duct.
- Acquired SV cysts result from ejaculatory duct obstruction, inflammation, or other abnormality.
- Cysts are filled with seminal fluid (nonmotile spermatozoa, red and white blood cells, and epithelial cells).
- Congenital SV cysts are typically associated with an ipsilateral ectopic ureter and/or ipsilateral renal abnormalities:
  - Lesions <5 cm are rarely symptomatic.
  - Lesions >12 cm have been described as giant cysts and are often associated with symptoms related to bladder outlet or colonic obstruction.
- In men, 30% of ectopic ureters insert into the SV.
- 3 patterns of spread of prostate cancer into SV
  - Direct spread along the ejaculatory duct
  - Prostatic capsular perforation followed by extension into the periprostatic tissues and the SV
  - Isolated deposits
- Direct invasion of the SVs can also occur in malignancies of the bladder and rectum

ASSOCIATED CONDITIONS
- Bladder cancer
- Ectopic ureter
- Ipsilateral renal dysplasia or agenesis
- Prostate cancer
- Rectal cancer

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Most SV cysts are asymptomatic
- When symptomatic, typical symptoms are:
  - Dysuria, irritative voiding
  - Perineal discomfort
  - Recurrent epididymitis
  - Painful ejaculation
  - Hematuria
  - Hematospermia
  - Infertility
- Determine history of other malignancy such as prostate, bladder, or rectal cancer.

PHYSICAL EXAM

ALERT
Normal seminal vesicles are not palpable on DRE. A palpable SV is abnormal.

- SV tumors are often palpable and nontender hard areas on digital rectal exam (DRE), just cranial to the base of the prostate.
- Primary tumors are usually unilateral and not contiguous with the prostate.
- Secondary tumors are usually bilateral and contiguous with a prostate or bladder tumor.
- SV cysts (when large) can usually be palpated on DRE as a ballotable mass.
- Indurated and/or tender epididymis and ductus deferens: Evidence of chronic epididymitis or obstruction

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Low semen volume and lack of fructose and liquefaction implies SV absence or ejaculatory duct occlusion.
- PSA elevation may suggest prostate cancer.

Imaging

- TRUS (transrectal ultrasound):
  - 1st-line imaging for suspected SV abnormality or SV mass on DRE
  - SV cystic lesions: Echopenic center with echogenic luminal folds
  - SV tumors: Isoechoic to the prostate, but hyperechoic to normal SV
- CT:
  - SV tumors: Enlarged SV, with a high-attenuation lesion and a normal bladder and prostate. Can be cystic if there is significant tumor necrosis
  - Cannot distinguish benign from malignant tumors. Obliterated tissue planes suggest a secondary tumor by direct extension
- MRI:
  - Cannot distinguish benign from malignant tumors
  - SV cyst: T1, low signal intensity; T2, unilocular smooth wall with uniform high intensity and well-defined margin
  - Hemorrhagic SV cyst: High intensity on both T1 and T2; heterogeneous intensity

Diagnostic Procedures/Surgery

- Cystoscopy
  - Hemitrigone with absent ipsilateral orifice
  - Intravesical cyst protrusion often noted with congenital SV cysts
- TRUS-guided needle placement for SV aspiration or biopsy for pathologic diagnosis
- Vasovesiculography: Limited value and use today in imaging the SV. Can help determine duct obstruction in azoospermic men; also helps distinguish SV cyst from a müllerian or other wolffian duct cyst

Pathologic Findings

Most primary SV masses are benign and rarely neoplastic.

DIFFERENTIAL DIAGNOSIS

- Müllerian duct cysts and ejaculatory duct cysts:
  - Both are midline in location
  - Spermatozoa in the aspirate may differentiate seminal vesicle cysts from müllerian duct cysts

- Prostatic cysts
- Diverticulosis of the ampulla of the vas deferens
- Ectopic ureterocele
- SV calcifications/masses can occur from chronic bilharziasis, TB, or old bacterial abscess (commonly from colonic flora):
  - Symptoms may include hematospermia, infertility, and pelvic pain
- SV cysts:
  - Seminal vesiculitis: SV infection is uncommon:
    - May occur as a consequence of prostatitis or epididymitis
  - SV abscess: Best imaged on MRI or US.
    - Predisposing factors include diabetes or chronic catheterization
    - Patients often have pelvic pain, fullness, and fever
  - SV calculi: Often present with pain, infection, or hematospermia; usually the result of infection and ejaculatory duct obstruction
  - Congenital vs. acquired cysts: Congenital cysts are typically associated with ipsilateral ectopic ureter and/or ipsilateral renal dysplasia
- Benign SV tumors:
  - Papillary adenoma or cystadenoma: Middle-aged men; mimics a simple cyst in presentation and on imaging
  - Amyloid: Subendothelial deposits of amyloid:
    - Usually presents in the elderly
    - Often concomitant with bladder or prostate cancer
  - Other rare tumors: Carcinoid
- Mixed SV tumors are extremely rare:
  - Only 15 cases reported
  - Variously described as cystadenoma, cystomyoma, low-grade phyllodes tumor, benign mesen-chymoma, adenomyosis, and mesonephric hamartoma
- Malignant SV tumors:
  - Most SV neoplasms are from secondary invasion from prostate, bladder, or rectal cancer, or lymphoma:
    - Direct extension into the SV can often be mistaken for primary SV cancer
  - Primary adenocarcinoma of the SV:
    - Age >50 yr; incidence is rare
    - Serum PSA and PAP are normal, and CEA elevated.
    - Stains positive for CA125 and negative for PSA
  - Primary sarcoma:
    - Extremely rare aggressive tumor; usually diagnosed late in disease course
    - Variants: Leiomyosarcoma, angiosarcoma, and müllerian adenosarcoma

TREATMENT

GENERAL MEASURES

- Asymptomatic cystic lesions do not require any specific intervention. Imaging of the urinary tract may reveal renal agenesis.
- Solid lesions require biopsy.

• Adjuvant therapy has no demonstrated efficacy in primary malignancy of the SV.

MEDICATION

First Line

Seminal vesiculitis is treated with standard antibiotic regimens used to treat prostatitis (eg, ciprofloxacin, ofloxacin)

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Symptomatic cysts
  - For small cysts, percutaneous transperineal or TRUS-guided aspiration/drainage (cysts typically recur)
  - Marsupialization (unroof into the prostate/bladder by TUR or TUI)
  - Laparoscopic or robotic-assisted laparoscopic excision. Laparoscopy has good efficacy with minimized morbidity (1)
  - Open surgical excision (by the transperineal, coccygeal, intravesical vesical, or retroperitoneal routes) is rarely performed today
  - If associated with a congenital ectopic ureter and dysplastic kidney: An ipsilateral nephroureterectomy, along with the SV, should be performed
  - SV duct stones: Lithopaxy is feasible in select patients via a ureteroscope
- SV tumors
  - All solid or noncystic SV masses on TRUS should undergo a US-guided biopsy:
    - If tumor is confirmed: Further stage with CT and/or MRI
  - Enlarging asymptomatic benign tumors are treated with simple seminal vesiculectomy
  - Historically, small benign tumors were excised transperineally or retrovesically, and large tumors, transvesically or transcoccygeally
  - Today, excisions are typically by transperitoneal laparoscopy (case series are small)
  - A diagnosis of malignancy (large in size or poorly differentiated) warrants radical cystoprostatectomy and regional lymph node dissection, en bloc with adherent surrounding structures
  - SV invasion by another malignancy: Directed at the primary tumor type

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Primary SV malignancies due to their rarity, typically present at an advanced stage and are

diagnosed late.
• Local invasion of SVs by secondary cancers are a poor prognostic sign.

COMPLICATIONS
ED can occur after SV excision since the neurovascular bundle lies lateral to the tip of the SV.

FOLLOW-UP
Patient Monitoring
Asymptomatic benign tumors: Close follow-up with DRE and TRUS. After radical surgery for malignancy, no clear follow-up consensus exists.

Patient Resources

• 608.0 Seminal vesiculitis
• 608.89 Other specified disorders of male genital organs

ICD10
• C79.82 Secondary malignant neoplasm of genital organs
• N49.0 Inflammatory disorders of seminal vesicle
• N50.8 Other specified disorders of male genital organs

CLINICAL/SURGICAL PEARLS
• Seminal vesical masses are most commonly secondary malignancies.
• During seminal vesiculectomy, limit cautery during dissection to limit damage to the

neurovascular bundle.

- Asymptomatic cystic lesions should be observed.

SEXUAL ABUSE, PEDIATRIC

Monica M. Metzdorf, MD
Julia S. Barthold, MD, FACS

BASICS

DESCRIPTION

- Sexual activity involving a child or a minor
- Spectrum of pediatric sexual abuse includes intercourse, fondling, pornography, and exhibitionism

EPIDEMIOLOGY

Incidence

~1% of children sexually abused each year

Prevalence

- 12–25% of girls and 8–10% of boys have been sexually abused by age 18 (12–40% overall)
- Of girls reporting abuse (1)
  - 65% reported abuse occurred more than once
  - 57% reported that abuser was family member
  - 53% reported that the abuse occurred at home

RISK FACTORS

- Occurs in all socioeconomic levels
- Increased risk with:
  - Parents who were abused
  - Poverty
  - Drug or alcohol abuse
  - Teen parents
  - Parental violence
  - Mental illness
  - Multiple child caretakers

PATHOPHYSIOLOGY

- American Academy of Pediatrics definition (2):
  - Child sexual abuse is the engaging of a child in sexual activities that the child cannot comprehend, for which the child is developmentally unprepared and cannot give informed consent, and that violate the social taboos of society.
  - Children cannot consent to any sexual activity, but note that the legal age of consent may vary on a state-by-state basis.

ASSOCIATED CONDITIONS

- Physical abuse
- Emotional abuse

GENERAL PREVENTION

- Education
- Social services

DIAGNOSIS

ALERT
Findings in the evaluation of children with straddle injuries to the external genitalia that should raise concern for sexual abuse include:
- Presence of other nonurogenital trauma.
- Patient < 9 mo.
- Perianal, rectal, injury without history of penetrating trauma.
- Findings of more extensive or severe trauma.
- Lack of correlation between reported history and physical findings.

HISTORY
- Child may make a statement of abuse, or abuse is witnessed
- Child brought by law enforcement/social services for evaluation for possible abuse as part of investigation
- Caregiver suspects child may have been abused
- Suspicious findings on routine exam
- Suspicious complaints: Rectal or vaginal bleeding or discharge, especially in prepubertal child
- Presenting symptoms may be general and nonspecific:
  - Sleep disturbances
  - Abdominal pain, enuresis, encopresis
  - Dysuria
- Consider evaluation by trained forensic interviewer
- Avoid leading questions or showing strong emotions/shock: Use “tell me more” or “and then what happened” approach?”
- Parent/caregiver should be interviewed separately to avoid influences/distraction
- Questions asked and verbatim answers in quotation marks should be documented as accurately as possible

PHYSICAL EXAM
- Be familiar with the normal appearance of the prepubertal introitus and hymen (image).
- Do not force exam on uncooperative children.
- Do not use speculum in prepubertal child.
- Do not touch hymen with swabs or other objects.
- Do not perform a digital rectal exam (DRE).
- Educate caretaker and patient that most sexually abused children have a normal physical exam. Absence of physical findings does not exclude abuse.
- Perform complete physical exam including skin, oropharynx, genitalia, and anal area.
- Use frog-leg position with gentle labial traction to visualize female anatomy.
- Consider exam in chest-knee position to confirm suspected abnormalities.
- Consult specialists as appropriate.
- Document thoroughly detailed exam findings and descriptions, using drawings or photos if

feasible.
- When severe rectal injury suspected, persistent bleeding or full thickness lacerations, consider exam under anesthesia.
- Exam findings of concern:
  – Abrasions or bruising of genitalia.
  – Acute or healed tear in posterior aspect of hymen.
  – A markedly decreased amount of hymenal tissue.
  – Injury or scarring of posterior fourchette, fossa navicularis, or hymen.
  – Anal bruising or lacerations.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Culture for gonorrhea and Chlamydia.
- Vesicles should be tested for HSV.
- All postmenarchal females should have pregnancy test.
- Presence of semen, sperm, or acid phosphatase; positive culture for gonorrhea or Chlamydia, or a positive test for syphilis or HIV (if prenatal transmission excluded for the STDs) makes sexual abuse a near medical certainty.

Imaging

None needed unless more extensive physical abuse is suspected

Diagnostic Procedures/Surgery

Consider exam under anesthesia

DIFFERENTIAL DIAGNOSIS

- Accidental trauma (straddle injuries, toilet-lid injury to penis, masturbation injuries)
- Anal fissure
- Hemangioma
- Hematochezia
- Henoch–Schönlein purpura
- Lichen planus
- Nonspecific vaginitis
- Normal anatomic variants (perihymenal bands, prominent linea vestibularis)
- Physical abuse
- Poor hygiene
- Urethral prolapse
- Vaginitis
- Vaginal foreign body

TREATMENT

GENERAL MEASURES

- Mental health evaluation is essential (3)
- Acute evaluation and treatment of injuries

MEDICATION

First Line

- Varies with presentation
  - Pain medication as appropriate
  - Postexposure prophylaxis (PEP) for prevention of pregnancy and STDs should be offered to adolescents
  - PEP generally not indicated for prepubertal children

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Consider exam under anesthesia
- Depends upon findings/injuries

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Need for mental health support, especially in:
  - Patients reporting suicidal or self-injurious thoughts
  - More intrusive forms of assault
  - More violent assaults
  - Longer period of molestation
  - Closer relationship of perpetrator to victim

COMPLICATIONS

- Psychological
  - Eating disorders
  - Depression and anxiety
    - Suicidal behaviors
    - Self-injury
  - Posttraumatic stress disorder
  - Sexual dysfunction
- Pregnancy
- STDs/STI's

FOLLOW-UP

Patient Monitoring

- Follow-up exams for healing of injuries
- Evaluation for development of STDs/STIs
- Evaluation for development of pregnancy and discussion of this possibility with the

postpubertal child
- Emotional support/therapy

Sexual Abuse, Pediatric Image

CODES

ICD9
- 995.53 Child sexual abuse
- V15.41 History of physical abuse

ICD10
- T74.22XA Child sexual abuse, confirmed, initial encounter
- T76.22XA Child sexual abuse, suspected, initial encounter
- Z62.810 Personal history of physical and sexual abuse in childhood

CLINICAL/SURGICAL PEARLS

- Pediatric providers should remain alert to signs and symptoms that suggest the possibility of sexual abuse.
- The clinician is obligated to report any suspected case of childhood sexual abuse.
- Sensitivity during the history and exam and providing the victim access to psychological and social work support are key factors in the case of children who have been sexually abused.

SEXUAL DYSFUNCTION, FEMALE

Samuel Walker Nickles, MD
Nima Baradaran, MD
Eric S. Rovner, MD, FACS

BASICS

DESCRIPTION

- Sexual dysfunction is a disorder involving sexual desire, orgasm, arousal, or sexual pain in females that results in significant personal distress. It includes the following:
  - Hypoactive sexual desire disorder
  - Subjective sexual arousal disorder
  - Genital sexual arousal disorder
  - Combined genital and subjective arousal disorder
  - Persistent sexual arousal disorder
  - Sexual aversion disorder
  - Women's orgasmic disorder
  - Dyspareunia
  - Vaginismus
  - DSM-IV defines femal sexual dysfunction (FSD) (formerly, inhibited female orgasm) as persistent or recurrent delay in, or absence of, orgasm following a normal sexual excitement phase
- Often multifactorial etiology

EPIDEMIOLOGY

Incidence

25–76% of adult women

Prevalence

N/A

RISK FACTORS

- Age
- Cardiovascular disease
- Depression, alcoholism, or drug abuse
- Diabetes mellitus
- Hyperlipidemia
- HTN
- Menopause
- Pelvic trauma or radiation
- Pelvic surgery for incontinence or prolapse
- Spinal cord injury (SCI)

Genetics

N/A

PATHOPHYSIOLOGY

- Vascular causes: Vascular insufficiency often secondary to atherosclerosis, causes diminished genital blood flow leading to vaginal and clitoral smooth muscle fibrosis (1,2)
- Hormonal influences: Estrogen plays a significant role in regulating sexual function and maintains the vaginal smooth muscle epithelium and lubrication
- Testosterone is the predominant female androgen that also supports sexual arousal and libido. Low estrogen or testosterone levels are associated with sexual dysfunction
- Neurogenic causes: SCI or disruption of the sacral reflex arcs interfere with vaginal sensation or the ability to reach orgasm
- Psychogenic causes: Emotional issues or psychological stressors such as depression, fatigue, or sexual abuse can negatively affect the female sexual response
- Iatrogenic:
  - Various medications such as antidepressants can decrease sexual desire and function
  - Prior pelvic surgery such as hysterectomy or cystectomy can disrupt the autonomic nerve plexus, thus contributing to sexual dysfunction
  - OCP: Exogenous estrogens

ASSOCIATED CONDITIONS

- Depression
- Endometriosis, vulvodynia, etc.
- Urinary incontinence
- Interstitial cystitis
- Menopause
- Multiple sclerosis
- Any disease that causes decreased estrogen or androgens

GENERAL PREVENTION

- Lifestyle modification to reduce CV disease or psychosocial stressors
- Improvements in surgical technique during pelvic surgery have lessened damage to nerves important in sexual arousal

DIAGNOSIS

HISTORY

- Age: Higher prevalence of sexual dysfunction in older women:
  - Physical and psychological factors associated with aging affect sexual desire and response
  - Decreased estrogen and testosterone after menopause decreases libido and promotes dryness and atrophy
- Sexual history
- Psychosocial history
- Self-administered, validated questionnaires such as the Female Sexual Function Index (FSFI) are useful objection tools to assess sexual function
- Childbirth: Short-term sexual dysfunction is common postpartum (22–86%) with loss of desire and dyspareunia
- Past medical history:
  - Hypertension (HTN), hyperprolactinemia (HPL), or diabetes mellitus

  - Thyroid disorders can also affect sexual dysfunction
  - Previous history of endometriosis, infections, or tumors should also be elucidated
- Past surgical history: Previous pelvic trauma, pelvic surgery, or radiation
- Medications:
  - Antidepressants such as seletive serotonin receptor inhibitors (SSRIs) or tricyclics can decrease libido
  - Oral contraceptives and tamoxifen can interfere with testosterone binding
  - Spironolactone or ketoconazole have antiandrogen properties
  - Antihypertensives and chemotherapeutic agents can also contribute to female sexual dysfunction
- Social history: Sexual, alcohol, or drug abuse; pertinent psychosocial factors or interpersonal relationships are also important

PHYSICAL EXAM
- A thorough physical and pelvic/bimanual exam:
  - Assess for vaginal atrophy, lichen sclerosis, vaginal depth, genital/perineal sensation
  - Examine for trigger points, scarring, or narrowing from prior surgery
  - Assess for prolapse, masses
- If neurologic signs are present, a more detailed neurologic assessment is then warranted including anal and vaginal tone, bulbocavernosal reflex, and voluntary tightening of the anus

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Basic chemistry panel, CBC, TSH, and lipid profile to help identify chronic medical conditions, renal failure, diabetes, or hyperlipidemia
- Hormonal profile
- Serum total and free testosterone
- Estradiol level
- LH, FSH, prolactin
- Sex hormone binding globulin (SHBG)

Imaging

Vaginal and clitoral plethysmography, duplex US, and selective pudendal arteriography can be used to assess genital blood flow.

Diagnostic Procedures/Surgery

Genital vibratory sensation threshold testing, genital temperature sensation, and the bulbocavernosal reflex can be evaluated to help rule out associated neurologic dysfunction

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS
- Desire phase disorders (3)
  - Hypoactive sexual desire (low sex drive)
  - Sexual aversion disorder: Panic disorder; active repulsion from sexual stimulation
- Impaired female sexual arousal

  - Failure to achieve or maintain vaginal lubrication
  - Swelling of genitalia; dyspareunia may result
- Orgasmic phase dysfunction
  - Orgasm in response to indirect stimulation: kissing, fantasy, breast stimulation
  - Orgasm only in response to clitoral stimulation
  - Lack of orgasm (Anorgasmy)
- Coital pain problems
  - Dyspareunia
  - Vaginismus
  - Reduced genital sensation
- Others
  - Urinary incontinence
  - Pelvic organ prolapse
  - Vascular causes
  - Surgical (Hysterectomy, oophorectomy, etc.)
  - Medication related
    - CNS depressants
    - Illicit drug abuse
    - Antihypertensives
    - Antiandrogens (cimetidine, ranitidine)
    - Chemotherapy

TREATMENT

GENERAL MEASURES

- Attempt to identify a correctable cause and treat when present.
- Exercise and pelvic floor training/massage can improve sexual function.
- Treat prolapse and incontinence in affected patients, as female sexual dysfunction may be in part related to inhibition due to leakage during sexual relations.

MEDICATION

First Line

- Hormone replacement therapy (HRT) is the mainstay of treatment in postmenopausal women or oophorectomized women (4)
  - Oral estrogen or topical vaginal estrogen may improve libido and ameliorate symptoms of dryness or irritation
  - Ospemifene is an estrogen agonist/antagonist indicated for the treatment of moderate to severe dyspareunia, a symptom of vulvar and vaginal atrophy, due to menopause
    - One tablet (60 mg) taken orally once daily with food
    - Do not use estrogens or estrogen agonist/antagonist or fluconazole concomitantly
  - Topical steroids for lichen sclerosis
  - Androgen replacement therapy can be considered in patients with androgen deficiency:
    - Combined estrogen and testosterone replacement therapy can be used or testosterone alone can be applied topically or with a patch (counsel patient on risks of virilization including: Acne, hirsutism, male pattern baldness, and clitoral hypertrophy)

  – Testosterone replacement is controversial and not FDA approved despite being one of the most commonly prescribed off label drugs for desire disorders
- Tibolone (synthetic steroid) is commonly used in Europe in postmenopausal women with desire and arousal disorders

Second Line
- Arousal disorders have been treated with several different classes of medications:
  – Alprostadil
  – Bupropion
  – Estrogen
  – Phentolamine and yohimbine
  – Sildenafil
  – Zestra

SURGERY/OTHER PROCEDURES
InterStim therapy is currently under investigation to treat sexual arousal disorders

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
- Eros Clitoral Therapy Device is a handheld mechanical device that has been FDA approved for the treatment of sexual arousal and orgasmic disorders in women.
- Several other pharmacologic agents are under investigation for treatment of female sexual dysfunction:
- PDE-5 inhibitors are thought to enhance vaginal lubrication and engorgement in postmenopausal women; however, the benefit is not well established.
- α-Adrenergic antagonists such as phentolamine and yohimbine produce vasodilation of the smooth muscle, increasing vaginal blood flow and lubrication.

Complementary & Alternative Therapies
- Education, sex therapy, psychotherapy, and cognitive behavioral therapy are also important in the multidisciplinary management of sexual dysfunction including those with a history of sexual abuse.
- Currently there are limited studies on the effectiveness of herbal remedies to aid female sexual dysfunction.

ONGOING CARE

PROGNOSIS
Outcome is improved if a specific cause can be identified.

COMPLICATIONS
Patients on HRT should be appropriately counseled on its risks and benefits.

FOLLOW-UP
Patient Monitoring
Close monitoring of progress and compliance is necessary.

Patient Resources

CLINICAL/SURGICAL PEARLS
- FSD is a complex condition with many etiologies.
- A multidisciplinary approach is often necessary.
- Search for reversible cause such as incontinence or prolapse and treat accordingly.

SEXUALLY TRANSMITTED INFECTIONS (STIs) (SEXUALLY TRANSMITTED DISEASES [STDs]), GENERAL

Ramiro J. Madden-Fuentes, MD
Judd W. Moul, MD, FACS

BASICS

DESCRIPTION

- Sexually transmitted infections (STIs) are viral, bacterial, or parasitic disease typically transmitted via exposure to infected secretions or infested genitalia.
  - Transmission is predominantly via sexual contact.
  - Nonsexual transmission: Mother–infant, blood transfusions, accidental needle injury.
  - STIs has generally replaced the term Sexually Transmitted Diseases (STDs)

EPIDEMIOLOGY

Incidence

- 20 million new infections yearly (1)[A]
  - Relative frequency of cases by disease: HPV > Chlamydia > Trichomonas > Gonorrhea > HSV-2 > syphilis > HIV > Hep B
  - 50% of new STIs in patients 15–24 yr old

Prevalence

- 110 million STIs estimated by the Centers for Disease Control and Prevention (CDC) (1)[A]
  - Most prevalent STI is human papilloma virus (HPV)
  - 25% STIs are incurable (HIV, HSV-2, Hep B)

RISK FACTORS

- Multiple sex partners, sexual contact with infected partner, unprotected sex
- Low socioeconomic status, drug abuse
- Exposure at delivery and/or in utero

Genetics

- CCR5 mutation provides relative protection against HIV infection (2)[C]

PATHOPHYSIOLOGY

- Ulcerative lesions
  - HSV-1 and HSV-2
    - Type 1: 85–90% of genital cases
    - Type 2: 10–15% usually oral to genital contact
    - Painful ulcer of genitalia or anus and concomitant painful inguinal lymphadenopathy
    - Prodrome (initial infection and recurrent flares): Flu-like symptoms
  - Chancroid (*Haemophilus ducreyi*)
    - Painful ulcer; tender inguinal adenopathy, suppurative with fistula to the skin
  - Syphilis (*Treponema pallidum*)
    - Primary syphillis presents with painless ulcer, may last 4–6 wk. ± nontender

adenopathy if untreated
    - Secondary syphillis presents with maculopapular rash of body and arms (including palms and soles of feet). If untreated 1/3 progress to 3° syphilis
    - Tertiary syphillis can affect any organ and can lead to aortitis, eye involvement, meningitis, spinal column (tabes dorsalis), and skin gummas
  - Granuloma inguinale (*Klebsiella granulomatis* or Donovanosis)
    - Painless ulcer without lymphadenopathy
    - Intracellular Donovan bodies (hairpin intracellular inclusions)
  - Lymphogranuloma venereum (LGV: *Chlamydia trachomatis* types L1–L3)
    - Transient genital ulcer
    - Tender inguinal/femoral lymphadenopathy
    - If untreated, may progress to a systemic infection or secondary bacterial infection
- Urethritis/cervicitis
  - *Neisseria gonorrhea*
    - May present as urethritis, epididymitis, proctitis, or prostatitis
    - Male: Purulent discharge, dysuria
    - Female: Usually asymptomatic, but may have pelvic discomfort, dysuria, dyspareunia
  - Nongonococcal *(C. trachomatis, Mycoplasma, Ureaplasma urealyticum*)
    - Chlamydia: Frequently asymptomatic, may present with urethritis, epididymitis, or prostatitis. Gonorrhea may coexist
    - 25% of women are symptomatic, and can have a mucopurulent cervical discharge
    - 40% of untreated women will develop pelvic inflammatory disease (PID). PID is associated with infertility and ectopic pregnancy
- Vaginal discharge
  - *Trichomonas vaginalis*
    - Male: Presents with urethritis but often asymptomatic
    - Female: Malodorous, yellow-green vaginal discharge with vulvar irritation
- Genital warts
  - Condyloma acuminata (HPV)
    - HPV 6 and 11 tend to cause warts, HPV 16, 18, 31, 33, and 35 are high risk for cellular dysplasia and increase cancer risk
  - Condyloma lata (*T. pallidum*)
    - Occurs in 10% of patients with 2° syphilis.
    - Moist, broad, wart-like, highly infectious lesions that may ulcer
- Parasites
  - Pubic lice (*Phthirus pubis*)
    - Presents with genital pruritus, insects may be visible on hair or clothing
  - Scabies (*Sarcoptes scabiei*)
    - Mites burrow under skin and lay eggs, pruritus results from an inflammatory reaction to excreta

ASSOCIATED CONDITIONS

- Coinfection is common (ie, gonorrhea and chlamydia)
- HPV may be associated with carcinomas (cervical, penile, vulvar)
- PID: (Chlamydia and gonorrhea), infertility, tuboovarian abscess, Fitz-Hugh–Curtis

syndrome
- Reiter syndrome: HLA B27
- Septic arthritis: Disseminated gonococcal infection

GENERAL PREVENTION
- Abstinence
- Female and male condoms
- Education and awareness of risky behavior
- HPV vaccine (Cervarix—against HPV 16, 18; Gardasil—against HPV 6, 11, 16, 18) (3)[A]

DIAGNOSIS
HISTORY
- Symptoms, duration, onset, quality, severity, related conditions
  - Especially: Dysuria, dyspareunia, urethral discharge, genital lesions
- Screen for IV drug use, drug/alcohol abuse
- Sexual history: Prior STIs, number partners, use of protection

ALERT
Rule out sexual abuse in children with a potential STI.

PHYSICAL EXAM
- Vitals: Fever, tachycardia
- Skin: Maculopapular rash (syphilis), examine soles and palms, linear burrows (scabies)
- Cardiac: Murmur (aortic insufficiency—syphilis)
- Abdomen: Tenderness, rebound, guarding
- GU: Ulcerations, vesicles, urethral discharge, warts (GU and anal)
- Pelvic: Cervical tenderness, petechial hemorrhages (Trichomonas), uterine tenderness
- Neuro: Tabes dorsalis, Argyll Robertson pupil (syphilis)

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- HSV (3)[A]
  - Growth of HSV in culture with serologic subtyping is gold standard
  - PCR assay for HSV DNA most sensitive for diagnosis: FDA approved only for vaginal swabs in symptomatic women
  - Cytologic detection (Tzanck smear) is not sensitive and should not be relied upon
- Syphilis (3)[A]
  - Dark field microscopy or direct fluorescence antibody of lesion exudate is diagnostic
  - Serologic: Nonspecific treponemal test
    - Rapid plasma reagin (RPR) and venereal disease research laboratory (VDRL): Sensitivity is ~80% in primary syphilis, 100% in secondary, and over 95% in tertiary syphilis
    - Must confirm with a specific treponemal test
    - Will revert to normal after therapy
  - Serologic: Specific treponemal test
    - FTA-ABS (fluorescent treponemal antibody absorbed) and TP-PA (*T. pallidum* particle agglutination)—detects antibodies against spirochetes

- Positive for life

- HIV (3)[A]
  - ELISA (an enzyme immunoassay): Rapid, sensitivity—99.7%, specificity—98.5%
  - Confirm ELISA + results by Western blot
- Chlamydia/Gonorrhea (3)[A]
  - Nucleic acid amplified test (NAAT) of urine: 1st 10–30 cc voided
  - Culture: Gonorrhea in Thayer–Martin or chocolate agar
- LGV: Swab lesion or aspirate node for culture (3)[A]
- Chancroid (3)[A]
  - *H. ducreyi* can be grown on culture, although sensitivity is $<80\%$
  - PCR is available, but not FDA approved
- Granuloma inguinale (3)[A]
  - Difficult to culture; requires visualization of dark-staining Donovan bodies in sample
- Trichomonas (3)[A]
  - Wet prep reveals flagellated protozoans
  - In men, wet prep not sensitive: Thus, culture urine, urethral swab, or semen
- Pubic lice/scabies
  - Detectable on low-power microscopy

Imaging

N/A

Diagnostic Procedures/Surgery

- HPV: Aceto-white test for occult disease
  - 3–5% acetic acid (white vinegar) application to HPV-infected mucosa turns white
  - Questionable utility: Not validated

Pathologic Findings

See “Lab” section

DIFFERENTIAL DIAGNOSIS

- Genital ulcer mnemonic **CHISEL**
  - **C**hancroid (painful)
  - **H**erpes genitalis (painful)
  - **I**nguinale (granuloma inguinale)
  - **S**yphilis (painless)
  - **E**ruption secondary to drugs
  - **L**GV
- Genital ulcer: Other causes
  - Behçet disease
  - Excoriations
  - Fixed drug eruption
  - Genital trauma
  - Pyoderma
  - Scabies
- Urethral discharge

  - Gonorrhea
  - Nongonococcal urethritis: *C. trachomatis* (35–45%), *Ureaplasma urealyticum* (15–25%), *Trichomonas vaginalis*
- Nonulcerative STDs
  - PID: *C. trachomatis, N. gonorrhea, Mycoplasma hominis*, facultative or anaerobic organisms
  - Syphilis (secondary/tertiary)
  - HIV, hepatitis B and C

TREATMENT

GENERAL MEASURES

- Screen for coinfection (including HIV)
- Educate for prevention of transmission
- Screen partner

MEDICATION

First Line

- HSV: Acyclovir 400 mg PO TID for 7–10 days, or famciclovir 250 mg PO TID for 7–10 days, or valacyclovir 1 g PO BID for 7–10 days (3)[A]
- Chancroid: Azithromycin 1 g PO in 1 dose or ceftriaxone 250 mg IM in 1 dose
- Syphilis
  - Primary: Benzathine penicillin G 2.4 million units IM in 1 dose
  - Latent: Early—benzathine penicillin G 2.4 million units IM once. Late—Benzathine penicillin G 2.4 million units IM weekly × 3 wk
  - Tertiary: Nonneurosyphilis - benzathine penicillin G 2.4 million units IM weekly × 3 wk. Neurosyphilis—aqueous crystalline penicillin G, 3–4 million units IV q4h for 10–14 days
- Granuloma Inguinale: Doxycycline 100 mg PO BID for 21 days or until all lesions are healed
- LGV: Doxycycline 100 mg PO BID for 3 wk
- Gonorrhea: Ceftriaxone 250 mg IM in 1 dose, or cefixime 400 mg PO in 1 dose; also treat for *Chlamydia*
- Chlamydia: Azithromycin 1 g PO in 1 dose or doxycycline 100 mg PO BID for 7 days
- Trichomoniasis: Metronidazole 2 g PO 1 dose
- Genital warts (condyloma)
  - Observation
  - Podofilox 0.5% solution or gel (lesion <10 cm) q12h for 3 days then off for 4 days; cycle may be repeated 4 times
- Pubic lice: Permethrin cream (1%) to affected areas and washed off after 10 min

Second Line

Please refer to the CDC's published Sexually Transmitted Diseases Treatment Guidelines 2010 for updates and alternatives

SURGERY/OTHER PROCEDURES

- Surgical intervention may be necessary secondary to complications from STIs
  - Urethritis: Urethral stricture
  - Gonorrhea/chlamydia: PID (tuboovarian abscess, ectopic pregnancy)

– HIV: Kaposi sarcomas
– Genital warts (condyloma): Ablation with laser, electrosurgery

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Many STIs cured with treatment
- HSV: Outbreaks reduced by prophylactic therapies
- HIV: Medical management portends long survival

COMPLICATIONS

Urethral stricture, carcinomas, PID, infertility, neurologic, and cardiovascular disease

FOLLOW-UP

Patient Monitoring

Screen nonpregnant females <25 yr old for gonorrhea/chlamydia. Screen nonpregnant females with risky behavior for gonorrhea/chlamydia/HIV/syphilis (4)[A]

Patient Resources

CDC. http://www.cdc.gov/std

CODES

ICD9

- 042 Human immunodeficiency virus [HIV] disease
- 099.41 Other nongonococcal urethritis, chlamydia trachomatis
- 099.9 Venereal disease, unspecified

ICD10

- A56.8 Sexually transmitted chlamydial infection of other sites
- A64 Unspecified sexually transmitted disease
- B20 Human immunodeficiency virus [HIV] disease

CLINICAL/SURGICAL PEARLS

- When treating gonorrhea treat for chlamydia as these often coexist.
- HPV vaccine recommended for Either HPV vaccine is recommended (by the CDC) for 11–12-year-old girls. Quadrivalent HPV vaccine is recommended for 11–12-year-old boys. Start series at age 9 years. Vaccination is also recommended for 13–26-year-old females and13–21-year-old males who have not completed the vaccine series. Quadrivalent HPV vaccine may be given to 22–26-year-old males and is routinely recommended for both men who have sex with men (MSM) and immunocompromised persons aged 22 through 26 years.
- Urethritis may lead to urethral stricture in males.

SICKLE CELL DISEASE, UROLOGIC CONSIDERATIONS

Philip J. Dorsey, Jr., MD, MPH
Benjamin R. Lee, MD, FACS

BASICS

DESCRIPTION

- Sickle cell (SC) disease is a chronic hemoglobinopathy transmitted genetically and marked by severe chronic hemolytic anemia and periodic acute painful episodes.
- The heterozygote is termed SC trait and usually has no symptoms.
- Major GU complications can include priapism and a spectrum of renal disorders from hematuria and decreased renal concentrating ability through renal medullary carcinoma and renal failure.

EPIDEMIOLOGY

Incidence

- 1:500 African American births
- 1:1,000 Hispanic American births
- 2 million Americans, or 1 in 12 African Americans, carry the SC trait.
- ~4,000–5,000 pregnancies are at risk of SC disease.
- Life expectancy: Men, 42 yr; women, 48 yr

Prevalence

- Prevalence estimated at 8% of African Americans
- 8–10% of African Americans have SC trait
- 25–30% of Western Africans have SC trait

RISK FACTORS

Family history of disease

Genetics

- Autosomal codominant inheritance pattern
- Allele is on chromosome 11
- Several haplotypes; allelic with β-thalassemia
- SC disease: Inheritance of 2 alleles, all RBCs contain hemoglobin (Hb)S
- SC trait: From 1 allele, 40% of Hb is HbS

PATHOPHYSIOLOGY

- Sickling of RBCs caused by HbS in ischemic state leading to vaso-occlusive state and causing most complications of SC disease:
  – Substitution of valine for glutamate at 6th amino acid position
- HbS tetramer: The deoxygenated state polymerizes into double-stranded filaments and bundles
- Chronic anemia is the hallmark of the disease; RBC mean lifespan: 17 days
- SC trait (heterozygote) usually asymptomatic
- Decreased renal concentrating ability is common and results in polyuria and nocturia

- Hematuria is due to chronic papillary infarctions:
- Predominantly left-sided
- Renal infarction due to ischemia; may present with nausea, vomiting, abdominal and flank pain, and HTN
- Renal papillary necrosis due to ischemia; may cause secondary infection or obstruction
- Progressive renal failure and proteinuria due to glomerular injury; renal failure in ~10%
- Renal medullary carcinoma:
  – An aggressive malignancy
  – Almost exclusively found in young African American patients with SC trait, or SC disease

ASSOCIATED CONDITIONS
- Acute papillary necrosis
- Anemia
- Hepatitis C and HIV (increased risk for these and other transfusion-associated infections)
- Priapism
- Renal medullary carcinoma
- Hyposthenuria (Urine with low specific gravity)
- Urinary tract infections

GENERAL PREVENTION
Avoid situations that precipitate sickling episodes (dehydration, hypoxia, cold, infections, fever, acidosis).

DIAGNOSIS
HISTORY
- Prior episodes of SC complications and outcomes
- Timing of sexual maturation (delayed puberty)
- Determine time length of any priapism episodes
- Painful crisis brought on by cold or dehydration
- Nocturnal enuresis

PHYSICAL EXAM
- HTN is unusual.
- Look for staging of sexual maturation.
- Palpate testes in men to check for atrophy.
- In cases of priapism, examine the glans to determine bi- or tricorporal involvement.
- Splenic sequestration causes painful enlargement of the spleen.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Complete blood count (CBC): Note degree of anemia
- Peripheral blood smear: Presence of sickled or deformed RBCs with high reticulocyte count
- Hb electrophoresis: Types and percentages of Hb present
- SC prep: Rapid determination of SC disease vs. trait vs. normal. Check fet al Hb level
- Urine analysis: Hematuria, proteinuria, or infection
- Urine culture: Infection if indicated by urine analysis or symptoms

- Serum creatinine
- Monitor for renal insufficiency, and calculate GFR as needed. The creatinine clearance may overestimate the GFR.
- Hyperphosphatemia may be present
- Blood Gas (BG) measurement on corporal blood aspirates in priapism setting to assess high- vs. low-flow state:
  – pH <7.10 (acidotic) suggests a low-flow state.

Imaging
- CT urogram using low osmolar contrast, as indicated for hematuria:
  – May not be useful in progressive renal insufficiency (poor concentrating ability limits visualization)
  – Papillary necrosis may be present
- Renal medullary carcinoma may present as a centrally located infiltrative lesion invading the renal sinus with peripheral caliectasis
- US: Noninvasive; look for renal source of hematuria if renal insufficiency precludes contrast use
- MRI when indicated

Diagnostic Procedures/Surgery
- Cystoscopy: As needed for hematuria
- Retrograde pyelograms: Upper-tract sources of bleeding if IVP limited or suspect papillary necrosis
- Ureteroscopy: For hematuria as indicated
- Renal biopsy: As needed for specific glomerulopathies
- Impotence evaluation with duplex blood flow studies. (Preferred over nocturnal penile tumesence (NPT) monitoring).

Pathologic Findings
- Peripheral blood smear: Presence of sickled or deformed RBCs
- Penile corporal fibrosis seen in patients with stuttering or recurrent priapism
- Hb electrophoresis: Types and percentage of Hb present
- Renal biopsy:
  – Early: Glomerular hypertrophy, hemosiderin deposits, focal areas of hemorrhage or necrosis
  – Late: Interstitial inflammation, edema, fibrosis, tubular atrophy, and papillary infarcts

DIFFERENTIAL DIAGNOSIS
- Other SC diseases: SC trait, sickle-β thalassemia, etc.
- Hematuria (see Section I topic)
- Papillary necrosis (see Section I topic)
- Priapism (see Section I topic)

TREATMENT

GENERAL MEASURES
- For acute SC crisis:

- Oxygenation, nasal canula
- Aggressive hydration: Counters dehydration, increases perfusion, and improves blood rheology
- Metabolic alkalinization limits further sickling
- Pain control
- Narcotics for pain: Risk of addiction is negligible in the acute setting
  - Patient controlled analgesia (PCA) for inpatients

MEDICATION

First Line

- Simple transfusion:
  - Transfusion performed to increase proportion of RBCs with normal Hb to decrease sludging
  - Blood transfusion performed less liberally than in past because of risks of exposure to antigens
  - Indications for transfusion:
    - Acutely: Persistent, recurrent priapism after failure of corporal irrigation, injection of vasoactive medications and other measures before shunting procedure or if life-threatening hemorrhage
    - Preoperative transfusion if significant anemia or if indicated by procedure
- Exchange transfusion:
  - Used when needed to remove RBCs and replace with transfused blood products if simple transfusion fails
  - Risk of cerebrovascular accidents with increased hematocrit, causing a relative hyperviscosity (ASPEN syndrome)
- Antibiotics: As needed for infections
- Hematuria:
  - Diuresis with IV hydration is standard
  - Alkalization decreases sickling and hematuria
  - Aminocaproic acid is used to induce thrombosis and control persistent and threatening hematuria, but can cause clot formation in the urinary tract
  - Persistent or life-threatening hematuria may rarely necessitate nephrectomy
  - High-dose urea in selected cases
- Priapism (see Section I “Priapism”):
  - Prompt corporal irrigation to induce detumescence and remove old clotted blood
  - Use α-adrenergic agents for corporal injection to decrease inflow to corpora for detumescence
  - Impotence due to fibrosis can be managed with penile prosthesis after 6 mo
- Delayed sexual maturation:
  - Cautious supplementation of testosterone

Second Line

NA

SURGERY/OTHER PROCEDURES

May be needed in the acute setting for priapism or urinary tract obstruction due to sloughed

papilla

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Follow-up and monitoring by hematologist
- Hydroxyurea
- α-Adrenergic medication (ie, pseudoephedrine) and low-dose PDE-5 inhibitors used for prevention of stuttering priapism
- Folic acid and penicillin in pediatrics
- Genetic counseling

Complementary & Alternative Therapies

NA

ONGOING CARE

PROGNOSIS

Several factors aside from genetic inheritance determine prognosis, including frequency, severity, and nature of specific complications.

COMPLICATIONS

- Nephropathy:
  - Renal insufficiency
  - Vaso-occlusion in renal medulla secondary to hypertonicity, inducing HbS sickling
  - Progressive cortical infarction leads to CRF; average age of onset is 23 yr
  - Hyposthenuria: Inability to maximally concentrate urine in the face of dehydration or vasopressin
  - Usually associated with renal insufficiency; able to dilute urine
  - Associated impairment of K excretion
    - Renal biopsy: Focal and segmental glomerulosclerosis, membranous glomerulopathy, or MPGN
    - Proteinuria can progress to full-blown nephrotic syndrome
- Hematuria:
  - Microscopic or gross hematuria; mechanism unknown. Source rarely identified; possibly due to papillary necrosis
  - Usually unilateral (left-sided)
  - Male > female
  - Usually remits with conservative measures (eg, bedrest, hydration) with 50% recurrence
- Papillary necrosis:
  - Due to medullary ischemia from sickling in vasa recta (see in 40% of patients with SCD)
  - Radiologic diagnosis can be difficult due to poor concentrating ability of kidneys
  - Can cause hematuria
  - Can obstruct, if sloughed papillae blocks the UPJ or ureter
- Priapism:

  - Affects ~66% of SC disease patients
  - 2 age peaks; onset usually after puberty
  - 5–13 yr, then at 21–29 yr
  - Initiating factors: Nocturnal penile tumescence and sexual arousal
  - Typically, bicorporal involvement
  - Pathophysiology: Engorgement and sludging of the corpora, with no outflow and low flow
  - Major risk is fibrosis and subsequent impotence; children have greater chance of recovery and subsequent erectile function
- Impotence:
  - Fibrosis from recurrent episodes of priapism
- Delayed sexual maturation:
  - Primary hypogonadism, due to testicular ischemia or infarction, hypopituitarism, or hypothalamic insufficiency
  - Correlates with severity of sickle disease
- Infertility:
  - Complication of hypogonadism and direct testicular insult by ischemia and infarction
- UTI:
  - Usually *Escherichia coli*, or other gram-negative bacteria
  - Can lead to more serious infections or bacteremia
- RTA:
  - Incomplete distal RTA (type IV) from progressive medullary infarction
  - Inability to lower urine pH to <5
  - Can develop hyperchloremic metabolic acidosis in SC disease and renal insufficiency
  - Not associated with nephrolithiasis
- Acute urinary retention:
  - Related to acute, painful SC; transient, resolves with resolution of the acute episode
- Renal medullary carcinoma:
  - Median age 13 yr
  - High mortality

FOLLOW-UP

Patient Monitoring

- Renal function over time
- Regular follow-up

Patient Resources

CLINICAL/SURGICAL PEARLS

Urologic complications are common in SC disease.

SPERMATIC CORD MASS AND TUMORS

Nima Baradaran, MD
James S. Rosoff, MD

BASICS

DESCRIPTION

- The spermatic cord extends from the internal inguinal ring to the testicle, passing through the inguinal canal.
- Cord structures consist of vas deferens, internal and external spermatic arteries, artery to the vas deferens, pampiniform plexus, lymphatics, nerves, investing layer of fascia, and cremaster muscle.
- Considered paratesticular tissue
- Masses or swelling can be cystic or solid:
  - Most cystic (70–75%)
  - Most benign (75–80%)
  - Usually asymptomatic
  - Most solid spermatic cord masses are also benign

EPIDEMIOLOGY

Incidence

Varies by type (see Pathophysiology)

Prevalence

Varies by type (see Pathophysiology)

RISK FACTORS

Varies by type (see Pathophysiology)

Genetics

Varies by type (see Pathophysiology)

PATHOPHYSIOLOGY

- Cord mass can arise from cord contents or from structures above or below the cord
- Generally nonacute and benign
- Most common malignant tumors are sarcoma
- Varicocele
  - Enlarged, tortuous spermatic veins above the testis; most common on the left side
  - Isolated right-sided varicocele is rare and may suggest retroperitoneal pathology
  - Asymptomatic, often found on routine exam
  - Grade I: Palpable, grade II: Palpable without Valsalva, grade III: Visible
  - May cause infertility; likely increasing scrotal temperature, impairing spermatogenesis
- Hydrocele
  - Patent processus vaginalis causes collection of peritoneal fluid between the visceral and pariet al layers of tunica vaginalis
  - Painless groin mass contiguous with the cord structures that transilluminates

- Communicating hydrocele with “indirect hernia”; more commonly seen in infancy
- Congenital; incidence of 4%, seen in early adolescence. May have associated inguinal hernia (usually children)

- Spermatic cord hydrocele
  - Loculated fluid collection along the spermatic cord, separated from and located above the testicle and the epididymis
  - Rare congenital anomaly from abnormal closure of the processus vaginalis distally and in some cases proximally; 2 types:
    - Encysted hydrocele of the cord: The fluid collection does not communicate with the peritoneum/tunica vaginalis
    - Funicular hydrocele of the cord: Distal closure of the processus vaginalis with fluid collection along the cord, communicating with the peritoneum at the internal ring
- Spermatocele:
  - Cloudy fluid and sperm-filled cyst arising from epididymal tubules; usually at the head of epididymis
  - Very common (up to 30% of general population), usually asymptomatic; incidental finding on ultrasound
- Inguinal hernia in adults:
  - Late-onset communicating “indirect” hernia in adults
  - “Direct” through the floor of the inguinal canal
  - Indirect presents as mass in inguinal cord or extends through external ring into scrotum
- Lipoma of the cord:
  - Benign; most common tumor of the cord and paratesticular tissues
  - From adipose tissue of the cord; fat collections around hernia sac; not true lipomas
- Adenomatoid tumor:
  - Benign neoplasms; most common epididymal tumor; no reliable echo pattern for diagnosis; can involve the spermatic cord
- Sarcomas:
  - Rare lesions of spermatic cord, epididymis, and paratesticular soft tissue, from muscle, adipose, or connective tissue
  - Incidence peaks: Adolescence and >40.
  - Rhabdomyosarcoma and leiomyosarcoma most common
  - High rate of recurrence after excision
- Other malignant tumors of spermatic cord:
  - Melanoma and metastatic cancers are rare.
- TB of spermatic cord:
  - Rare; 70% of cases have history of TB; usually in young, sexually active males
  - Presents as TB epididymitis; difficult to differentiate from acute epididymoorchitis
  - Usually secondary to infection of epididymis via direct extension
- Sarcoidosis:
  - Systemic granulomatous disease; increased intestinal adsorption of calcium; hypercalcemia and hypercalciuria
- Funiculitis:
  - Inflammation of spermatic cord secondary to severe epididymitis or due to trauma

- Filarial hydroceles:
  – Caused by *Wuchereria bancrofti*; often have a thickened spermatic cord and epididymis
- Undescended testicle
- Retractile testicle

ASSOCIATED CONDITIONS
- Renal tumor invading renal vein or retroperitoneal mass compressing right gonadal vein with isolated right-sided varicocele or any acute onset of varicocele
- TB with spermatic cord involvement
- Filariasis

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Patients present with symptomatic or asymptomatic mass with or without swelling.
- Most masses are painless at onset.
- Presence or absence of pain does not differentiate benign or malignant mass.
- Scrotal elevation may provide relief.
- Recumbent position may resolve mass and pain in varicocele and communicating hydrocele.
- History of cryptorchidism is important.

ALERT
Always rule out torsion of cord if pain is acute.

PHYSICAL EXAM
- Examine patient in warm room in both upright and supine positions (1).
- Cord mass can be palpated in the inguinal region or the upper scrotum.
- Palpate mass with thumb and 1st 2 fingers of both hands and note character (hard, firm, cystic).
- Transillumination signifies cystic mass:
  – Cystic mass may not transilluminate if thick wall, chronic inflammation, or blood present.
- Spermatic cord can be followed to the internal inguinal ring by palpitation.
- Verify both testicles present in scrotum.
- The vas deferens can be felt in the scrotum by 1st encircling the cord with the fingers and allowing small amounts of cord to pass through.
- Valsalva maneuver performed with patient in supine and standing positions for varicocele or hernia:
  – Usually palpable posterior to and above the testicle and can mimic solid mass.
  – Crucial to assess testicular volume and consistency in boys with varicocele.
  – Ipsilateral testis may be atrophic.
  – Palpation can determine superior and inferior extent of mass (unlike inguinal hernia).
- Communicating hydrocele:
  – Enlarges when upright and with activities that increase intra-abdominal pressure.
  – Supine position drains fluid into peritoneal cavity and decreases size.

  – Abdominal contents may be found in the sac: Small intestine, omentum, or bladder.
  – Proximal limit not palpable since contents extend through internal ring.
- Adult inguinal hernia:
  – May be direct or indirect, reducible or incarcerated.
  – Superior extent of the mass not palpable.
  – May have bowel sounds over the mass.
  – Attempt to reduce hernia with gentle pressure in supine or Trendelenburg position.
  – After reduction, insert finger through external ring into inguinal canal.
  – Cough or Valsalva maneuver produces impulse, caused by abdominal contents felt at fingertip.
- Lipoma of the cord is palpated as smooth, firm mass in inguinal canal or upper scrotum:
  – Nontender; does not transilluminate.
  – Usually incidental finding during inguinal procedures.
  – Important to rule out concomitant inguinal hernia by noting the intact external inguinal ring on exam.
- Adenomatoid tumors found on routine exam:
  – Painless, well-circumscribed, hard; nearly 50% at the head of the epididymis
  – Most common solid paratesticular mass.
  – Usually asymptomatic and slow growing.
- Sarcomas present as firm to hard mass, occasionally tender:
  – May be distinct and well circumscribed or invade the surrounding tissues.
  – Explore all solid masses for malignancy.

ALERT
No clinical signs or symptoms reliably distinguish between benign or malignant solid mass.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Urinalysis to rule out infectious processes

Imaging

- Scrotal US: Solid vs. cystic mass (2)
  – Cannot differentiate benign or malignant mass
- MRI or CT in certain clinical scenarios

Diagnostic Procedures/Surgery

Solid masses: Biopsy (mostly excisional) with surgical exposure

Pathologic Findings

Distinguish leiomyosarcoma from leiomyoma based on occasional or absent mitotic figures and uniform cellular arrangement

DIFFERENTIAL DIAGNOSIS

- Adenomatoid tumor of the cord (1,2)
- Epidermoid cyst, epididymitis/epididymo-orchitis, funiculitis, tuberculoma
- Hernia
- Hydrocele
- Hydrocele of the cord

- Hemangioma
- Inguinal lymphadenopathy
- Leiomyoma
- Malignant tumor: Liposarcoma, rhabdomyosarcoma, leiomyosarcoma, malignant fibrous histiocytoma, metastatic melanoma, and others
- Undescended/retractile testicle, polyorchidism
- Sperm granuloma, spermatocele
- Testis tumor
- Varicocele
- Vasitis and vasitis nodosa (usually associated with epididymitis)

ALERT
Torsion of the cord or incarcerated/strangulated hernia is surgical emergency.

TREATMENT

GENERAL MEASURES
- Distinguish testis and epididymis (physical exam, transillumination, scrotal US).
- Most cystic masses do not need treatment.
- Investigate pain as presenting feature; sarcoma is often misdiagnosed as inflammatory lesion.

MEDICATION
First Line
Anti-TB drug therapy for 6–9 mo for TB (tuberculoma) in spermatic cord

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Spermatocelectomy if painful or symptomatic
- Hydrocelectomy (only if large or symptomatic)
- In children, repair hydrocele by age 2 if it does not resolve; usually associated with indirect hernia
  – Communicating hydrocele often resolves in children within 1st yr
- Inguinal hernia (adults): Herniorrhaphy
- Communicating hydrocele with hernia:
  – Explore through inguinal incision
  – Exploration of asymptomatic contralateral inguinal canal in children with inguinal hernia or communicating hydrocele is controversial
- Varicocele:
  – Varicocelectomy *may* relieve pain and improve fertility
  – Standard testis volume measurements are mainstay of assessing need for surgical management of varicocele
- Explore solid masses for malignancy:
  – Inguinal incision; testis is delivered and inspected
  – Early control of cord at internal ring

– Biopsy to confirm diagnosis
- TB of cord: Excision of the mass
- Sarcoma: Radical orchiectomy with high ligation of the cord (wide resection margins if possible); possible flaps to reconstruct large anatomic defects

ADDITIONAL TREATMENT

Radiation Therapy

Retroperitoneal lymphadenopathy with adjuvant radiation or chemotherapy indicated for malignant tumor

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Excellent for benign lesions

COMPLICATIONS

Risk of infertility in varicocele

FOLLOW-UP

Patient Monitoring

- None for benign masses
- Liposarcoma, leiomyosarcoma, and rhabdomyosarcoma may recur; closely monitor (physical exam, imaging)

Patient Resources

N/A

- 222.8 Benign neoplasm of other specified sites of male genital organs
- 608.9 Unspecified disorder of male genital organs

ICD10

- C49.5 Malignant neoplasm of connective and soft tissue of pelvis
- D29.8 Benign neoplasm of other specified male genital organs
- N50.9 Disorder of male genital organs, unspecified

CLINICAL/SURGICAL PEARLS

- Pain may be attributed to emergencies such as torsion.
- Ultrasound is a valuable diagnostic tool.

SPERMATOCELE

Irvin H. Hirsch, MD
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION

- Spermatocele is a benign, fluid-filled cystic mass most often in the head (caput) of the epididymis. The spermatocele can occur in other areas of the epididymis, rete testis, or along the vas deferens.
- Sometimes referred to a "spermatic cyst" or "acquired epididymal cyst."
- Clinically, spermatocele is differentiated from a hydrocele in that the spermatocele may contain viable or nonviable spermatozoa.
- Usually not a cause of epididymal obstruction.
- Also called an epididymal cyst or acquired epididymal cyst in the literature (1):
  - Some sources state that the epididymal cyst is congenital and represents the most common epididymal mass.
  - The origin of the epididymal cyst is thought to be lymphatic.
  - Epididymal cyst fluid does not contain spermatozoa.
  - Clinical management is similar, so the differentiation between spermatocele and epididymal cyst may not be significant.

EPIDEMIOLOGY

Incidence

- Peak incidence in 4th–5th decades
- Rare in children
- No racial or ethnic predilection
- Reported in 30–70% of postpubertal males undergoing high-resolution scrotal US

Prevalence

N/A

RISK FACTORS

- Diethylstilbesterol (DES) exposure in utero
- Inflammation
- Not clearly related to prior vasectomy, prior epididymitis, or herniorrhaphy
- Trauma
- Von-Hippel Lindau (VHL) syndrome
  - Mostly epididymal cystadenomas with simple cysts less common

Genetics

- VHL syndrome:
  - Mutations of the VHL suppressor gene on 3p.
  - Increased incidence of epididymal cysts and papillary cystadenomas of the epididymis

PATHOPHYSIOLOGY

- Main concern is usually that of confusion with a true testicular mass.
- Precise mechanism is unknown.
  - Cystic dilatations of tubules of the epididymis
  - The efferent ductules in the head of the epididymis.
- The distinction between a spermatocele and an epididymal cyst is based on size; epididymal cystic masses >2 cm are spermatoceles. Spermatoceles are always located superior to the testis and are palpated as distinct from the testis, which differentiates them from hydroceles.
- Spermatoceles generally range in size from 2 to 5 cm.
- Trauma and inflammation may result in obstructed efferent ductules or epididymal tubules, resulting in a dilated spermatocele.
- No effect on fertility.
- Most are idiopathic.
- Most ≤ 1 cm in size.

ASSOCIATED CONDITIONS
- Epididymal obstruction may rarely be present
- Prior vasectomy
- High association with tubular ectasia of the rete testis

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Typical presentation is a painless, asymptomatic, intrascrotal mass found on testicular self-exam or on routine office exam.
- Occasionally may present with orchialgia or scrotal heaviness.
- No associated urinary symptoms

PHYSICAL EXAM
- Palpation shows a smooth, soft, spherical nontender mass at the head (caput) of the epididymis.
- Lies just superior and posterior to the testis but is distinct from testis.
- A cystic mass above the testis is usually demonstrated on scrotal transillumination.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urine analysis
- Urine culture
- Serum AFP, hCG, LDH if there is concern over testis tumor

Imaging
- Scrotal US is diagnostic:
  - Lesion is hypoechoic with posterior acoustic enhancement
  - May have internal echoes
  - MRI if US is indeterminate

Diagnostic Procedures/Surgery

Needle aspiration for diagnosis is not usually indicated. If indicated, a 30-gauge needle can be used to aspirate the cyst fluid.

Pathologic Findings

- Clear or opaque fluid-filled mass
- Fluid contains spermatozoa (live or dead), lymphocytes, and cellular debris
  - Hydrocele, the other common cystic lesion is devoid of spermatozoa
- Fibromuscular wall lined by cuboidal epithelium

DIFFERENTIAL DIAGNOSIS

- Adenomatoid tumor of the epididymis:
  - Most common solid tumor of the epididymis
- Ectopic tissues:
  - Adrenal cortical rests
  - Splenogonadal fusion
- Epidermoid cyst
- Epididymal calcinosis
- Epididymal cystadenoma/papillary cystadenoma;
  - 2/3 associated with von Hippel–Lindau syndrome
  - 1/3 of all epididymal tumors
  - 2/3 associated with VHL syndrome
  - On US, most common appearance is 15–20-mm solid mass with small cystic components.
- Epididymitis Epididymo-orchitis:
  - Acute; very tender on exam
  - Chronic; may have secondary calcification
  - Common cause of epididymal pain
- Fibroma of epididymis
- Fibrous pseudotumor
- Funiculitis
- Granulomas: Sarcoidosis, TB, histoplasmosis
- Hernia
- Hydrocele
- Hydrocele of the cord
- Leiomyoma
- Malignant epididymal tumor:
  - Primary (very rare): Liposarcoma, rhabdomyosarcoma (high on differential in children), leiomyosarcoma, adenocarcinoma, lymphoma
  - Metastatic: Prostate, kidney, stomach most common
- Papillary cystadenoma:
- Polyorchidism
- Sarcoid
- Sperm granuloma:
  - Seen in 40% post vasectomy or 2.5% idiopathic in general population
  - Granulomatous lesion with few giant cells
  - Consequence of extravasation of spermatozoa generally post vasectomy (of vasectomized men and of general population)

- Testis tumor
- TB of the epididymis
- Varicocele
- Vasitis and vasitis nodosa (usually associated with epididymitis)
- Young syndrome (obstructive azoospermia, sinusitis, bronchiectasis)

TREATMENT

GENERAL MEASURES

- Most do not require treatment unless symptomatic.
- Supportive care is usually sufficient:
  - Scrotal supporter
  - Heat
  - NSAIDs
  - Continued testicular self-exam

MEDICATION

First Line

Oral analgesics or NSAIDs

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Spermatocelectomy is elective and indicated for progressive enlargement or persistent pain
- Performed by magnified or microsurgical dissection of cyst from epididymal bed to preserve arterial supply and avoid injury to the epididymal tubules and resultant epididymal obstruction (2)
- Ligation of spermatocele at its stalk
- Surgery should be deferred in men seeking fertility since the spermatocelectomy can occasionally cause epididymal obstruction

ADDITIONAL TREATMENT

- Transscrotal cyst aspiration with or without sclerotherapy:
  - Agents used have included tetracycline, fibrin glue, phenol, talc powder, and others
  - Not usually recommended due to high recurrence rate and chemical epididymitis
  - Spermatocele aspiration may provide a sperm source for azoospermic men treated by IVF or ICSI

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Most require no intervention and do not lead to epididymal obstruction.

- Recurrence rate is low postoperatively.

COMPLICATIONS
- Orchalgia
- Concern for cancer
- Postoperative spermatocelectomy:
  - Regrowth of spermatocele
  - Vascular injury during spermatocelectomy causing testicular atrophy
  - Infection
  - Epididymal obstruction: Very concerning in cases of bilateral spermatocele surgical repair. Some authors recommend sperm cryopreservation in this setting

FOLLOW-UP

Patient Monitoring
- Periodic scrotal/testicular self-exam
- Subsequent scrotal US if symptoms recur

Patient Resources
- Urology Care Foundation (AUA). http://www.urologyhealth.org/urology/index.cfm?article=117

CODES

ICD9

608.1 Spermatocele

ICD10

- N43.40 Spermatocele of epididymis, unspecified
- N43.41 Spermatocele of epididymis, single
- N43.42 Spermatocele of epididymis, multiple

CLINICAL/SURGICAL PEARLS

- A common pitfall is the failure to distinguish between hydrocele and spermatocele preoperatively.
- Spermatoceles are always located superior to the testis and are palpated as distinct from the testis, which differentiates them from hydroceles.
- Ideal surgical approach: Incise the tunica vaginalis over the tunica albuginea testis to maintain the spermatoceles definition throughout its excision.

SPINAL CORD INJURY, UROLOGIC CONSIDERATIONS

Jessica Wetterlin, MD
Derek Matoka, MD

BASICS

DESCRIPTION

- Spinal cord injury (SCI) may result from damage to the spinal column secondary to trauma, vascular injury, infection, or disc prolapse
- SCI can impact lower urinary tract and sexual function and varies based on level and completeness of injury
- Upper and lower urinary tract dysfunction due to SCI can lead to significant morbidity/mortality
  - Increased risk for renal failure, UTI (urinary tract infection), renal/bladder calculi, and malignancy

EPIDEMIOLOGY

Incidence

40 cases per million in US; 12,000 new cases per year (1)

Prevalence

- 270,000 people alive in US in 2012 with SCIs
- Extent of lesion
  - SCI are graded using the ASIA scale (American Spinal Injury Association)
  - 45% of injuries are neurologically complete (ASIA grade A), 55% incomplete (ASIA B-D)
- Age: SCI previously affected young adults with most injuries occurring between the ages of 16 and 30. Since 2005, the average age of injury is 41 yr
- 53% tetraplegia, 46% paraplegia, and less than 1% experience complete neurologic recovery
- Gender: 80.6% of spinal cord injured patients in US are male
- Race/ethnicity: Since 2005, 66% of SCI patients are Caucasian, 26.2% African American, 2.1% Asian, and 0.9% Native American

RISK FACTORS

- Trauma
  - Since 2005, motor vehicle accidents account for nearly 40% of SCI cases, followed by falls and acts of violence (primarily gunshot wounds)
- Vascular injury
- Disc prolapse
- Spinal cord tumors

Genetics

Congenital malformations (myelodysplasia)

PATHOPHYSIOLOGY

- Spinal control of micturition is located at the S2–S4 level of the spinal cord
- The sacral cord begins at spinal column level T12–L1. The cord terminates in the cauda

equina at approximately spinal column level L2
- Spinal shock = a period of decreased excitability of spinal cord segments at or below the level of the lesion
  - Involves suppression of autonomic and somatic activity resulting in an acontractile, areflexic bladder
  - Bladder neck (smooth sphincter) generally remains competent/closed
  - Urinary retention is generally the rule
  - Generally lasts 6–12 wk after injury
- A significant association exists between the level of a spinal cord lesion and the corresponding bladder and sphincter behavior
- Most patients with complete SCI show clinical signs and symptoms of bladder dysfunction; incomplete SCI demonstrates variable function
  - Suprasacral lesions generally result in an upper motor neuron deficit with NDO (neurogenic detrusor overactivity) with or without DSD (detrusor sphincter dyssynergia)
  - Sacral lesions generally produce a lower motor neuron deficit with resulting detrusor areflexia
- NDO: Involuntary detrusor contraction during the filling and storage phase
  - Symptoms: Urinary urgency, frequency, incontinence
  - Can lead to upper tract damage due to detrusor hypertonicity, high voiding pressures, high-pressure reflux, recurrent UTIs and their sequelae
- DSD: Abnormal reflexive sphincter contraction during involuntary detrusor contraction
  - Causes bladder outflow obstruction, increased post void residuals (PVRs) and elevated intravesical pressures
  - Can lead to damage to upper tracts, UTIs, urolithiasis
  - Intravesical pressure >40 cm H_2O is responsible for sequelae of NDO-DSD
  - DO (detrusor overactivity) must be present for DSD, but NDO may occur without DSD
  - 10–20% of patients have internal (bladder neck) sphincter dyssynergia with external sphincter dyssynergia
- Detrusor areflexia
  - Results from damage to sacral reflex arc which results in absent detrusor contraction
  - Results in low-pressure storage (volumes up to 500 mL)
  - Decreased risk of upper tract damage

ASSOCIATED CONDITIONS
Arachnoiditis, Guillain–Barré, multiple sclerosis, spinal stenosis, transverse myelitis, tumor, or malignancy

GENERAL PREVENTION
- Drive safely, wear seatbelt, prevent falls
- Prevent secondary complications of SCI

DIAGNOSIS
HISTORY
- Onset, duration, etiology of injury
- Voiding symptoms

  – Irritative or obstructive
  – Incontinence: Stress, urge, overflow
- Method of urinary management
  – Voluntary voiding, clean intermittent catheterization (CIC), indwelling catheter or Credé/Valsalva voiding with or without external catheter
- Urinary tract infection (UTI)
  – Associated symptoms, severity, and frequency of recurrence
- Urolithiasis episodes, interventions, calculus composition
- Erectile dysfunction

PHYSICAL EXAM
- Temperature, blood pressure
- Palpable flank mass/tenderness
- Suprapubic fullness: Distended bladder
- Evaluate incontinence; spontaneous or with stress maneuvers
- GU exam for testicular or prostate abnormality
- Complete Neurologic exam: Sensation, tone, and sphincter control
- Bulbocavernosus reflex: Contraction of anal sphincter with stimulation of glans penis/clitoris

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Blood studies:
  – Serum chemistry: Basic metabolic panel (BMP) (assess renal function and acidosis), CBC
  – Urinalysis

Imaging
- Renal US (ultrasound): To screen for calculi, hydronephrosis, masses
- VCUG (voiding cystourethrogram)
  – Trabeculation, diverticulum, incomplete emptying, vesicoureteral reflux
- Nuclear medicine renal scan:
  – Performed to evaluate for compromised function or presence of obstructive element

Diagnostic Procedures/Surgery
- PVR: To ensure complete bladder emptying
- Video urodynamics: Essential to assess and follow bladder dynamics and anatomical changes so that effective urologic management can be tailored appropriately

Pathologic Findings

Bladder wall thickening and fibrosis common

DIFFERENTIAL DIAGNOSIS
- Infection
- Intervertebral disc disease
- Malignancy (metastasis)
- Spinal cord vascular disease
- Traumatic
- Vertebral body injury

TREATMENT

GENERAL MEASURES

- Goal of treatment: Optimize intravesical bladder pressures to protect upper urinary tract
- Spontaneous voiding with continence
- Indwelling catheterization should be avoided when possible to avoid complications (urethral strictures, UTIs, calculi, malignancy)
  - Indwelling urethral catheter or suprapubic tube (SPT)
- Intermittent self-catheterization: Most effective treatment, requires manual dexterity
  - If unable to self-catheterize urethra
    - Males: External catheter, outlet obstruction procedure, urinary diversion, or creation of continent catheterizable stoma
    - Females: Urinary diversion or creation of continent catheterizable stoma
  - Incontinence between catheterizations may suggest elevated intravesical pressure due to poor compliance or DO
    - Reduce storage pressure: Increase frequency of catheterizations, anticholinergics, or augmentation cystoplasty
- Lower urinary tracts that cannot be reconstructed require urinary diversion with or without cystectomy
  - Incontinent urostomy
  - Continent urinary reservoir

MEDICATION

First Line

- Anticholinergics improve urinary storage pressure and decrease involuntary contraction
  - Oxybutynin 5 mg PO BID–TID
  - Tolterodine 2 mg PO BID, others
- α-adrenergic blockers: Decrease internal sphincter function, lower voiding pressures; ineffective for DSD
  - Agents include: doxazosin 1–8 mg PO QD, terazosin 1–10 mg PO QHS, tamsulosin 0.4 mg PO QD

Second Line

Botulinum toxin injected into detrusor

SURGERY/OTHER PROCEDURES

- Sphincterotomy: Requires external catheter
- Augmentation cystoplasty: Use of intestinal segment to enlarge the bladder, increasing bladder volume to decrease intravesical pressure
  - Usually requires clean intermittent catheterization (CIC)
- Ileovesicostomy
  - Useful for those unable to perform CIC
- Sacral neuromodulation
  - Deafferentation with dorsal rhizotomy abolishes spontaneous detrusor contraction, improving urinary storage
  - Nerve root stimulation allows for control over detrusor contraction

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Sacral nerve root stimulator

Complementary & Alternative Therapies

Vanilloid agents (capsaicin and resiniferatoxin) suppress uninhibited detrusor contraction

ONGOING CARE

PROGNOSIS

- Proper urologic care improves morbidity, mortality, and quality of life in SCI individuals
- Early data suggested renal disease was major cause of death in the paraplegic patient. However more recent data has revealed that pneumonia, septicemia, heart attack, accidents, and suicides are now leading causes of morbidity (2)

COMPLICATIONS

- UTI/sepsis (3)
- Urolithiasis
  - Due to urinary stasis, chronic infection, acidosis associated with immobility, bladder calculi related to chronic indwelling catheters
- Upper urinary tract deterioration
  - Hydroureteronephrosis due to elevated intravesical pressure
- Lower urinary tract deterioration
  - Detrusor hypertrophy, decreased compliance
  - Urethral erosion, fistula with chronic catheterization
- Autonomic dysreflexia
  - Can occur with SCI at T6 level or higher, with complete/incomplete spinal cord lesions
  - Triggered by a noxious stimuli below the level of the lesion; bladder and bowel manipulation are the most common causes
  - Unopposed sympathetic activity results in vasoconstriction and HTN (hypertension)
  - HTN sensed by baroreceptors in carotid and aortic arch activating parasympathetics above lesion to counter the sympathetic response. However, the SCI inhibits parasympathetic activity below the level of the lesion
  - Signs and symptoms include HTN, headache, bradycardia, flushing, diaphoresis, blurred vision
    - Treatment: Remove offending stimuli
    - Address HTN with rapid onset/short duration agent (nifedipine, captopril, hydralazine)
- Neoplastic transformation
  - Associated with chronic catheter
- Depression
- Skin complications (related to incontinence)

FOLLOW-UP

Patient Monitoring

- UTI screening: Routine urine cultures are unnecessary in healthy, asymptomatic individuals.
- UDS: Completed periodically. However, no consensus exists regarding frequency. Obtain UDS after resolution of spinal shock and every 5 yr in stable patients. If a change in bladder-related symptoms (incontinence) is noted, UDS should be repeated to evaluate for change in bladder dynamics.
- Renal US: Useful, noninvasive screening method to monitor upper and lower tracts.
  – Recommended initially and annually for 5–10 yr, then every other year.
- Basic metabolic panel: Biennially.
- Renal function scan: In setting of progressive hydroureteronephrosis on renal US.
- Bladder cancer surveillance: Cystoscopy is recommended annually for patients with chronic indwelling catheters or augmentation cystoplasty.

Patient Resources

None

ICD9

- 586 Renal failure, unspecified
- 599.0 Urinary tract infection, site not specified
- 952.9 Unspecified site of spinal cord injury without evidence of spinal bone injury

ICD10

- N19 Unspecified kidney failure

- N39.0 Urinary tract infection, site not specified
- S34.109A Unsp injury to unsp level of lumbar spinal cord, init encntr

CLINICAL/SURGICAL PEARLS

- Suprasacral lesions generally result in an upper motor neuron deficit with NDO.
- Sacral lesions generally produce a lower motor neuron deficit with resulting detrusor areflexia.
- UDS should be obtained at least 6 wk after injury and repeated when appropriate.

STRESS URINARY INCONTINENCE, FEMALE

Nima Baradaran, MD
Samuel Walker Nickles, MD
Eric S. Rovner, MD, FACS

BASICS

DESCRIPTION

- Stress urinary incontinence (SUI) is subjectively defined by the International Continence Society as the"the complaint of involuntary leakage on effort or exertion, or on sneezing or coughing" (1)
- Urinary incontinence (UI) should be further described by specifying: Type, frequency, severity, precipitating factors, social impact, effect on hygiene and quality of life, the measures used to contain the leakage and whether or not the individual seeks or desires help because of urinary incontinence (1)

EPIDEMIOLOGY

Incidence

Annual incidence of any type of new UI ranges from 3 to 11% and increases with age, with approximately 50–70% attributed to SUI alone or in association with urge incontinence (mixed urinary incontinence or MUI)

Prevalence

~30% of women aged 30 to 60 have urinary incontinence, with approximately 50–70% attributed to SUI with or without urge urinary incontinence (UUI). Significant variation is seen in specific populations, eg, community dwelling vs. long-term facility occupants, and nulliparous vs. postpartum females.

RISK FACTORS

Aging, obesity, smoking, pregnancy, and child birth

Genetics

Deficient collagen structures

PATHOPHYSIOLOGY

- Anatomical: Weakness of urethral supportive structures (vaginal wall and surrounding connective tissue) leads to hypermobility and loss of urethral compression (1)
- Intrinsic sphincter deficiency: Loss of intrinsic urethral closure, coaptation, and function
- Neurologic: Rarely, loss of spinal sympathetic reflex and/or pudendal nerve efferents leading to relaxation of the extrinsic and intrinsic closure forces of the urethra.

ASSOCIATED CONDITIONS

- Chronic cough, COPD, obesity
- Pelvic organ prolapse (cystocele, rectocele) and/or anal incontinence
- 40% of women with urethral sphincter incompetence will have a cystocele
- Occult incontinence: Urethral sphincteric incompetence masked by the presence of pelvic

prolapse

GENERAL PREVENTION
See treatment

DIAGNOSIS

HISTORY
- Subjective characterization of UI (aggravating factors)
- Duration of symptoms
- Impact on life
- Daytime vs. nocturnal UI
- Urinary frequency, urgency, nocturia
- UTI history
- Pad use
- Past medical/surgical history
  - Neurologic conditions (Parkinson, MS, back surgery, etc.)
  - Medical conditions (DM, dementia, etc.)
  - Radiation and trauma
  - Gynecologic history (parity, hormonal status)
  - Previous pelvic surgery
- Medications (sympatholytics and diuretics)

PHYSICAL EXAM
- Focused pelvic exam and evaluation of estrogen status (urethral caruncle/prolapse and labial adhesions indicate deficiency)
- Cough stress test to visualize and confirm SUI
- Evaluation of urethral position and mobility
- Presence of pelvic organ prolapse
- Neurologic exam: Gait, cognitive status, sensation, motor, and reflexes (bulbocavernous reflex)
- Digital rectal exam

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis
- Routine renal function evaluation unnecessary

Imaging
Diagnosis is mainly based on history and physical exam

Diagnostic Procedures/Surgery
- Postvoid residual measurement
- Voiding diary
- Quality-of-life questionnaires
- Pad test
  - A preweighed sanitary pad is examined after a defined period of time
  - 1-g increase in weight = 1 mL of urine

- The International Continence Society: Weight change of <1 g during its standardized 1-hr test to be negative.

- Cystoscopy in the presence of urinary urgency, hematuria, UTI, or other irritative symptoms, particularly if they have previously undergone a previous anti-incontinence procedure, pelvic radiation, or pelvic prolapse repair
- Urodynamics indicated especially in patients who have failed previous pelvic floor reconstruction or with mixed incontinence, urinary urgency, or obstructive symptoms, and in those who have elevated PVRs or neurologic disease

Pathologic Findings

- Sphincter muscle deficiency is the main pathology.
- SUI may occur in the absence of urethral hypermobility.

DIFFERENTIAL DIAGNOSIS

- Enuresis means any involuntary loss of urine. If it is used to denote incontinence during sleep, it should always be qualified with the adjective "nocturnal"
- Fistula: Vesicovaginal, urethrovaginal
- Mixed urinary incontinence (MUI) is the complaint of involuntary leakage associated with urgency and also with exertion, effort, sneezing, or coughing
- Neurogenic bladder (CNS and spinal cord lesions)
- Pelvic organ prolapse
- Polyuria/polydipsia
- Potentially reversible conditions (DIAPERS):
  - **D**rugs
  - **I**nfection
  - **A**trophic vaginitis
  - **P**sychological (depression, delirium, dementia)
  - **E**ndocrine (hyperglycemia, hypercalcemia)
  - **R**estricted mobility
  - **S**tool impaction
- Situational incontinence: eg, the report of incontinence during sexual intercourse, or giggle incontinence.
- Urethral abnormalities (diverticulum)
- Urge vs. stress vs. overflow incontinence
  - Urge urinary incontinence: Involuntary leakage accompanied by or immediately preceded by urgency
- Urinary leakage may need to be distinguished from sweating or vaginal discharge
- Urinary tract infection
- Vaginal voiding

TREATMENT

GENERAL MEASURES

- Initial therapy includes behavioral modification and pelvic floor exercise
- Lifestyle modifications
- Weight loss, smoke cessation, moderation of fluid intake, caffeine and/or alcohol

MEDICATION

First Line

- Treatment for pure SUI is generally nonpharmacologic in US.
  - However medication may be indicated in MUI when predominant symptoms of OAB or urge incontinence coexist and in such cases antimuscarinic therapy is utilized (see Section I "Overactive Bladder").

Second Line

- In rare cases an α-adrenergic receptor agonist (phenylpropanolamine) or tricyclic antidepressant (imipramine) may be utilized but this is an off-label use.
- Duloxetine is a serotonin and norepinephrine reuptake inhibitor approved for major depression and other indications and is approved for treatment of SUI in Europe but not in US.

SURGERY/OTHER PROCEDURES

- Surgery is the single most effective long-term treatment (2,3)
- Suburethral slings:
  - Midurethral slings:
    - Currently these are the procedure of choice for primary surgical treatment of SUI
    - Made from synthetic material (mesh)
    - As effective as other surgical therapies but associated with less operative time and shorter convalescence rate
    - 3 types include: Retropubic including tension-free vaginal tape (TVT), transobturator, single incision ("mini-sling")
  - Bladder neck (proximal urethral) sling generally fashioned from autologous rectus abdominis fascia or fascia lata (leg)
- Transurethral injectable bulking agents
- Retropubic colposuspension (Burch procedure)
- Artificial urinary sphincter
  - Rarely used in US and only reserved for patients with severe intrinsic sphincter deficiency

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Behavioral therapy (4)
  - Patient education
  - Fluid and dietary management
  - Timed voiding
  - Patient compliance and periodic reinforcement are essential
- Pelvic floor muscle training (PFMT)
  - Strong pelvic floor contraction increases intraurethral pressure against increased intra-abdominal pressure
  - Inhibits detrusor contractions
- Adjunctive measures for PFMT
  - Vaginal cones and weights

– Biofeedback: Helps patients identify and isolate correct pelvic muscles
– Pelvic floor electrical stimulation
– Magnetic therapy
- Intra- or extraurethral and intravaginal support and occlusive devices (pessaries, plugs, urethral inserts, etc.)

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Nonsurgical therapy can be effective in carefully selected, highly motivated, and compliant individuals and in such individuals may improve symptoms and subsequent quality of life in up to 50–80% of mild–moderate cases.
- Excellent outcomes are expected with the use of 1st-line surgical options in uncomplicated patients with all degrees of SUI with success rates in excess of 85–90% at 5–10 yr of follow-up.

COMPLICATIONS
- Untreated SUI may result in skin rash and chronic irritation
- Complications of sling procedures include: Urethral/bladder perforation, mesh exposure in the vagina and erosion into the urinary tract, voiding dysfunction (due to obstruction), UTI, pain, and dyspareunia
- Vaginal, urethral, and intravesical erosion of the midurethral slings is a particularly feared complication
- Vascular injury or intestinal perforations are rare and associated with slings, as well as open abdominal approaches.

FOLLOW-UP
Patient Monitoring
Conservative management requires regular reinforcement and education

Patient Resources
National Association for Continence. http://www.nafc.org

CODES

ICD9

625.6 Stress incontinence, female

ICD10

N39.3 Stress incontinence (female) (male)

CLINICAL/SURGICAL PEARLS

- It is imperative to distinguish different types of urinary incontinence in female.
- Lifestyle modification and conservative treatment is the 1st step in management.
- Midurethral slings are the standard surgical treatment and are highly effective in properly selected patients.

STRESS URINARY INCONTINENCE, MALE

Jack Matthew Zuckerman, MD
Kurt A. McCammon, MD, FACS

BASICS

DESCRIPTION

- Stress urinary incontinence (SUI) is subjectively defined by the International Continence Society (ICS) as the "the complaint of involuntary leakage on effort or exertion, or on sneezing or coughing" (1).
- SUI is also seen objectively on pressure flow urodynamics (UDS) as unintended leakage of urine during an increase in intra-abdominal pressure.

EPIDEMIOLOGY

Incidence

True SUI is rare in young men, but the incidence increases as men age. This predominance in the elderly mirrors the increased likelihood of having undergone prostate surgery as men age.

Prevalence

- The prevalence of UI in women is approximately twice that in men; however this gap narrows over time (2)
- Overall prevalence of moderate–severe urinary incontinence in men 20 yr of age and older is approximately 4.5% (3)
  - 0.7% for men aged 20–34 yr
  - 16% for men aged ≥75 yr
  - SUI accounts for only 12.5% of moderate to severe UI, the remainder predominantly urge or mixed incontinence

RISK FACTORS

- Urologic procedures are the primary risk factor for male SUI
  - Radical prostatectomy (RP)
    - Leading cause of male SUI, especially in older men
    - Postprostatectomy incontinence (PPI) has widely variable rates reported, from 3–89% depending on the timeframe and definition used for incontinence
    - Rates appear similar regardless of technique (retropubic, laparoscopic, or robotically assisted laparoscopic)
  - Transurethral resection of the prostate:
    - Uncommonly results in sphincteric injury leading to SUI
- Urethral distraction injuries involving the membranous urethra
- Acquired or traumatic spinal cord pathology
- Congenital malformations
  - Spinal dysraphism
  - Exstrophy/epispadias complex

Genetics

N/A

PATHOPHYSIOLOGY

- Male continence relies on an intact internal and external urinary sphincter and a compliant bladder for storage of urine
  - Internal sphincter
    - Bladder neck and prostate
    - Smooth muscle/involuntary
  - External sphincter
    - Rhabdosphincter/voluntary
- Internal sphincter dysfunction can be caused by:
  - Prior pelvic surgery, such as RP
  - Traumatic or iatrogenic injury to the bladder neck or prostate
  - Injury or dysfunction of the sympathetic innervation to the internal sphincter
  - Congenital internal sphincter dysfunction
- Dysfunction or the external sphincter is termed intrinsic sphincter deficiency (ISD) and most frequently occurs following radical prostatectomy (RP) (5)
- A noncompliant bladder may exacerbate UI, however, by definition sphincteric dysfunction is required for SUI to be present

ASSOCIATED CONDITIONS

- Urinary incontinence negatively affects a man's quality of life, even in those with minimal urine leakage (6)
- Depression is consistently associated with UI. It is unclear whether this incontinence is cause by depression and meds used to treat it or whether UI is actually causing the depression (3)
- Neurologic diseases
- Pelvic trauma
- Benign prostatic hypertrophy (BPH)
- Prostate cancer
  - Prostate surgery, usually RP
- Pelvic radiation for urologic and nonurologic malignancy

GENERAL PREVENTION

- Careful surgical technique in avoiding damage to the external sphincter during RP.
- If postoperative radiation is used for adverse pathology following RP it is desirable to have the patient continent before radiation since this can adversely affect the return of continence postop.
- Patients with neurogenic bladder such as spina bifida, incontinence episodes can be limited through the use of intermittent catheterization and anticholinergics.

DIAGNOSIS

HISTORY

- Incontinence history
  - Duration
  - Severity (pads, diapers, tissues, etc.)
    - The nature of the absorptive device helps with the assessment of the degree of leakage

  – Precipitating events (cough, sneeze, etc.)
- Presence/absence of urge symptoms
  – Suggests pharmacologic therapy may benefit
- Frequency of urination
- Fluid intake, including use of caffeine, alcohol
- Use of medications such as diuretics or antihypertensive medications
- Neurologic or spinal cord disease or injury
- Voiding diary
- Prior pelvic surgery or other urologic surgery
- Prior pelvic radiation
- Prior anti-incontinence procedures
- AUA symptom score
- ICIQ (International Consultation on Incontinence Questionnaire), ICIQ-MLUTS

PHYSICAL EXAM
- Abdominal exam
  – Surgical scars
  – Palpable suprapubic mass suggests retention
- External genitalia and groin
  – Skin breakdown or fungal/bacterial infection secondary to UI
  – Scrotal exam to rule out hydrocele or testicular mass
  – Digital rectal exam for assessment of the prostate as well as rectal tone
  – Inguinal hernia
- Spine/back for deformity
- Cutaneous signs for spinal dysraphism
  – Subcutaneous lipoma
  – Vascular malformation
  – Tuft of hair
  – Skin dimple
- Reflexes
  – Anal reflex (S2–S5)
    - Stroking circumanal skin leads to visible contraction; absence suggests peripheral or sacral nerve dysfunction
  – Bulbocavernosus reflex (S2–S4)
    - Squeezing the glans leads to anal contraction
    - Absence suggests sacral nerve dysfunction

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urinalysis and urine culture
- PSA if known history of prostate cancer or has had a prostatectomy

Imaging
- Postvoid residual urine (PVR) measurement to rule out urinary retention
- Other routine imaging not indicated

Diagnostic Procedures/Surgery

- Pressure flow UDS are helpful to confirm stress incontinence and rule out other complicating factors such as urge incontinence/detrusor overactivity, detrusor underactivity, bladder outlet obstruction, and poor bladder compliance.
- Cystoscopy to rule out urethrovesical anastomotic stenosis (most often after radical prostatectomy) or urethral stricture is essential prior to any planned surgical intervention.

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Stress urinary incontinence
- Urge urinary incontinence: Involuntary leakage accompanied by or immediately preceded by urgency
- Mixed urinary incontinence
- Overflow incontinence/urinary retention
- Postvoid dribbling (urine retained in the urethra)
- Situational incontinence: eg, the report of incontinence during sexual intercourse
- Urethrocutaneous fistula
- Urinary leakage may need to be distinguished from sweating

TREATMENT

GENERAL MEASURES

- Pelvic floor physical therapy ("Kegel" exercises)
  - Efficacious following RP to allow quicker return of continence, though not found to improve overall continence (7)
  - May also be used in men with SUI from other causes to strengthen the pelvic floor
- Lifestyle changes
  - Limiting fluid intake
  - Decreasing certain activities that cause SUI
- Penile clamps
- Condom catheter

MEDICATION

First Line

- Medication generally is not efficacious for male SUI. However, medical therapy is sometimes used in this population. None are officially FDA approved for this indication
  - Tricyclic antidepressants
    - Imipramine 10–25 mg PO BID–TID
  - Duloxetine 30–60 mg PO QD (8)

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Post prostatectomy incontinence (PPI)
  - Artificial urinary sphincter (AUS)
    - Gold standard

- Excellent long-term outcomes and high patient satisfaction (9)
- Urethral slings
  - Transobturator
  - Bone-anchored
  - Combined prepubic and transobturator
- Urethral bulking agents
  - Least effective and generally not used as a 1st-line surgical treatment
  - May be useful in the salvage setting after a failed sling

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Generally speaking SUI is stable or progressive in nature. It is not likely spontaneously resolved.
- PPI differs from other causes of SUI in that it has been shown to improve over time. However, a plateau is seen after approximately 2 yr and further improvements are not anticipated (4).
- With surgical treatment, and occasionally medical management, male SUI can be expected to improve dramatically in most cases.

COMPLICATIONS

- Urinary incontinence
  - Social isolation/embarrassment
  - Dermatitis
  - Candidiasis
  - Skin breakdown
  - Foul odor
- Artificial urinary sphincter (AUS)
  - Urinary retention
  - Device infection or malfunction
  - Urethral erosion
  - Urethral atrophy
- Urethral slings
  - Urinary retention
  - Perineal pain
  - Infection/sling erosion (rare)
  - Osteitis pubis or chronic pain from bone-anchored slings

FOLLOW-UP

Patient Monitoring

- Following surgical or medical treatments patients should be followed with standardized questionnaires, such as the International Consultation on Incontinence Questionnaire Short Form.
- Patients may also be followed with 1-hr or 24-hr pad weight testing, but this can be burdensome to obtain regularly in the office.
- Self-reported pad counts are easier to obtain, but not as accurate as a pad weight test.
- No routine labs or imaging are required unless complicating factors in the initial history and physical were identified.

CODES

ICD9

788.32 Stress incontinence, male

ICD10

N39.3 Stress incontinence (female) (male)

CLINICAL/SURGICAL PEARLS

- SUI is uncommon in young men, but becomes more common with age as more patients are undergoing urologic procedures.
- Most effective treatments are surgical, though medical therapy may be helpful in men with very mild incontinence.
- The artificial urinary sphincter (AUS) remains the gold standard procedure for male SUI, however urethral slings are now commonly used with success approaching that of the AUS with proper patient selection.

STROKE (CVA), UROLOGIC CONSIDERATIONS

Katie S. Murray, DO
Tomas L. Griebling, MD, MPH, FACS

BASICS

DESCRIPTION

- Stroke (CVA-cerebovascular accident) is the 3rd leading cause of death, and the leading cause of chronic morbidity in the United States
- Stroke can be ischemic or hemorrhagic
- Stroke can lead to urinary tract disturbances
- Initially, transient (occasionally permanent) urinary retention ± overflow incontinence
- Likelihood of voiding disturbances is directly associated with stroke severity
- May eventually develop bladder overactivity and urgency with or without incontinence
- Urinary symptoms post-CVA are very common
  - 25% of people have urinary incontinence at time of discharge and 15% have these issues at 1 yr post-CVA (1)[A]

EPIDEMIOLOGY

- 270/100,000 Americans experience a stroke each year
- Mean age 72 yr

RISK FACTORS

- Urinary disturbances after stroke are common, the risk factor is stroke and extent of hemorrhage or ischemia
  - Those with dysphagia, >75 yr, motor weakness, and visual field defects were more likely to have long-term incontinence issues (2)[A]

Genetics

N/A

PATHOPHYSIOLOGY

- Urinary retention due to cerebral shock and detrusor areflexia
- Incontinence-multifactorial (4)[B]
  - Overflow urinary incontinence from retention
  - Detrusor overactivity (DO) with urge urinary incontinence (UUI)
  - Functional incontinence due to mobility and/or cognitive impairment

ASSOCIATED CONDITIONS

- Prostatic hyperplasia
- Underlying urinary incontinence
- Fecal incontinence and/or constipation
- Depression
- See also Differential Diagnosis

GENERAL PREVENTION

- Stroke prevention measures
  - Smoking cessation
  - Blood pressure control
  - Cholesterol control
  - Diabetic control
  - Avoid hormonal replacement therapy in older women
  - Identify and control atrial fibrillation
  - Balanced diet and exercise
  - Low-dose aspirin if appropriate

DIAGNOSIS

HISTORY

- Based on diagnosis of CVA
- Evaluate for previous or underlying urologic issues or complaints
- Obtain medication history
- Detailed past surgical history

PHYSICAL EXAM

- Abdominal exam for bladder distention
- Neurologic exam (usually already done by primary team during initial diagnosis)
- Digital rectal exam (DRE) to evaluate rectal tone and prostate size in males
- Pelvic exam in females

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis with or without urine culture as clinically appropriate
- Creatinine to evaluate renal function

Imaging

- Postvoid residual bladder scan
- Abdominal imaging
  - Renal/bladder ultrasound
  - KUB

Diagnostic Procedures/Surgery

- Voiding/fluid intake diaries
  - Bladder capacity
  - Daily/nightly trends
- Urodynamic studies: Should not be performed until after stability in neurologic symptoms following stroke (not immediately)
  - Typically 3–6 mo following stroke
  - Evaluate bladder function and detrusor function vs. bladder outlet obstruction
  - May be used for surgical guidance and management if necessary

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Urinary Retention (see Section I "Urinary Retention, Adult Male," "Urinary Retention, Adult Female")
- Urge incontinence
  - Loss of urine accompanied by urgency; often related to triggers such as sounds of running water, cold weather, passing a restroom
- Stress incontinence
  - Urinary leakage associated with exertion, lifting, coughing, sneezing
- Mixed incontinence
  - Urinary leakage associated with both stress and urge incontinence
- Low bladder compliance resulting in overflow incontinence
- Continuous urinary incontinence is the continuous loss of urine
- Postmicturition dribble
  - The involuntary loss of urine immediately after passing urine, usually after leaving the toilet
- Mobility or cognitive impairment post stroke

TREATMENT

GENERAL MEASURES

- General stroke rehabilitation interventions (3)
  - Physical therapy
  - Occupational therapy
- Initially and short term
  - Ensure bladder drainage with Foley catheter vs. clean intermittent catheterization (CIC)
- Long term
  - CIC, Foley or suprapubic catheter for urinary retention and elevated post void residuals
  - Caution to avoid long-term indwelling urethral catheter to avoid risk of bladder neck erosion or urethral injury
  - Bladder overactivity
    - Behavioral modifications regarding voiding habits and fluid intake
    - See medication therapy below

MEDICATION

First Line

- Antimuscarinics or β_3-agonists: Decrease detrusor overactivity (DO) that is demonstrated as urinary frequency and urgency ($\pm$ incontinence)
  - Side effects
    - Dry mouth, constipation, blurred vision, confusion
    - Use cautiously in geriatric patients secondary to potential central nervous system effects

Second Line

- α-Blockers for prostatic hyperplasia and retention related to BPH if necessary
- 5α-reductase inhibitors for BPH especially in those men with large prostate glands

SURGERY/OTHER PROCEDURES

- Suprapubic catheter placement if long-term urinary retention
- Intravesical botulinum toxin injections for DO
  - Temporary effect and may require patients to perform CIC
- Neuromodulation
- Transurethral resection of prostate if concomitant BPH with clinical obstruction
- Urinary diversion

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Psychological support and re-enforcement

Complementary & Alternative Therapies

- Absorbent pads and products
- Pelvic floor physical therapy with or without biofeedback
- Acupuncture

ONGOING CARE

PROGNOSIS

- Health-related quality of life is impaired in general in those with urgency incontinence post neurologic event (4)[B]
- Urinary symptom outcome is proportional to the extent of resolution of other stroke sequelae
  - Those who resolve cognitive and/or motor function often resolve urinary issues

COMPLICATIONS

- Short term
  - Acute renal failure if acute urinary retention
  - Urinary tract infection if not draining bladder appropriately
  - Urinary incontinence because of overflow incontinence in retention
  - Depression
- Long term
  - Renal dysfunction and possible renal failure
  - Urinary tract infections—recurrent
  - Decreased quality of life
  - Depression

FOLLOW-UP

Patient Monitoring

- Detrusor overactivity (DO): yearly checkups, medicine monitoring
- Neurogenic bladder and performing CIC
  - Evaluate renal function with yearly (or more often if clinically indicated) creatinine and renal ultrasound
  - Urodynamic evaluation for significant change in clinical symptoms
  - If indwelling catheter dependent, needs regular cystoscopy to visualize bladder and

monitor for cancer or stones
  - Increased risk of bladder cancer is secondary to chronic foreign body in urinary tract

CODES

ICD9

- 434.91 Cerebral artery occlusion, unspecified with cerebral infarction
- 788.29 Other specified retention of urine
- 788.38 Overflow incontinence

ICD10

- I63.9 Cerebral infarction, unspecified
- R33.8 Other retention of urine
- N39.490 Overflow incontinence

CLINICAL/SURGICAL PEARLS

- Important to determine residual urinary effects after near full recovery from stroke.
- Prior to operation, ensure stability of urinary function.

SUPRAPUBIC PAIN, GENERAL CONSIDERATIONS

Kristin A. Greco, MD
Ahmer V. Farooq, DO

BASICS

DESCRIPTION

- Suprapubic pain describes a pain located in the midline of the abdomen, above the pubic symphysis and below the umbilicus.
- Multiple organ systems can cause suprapubic pain including urologic, gastrointestinal, gynecologic, and other rare causes.

RISK FACTORS

- History of urinary tract infections (UTIs)
- BPH as it may cause urinary retention
- Urolithiasis
- Immunocompromised patients have increased susceptibility to infections
- Pelvic radiation treatment
- Chronic pain syndromes
- Strenuous athletic activity

PATHOPHYSIOLOGY

- The pathophysiology of suprapubic pain is dependent on the etiology and various reproductive, GI, urologic, and neuromuscular disorders may cause pain in this area. This section will focus on urologic pathophysiology.
- Suprapubic pain resulting from the urinary tract is usually associated with inflammation or obstruction such as in UTI or acute urinary retention.
  - Bacterial cystitis causes a sharp and stabbing pain that is worse at the end of micturition. The pain is often referred to the distal urethra and is associated with the symptoms of frequency and urgency of urination.
    - UTI also causes intermittent suprapubic discomfort secondary to inflammation of the urothelium. This is often more severe with a full bladder and improves when the bladder is relieved of distention.
  - Acute urinary retention causes suprapubic pain by overdistention of the bladder (1). In contrast, chronic, slowly progressing urinary retention is usually asymptomatic despite large residual volumes.
- Malignancies in the urinary tract generally do not produce pain unless they cause obstruction or extend into adjacent nerves. Pain can be a late manifestation of malignancy.
- Prostatitis typically causes pain in the perineum, but this pain is frequently referred to the suprapubic area. Pain is secondary to inflammation with resulting edema and distention of prostatic capsule.
- Interstitial cystitis or painful bladder syndrome (IC/PBS) is defined as an unpleasant sensation (pain, pressure, discomfort) perceived to be related to the urinary bladder, associated with lower urinary tract symptoms of more than 6-wk duration, in the absence of

infection of other identifiable causes.
  – The pathophysiology of this disorder is currently under investigation. It is associated with other chronic systemic pain syndromes.

ASSOCIATED CONDITIONS
- BPH with urinary retention
- IC/PBS
- Prostatitis
- UTI
- Urolithiasis

DIAGNOSIS
HISTORY
- History taking in the patient presenting with suprapubic pain should be broad and consider all possible organ systems involved. A thorough history can lead the clinician to appropriate diagnostic tests in this patient
- Associated urinary symptoms such as frequency, urgency, dysuria, nocturia, and ability to empty the bladder
- Onset and duration of suprapubic pain
- Perineal pain
- Gross hematuria or hematospermia
- History of urinary retention
- Benign prostatic hypertrophy (BPH)
- Urolithiasis
- History of pelvic malignancy
- Trauma
- Radiation treatment for cancer
- History of diarrhea or bowel disease
- Last menstrual period and possibility of pregnancy
- History of STI/STD
- Dyspareunia

PHYSICAL EXAM
- Abdominal exam:
  – Palpable bladder suggests urinary retention
  – Suprapubic tenderness is common with inflammation and infection of the genitourinary system
  – Umbilical discharge with urachal abnormality
- Pelvic exam:
  – Chandelier sign (tenderness with movement of the cervix) with PID
  – Cervical discharge
  – Pelvic masses
- Rectal exam:
  – Tender, swollen, or boggy prostate during palpation may indicate prostatitis
  – Evidence of masses or blood with GI tract disease

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine analysis and culture:
  - Pyuria, nitrite, and bacteria with infection
  - pH, crystals/calcium, uric acid, oxalate, citrate, 24-hr excretion with urolithiasis
- CBC: Leukocytosis with left-shift; nonspecific infection and inflammation
- Urine cytology for malignancy
- Pregnancy testing in women

Imaging

- Plain x-ray: Important for evaluation of bowels, urolithiasis, or foreign body.
- CT pelvis: Useful for diagnosing GI etiology, urolithiasis, or pelvic masses. Has no role in uncomplicated infections of the GU tract.
- US bladder: Assess postvoid residual volume, calculi, or mass.
- Pelvic US for gynecologic causes. Transvaginal US is best for uterine or ovarian evaluation.

Diagnostic Procedures/Surgery

- Cystoscopy:
  - Evaluate for bladder tumor, stone, outlet obstruction, urethral stricture and IC/PBS (may see inflammatory lesions or Hunner's ulcers).
  - Contraindicated during acute GU infection such as UTI or prostatitis.
- Mears–Stamey 4-glass test for prostatitis evaluation.
- Urodynamics:
  - Assess bladder capacity, bladder contraction, pressure, and outlet obstruction. Not indicated for acute suprapubic pain.

Pathologic Findings

Based on the specific entity

DIFFERENTIAL DIAGNOSIS

- Urologic:
  - UTI
    - Cystitis
    - Prostatitis, acute bacterial
    - Pyelonephritis
  - Urinary Retention
  - Urolithiasis (bladder or distal ureter)
  - Prostatitis including acute bacterial, chronic nonbacterial, inflammatory and noninflammatory (NIH CP/CPPS III A and B)
  - Bladder perforation
  - IC/PBS
  - Malignancy (bladder, prostate)
  - Urachal abnormality
- Gastrointestinal:
  - Acute appendicitis
  - Colitis
  - Diverticulitis

- Inflammatory bowel disease
- Gynecologic:
  - Dysmenorrhea
  - Endometriosis
  - Malignancy (uterine, ovarian)
  - Miscarriage
  - Mittelschmerz
  - Ovarian cyst (hemorrhagic or ruptured)
  - Ovarian torsion/ovarian vein thrombosis
  - Pelvic Inflammatory disease
  - Pregnancy (including ectopic)
  - Uterine fibroids
- Other:
  - Trauma
  - Sexual abuse
  - Osteitis pubis
  - Abdominal wall myofascial pain
  - In athletes (2):
    - Sports hernia (athletic pubalgia, Sportsman's hernia)
    - Adductor strain
    - Muscle tears
    - Avulsion injuries
    - Stress fractures
    - Tears of acetabular labrum

TREATMENT

- The focus of this discussion is on urologic pathologic processes.
- Some common urologic conditions and interventions are noted below. Other conditions are beyond the scope of this section.

MEDICATION

First Line

- Acute uncomplicated UTI in women (3,4):
  - Nitrofurantoin monohydrate/macrocrystals (100 mg twice daily for 5 days is appropriate due to minimal resistance and propensity for collateral damage.)
  - Trimethoprim–sulfamethoxazole (160/800 mg [1 double-strength tablet] twice daily for 3 days) given its efficacy in numerous clinical trials.
- Complicated UTI: Treat for 7–14 days with culture-specific antibiotics.
  - Risk factors that make a UTI complicated include:
    - Indwelling catheter
    - Immunosuppression
    - Male sex
    - Urinary retention
    - Functional or anatomical abnormality of the urinary tract

- History of urinary tract surgery

- Prostatitis
  - Antibiotics empirically for 2 wk. If cultures are positive or the patient has improved clinical symptoms then continue antibiotics for 4–6 wk. Antibiotics with excellent prostatic penetration include fluoroquinolones (so they should not be used with concomitant UTI).
- BPH/urinary retention
  - α-Blockers, such as tamsulosin, may be used. 5α-reductase inhibitors, such as finasteride can be added if the prostate gland is estimated to be over 40 g.
- Bladder calculi
  - Often require surgical removal. Medical therapy can be considered for uric acid stones.
- Interstitial cystitis/painful bladder syndrome (IC/PBS) (5)
  - 1st-line treatment is behavioral modifications, counseling and stress management, and coping techniques.
  - 2nd-line treatment includes manual physical therapy techniques that resolve pelvic, abdominal and hip muscular trigger points, and lengthen muscle contractures.
  - Amitriptyline, cimetidine, hydroxyzine or pentosan polysulfate may be used as 2nd-line oral medications.

Second Line

N/A

SURGERY/OTHER PROCEDURES

- BPH/urinary retention
  - Transurethral catheterization to relieve acute obstruction; if unable to perform then suprapubic catheter should be considered.
  - Transurethral resection of prostate or other ablative procedure (laser, microwave) if appropriate.
- Bladder calculi
  - Remove transurethrally and fragment manually with lithotrite or with Holmium laser
  - Open cystolithotomy rarely needed
- IC/PBS
  - 3rd-line treatment of IC/PBS can involve cystoscopy under anesthesia with short-duration, low-pressure hydrodistention
  - If Hunner's lesions are present, then fulguration with laser or electrocautery and/or injection of triamcinolone should be performed.
- Bladder cancer
  - Superficial tumors:
    - TURBT ± intravesical BCG
  - Invasive tumors: Radical cystectomy with urinary diversion

ONGOING CARE

PROGNOSIS

Good prognosis with treatment of a clearly identified problem. Patients with IC/PBS often have a chronic course with flares that can last days to weeks to months. These patients

require a multimodal treatment approach.

FOLLOW-UP

Patient Monitoring

- Patient monitoring and follow-up is dependent on the specific pathologic process.
- Assessment of postobstructive diuresis following relief of urinary obstruction includes measurement of serum electrolytes.
- Urine culture following treatment of complicated UTI should be performed to ensure adequate treatment. This is not needed for uncomplicated UTI in women.

CODES

ICD9

- 592.9 Urinary calculus, unspecified
- 599.0 Urinary tract infection, site not specified
- 789.09 Abdominal pain, other specified site

ICD10

- N20.9 Urinary calculus, unspecified

- N39.0 Urinary tract infection, site not specified
- R10.8 Other abdominal pain

CLINICAL/SURGICAL PEARLS

- Multiple organ systems can cause suprapubic pain including urologic, gastrointestinal, gynecologic, neuromuscular and other rare causes.
- Bacterial cystitis typically causes a sharp and stabbing pain that is worse at the end of micturition. This is secondary to inflammation of the urothelium.
- Acute urinary retention causes suprapubic pain by overdistention of the bladder.
- CT imaging can be useful for diagnosing GI etiology, urolithiasis or pelvic masses, but CT has no role in uncomplicated infections of the GU tract.
- Cystoscopy can be used to evaluate for bladder tumor, stone, outlet obstruction or urethral stricture.
- 1st-line treatment for interstitial cystitis/painful bladder syndrome (IC/PBS) involves behavioral modifications, counseling and stress management and coping techniques.

SYPHILIS

John L. Phillips, MD, FACS
Dawud Lankford, MD, MPH

BASICS

DESCRIPTION

- "Syphilis" coined by Fracastoro in 1500s
- Describes infection by the spirochete *Treponema pallidum,* 1st discovered in 1905 by Hoffman
- Primary, secondary, and tertiary forms
- Congenital or acquired
- Often there is an asymptomatic, latent period (serology positive without clinical disease) between forms

EPIDEMIOLOGY

Incidence

- 2011 CDC data
  - In US, 55,400 new cases (est.) per year
  - 1/3 of new cases primary (P) or secondary (S)
  - From 2004 to 2008, rates increased most in 15–20-yr-old men and women
  - Rates highest in men who have sex with men (MSM), accounting for 2/3 of primary and secondary cases
  - Minorities make up majority of new P & S cases
  - Congenital syphilis now more common than perinatal HIV infection (3.4–15.0 times higher in blacks/Hispanics than in whites)

Prevalence

- US (NHNE) (1)
  - 0.71% seropositive (SP) in 18–49 yr olds
  - 4.1% SP in non-Hispanic blacks
  - 0.07% SP in non-Hispanic whites
- China (2) SP rates
  - Low-risk groups
    - Antenatal women (0.45%)
    - Food & service employees (0.3%)
  - High-risk groups
    - Female sex workers 12.49%
    - Drug users 6.81%
    - MSM 14.56%

RISK FACTORS

- Unprotected sex
- Sex with infected partner
- History of other STDs

- High-risk behaviors
  - Multiple partners
  - Prostitution
  - Illicit drug use
  - MSM

PATHOPHYSIOLOGY

- Contact inoculation through fluids, in utero; rare dissemination through transfusion
- Incubation 10–90 days
- Primary syphilis
  - Chancre: A dry, *painless*, erosion with raised border (not a true ulcer)
    - Glans, penile shaft, foreskin
    - Vulva, cervix
  - Regional lymphadenopathy: *Painless, nonsuppurating*
- Secondary syphilis: Develops 4–10 wk later if primary untreated
  - Flu-like symptoms (eg, fatigue, fever, headache)
  - Generalized lymphadenopathy
  - Generalized eruption
    - Diffuse, pale, red papules, usually <1 cm
    - Scaling
    - Plaques, can be >1 cm
    - Symmetric on palms, soles of feet, and trunk
  - Condyloma lata: Highly infectious, hypertrophic intertriginous genital lesions
- Latent period
  - Early <1 yr
  - Late >1 yr
  - Typically precedes tertiary disease but can take years
- Tertiary syphilis may take 10–20 yr
  - Central nervous system involvement: 6–10%
    - Tabes dorsalis (syphilitic myelopathy); demylenation of dorsal/posterior column of the spinal cord; causes problems with proprioception
    - Dementia
    - Seizures
    - Argyll Robertson pupils (constricting with accommodation but not to light)
  - Cardiac Involvement: 10% over 10–30 yr
    - Aortitis
    - Aortic aneurysms
    - Fatal hemorrhage
  - Gummatous syphilis: 15% over 45 yr where soft, inflammatory gummas destroy local tissues of:
    - Bone
    - Face
    - Skin
    - Legs
- Congenital Syphilis: Infection occurs in utero or during vaginal delivery. Nearly 2/3 of

neonates asymptomatic but can develop as children:
- Hepatosplenomegaly (75%)
- Fever, chills, rash (50%)
- Pneumonitis (20%)
- Late congenital syphilis (40%)
  - Saddle nose deformity
  - Hutchinson teeth (peg-shaped incisors)
  - Frontal bossing
  - Higoumenakis sign (unilateral enlargement of sternoclavicular joint)
  - Painless synovitis (Clutton joints)
  - Neurosyphilis

ASSOCIATED CONDITIONS
- Other sexually transmitted conditions
  - HIV
  - Gonorrhea
  - Hepatitis B and C
  - Chlamydia

GENERAL PREVENTION
- Protected sex
- Early Diagnosis and Treatment

DIAGNOSIS
HISTORY
- Genital lesion
- Risk behavior
- Urethritis, urinary symptoms, burning
- Known history of other STDs
- Drug allergies (which may cause fixed eruptions)
- Vision changes, dyspnea, fever/headache, paresis, neurologic impairment

PHYSICAL EXAM
- Primary syphilis
  - Classic *painless* chancre
    - Small, solid, raised lesion <1 cm across that becomes a red open sore with a scooped-out appearance. It usually does not bleed
    - Can be on the genitalia, anus, or mouth
  - Painless regional lymph nodes
- Secondary syphilis
  - Maculopapular and *symmetric* rash on trunk, arms, especially soles of feet
  - Lymphadenopathy painless
- Tertiary Syphilis
  - Hemiparesis
  - Tabes dorsalis (ie, decreased proprioception, touch)
  - Cardiac murmur

- Pulmonary edema
- Generalized dementia

DIAGNOSTIC TESTS & INTERPRETATION

- Lab: Critical to diagnosis (2,3)
- Indirect tests (ie, measure serologic response to treponemes)
  - *Non–treponemal-based tests* (screening or preliminary)
    - Rapid, cheap, simple
    - Can monitor for reinfection
    - Reduced sensitivity in primary and late disease
    - False positivity due to cross-reactions
    - False negatives due to high antibody levels
    - Examples: Venereal Disease Research Lab (VDRL); rapid plasma reagin (RPR); unheated serum reagin (USR)
  - *Treponemal-based tests* (confirmatory)
    - Expensive, technically difficult
    - Fluorescent anti-treponemal antibody absorption (FTA-ABS) (manually read)
    - Treponema pallidum particle agglutination (TP-PA) (manually read but simpler than FTA-ABS)
    - Enzyme immunoassay (EIA) (automated, rapid)
    - Western blot (helps resolve ambiguity)
- Direct tests (ie, measure treponemes or treponemal antigens directly)
  - Dark field microscopy of fresh lesion fluid
    - Simple, reliable
    - Requires expertise, limited sensitivity
  - Fluorescent antibody against *T. pallidum*
    - Most specific test when lesions present
    - False positive for other treponemes (eg, yaws, pinta)
  - Nonfluorescent staining (IHC [immunohistochemistry] + H&E)
  - PCR amplification (in development)
    - For congenital and neurosyphilis
    - Better sensitivity than traditional tests
- Culture: *T. pallidum* cannot be cultured

Imaging

Chest x-ray (eg, assess cardiac shadow in late syphilis)

Diagnostic Procedures/Surgery

- Serologic indirect testing
- Wound fluid microscopy
- Confirmatory direct testing
- Spinal tap to assess for neurosyphilis
- Biopsy of atypical lesions

Pathologic Findings

- Tertiary syphilis
  - Gummas: Nonspecific granulomatous reaction destroying involved tissue

- Cardiac: Endarteritis obliterans of vasa vasorum with consequent aortic aneurysm formation

DIFFERENTIAL DIAGNOSIS

ALERT
Syphilis is often called the "Great Pretender" as it can resemble other diseases.

- Rule out chancroid (painful ulcer and lymphadenopathy)
- Rule out lymphogranuloma venereum (nodes classically suppurate)
- Rule out granuloma inguinale (painless, beefy red raised ulcer, "pseudobubos" without nodes)
- Rule out herpes (usually clusters of vesicles in varying stages, burning pain)
- Annular syphilis can resemble cutaneous sarcoid (especially in African Americans)
- Condyloma lata do not have the digitate elevations seen in viral condyloma acuminata
- Pityriasis rosea may appear like secondary syphilis
- Psoriasis guttate (follow strep infections, drop-like raised plaques)
- Rule out fixed drug reaction (usually itchy)
- Bacterial meningitis
- Stroke
- Multiple sclerosis

TREATMENT

GENERAL MEASURES
- Antibiotic therapy is mainstay
- Serologic monitoring thereafter
- Contact public health service

MEDICATION
First Line
- Penicillin: 2.4 MU Benzathine PCN G IM × 1 (4)
- PCN-allergy: Tetracycline 500 mg PO q6h or doxycycline 100 mg PO q12 × 2 wk
- If pregnant: Ceftriaxone 1 g IM
- Widespread erythromycin resistance noted

Second Line
- Latent cardiovascular syphilis (duration over 1 yr)
  - Benzathine PCN G 2.4 MU IM qwk × 3 wk
  - If PCN allergic: Tetracycline 500 mg PO QID × 4 wk or doxycycline 100 mg PO bid × 4 wk

SURGERY/OTHER PROCEDURES
Aortic graft replacement has been used for late syphilitic aortic dissection.

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies

- Postexposure prophylaxis
  - Ceftriaxone 250 mg IM and Doxycycline 100 mg for 14 days
  - or Azithromycin (Zithromax) 1 g PO × 1
- Treat partners (chance of infection within 30 days of sex with infected partner is 15–30%)
- Retreatment if titers rise

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Excellent in primary syphilis
- Good in asymptomatic neurosyphilis
- Poor if symptomatic tabes dorsalis
- Syphilic aneuryms can cause death within 6 mo
- 1/3 of patients treated for above have a negative FTA-ABS by 36 mo

COMPLICATIONS

- Jarisch–Herxheimer reaction to treponemolysis after penicillin therapy begun
  - In up to 60% with initial therapy; 90% with secondary syphilis
  - Minor: Fever, flu-like symptoms, inflammation of affected structures (watch if cardiac involvement)
  - Major: Tachycardia, premature labor, transient paralysis (in tertiary syphilis), iritis, aortitis
  - Treatment is supportive
    - Undertreatment and development of late disease
    - Tabes dorsalis (poor prognosis)
    - Aortic aneurysm rupture

FOLLOW-UP

Patient Monitoring

- Repeat serologic testing q3mo × 4 then q6mo × 2
- Yearly thereafter
- 4-fold decrease should be seen in 12–24 mo
- Treatment failure: 4-fold increase in titer
  - Check CNS/spinal fluid
  - Check HIV status
  - Retreatment

Patient Resources

- CDC fact sheet. www.cdc.gov/std/syphilis/syphilis-Fact-Sheet.pdf

CODES

ICD9

- 091.2 Other primary syphilis
- 091.9 Unspecified secondary syphilis
- 097.9 Syphilis, unspecified

ICD10

- A51.0 Primary genital syphilis
- A51.49 Other secondary syphilitic conditions
- A53.9 Syphilis, unspecified

CLINICAL/SURGICAL PEARLS

- Screen pregnant women for syphilis (USPSTF grade A recommendation).
- Screen people-at-risk for syphilis (USPSTF grade A recommendation).
- Pregnancy is an absolute contraindication for doxycycline or tetracycline.
- Nonpenicillin, Nontetracyline alternatives are inferior to PCN but include ceftriaxone.
- Patients with syphilis, or being screened for syphilis, should be counseled to undergo HIV testing.
- Late syphilis may be asymptomatic.
- Condyloma lata are highly infectious and must be differentiated from HPV-related condyloma acuminate largely on physical exam.

TESTIS CANCER, ADULT GENERAL CONSIDERATIONS

Brett S. Carver, MD

BASICS

DESCRIPTION

- Testicular cancer is a malignancy of germ cell origin originating in the testis and is the most common malignancy in males 15–35 yr of age.
- Testicular cancer must always be considered in males presenting with testicular swelling.
- Patients with testicular cancer may present with a testicular mass, gynecomastia, infertility, abdominal mass, or symptoms related to metastatic disease such as back pain or cough.

EPIDEMIOLOGY

Incidence

- It is projected that in US, 8,820 new cases of testicular cancer would be diagnosed and 380 men would die of this disease in 2014.
- Germ cell tumors (GCTs) of the testis occur predominantly in Caucasian males.
- Lifetime risk of developing testis cancer is ~1 in 270, and the lifetime risk of dying of testicular cancer is 1 in 5,000.

Prevalence

N/A

RISK FACTORS

- Risk factors associated with the development of testicular cancer:
  - Cryptorchidism 4–6 fold increased risk
  - Family history 8–12 fold risk if affected brother
  - Testicular atrophy
  - Infertility
  - Klinefelter syndrome
- Cannabis use controversial

Genetics

Identification of isochromosome 12p amplification.

PATHOPHYSIOLOGY (1)

- GCTs of the testis can be divided into 2 major subgroups based on histology: Seminoma and nonseminoma germ cell tumor (NSGCT).
  - Seminoma: ~50% of all testicular cancers most frequently appear in the 4th decade of life.
  - ~10–15% of will produce the serum tumor marker, human chorionic gonadotropin (HCG).
  - The remainder of GCTs is comprised of nonseminomatous histology (embryonal cell carcinoma, yolk sac tumor, choriocarcinoma, and teratoma) and frequently present in the 3rd decade of life.
    - ~50–70% of nonseminomas will produce α-fetoprotein (AFP) and/or HCG.

- Most nonseminomatous tumors are mixed, composed of 2 or more cell types of which seminoma may be a component
  - The definition of a pure seminoma excludes the presence of any nonseminomatous elements or an elevated serum AFP.

ASSOCIATED CONDITIONS
- Infertility
- Cryptorchidism
- Gynecomastia

GENERAL PREVENTION
- Possibly early orchidopexy for undescended testicle
- USPSTF: Against routine screening for testicular cancer in asymptomatic adolescent and adults including routine testicular self-exams.
- American Cancer Society suggests that men with family history do monthly self-exams.
- American Urological Association (AUA): Monthly self-exams for all young men.

DIAGNOSIS
HISTORY
- The most common symptom at the time of diagnosis is painless swelling or enlargement of the testis.
- Acute testicular pain is reported to occur in ~10% of patients with testicular cancer and often represents infarction or hemorrhage within the tumor.
- At initial presentation, symptoms manifesting secondary to metastatic disease occur in ~20% of patients and include:
  - A mass in the left neck, pulmonary complaints such as hemoptysis or dyspnea, an abdominal mass, or back pain that can often be disabling.
- In ~5% of patients, gynecomastia or tenderness of the breast is reported.

PHYSICAL EXAM
- The most common finding on physical exam is a solid intratesticular mass or swelling.
- Patients should undergo a complete physical exam with emphasizing palpation of the cervical lymph nodes (lymphadenopathy), breasts (gynecomastia), abdomen (retroperitoneal masses/lymphadenopathy, liver masses), and the contralateral testis (bilateral testicular tumors).

ALERT
Markers must be drawn prior to radical orchiectomy.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum tumor markers (AFP, HCG, LDH) should be obtained prior to and following radical orchiectomy. The serum tumor markers are necessary for diagnosis, staging, and risk classification.
- Tumor markers obtained prior to orchiectomy:
  - 1 or more elevated in 85–90% of NSGCT
- β-hCG:

  - Half-life: 24–36 hr
  - Elevated in 40–60% with testis cancer; 100% of choriocarcinomas;10–15% pure seminomas
- AFP:
  - Half-life: 5–7 days
  - Produced by yolk sac tumors, embryonal cell carcinoma, and teratocarcinomas
  - Not produced in pure seminoma or pure choriocarcinoma. If AFP elevated in case of pure seminoma, NSGCT elements are present.
- LDH
  - Nonspecific marker for GCT
  - Elevated in 20% of low-stage and 50% of high-stage GCT
  - Useful in prognosis as magnitude of elevation correlates with disease bulk
  - Half-life: 1 day
- Serum and urine estrogens may be elevated in Leydig cell tumors
- While normal postorchiectomy serum tumor markers does not preclude the finding of metastatic disease, an elevation of either AFP or HCG does signify the presence of metastasis.

Imaging

- Testicular ultrasonography is the initial imaging modality of choice with a $>95\%$ sensitivity/specificity in identifying intratesticular lesions.
- Testicular ultrasonography often reveals a solid hypoechoic mass present within the testis.
- The contralateral testis should also be imaged as $\sim 2\%$ of patients will have bilateral testicular cancers.
- The initial staging evaluation should include a CT scan of the chest, abdomen, and pelvis with and without contrast.
  - CT is the most effective radiographic technique for identifying metastatic disease both above and below the diaphragm.
  - No evidence of metastases in $\sim 70\%$ of patients with seminoma and 30% of patients with nonseminoma.

Diagnostic Procedures/Surgery

A radical orchiectomy with high ligation of the spermatic cord at the level of the inguinal ring provides histopathologic diagnosis, primary tumor staging, and excellent local control of the tumor, with minimal morbidity and no mortality.

Pathologic Findings

- Histologic findings of seminoma, embryonal carcinoma, choriocarcinoma, yolk sac tumor, teratoma.
- Documentation of lymphovascular invasion.
- Pathologic and clinical staging follows the TNMS classification and risk assessment if performed using the International Germ Cell Cancer Collaborative Group (IGCCCG) risk classification.

ALERT

18–33% of patients with testicular cancer were initially treated for epididymitis resulting in a delay in diagnosis of testicular cancer.

DIFFERENTIAL DIAGNOSIS

- Benign lesions
  - Epididymitis/orchitis: Bacterial, STD, mumps
  - Testicular trauma: Usually blunt; contusion, rupture; usually associated hematocele
  - Torsion (testicle or appendages)
  - Incarcerated/strangulated hernia
  - Cysts (simple, tunica albuginea, epidermoid)
  - Adrenal rest tumors: In general benign, but can contribute to infertility in patients with congenital adrenal hyperplasia
  - Fibrous pseudotumor of the tunica albuginea: Painless fibrous mass often associated with prior history of trauma or infection
  - Adenomatoid tumor of testis or epididymis
  - Other rare benign lesions: Angioma, fibroma, leiomyoma, hamartoma, carcinoid, neurofibroma
- Malignant lesions
  - Testicular primary tumors (GCT, stromal and mixed as discussed above)
  - Leukemia involving testis: Testis can be a site of solitary recurrence of leukemia posttreatment (sanctuary site). Biopsy to confirm diagnosis. Treat with testis-sparing radiation, treat bilaterally.
  - Lymphoma involving testis: Usually represents extension from extratesticular sites, rarely can represent a primary lymphoma site (1% of lymphoma cases); can present bilaterally one-third of the time; mostly involves older men >60 yr; constitutional symptoms commonly present (fever, chills, night sweats, weight loss).
  - Metastatic solid tumors: Common: Prostate, lung, GI tract; more rare: Kidney, malignant melanoma, pancreas, bladder, and thyroid
  - Adenocarcinoma of the rete testis: Arises in the testis collecting system, high-stage presentation, poor response to chemotherapy and radiation, with median survival of 1 yr.
  - Mesothelioma of tunica vaginalis: Rare, similar to the more common pleural histology, associated with asbestos exposure
  - Paratesticular sarcomas: Rhabdomyosarcoma, malignant fibrous histiocytoma (most common soft tissue sarcoma in late adult life)

TREATMENT

GENERAL MEASURES

- Inguinal radical orchiectomy/high ligation of the spermatic cord is diagnostic and therapeutic.
- Patients are then staged based on TNM classification (see Section VII: "Reference tables: TNM: Testis Cancer")

ALERT
Discuss sperm banking prior to treatment.

MEDICATION

First Line (1,2)

- Regardless of histology, patients with advanced GCTs (cIIB–cIII) and with persistently

elevated tumor markers following radical orchiectomy (cIS), are initially treated with platinum-based chemotherapy according to the IGCCCG risk stratification.
  – Good risk disease: 3 cycles of bleomycin, etoposide, and cisplatin (BEP) or 4 cycles of etoposide and cisplatin (EP).
  – Intermediate-risk or high-risk disease: 4 cycles of BEP; ~30–40% of patients with poor-risk disease fail to achieve a durable response to conventional chemotherapy.

Second Line

Second-line chemo: Reserved for advanced testicular cancer in whom serum tumor markers do not normalize following initial chemo.

SURGERY/OTHER PROCEDURES

- Radical orchiectomy should be performed for diagnosis and treatment of the primary tumor.
- In US, the preferred management for patients at high risk for relapse in the retroperitoneum, ie, predominant embryonal carcinoma, lymphovascular invasion, or extension into the tunica or scrotum, is primary RPLND if serum tumor markers have normalized.
- Postchemotherapy RPLND (PC-RPLND) and resection of residual masses should be done. Following chemo, 40% undergoing RPLND will have teratoma; 10–15% have GCT.

ADDITIONAL TREATMENT

Radiation Therapy

In US, radiation therapy to the retroperitoneum remains the treatment of choice for patients with clinical stage I and IIa seminoma.

Additional Therapies

- Surveillance, with serial imaging and tumor markers, in well-selected low-risk patients:
  – Stage I seminoma
  – Stage I NSGCT: No teratomatous elements, no lymphovascular invasion, and no embryonal cell carcinoma in the primary specimens. Patients must be reliable

Complementary & Alternative Therapies

Discuss sperm banking before therapy

ONGOING CARE

PROGNOSIS

- Prognosis is dependent on initial clinical stage, risk stratification, and histology.
- The multidisciplinary approach to GCTs has survival rates at >90%.

COMPLICATIONS

- Radical orchiectomy: Wound infection, scrotal and/or retroperitoneal hematoma
- RPLND: Wound infection, pancreatitis, venous thrombosis, chylous ascites, anejaculation, and small-bowel obstruction.
- Chemotherapy: Neutropenia, gastrointestinal symptoms, alopecia, pulmonary fibrosis, and cardiovascular events.

FOLLOW-UP

Patient Monitoring

History and physical exam, serum tumor markers, chest x-ray, and periodic CT imaging of the

chest, abdomen, and pelvis for life. Follow-up according NCCN guidelines.

Patient Resources

CODES

ICD9

- 186.0 Malignant neoplasm of undescended testis
- 186.9 Malignant neoplasm of other and unspecified testis
- 608.3 Atrophy of testis

ICD10

- C62.00 Malignant neoplasm of unspecified undescended testis
- C62.90 Malig neoplasm of unsp testis, unsp descended or undescended
- N50.0 Atrophy of testis

CLINICAL/SURGICAL PEARLS

- All intratesticular masses should be assumed to be testicular cancer until proven otherwise.
- Elevated AFP is diagnostic for nonseminomatous GCT.

- Inguinal radical orchiectomy with high ligation of the spermatic cord is the initial treatment.

TESTIS CANCER, CHORIOCARCINOMA

Brett S. Carver, MD

BASICS

DESCRIPTION

- Choriocarcinoma is a type of germ cell tumor (GCT) composed of syncytiotrophoblastic, cytotrophoblastic, and other trophoblastic cells.
- Histologic cell type for nonseminomatous GCTs.
- Pure choriocarcinomas are commonly associated with metastatic disease and high levels of β-hCG at the time of presentation

EPIDEMIOLOGY

Incidence

- It is projected that in US, 8,820 new cases of testicular cancer would be diagnosed and 380 men would die of this disease in 2014.
- Pure choriocarcinoma compromises <1% of testicular GCT.
- Choriocarcinoma is a histologic cell type in ~10% of nonseminomas.

Prevalence

N/A

RISK FACTORS

- Risk factors associated with the development of testicular cancer include:
  - Cryptorchidism, family history, testicular atrophy, infertility.

Genetics

Identification of isochromosome 12p amplification.

PATHOPHYSIOLOGY

- Choriocarcinoma is a histologic subtype of nonseminomatous GCTs composed primarily of syncytiotrophoblasts and cytotrophoblasts.
- Syncytiotrophoblastic cells produce human chorionic gonadotropin (HCG) which may be detected by immunohistochemistry or measurement of serum levels.
- Pure choriocarcinoma is associated with significantly elevated levels of serum HCG. Choriocarcinoma represents a germ cell transformed through extraembryonic differentiation.
- Relationship between size of primary tumor and metastatic disease may seem paradoxical, with widespread disease associated with a relatively small primary tumor.
- Route of metastatic spread is variable compared to other GCTs, which are often stepwise and predictable. Choriocarcinoma is associated with a greater propensity for hematogenous dissemination.
- β-hCG is produced by syncytiotrophoblasts and is elevated in 100% of choriocarcinomas. The serum half-life of β-hCG is 24–36 hr.
  - Elevated serum levels of β-hCG are also noted in 40–60% of embryonal carcinomas and 5–10% of pure seminomas.

ASSOCIATED CONDITIONS
- Infertility
- Cryptorchidism
- Gynecomastia

GENERAL PREVENTION
Conflicting data if early orchiopexy reduces testis cancer risk in cryptorchidism

DIAGNOSIS
HISTORY
- Past medical history focusing on history of cryptorchidism
- The most common symptom at the time of diagnosis is painless swelling or enlargement of the testis.
  - Acute testicular pain is reported to occur in ~10% of patients with testicular cancer and often represents infarction or hemorrhage within the tumor.
- At initial presentation, symptoms manifesting secondary to metastatic disease occur in ~20% of patients and include, a mass in the left neck, pulmonary complaints such as hemoptysis or dyspnea, an abdominal mass, or back pain that can often be disabling.
  - Patients with choriocarcinoma may present with gynecomastia or tenderness of the breast secondary to elevated serum HCG.
- Neurologic symptoms related to brain metastases may be present in patients with advanced pure choriocarcinoma.

PHYSICAL EXAM
- The most common finding on physical exam is a solid intratesticular mass or swelling.
- Thorough exam of both gonads
  - Careful palpation of surrounding spermatic cord structures on involved side to evaluate extent of disease
  - Transillumination of scrotal contents if hydrocele is associated or suspected.
- Exam for metastatic disease including inguinal, abdominal, thoracic, neurologic exams.
  - Cervical lymph nodes (lymphadenopathy), breasts (gynecomastia), abdomen (retroperitoneal masses/lymphadenopathy, liver masses)
- Gynecomastia can be noted in ~5% of patients with GCT:
  - β-hCG can stimulate estrogen production from Leydig cells, leading to breast enlargement and tenderness, and the contralateral testis (bilateral testicular tumors).

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum tumor markers (AFP, HCG, LDH) should be obtained prior to and following radical orchiectomy. The serum tumor markers are necessary for diagnosis, staging, and risk classification. While normal postorchiectomy serum tumor markers does not preclude the finding of metastatic disease, an elevation of either AFP or HCG does signify the presence of metastasis.
- Pure choriocarcinomas are often associated with significantly high levels of serum HCG.

Imaging

- Testicular ultrasonography is the initial imaging modality of choice with a >95% sensitivity and specificity in identifying intratesticular lesions.
- Testicular ultrasonography often reveals a solid hypoechoic mass present within the testis.
- The initial staging evaluation should include a CT scan of the chest, abdomen, and pelvis. CT is the most effective radiographic technique for identifying metastatic disease both above and below the diaphragm.
- MRI of the brain should be performed to evaluate for metastases in patients with pure choriocarcinoma.

Diagnostic Procedures/Surgery

A radical orchiectomy with high ligation of the spermatic cord at the level of the inguinal ring provides histopathologic diagnosis, primary tumor staging, and excellent local control of the tumor, with minimal morbidity and no mortality.

Pathologic Findings

- Choriocarcinoma may be associated with other nonseminomatous germ cell histologies, as well as seminomatous histologies.
- Histology revealing syncytiotrophoblasts and cytotrophoblasts.
  - Macroscopically, tumors are often hemorrhagic with areas of necrosis, and can be associated with areas of fibrosis and tumor regression. Hemorrhage is usually central with viable tumor located peripherally.
- Mix of mononuclear cells with lightly staining cytoplasm (cytotrophoblasts) combined with multinucleated cells with smudged/degenerating nuclei and densely eosinophilic cytoplasm (syncytiotrophoblasts)
- Multiple fields need to be examined to clearly identify the cytotrophoblasts. Syncytiotrophoblasts stain strongly with HCG
- Pathologic and clinical staging follows the TNM classification and risk assessment if performed using the IGCCCG risk classification.

DIFFERENTIAL DIAGNOSIS

- These are a delineation of testicular masses only. For a complete listing of intrascrotal and testicular masses see Section I: “Scrotum and Testicle Mass”:
- Benign lesions
  - Epididymitis/orchitis: Bacterial, STD, mumps, TB
    - Often delayed testicular cancer diagnosis due to treatment of presumed epididymitis
  - Testicular trauma: Usually blunt; contusion, rupture; usually associated hematocele
  - Torsion (testicle or appendages)
  - Incarcerated/strangulated hernia
  - Cysts (simple, tunica albuginea, epidermoid)
  - Adrenal rest tumors: In general benign, but can contribute to infertility in patients with congenital adrenal hyperplasia
  - Fibrous pseudotumor of the tunica albuginea: Painless fibrous mass often associated with prior history of trauma or infection
  - Adenomatoid tumor of testis or epididymis
  - Other rare benign lesions: Angioma, fibroma, leiomyoma, hamartoma, carcinoid, neurofibroma

- Malignant lesions
  - Testicular primary tumors (seminoma and nonseminomatous GCT, stromal and mixed as discussed above)
  - Leukemia involving testis—testis can be a site of solitary recurrence of leukemia posttreatment (sanctuary site). Biopsy can be utilized to confirm diagnosis in a patient with history of leukemia.
    - Treatment can be testis-sparing with radiation, though contralateral testis should be treated as bilateral disease can be present.
  - Lymphoma involving testis—usually represents extension from extratesticular sites, rarely can represent a primary lymphoma site (1% of lymphoma cases); can present bilaterally one-third of the time; mostly involves older men >60 yr; constitutional symptoms commonly present (fever, chills, night sweats, weight loss).
  - Metastatic solid tumors: More common—prostate, lung, GI tract; more rare—kidney, malignant melanoma, pancreas, bladder, and thyroid
  - Adenocarcinoma of the rete testis: Arises in the testis collecting system, high-stage presentation, poor response to chemotherapy and radiation, with median survival of 1 yr.
  - Mesothelioma of tunica vaginalis: Rare, similar to the more common pleural histology, associated with asbestos exposure
  - Paratesticular sarcomas: Rhabdomyosarcoma, malignant fibrous histiocytoma (most common soft tissue sarcoma in late adult life)

TREATMENT

GENERAL MEASURES (1)

- Inguinal radical orchiectomy with high ligation of the spermatic cord is diagnostic and therapeutic.
- Treatment options are based on clinical staging. Staging following removal of the primary tumor is similar to all GCT and is based on physical exam, radiographic studies, serum tumor markers, and histologic tumor features according the TNMS staging system.

MEDICATION

First Line (2)

- Regardless of histology, patients with advanced GCTs (cIIB–cIII) and those with persistently elevated tumor markers following radical orchiectomy (cIS), are initially treated with platinum-based chemotherapy according to the International Germ Cell Cancer Collaborative Group (IGCCCG) risk stratification.
  - Patients with good-risk disease are treated with 3 cycles of bleomycin, etoposide, and cisplatin (BEP) or 4 cycles of etoposide and cisplatin (EP).
  - While patients with intermediate-risk or high-risk disease receive 4 cycles of BEP.
- Choriocarcinomas are often associated with hemorrhage, neurologic and pulmonary monitoring is critical following chemotherapy.

Second Line

Second-line chemotherapy is reserved for patients with advanced testicular cancer in whom serum tumor markers do not normalize following initial chemotherapy regimen.

SURGERY/OTHER PROCEDURES

- Radical orchiectomy should be performed for diagnosis and treatment of the primary tumor.
- In US, the preferred management for patients at high risk for relapse in the retroperitoneum, ie, predominant embryonal carcinoma, lymphovascular invasion, or extension into the tunica or scrotum, is primary RPLND if serum tumor markers have normalized.
- Postchemotherapy RPLND (PC-RPLND) and resection of residual masses are an integral component in the management of advanced nonseminoma.

ADDITIONAL TREATMENT

Radiation Therapy

Occasionally radiation therapy for cerebral metastases is utilized, but systemic therapy remains the initial treatment of choice for the management of metastatic disease including cerebral metastasis.

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- The multidisciplinary approach to the management of GCTs of the testis has resulted in survival rates of >90% overall.
- The prognosis for patients with testicular cancer including choriocarcinoma depends on stage, risk stratification, and histology.
- Prognosis for patients with metastatic disease estimated using the IGCCC system for NSGCT:
  - Good prognosis: Testis or retroperitoneal primary, no nonpulmonary visceral metastases, AFP <1,000, β-hCG <5,000, and LDH <1.5 for upper limit of normal (ULN)
  - Intermediate prognosis: Testis or retroperitoneal primary, no nonpulmonary visceral metastases, AFP 1,000–10,000, β-hCG 5,000–50,000, or LDH 1.5–10 ULN
  - Poor prognosis: Mediastinal primary, nonpulmonary visceral metastases, AFP >10,000, β-hCG >50,000, or LDH >10 ULN

COMPLICATIONS

- The complications of radical orchiectomy include: Wound infection, scrotal hematoma, and retroperitoneal hematoma.
- Complications of RPLND: Wound infection, pancreatitis, venous thrombosis, chylous ascites, anejaculation, and small-bowel obstruction.
- Complications of chemotherapy: Neutropenia, gastrointestinal symptoms, alopecia, pulmonary fibrosis, and cardiovascular events; propensity for choriocarcinomas to hemorrhage

FOLLOW-UP

Patient Monitoring

Following management of GCTs, patients should be followed with history and physical exam, serum tumor markers, chest x-ray, and periodic CT imaging of the chest, abdomen, and pelvis

for life. Follow-up protocols should be followed according to guidelines established by the National Comprehensive Cancer Network.

CODES

ICD9

- 186.9 Malignant neoplasm of other and unspecified testis
- 608.3 Atrophy of testis
- 752.51 Undescended testis

ICD10

- C62.90 Malig neoplasm of unsp testis, unsp descended or undescended
- N50.0 Atrophy of testis
- Q53.9 Undescended testicle, unspecified

CLINICAL/SURGICAL PEARLS

- All intratesticular masses should be assumed to be testicular cancer until proven otherwise.
- Choriocarcinomas are associated with production of HCG.
- Choriocarcinomas have a predilection for brain metastases.
- Inguinal radical orchiectomy with high ligation of the spermatic cord is the initial treatment.

TESTIS CANCER, EMBRYONAL CARCINOMA

Nicholas J. Kuntz, MD
Judd W. Moul, MD, FACS

BASICS

DESCRIPTION

- Embryonal carcinoma (EC) is the most common (43%) nonseminoma germ cell tumor (NSGCT) histologic subtype of the testis (1)[B]
- Pure EC histology is present in 2–4% of all germ cell tumors (GCTs)
- EC is present in 85% of mixed GCTs
- Most common in age 20–40 yr
- Right more common, bilateral in 2–3%

EPIDEMIOLOGY

Incidence

- US age-adjusted incidence (SEER data)
  - 5.5 per 100,000/yr (all testicular cancers)
- 2014 estimated new cases of testicular cancer
  - 8,820 with 380 deaths
- Lifetime risk of developing testicular cancer:
  - 1 in 270

Prevalence

Testicular cancer: 221,020 US men in 2010

RISK FACTORS

- Cryptorchidism
  - 4–6-fold increased risk for all GCTs
  - Increased risk in contralateral testes
- Previous testicular malignancy
  - 12-fold increases risk to develop cancer in the contralateral testicle
- Family history
  - 8–12-fold increased risk with affected brother
- Intratubular germ cell neoplasia (ITGCN)
- Testicular atrophy
  - Nonspecific or mumps-associated
- Klinefelter syndrome

Genetics

- Isochromosome of the short arm of chromosome 12–i(12p) (2)[B]
- ITGCN
  - p53 alterations found in 66% (3)[B]

PATHOPHYSIOLOGY

- EC is an aggressive GCT subtype
- 74% have metastases at presentation (1)[B]
- Predominant EC component (>50%) increases the risk of occult metastasis (3)[A]
- High associated relapse rate (35–40%)
- Predictable lymphatic spread
  - Retroperitoneum (primary site)
    - Left-sided tumors spread to preaortic and para-aortic lymph nodes; left-to-right spread is rare.
    - Right-sided tumors spread to precaval, interaortocaval, and then may spread to preaortic and para-aortic nodes.
  - Most common visceral sites
    - Lungs, liver

ASSOCIATED CONDITIONS
- Infertility
- Cryptorchidism
- Seminoma

GENERAL PREVENTION
- Possibly early orchidopexy for undescended testicle
- Testicular self-exam

DIAGNOSIS
HISTORY
- Signs and symptoms
  - Painless testicular mass (50–60%)
  - Testicular pain or dull ache (30–40%)
  - Symptomatic metastases (10%)
    - Cough, dyspnea, supraclavicular nodal
  - Gynecomastia (2%)
  - Trauma (4%)
  - Infertility
- History of undescended testes in 10%

PHYSICAL EXAM
- Thorough genital, lymph node, abdominal, chest, and neurologic exam
  - 2–3% of patients with disseminated testicular cancer present with central nervous system (CNS) metastasis.
  - Gynecomastia noted in 7% of GCTs (2)[B]
- Include palpation of spermatic cord structures
- Scrotal ultrasound (US) (see “Imaging”)
- Transillumination test
  - Reactive hydrocele may be secondary to underlying malignancy

DIAGNOSTIC TESTS & INTERPRETATION
Lab

- Tumor markers (4)[A] (drawn at diagnosis and following orchiectomy according to half-life)
  - α-Fetoprotein (AFP)
    - Produced by fet al gut, liver, and yolk sac
    - Half-life of ~5 days.
    - Elevated in 80% of EC
    - Absent in pure seminoma and choriocarcinoma.
  - Human chorionic gonadotropin (hCG)
    - Normally secreted by placental syncytiotrophoblasts
    - Half-life of ~24–36 hr. Consists of α- and β-chains: α-chain analogous to luteinizing hormone and thyroid-stimulating hormone.
    - Elevated in 60% of all NSGCT, 30% of seminomas, and all choriocarcinomas.
  - Lactate dehydrogenase (LDH)
    - Most useful when other markers are negative.
    - Relates to tumor bulk.
- Chemistry profile
  - Renal function (future chemo, ureteral obstruction from RP disease)

Imaging

- Scrotal US (4)[A]
  - Well circumscribed, heterogeneous, hypoechoic mass is highly suspicious for cancer
  - Cannot distinguish subtypes on imaging
- Clinical staging
  - Computed tomography (CT) of chest abdomen and pelvis (4)[A]
  - Head magnetic resonance imaging (MRI) if:
    - Neurologic symptoms
    - High risk for CNS disease (mets, high hCG, or choriocarcinoma)
  - Positron emission tomography (PET): Not indicated for NSGCT (2)[B]

Diagnostic Procedures/Surgery

- Biopsy of primary mass is contraindicated
  - Contamination of lymph drainage
- Consider inguinal biopsy of contralateral testis if (2)[B]:
  - Concerning US findings
  - Cryptorchid testis
  - Significant atrophy

Pathologic Findings

- Gross
  - Tan to yellow, fleshy tumor
  - Areas of necrosis or hemorrhage
  - Poorly defined capsule
- Histologic
  - Epithelioid cells arranged in glands or tubules, indistinct cell borders
  - Pale or vacuolated cytoplasm
  - Rounded nuclei with coarse chromatin

- Large nucleoli; pleomorphism, mitotic figures, and giant cells
- Staining:
  - Positive: AE1/AE3, PLAP, and OCT3/4
  - Negative: c-KIT

DIFFERENTIAL DIAGNOSIS

See Section I "Testis, Tumor and Mass, Adult, General Considerations" and Testis, tumor and mass, pediatric, general considerations

ALERT
Up to 33% of testicular tumors are initially misdiagnosed

TREATMENT

ALERT
Discuss sperm banking prior to treatment, due the increased risk of infertility following treatment (4)[A].

GENERAL MEASURES

- Surgery (radical inguinal orchiectomy) is the primary treatment for all testicular malignancies (4)[A]
- Chemotherapy prior to orchiectomy may be warranted in severe cases (4)[A]
- Subsequent primary treatments include chemo, radiation, or retroperitoneal lymph node dissection (RPLND)
- Treatment options for EC are based on clinical stage (4)[A]. (see Table "TNM: Testis Cancer")
  - Stage IA, IB:
    - Surveillance (IA or IB T2 only)
    - RPLND
    - Chemotherapy (2 cycles bleomycin, etoposide, cisplatinum (BEP) × 2 or BEP × 1
  - Stage IIA and IIB:
    - RPLND
    - Chemotherapy (EP × 4, or BEP × 3)
  - Stage IIc or stage III:
    - Good risk (EP × 4 or BEP × 3)
    - Intermediate risk (BEP × 4)
    - Poor risk (BEP × 4, clinical trial, VIP × 4)

MEDICATION

First Line

- BEP or EP regimens
- See Section I: "Testis, Cancer, Adult General Considerations" for specific regimens

Second Line

- Vinblastine, ifosfamide, cisplatinum (VIP)
  - Poor tolerance to bleomycin

  – Salvage protocol
  – Pretreat with MESNA to reduce incidence of hemorrhagic cystitis
- Paclitaxel, ifosfamide, cisplatin (TIP)
- High-dose chemotherapy

SURGERY/OTHER PROCEDURES
- Radical inguinal orchiectomy
  – Recommended first-line treatment for testicular tumors (4)[A]
- Partial orchiectomy
  – Small tumor (< 30% of testicular volume), solitary testes, or bilateral tumors
  – Adjuvant radiation at some point (16–20 Gy) given high rate of associated ICGCN (2)[B]
- RPLND
  – Nerve-sparing approach minimizes ejaculatory dysfunction
  – stage IIa, IIb, or high-risk stage I (4)[A]
- Salvage RPLND
  – Consider referral to high-volume center
  – Full bilateral template recommended in this setting

ADDITIONAL TREATMENT

Radiation Therapy

No role in treatment of NSGCT

Additional Therapies

Palliative chemotherapy

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS
- Stage I:
  – > 30% relapse with observation alone
- Stage II and III:
  – > 60% have complete response following adjuvant treatment

COMPLICATIONS
- RPLND:
  – Loss of seminal emission: 10%
  – Bowel obstruction: 1–3% lifetime risk
  – ARDS: Patients previously been treated with bleomycin
- Chemotherapy:
  – Bleomycin: Pulmonary fibrosis, ARDS
  – Etoposide: Myelosuppression, alopecia secondary leukemia
  – Cisplatin: Renal insufficiency, nausea/vomiting, neuropathy
  – Ifosfamide: Hemorrhagic cystitis
  – Vinblastine: Neuromuscular toxicity

FOLLOW-UP

Patient Monitoring

- Primary surveillance
  - ~30% recurrence, most common 1st 2 yr
  - NCCN follow-up protocol:
    - Year 1: Tumor markers and chest x-ray every 1–2 mo; abdominal CT every 3–4 mo
    - Year 2: Tumor markers and chest x-ray every 2 mo; abdominal CT every 4–6 mo
    - Years 3–5: Tumor markers and chest x-ray every 3–6 mo; abdominal CT every 6–12 mo
    - After year 5: Tumor markers and chest x-ray once a year; abdominal CT every 1–2 yr
- RPLND
  - Most likely site of recurrence is the chest (3)
  - NCCN follow-up protocol:
    - Year 1: Tumor markers and chest x-ray every 2–3 mo, baseline abdominal/pelvic CT
    - Year 2: Tumor markers and chest x-ray every 2–3 mo, abdominal/pelvic CT as indicated
    - Years 3–5: Tumor markers and chest x-ray every 3–12 mo, abdominal/pelvic CT as indicated.
    - After year 5: Tumor markers and chest x-ray once a year
- Chemotherapy and RPLND
  - NCCN follow-up protocol:
    - Year 1: Tumor markers and chest x-ray every 2–3 mo; abdominal/pelvic CT every 6 mo
    - Year 2: Tumor markers and chest x-ray every 2–3 mo; abdominal/pelvic CT every 6–12 mo
    - Years 3–5: Tumor markers and chest x-ray every 3–12 mo; abdominal/pelvic CT every year
    - After year 5: Tumor markers and chest x-ray once a year; abdominal/pelvic CT as indicated

CLINICAL/SURGICAL PEARLS

• Painless testicular mass is testicular cancer until proven otherwise.
• Transscrotal orchiectomy or biopsy is contraindicated.
• EC is aggressive histologic subtype with increased risk of occult disease.
• Second opinion of pathologic specimens by experienced pathologists is encouraged.
• Current treatment approaches achieve excellent long-term survival rates.

TESTIS CANCER, ENDODERMAL SINUS TUMORS (YOLK SAC TUMORS)

Elizabeth V. Dray, MD
Marcus L. Quek, MD, FACS

BASICS

DESCRIPTION

- Endodermal sinus tumors (yolk sac tumors [YSTs]) are germ cell tumor (GCT) that resembles cells of allantois, yolk sac, and mesenchyme
  - AKA endodermal sinus tumors, Teilum tumor, orchioblastoma, juvenile embryonal
- Bimodal age distribution
  - Children < 3 yr, young adults
- Staging
  - Adults: Per TNM staging for non seminomtous germ cell tumors (NSGCT) (See Section VI: Reference tables: TNM: Testis Cancer)
  - Children: Children's Oncology Group Staging
    - Stage I: Tumor limited to the testis, completely resected by high inguinal orchiectomy with negative margins. No clinical, radiographic or histologic evidence of disease beyond the testis. Tumor markers negative after appropriate half-life decline.
    - Stage II: Microscopic residual disease present in the scrotum or spermatic cord (< 5 cm from proximal end). Tumor markers elevated after appropriate half-life. Tumor rupture or scrotal biopsy prior to completion orchiectomy.
    - Stage III: Retroperitoneal lymph node involvement (LN > 4 cm on CT).
    - Stage IV: Distant metastases.
- 85% of children present with stage I disease, compared to 35% of postpubertal cases

EPIDEMIOLOGY

Incidence

- Children
  - Incidence of pediatric testis tumors is 0.5–2 per 100,000.
  - YST comprise 62% of all testicular tumors in childhood based on AAP tumor registry.
- Adults
  - In US, ~8,820 new cases of testicular cancer would be diagnosed and 380 men would die of this disease in 2014.
  - Lifetime risk of developing testis cancer is ~1 in 270, and the lifetime risk of dying of testicular cancer is 1 in 5,000
  - Pure YST is extremely rare, but found in 42% of mixed GCTs.

Prevalence

N/A

RISK FACTORS

- General risk for testicular cancer

- Cryptorchidism
- Klinefelter's syndrome.
- Family history.
- Male infertility
- Low birthweight, young maternal age, young paternal age, multiparity, breech delivery
- Infant hernia.
- Height-taller men
- Testicular microlithiasis

Genetics

Heredity unknown

PATHOPHYSIOLOGY

- Associated with gains in chromosome 12p in adults, RUNX promotor methylation on chromosome 1p in children (1)
- ITGCN precursor lesion in adults, unclear relationship in children.
- Lymphatic and hematogenous spread
  - Up to 20% of children present with lung metastases compared to 4–6% of adults

ASSOCIATED CONDITIONS

- Adults
  - Cryptorchidism
    - Later age at orchiopexy associated with higher relative risk of cancer.
    - Risk also increased with intra-abdominal testis and bilateral cryptorchidism.
- Children
  - Disorders of sex development

DIAGNOSIS

HISTORY

- Presents as painless testicular mass
  - May also present as retroperitoneal mass in mediastinal GCT
  - Incidentally associated with trauma in $<10\%$ of cases.

PHYSICAL EXAM

- Painless testicular mass
  - 15–50% have associated hydrocele

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum tumor markers
  - β-hCG never elevated in pure YST.
  - 90% of YST produce AFP
    - Also produced by liver and GI tract.
    - Half-life 5–7 days.
    - AFP often elevated in infants. Normal adult levels not reached until 8 mo of age.

Imaging

- Scrotal US

- Hyperechoic or heterogenous mass with increased blood flow on Doppler
  - Note: In children, anechoic cystic lesions with normal AFP suggestive of benign mass, can attempt testis-sparing surgery.
- CT chest/abdomen/pelvis with PO and IV contrast
  - For staging in all age groups.

Diagnostic Procedures/Surgery

Inguinal orchiectomy with high ligation of spermatic cord within 1–2 wk of presumed diagnosis.

Pathologic Findings

- Gross
  - Endodermal sinus tumors appear firm, yellow-white mass
- Microscopic
  - Resemble cells of allantois, yolk sac, mesenchyme arranged in glandular, papillary, or microcytic pattern with hyaline globules.
  - Schiller–Duval bodies characteristic finding
  - Stains positive for AFP.

DIFFERENTIAL DIAGNOSIS

- Adults: See Section I "Testis, Tumor and Mass, Adult, General Considerations"
- Painful childhood testicular masses:
  - Epididymitis/orchitis; bacterial, mumps
  - Henoch–Schönlein purpura (usually no mass)
  - Incarcerated/strangulated hernia
  - Testicular or paratesticular tumor
  - Testis trauma: Contusion, hematocele
  - Torsion (testicle, testicular, or epididymal appendage); more common after puberty
- Painless childhood testicular masses:
  - Adenomatoid tumor of testis or epididymis
  - Adrenal rest tumors
  - Cystic dysplasia of the testis
  - Chylocele: Usually associated with filariasis
  - Fibrous pseudotumor of the tunica albuginea
  - Hydrocele, primary or due to trauma, torsion, tumor, epididymitis; hydrocele of cord
  - Hernia
  - Lipoma of the cord
  - Polyorchidism
  - Scrotal edema (insect bite, nephrotic syndrome, acute idiopathic scrotal edema)
  - Spermatocele (epididymal cyst)
  - Testicular cysts
  - Testicular tumors:
    - GCTs: YST, teratoma, seminoma, embryonal, choriocarcinoma, mixed tumors
    - Gonadal stromal tumors: Leydig tumor, Sertoli cell, granulosa cell tumors
    - Metastatic tumors
    - Hamartoma, carcinoid, and neurofibroma

- Testis tumor of adrenogenital syndrome
- Leukemia or lymphoma

• Varicocele

TREATMENT

GENERAL MEASURES

• Adults
  – Management I handled as for nonseminomatous GCT: Section I "Testis Cancer, Nonseminomatous Germ Cell Tumors, General."
• Children (2,3)
  – Inguinal orchiectomy curative in 80% of children with stage I disease
  – Adjuvant chemotherapy recommended for stage II–IV disease.

MEDICATION

First Line (4)

• Chemotherapy: Bleomycin, etoposide, cisplatin (BEP)
  – Carboplatin may have equivalent outcomes compared to cisplatin with decreased ototoxicity and nephrotoxicity.

Second Line

• Etoposide, ifosfamide, cisplatin (VIP)
  – High-dose chemotherapy regimens for treatment failures.

SURGERY/OTHER PROCEDURES

• In children: LN >2 cm and <4 cm in size at diagnosis should undergo excisional or interventional radiologybiopsy biopsy to confirm histology.
• Postchemotherapy residual retroperitoneal disease should undergo retroperitoneal lymphadenectomy.

ADDITIONAL TREATMENT

Radiation Therapy

No role for radiation in endodermal sinus tumor.

Additional Therapies

• Sperm banking should be offered prior to chemotherapy in adolescents and adults.
  – Fertility-sparing procedure for prepubertal boys are controversial, but include Testicular sperm extraction (*TESE*) and cryopreservation of testicular tissue

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

• Adults: See "NSGCT"
• Children
  – Survival for all stages approaches 100% at 6 yr.
  – 20% of children with stage I disease will relapse during surveillance; however, excellent

cure rates with chemotherapy.

COMPLICATIONS

- Chemotherapy toxicity
  - Bleomycin: Pulmonary fibrosis
  - Cisplatin: Ototoxicity, nephrotoxicity, neuropathy.
  - Etoposide: Pancytopenia
- Infertility

FOLLOW-UP

Patient Monitoring

- Children
  - CXR, CT or MRI, AFP, and history and physical exam monthly for 3 mo, then at 6 mo postoperatively, and subsequently every 6 mo for 36 mo.
    - Note: Imaging guidelines evolving in light of increasing awareness of the impact of radiation on pediatric populations.

• Torsion, Testis and Testicular Appendages

CODES

ICD9

• 186.9 Malignant neoplasm of other and unspecified testis
• 608.89 Other specified disorders of male genital organs
• 752.51 Undescended testis

ICD10

• C62.90 Malig neoplasm of unsp testis, unsp descended or undescended
• N50.8 Other specified disorders of male genital organs
• Q53.9 Undescended testicle, unspecified

CLINICAL/SURGICAL PEARLS

• Endodermal sinus tumor is the most common GCT of childhood.
• Inguinal orchiectomy with high ligation of spermatic cord mainstay of therapy.
• Excellent prognosis for all stages in children.

TESTIS CANCER, NONSEMINOMATOUS GERM CELL TUMORS, GENERAL

Robert H. Blackwell, MD
Marcus L. Quek, MD, FACS

BASICS

DESCRIPTION

- Nonseminomatous germ cell tumors (NSGCTs) are malignant neoplasms of the testicle originating from germ cells, excluding seminoma
- 4 histologic types: Choriocarcinoma, embryonal cell, teratoma, and yolk sac
- >50% of NSGCT have a mixed histology; may also include a seminoma component (mixed GCT)
- Testicular cancer accounts for 1–1.5% of male cancer, of which GCTs make up 90–95%
- This section provides an overview of NSGCT. Details on each subtype can be found in their respective chapters

EPIDEMIOLOGY

Incidence

- SEER age-adjusted incidence of testicular cancer in US is 5.5 per 100,000 men
- In US (2014), ~8,820 new cases will be diagnosed with about 370 deaths

Prevalence

SEER prevalence of testicular cancer in US in 2010 was 221,020

RISK FACTORS

- Family history: ~1.4% of patients with newly diagnosed GCTs report a family history
  - Sons have a 4–6× increased risk of GCT, siblings have a 8–10× increased risk
- Cryptorchidism: ~3.7× increased risk of GCT
  - 7–10% incidence in cryptorchid patients in the ipsilateral undescended testicle, ~5% in the contralateral testicle
- Environment: Higher incidence in Northern Europe > North America > Africa/Asia
- Prior testicular tumor: 2% incidence of malignancy in the contralateral testicle
- ITGCN: 70% progresses to GCT over 7 yr

Genetics

- Identification of isochromosome 12p amplification; found in nearly all GCTs
- 2–3% incidence of bilateral testis tumors may suggest congenital predisposition

PATHOPHYSIOLOGY

- ITGCN (intracellular germ cell neoplasia also referred to as CIS) is believed to be the precursor lesion of all GCTs, excluding spermatocytic seminoma
  - ~2.5% of patients with a GCT will have ITGCN in the contralateral testicle
- GCTs typically spread in a predictive manner via the retroperitoneal lymph nodes (although choriocarcinoma also spreads hematogenously)

  - Left-sided tumors typically spread to para-aortic lymph nodes, right-sided tumors spread to interaortocaval lymph nodes. Tumor may spread right-to-left, but usually not left-to-right
  - Subsequent drainage through the cisterna chyli, thoracic duct, and supraclavicular nodes (usually left) or retrograde to iliac/inguinal nodes
- Nearly 60% of NSGCTs contain >1 histologic subtype in varying amounts (mixed GCTs)
- Choriocarcinoma
  - Expected presenting age: 20–30 yr
  - Tumor markers: Markedly elevated HCG, normal AFP
  - Rare in pure form (1%)
  - Often presents as small primary tumor
  - Can spread hematogenously to lung/brain
- Embryonal cell carcinoma
  - Expected presenting age: 25–35 yr
  - Tumor markers: Elevated or normal HCG/AFP
  - Present in up to 85% of mixed GCTs
  - Only pure embryonal in 2–3% of cases
  - >40% of embryonal component in primary tumor puts patient at high risk for relapse
- Teratoma
  - Expected presenting age: 25–35 yr
  - Tumor markers: Normal AFP and HCG
  - Composed of 2 or more germ cell layers: Endoderm, mesoderm, ectoderm
  - Benign lesions when prepubertal, malignant lesions after puberty
  - May be mature (completely differentiated cell types and somatic tissue) or immature (incompletely differentiated) teratoma
  - Areas may undergo malignant transformation according to which layer transforms (eg, endoderm to adenocarcinoma).
- Yolk sac (endodermal sinus)
  - Expected presenting age: 0–10 yr
  - Tumor markers: Markedly elevated AFP, normal HCG
  - Most common prepubertal testicular tumor
  - Absence of yolk sac elements in mixed GCT is a predictor of relapse

ASSOCIATED CONDITIONS

- Cryptorchidism
- Infertility

GENERAL PREVENTION

- In cases of cryptorchidism, orchiopexy does not decrease incidence of malignancy, but allows for earlier detection
- USPSTF: Against routine screening for testicular cancer in asymptomatic adolescent and adults including routine testicular self-exams.
- American Cancer Society suggests that men with family history do monthly self-exams.
- American Urological Association (AUA): Monthly self-exams for all young men.

DIAGNOSIS

HISTORY

- Presents as painless mass or swollen testicle
- May be initially detected following testicular trauma, but not associated with trauma
- Back or flank pain present in ~10% of cases

PHYSICAL EXAM

- Scrotal exam including both testes, epididymis, and cord structures
- Abdominal exam with attention to palpable lymphadenopathy and/or viscera
- Supraclavicular nodes
- Gynecomastia (present in ~7%)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Tumor markers: Used preop, postop, surveillance
  - β-HCG: Produced by syncytiotrophoblasts. Half-life 24–36 hr
  - AFP: Produced by epithelial lining of endodermal sinus. Half-life 5–7 days
  - LDH: Elevated with increased tumor burden. Half-life 4–4.5 days

Imaging

- Scrotal US: Tumors tend to be hypoechoic, with blood flow seen within the tumor
  - Microlithiasis: Prevalence of ~6% in patients undergoing testicular ultrasound, although controversial if associated with malignancy

Diagnostic Procedures/Surgery

- No role for percutaneous biopsy for intratesticular masses
- Radical inguinal orchiectomy for histologic confirmation and may be therapeutic
- Metastatic evaluation: Abdominal/pelvic CT with CXR or chest CT
- MRI of brain and bone scan indicated only for suspicious symptoms or if choriocarcinoma

Pathologic Findings

- Choriocarcinoma: Have both syncytiotrophoblasts and cytotrophoblasts
- Embryonal: Distinct cell arrangements and vascular invasion often present
- Teratoma: At least 2 germ cell layers present
- Yolk sac: Schiller–Duval bodies are present in 50% of cases (resemble a glomerulus)

DIFFERENTIAL DIAGNOSIS

See Section I “Testis Cancer, Adult General Considerations” and “Testis Cancer, Pediatric, General Considerations”

ALERT

Encourage sperm banking prior to any definitive treatment.

TREATMENT

GENERAL-MEASURES (1)

- Radical inguinal orchiectomy standard of care
  - Risk altering lymphatic drainage patterns with scrotal incision

– Additional therapy for NSGCTs depend on staging (TNM staging, risk stratification based on International Germ Cell Consensus Collaborative Group (IGCCCG) system

MEDICATION

First Line (2,3)

- Regardless of histology, patients with advanced germ cell tumors (cIIB—cIII) and those with persistently elevated tumor markers following radical orchiectomy (cIS), are initially treated with platinum-based chemotherapy according to the IGCCCG risk stratification.
  – Patients with good-risk disease are treated with 3 cycles of bleomycin, etoposide, and cisplatin (BEP) or 4 cycles of etoposide and cisplatin (EP). While patients with intermediate-risk or high-risk disease receive 4 cycles of BEP, ~30–40% of patients with poor-risk disease fail to achieve a durable response to conventional chemotherapy.

Second Line

Chemotherapy is reserved for patients with advanced disease where serum tumor markers do not normalize following initial chemotherapy.

SURGERY/OTHER PROCEDURES

- Radical inguinal orchiectomy for treatment and pathologic diagnosis
  – Follow serum tumor markers and compare to preoperative values
  – Pathologic risk factors for relapse
    - ≥T2 disease
    - Lymphovascular invasion (50% chance of relapse)
    - >40% embryonal component
    - Absence of yolk sac component
- Testicular-sparing surgery can be selectively considered in patients with bilateral testicular tumors or a solitary testicle
- RPLND—if necessary (see below)
  – For low-stage disease a unilateral sympathetic nerve-sparing template may be used
    - Superior boundary: Renal hilum bilaterally
    - Lateral boundary: Ipsilateral ureter down to level where it crosses the ipsilateral common iliac artery. The ipsilateral gonadal vessels and spermatic cord stump are included in the specimen.
    - Right-sided template medial boundary: Lateral edge of aorta down to level of IMA, then from aorta down along the right common iliac artery to where the right ureter crosses
    - Left-sided template medial boundary: Lateral edge of the IVC down to level of the IMA, then from the aorta down along the left common iliac artery to left ureter crossing
  – Postchemotherapy: A full bilateral template is utilized with prospective nerve sparing
  – The templates should not be strictly upheld should palpable disease be found.

ADDITIONAL TREATMENT

Radiation Therapy

Unlike seminomas, NSGCTs are not treated with radiation (teratoma is radioresistant).

Additional Therapies

- See Section III “Testis Cancer: Nonseminomatous Germ Cell Tumor” for treatment algorithm
- Stage Ia/Ib disease treatment options

- Surveillance: In reliable patients with no risk factors (no teratomatous elements, no lymphovascular invasion, and no embryonal cell carcinoma in the primary). Reliable patient; cure rate >95% with close follow-up
  - 20–30% relapse rate; these patients can be salvaged with subsequent chemotherapy
- RPLND: Modified unilateral template/nerve-sparing. 70–75% will have no tumor (pN0)
  - Perform within 4 wk of CT and 7–10 days of tumor for accurate clinical staging
  - >95% cure rate if nodes negative, but may be curative for low-volume nodal disease
  - 5% relapse rate
- Chemotherapy: 95% cure rate with BEP

• Stage IS disease: Elevated tumor markers postorchiectomy without radiographic evidence of disease. Treat with chemotherapy. Preferable to RPLND given suspected disseminated disease

• Stage IIa/IIb disease
- Postorchiectomy tumor markers positive; induction chemotherapy
- Postorchiectomy tumor markers negative; either RPLND or chemotherapy
  - No viable tumor (pN0), observe patient
  - Low-volume tumor, surgery curative in 60–90%; surveillance or chemotherapy
  - High-volume disease (pN2–3—risk of relapse >50%) or tumor left behind; adjuvant BEP chemotherapy decreases relapse to <1%

• Stage IIc or III disease
- Either 3 or 4 cycles of BEP chemotherapy
- Complete response, observe
- Partial response with residual masses, full bilateral RPLND (nerve sparing if applicable)
  - Residual masses: 40% fibrosis, 40% teratoma, 20% viable malignancy
  - Teratoma/fibrosis on pathology: Observe
  - Viable tumor and tumor markers are elevated or tumor is left behind; consider salvage chemotherapy
- If no response to primary chemotherapy consider second-line chemotherapy (ifosfamide, vinblastine, cisplatin) or bone marrow transplant

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

• Has been divided into good, intermediate, and poor prognosis based on stage and risk factors.

• See Section I “International Germ Cell Cancer Collaborative Group (ICGCCCG)”
- Good: 5-yr survival 94%.
- Intermediate: 5-yr survival 83%
- Poor: 5-yr survival 71%.

COMPLICATIONS

• Surveillance: Risk of recurrence, risk for secondary malignancy due to repeat CT imaging

• RPLND

  - Ejaculatory dysfunction can impair fertility; a nerve-sparing template can preserve antegrade ejaculation in more than 90% of cases.
  - Morbidity (atelectasis, ileus, lymphocele, pancreatitis, chylous ascites); rate 5–25%, late bowel obstruction rate 1–2%, mortality rate < 1%
- Chemotherapy
  - Bleomycin: Pulmonary fibrosis. Need to limit IV fluid hydration and supplemental oxygenation
  - Cisplatin: Nephrotoxicity, ototoxicity, peripheral neuropathy
  - Secondary malignancy, especially leukemias, skin malignancies, and lymphomas
  - Metabolic syndrome
  - Infertility (50% with normal semen 2 yr after chemotherapy, 25% remain azoospermic)

FOLLOW-UP

Patient Monitoring

- Physical exam, tumor markers, and imaging (CXR, abdominal/pelvic CT)
- Frequency of follow-up may be tailored depending on therapy, stage, and disease risk

- Testis, Tumor and Mass, Adult, General

CODES

ICD9

- 186.9 Malignant neoplasm of other and unspecified testis
- 752.51 Undescended testis

- V16.43 Family history of malignant neoplasm of testis

ICD10

- C62.90 Malig neoplasm of unsp testis, unsp descended or undescended
- Q53.9 Undescended testicle, unspecified
- Z80.43 Family history of malignant neoplasm of testis

CLINICAL/SURGICAL PEARLS

- At radical inguinal orchiectomy, tag the residual spermatic cord stump with a long silk suture for identification at future RPLND.
- Lymphatic drainage is predictable unless there is a history of scrotal/inguinal surgery.
- Tumor marker half-lives can be followed to assess if they fall appropriately after treatment (should nadir after 5 half-lives).

TESTIS CANCER, PEDIATRIC, GENERAL CONSIDERATIONS

Mark R. Anderson, MD, MSc
Sherry S. Ross, MD

BASICS

DESCRIPTION

- In contrast to adults, testicular tumors in children are often benign including teratoma, dermoid, and epidermoid cyst.
- The majority of malignant germ cell tumors in children are yolk sac tumors
- Differentiate testicular mass from scrotal wall and paratesticular mass with scrotal US.
- The most common causes of scrotal swelling or mass in pediatrics include hernias (organ protrusion required) and hydrocele (likely communicating in younger children), with lesions such as varicocele (see incidence section), scrotal wall swelling (insect bite or nephrotic syndrome), with testicular neoplasms less common (peak incidence at 2 yr old and adolescence).
- Though very rare, most common malignant paratesticular tumor is rhabdomyosarcoma.

EPIDEMIOLOGY

Incidence

- Testicular tumors (tumor-registry data not presented due to reporting bias toward yolk sac):
  - Total 0.5–2/100,000 males; 2% of
    - Teratoma (well differentiated): ~66%
    - Yolk sac (endodermal sinus) tumor 15%
    - Stromal tumors: ~15%
    - Gonadoblastoma: 1%
    - Lymphoma testicular primary: Rare
    - Epidermoid cysts: <1%

Prevalence

N/A

RISK FACTORS

- Cryptorchidism: Postpubertal germ cell tumors
- Congenital adrenal hyperplasia (CAH): In boys often presents with precocious puberty. Adrenal rests, commonly present along the spermatic cord and in the testicular hilum, may hypertrophy in patients with CAH, leading to testicular nodules that are clinically indistinguishable from testicular tumors.
- Kleinfelters syndrome
- Family history of testicular cancer
- More common in white men than black men

Genetics

- Gonadoblastoma is associated with gonadal dysgenesis and a 45XO/46XY karyotype.
- Yolk sac tumors: Abnormalities: 1p, 6q, 3p

- Large-cell calcifying Leydig tumor is associated with Peutz–Jeghers syndrome and Carney complex.
- No clear genetic etiology exists for teratoma, Leydig cell tumor, and granulosa cell tumor.

PATHOPHYSIOLOGY

- Non–germ cell and germ cell tumors originate from the celomic epithelium and primordial germ cells, respectively
- Totipotent germ cells can evolve into seminoma or embryonal carcinoma
- Embryonal carcinoma is capable of differentiating into embryonic structures, such as mature (peds) or immature (adults) teratomas and extraembryonic structures such as yolk sac and choriocarcinoma tumors.
- Seminoma (dysgerminoma) is a primitive germ cell neoplasm that cannot further differentiate (unusual in childhood, except with gonadal dysgenesis).
- Teratoma: Monodermal (epidermoid cyst) or multiple histologic types present (nerve, cartilage, intestinal epithelium, etc.). Benign and no prepubertal metastasis
- Yolk sac tumors characterized by Schiller–Duval bodies (glomerulus in appearance, contain AFP)
- Leydig tumors which can secrete testosterone are malignant 10% of time. (Reinke crystals—40%, increased mitotic figures absent in peds), Sertoli (10% malignant) can secrete estrogen or testosterone, and granulosa cells (75% diagnosed within 1 mo of birth) have a common embryologic origin from a mesenchymal stem cell
- Gonadoblastomas are small benign tumors found in patients with gonadal dysgenesis, including those who have at least a portion of the Y chromosome. Although benign have high risk of malignant transformation.
- 15–20% of all RMS arise from the genitourinary system.
  - Most common genitourinary sites are the prostate, bladder, and paratesticular (vagina and uterus are relatively unusual sites).
  - Survival rates vary with site (vagina and paratesticular have a better prognosis than bladder/prostate primaries).
- 2 main histologic types of RMS
  - Embryonal RMS is the most common subtype of RMS and accounts for most of the genitourinary tumors.
  - Alveolar RMS occurs more commonly in the trunk and extremities than in GU; worse prognosis than embryonal tumors
- Epididymitis usually not infectious in pediatrics; likely due to refluxing fluid from urethra. Obtain urinalysis and culture. If infected need renal ultrasound to rule out ectopic ureter.
- Varicocele pathogenesis not known. Body habitus (tall, thin), genetics (risk increased if brother or 1st-degree relative has varicocele), or intrinsic venous anomalies (“nutcracker” by SMA, left renal vein insertion), and rarely central outflow obstruction from tumor.
- In neonates and young children “hernia” will be used to describe a communicating hydrocele with a “hernia sac” present though no organ protrusion present: Patent process vaginalis

ASSOCIATED CONDITIONS

- Hernia: Prematurity
- Testicular tumor: Undescended testicle (UDT), gonadal dysgenesis, precocious puberty in

non–germ cell tumors (NGCT).
- Hernia: 1–5% newborns, 3-fold increase in preterm infants, 15% bilateral, clinical synchronous hydrocele 20% ; asymptomatic patent process vaginalis present ~66% of time.
- Varicoceles: ~0% <10 yr old, increasing to 15% through puberty into adulthood
- Paratesticular tumors: Very rare, bimodal—mo & adolescence
- Epididymitis: Less common than adults

GENERAL PREVENTION
- Unclear if orchidopexy reduces risk in undescended testicles
- USPSTF: Against routine screening for testicular cancer in asymptomatic adolescent and adults including routine testicular self-exams.
- American Cancer Society suggests that men with family history do monthly self-exams.
- American Urological Association (AUA): Monthly self-exams for all young men.

DIAGNOSIS

HISTORY
- Painless testicular mass (testicular tumor)
- Acute onset of pain (torsion, epididymitis)
- Symptoms of precocious puberty (non–germ cell testicular tumors)
- Subacute achy pain (varicocele)
- Past history of UDT
- Flank pain from kidney obstruction secondary to enlarged retroperitoneal nodes

PHYSICAL EXAM
- Systematic exam identifying intrascrotal structures (testicular mass vs. intrascrotal mass)
- Testicle should be smooth and firm and within 20% size of contralateral testicle (use orchiometer or ultrasound measurements)
- Epididymis: Posterolateral adjacent to testicle
- Hydrocele transilluminates (communicating if fluid manipulated back into abdomen)
- Solid masses do not transilluminate
- Varicoceles (“bag of worms”)
  – If does not diminish when supine/under manual pressure may be due to tumor
- Lymph nodes: Lymphoma or metastasis
- Breast exam, signs of virilization (consider adrenal tumor) for NGCT tumors

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Order tumor markers immediately, but *post* orchiectomy markers determine staging
- AFP: Elevated postnatal up to 8 mo; AFP >1,000 ng/mL almost always due to yolk sac tumor (vs. teratoma) at any prepubertal age; only 15% of yolk sac tumors have AFP <100 ng/mL under age of 5.
  – AFP <100 ng/mL and >5 yo suspect teratoma
  – AFP never elevated in pure seminoma, choriocarcinoma, or teratoma
- β-HCG always elevated with choriocarcinoma (rarely pediatric), <10% of pure seminomas, and never elevated in pure teratoma
  – Rarely falsely elevated (increases with marijuana use or LH cross-reactivity)

- Embryonal and yolk sac: May secrete both AFP/HCG
- Half lives: HCG ~24 hr, AFP ~5–7 days, LDH ~4–5 days
- Testosterone/estrogen levels for NGCT
- LDH: Elevated if large tumor burden

Imaging
- Scrotal ultrasound very helpful (use color Doppler) for any scrotal or testicular concern
- No reliable sonographic features that can distinguish benign from malignant testis tumors
- Anechoic cysts trend toward benign
- Epidermoid cyst "onion skin" appearance
- Paratesticular RMS appears large, hypervascular and ipsilateral testicle may not be visualized
- Testicular microlithiasis not associated with increased risk of cancer
- Indeterminate lesions on US that resemble testicular neoplasm include tubular ectasia of the rete testis, inflammation, infarction, fibrosis, and traumatic hematoma.
- CT scan of abdomen and chest can be done before or after orchiectomy but reactive lymph nodes may appear postoperatively

Diagnostic Procedures/Surgery
Biopsy not indicated. The diagnostic procedure of choice is the radical orchiectomy.

Pathologic Findings
See Section I and II "Individual Tumor Types"

DIFFERENTIAL DIAGNOSIS
- Painful scrotum:
  - Torsion (testicle, testicular, or epididymal appendages); more common after puberty
  - Epididymitis/orchitis; bacterial, mumps
  - Fournier gangrene
  - Henoch–Schönlein purpura (usually no mass)
  - Incarcerated/strangulated hernia
  - Testis trauma: Contusion, rupture; hematocele
  - Tumor (pain infrequent unless traumatized or rapidly growing; see below)
- Painless mass:
  - Adenomatoid tumor of testis or epididymis
  - Adrenal rest tumors
  - Cystic dysplasia of the testis
  - Chylocele: Usually associated with filariasis
  - Fibrous pseudotumor of the tunica albuginea
  - Hydrocele, primary or due to trauma, torsion, tumor, epididymitis; hydrocele of cord
  - Hernia; lipoma of the cord
  - Polyorchidism
  - Paratesticular rhabdomyosarcoma (bimodal age 3–4 and teens)
  - Scrotal edema (insect bite, nephrotic syndrome, acute idiopathic scrotal edema)
  - Spermatocele (epididymal cyst): Uncommon
  - Testicular cysts
  - Testicular tumor: Germ cell tumors: Yolk sac carcinoma, teratoma, seminoma, embryonal

cell carcinoma, choriocarcinoma; Gonadal stromal tumors: Leydig, Sertoli cell, granulosa cell.
- Metastatic tumors: Unusual in childhood
- Mixed germ cell and stromal tumor (gonadoblastoma)
- Hamartoma, carcinoid, and neurofibroma
- Testis tumor of adrenogenital syndrome
- Leukemia or lymphoma
- Varicocele: Fullness and not a firm mass; changes with position

TREATMENT

GENERAL MEASURES

- If concern for tumor obtain tumor markers pre- and postoperatively (1–4 wk)
- Discuss sperm banking, especially if chemotherapy needed
- Do not make incision through scrotum (inguinal incision only)
- Use long tag nonabsorbable suture when ligating cord to help with lymph node dissection in future if necessary
- Open inguinal fascia so cord ligated as cephalad as possible
- International Germ Cell Cancer Collaborative Group (IGCCCG) staging:
  - Stage 1: Limited to testis, markers normalize in the half-life. Normal markers at diagnosis require normal imaging and a negative ipsilateral retroperitoneal node dissection.
  - Stage 2: Microscopic residual disease is present in the scrotum or high in spermatic cord (<5 cm from proximal end). Markers elevated after appropriate half-life interval. Tumor rupture or scrotal biopsy prior to complete orchiectomy.
  - Stage 3: Retroperitoneal lymph node involvement. Nodes >4 cm by CT are considered metastases. Nodes 2–4 cm need biopsy to document nodal metastases.
  - Stage 4: Distant metastases

MEDICATION

First Line

- Chemotherapy for all yolk sac tumor stage II or greater or other germ cell tumor
- Platinum-based as for other nonseminomas (cisplatin, etoposide, and bleomycin); see Section I: "Testis, Cancer General"
- Rhabdomyosarcoma: Adriamycin and dactinomycin chemotherapy

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Testis preservation with benign lesions most common in children as opposed to adults.
- Prepubertal testicular teratomas, Leydig and Sertoli cell tumors are benign; orchiectomy or testicular-sparing surgery is curative and no additional therapy is indicated in benign lesions.
- Yolk sac tumor or other malignant tumor; radical orchiectomy and observation if low stage
- Retroperitoneal lymph node dissection (RPLND):
  - Postchemotherapy with residual mass.

– Rarely indicated: 90% of yolk sac tumors are stage 1 at presentation.
– 60–80% of paratesticular RMS are stage I at diagnosis. Patients >10 yr have a higher risk for retroperitoneal relapse and should undergo ipsilateral RPLND before chemo.

ADDITIONAL TREATMENT

Radiation Therapy

Used in rhabdomyosarcoma

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Prepubertal teratoma is uniformly benign
- 90% of yolk sac tumors are stage I at presentation;85% 6-yr survival in stage 4 patients
- Paratesticular RMS: Variable survival rates; modern surgical technique, and chemotherapy 90% overall survival in most patients.

COMPLICATIONS

- Chemotherapy toxicity
- Iatrogenic secondary cancers
- Infertility
- RPLND: Retrograde ejaculation, lymphocele

FOLLOW-UP

Patient Monitoring

Testicular and paratesticular cancer varies. Refer to NCCN guidelines@www.nccn.org

ADDITIONAL READING

N/A

CODES

ICD9

- 186.9 Malignant neoplasm of other and unspecified testis
- 608.89 Other specified disorders of male genital organs

- 171.6 Malignant neoplasm of connective and other soft tissue of pelvis

ICD10

- C62.90 Malig neoplasm of unsp testis, unsp descended or undescended
- N50.8 Other specified disorders of male genital organs
- C49.6 Malignant neoplasm of conn and soft tissue of trunk, unsp

CLINICAL/SURGICAL PEARLS

- The presence or absence of pain or tenderness alone cannot reliably rule in or out benign vs. malignant processes in the scrotum.
- Acute onset of testicular pain in a child is most likely torsion, and emergent evaluation is indicated, early surgical intervention; do not delay surgery for imaging.
- Painless testicular mass is highly suspicious for tumor and should be confirmed with imaging.

TESTIS CANCER, SEMINOMA

Robert B. Den, MD
Mark Hurwitz, MD

BASICS

DESCRIPTION

- Seminoma is a GCT (germ cell tumor) of the testicle composed of cells that are considered the malignant counterpart of gonocytes
- These tumors are generally very sensitive to both chemotherapy and radiation therapy.
- GCTs account for 95% of testicular cancer and are broadly classified as seminoma or NSGCT.
  - Seminoma accounts for 50% of GCTs
  - Represents 20% of mixed GCTs (combinations of seminomatous and NSGCT)
- Histologic subtypes:
  - Classic seminoma (peak age 35–39)
  - Spermatocytic seminoma typically found in men >50–60
  - Anaplastic seminoma is no longer recognized as distinct entity.

EPIDEMIOLOGY

Incidence

- Peak incidence among men aged 20–40
- 4–5 times more common among white than African American men.
- Patients who have had 1 seminoma are at an increased risk of developing a contralateral seminoma.

Prevalence

N/A

RISK FACTORS

- Cryptorchidism; 3–14 times the normal incidence
- HIV infection
- Gonadal dysgenesis with Y chromosome
- Testicular feminization >30 yr of age

Genetics

- Genetic changes in the form of amplifications and deletions are observed mainly in the 12p11.2–p12.1 chromosomal regions (1).
- A gain of 12p sequences is associated with invasive growth of both seminomas and NSGCTs.
- In contrast, spermatocytic seminoma shows a gain of chromosome 9, whereas most infantile yolk sac tumors and teratomas show no chromosomal changes.
- p53 mutations are also seen with seminoma.

PATHOPHYSIOLOGY

- The slow growth characteristics of most seminomas result in them most commonly being diagnosed at an early stage (≥85% stage I) (2).

- Right-sided tumors tend to spread in the following sequence: Interaortocaval nodes, precaval zone, and para-aortic nodes.
- Left-sided tumors spread in the following order: The para-aortic, preaortic, and renal hilar nodes. Interaortocaval nodes are involved with typically higher-stage disease.
- Rarely presents as an extragonadal GCT in a site remote from the testicle.
- Hematogenous dissemination is much less common than in NSGCT.
- β-hCG elevation can sometimes be seen in seminoma.
- The presence of elevated AFP during evaluation usually suggests nonseminomatous elements
- Due to slower growth pattern, relapses tend to be later than with NSGCT, and many can occur 2–3 yr after therapy.

ASSOCIATED CONDITIONS
Increased risk in patients with cryptorchidism; risk is >35 times the general population

GENERAL PREVENTION
Unclear if orchidopexy reduces risk in undescended testicles

DIAGNOSIS
HISTORY
- Painless mass or swelling in the testes
- History of undescended testicle or inguinal surgical procedure as a child

PHYSICAL EXAM
- Palpate the testes bilaterally.
- Transilluminate the mass.
- Examine the groin for evidence of surgical scar (prior orchiopexy).
- Inspect for lymphedema of the groin or lower extremities.
- Lymphatic spread is not typically inguinal; however, prior scrotal surgery may change lymphatic drainage.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CBC and chemistry
- β-hCG and AFP to rule out NSGCT:
  – Seminoma never have elevated AFP.
  – 10–20% may have elevated β-hCG.
- Placental alkaline phosphatase: Pulmonary and renal function tests for patients who may receive chemotherapy

Imaging (3)
- Scrotal US: Often diagnostic, characterizes solid vs. cystic lesions, flow
- Chest x-ray: To rule out metastatic lesions
- CT of chest, abdomen, and pelvis to evaluate for lymphatic spread:
  – Studies suggest that in seminoma patients treated for retroperitoneal adenopathy, up to 50% will resolve on subsequent imaging.
  – Bipedal lymphangiography was once the standard of care to identify retroperitoneal nodes to direct radiation planning. It is no longer routinely used.

- PET: Limited role in patients with postchemotherapy residual masses to determine the presence of viable tumor.

Diagnostic Procedures/Surgery

Biopsy not indicated. The diagnostic procedure of choice is the radical orchiectomy.

Pathologic Findings

- Classic seminoma (most common):
  - Large cells or uniform size with clear cytoplasm and distinct cell borders
  - Stains positive for PLAP
- Spermatocytic seminoma (up to 4%):
  - Cells of varying size that resemble maturing spermatogonia (peak age >50)
  - Does not stain for PLAP
- Anaplastic seminoma is no longer considered a distinct subtype of seminoma:
  - Same histology as classic seminoma, with high mitotic activity and unchanged prognosis using current treatment standards
  - Histologically, must differentiate from lymphoma and embryonal carcinoma

DIFFERENTIAL DIAGNOSIS

- Adult/pediatric painful mass:
  - Epididymitis/orchitis; bacterial, STD, mumps, TB
  - Incarcerated/strangulated hernia
  - Testicular trauma: Usually blunt; contusion, rupture; usually associated hematocele
  - Torsion (testicle, testicular, or epididymal appendage)
  - Tumor (pain infrequent unless traumatized or rapidly growing; see below)
- Adult painless mass:
  - Adenomatoid tumor of testis or epididymis
  - Adrenal rest tumors
  - Adenocarcinoma of the rete testis
  - Chylocele: Usually associated with filariasis
  - Fibrous pseudotumor of the tunica albuginea
  - Hydrocele, primary or due to trauma, torsion, tumor, epididymitis; hydrocele of the cord
  - Lipoma of the cord
  - Mesothelioma of tunica vaginalis
  - Polyorchidism
  - Paratesticular sarcomas: Rhabdomyosarcoma, fibrosarcoma, leiomyosarcoma, liposarcoma
  - Scrotal edema (insect bite, nephrotic syndrome, acute idiopathic scrotal edema)
  - Scrotal wall: Sebaceous and inclusion cysts, idiopathic calcinosis, fat necrosis, malignancy
  - Sperm granuloma following vasectomy
  - Spermatocele (epididymal cyst)
  - Testicular cysts (simple, tunica albuginea, epidermoid)
  - Testicular tumor:
    - GCTs (95% of testicular malignancies): Seminoma, embryonal cell carcinoma, choriocarcinoma, yolk sac carcinoma teratoma (1–5%), teratocarcinoma
    - Gonadal stromal tumors: Leydig tumor, Sertoli cell, granulosa cell tumors
    - Metastatic tumors: Prostate, lung, and GI tract; rare kidney, malignant melanoma,

pancreas, bladder, and thyroid.
    - Mixed germ cell and stromal tumor (gonadoblastoma)
    - Angioma, fibroma, leiomyoma, hamartoma, carcinoid, mesothelioma, and neurofibroma
    - Malignant fibrous histiocytoma (most common soft tissue sarcoma in late adult life)
    - Leukemia or lymphoma
  - Varicocele
- Pediatric painless mass:
  - Similar to adult list; most/more common are: Hydrocele, hernia, varicocele, testicular teratoma, adrenal rest tumors, rhabdomyosarcoma, endodermal sinus tumor

TREATMENT

GENERAL-MEASURES (4)

- Discuss sperm banking
- Stage IA,B: Radical orchiectomy and adjuvant RT in low stage most common treatment:
  - Close surveillance with CT scanning in lieu of RT for low-stage seminoma is gaining acceptance.
  - Single-agent chemotherapy (carboplatin)
- Stage IS: RT as adjuvant therapy
- Stage II: Radical orchiectomy and adjuvant therapy:
  - Nonbulky retroperitoneal nodes: RT 35 Gy or chemotherapy
  - Bulky lymphadenopathy (>5–7 cm nodes) or higher visceral metastasis (retroperitoneal adenopathy) and is treated with standard platinum-based chemotherapy (BEP = bleomycin/etoposide/cisplatinum or EP = etopiside/cisplatinum).

MEDICATION

First Line

- Regardless of histology, patients with advanced germ cell tumors (cIIB–cIII) and those with persistently elevated tumor markers following radical orchiectomy (cIS), are initially treated with platinum-based chemotherapy according to the IGCCCG risk stratification.
  - Patients with good-risk disease are treated with 3 cycles of bleomycin, etoposide, and cisplatin (BEP) or 4 cycles of etoposide and cisplatin (EP). While patients with intermediate-risk or high-risk disease receive 4 cycles of BEP, ~30–40% of patients with poor-risk disease fail to achieve a durable response to conventional chemotherapy.

Second Line

High-dose chemotherapy or clinical trial

SURGERY/OTHER PROCEDURES

- Radical inguinal orchiectomy
- RPLND is not usually for seminoma.

ADDITIONAL TREATMENT

Radiation Therapy

- Stage I:
  - Standard RT is para-aortic field to 20–25 Gy following surgery
  - If prior ipsilateral pelvic surgery, treat para-aortic and ipsilateral iliac lymph nodes.

- Shield contralateral testis
- Stage II:
  - Subdiaphragmatic radiation to 35 Gy to the para-aortic and ipsilateral iliac lymph nodes following radical orchiectomy (hockey stick template).
- Prophylactic mediastinal RT has generally been abandoned due to side-effect profile (cardiovascular) and failure to significantly improve outcomes. It also interferes with ability to administer salvage chemotherapy.

Additional Therapies

- Active surveillance for low-risk, early disease:
  - Avoids unnecessary treatment and related side effects
  - CT every 4–6 mo; reduce interval after ~5 yr
  - Traditional risk factors that increase the recurrence risk: Tumor >4 cm, invasion of the rete testis, anaplastic features, small vessel invasion
- The role of salvage chemotherapy, surgical removal, or RT of persistent masses detected by CT continues to be controversial.

Complementary & Alternative Therapies

Patients should consider sperm banking prior to treatment to aid in avoiding risk of infertility.

ONGOING CARE

PROGNOSIS

- Elevation of LDH, hCG, or both and number of metastatic sites are the most important prognostic factors in patients with GCTs
- ~75% have localized disease (stage I) at diagnosis. ~15% have metastatic disease to the regional lymph nodes, and 5–10% have involvement of regional nodes or visceral metastases.
- All stages have at least a 90% cure rate:
  - Stage I: 98–100%
  - Stage II (B1/B2 nonbulky): 98–100%
  - Stage II (B3 bulky) and stage III: >90% complete response to chemotherapy and 86% durable response rate to chemotherapy
- Response rates to chemotherapy seem to be slightly better without prior radiation.

COMPLICATIONS

- Infertility, GI complications, and possible induction of secondary malignancies are a concern following adjuvant RT.
- Involvement of retroperitoneal lymph nodes may produce backache.

FOLLOW-UP

Patient Monitoring

- Surveillance:
  - H&P, AFP, β-hCG, LDH:
    - Every 3–4 mo for years 1–2
    - Every 6–12 mo for years 3–4, then annually

  - Abdominal/pelvic CT every 6 mo for yr 1–2, every 6–12 mo for yr 3, then annually for yr 4–5
  - CXR as clinically indicated for yr 1–5
- Carboplatin:
  - H&P, AFP, β-hCG, LDH:
    - Every 3 mo for yr 1
    - Every 4 mo for yr 2
    - Every 6 mo for yr 3, then annually
  - Abdominal/pelvic CT annually for yr 1–3
  - CXR as clinically indicated
- RT:
  - H&P, AFP, β-hCG, LDH:
    - Every 4 mo for yr 1–2, then annually
    - Abdominal/pelvic CT annually for yr 1–3 (for patients post only para-aortic RT)
  - CXR as clinically indicated

CLINICAL/SURGICAL PEARLS

Anaplastic seminoma is no longer recognized as distinct entity.

TESTIS, LEYDIG CELL TUMOR

Austin R. Younger, MD
James S. Rosoff, MD

BASICS

DESCRIPTION

- Leydig cell tumors (LCTs) are hormonally active steroid secreting tumors that may produce feminizing/virilizing syndromes
- Most common sex cord/stromal tumors
  - (Neoplasms containing Leydig, Sertoli, granulosa, or thecal cells) commonly referred to as nongerm cell tumors
- Usually benign, 10% malignant variants reported in adults only (1)
- TNM staging follows current NCCN Guidelines for Testis Cancer

EPIDEMIOLOGY (1)

Incidence

- An estimated 8,820 new cases of testicular cancer were diagnosed in 2014
- LCTs represent 1–3% of all testicular neoplasms (90% of nongerm cell tumors)
- Bimodal distribution with peak incidences occurring between ages 4–5 and 30–60
- Equal incidence between right and left testis with 4–10% occurring bilaterally

Prevalence

Roughly 25% of cases of LCT occur in the pediatric population

RISK FACTORS

- No association with cryptorchidism
- Increased prevalence in Caucasians

Genetics

- No documented familial inheritance pattern or associated syndromes
- Association with specific activating mutation of luteinizing hormone receptor (LHR) gene (2)
  - LHR is a stimulatory G-protein–coupled receptor present on surface of Leydig cell
- Hypothesized that oncogenesis is increased by (1) hyperstimulation of LHR and (2) Long-term estrogen exposure from aromatase conversion (seen in animal studies only)

PATHOPHYSIOLOGY

- Leydig cells are located in the interstitium of testicle between seminiferous tubules; produce testosterone in response to stimulation by luteinizing hormone
  - Hypothalamic–pituitary axis is directly involved in Leydig cell stimulation and testosterone production
    - Vital role in development of male secondary sex characteristics and spermatogenesis
    - In neoplasia, feedback regulation is disrupted resulting in uncontrolled hormone production.
- LCTs usually secrete testosterone, may also secrete other androgens, corticosteroid, estrogen,

and progesterone.
- Feminization may result directly from estradiol producing tumors or from peripheral conversion of testosterone to estrogens by aromatase
- Virilization occurs due to unopposed testosterone/androgen production independent of LH stimulation.

ALERT
- Virilizing signs are often not observed in adults.
- More frequently present with feminizing signs due to peripheral conversion of testosterone to estrogens.

ASSOCIATED CONDITIONS
- Adrenogenital syndromes—adrenal rest tumors are often misdiagnosed as LCTs.
  - 80% of these are bilateral whereas only 4–10% of LCT are bilateral (1)
  - Hyperplastic nodules will resolve with appropriate steroid replacement
- LCTs are not associated with cryptorchidism

GENERAL PREVENTION
- Routine self-exam in adult population
- Regular pediatric office visit during childhood development to identify any deviation in normal growth and maturation

DIAGNOSIS
- Low estradiol, increased testosterone, gynecomastia, and hypoechoic lesion on ultrasound are highly suspicious for LCT
- Histopathology confirms diagnosis

HISTORY
- Children commonly present with:
  - Precocious puberty due to androgen secreting tumors; irreversible and profound physical changes—early diagnosis is critical
  - Feminization from estrogen-secreting tumors
- Adults commonly present with:
  - Nontender testicular mass/nodule
  - Incidental finding on imaging for other conditions
  - Feminization symptoms—low energy, anhedonia, gynecomastia, infertility

PHYSICAL EXAM
- A unilateral mass is palpable in 90% of cases with careful exam
- Hormonal imbalance responsible for physical changes
  - Virilizing changes
    - Children: Precocious puberty, early growth, early change in penile length, deepened voice, increased muscle mass
    - Adults: Usually asymptomatic
  - Feminizing change
    - Children: Delayed maturation, testicular atrophy, gynecomastia
    - Adults: Female hair distribution, gynecomastia, testicular atrophy

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Increased testosterone (with normal LH and FSH) is most common positive lab finding. With feminization syndrome, serum estradiol may be elevated
  - All other tests should be within normal limits if leaning toward diagnosis of pure LCT
- Testicular mass work-up (AFP, β-hCG, LDH, testosterone, basic chemistry panel)
- Precocious puberty work-up (LH, FSH, testosterone, serum cortisol, urinary ketosteroids, 17-OH progesterone, ACTH stimulation test, dexamethasone suppression)
  - Rule out:
    - Pituitary lesions—increased LH and FSH
    - Leydig cell hyperplasia—normal urinary ketosteroids, histopathology
    - Congenital adrenal hyperplasia (CAH): Elevated 17-OH progesterone, elevated urinary ketosteroids

Imaging

- CXR
- Testicular ultrasound—preferred imaging if mass is palpable (3)
  - Solid hypoechoic mass
- MRI: May detect smaller nonpalpable lesions (4)
- CT chest/abdomen/pelvis: If concern for malignancy, lungs and retroperitoneal nodes are common metastatic sites

Diagnostic Procedures/Surgery

- Historically, radical inguinal orchiectomy was gold standard treatment
- Testis-sparing surgery (TSS): Enucleation of tumor and frozen-section analysis is acceptable option in some cases; no evidence of local recurrence or metastases on long-term follow-up (3,5)

Pathologic Findings

- Gross pathology
  - Benign LCT: 3–5 cm, sharply delineated, solid mass, embedded within testicle, displaces normal stromal/tubular architecture (1)
    - Brown to yellow-white depending on total lipid content
  - Malignant LCT: Larger, >5 cm, infiltrative margins, hemorrhage/necrosis present, replace or spread beyond testicular parenchyma
- Microscopic pathology (1)
  - Tumor cells in nests/sheets, large polygonal cells with eosinophilic/granular cytoplasm, round regular nuclei, rare mitotic figures, prominent nucleoli
  - Reinke crystals: Pathognomonic for LCT, rhomboid/cylindrical crystals, pale staining within cytoplasm and nucleus.
    - Confirms diagnosis but are only present in 40% of tumors
- Findings that correlate with malignancy
  - Cytologic/nuclear atypia, increased mitotic activity 3–5 per 10 hpf, DNA aneuploidy
  - Coagulative tumor necrosis, lymphovascular invasion
  - Extension of the tumor to the spermatic cord, invasion of the capsule
  - Abscence of Reinke's crystals

- Immunohistochemistry (IHC)—beneficial if challenging diagnosis. May stain for inhibin A, calretinin, melan-A (1)

DIFFERENTIAL DIAGNOSIS

- Testicular masses (see Section I: "Testis Cancer, Adult General Considerations" and "Testis Cancer, Pediatric, General Considerations")
- Precocious puberty
  - Adrenocortical syndromes: CAH
  - Large-cell Sertoli cell tumors
  - Leydig cell hyperplasia
  - Pituitary lesions
- Gynecomastia/feminization
  - Pituitary lesions
  - Paraneoplastic syndromes
  - Marijuana use

TREATMENT

GENERAL MEASURES

- Management is primarily surgical
- Radical orchiectomy is the gold standard
- TSS is being performed more frequently with good results (5)
  - Especially applies to cases of bilateral testicular tumors, subfertility, monorchidism, and in children where preservation of testicular function is of high importance
  - There is no evidence for increased risk of local recurrence on long-term follow-up (3)
  - TSS is a safe procedure in patients with LCT < 25 mm (5)
- Malignant disease
  - 3–10% of cases
  - RPLND is indicated if concerned for malignancy based on histopathologic findings or presentation
  - Malignant LCT responds poorly to radiation and chemotherapy
  - Elevated serum estrogen after resection may indicate micrometastatic disease and requires monitoring
  - Median survival: 2–4 yr

MEDICATION

First Line

Chemotherapy regimens using standard bleomycin-etoposide-platinum regimens for germ cell tumors have limited efficacy for malignant Leydig cell tumors

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Radical inguinal orchiectomy:
  - Definitive method of diagnosis and treatment for stages I, II neoplasm
- Enucleation of mass with TSS:

  - Inguinal exploration as for radical orchiectomy with use of intraoperative US and frozen-section confirmation of benign Leydig cell tumor
  - May have a role in children and younger adults to preserve fertility.
- RPLND if suspicion of malignancy by CT criteria

ADDITIONAL TREATMENT

Radiation Therapy

Responds poorly to radiation

Additional Therapies

N/A

Complementary & Alternative Therapies

Patients should consider sperm banking prior to treatment to aid in avoiding risk of infertility.

ONGOING CARE

PROGNOSIS

Benign/local disease in the majority of patients portends a good prognosis

COMPLICATIONS

- Residual gynecomastia
- Physical changes of precocious puberty are permanent

FOLLOW-UP

Patient Monitoring

- Focused physical exam: Remaining testis, regional lymph nodes, abdomen
- Tumor markers, serum testosterone, estradiol
- CBC, electrolytes, and endocrine markers
- CT imaging of the chest and abdomen may be indicated
- RPLND patients should be evaluated every 3 mo for 2 yr, then every 6 mo for 3 yr, then yearly.

ICD9

- 186.9 Malignant neoplasm of other and unspecified testis
- 222.0 Benign neoplasm of testis
- 259.51 Androgen insensitivity syndrome

ICD10

- C62.90 Malig neoplasm of unsp testis, unsp descended or undescended
- D29.20 Benign neoplasm of unspecified testis
- E34.50 Androgen insensitivity syndrome, unspecified

CLINICAL/SURGICAL PEARLS

- Leydig cell tumors (LCT's) are hormonally active steroid-secreting tumors that may produce feminizing/virilizing syndromes.
- LCTs are usually benign, 10% malignant variants reported in adults only.
- Low estradiol, increased testosterone, gynecomastia, and hypoechoic lesion on ultrasound are highly suspicious for LCT.
- Scrotal exploration with frozen section is reliable in diagnosing LCT.
- Testicular sparing surgery (TSS) is a reasonable option in certain cases and has no reported increased risk of local recurrence or metastasis compared with radical orchiectomy.

TESTIS, PAIN (ORCHALGIA)

Alosh Madala, MD
Dmitriy Nikolavsky, MD

BASICS

DESCRIPTION

- Orchalgia is scrotal or testicular pain
  - Acute or chronic
  - Intermittent or constant
  - Unilateral, bilateral, or alternating
- Characteristics:
  - Localized to scrotum
  - May radiate to groin, perineum, back, or legs
  - Chronic orchalgia
    - Lasting >3 mo
    - Constant or intermittent pain.
    - No specific cause is identified in most cases.
  - Synonym(s) for chronic testicular pain: Orchalgia; idiopathic testicular pain; orchiodynia; chronic scrotal pain syndrome

EPIDEMIOLOGY

Incidence

- Majority in mid to late 30s
- Increased in men with psychological issues

Prevalence

- Chronic testicular pain
  - Idiopathic 25–50%
  - Postvasectomy chronic orchalgia
    - ~15%

RISK FACTORS

- Organic risk factors
  - Previous trauma or surgery
    - Post-vasectomy pain syndrome in 5–43% of men who have undergone this procedure (1)
    - Posthernia repair
  - Scrotal masses
    - Testicular tumors
    - Varicocele
    - Hydrocele
    - Epididymal cysts or spermatoceles
  - Infections
    - Chronic epididymitis
  - Neuropathic conditions

    - Diabetic neuropathy
    - Withdrawal from imipramine
- Psychological risk factors
  – Life stressors
  – Depression
  – Secondary gain with malingering

Genetics

No studies exist at this time

PATHOPHYSIOLOGY

- Poorly understood
- Idiopathic in most cases
- Testis innervation
  – Sympathetic nerve supply from T10–T12 segments
  – Accompany the internal spermatic vessels
  – Penetrate the tunica albuginea
  – Distributed between the seminiferous tubules
  – Stimulates smooth muscles of the tunica albuginea
  – Testis shares innervations with the epididymis
- Epididymis and vas deferens innervation
  – Sympathetic fibers from T10–L1.
  – Supply smooth muscles of vas deferens and epididymis.

ASSOCIATED CONDITIONS

- Often idiopathic (~25%)
- Can be associated with:
  – Previous surgery (vasectomy, hernia repair)
  – Trauma
  – Intermittent torsion
  – Hydrocele, varicocele, spermatocele
  – Tumor
  – Infection
  – Herniated intervertebral disc
  – Vasculitis (polyarteritis nodosa)

GENERAL PREVENTION

- USPSTF: Against routine screening for testicular cancer in asymptomatic adolescent and adults including routine testicular self-exams.
- American Cancer Society suggests that men with family history do monthly self-exams.
- American Urological Association (AUA): Monthly self-exams for all young men.

ALERT

Acute onset of testicular pain in a child is most likely torsion, and emergent evaluation is indicated, early surgical intervention; do not delay surgery for imaging.

DIAGNOSIS

HISTORY

- Onset, location, duration, quality, aggravating (exercise, sexual intercourse, or ejaculation) and relieving factors.
- Visual analogue scale (VAS) of 0–10 helps quantify degree of pain
- Consult with multiple physicians including urologists
- Multiple treatments (antibiotics, anti-inflammatory drugs)
  - Little or no relief
- Previous surgery
  - Scrotal/inguinal
  - Vasectomy
  - Retroperitoneal/pelvic
- Social/psychological history
  - Current life stressors
  - Social support
  - Sexual function
  - Mood and anxiety
  - Sexual abuse, relationship stress
- Back injuries or spinal trauma

PHYSICAL EXAM

- Often does not reveal abnormality
- Evaluate genitalia for reversible causes
  - Testicular torsion
  - Scrotal mass
  - Hernia
  - Infection
  - Varicocele
  - Spermatocele
- Sperm granuloma following vasectomy
- Digital rectal exam
  - Evaluate prostate and rectum.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine analysis and culture
  - Before and after prostatic massage
- Semen analysis (for chronic epididymitis)
- Consider STD/STI screening

Imaging

- Scrotal US exam with color flow doppler
  - Evaluate scrotal contents
  - Rule out testicular torsion and tumor

Diagnostic Procedures/Surgery

Cystoscopy and urodynamics are of limited value

Pathologic Findings
Based on etiology

DIFFERENTIAL DIAGNOSIS (2)
- Chronic pelvic pain syndrome (CPPS)
- Cremasteric spasm
- Hydrocele, spermatocele
- Idiopathic orchalgia
- Infection
  - Epididymitis and epididymo-orchitis
  - Urethritis
  - Prostatitis
  - Viral orchitis
  - Testicular abscess
- Inguinal hernia (incarcerated, other)
- Nerve entrapment (ilioinguinal or genitofemoral)
- Medical causes: Diabetic neuropathy, polyarteritis nodosa
- Paratesticular tumor
- Postoperative (vasectomy, inguinal herniorrhaphy)
- Psychogenic
- Referred pain (nerve root irritation)
  - Disk herniation, back injury, other
- Testicular torsion
- Testicular/scrotal trauma
- Testicular tumor
- Testicular vasocongestion from sexual arousal without ejaculation
- Torsion of testicular/epididymal appendices
- Varicocele

TREATMENT

GENERAL MEASURES
- For acute testicular pain: See Section I “Acute Scrotum”
- For chronic testicular pain
  - Scrotal support
  - Restrict physical activity
  - Sitz baths

MEDICATION
First Line
- NSAIDs
  - Variable and usually temporary relief
  - Regimens described include ibuprofen 400–600 mg PO q6h for 1 mo
- Antibiotics
  - Usually empiric unless specific agent such as STD/STI (chlamydia, etc.) identified
  - Often prescribed, rarely beneficial

- Common regimens
  - Doxycycline 100 mg PO BID or ciprofloxin 250–500 mg PO BID for 2–3 wk

Second-Line (5,6)

- Antidepressants and anticonvulsants
  - Demonstrated benefit in chronic idiopathic orchalgia
  - Poor response to postvasectomy pain
- Tricyclic antidepressants
  - Amitriptyline 10–25 mg qhs
  - Nortriptyline 10–150 mg daily
- Anticonvulsants
  - Gabapentin 300 mg titrated up to 3,600 mg/d daily
- α-Adrenergic antagonists
  - Tamsulosin; no proven benefit

SURGERY/OTHER PROCEDURES

- Acute testicular pain in a child: See Section I "Torsion, Testis or Testicular/Epididymal Appendages".
- The following are used for the management of chronic pain in an adult.
- Minimally invasive treatment options (7,8)
  - Enucleation of cystic lesions
  - Local anesthetic infiltration
    - Spermatic cord
    - Pelvic plexus under TRUS guidance
- Denervation of spermatic cord (3,9)
  - Division of ilioinguinal nerve and its branches
  - Microscopic or laparoscopic or robotic
  - Best outcome is initial response to spermatic cord block with local anesthetic
- Orchiectomy
  - Last resort: Many will continue to have pain
  - Inguinal approach superior to scrotal
  - >75% patients have relief after surgical removal of varicocele, hydrocele, spermatocele, or intermittent torsion.
- Epididymectomy
  - Poor results except in the setting of postvasectomy pain syndrome
- Vasovasostomy in the setting of postvasectomy pain

ADDITIONAL TREATMENT

- Physical therapy
  - May be helpful in patients with spinal disk and back problems with nerve root irritation

Radiation Therapy

N/A

Additional Therapies (10,11)

- Pulsed radiofrequency denervation of the spermatic cord (4)
  - Not well studied

- Sacral nerve stimulation
  - 80% decrease in pain

Complementary & Alternative Therapies

- Mental health consult
  - Psychological evaluation
  - Psychotherapy
  - Should be strongly considered before surgical intervention
- Pelvic muscle exercises

ONGOING CARE

PROGNOSIS

Depends on etiology

COMPLICATIONS

- Surgery
  - Epididymectomy may result in loss of testicle or infertility

FOLLOW-UP

Patient Monitoring

Periodic follow-up with urology or other providers depending on etiology (if known)

Patient Resources

Urology Care Foundation: Epididymitis and Orchitis.
http://www.urologyhealth.org/urology/index.cfm?article=114&display=1

CODES

ICD9

- 307.89 Other pain disorders related to psychological factors
- 608.89 Other specified disorders of male genital organs
- 959.14 Other injury of external genitals

ICD10

- F45.41 Pain disorder exclusively related to psychological factors
- N50.8 Other specified disorders of male genital organs
- S39.94XA Unspecified injury of external genitals, initial encounter

CLINICAL/SURGICAL PEARLS

- The presence or absence of pain or tenderness alone cannot reliably rule in or out benign vs. malignant processes in the scrotum or testis.
- Physical exam is often normal with testicular pain.
- Ultrasound is the most valuable study.
- Surgical options should only be considered after medical and conservative management fails for chronic testicular pain.

TESTIS, SERTOLI CELL TUMOR

Tariq A. Khemees, MD
Ahmad Shabsigh, MD, FACS

BASICS

DESCRIPTION

- Sertoli cell tumor is a rare sex cord stromal tumor; 90% are benign
  - No reliable criteria for malignancy
  - Presence of metastasis indicate malignancy
- 3 different subtypes has been described with distinctive clinical, histologic, and prognostic characteristics:
  - Classic "tumors that are not otherwise specified"
  - Large-cell calcifying Sertoli cell tumor (LCCSCT)
  - Sclerosing

EPIDEMIOLOGY

Incidence

- Comprise <1% of testicular neoplasms
- Majority are sporadic
- Classic and sclerosing subtypes are mainly reported in young adult with rare occurrence in prepubertal boys
- LCCST has bimodal age incidence:
  - Early onset: Prepubertal
  - Late onset: Adulthood

Prevalence

< 1/1,000,000

RISK FACTORS

Usually arise in normal intrascrotal testes; however, may occur in cryptorchid or maldescended testes

Genetics

- 40% of LCCSCT are hereditary and are associated with multiple neoplasia syndromes (MNSs) namely:
  - Carney complex (CNC): Autosomal dominant; often caused by PRKAR1A gene mutations and characterized by
    - Spotty skin pigmentation
    - Myxomas (cardiac, cutaneuos, and mucosal)
    - Primary pigmented nodular adrenocortical disease
    - Thyroid tumors
    - Acromegaly due to growth hormone-producing adenoma
    - LCCSCTs
  - Peutz–Jeghers syndrome (PJS): Autosomal dominant; mainly caused by STK11 gene

mutations and characterized by
  - Multiple hamartomatous polyps along the whole gastrointestinal tract
  - Mucocutaneous hyperpigmented macules
- Tuberous sclerosis (TS) (possible): Autosomal dominant caused by TSCI and TSC2 mutations and characterized by
  - Mental retardation
  - Cutaneuos lesions
  - Nonmalignant brain tumors
  - Malformation of internal organs

PATHOPHYSIOLOGY

- Sertoli cells are supporting cells of the testis
  - During fet al development: Secrete anti-Mullerian hormone, which lead to regression of Mullerian ducts.
  - During adulthood: Promote differentiating of spermatocyte.
- Normally, Sertoli cells do not have aromatase activity (the enzyme that converts testosterone to estradiol); however, neoplastic Sertoli cells may express aromatase.
- Excess estrogens in prepubertal boy will lead to accelerated skelet al maturation and gynecomastia

ASSOCIATED CONDITIONS

- Gynecomastia
- Carney complex (CNC)
- Peutz–Jeghers syndrome (PJS)
- Tuberous sclerosis (TS)

GENERAL PREVENTION

In familial cases and in those who present with bilateral testicular Sertoli cell tumor, periodic screening for other tumors and associated conditions with MNS is highly recommended

DIAGNOSIS

HISTORY

- Painless or painful testicular mass/enlargement
- Breast pain and/or gynecomastia
- Growth spurt
- Family history of MNS
- Fertility

PHYSICAL EXAM

- General physical exam: Look for
  - Feminization, hair pattern, and other signs of estrogen access
  - Stigmata of MNS
- Testicular exam: Look for
  - Mass
    - Bilateral in 20% of LCCSCT with occasional coarse irregularities due to macrocalcifications

- Breast exam: Look for
  - Tenderness
  - Gynecomastia

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Sex steroid: Check for age-appropriate levels of
  - FSH
  - LH
  - Androgens
  - Estrogen
  - Progesterone
- Tumor markers:
  - AFP is usually negative
  - β-hCG is usually negative.
  - Placental alkaline phosphatase is usually negative.

Imaging

- Testicular US
  - Usually appear as solid, well-circumscribed, and hypervascularized mass
  - Bilateral increase in testicular volume
  - Occasionally cysts are seen
  - Calcifications: Microcalcifications within the tumor mass
    - Christmas tree–like appearance of multiple calcifications in syndromic LCCSCT is almost always pathognomonic for this tumor
- Metastatic workup: Includes
  - Chest x-ray
  - CT pelvis and abdomen
  - Bone scan

Diagnostic Procedures/Surgery

- Excisional biopsy usually by radical orchiectomy, can be curative
- Fine needle biopsy or nonexcisional biopsy of mass should never be done due to the risk of spread of the more common malignant tumors such as embryonal cell carcinoma or seminoma
- Partial orchiectomy, inguinal approach for patient with familial syndrome

Pathologic Findings

- Gross: Generally well circumscribed, yellow-gray, and lobulated on cut-surface
- Histologically:
  - Solid, tubular, or cord-like growth pattern of stromal epithelial tumor cells
  - Ovoid or spindle-shaped nuclei
  - Eosinophilic or clear cytoplasm
  - Variably scanty, edematous, hyalinized, or sclerotic connective tissue stroma
  - Call-Exner-like bodies sometimes seen
- Immunopathology:
  - Positive for vimentin, cytokeratin, and epithelial membrane antigen stains

  - Negative or focally positive for CD30, OCT3/4, and placental alkaline phosphates
- Histologic subtypes:
  - Classic or tumors that are not otherwise specified:
    - Low malignant potential (around 10–20%)
    - Mean age of 45 yr
    - No hereditary or MNS association
    - Occasionally causes access estrogen
    - Medium-size cells, scanty stroma with no calcifications
  - LCCSCT:
    - Mostly have benign clinical course, but malignancy can occur especially in older ages
    - Bimodal age: Early and late onset
    - Frequently associated with MNS
    - Occasionally causes access estrogen
    - Bilateral in 20% of reported cases, especially in syndromic disease
    - Often multifocal
    - Large eosinophilic cells surrounded by myxoid to collagenous stroma with occasional neutrophilic infiltrate
    - Necrosis and calcifications are common
  - Sclerosing:
    - Malignancy has never been reported
    - Affects young adults mainly
    - No hereditary association
    - Unilateral affection only
    - No hormonal imbalances
    - Usually small in size, <4 cm
    - Small pale cells with scanty cytoplasm surrounded by dense fibrous stroma

DIFFERENTIAL DIAGNOSIS

- Always rule out precocious puberty in any child who present with testicular enlargement and accelerated growth pattern
- Adult/pediatric painful mass:
  - Epididymitis/orchitis; bacterial, STD, mumps, TB
  - Fournier gangrene
  - Henoch–Schönlein purpura (usually no mass)
  - Incarcerated/strangulated hernia
  - Postvasectomy syndrome (usually no mass)
  - Testicular trauma: Usually blunt; contusion, rupture; usually associated hematocele
  - Torsion (testicle, testicular, or epididymal appendage)
  - Tumor (infrequent unless traumatized or rapidly growing; see below)
- Adult painless mass:
  - Adenomatoid tumor of testis or epididymis
  - Adrenal rest tumors
  - Adenocarcinoma of the rete testis
  - Chylocele: Usually associated with filariasis
  - Fibrous pseudotumor of the tunica albuginea

- Hydrocele, primary or due to trauma, torsion, tumor, epididymitis; hydrocele of the cord
- Lipoma of the cord
- Mesothelioma of tunica vaginalis
- Polyorchidism
- Paratesticular sarcomas: Rhabdomyosarcoma, fibrosarcoma, leiomyosarcoma, liposarcoma
- Scrotal edema (insect bite, nephritic syndrome, acute idiopathic scrotal edema)
- Scrotal wall: Sebaceous and inclusion cysts, idiopathic calcinosis, fat necrosis, malignancy
- Sperm granuloma following vasectomy
- Spermatocele (epididymal cyst)
- Testicular cysts (simple, tunica albuginea, epidermoid)
- Testicular tumor:
  - Germ cell tumors (95% of testicular malignancies): Seminoma, embryonal cell carcinoma, choriocarcinoma, yolk sac carcinoma teratoma (1–5%), teratocarcinoma
  - Gonadal stromal tumors: Leydig tumor, granulosa cell tumors
  - Metastatic tumors: Prostate, lung, and GI tract; rare kidney, malignant melanoma, pancreas, bladder, and thyroid
  - Mixed germ cell and stromal tumor (gonadoblastoma)
  - Angioma, fibroma, leiomyoma, hamartoma, carcinoid, mesothelioma, and neurofibroma
  - Malignant fibrous histiocytoma (most common soft tissue sarcoma in late adult life)
  - Leukemia or lymphoma
- Varicocele

• Pediatric painless mass:
- Similar to adult list; most/more common are: Hydrocele, hernia, varicocele, testicular teratoma, adrenal rest tumors, rhabdomyosarcoma

TREATMENT

GENERAL MEASURES

• Radical inguinal orchiectomy is the primary procedure of choice as these rare tumors are usually thought to be a more common malignancy of the testicle
• LCCSCT in the setting of CNC in children and young adults are typically benign and can be treated with pharmacotherapy for symptomatic relief of gynecomastia and/or advanced puberty

MEDICATION

First Line

• Platinum-based chemotherapy
- Used in metastatic disease, but unproven benefit

Second Line

N/A

SURGERY/OTHER PROCEDURES

• Radical inguinal orchiectomy
• In prepubertal boys, testis-sparing local excision has been reported (none are malignant) after frozen-section biopsy confirms the diagnosis

- Testis-sparing (partial orchiectomy) inguinal approach for patient with familial syndrome
- Retroperitoneal lymph node dissection: Reported but unproven efficacy

ADDITIONAL TREATMENT

Radiation Therapy

No proven role

Additional Therapies

Aromatase inhibitors may be an effective mode of therapy for patients with increased aromatization; currently, only limited number of patients has been treated and no definite recommendations can be made

Complementary & Alternative Therapies

Used in metastatic disease, but unproven benefit

ONGOING CARE

PROGNOSIS

- Benign, completely excised: Excellent
- Malignant, poor

COMPLICATIONS

- Recurrence: Rare
- Metastasis: Uncommon
- Infertility/subfertility
  - Bilateral LCCSTs can gradually increase in size, block the seminiferous tubules, and decrease fertility
  - Effect of treatment
  - Inhibin: Has been proposed as marker for LCCST cell activity and can inhibit FSH, but larger studies are needed to confirm the finding

FOLLOW-UP

Patient Monitoring

- Benign tumors: Periodic scrotal exam
- Malignant tumors: Imaging for metastasis
- Periodic screening for conditions associated with MNS is necessary in syndromic LCCSCT

Patient Resources

- D29.22 Benign neoplasm of left testis

CLINICAL/SURGICAL PEARLS

- Consider hereditary syndromes.
- Most Sertoli cell tumors are benign.

TESTIS, TERATOMA, MATURE AND IMMATURE

John L. Phillips, MD, FACS
Vladimir A. Valera, MD, PhD

BASICS

DESCRIPTION

- Testicular teratomas (TTs) are germ cell tumors (GCTs) which form somatic tissues in varying stages of maturity (ie, differentiation)
  - Mature (M) = well-differentiated endoderm, mesoderm, and/or ectoderm germ cell (GC) layers
  - Immature (I) = fet al or embryonal GC layers
- Most common GCT in childhood
- Adult TT, mature and immature: Consider as malignant
- Pediatric TT, mature and immature: Behave in general as benign lesions

EPIDEMIOLOGY

Incidence

- 8,820 cases of testicular cancer in the US in 2014
- 5.2 cases 100,000 men
- Adults: 2nd to 4th decade
- Mature: Immature types 10:1 (1)
- Pure teratoma (T) in 5% of adult GCTs but 35–40% of pediatric GCT
- T + GCT (ie, mixed) more common in adults (up to 50% of cases)
- Pure T more common in children
- T found in retroperitoneum in
  - 22% stage IIa
  - 1/3 of patients after chemo for NSGCT (2)

Prevalence

- US has 195,000 survivors of testicular cancer
- 5-yr survival
  - 99% when confined to testis
  - 96% for stage II
  - 40% 4-yr survival with malignant transformation of teratoma (3)

RISK FACTORS

- Same for all GCTs
  - Cryptorchidism
  - Klinefelter syndrome
  - Cannabis use controversial
  - Family history
  - Testicular atrophy/maldevelopment
  - DDT exposure (see http://www.cancer.gov/cancertopics/causes/testicular/pesticides0408 Accessed August 22, 2014)

Genetics
- Isochromosome 12p
- Adult tumors hypotriploid
- pRB expressed in epithelial component

PATHOPHYSIOLOGY
- GC tumor model
  - Initiation possibly in utero
  - Intratubular GC neoplasia unclassified (ITGCNU) undergoes progression
  - Differentiation of malignant embryonal GCs into mature teratoma thus mixed elements may occur
  - Adult and not pediatric TT genetically unstable
  - Adult and not pediatric TT has transforming capability
- Dermoid cysts are different in that they may differentiate from nonmalignant GCs

ASSOCIATED CONDITIONS
- Infertility and oligospermia
- Cryptorchidism
- Gynecomastia

GENERAL PREVENTION
- Self-exam for early diagnosis and treatment
- Possibly early orchidopexy for undescended testicle

DIAGNOSIS

ALERT
Identify symptoms of metastatic disease.

HISTORY
- The most common symptom at the time of diagnosis is painless swelling or enlargement of the testis.
- Scrotal injury
- Cryptorchidism
- Symptoms of metastatic disease may include:
  - Weight loss
  - Inanition
  - Abdominal distention
  - Joint, neck, or back pain
  - Sweats, lethargy

PHYSICAL EXAM
- Most common: Painless scrotal mass
  - Assess for tenderness, mobility, fixation
- Abdominal exam
- Breast exam
- Lymph node evaluation

- Document normal contralateral testis

DIAGNOSTIC TESTS & INTERPRETATION

ALERT
Markers must be drawn prior to orchiectomy.

Lab

- Tumor markers
  - α-Fetoprotein (AFP) (10%, can be made seen if hepatoid differentiation has occurred)
  - β-hCG (only elevated if chorio- or seminomatous elements present)
  - LDH
  - CEA (rare, can be seen if GI tissues present)
- Complete metabolic profile
  - Electrolytes
  - Liver function tests
- Complete blood count
- PT/INR

Imaging

- Ultrasound is critical in assessing for intratesticular mass, typically hypoechoic
- Microlithiasis in contralateral testis should be documented and followed; role of biopsy is controversial, more common in Europe
- Chest x-ray or better chest CT
- Abdomen–pelvis CT scan with and without contrast (if creatinine normal)
- PET scan not usually indicated; may have a role in the postchemotherapy setting

Diagnostic Procedures/Surgery

- Inguinal orchiectomy, radical, is standard of care for a solid testicular mass in adults
- Stage patient per TNMS
  - Document tumor markers: Important for staging
  - Document presence of nonteratomatous elements: Important for treatment algorithm

Pathologic Findings

- Large (5–10 cm), multinodular, heterogenous (solid, cartilaginous, cystic)
- May contain teeth, hair, bone, cartilage
- Cystic areas mixed with solid
- Mature teratoma
  - Mixture of elements of ectoderm (eg, hair), endoderm (eg, GI), and mesoderm (eg, bone)
- Immature teratoma
  - Neuroepithelium with embryonic features,
  - Poorly formed cartilage
  - Primitive glandular structures
  - High grade if mitotically active
- Dermoid cysts
  - Truly benign, no atypia or mitoses
  - Keratin, hair, dermatoectoderm

DIFFERENTIAL DIAGNOSIS

- These are a delineation of testicular masses only. For a complete listing of intrascrotal and testicular masses see Section I: "Scrotum and Testicle Mass"
- Benign lesions
  - Epididymitis/orchitis: Bacterial, STD/STI, mumps, TB
    - Often delayed testicular cancer diagnosis due to treatment of presumed epididymitis
  - Testicular trauma: Usually blunt; contusion, rupture; usually associated hematocele
  - Torsion (testicle or appendages)
  - Incarcerated/strangulated hernia
  - Cysts (simple, tunica albuginea, epidermoid)
  - Adrenal rest tumors: In general benign, but can contribute to infertility in patients with congenital adrenal hyperplasia
  - Fibrous pseudotumor of the tunica albuginea: Painless fibrous mass often associated with prior history of trauma or infection
  - Adenomatoid tumor of testis or epididymis
  - Other rare benign lesions: Angioma, fibroma, leiomyoma, hamartoma, carcinoid, neurofibroma
- Malignant lesions
  - Testicular primary tumors (seminoma and nonseminomatous GCT)
  - Leukemia involving testis—testis can be a site of solitary recurrence of leukemia posttreatment (sanctuary site). Biopsy can be utilized to confirm diagnosis in a patient with history of leukemia.
    - Treatment can be testis sparing with radiation, though contralateral testis should be treated as bilateral disease can be present.
  - Lymphoma involving testis—usually represents extension from extratesticular sites, rarely can represent a primary lymphoma site (1% of lymphoma cases); can present bilaterally 1/3 of the time; mostly involves older men >60 yr; constitutional symptoms commonly present (fever, chills, night sweats, weight loss).
  - Metastatic solid tumors: More common—prostate, lung, GI tract; more rare—kidney, malignant melanoma, pancreas, bladder, and thyroid
  - Adenocarcinoma of the rete testis: Arises in the testis collecting system, high-stage presentation, poor response to chemotherapy and radiation, with median survival of 1 yr.
  - Mesothelioma of tunica vaginalis: Rare, similar to the more common pleural histology, associated with asbestos exposure
  - Paratesticular sarcomas: Rhabdomyosarcoma, malignant fibrous histiocytoma (most common soft tissue sarcoma in late adult life)

TREATMENT

GENERAL MEASURES

- Radical orchiectomy for adult solid testicular mass
  - Staging and then treatment based on histology and stage
  - Treat most aggressive subelement
- Chemo for high-stage disease followed by retroperitoneal lymph node dissection (RPLND)
- Prior to systemic therapy, discuss sperm banking

MEDICATION

First Line

- Teratomas are *not* chemosensitive
- Platinum-based chemotherapy used in teratoma only to treat the non-teratomatous elements, eg, embryonal, choriocarcinoma
- RPLND is only treatment to address teratoma in retroperitoneum, esp. after chemo

Second Line

N/A

SURGERY/OTHER PROCEDURES

- RPLND important in teratoma
  - Primary (no prior treatment)
    - 20% of stage I teratomas have retroperitoneal (retroperitoneum) disease and the retroperitoneum nodes should be resected
  - Secondary (after chemotherapy/RT)
    - 20–30% of residual retroperitoneum masses after chemotherapy in NSGCT may harbor teratoma and should be resected
  - Tertiary (ie, "growing teratoma syndrome")
    - Recurrent retroperitoneal teratoma after RPLND may occur after incomplete resection or recurrent differentiated tumor
    - Retroperitoneal lymph node reresection best option if feasible

ADDITIONAL TREATMENT

Radiation Therapy

- Teratomas are *not* radiosensitive
- In stage I seminomatous GCT, radiation to the retroperitoneum may be used for patients at risk of occult stage II disease but must be monitored for retroperitoneum teratoma

Additional Therapies

Discuss sperm banking before treatment

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Excellent with low stage & complete resection
  - 95–100% cure rate in adults
  - 100% cure rate in children
- Fair to poor if metastatic/incomplete resection
  - 86% 2-yr survival for retroperitoneal disease only
  - 40% 2-yr survival for retroperitoneal + multiple sites

COMPLICATIONS

- Infertility
  - Preorchiectomy oligospermia

  – Post-RPLND loss of emission (infertility)
- Chemotherapy toxicity
  – Platinum: Renal
  – Bleomycin: Pulmonary toxicity and fibrosis (watch for ARDS)
  – Etoposide: Myelosuppression

FOLLOW-UP

Patient Monitoring

- Surveillance not good option in primary teratoma because of occult GC elements in retorperitoneum
- If markers elevated, look for occult nonteratoma elements or, rarely, GI elements within teratoma.
- NCCN guidelines for teratoma *after* RPLND
  – Year 1–2
    ◦ Chest x-ray (CXR) + markers q3mo
    ◦ CT abdomen/pelvis baselines and q6mo
  – Year 3–4
    ◦ CXR + markers q3–6mo
    ◦ CT annual
  – Year 4–6, 6+
    ◦ CXR + markers q6–12mo
    ◦ CT biannual

CODES

ICD9

- 186.9 Malignant neoplasm of other and unspecified testis
- 222.0 Benign neoplasm of testis
- 752.51 Undescended testis

ICD10

- C62.90 Malig neoplasm of unsp testis, unsp descended or undescended
- D29.20 Benign neoplasm of unspecified testis
- Q53.9 Undescended testicle, unspecified

CLINICAL/SURGICAL PEARLS

- Teratomas are resistant to chemotherapy and radiotherapy.
- Metastatic embryonal germ cell tumor may mature into teratoma in adult cases. Therefore, mature teratomas in adults should be treated aggressively.
- Immature and mature teratomas in children are benign.
- Pure teratomas do not secrete AFP (but may harbor GI elements that do).
- Pure teratomas do not secrete β-hCG (but may harbor choriocarcinomatous or seminomatous elements that do).
- Postchemo RPLND has double the rate of teratomas than RPLND for stage I tumors.

TESTIS, TUMOR AND MASS, ADULT, GENERAL CONSIDERATIONS

Srinivas Vourganti, MD
Allen D. Seftel, MD, FACS

BASICS

DESCRIPTION

- Testis cancer is the most common malignancy in men aged 20–40 yr in US.
- Mortality has dropped from >50% in the 1970s to <5% today, due to improved imaging, better tumor markers, and multidrug chemotherapy.
- 95% of testicular tumors are germ cell tumors, other types are rare (sex cord/stromal)
- While benign lesions can be found in the testis (see section on "Differential Diagnosis"), all solid lesions should be considered cancer until definitively proven otherwise

EPIDEMIOLOGY

Incidence (1)

- ~8,820 new cases of testis cancer in US in 2014, and 380 men will die of this disease.
- Median age at diagnosis was 33 (2006–2010)
- Incidence rate was 5.5/100,000 men per year:
  - By race/100,000 men/yr: White men 6.6; black men 1.4, Asian men 1.9; Hispanic men 4.7

Prevalence

In 2010, in US there were ~221,020 men alive with history of testicular cancer.

RISK FACTORS (2)

- History of cryptorchidism:
  - 7–10% of cases; 4–6 times more likely to develop testicular cancer
  - Seminoma is most common tumor type
  - Orchiopexy reduces relative risk (RR) from 3 to 2 if performed prior to onset of puberty
- Family history (affected 1st-degree relative):
  - Father with testis cancer—RR 4.63
  - Brother with testis cancer—RR 8.3
  - Son with testis cancer—RR 5.23
- Cannabis use controversial
- Testicular atrophy
- Infertility
- Klinefelter syndrome

Genetics

Isochromosome 12p amplification seen in the majority of tumors

PATHOPHYSIOLOGY

- Germ cell tumors (seminoma, embryonal cell carcinoma, teratoma, choriocarcinoma, and yolk sac tumor) comprise 90–95% of testicular tumors.

  – Mixed germ cell tumors common (60% of all)
- Seminoma: 35–65% of germ cell tumors; classified into 3 subtypes:
  – Typical (classic) seminoma: 82–85% of seminomas; most commonly men in 30s; less common in men in 40s–50s
    - Syncytiotrophoblast in 10–15% of typical seminomas and makes to β-hCG.
  – Spermatocytic seminoma:
    - 2–12%; roughly 1/2 in men >50 yr
  – Lower malignant potential
- Embryonal cell carcinoma:
  – Occurs in 40% of germ cell tumors
- Choriocarcinoma
  – Rarely found in pure form; pure form is often advanced, with a small primary tumor.
  – Prognosis for pure choriocarcinoma is poor.
- Yolk sac tumor: 92% stain for AFP
- Teratoma:
  – Frequently found at metastatic sites
  – Locally invasive, chemotherapy resistant
- Nongerm cell tumors (5–7%):
  – Leydig cell tumors: 2–3% of tumors; not associated with cryptorchidism;10% malignant
  – Sertoli cell tumors:
    - 1% of testicular tumors; 90% benign
  – Gonadoblastoma: Rare; most in men <30 yr

ASSOCIATED CONDITIONS
- Cryptorchidism
- Infertility seen in men upon diagnosis (half with oligospermia, 1/10th with azoospermia)

GENERAL PREVENTION
Testicular self-exam should be performed monthly for earlier diagnosis.

DIAGNOSIS
HISTORY
- Local symptoms: Change in testicular size or texture; testicular pain (uncommon)
- Systemic symptoms: Weight loss; abdominal pain/discomfort; fevers; mastodynia or other changes in secondary sex characteristics:
- History: Cryptorchidism, infertility, orchiopexy

PHYSICAL EXAM
- Check all lymph nodes, including supraclavicular nodes.
- Abdominal exam for masses
- Examine for gynecomastia (5% of cases).
- Testicular exam: Examine both testes:
  – Any firm or hard area in the testis should be evaluated; determine if mass is distinct from epididymis. Note consistency of testis, whether it is fixed to scrotum, and size of lesion
  – Palpate for hydrocele, hernia.

ALERT
Markers must be drawn prior to orchiectomy.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Tumor markers obtained prior to orchiectomy:
  - 1 or more elevated in 85–90% of non-seminomatous germ cell tumor (NSGCT)
- β-hCG:
  - Half-life: 24–36 hr
  - Elevated in 40–60% with testis cancer; 100% of choriocarcinomas;10–15% pure seminomas
- AFP:
  - Half-life: 5–7 days
  - Produced by yolk sac tumors, embryonal cell carcinoma, and teratocarcinomas
  - Not produced in pure seminoma or pure choriocarcinoma. If AFP elevated in case of pure seminoma, NSGCT elements are present.
- LDH
  - Nonspecific marker for GCT
  - Elevated in 20% of low stage and 50% of high-stage GCT
  - Useful in prognosis as magnitude of elevation correlates with disease bulk
  - Half-life: 1 day
- Serum and urine estrogens may be elevated in Leydig cell tumors

Imaging

- Scrotal US:
  - Diagnostic imaging mainstay for identifying testicular tumors
  - Any hypoechoic lesion within the testicular parenchyma should be considered cancer until proven otherwise.
  - 80% of testicular tumors are hypoechoic.
- Abdominal CT:
  - Critical for staging of testicular tumors
  - Should be performed prior to orchiectomy if possible, as postoperative retroperitoneal hematoma can distort imaging.
  - Accuracy is 70–90%, depending upon stage.
  - Cannot detect micrometastasis in normal-sized lymph nodes
- Chest x-ray: Staging for metastases; if abnormal, chest CT is obtained.

Diagnostic Procedures/Surgery

- Radical inguinal orchiectomy:
  - Important for determining pathology of primary tumor. Is also therapeutic in that chemotherapy does not penetrate testis well.
- Transscrotal testicular biopsy or orchiectomy should NOT be performed.

DIFFERENTIAL DIAGNOSIS

These are a delineation of testicular masses only. For a complete listing of intrascrotal and testicular masses see Section I “Scrotum and Testicle Mass”:

- Benign lesions
  - Epididymitis/orchitis: Bacterial, STD/STI, mumps, TB
    - Often delayed testicular cancer diagnosis due to treatment of presumed epididymitis
  - Testicular trauma: Usually blunt; contusion, rupture; usually associated hematocele
  - Torsion (testicle or appendages)
  - Incarcerated/strangulated hernia
  - Cysts (simple, tunica albuginea, epidermoid)
  - Adrenal rest tumors: In general benign, but can contribute to infertility in patients with congenital adrenal hyperplasia
  - Fibrous pseudotumor of the tunica albuginea: Painless fibrous mass often associated with prior history of trauma or infection
  - Adenomatoid tumor of testis or epididymis
  - Other rare benign lesions: Angioma, fibroma, leiomyoma, hamartoma, carcinoid, neurofibroma
- Malignant lesions
  - Testicular primary tumors (seminoma and nonseminomatous GCT)
  - Leukemia involving testis—testis can be a site of solitary recurrence of leukemia post-treatment (sanctuary site). Biopsy can be utilized to confirm diagnosis in a patient with history of leukemia.
    - Treatment can be testis sparing with radiation, though contralateral testis should be treated as bilateral disease can be present.
  - Lymphoma involving testis—usually represents extension from extratesticular sites, rarely can represent a primary lymphoma site (1% of lymphoma cases); can present bilaterally one-third of the time; mostly involves older men >60 yr; constitutional symptoms commonly present (fever, chills, night sweats, weight loss).
  - Metastatic solid tumors: More common—prostate, lung, GI tract; more rare—kidney, malignant melanoma, pancreas, bladder, and thyroid
  - Adenocarcinoma of the rete testis: Arises in the testis collecting system, high-stage presentation, poor response to chemotherapy and radiation, with median survival of 1 yr.
  - Mesothelioma of tunica vaginalis: Rare, similar to the more common pleural histology, associated with asbestos exposure
  - Paratesticular sarcomas: Rhabdomyosarcoma, malignant fibrous histiocytoma (most common soft tissue sarcoma in late adult life)

TREATMENT

GENERAL MEASURES

- Radical inguinal orchiectomy is considered standard of care for initial management.
- Additional therapy depends on staging. Commonly used staging system is the TNM staging and group staging by the AJCC.
  - For NSGCT: RPLND, primary chemotherapy (platinum based), or surveillance
- For seminoma: Surveillance, primary radiotherapy, or primary chemotherapy (single-agent carboplatin)
- Surveillance, with serial imaging and tumor markers, is appropriate in well-selected low-risk patients:

- Stage I seminoma
- Stage I NSGCT: No teratomatous elements, no lymphovascular invasion, and no embryonal cell carcinoma in the primary specimens. Patients must be reliable.

MEDICATION

First Line

- Treatment depends upon primary cell type of tumor and stage at presentation.
- Cisplatin-based chemotherapy is the 1st-line regimen for treating testicular cancer:
  - Commonly used for stage IIc and higher seminoma; numerous regimens used.
  - 2 cycles of BEP (bleomycin/etoposide/cisplatinum) in stage I NSGCT
  - 3 cycles of BEP commonly used for stage IIa, IIb; good-risk stage IIc and III disease
  - Poor-risk stage IIc and II disease: 4 cycles of BEP have been used:
    - Some centers have replaced etoposide with ifosfamide and some use advocated 4 cycles of vinblastine, ifosfamide, and cisplatin.

Second Line

High-dose chemotherapy with autologous bone marrow transplantation in patients with residual disease and or recurrent disease or rather, enrollment in a clinical trial

SURGERY/OTHER PROCEDURES

- Radical orchiectomy:
  - Inguinal approach is used to prevent violation of tissue planes
  - May be adequate treatment for stage I seminoma and certain stage I NSGCTs
- Retorperitoneal lymph node dissection (RPLND):
  - Indicated in patients with stage I and IIa NSGCT, particularly those with teratoma in the primary specimen
  - With residual mass after chemotherapy
    - For low-stage disease, a modified nerve-sparing template is normally used.
  - For RPLND description, see Section I: “Testis Cancer, Nonseminomatous Germ Cell Tumors”

ADDITIONAL TREATMENT

Radiation Therapy

- Commonly used in stage I and IIa seminomas
- External beam radiation to retroperitoneal and ipsilateral ilioinguinal lymph nodes
- Contralateral inguinal region is included if history of inguinal or scrotal procedures

Additional Therapies

Patients should consider sperm banking prior to treatment to aid in avoiding risk of infertility.

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Depending upon stage and cell type of primary tumor, prognosis is excellent, with 95% of

patients experiencing a long-term cure.

COMPLICATIONS

- Infertility
- RPLND: Retrograde ejaculation, ileus, atelectasis, chylous ascites, chylothorax, pneumonitis, lymphocele, pancreatitis, and vascular or bowel injury
- Increased risk of secondary malignancies in patients undergoing chemotherapy or radiation

FOLLOW-UP

Patient Monitoring

- In patients who underwent RPLND:
  - Serial monitoring with chest x-ray, physical exam, and tumor markers. Retroperitoneal recurrence is rare, so imaging of this region is not usually needed.
  - Follow-up depends upon initial stage and cell type of primary tumor and response to therapy.
- In patients who did not undergo RPLND:
  - Follow-up similar; serial monitoring of retroperitoneum using CT scanning
  - Frequency of follow-up is based on initial stage and cell type and the response to therapy.

CODES

ICD9

- 186.9 Malignant neoplasm of other and unspecified testis
- 239.5 Neoplasm of unspecified nature of other genitourinary organs
- 608.89 Other specified disorders of male genital organs

ICD10

- D49.5 Neoplasm of unspecified behavior of other genitourinary organs
- N50.8 Other specified disorders of male genital organs
- C62.90 Malig neoplasm of unsp testis, unsp descended or undescended

CLINICAL/SURGICAL PEARLS

- Increased risk of malignancy in patients with history of cryptorchidism and family history of testis cancer.
- Ultrasound should be performed to resolve any concerns of abnormal scrotal exam.
- Initial diagnosis of radical orchiectomy using an inguinal approach to avoid scrotal violation.
- All testis masses in adults should be considered malignant until proven otherwise.

TESTIS, TUMOR AND MASS, PEDIATRIC, GENERAL CONSIDERATIONS

Nicholas G. Cost, MD
Paul H. Noh, MD, FACS, FAAP

BASICS

DESCRIPTION

- Important to distinguish prepubertal "pediatric" testis tumors from the postpubertal "adolescent" testis tumors (1).
- Prepubertal testicular tumors in children are much more often benign than the postpubertal tumors which are more often malignant.
- Must differentiate a true testicular tumor or mass from paratesticular and scrotal masses
- The most common causes of painless scrotal swelling in a child include hernias, hydrocele, varicocele, and scrotal wall swelling
- Testis accounts for 2% of pediatric tumors

EPIDEMIOLOGY

Incidence

- 0.5–2 per 100,000 children/yr
- Peak age of 2 yr
- Lower incidence of germ cell tumors (GCTs) when compared to adults
- 25–30% of pediatric tumors are malignant (2).
- Rare in black and Asian children
- Testicular tumors in children (2):
  - Teratoma: 40–50%
  - Epidermoid cyst: 10–15%
  - Yolk sac tumor (YST): 25–35%
  - Gonadal stromal tumors: 10–15%
  - Others: Gonadoblastoma: 1–2% (3), leukemia: 1–2%, cystic dysplasia: $<1\%$

Prevalence

N/A

RISK FACTORS

- Risk factors for GCTs:
  - Cryptorchidism (4)
  - Family history
  - Intratubular germ cell neoplasia
  - Past personal history
- Congenital adrenal hyperplasia (CAH) increases risk for intratesticular adrenal rests

Genetics

- Gonadoblastoma is associated with gonadal dysgenesis and a 45XO/46XY karyotype.
- YST: Abnormalities in 1p, 6q, and 3p

- GCTs: Excess genetic material from the short arm of chr 12, including isochromosome 12p.
- Large-cell calcifying Leydig tumor is associated with Peutz–Jeghers syndrome and Carney complex.

PATHOPHYSIOLOGY

- GCTs typically develop from a precursor lesion, which, in turn, appears to develop from arrested primordial germ cells or gonocytes
- Teratoma: Monodermal (epidermoid cyst) or multiple histologic types present
  - Not associated with an elevated AFP
  - Metastasis not reported before puberty
  - Testis-sparing enucleation via an inguinal incision is possible in prepubertal patients and normal serum tumor markers.
- YST (also called endodermal sinus tumor):
  - AFP elevated in 80% of YST, and normally elevated in a neonate (physiologic).
    - AFP half-life is 5–7 days; elevation after orchiectomy implies metastatic disease.
  - Yolk sac elements stain positive for AFP
  - β-hCG produced by syncytiotrophoblast indicates a mixed GCT.
- Gonadoblastoma:
  - Most common tumor in disorders of sexual development; germ cell component prone to malignant degeneration
- Seminomas and mixed GCT rare in prepubertal children.
- Gonadal stromal tumors (3):
  - Leydig cell tumors:
    - Peak age of 4–5 yr; increased testosterone production with normal LH
    - Differential diagnosis includes pituitary lesions, Leydig cell hyperplasia, CAH based on hormonal production
    - Reinke crystals classically described in adults, rare in children on histology
    - Malignancy not reported in Leydig cell tumors in children
  - Sertoli cell tumor:
    - Peak age <4; most not hormonally active
    - Gynecomastia when hormonally active
    - Retroperitoneal spread rarely reported
  - Granulosa cell tumor:
    - Rarely metastasizes
- Testis tumor of adrenogenital syndrome:
  - Benign, suppressible with glucocorticoids
- Lymphoma, leukemia
  - May serve as a sanctuary site of these malignancies because of blood–testis barrier
- Cystic dysplasia of the testis:
  - Irregular cysts in rete testis; associated with renal agenesis and multicystic dysplasia
- Children's Oncology Group (COG) staging:
  - Stage 1: Limited to testis, markers normalize according to half-life. No radiologic evidence of metastatic disease
  - Stage 2: Transscrotal orchiectomy or tumor rupture during orchiectomy, persistent elevated markers, residual disease in scrotum or disease on pathology <5 cm from

testicular cord margin
  – Stage 3: Nodes >4 cm, no visceral or distant disease. Nodes 2–4 cm require biopsy.
  – Stage 4: Distant metastases
- Postpubertal GCTs staged and managed according to adult testicular cancer guidelines

ASSOCIATED CONDITIONS
- Disorders of sexual development with a dysgenetic gonad and the presence of a Y chromosome
- Congenital adrenal hyperplasia (CAH)
- Cryptorchidism
- Precocious puberty

GENERAL PREVENTION
- Orchidopexy does not eliminate the risk of developing testicular cancer in cryptorchidism, but early intervention may reduce the risk (4).
- Early orchidopexy permits earlier detection of testicular masses. Other benefits include improved fertility and a reduced risk of torsion.
- Routine exam of the scrotal contents

DIAGNOSIS

HISTORY
- Asymptomatic scrotal mass or asymmetry
- Acute pain or fever with hemorrhage, trauma, rapid growth of the tumor, infection
- Precocious sexual development
- Breast tenderness with gynecomastia
- Undescended testicle or hernia repair
- Family history of testicular tumors

PHYSICAL EXAM
- Scrotal asymmetry
- Abnormality intratesticular vs. intrascrotal, testicular vs. paratesticular
- Diffusely enlarged testicle or palpable nodularity in the testicle
- Does not transilluminate (solid)
- Inguinal canal and cord structures are usually normal in a boy with a testicular tumor
- Signs of precocious puberty

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum markers AFP and β-hCG:
  – Obtain prior to orchiectomy in all patients with a testicular mass
  – Marked AFP elevations present in newborn; may be detectable up to 8 mo of age
- Serum testosterone, LH, and FSH levels if a gonadal stromal tumor is suspected.

Imaging
- Scrotal ultrasound (US):
  – Differentiate intratesticular vs. extratesticular
  – Does not differentiate benign from malignant

  - Paratesticular rhabdomyosarcoma (PT-RMS):
    - Hypervascular, solid extratesticular mass
    - Often large; testicle not seen on US
  - Indeterminate lesions on US that resemble testicular neoplasm include tubular ectasia of the rete testis, inflammation, and hematoma.
- Chest x-ray: Evaluate for metastatic YST
- Abdominal and pelvic CT or MRI:
  - Obtained after histology confirms malignancy
  - Evaluate retroperitoneum for lymph node metastases and liver for metastases
- MRI may have utility in the evaluation of indeterminate lesions seen on US.

Diagnostic Procedures/Surgery

- All suspicious testicular and paratesticular lesions should be approached inguinally.
- Prepubertal patients with a primary testicular lesion and normal tumor markers may be considered for testis-sparing surgery (TSS).
  - Such approaches require intraoperative assessment including immediate frozen-section analysis to ensure complete resection
  - If frozen section reveals GCT elements or concern for incomplete resection, radical orchiectomy should be performed
  - Intraoperative US may be helpful
  - Postpubertal patients with a normal contralateral testicle should undergo radical inguinal orchiectomy.
  - Paratesticular lesions consistent with malignancy should be managed with radical inguinal orchiectomy

Pathologic Findings

- GCTs
  - Teratoma: Contain elements of at least 2 of the 3 germ cell layers of endoderm, mesoderm, and ectoderm.
  - YST: Epithelioid cells that form glandular and ductal structures arranged in columns, papillary projections, or solid islands within a primitive mesenchymal stroma. The cells have poorly defined cell borders and vacuolated cytoplasm with glycogen and fat.
  - Seminoma: Islands or sheets of relatively large cells with clear cytoplasm and densely staining nuclei.
  - Embryonal carcinoma: Malignant epithelioid cells arranged in glands or tubules. Cell borders indistinct, cytoplasm pale or vacuolated, and nuclei rounded with coarse chromatin.
  - Choriocarcinoma: 2 distinct cell types must be demonstrated to satisfy the histologic diagnosis of choriocarcinoma: Syncytiotrophoblasts and cytotrophoblasts.
  - Gonadoblastoma: Must have 3 elements: Sertoli cells, interstitial tissue, and germ cells
- Stromal tumors
  - Leydig cell tumors: Uniform, closely packed cells with round, slightly eccentric nuclei and eosinophilic granular cytoplasm with lipoid vacuoles, brownish pigmentation, and inclusions known as Reinke crystals.
  - Sertoli cell tumors: Epithelial elements resembling Sertoli cells and varying stroma.
  - Granulosa cell tumors: Characteristic Call–Exner bodies may be identified, consisting of

PAS-positive material similar to that seen in the basement membrane of the tubules.

DIFFERENTIAL DIAGNOSIS

- Painful childhood testicular masses:
  - Epididymitis/orchitis; bacterial, mumps
  - Henoch–Schönlein purpura (usually no mass)
  - Incarcerated/strangulated hernia
  - Testicular or paratesticular tumor
  - Testis trauma: Contusion, hematocele
  - Torsion (testicle, testicular or epididymal appendage); more common after puberty
- Painless childhood testicular masses:
  - Adenomatoid tumor of testis or epididymis
  - Adrenal rest tumors
  - Cystic dysplasia of the testis
  - Chylocele: Usually associated with filariasis
  - Fibrous pseudotumor of the tunica albuginea
  - Hydrocele, primary or due to trauma, torsion, tumor, epididymitis; hydrocele of cord
  - Hernia
  - Lipoma of the cord
  - Polyorchidism
  - Rhabdomyosarcoma (RMS) (bimodal age 3–4 and adolescence)
  - Scrotal edema (insect bite, nephrotic syndrome, acute idiopathic scrotal edema)
  - Spermatocele (epididymal cyst)
  - Testicular cysts
  - Testicular tumors:
    - GCTs: YST, teratoma, seminoma, embryonal, choriocarcinoma, mixed tumors
    - Gonadal stromal tumors: Leydig tumor, Sertoli cell, granulosa cell tumors
    - Metastatic tumors
    - Hamartoma, carcinoid, and neurofibroma
    - Testis tumor of adrenogenital syndrome
    - Leukemia or lymphoma
  - Varicocele

TREATMENT

GENERAL MEASURES

- TSS for most lesions in prepubertal children
- Prepubertal testicular teratomas, and Leydig and Sertoli cell tumors are benign; orchiectomy or TSS is curative and no additional therapy is indicated.
- YST or other malignant tumor; radical orchiectomy and observation if low stage
- PT-RMS require specific RMS management

MEDICATION

First Line

- Chemotherapy for all GCTs stage II or greater
  - Bleomycin, etoposide, cisplatin

SURGERY/OTHER PROCEDURES

- Inguinal approach for primary lesion in all patients regardless of age
- RPLND
  - Postchemotherapy for residual retroperitoneal mass
    - Rare given the rarity of metastatic disease and exquisite sensitivity to chemotherapy
  - Staging RPLND in all boys >10 yr with PT-RMS regardless of staging imaging and those <10 yr with abnormalities on staging imaging

ADDITIONAL TREATMENT

Radiation Therapy

As indicated for PT-RMS depending on stage and histology

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Prepubertal teratoma is uniformly benign
- GCTs (5)
  - 100% 6-yr overall survival for Stages I–III
  - 91% 6-yr overall survival for Stage IV

COMPLICATIONS

Long-term complications after chemotherapy

FOLLOW-UP

Patient Monitoring

- Routine follow-up not necessary for teratoma
- Surveillance for malignancy based on stage of disease and adjuvant therapy

CODES

ICD9

- 222.0 Benign neoplasm of testis
- 239.5 Neoplasm of unspecified nature of other genitourinary organs
- 608.89 Other specified disorders of male genital organs

ICD10

- D29.20 Benign neoplasm of unspecified testis
- D49.5 Neoplasm of unspecified behavior of other genitourinary organs
- N50.8 Other specified disorders of male genital organs

CLINICAL/SURGICAL PEARLS

- Scrotal US can generally distinguish a tumor from other causes of testicular swelling or pain and discriminate between a testicular and paratesticular mass.
- While infant and prepubertal boys with a testicular mass and normal serum tumor markers may be treated with attempted testis sparing surgery (TSS), peripubertal boys should be managed with a radical inguinal orchiectomy.

TESTOSTERONE REPLACEMENT THERAPY, GENERAL PRINCIPLES

Robert L. Segal, MD, FRCS(C)
Arthur L. Burnett, II, MD, MBA, FACS

BASICS

DESCRIPTION

- Hypogonadism is the clinical syndrome associated with low serum testosterone (T)
  - Can occur in early age (early onset), although most commonly seen in aging males
  - Late-onset male hypogonadism may also be referred to as andropause, androgen deficiency in the aging male, or androgen deficiency syndrome

EPIDEMIOLOGY

Incidence

N/A

Prevalence

- 2–4 million men in US
- Hypogonadism increases with age
  - Overall 5.6–38.7% men are affected, depending on study
  - 6th decade: 12%; 7th: 19%; 8th: 29%; 9th: 49%

RISK FACTORS

- Medical comorbidities (chronic liver disease, chronic renal failure/hemodialysis, HIV/AIDS, hyperthyroidism, obesity)
- Medication (GnRH agonists/antagonists, androgen antagonists, estrogen, opiates, ketoconazole, amiodarone, thiazide diuretics, cimetidine)
- Low protein diet

Genetics

N/A

PATHOPHYSIOLOGY

- As age increases, there is:
  - Decreased number of Leydig cells within the testicle (site of T production)
  - Decreased testicular responsiveness to LH
  - Dampening in the amplitude of circadian release of T
  - Increased serum sex hormone binding globulin (SHBG); binds T, therefore less bioavailable (functionally active) T

ASSOCIATED CONDITIONS

- Metabolic syndrome (obesity, hypertension, dyslipidemia)
- Impaired fasting glucose/insulin resistance/diabetes mellitus type II (DMII)
- Asthma/chronic obstructive pulmonary disease/obstructive sleep apnea (OSA)
- Osteoporosis

GENERAL PREVENTION
N/A

DIAGNOSIS

HISTORY
- Low energy level/daytime sleepiness (2)[B]
- Decreased sexual interest/libido (2)[A]
- Erectile dysfunction (ED)/absence of spontaneous erections/delayed ejaculation (2)[A]
- Diminished mood/memory/concentration
- Hot flushes/sweats
- Loss of muscle mass/visceral obesity
- Visual field defects
- Several validated questionnaires to screen for T deficiency have been developed, but are unreliable with low specificity (1)[C]

PHYSICAL EXAM
- May not be contributory (2)[B]
- Small testicular size/soft consistency (2)[B]
- Hair distribution and pattern (2)[B]
- Gynecomastia (2)[B]
- Digital rectal exam (DRE) to rule out palpable prostate abnormality

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Total serum T (best before 11:00 am) (1)[A]
- Free T
- Bioavailable T
  - No universally accepted lower limit of normal serum T
  - It is generally agreed that serum T >12 nmol/L (3.5 ng/mL, 350 ng/dL) does not usually need replacement (2)[A]
  - If T <8 nmol/L (2.3 ng/mL, 230 ng/dL) replacement is typically beneficial (2) [A]
- FDA research trial definition: Hypogonadism is total T levels of ≤ 300 ng/dL
- Serum albumin
- SHBG
- If secondary hypogonadism is suspected:
  - Serum prolactin; Serum gonadotropins (LH); thyroid function

Imaging
- Cranial imaging (MRI, CT) if prolactinoma suspected
- Dexa scan for the assessment of bone mineral density if at risk for osteopenia/osteoporosis (1)[B]

Diagnostic Procedures/Surgery
N/A

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Acute critical illness (surgery, head trauma)
- Age-related decline ("andropause")
- Alcoholism
- Chronic illness (liver failure, chronic renal failure, hypertension, hypothyroidism, diabetes, sleep apnea, obesity, anorexia nervosa, depression, HIV)
- Hematologic (sickle cell disease, thalassemia)
- Hemochromatosis of the pituitary, Leydig cells
- Hypopituitarism (hypothalamic/pituitary)
- Kallmann, Klinefelter, or Noonan syndrome
- Medications: LHRH analogues/antagonists, glucocorticoids, androgens, estrogens, progestins (eg, megestrol), chronic opioids, marijuana (controversial)
- Pituitary infections, infiltration, trauma, radiation (decreased LH/FSH production)
- Pituitary tumors, macroadenomas, hyperprolactinemia
- Syndromes Prader–Willi and Sertoli only
- Testicular failure (primary): Congenital or acquired anorchia, cryptorchidism, mumps orchitis, radiation therapy, chemotherapy
- Testicular tumors

TREATMENT

GENERAL MEASURES

- Treatment is warranted for men with clinical symptoms associated with objective biochemical findings of low T (2)[C]
  - In the context of significant symptoms and normal or borderline T levels, a trial of TRT is acceptable with appropriate follow-up to ensure improvement in symptoms (2)[C]. If no improvement is noted, further workup to delineate cause is warranted
- In the presence of visceral obesity, weight loss through regular exercise and low-caloric intake is recommended (2)[A]
- Appropriate glycemic, blood pressure, and lipid management is recommended
- TRT contraindications include:
  - Known prostate cancer (absolute)
  - Known breast cancer (absolute)
  - Unexplained prostate-specific antigen (PSA) elevation/suspicious DRE finding (absolute)
  - Severe lower urinary tract symptoms (LUTS) associated with BPH
  - Erythrocytosis (hematocrit >52–54%)
  - Uncontrolled/poorly controlled heart failure
  - Untreated OSA, although no scientific evidence exists demonstrating a direct causal relationship between T and OSA
  - Men seeking fertility
- Improvement is expected in:
  - Reduction of body fat/visceral obesity (2)[A]
  - Increase in fat-free mass/possibly muscle strength (1)[A]

- Insulin resistance/glycemic control in men with DMII (2)[A]
- Bone mineral density at lumbar spine (1)[A]
- Hypoactive sexual desire/ED/delayed ejaculation (1)[B]

- Considerations in the older male: The American Geriatrics Society (AGS) lists T as a medication to generally avoid in older adults because of potential for cardiac problems and men with personal history of prostate cancer.
- TRT agents/options outlined below
  - Transdermal agents may have best compliance; all provide uniform T level for 24 hr
  - Topical agents: Interpersonal transfer possible and should be avoided, especially for women and children
  - Gels should be dry before putting on clothes over application site; delay swimming
  - Brand names provided to avoid patient confusion; see FDA label for details

MEDICATION

First Line

- Buccal (Striant) 30 mg T/tab system
  - Dose: 30 mg BID
  - Avoids 1st-pass effect of hepatic inactivation
  - Apply to gum over incisor; do not chew/swallow
- Transdermal (Androderm): Apply to nonscrotal skin (back, abdomen, upper arms, thighs); avoid bony prominences; delivery 2 mg or 4 mg T/patch
  - Dose: Based on patch; start one 4 mg/patch/24 h; adjust to 1 or more patch combinations for desired effect
  - Skin irritation may be noted; remove for MRI
- Transdermal gels; product-specific dosing; apply clean dry: Shoulder, upper arm, or abdomen
  - (AndroGel 1%)
    - Dose: Topical daily 5–10 g (max)
  - (AndroGel 1.62%)
    - Dose: Topical 2 pump activations or 40.5-mg pack; adjust from 1 activation 20.25 mg or single 20.25 mg pack; 81 mg/d (max)
  - [Fortesta] 10 mg T/0.5 mg gel/activation; apply to inner thigh area only
    - Dose: Start 4 pump activations (40 mg) QAM; adjust 1–7 pump activations (10 mg–70 mg daily; 70 mg max
  - (Testim 1%) 50 mg T/5 g gel; 50 mg/unit dose tube; apply shoulder or upper arm
    - Dose: Topical 5–10 g/d/2 tubes MAX
- Transdermal solution
  - (Axiron) 30 mg T/1.5 mL of solution
    - Dose 60 mg T (1 pump = 30 mg of T solution to each axilla) daily; adjust based on levels
- IM short-acting formulations; may be associated with fluctuations in serum T (supraphysiologic 2–5 d after injection, subphysiologic 10–14 d after injection) which may be associated with symptom fluctuation
  - T cypionate (Depo-Testosterone) 200–400 mg IM every 3–4 wk or 100–150 mg
  - every 2 wk preferred

  - T enanthate (Delatestryl) 100–400 mg IM every 4 wk or 100–150 mg every 2 wk preferred
  - *Prepubertal boys*: 50–100 mg IM agent monthly or 25–50 mg every 2 wk, increase to 50–100 mg every 2 wk and then adult dose over 2–4 yr or until pubertal development occurs
- T implant
  - Pellets (Testopel) (75 mg/each) 150–450 mg SC implant every 3–6 mo
  - 2 pellets for each 25 mg T required weekly; in upper buttock with local anesthesia
  - Local symptoms such as pain, bleeding
  - Pellet infection and extrusion (up to 10%)
- Parenteral T undecanoate (Aveed): 750 mg IM (3 mL) initially, at 4 wk, then 750 mg every 10 wk
- T nasal gel (Natesto) 2 pumps each nostril (11 mg testosterone) one in each nostril TID (total 33 mg/day)
- T formulations outside the US:
  - Oral T undecanoate: 40–80 mg PO with meals BID to TID
  - T-in-adhesive matrix patch: 2 patches (4.8 mg T/d) applied every 2 days
  - T gel 2%: 3–4 g (60–80 mg of T) applied to abdomen or both inner thighs daily

Second Line

Any agent form the Frist Line medication can be used as second line if the product is ineffective or there are proactical use issues with an individual patient

SURGERY/OTHER PROCEDURES

Insertion of subdermal T pellets (see above MEDICATION: First Line)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- There may be therapeutic synergism with combined TRT and phosphodiesterase-5 inhibitors in men with low T and ED (2)[A]
- Other forms of androgen therapy include the usage of dehydroepiandrosterone (DHEA), dihydrotesto-sterone (DHT), although their use has not been proven effective (2)[B]
- Human chorionic gonadotropin (hCG) may preserve spermatogenesis in young men with hypogonadism (1)[B] (See Section I “Testosterone, Decreased [Hypogonadism]”)
- Antiestrogens and aromatase inhibitors may raise endogenous T in secondary hypogonadism if the hypothalamic–pituitary–testicular axis is intact
- Selective androgen receptor modulators (SARMs) may have a role in hypogonadism

Complementary & Alternative Therapies

There are no alternative therapies that will cure low T. Some stress management techniques can relieve the stress and anxiety associated with hypogonadism: Yoga, meditation techniques, emotional support/counseling, healthy lifestyle (nutritious diet, active exercise, adequate rest)

ONGOING CARE

PROGNOSIS

- Goal is for the restoration of serum T within normal lab limits; supraphysiologic levels should be avoided (2)[C]
- Target serum T should be 40–70% of upper limit of normal serum T (2)[C]
- There is no evidence of benefit for maintaining a circadian rhythm of serum T (2)[C]

COMPLICATIONS

- Erythrocytosis; gynecomastia; fluid retention
- No conclusive evidence that TRT increases the risk of or worsens pre-existing prostate cancer or LUTS secondary to BPH. Men effectively treated for prostate cancer, after sufficient period of surveillance has elapsed (at least 1 yr), may be candidates for symptomatic TRT (1)[B]
  - TRT should be reserved for patients with low-risk prostate cancer (Gleason grade <8, pT1-2, PSA <10 ng/mL)
  - Men considering TRT in this context must be counseled and understand the theoretical risks and the fact that T medications carry prostate cancer risk labeling

FOLLOW-UP

Patient Monitoring

- Clinical and biochemical verification of treatment effect should occur 1–6 mo after initiating TRT (depending on TRT modality) (1)[C]
  - Repeat assessment of serum T parameters
  - Dosage may be adjusted if still subphysiologic
  - Once the proper dose established, annual T measurements are usually sufficient
- Monitor hematocrit 3, 6, and 12 mo after initiating TRT, then annually (1)[A]
- Monitor prostate heath (DRE/PSA) 3, 6, and 12 mo after initiating TRT, then annually (1)[A]
- In men with known osteopenia or osteoporosis, bone mineral density should be verified after 6, 12, or 24 mo of TRT (1)[C]
- Monitoring lipids and glycemia is not routinely required for safety but should be done as part of general health maintenance

CODES

ICD9

- 257.2 Other testicular hypofunction
- V07.4 Hormone replacement therapy (postmenopausal)

ICD10

- E29.1 Testicular hypofunction
- Z79.890 Hormone replacement therapy (postmenopausal)

CLINICAL/SURGICAL PEARLS

- Treatment is usually indicated for men with both symptoms and lab evidence of low serum T.
- The risks and benefits of each TRT modality should be thoroughly discussed.
- Post-TRT initiation, patient monitoring for treatment effect, biochemical resolution, and development of adverse effects is critical.
- Patients who have completed prostate cancer treatment for localized disease cancer treatment may cautiously be initiated on TRT in certain circumstances.

TESTOSTERONE, DECREASED (HYPOGONADISM)

Philip T. Zhao, MD
Allen D. Seftel, MD

BASICS

DESCRIPTION

- Hypogonadism is the clinical syndrome associated with low serum testosterone (T)
  - Can occur in early age (early onset), although most commonly seen in aging males
  - Late-onset male hypogonadism may also be referred to as andropause, androgen deficiency in the aging male, or androgen deficiency syndrome
  - Usually associated with impaired sperm production; or with an isolated impairment of sperm production or function with normal T production.
- T is essential for:
  - Normal sexual function, growth and development of male sexual organs, and maintenance of male secondary sexual characteristics
- Normal levels and function result in:
  - Enhanced libido, increased energy, and production of RBCs; osteoporosis protection
- In utero hypogonadism
  - Ambiguous genitalia, normal female genitalia, microphallus, pseudovaginal perineoscrotal hypospadias, bifid scrotum, cryptorchidism
- Prepubertal hypogonadism:
  - Delayed puberty, microphallus, small testes, no male hair pattern, disproportionately long arms/legs, high-pitched voice, poor muscle mass
- Postpubertal/adult hypogonadism:
  - Lack of libido, erectile dysfunction (ED), hot flushes/sweats, gynecomastia, spermarche, infertility (oligospermia/azoospermia), poor vitality, depression, increased body fat/BMI, osteopenia/osteoporosis, hypercholesterolemia

EPIDEMIOLOGY

Incidence

N/A

Prevalence (1)

- 2–4 million men in US Hypogonadism increases with age
  - Overall 5.6–38.7% men are affected, depending on study
  - 6th decade: 12%; 7th: 19%; 8th: 29%; 9th: 49%

RISK FACTORS

- Testicular trauma/orchiectomy
- Medications
  - Decreased T production: Dopamine antagonists, corticosteroids, ethanol, ketoconazole, GnRH analogues/antagonists, metoclopramide
  - Decreased conversion of T to dihydrotestosterone (DHT): 5α-Reductase inhibitors
  - Androgen receptor blockade: Flutamide, spironolactone, cyproterone, cimetidine

- Infections (mumps orchitis, HIV)
- Medical conditions:
  - Iron toxicity to pituitary gonadotrophs, autoimmune diseases, endstage renal disease (ESRD)/uremia, histiocytosis X, pituitary apoplexy, myotonic dystrophy

Genetics

- Klinefelter syndrome
- Kallmann syndrome; mutation in Dax-1
- Laurence–Moon–Bardet–Biedl syndrome
- Prader–Willi syndrome
- Y chromosome microdeletion
- Congenital androgen resistance/insensitivity
- Alstrom, Rud, Bloom syndromes; mutations in leptin

PATHOPHYSIOLOGY

- T is regulated by the hypothalamic–pituitary–testicular axis
- Gonadotropin-releasing hormone (GnRH) neurons originate in the olfactory placode and migrate through the cribriform plate of the ethmoid to localize in the hypothalamus.
- Hypothalamus secretes GnRH, stimulates the pituitary to secrete leuteinizing hormone (LH) and follicle-stimulating hormone (FSH).
- GnRH pulse amplitude and frequency activate intracellular signalling mechanisms, which results in differential gene expression of the 2 subunits forming LH and FSH.
- LH stimulates testis Leydig cells to produce T. Feedback inhibition by T on the hypothalamus and pituitary maintains hormonal balance.
- FSH stimulates Sertoli cells to support spermatogenesis and secrete inhibin, which provides feedback on the pituitary
- Week long night/day shift work does not seem to change T levels
- T levels decrease 0.8–1.6% per year in men aged 40–70

ASSOCIATED CONDITIONS

- Increased risk for developing type 2 diabetes mellitus, metabolic syndrome, cardiac events, and a general reduction in survival
  - Impact on cardiac events is controversial with most publications supporting a protective effect of “normal” T levels

GENERAL PREVENTION

Screening: The Endocrine Society in US recommends against screening for androgen deficiency in the general population.

DIAGNOSIS

HISTORY

- Development:
  - Genital abnormalities (eg, hypospadias, microphallus, cryptorchidism); delayed sexual development/growth; need for hormone therapy; family history of delayed puberty or reproductive disorders; psychological impact of delayed puberty or growth; difficulty in school or learning disability; inability or reduced ability to smell

- Sexual function:
  - Poor erections; reduced spontaneous, nighttime, morning erections; inability to perform sexually; decreased sexual activity; inability to father children despite unprotected sexual relations (>1 yr); small or shrinking testes
- Brain function:
  - Poor general well-being; reduced sexual desire, interest, and motivation (libido); poor energy/vitality; excessive fatigue; poor motivation and initiative, passivity, low self-confidence/self-esteem; depressed mood; irritability; difficulty sleeping; hot flushes/sweats; poor concentration and memory
- Body function
  - Decreased muscle bulk/strength; reduced physical activity or performance; breast enlargement/tenderness, especially if recent in onset; height loss, history of low trauma or vertebral compression fractures, osteopenia, or osteoporosis; body hair loss; reduced beard growth and shaving frequency.

PHYSICAL EXAM

- Assess height and eunuchoidal proportions:
  - Arm span >2 cm > height; heel–pubis >2 cm > pubis–crown normal
- Secondary sexual characteristics, gynecomastia, bone age determination
- External genitalia: Testis and phallus
  - Testis volume
    - Measure with a Prader orchidometer (normal adult 15–25 mL)
    - <6 mL characteristic of prepubertal hypogonadism
    - Soft and atrophic but normal sized suggestive of postpubertal hypogonadism
    - Small, firm suggests Klinefelter syndrome
  - Genital ambiguity; hypospadias/micropenis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- There is no consensus among specialists (endocrinologists, urologists, pathologists) as to what lab values define a “low” T level.
- The Food and Drug Administration (FDA) uses a cutoff value of 300 ng/dL to define hypogonadism for clinical trial development and enrollment.
- Society definitions of T levels and hypogonadism are summarized in Section II: “Hypogonadism, Society Definitions”.
- Total T concentrations are affected by alterations in sex hormone-binding globulin (SHBG), and T levels may be suppressed transiently with illness, certain medications, and some nutritional deficiencies
- If an isolated serum T is low, measure an early morning total serum T, bioavailable T (useful in equivocal cases), and LH.
- If the morning T is low, check serum prolactin:
  - Prolactin elevated: Obtain MRI and consult with an endocrinologist
  - Prolactin normal/low: 1) LH elevated: Primary hypogonadism; 2) LH normal/low: Obtain serum FSH and evaluate causes of secondary hypogonadism in consultation with an endocrinologist

Imaging
MRI if lab suggests pituitary tumor

Diagnostic Procedures/Surgery
N/A

Pathologic Findings
Atrophic testes in primary hypogonadism

DIFFERENTIAL DIAGNOSIS
- Hypergonadotropic hypogonadism (primary testicular failure); inadequate production of T despite adequate/elevated levels of LH/FSH:
  – Klinefelter syndrome (most common); congenital XXY karyotype (1 in 576 male births)
  – Impaired secretion of T and spermatogenesis
  – Cryptorchidism, varicocele, bilateral anorchia
  – Gonadal failure (chemotherapy/radiotherapy)
  – Inactivating mutations of GnRH or gonadotropin receptor
- Hypogonadotropic hypogonadism (secondary hypogonadism): Inadequate stimulation of production of testicular androgen/spermatogenesis (low FSH/LH associated with low T)
  – Kallmann syndrome: Abnormal migration of the GnRH neurons; anosmia and small testes
  – Adrenal hypoplasia congenita: Constitutional delay of growth and puberty
  – Chronic illness (celiac disease, Crohn disease, sickle cell, cystic fibrosis, diabetes)
  – Malnutrition, hyperprolactinemia, hypothyroidism
  – Hypopituitarism: Congenital vs. acquired (radiotherapy, CNS malignancy, infection, trauma)
  – Isolated gonadotropin deficiency
  – Congenital: Kallmann syndrome
  – Acquired: Intracranial neoplasm (craniopharyngiomas, gliomas, prolactinomas)
  – Syndromes with hypogonadotropism: See “Genetics” above

TREATMENT

GENERAL MEASURES
- Treatment should be guided by the intentions and desires of the patient.
- Avoid T replacement in a man with infertility seeking to regain fertility.
- Consider whether low serum T might be transient suppression caused by a critical, acute/subacute illness, or recovery from an acute illness; short-term use of certain medications; transient malnutrition; or excessive and chronic strenuous endurance exercise.
- A consensus statement from a group of professional societies (ISA, ISSAM, EAU, EAA, and ASA see Section II: “Hypogonadism, Society Definitions”) recommended (2,3):
  – T >350 ng/dL do not treat
  – T <230 ng/dL (with symptoms) may require T replacement therapy (TRT)
  – Levels between 230–350 ng/dL, the recommendation is to repeat the T with SHBG for calculation of free testosterone or direct measurement of free testosterone by equilibrium dialysis.
  – It has been previously recommended that men with T <200 ng/dL be treated as

hypogonadal; T >400 ng/dL be considered normal and those with TT 200–400 ng/dL be treated based on their clinical presentation if symptomatic.

- Hypogonadotropic hypogonadism:
  - Treat the underlying cause
  - TRT may still be required
- Hyperprolactinemia:
  - Discontinue offending medications
  - Dopamine agonists (bromocriptine)
- If fertility is not desired, TRT may be instituted.
- Obtain baseline digital rectal exam (DRE), CBC, lipid profile, PSA
  - T replacement may be associated with lipid abnormalities, polycythemia, azoospermia, sleep apnea, and possible prostatic changes.
- The overall goal of TRT is to correct or improve the clinical manifestations of androgen deficiency in men
- TRT agents/options outlined below
  - Transdermal agents may have best compliance; all provide uniform T level for 24 hr
  - Topical agents: Interpersonal transfer possible and should be avoided, especially for women and children
  - Gels should be dry before putting on clothes over application site; delay swimming
  - Brand names provided to avoid patient confusion; see FDA label for details

MEDICATION

First Line

- Buccal (Striant) 30-mg T/tab system
  - Dose: 30 mg BID
  - Avoids 1st-pass effect of hepatic inactivation
  - Apply to gum over incisor; do not chew/swallow
- Transdermal (Androderm): Apply to nonscrotal skin (back, abdomen, upper arms, thighs); avoid bony prominences; delivers 2- or 4-mg T/patch
  - Dose: Based on patch; start one 4 mg/patch/24 h; adjust to 1 or more patch combinations for desired effect
  - Skin irritation may be noted; remove for MRI
- Transdermal gels; product-specific dosing; apply clean dry: Shoulder, upper arm, or abdomen
  - (AndroGel 1%)
    - Dose: Topical daily 5–10 g (max)
  - (AndroGel 1.62%)
    - Dose: Topical 2 pump activations or 40.5-mg pack; adjust from 1 activation 20.25 mg or single 20.25-mg pack; 81 mg/d (max)
  - (Fortesta) 10-mg T/0.5 mg gel/activation; apply to inner thigh area only
    - Dose: Start 4 pump activations (40 mg) QAM; adjust 1–7 pump activations (10–70 mg daily; 70 mg max
  - (Testim 1%) 50-mg T/ 5 g gel; 50 mg/unit dose tube; apply shoulder or upper arm
    - Dose: Topical 5–10 g/d/2 tubes MAX
- Transdermal solution

- (Axiron) 30-mg T/1.5 mL of solution
  - Dose 60-mg T (1 pump = 30 mg of T solution to each axilla) daily; adjust based on levels

- IM short acting formulations; may be associated with fluctuations in serum T (supraphysiologic 2–5 days after injection, subphysiologic 10–14 days after injection) which may be associated with symptom fluctuation
  - T cypionate (Depo-Testosterone) 200–400 mg IM every 3–4 wk or 100–150 mg every 2 wk preferred
  - T enanthate (Delatestryl) 100–400 mg IM every 4 wk or 100–150 mg every 2 wk preferred
  - *Prepubertal boys*: 50–100 mg IM agent monthly or 25–50 mg every 2 wk, increase to 50–100 mg every 2 wk and then adult dose over 2–4 yr or until pubertal development occurs
- T implant
  - (Testopel) pellets (75 mg/each) 150–450 mg SC implant every 3–6 mo
  - 2 pellets for each 25-mg T required weekly; in upper buttock with local anesthesia
  - Local symptoms such as pain, bleeding
  - Pellet infection and extrusion (up to 10%)
  - T nasal gel (Natesto) 2 pumps each nostril (11 mg testosterone) one in each nostril TID (total 33 mg/day)
- T formulations outside US:
  - Oral T undecanoate: 40–80 mg PO with meals BID to TID
  - Parenteral T undecanoate: 1,000 mg IM initially, at 6 wk, then 1,000 mg every 10–14 wk; long lasting
  - T-in-adhesive matrix patch: 2 patches (4.8-mg T/d) applied every 2 days
  - T gel 2%: 3–4 g (60–80 mg of T) applied to abdomen or both inner thighs daily

Second Line

Any of the agents noted as First line can be potentially used a second line alternative agents

SURGERY/OTHER PROCEDURES

Pituitary adenoma: Transsphenoidal resection

ADDITIONAL TREATMENT

Radiation Therapy

- Pituitary microadenoma or macroadenoma (>1.0 cm):
  - Transsphenoidal resection ± radiation therapy

Additional Therapies

- If hypogonadotropic: May provide GnRH/gonadotropins to stimulate testicular production of androgen
- To initially stimulate T and sperm production:
  - Human chorionic gonadotropin (hCG): 500–2,000 IU given SQ 2–3x weekly to maintain serum T levels within the normal range for 6–12 mo
- Added to hCG to stimulate sperm production:
  - FSH/human menopausal gonadotropin (hMG), human FSH (hFSH), recombinant human FSH (rhFSH): After 6–12 mo of hCG treatment alone resulting in normal T levels, add FSH 75–300 IU is given SQ 3 times weekly for an additional 6–12 mo or longer
- To stimulate T/sperm production:

– GnRH: 5–25 ng/kg SQ every 2 hr by programmable infusion pump for 6–12 mo

Complementary & Alternative Therapies

- There are no alternative therapies that will cure hypogonadism
  – No data to support the use of over the counter or direct to consumer "natural" T supplements.
- Some stress management techniques can relieve the stress and anxiety associated with hypogonadism:
  – Yoga, meditation techniques, emotional support/counseling, healthy lifestyle (nutritious diet, active exercise, adequate rest)

ONGOING CARE

PROGNOSIS

Excellent ability to restore T levels to the normal range by adjusting dosage of medication and improve symptoms of hypogonadism (4)

COMPLICATIONS

- Hypogonadism (5):
  – "Metabolic syndrome": Anemia, increased fasting blood sugar, increased uric acid, increased cholesterol, increased body fat
  – Appetite changes (increased or decreased)
  – Balance problems
  – Body hair loss
  – Dry eyes
  – Edema or leg pain
  – Fatigue
  – GI and/or respiratory disturbances
  – Gynecomastia/breast tenderness
  – Hot flushes/flashes/sweats
  – Loss of libido/impotence
  – Muscle weakness/wasting
  – Osteoporosis
  – Psychologic: Depression, memory difficulties, emotional lability
  – Testicular atrophy
  – Weight gain/increased body fat
- T replacement:
  – Fluid retention
  – Gynecomastia
  – Hepatotoxicity
  – Sleep apnea
  – Theoretical risk of progression of prostate cancer: Unsubstantiated in recent studies

FOLLOW-UP

Patient Monitoring

- Every 3 mo (CBC, PSA, DRE) after starting treatment annually for response and adverse effects

- In men with known osteopenia or osteoporosis, bone mineral density should be verified after 6, 12, or 24 mo of TRT
- Monitoring lipids and glycemia is not routinely required for safety but should be done as part of general health maintenance

Patient Resources

- Guidelines on male hypogonadism (U.S. Department of Health & Human Services). http://guideline.gov/content.aspx?id=37626

CODES

ICD9

- 257.2 Other testicular hypofunction
- 792.2 Nonspecific abnormal findings in semen
- 799.81 Decreased libido

ICD10
- E29.1 Testicular hypofunction
- R68.82 Decreased libido
- R86.9 Unsp abnormal finding in specimens from male genital organs

CLINICAL/SURGICAL PEARLS

- Early morning serum total T below 300 ng/dL on at least 2 occasions in a symptomatic man usually confirms hypogonadism.
- Gonadotropins (LH and FSH) distinguish between a primary and a secondary cause.
- When caused by pituitary adenoma, patients can have additional symptoms due to mass effects, such as headaches or peripheral visual disturbance. There may also be signs and symptoms of other pituitary hormone deficiencies.
- Low T might be transient suppression (critical, acute/subacute illness, short-term use of certain medications; transient malnutrition; or excessive and chronic strenuous endurance exercise).

TORSION, TESTIS OR TESTICULAR/EPIDIDYMAL APPENDAGES

Julia S. Barthold, MD, FACS

BASICS

DESCRIPTION

- Torsion of the testicle or testicular/epididymal appendages results in vascular compromise to the testicle or 1 of the appendages.
- Impaired perfusion of the testis, appendix testis, or appendix epididymis is caused by spermatic cord (testicular) torsion or appendix torsion
- Presents as acute scrotal and/or inguinal pain with or without scrotal erythema and swelling
- Occurs primarily in children

EPIDEMIOLOGY

Incidence

- Most scrotal pain occurs at age 12–18
- Bimodal age distribution
  - Perinatal: Extravaginal testicular torsion
  - Prepubertal:
    - More commonly appendix torsion
    - Some data suggests this may be the most common cause of acute scrotal pain in children
  - Puberty: Peak incidence of intravaginal testicular torsion, but can occur at any age

Prevalence

1:4,000 males < 25 yo

RISK FACTORS

- Usually none
- Cryptorchidism
- History of contralateral torsion
- Familial clustering has been reported

Genetics

- Testicular torsion reported in 10% of family members; may be autosomal or X-linked recessive (1)
- No specific genetic defects identified

PATHOPHYSIOLOGY

- Testicular torsion can be either intravaginal or extravaginal
  - Intravaginal testicular torsion
    - Twisting of the spermatic cord *within* the tunica vaginalis
    - Due to congenital incomplete fixation of testis within the tunica vaginalis (bell-clapper deformity, see image)
    - Intermittent or sustained

- Impaired venous outflow, impaired arterial inflow, ischemia, potential testicular necrosis
- May progress to compartment syndrome
- Ischemia/reperfusion injury causes impaired spermatogenesis in animal models

• Extravaginal testicular torsion
– Twisting of both the spermatic cord *and* tunica vaginalis
– Due to incomplete fixation of the tunica vaginalis to the scrotum in the perinatal period
• Appendix torsion: Vascular compromise may be related to pedunculated anatomy of the appendage (image)
– Appendix testis (also known as hydatid of Morgagni)
- A vestigial Müllerian duct remnant present in majority of males (92%)
- Typical position: The superior testicular pole in the groove between the testicle and the epididymis.
- Accounts for 95% of appendage torsions

– Appendix epididymis
- A vestigial Wolffian duct remnant is less commonly present

– The paradidymis (organ of Giraldes) and the vas aberrans (organ of Haller) are 2 other appendages that are not clinically important.

ASSOCIATED CONDITIONS
• Bell-clapper deformity: 10–15% of males
• Cryptorchidism

GENERAL PREVENTION
• Reduce testicular necrosis risk by:
– Early diagnosis and treatment
– Community awareness about testis pain
– Elective bilateral orchidopexy for intermittent pain or contralateral orchidopexy at surgery for an episode of acute torsion

DIAGNOSIS

HISTORY
• Intravaginal testicular torsion
– Usually severe pain, sudden onset
– Nausea/vomiting more common
– May be recurrent usually same side
• Extravaginal testicular torsion
– Usually painless and asymptomatic
• Appendix torsion
– Usually more gradual but may be acute
– Pain may be mild or severe
– Nausea/vomiting uncommon
– No prior episodes
• Inguinal or abdominal pain may be associated or may be only site of pain in younger boys
• Irritative voiding symptoms possible
• History alone is suggestive only and often not reliable in differentiating testicular torsion,

appendix torsion, and other causes of scrotal pain

PHYSICAL EXAM

- Note: Phren sign (elevation of scrotum relieves pain in epididymitis but in torsion it is no longer considered reliable)
- Intravaginal testicular torsion: These are possible findings but these may be highly variable.
  - Early
    - Generalized testicular tenderness
    - Loss of ipsilateral cremasteric reflex
    - Elevated ipsilateral testis or transverse lie (look for this in intermittent testicular torsion cases)
    - Anterior epididymis
  - Late
    - Any of the above; increasing scrotal swelling and erythema
    - Loss of scrotal rugation ± hydrocele
    - Inability to distinguish epididymal landmarks
- Extravaginal testicular torsion
  - Firm to hard nontender testis
  - Scrotal discoloration
- Appendix torsion
  - Early
    - Localized tenderness superior to testis
    - Supratesticular nodule
    - Preserved ipsilateral cremasteric reflex
    - Normal testicular position and orientation
    - Blue dot sign: Rare, more likely in prepubertal boys; tender nodule with blue discoloration on the upper pole of the testis and more easily see in light-skinned individuals
  - Late
    - Any of the above
    - Generalized tenderness
    - Increasing scrotal swelling and erythema
    - Hydrocele

ALERT

- No H&P findings are completely reliable in diagnosis of the acute scrotum.
- Urgent surgery always needed if evaluation does not rule out the possibility of spermatic cord torsion.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis
  - If pyuria suspect epididymitis/UTI
  - If hematuria consider renal or ureteral source of pain (eg, stone)
- Urine culture if indicated
- Additional labs not needed

Imaging

- Scrotal US with Doppler
  - Need to identify **waveforms** that originate in the central parenchyma
  - Intravaginal testicular torsion findings:
    - Usually shows decreased or absent arterial flow but may be normal
    - Increased flow possible in intermittent testicular torsion
    - Increased or mixed echogenicity suggests torsion: Compare both sides
    - Hydrocele and/or enlarged epididymis may be present
    - Visible twist of cord: Requires expertise but highly specific if present
  - Extravaginal testicular torsion findings:
    - Heterogeneous appearance typical
    - Doppler flow may be hard to demonstrate in neonatal testes
    - Calcification may be present
  - Appendix torsion findings:
    - Normal exam most common
    - Supratesticular complex mass w/o vascular flow may be present
    - Enlarged epididymis reported as “epididymitis” often present
    - Doppler flow normal or increased
  - Doppler flow normal
  - Thickened scrotal skin and hydrocele are nonspecific findings in acute scrotum cases
- Nuclear scan: Rarely performed

Diagnostic Procedures/Surgery

Exploration for diagnosis if equivocal findings on exam and/or US, suspicion of testicular rupture, or tumor

Pathologic Findings

- Testicular necrosis (intravaginal) or subtotal loss of tubules with calcification (extravaginal) testicular torsion
- Severity of injury depends on age, duration of testicular torsion, number of twists/thickness of spermatic cord
- In cases of appendicular torsion the necrotic tissue is reabsorbed usually without any sequelae

DIFFERENTIAL DIAGNOSIS

- Acute testicular pain
  - Appendix torsion most common in prepubertal boys
  - Testicular torsion most common in peripubertal boys but can occur at any age; less common than appendix torsion
  - Epididymitis due to UTI or STD: Rare or uncommon in pediatric age group; more likely in adult
  - Communicating hydrocele ± meconium
  - Incarcerated inguinal hernia
  - Trauma and possible testicular rupture
    - Hematocele present
  - Orchitis (eg, mumps)

- Henoch–Schönlein purpura
  - Rash usually present
- Fournier gangrene (rare in children)
- Referred pain from urolithiasis or intra-abdominal process such as appendicitis
- Orchalgia; consider voiding dysfunction

TREATMENT

GENERAL MEASURES

- Testicular torsion: Consider manual detorsion in ER
  - Not routine; consider if surgical delay
  - Most likely to be effective early in course
  - Sedation recommended
  - External rotation of testis when viewed from the feet ("opening a book")
  - Not always effective, 1/3 of cases may rotate laterally
  - Does not preclude need for immediate surgery
- Appendix torsion: Rest until pain resolves
  - Urgent re-evaluation if pain worsens or is recurrent

MEDICATION

First Line

- Ibuprofen to reduce inflammation in appendix torsion
- Antibiotics for UTI, STDs

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Testicular torsion
  - Emergent exploration indicated if evaluation suggests intravaginal testicular torsion or diagnosis is equivocal
  - Detorsion, observation for reperfusion, and bilateral orchidopexy via scrotal approach with fixation of testis extravaginally
  - Consider capsulotomy; if flow improves with placement of tunica vaginalis patch
  - Urgent exploration, bilateral fixation for extravaginal testicular torsion to avoid asynchronous contralateral torsion (2)
  - Avoid imaging/delay if findings are classic
  - Elective surgery for resolved intermittent testicular torsion (3)
  - Orchiectomy in antenatal extravaginal testicular torsion or if testis appears nonviable after detorsion ± capsulotomy
  - Consider delayed prosthesis placement for monorchia
- Appendix torsion
  - Prolonged pain not responsive to conservative measures
  - Recurrent episodes (rare) or diagnostic uncertainty

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Experimental agents such as nitric oxide (NOS) inhibitors to reduce reperfusion injury in testicular torsion not used clinically

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Intravaginal testicular torsion
  - Risk of postoperative atrophy increases with duration of torsion
  - Testicular loss 1st seen at 4 hr, increasing after 6 hr, 80% after 12 hr and essentially universal after 24 hr
  - Risk of subfertility unclear but probably higher after postpubertal torsion
- Extravaginal testicular torsion
  - No salvage in cases of antenatal torsion
  - Risk of contralateral torsion in the neonatal period low but present with contralateral fixation recommended
  - Long-term risks unknown but fertility potential presumed normal

COMPLICATIONS

- Recurrent testicular torsion: Rare, occurs with failure of absorbable or nonabsorbable suture fixation of a testis that remains within an intact tunica vaginalis
- Testicular atrophy

FOLLOW-UP

Patient Monitoring

- Follow for at least 6 mo to determine risk of atrophy
- Monitor for recurrent testicular pain
- Scrotal protection in contact sports
- Education of healthy adolescent populations about the signs/symptoms of testicular torsion and the benefits of early evaluation and treatment
- Specific educational focus on family members of affected individuals

Patient Resources

CODES

ICD9

- 608.20 Torsion of testis, unspecified
- 608.23 Torsion of appendix testis
- 608.24 Torsion of appendix epididymis

ICD10

- N44.00 Torsion of testis, unspecified
- N44.03 Torsion of appendix testis
- N44.04 Torsion of appendix epididymis

CLINICAL/SURGICAL PEARLS

- Diagnosis of spermatic cord torsion requires a high index of suspicion, particularly in patients with intermittent testicular pain.
- Emergent surgery is indicated for all cases of suspected spermatic cord torsion.
- The risk of testicular loss increases after 4–6 hr of untreated spermatic cord torsion.

TRANSPLANT REJECTION, RENAL

Eric Langewisch, MD
Jason C. Hedges, MD, PhD

BASICS

DESCRIPTION

- The hallmark of renal transplant rejection is immunologic damage to the transplanted kidney due to donor-specific response by recipient immune system
- Classification of rejection:
  - Hyperacute (immediately after revascularization of the kidney graft)
    - Kidney becomes mottled and cyanotic usually in the OR
  - Accelerated (days to weeks after transplantation)
  - Acute (weeks to months after transplantation)
  - Chronic (months to years after transplantation)

EPIDEMIOLOGY

Incidence

15% rejection rate in 1st yr for those rejection-free at hospital discharge after transplantation

Prevalence

N/A

RISK FACTORS

- Presence of preformed human leukocyte antigen (HLA) antibodies
- Positive crossmatch between donor and recipient
- Previous transplant, pregnancy, blood transfusion
- Prior rejection episodes
- Delayed graft function
- African American race
- Noncompliance with immunosuppressant medications

Genetics

Greater degree of HLA mismatch between donor and recipient increases risk of rejection

PATHOPHYSIOLOGY (1)

- Hyperacute rejection: Mediated by preformed cytotoxic antibodies against kidney graft (develop after prior transfusion, transplantation, and child birth)
- Acute rejection: Most cases are acute cellular rejection (ACR) mediated by T-cell recognition of donor major histocompatibility (MHC) proteins that are presented by antigen-presenting cells (APCs) and T-cell activation. This results in mononuclear cell infiltration of interstitium, tubules (tubulitis), and endothelium (vasculitis)
- Acute antibody-mediated rejection (AMR) is mediated by circulating donor-specific antibodies (DSAs) to foreign donor HLA. Recipient antibodies bind to donor HLA, activate complement, and recruit inflammatory mediators.
- Chronic rejection: Fibrosis and atrophy from chronic allograft damage. Limited viable

allograft with active inflammation.

ASSOCIATED CONDITIONS

Common causes of end-stage renal disease: Diabetes, hypertension, glomerulonephritis, cystic renal disease

GENERAL PREVENTION

- Avoid incompatible donors for kidney transplant recipient. Avoid transplants across a positive crossmatch or with preformed DSAs.
- Induction immunosuppression with lymphocyte-depleting agents, especially for high immunologic risk recipients
- Compliance with immunosuppressant medications
- Monitor renal function and maintain therapeutic immunosuppressant drug levels
- Minimize sensitizing events (eg, blood transfusions and pregnancies)

DIAGNOSIS

HISTORY

- Medication noncompliance or tapering off immunosuppression for a failed allograft
- Often asymptomatic with plasma creatinine elevation as sole abnormality.
- Severe rejection may result in decreased urine output and pain over kidney transplant.
- Fluid retention/weight gain

PHYSICAL EXAM

- May be normal
- Increased blood pressure
- Volume overload
- May have tenderness over kidney transplant

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Rising BUN/plasma creatinine
  - Otherwise unexplained plasma creatinine rise >20% over baseline is suggestive of rejection.
- Urinalysis and urine culture
  - Rule out pyelonephritis.
- Determine drug levels (tacrolimus or cyclosporine)
  - 12-hr trough level (usually before morning dose)
  - Suspect calcineurin inhibitor (CNI: Tacrolimus or cyclosporine) toxicity if abnormally high levels
  - Target levels vary by patient and assay
- If antibody-mediated rejection (AMR) is suspected, test for donor-specific antibodies (DSAs)

Imaging

- Renal ultrasound
  - Rule out obstructive uropathy or stone.
  - Assess for diminished renal blood flow.
    - Color flow Doppler evaluates vascular status

– Detect graft swelling (with acute rejection; graft may be small with chronic rejection).
- Nuclear medicine renal scan:
  – Rejection: Decreased renal blood flow/glomerular filtration rate
  – Arterial or venous thrombosis: Decreased or absent perfusion. With complete obstruction, a reniform photopenic area can be seen
  – Acute rejection/acute tubular necrosis: Marked parenchymal retention with normal or mildly reduced perfusion. Rejection will show progressive decrease in function over time.

Diagnostic Procedures/Surgery
- Needle biopsy of transplant kidney (confirmation of rejection)
  – Usually under ultrasound guidance
  – Automated biopsy gun device, needle sizes 14–18 gauge
  – Adequate sample
    - ≥2 cores of cortex, ≥7 glomeruli, and ≥2 arteries required

Pathologic Findings
- Acute cellular rejection
  – Interstitial mononuclear cell infiltrate
  – Tubulitis
  – Vasculitis (in more severe cases)
- Acute antibody-mediated rejection
  – Pathology variable
  – Acute tubular necrosis (ATN)
  – Glomerulitis
  – Peritubular capillaritis
  – Fibrin thrombi
  – C4d staining (C4d is a complement split product that covalently binds to tissue indicating antibody-mediated complement activation)
- Chronic rejection
  – Interstitial fibrosis
  – Tubular atrophy

DIFFERENTIAL DIAGNOSIS
- Prerenal: volume depletion or hypotension
- CNI (calcineurin inhibitor) toxicity (tacrolimus or cyclosporine)
- Pyelonephritis
- ATN
- Technical complications
  – Arterial or venous thrombus,
  – Arterial stenosis
  – Ureteral obstruction or urine leak (early posttransplant)
- Obstructive uropathy
- Recurrence of original renal disease

TREATMENT

GENERAL MEASURES

- Attempt to reverse rejection with medical therapy
- Graft removal may be necessary in severe rejection eg, hyperacute rejection.

MEDICATION

First Line

- Acute cellular rejection: High-dose glucocorticoids
  - Methyl prednisolone IV or high-dose oral prednisone (eg, 5 mg/kg) for 3–5 days followed by taper to maintenance dosing
- Antibody-mediated rejection: Plasmapheresis and intravenous immune globulin (IVIG) ± rituximab in attempt to remove, neutralize, or prevent the production of DSAs, respectively
- Chronic rejection: No effective therapy.
- Hyperacute rejection: Remove transplanted kidney (2)[A]
  - Can result in DIC if not removed promptly

Second Line

- Acute cellular rejection: Lymphocyte-depleting agents such as antithymocyte globulin (ATG) or alemtuzumab may be given for severe rejection or rejection refractory to high-dose glucocorticoid therapy (3)[A].
  - Significant reactions possible with 1st doses including anaphylaxis, pulmonary edema, fever, hemodynamic instability
  - Must be inpatient for initiation of therapy
  - Pretreat with glucocorticoids, diphenhydramine, and acetaminophen
  - Monitor CBC for therapy-related leukopenia or thrombocytopenia (may be severe)
  - Consider prophylaxis against cytomegalovirus (CMV) (eg valganciclovir)
  - Continue maintenance immunosuppression

SURGERY/OTHER PROCEDURES

- Allograft nephrectomy
  - Remove a symptomatic, irreversibly rejected kidney transplant.
  - Remove an asymptomatic, chronically rejected kidney to withdraw immunosuppression and prevent further development of anti-HLA antibodies

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Severe rejection and graft failure may require acute dialysis

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Repeated episodes of acute rejection reduce allograft survival
- Relative risk of graft failure is 1.8 for patients who have had 1 episode of rejection

compared to none (4)

COMPLICATIONS

- DIC can accompany hyperacute rejection
- Graft loss can result from untreated or unrecognized rejection episode
- Cyclosporin toxicity can resemble mild acute rejection.
- Need to resume dialysis

FOLLOW-UP

Patient Monitoring (5)

- Compliance with anti rejection critical
- Therapeutic drug levels: Including monitoring of CNI toxicity
- Plasma creatinine
- Monitor for recurrence of native kidney disease (ie, diabetes, hypertension, etc.)
- Protocol transplant biopsies (optional)

CODES

ICD9

996.81 Complications of transplanted kidney

ICD10

- T86.11 Kidney transplant rejection
- T86.12 Kidney transplant failure

CLINICAL/SURGICAL PEARLS

- Don’t confuse kidney transplant rejection with pyelonephritis.
- Cyclosporin toxicity can resemble mild acute rejection.

TRANSURETHRAL RESECTION (TUR) SYNDROME

Philip J. Dorsey, Jr., MD, MPH
Raju Thomas, MD, MHA, FACS

BASICS

DESCRIPTION

- Transurethral resection (TUR) syndrome is classically associated with TUR of the prostate (TURP) and is characterized by confusion, hypertension (HTN), bradycardia, and visual disturbances.
- Symptoms are caused by hypervolemia, dilutional hyponatremia, and solute effects from irrigant absorption during resection.
- While traditionally associated with prostate resection, it can also be seen in TUR of bladder tumor (TURBT) and has also been described for procedures such as hysteroscopy.
- Use of bipolar TURP and laser TURP techniques with normal saline irrigant has led to decreased incidence of TUR syndrome.
- Synonym(s): TURP syndrome

EPIDEMIOLOGY

Incidence

- 0.3–2% incidence (1)[B]
- Can occur as early as 15 min into resection or up to 24 hr after a TUR procedure
- Higher risk when hypotonic irrigation is used
- The declining use of TURP, because of medical management options, for the management of benign prostatic hypertrophy (BPH) has led to a reduction in the incidence of this syndrome

Prevalence

N/A

RISK FACTORS

- Resection time >60 min
- Gland size >45 g
- Intravesical pressures >30 mm Hg
- Operative technique (open venous sinuses, capsular perforations increase risk)
- Sympathetic blockade associated with spinal anesthesia may contribute to late hypotension.

Genetics

N/A

PATHOPHYSIOLOGY

- Irrigants used are osmotically active.
- Osmolarity of TUR irrigant solutions:
  - Normal serum: 280–310 mOsm/L
  - 5% mannitol: 275 mOsm/L
  - 1.5% glycine: 200 mOsm/L
  - 2.7% sorbitol/0.5% mannitol: 178 mOsm/L

  – 3% sorbitol: 165 mOsm/L
- Irrigant is absorbed by venous sinuses opened during resection or by slow absorption from the periprostatic and perivesical spaces in case of capsular perforation.
- As osmotically active solute enters the intravascular space, the plasma sodium concentration drops, leading to hypo-osmolality.

Volume effects:

- Increase in intravascular volume initially leads to hypervolemia, HTN, and reflex bradycardia; later hypotension can occur.
- Volume overload of the left ventricle may also lead to PE and respiratory failure.

ALERT
After 30–40 min of resection, flow from the intravascular space to peripheral tissues increases and can cause hypovolemia and hypotension (2)[B].

- Hyponatremia:
  – Caused by loading the intravascular space with nonelectrolyte solution
  – Contributes to CNS disturbances
  – If serum sodium levels rapidly decrease to <120 mEq/L, negative inotropic effects are manifested as hypotension and ECG changes of widened QRS complexes, ventricular ectopy, ST-segment depression, or T-wave inversions

Sodium Concentration	Symptoms
130–135 mEq/L	Asymptomatic
120–130 mEq/L	Restlessness, confusion
115–120 mEq/L	Nausea
<115 mEq/L	Seizures, coma

- Hypo-osmolality:
  – Blood–brain barrier is basically impermeable to sodium, but water crosses freely.
  – Osmotic gradient causes uptake of water by CNS tissue.
  – Resulting cerebral edema can exacerbate HTN and bradycardia via the Cushing reflex.
- Hypo-osmolar plasma results in RBCs taking on water, causing hemolysis.
- Renal failure secondary to hypotension and hemoglobinemia
- Hyperglycemia:
  – Glycine is a GABA-like inhibitory neurotransmitter.
  – Serum levels of glycine 17 times that of normal adults have been recorded in patients after TURP using glycine irrigant.

ALERT
Signs of glycine toxicity mimic the hyponatremic symptoms of the TUR syndrome (visual disturbances, nausea, vomiting, headache, malaise, and weakness) (3)[B].

- Glycine can cause visual disturbances and even transient blindness independent of hyponatremic or hypo-osmolar effects.
- Glycine may also have direct toxic effects on the kidney, possibly via metabolism to oxalate.
- Hyperammonemia:
  – Glycine is metabolized by the liver and kidneys to 2 potential toxins, glyoxylic acid and ammonia.

– Elevated serum ammonia may contribute to CNS derangement.

ASSOCIATED CONDITIONS

- BPH
- Bladder tumors

GENERAL PREVENTION

- Using irrigants such as glycine, sorbitol, and mannitol solutions reduces the hemolytic effects associated with sterile water irrigation.
  – Glycine is no longer recommended as an irrigation fluid.
- Intravesical pressure can be reduced by using continuous-flow equipment, draining the bladder with a suprapubic tube, or lowering the fluid height to <60 cm.
- If a significant extraperitoneal perforation occurs during the TURP or TURBT, it may be best to abandon the procedure after achieving hemostasis to prevent excessive fluid absorption.
- Appropriate selection of patients for TURP is based on gland size:
  – Limit resection time to <60–90 min.
  – Consider open prostatectomy, or other appropriate options, for adenoma >100 g measured by imaging studies.
- Judicious use of IV diuretics
- Use of bipolar resectoscopes to perform TURP allows for saline irrigation:
  – Reduces the hypo-osmotic effect of the absorbed fluid
- Use of laser energy sources for TUR management also decreases occurrence of TUR syndrome.

DIAGNOSIS

A patient who is slow to awaken from anesthesia or complains of visual disturbances should be considered to have the TUR syndrome following TURP.

HISTORY

- During TUR procedure: HTN and brachycardia may be a prodrome to rapid reduction in BP
- Postoperatively: No classic presentation, but patient may complain of any of the following:
  – Chest pain
  – Confusion
  – Headache
  – Itching
  – Lethargy
  – Nausea and vomiting
  – Shortness of breath

PHYSICAL EXAM

- Nonspecific physical findings: Although skin may be clammy
- Neurologic exam will reveal altered sensorium and confusion, but no focal signs

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum sodium <125 mEq/L
- Serum ammonia and glycine may be elevated if glycine solution is used

- Determine measured and calculated plasma osmolality:
  - Posm = 2 × plasma Na + (glucose)/18 + BUN/2.8
  - The difference between measured osmolality and calculated osmolality is known as the osmolality gap.
  - Normal osmolality gap: <5–10 mOsm/kg
  - Clinically significant gap is usually >14 and may be due to the presence of substances such as ethanol, ethylene glycol, or in this case irrigating solutions.
  - Osmolality gap can be >30–60 mOsm/kg following TUR due to the accumulation of glycine or sorbitol.

Imaging
- Cystogram or computed tomography (CT) cystogram in cases where perforation suspected to be cause of excess fluid absorption
- CT/MRI of brain to r/o cerebrovascular accident when other causes have been excluded

Diagnostic Procedures/Surgery
- ECG changes as noted above
- Arterial blood gas (ABG)

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Cerebrovascular accident
- Myocardial infarction
- Narcotic overdose
- Pulmonary embolism (PE)
- Seizure

TREATMENT

GENERAL MEASURES
- No specific therapy is necessary in the absence of symptomatology.
- Patients with normal renal function need no intervention to correct mild hyponatremia.
- Hemodynamic and cardiopulmonary support should be provided as needed.
- Vasoactive agents may be required to increase systemic vascular resistance in case of severe hypotension and circulatory collapse.

MEDICATION
First Line
- Furosemide:
  - Indicated to treat PE and hypervolemia when diuresis does not occur spontaneously
  - Furosemide: 20–100 mg IV
  - Water diuresis outpaces sodium diuresis, correcting both hypervolemia and hyponatremia.
  - Routine use to counteract fluid absorption is not supported by the literature.

Second Line
- Hypertonic saline:

  - Indicated for serum Na^+ <120 mEq/L or multiple symptoms
  - Na^+ deficit is calculated: (preop Na^+ - postop Na^+) for total body water (TBW)
  - TBW in males = 0.6 for weight in kg
  - Determine amount of 3% hypertonic saline (513 mEq/L) needed to correct deficit
  - Increasing serum Na by 0.5–1 mEq/L/h is considered a safe rate to avoid central pontine myelinolysis.
- In case of cerebral edema, more rapid correction is indicated, as the risk of brainstem herniation exceeds that of osmotic demyelination.

ALERT
Correcting sodium too quickly in hyponatremia can lead to central pontine myelinolysis and permanent neurologic injury. Recommended correction for life-threatening hyponatremia is no more than 1 mmoL/L/h in the ICU setting (4)[B].

SURGERY/OTHER PROCEDURES
Very rarely, decompression of a large retroperitoneal or pelvic irrigant collection is indicated in order to prevent further absorption of hypo-osmolar fluid.

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE
PROGNOSIS
- When recognized and treated early, prognosis is favorable.
- Mortality 0.2–0.8%
- If therapy is delayed and hyponatremia is severe, risk of significant morbidity and mortality.

COMPLICATIONS
- Cardiopulmonary collapse
- Central pontine myelinolysis
- Cerebral edema and brainstem herniation
- Seizures
- Transient blindness

FOLLOW-UP
Patient Monitoring
- Hemodynamic monitoring and close attention to serum electrolytes, especially sodium, is essential during and after procedure.
- Serial neurologic exams/mental status exams should be performed until symptoms improve.

- 276.69 Other fluid overload
- 997.5 Urinary complications, not elsewhere classified

ICD10

- E87.1 Hypo-osmolality and hyponatremia
- E87.70 Fluid overload, unspecified
- N99.89 Oth postprocedural complications and disorders of GU sys

CLINICAL/SURGICAL PEARLS

- Diagnosis of the TUR syndrome requires high clinical suspicion.
- Prompt diagnosis, evaluation, and management are essential to prevent adverse events.
- If a significant extraperitoneal perforation occurs during the TUR, consider abandoning

procedure after achieving hemostasis to prevent excessive fluid absorption.

- Limit resection time to <60–90 min.
- Consider open prostatectomy, or other appropriate options (eg, laser assisted techniques), for adenoma >100 g.
- Use of bipolar resectoscopes to perform TURP permits use of saline irrigation reducing risk of TUR syndrome.

TROCAR INJURY DURING LAPAROSCOPY

Costas D. Lallas, MD, FACS
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION

- Vascular or visceral injury during placement of trocars in laparoscopic surgery commonly referred to as "access injuries."
- Initial trocar placement is generally considered the most hazardous portion of minimally invasive surgery.
- Hemorrhage due to vessel injury and infection secondary to bowel injury, especially when diagnosis is delayed, are the most serious complications and the most likely to result in death.

EPIDEMIOLOGY

Incidence

- Vascular injury: 0.04–0.5%
- Visceral: 0.06%

Prevalence

N/A

RISK FACTORS

- Blind port placement
- Dilated viscus
- Inexperienced surgeon
- Prior intra-abdominal surgery
- Thin patient

Genetics

N/A

PATHOPHYSIOLOGY (1,2,3)

- During transperitoneal laparoscopy at risk structures are in proximity to port:
  - Umbilicus: Right common iliac artery
  - Upper midline: Aorta or vena cava
  - Right upper quadrant: Liver or gall bladder
  - Left upper quadrant (LUQ): Spleen or stomach
  - Pelvis: Bladder
  - Right and left lower quadrant: Epigastric vessels
- Bifurcation of the aorta and vena cava is generally at the level of the umbilicus or at the level of the anterior-superior iliac spine.
  - Direct perpendicular trocar or Veress needle entry created a situation whereby a great vessel (aorta, vena cava, common iliac artery, and vein) can be injured.
- Life-threatening gas embolism is rare and most often caused by direct insufflation of CO_2 gas

into a vessel by the Veress needle.
  – The 1st sign of intravascular insufflation is acute cardiovascular collapse. The diagnosis is usually made by the anesthesiologist based on an abrupt increase of end-tidal CO_2 accompanied by a sudden decline in oxygen saturation and then a marked decrease in end-tidal CO_2
- The bladder is most likely injured during initial trocar placement.
- Extraperitoneal laparoscopy decreases the risk of visceral and vascular injury.

ASSOCIATED CONDITIONS

- For urologic laparoscopy the underlying indication for the laparoscopy:
  – Malignancy (kidney, prostate, testicular, ureteral, bladder)
  – Obstruction: Ureteropelvic junction obstruction
  – Masses: Adrenal, retroperitoneal
  – Others: Lymphocele, hernia

GENERAL PREVENTION

- Hasson technique ("cut down," or "open trocar placement") for initial access; allows direct visualization of peritoneum.
- Use of visual obturator trocar for primary port placement.
- Use of a nonbladed port for all ports.
- Utilization of confirmatory testing to insure proper placement of initial Veress needle before full insufflation (4):
  – Aspiration of colored (red, yellow, green, brown) or malodorous fluid suggests improper placement.
  – *Drop test*: Apply a drop of saline inside the hub of the needle and lift the abdominal wall. If in proper position, the drop will enter the abdomen due to the negative intraperitoneal pressure.
  – *Advancement test*: If the needle has truly just entered the peritoneal cavity, then the surgeon ought to be able to advance the needle 1 cm deeper without the tip meeting any resistance.
  – *Modified Palmer test*: Inject 10 mL of saline into the needle and attempt to aspirate. Inability to aspirate the fluid suggests that the fluid has dispersed into the abdomen and the needle is in correct position.
  – *Initial pressure reading <8 mm Hg*. The insufflator is turned on with no flow to obtain a pressure reading.
    ◦ A decrease in pressure with elevation of the abdominal wall.
  – If perforation of a viscus occurs, the needle should be removed and discarded. A new needle may then be inserted at another location or the surgeon may choose to obtain open access using the Hasson technique. The injury should be observed laparoscopically or through open intervention if there is any concern over the degree of injury
- Utilizing a LUQ insertion site (Palmer point), located 3 cm below the middle of the left costal margin, for primary port
  – Patients with a history of prior abdominal surgery should be a 1st-line option to eliminate major vessel injury and entry injuries into the bowel which might adhere to a previously made lower abdominal incision

- Angle ports at insertion to 45° into the pelvis; critically important in very thin patients
- Increase pneumoperitoneum to 20–25 mm Hg during port placement to increase tension of abdominal wall and decrease posterior displacement during trocar insertion
- Ensure adequate skin incision for trocar size to avoid excess insertion pressure
- Stabilize abdominal wall when inserting trocar
- Direct vision of secondary port placement and transillumination of abdominal wall to avoid more superficial vessels.
- Bladder catheter placement
- Nasogastric tube placement
- Surgeons should completely familiarize themselves with a new trocar device or design before 1st-time use.
- Visualization of port removal can help identify unrecognized anterior abdominal wall vascular injury.

DIAGNOSIS

HISTORY

Prior abdominal surgery records should be reviewed if appropriate

PHYSICAL EXAM

- Intraoperative findings that suggest trocar injury:
  - Blood in the port after initial placement
  - Bile in the port after initial placement
  - Retroperitoneal hematoma on initial abdominal inspection
  - Air in the bladder catheter bag after initial trocar
  - Drip of blood form trocar
    - Visualization of port removal can help identify unrecognized anterior abdominal wall vascular injury
  - Drop pneumoperitoneum to 5 mm Hg at the end of the case to uncover possible significant small vessel or venous bleeding.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Sudden unexplained drop in blood pressure at the beginning of the case consistent with unrecognized major vascular injury
  - Need to differentiate from insufflation causing compromised blood pressure

Imaging

Not usually used acutely

Diagnostic Procedures/Surgery

N/A

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

Serosal tear in viscera without mucosal violation

TREATMENT

GENERAL MEASURES

- In general Veress needle injuries often heal with conservative management whereas trocar injuries or gross spillage of bowel contents require formal repair
- Direct injury may be observed laparoscopically or during conversion laparotomy
- Abdominal wall/epigastric vessel bleeding may be recognized after ports are removed under direct visualization
- If a port is placed into a major vessel, do not remove but keep in place during laparotomy
  - During an emergent open conversion, use anteriorly deflected port or laparoscope to cut down into abdomen (unless in major vessel)

MEDICATION

First Line

N/A

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Laparoscopic or open repair of injury
  - Always have open tray available for each case
- If the Veress needle aspiration returns frank blood or other fluid (5)
  - Consider leaving the needle in place to help tamponade and identify the injury site
  - If the patient is unstable due to a presumed major vascular injury, immediate laparotomy is indicated
  - If the patient is stable, consider an alternate access site and laparoscopically evaluate the site.
- For abdominal wall bleeding:
  - Clip or electrocautery
  - Intra-abdominal suture placement under laparoscopic guidance.
  - Transcutaneous suture placement using Endo Close or other technique used to close the fascia.
  - Acute placement of Foley inflated to tamponade bleeding.
- For gas embolism (4):
  - Immediate cessation of insufflation and prompt desufflation of the peritoneal cavity.
  - The patient is turned into a left lateral decubitus position and hyperventilated with 100% oxygen.
  - Advancement of a central venous line into the right heart with subsequent attempts to aspirate gas may sometimes be helpful.
- Bladder injury:
  - Veress needle injury can usually be managed by bladder catheter for 7–10 days.
  - More significant injury requires 2-layer closure with absorbable suture and catheter drainage.
- Bowel injury:
  - Requires further inspection and repair either laparoscopically or via laparotomy.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Correction of any coagulopathy

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Excellent if injury is recognized and managed quickly.
- Delayed or unrecognized visceral injury can lead to significant morbidity or mortality.
  - Many bowel injuries are not recognized initially and typically present with peritonitis.

COMPLICATIONS

Unrecognized injury can lead to ongoing hemorrhage, infection

FOLLOW-UP

Patient Monitoring

Dependent on injury and management.

- S35.91XA Laceration of unspecified blood vessel at abdomen, lower back and pelvis level, initial encounter
- S36.90XA Unspecified injury of unspecified intra-abdominal organ, initial encounter

CLINICAL/SURGICAL PEARLS

- Drop pneumoperitoneum to 5 mm Hg at the end of the case to uncover possible significant small vessel or venous bleeding.
- Remove ports under direct visualization to detect latent abdominal wall/epigastric vessel bleeding.
- During an emergent open conversion, use anteriorly deflected port to cut down into abdomen (unless port in major vessel).
- Have open tray available for each laparoscopy case.

TUBERCULOSIS, GENITOURINARY, GENERAL CONSIDERATIONS

Mark R. Anderson, MD, MSc
Judd W. Moul, MD, FACS

BASICS

DESCRIPTION

- Genitourinary tuberculosis (TB) refers to urinary and GU infection with *Mycobacterium tuberculosis*. Common GU sites include the kidney, ureter, bladder, prostate, and testis/epididymis.
- GU tract is 2nd most common site after lungs for tuberculous infection. Urogenital TB represents 27% of extrapulmonary cases (1).
- Tubercle bacilli found in 7–29% of urine in patients with extrarenal TB.
- In 1882, the bacillus causing TB, *M. tuberculosis,* was 1st identified and described by Robert Koch.
- 10% of TB is extrapulmonary with GU locations accounting for 33% of these sites and these rates double in developing countries.
- TB is 2nd only to HIV/AIDS as the greatest killer worldwide due to a single infectious agent.
- In 2010, there were about 10 million orphan children as a result of TB deaths among parents.
- TB is a leading killer of people living with HIV causing one-quarter of all deaths.
- Although declining, multidrug-resistant TB (MDR-TB) is present in virtually all countries surveyed.
- The world is on track to achieve the Millennium Development Goal to reverse the spread of TB by 2015.
- The TB death rate dropped 41% between 1990 and 2011.

EPIDEMIOLOGY

Incidence

- 1/3 of the world's population are infected with TB.
- In 2011, 8.7 million people fell ill with TB and 1.4 million died from TB.
- Over 95% of TB deaths occur in low- and middle-income countries, and it is among the top 3 causes of death for women aged 15–44.
- About 1/3 of the world's population has *latent* TB and can transmit infection.

Prevalence

In US, the peak surge in 1992 of reported TB cases has steadily declined to about half its peak value.

RISK FACTORS

- Health care providers
- Immunosuppression (eg, HIV)
- TB is spread from person to person through the air.

- Smoking

PATHOPHYSIOLOGY

- Hematogenous spread to kidneys from pulmonary disease proved by Medlar, et al. in 1949
- 2–12 wk often ensue before mycobacterial numbers are sufficient to mount a clinically detectable cellular immune response.
- *M. tuberculosis* infections acquired by inhalation of aerosolized droplet nuclei (1–5 μm), which reach pulmonary alveoli
- Invasion of GU organs by ascent (prostate to bladder) or descent (kidney to bladder, prostate to epididymis)
- Kidney and epididymis are primary sites of TB infection in the GU tract in men, and fallopian tubes in women.
- Tuberculomas develop in glomerular capillaries as a result of hematogenous seeding from lungs.
- Renal TB may take years to develop in patients with normal immune system.
- Normal renal parenchyma is slowly replaced by caseous material; calcium is laid down as part of the reparative process.
- Adrenal TB is seen in $<6\%$ of active TB cases (up to 56% of patients with adrenal TB will have a subnormal cortisol response to corticotrophin stimulation).

ASSOCIATED CONDITIONS

- Chronic TB infection
- Immunocompromised states (eg, AIDS)
- Malnutrition
- Poor living conditions/poverty/drug use

GENERAL PREVENTION

- Diagnose and treat patients with TB before development of active disease.
- Take careful precautions with patients hospitalized with TB (N95 mask, negative pressure room flow)
- Test annually with PPD if at high risk for exposure.
- Females of the childbearing age should be advised to avoid pregnancy while on antituberculous treatment.

DIAGNOSIS

HISTORY

- Initial symptoms may be minimal, even in presence of extensive disease. No classical clinical picture, most symptoms are of bladder/lower urinary origin.
- History or exposure to TB; determine last PPD testing results; latency can be >20 yr after primary TB.
- Vague, intermittent, nonspecific complaints such as malaise, lethargy, weight loss, and low-grade fevers common.
- Men commonly present with epididymitis.
- Bacterial cystitis may be superimposed on bladder TB. Common to see recurrent UTIs with *Escherichia coli*
- Dysuria from seeding of the bladder with TB

- Chronic cystitis unresponsive to therapy
- Urinary tract involvement occurs in up to 50% of transplant recipient cases. PPD skin testing may be falsely negative in 70% of cases due to anergy.

PHYSICAL EXAM

- Physical exam is often of limited value in the diagnostic process, because physical signs develop late in the disease. The most common physical finding is an abnormal scrotal exam in about half the patients.
- Suprapubic pain when disease is extensive
- Painful swollen testis
- Chronic draining scrotal sinuses should be considered TB until proven otherwise.
- Nontender, enlarged epididymis with beaded or thickened vas deferens
- Nodular, indurated prostate and thickened seminal vesicles on rectal exam mimic neoplasm.
- Upper abdominal bruit may be indication of advanced renal disease.
- Up to 25% of patients will present only with sterile pyuria and 13% might have gross or microscopic hematuria as their only presentation

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Routine urine analysis (13% might have gross or microscopic hematuria as their only presentation), plus standard culture
- Sterile pyuria classic finding (25%); typically >20 WBC/HPF.
- 20% of patients will also have bacterial cystitis or urinary tract infection with *E. coli.*
- Specific staining of urine for acid-fast bacteria and mycobacterial culture is gold standard:
  - Ziehl–Neelsen or Kinyoun acid-fast stain; more rapid fluorochrome (fluorescence microscopy) procedure 1st morning specimen has highest yield of tubercle bacilli.
- Minimum 3 and up to 6 early-morning urine specimens are recommended, as TB organisms shed into urine intermittently.
- Acid-fast stains from 24-hr urine specimen are positive in 60% of cases.
- High index of suspicion for persistent pyuria without bacteria on repeated cultures (stain with methylene blue)
- PCR assay may identify organisms
- CBC, electrolytes, ESR: Measure monthly as indicator of response to therapy
- 88% have positive skin tests of PPD
- Heavy proteinuria in a patient with TB suggests secondary involvement of the kidney with amyloid.

Imaging

- Chest x-ray: Abnormal in 75%
- KUB: Enlargement of 1 kidney
- Punctuate calcifications in renal parenchyma
- Large calcified structures in prostate
- Renal stones in 10%
- Obliteration of psoas shadow due to perinephric abscess
- Excretory urogram: Considered a mandatory study; moth-eaten appearance in ulcerated calyces; dilation of upper tract secondary to ureteral stricture; obliteration of calyces

- Loss of kidney function due to complete occlusion or renal destruction
- Retrograde pyelography with selective culture for TB; assessment of ureteral stricture
- CT is an option if IVP contraindicated: Useful in delineating disease in seminal vesicles; limited value in early management

Diagnostic Procedures/Surgery

- Tuberculin skin test: Induration >10 mm in diameter is considered positive reaction; >5 mm in high-risk patient. Positive reaction indicates exposure, not necessarily active disease; – May be negative in a patient with miliary TB, AIDS, or advanced age.
- Negative tuberculin skin test makes diagnosis of TB unlikely.
- Must not have had BCG vaccine or therapy in the past due to false-positive effect
- Cystoscopy: TB appears as a patchy erythematous ulceration with exudate.
- TB may mimic urothelial carcinoma including carcinoma in situ (CIS).

Pathologic Findings

- Microscopically, the inflammation produced with TB infection is granulomatous, with epithelioid macrophages and Langhans giant cells along with lymphocytes, plasma cells, maybe a few PMN's, fibroblasts with collagen, and characteristic caseous necrosis in the center.
- The inflammatory response is mediated by a type IV hypersensitivity reaction which can be utilized as a basis for diagnosis by a TB skin test.
- An acid-fast stain (Ziehl–Neelsen or Kinyoun acid-fast stains) will show the organisms as slender red rods.
- An auramine stain of the organisms as viewed under fluorescence microscopy will be easier to screen and more organisms will be apparent.

DIFFERENTIAL DIAGNOSIS

- Amicrobic cystitis
- BCG sepsis/BCGosis
- Chronic nonspecific cystitis or pyelonephritis
- Disseminated coccidioidomycosis
- Granulomatous prostatitis; prostate cancer
- Medullary sponge kidney
- Necrotizing papillitis
- Nonspecific epididymitis
- Renal stones or nephrocalcinosis
- Urinary bilharziasis (schistosomiasis)

TREATMENT

GENERAL MEASURES

- Quarantine until on appropriate medications
- Screen close contacts

MEDICATION

First Line (2)

- Antituberculous drugs are 1st choice: Isoniazide, rifampicin, pirazinamide, ethambutol, and

streptomycin.
- Patient with uncomplicated TB infection: Isoniazid (300 mg/d), rifampin (450–600 mg/d), and pyrazinamide (25 mg/kg/d) once a day in the morning, 3 times a week, for 2–4 mo, followed by isoniazid and rifampin once a day, 3 times a week, for an additional 2–4 mo. (add 1 g of vitamin C, 3 times a week, for 4 mo with above regimen).

Second Line
- Patient with complicated TB infection: Add streptomycin to the above for severe infection or severe bladder symptoms.
- Drug resistance is increasing and necessitates tight therapy control, expanded antibiotic regimen of 4 of the following: Ethionamide, prothionamide, quinolones, clarithromycin, cycloserine, kanamycin, viomycin, capreomycin, thiacetazone, and para-aminosalicylate.
- Steroids: No role in initial therapy but can be used for acute TB cystitis or stricture at distal ureter (prednisone 20 mg PO TID)

SURGERY/OTHER PROCEDURES
- Nephrectomy for symptomatic (HTN, obstruction, pyelonephritis) nonfunctioning kidney with extensive disease or coexistent renal cell carcinoma.
- Perform 4–6 wk after start of antituberculous drugs
- Epididymectomy: Indicated for caseating abscess unresponsive to chemotherapy
- Ureteral strictures: Stenting vs. reconstruction
- Bladder augmentation: Small capacity, fibrotic bladder.
- Surgery not necessary for TB abscesses: Treat medically

ONGOING CARE

PROGNOSIS
- Awareness of renal TB is urgently needed by physicians to suspect this disease in patients with unexplained urinary tract abnormalities, mainly in those with any immunosuppression and those coming from TB-endemic areas (1).
- No specific statistics, but overall patients can do well with appropriate, early antituberculosis medications and surgical interventions.

COMPLICATIONS
- Ureteral TB: Stricture formation, hydronephrosis
- Complete nonfunctioning of an affected kidney (“autonephrectomy”) described
- Renal TB: Obliteration of the renal and psoas shadow on plain radiographs, perinephric abscess may cause an enlarging mass in the flank.
- Genital TB: Sterility a consequence
- An abscess of the epididymis may erode through the scrotal wall or testis, creating a sinus tract and drainage.
- Bladder TB: Stenosis of ureterovesical junction, fibrosis, and contraction of bladder
- Nephrotoxicity induced by antimicrobial agents (especially rifampin)

FOLLOW-UP
- Completion of TB regimens long term is essential.
- Strictures can evolve after organism is eradicated.

- Follow regularly after completion of therapy as stricturing can continue: 3, 6, 9, 12 mo with urine culture and TB staining and excretory urography.
- Need long-term imaging follow-up of calcifications if present.

CODES

ICD9

- 016.00 Tuberculosis of kidney, unspecified
- 016.10 Tuberculosis of bladder, unspecified
- 016.90 Genitourinary tuberculosis, unspecified, unspecified

ICD10

- A18.10 Tuberculosis of genitourinary system, unspecified
- A18.11 Tuberculosis of kidney and ureter
- A18.12 Tuberculosis of bladder

CLINICAL/SURGICAL PEARLS

- Chronic draining scrotal sinuses should be considered TB until proven otherwise.
- Sterile pyuria is the classic finding, typically >20 WBC/HPF.

- Renal involvement by TB infection is underdiagnosed in most health care centers.
- Posttreatment follow-up is essential as strictures can evolve after organism is eradicated.

TUBERCULOSIS, KIDNEY AND URETER

Mohamed S. Ismail, MBChB, MRCS, PhD
Jayram Krishnan, DO, MBA

BASICS

DESCRIPTION

- *Mycobacterium tuberculosis* (TB) may affect the urinary system including the kidney and ureter
- Most TB occurs in the lung but 15% occurs in extrapulmonary sites
  - GU system is the most common extrapulmonary site
    - Kidneys are the most common GU site

EPIDEMIOLOGY

Incidence

- Worldwide—9.27 million worldwide (140 per 100,000) (2007)
- US—12,904 cases (4.2 per 100,000) (2008)

Prevalence

- GU TB:
  - Developed countries—2–10%
  - Developing countries—15–20%
- Male > female (2:1) (1)[C]
- Mean age 40.7 yr (1)[C]

RISK FACTORS

- Human immunodeficiency virus/acquired immunodeficiency syndrome (HIV/AIDS)
- Chronic dialysis patients
- Immunocompromised states (renal transplants)
- Foreign travel

PATHOPHYSIOLOGY

- *M. tuberculosis* infections are acquired by inhalation of aerosolized droplet nuclei which reach the pulmonary alveoli
- Hematogenous spread to kidneys from pulmonary disease
  - Tuberculomas develop in glomerular capillaries as a result of hematogenous seeding
  - Normal renal parenchyma is slowly replaced by caseous material and calcium is laid down as part of the reparative process
  - Renal papilla involvement results in sloughing and caseous material gaining access to the collecting system by calyceal ulceration
  - Extensive fibrosis with healing tubercles results in disfiguration and hydronephrosis with obstruction
- Ureteral involvement is almost always from direct extension from the kidney
  - Mycobacteria caseous material leads to tubercle formation within the ureteric mucosa
  - This usually affects the lower ureter and the ureterovesical junction with the middle and

upper ureter less commonly affected (2)[C]
  - Dense fibrosis on the ureteric serosa leads to stricture formation and/or shortening in 50% of patients with renal involvement
- Secondary amyloidosis can be found; often resulting in proteinuria and nephrotic syndrome

ASSOCIATED CONDITIONS
- Chronic TB infection
- Immunocompromised states (HIV/AIDS)
- Malnutrition
- Poor living conditions/poverty

GENERAL PREVENTION
- Diagnose and treat patients with TB before development of active disease
- Take careful precautions with patients hospitalized with TB
- Test annually with the purified protein derivative (PPD) skin test if at high risk for exposure

DIAGNOSIS
HISTORY
- Often mimics a wide range of nonspecific urologic symptoms and are often minimal even with extensive disease
- History or exposure to TB; determine last PPD test results; latency can be >20 yr after primary TB
- Vague, intermittent, nonspecific complaints such as malaise, lethargy, weight loss, and low-grade fevers common
- Men commonly present with epididymitis
- Bacterial cystitis may be superimposed on bladder TB. Common to see recurrent urinary tract infections with *Escherichia coli*
- Dysuria from seeding of the bladder with TB
- Chronic cystitis unresponsive to therapy

PHYSICAL EXAM
- Significant physical signs develop late and with extensive disease
- Storage symptoms are the most common overall presentation (50.5%) (1)[C]
  - Hematuria (35.6%) (1)[C]
  - Lumbar pain (34.4%) (1)[C])
  - Most common physical finding in men is an abnormal scrotal exam (49.8%) (1)[C]
    - Scrotal lumps, epididymal hardening, or draining scrotal fistulas
- Upper abdominal bruits may indicate advanced renal disease

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis and culture:
  - Classic finding: Sterile pyuria (>20 white blood cells/high power field)
  - 20% of patients will also have bacterial cystitis or urinary tract infection with *E. coli*
  - 13% of patients will present with gross or microscopic hematuria (3)[C]
- **GOLD STANDARD:** Specific staining of urine for acid-fast bacteria and mycobacterial

culture
  - Nonpathogenic mycobacteria can also stain positive, so culture more useful
  - Ziehl–Neelsen or Kinyoun acid-fast stain; more rapid fluorochrome (fluorescence microscopy) procedure
  - 1st morning urine specimen has highest yield of tubercle bacilli
  - Minimum 3 and up to 6 early-morning urine specimens are recommended, as TB organisms shed into urine intermittently
  - 64.2% of patients had *M. tuberculosis* in their urine (1)[C]
  - High index of suspicion for persistent pyuria without bacteria on repeated cultures (stain with methylene blue)
- Polymerase chain reaction (PCR) assay may identify organisms
- Complete blood count and electrolytes
  - Renal failure is present in 7.4% of cases (creatinine >1.5) (1)[C]
    - Functional loss of the affected kidney can be present in up to 25% of cases (1)[C]
- Erythrocyte sedimentation rate (ESR):
  - Measure monthly as indicator of response to therapy
- Heavy proteinuria may suggest secondary involvement of the kidney with amyloid

Imaging
- Chest radiograph: Abnormal in 75%
- Abdominal radiograph:
  - Enlargement of 1 kidney
  - Renal stones in 10%
  - Focal punctate calcifications occur within the caseating lesions in renal parenchyma
  - Obliteration of psoas shadow due to perinephric abscess
  - Characteristic diffuse, uniform, extensive parenchymal calcifications are present with lobar cast of the kidney (autonephrectomy)
- Excretory urogram:
  - Moth-eaten appearance in ulcerated calyces (4)[C]
  - Dilation of upper tract secondary to ureteral stricture (4)[C]
  - Obliteration of calyces
  - Loss of kidney function due to complete occlusion or renal destruction
- Computed tomography (4)[C]:
  - Most common finding: Renal parenchymal scarring (76%)
  - Hydrocalycosis, hydronephrosis, or hydroureter due to stricture (67%)
  - Thick walls of the renal pelvis, ureters, or bladder (61%)

Diagnostic Procedures/Surgery
- Tuberculin skin test (PPD):
  - 88% patients have positive skin tests
  - 5 mm or more of induration is considered positive in persons with the highest likelihood of developing active disease
    - HIV, immunosuppression, organ transplants
  - 10 mm or more of induration is considered positive in those who are at high risk for TB
    - Drug abuse, health care workers, family members
  - 15 mm or more of induration is considered positive in any patient

  - Positive reaction indicates exposure, not necessarily active disease
  - May be negative in a patient with miliary TB, AIDS, or advanced age
  - Negative tuberculin skin test makes diagnosis of TB unlikely
  - Not used in patients with history of Bacille Calmette–Guérin (BCG) vaccine or therapy
- Retrograde pyelography
  - Obtain selective cultures for TB
  - Assessment of ureteral stricture
- Cystoscopy and ureteroscopy play a limited role

Pathologic Findings

Tubercles replaced by caseating necrosis

DIFFERENTIAL DIAGNOSIS

- Amicrobic cystitis
- Systemic BCG infection
- Chronic nonspecific cystitis or pyelonephritis
- Disseminated coccidioidomycosis
- Medullary sponge kidney
- Necrotizing papillitis
- Nonspecific epididymitis
- Renal stones or nephrocalcinosis
- Urinary bilharziasis (schistosomiasis)

TREATMENT

GENERAL MEASURES

- Early diagnosis of active disease is imperative and requires prompt initiation of adequate drug regimens
  - Surgical treatment is reserved for advanced cases and with the goal of renal preservation
  - Correct the obstructive effects of fibrosis and scarring rather than removal of infected tissues
  - Drainage of abscesses
- Balanced approach is required between medications and surgery to preserve function and eradicate mycobacteria
- Supervision of therapy is required to ensure compliance and to monitor for complications

MEDICATION

First Line

- Initial treatment requires 6 mo of anti-TB medications
- 1st 2 mo: Isoniazid (INH), rifampin (RIF), pyrazinamide (PZA), and ethambutol (EMB)
- Following 4 mo: INH and RIF
- Ascorbic acid given with treatment
  - INH – 5 mg/kg (300 mg/d)
    - Pyridoxine supplementation required (peripheral neuropathy)
    - Hepatic toxicity
  - RIF – 10 mg/kg (450–600 mg/d)

- Hepatic toxicity, flu-like syndrome, pruritics
- PZA – 25 mg/kg/d
  - Hepatic toxicity, arthralgias, rash, gastrointestinal upset
- EMB – 15–25 mg/kg/d
  - Irreversible optic neuritis, visual changes
  - Renal excretion (caution in renal failure)

Second Line

- Complicated/resistant TB infections requiring the use of streptomycin, ethionamide, quinolones, and aminoglycosides
  - Streptomycin 15 mg/kg (max 1 g)
    - Vestibular and auditory toxicity, renal damage
  - Ethionamide 15–20 mg/kg (max 500 mg/BID)
    - Gastrointestinal and hepatic toxicity, hypothyroidism
- Multidrug-resistant TB (MDR-TB)
  - Resistant to at least isoniazid and rifampin, and possibly additional agents
- Extensively drug-resistant TB (XDR-TB)
  - Resistant to at least isoniazid and rifampin, and additionally resistant to fluoroquinolones and either aminoglycosides or both

SURGERY/OTHER PROCEDURES

- 55% of patients with GU TB will require surgical intervention
  - Ureteral obstruction
    - Early stent or nephrostomy may decrease loss of renal function and increase opportunity for later reconstruction (2)[C]
    - Some strictures may resolve after medical therapy
  - Nephrectomy
    - Symptomatic (hypertension, obstruction, pyelonephritis)
    - Removal of nonfunctional unit
    - Indicated for coexistent renal malignancies
    - Best delayed 4–6 wk after medical treatment

ADDITIONAL TREATMENT

Additional Therapies

- Steroids
  - Used for treatment of TB-induced ureteral strictures or cystitis
    - Prednisone 20 mg 3 times daily orally
  - Not recommended for routine use
- Latent TB
  - Consider treatment to avoid conversion to active disease

ONGOING CARE

PROGNOSIS

- Prognosis is good in patients who are compliant in therapy
- Better prognosis with early diagnosis of disease

COMPLICATIONS

- Renal TB:
  - Autonephrectomy: Complete nonfunctioning of an affected kidney
  - Perinephric abscess may cause an enlarging flank mass
- Ureteral TB:
  - Stricture formation
  - Hydronephrosis
  - Loss of renal function

FOLLOW-UP

Patient Monitoring

- All TB patients should be screened for HIV/AIDS
- Strictures can evolve after mycobacteria is eradicated
  - Imaging (excretory urography/contrast computed tomography) and urine culture every 3 mo for 1st yr then annual abdominal radiographs
  - Continue long-term imaging if calcifications present

CLINICAL/SURGICAL PEARLS
Compliance to treatment regimen is essential for adequate disease response.

TUNICA ALBUGINEA/PARATESTICULAR TUMORS AND CYSTS

John L. Phillips, MD, FACS
Vladimir A. Valera, MD, PhD

BASICS

DESCRIPTION

- Lesions can arise from the paratesticular regions of the scrotum and testes. These soft tissues include
  - tunica albugenia, tunica vaginalis, spermatic cord structures and mullerian remnants (eg, appendix testis or appendix epididymis)
  - Benign 70%
    - Lipomas (90% of adult PT tumors)
    - Adenomatoid tumors 30%
    - Tunica albugenia cysts
    - Leiomyomas
    - Cystadenomas
    - Adrenal rests
    - Cysts of the appendix testis
    - Hamartomas/pseudotumors (rare)
  - Malignant 30%
    - Leiomyosarcoma
    - Rhabdomyosarcoma (RMS) 24–40%
    - Liposarcoma
    - Malignant mesothelioma (MM)
    - Desmoplastic round cell tumor (DRCT)

EPIDEMIOLOGY

Incidence

- Rare, true incidence unknown
- Europe: 5–7 cases per million
- Adenomatoid tumors typically seen in 4th decade
- Leiomyosarcoma and MM peak in 5th–7th decade
- RMS: Bimodal
  - 2–6 yr & 15–19 yr
    - Most common tumor of lower GU tract in the 1st 2 yr
  - 5–7 cases/10 million children

Prevalence

- Reported in 1 of 20–40 orchiectomy specimens
  - China: 4.7% of pediatric scrotal tumors over 12 yr (1)
  - High in SW Nigeria: 38.5% of adult orchiectomy specimens over 17 yr (2)

RISK FACTORS

- Cryptorchidism not a risk factor for PT tumors

- Asbestos exposure may be risk factor for MM
- Cystadenomas seen in Von Hippel–Lindau (VHL) disease are typically bilateral
- Parental cocaine or THC use seen in pediatric RMS

Genetics

- RMS, embryonal subtype, frequently has monosomy of chromosome 11.
  - Alveolar subtypes express t(2;13)(q35;q14) or t(1;13)(p36;q14) and bodes poorly
- DRCT express t(11;22)(p13;p12) fusions of EWS and WT1.

PATHOPHYSIOLOGY

- Arise from epithelial, mesothelial, or mesenchymal tissues
  - Epididymis
    - Adenomatoid tumor
    - Cystadenoma (1/3 occur in VHL)
  - Spermatic cord
    - Sarcoma (arise from undifferentiated mesoderm)
    - Adrenal rest (found incidentally during hernia repair)
    - Lipoma/leiomyoma/liposarc, etc.
  - Tunica vaginalis (TV)
    - MM

ASSOCIATED CONDITIONS

- Germline conditions
  - Von Hippel–Lindau disease
    - Infertility low even in bilateral cases
  - Li–Fraumeni syndrome confers predisposition
- Somatic (ie, acquired) conditions
  - Ipsilateral hydrocele (eg, reactive)
  - Ipsilateral hernia (ie, cause for exploration)
  - Pulmonary mesothelioma (and asbestos exposure in MM of the TV)
  - Scrotal trauma
  - Epididymitis–orchitis
  - Infertility (ie, cause for workup or exploration)

GENERAL PREVENTION

No known environmental or occupational risk

DIAGNOSIS

HISTORY

- Slowly growing inguinal or scrotal mass
- Often painless
- Found in workup for hernia
- Found in evaluation of scrotal trauma or inflammatory/infectious scrotal conditions

PHYSICAL EXAM

- Inguinal or scrotal mass
- Testis often discrete and normal

  - Adenomatoid tumors may occur more inferiorly on the testis.
  - Superior pole tumors may mimic a spermatocele (SC)
- Evaluate for hernia, hydrocele, SC, and varicocele

ALERT
Fixation to inguinal canal or testis suggests malignancy. Prepare for and rule out sarcoma.

- Fixation or involvement of testis and not the chord suggests primary testicular or MM
  - Rule out germ cell tumor or MM
- Large size >5 cm suggests RMS

ALERT
- Transillumination does not rule out tumor
- Rule out secondary or, more rare, primary lymphoma.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Rule out concurrent infection or inflammation
  - Urinalysis
  - Urine culture
- Rule out concurrent mycobacterial infection (can mimic tumor)
  - PPD history
  - Chest x-ray (rule out granulomas, tumor)
- Assess testicular germ cell tumor (GCT) markers
  - AFP
  - β-hCG
  - LDH
  - PLAP

Imaging

- Scrotal ultrasound critical in evaluation
  - Differentiate testicular from PT process
    - 3D or elastosonography not necessary if tumor distinctly separate from testis
  - Solid masses require exploration
  - Cystic structures such as tunica albuginea cyst may be monitored serially
- CT scan of the chest, abdomen, and pelvis required when malignancy suspected and to rule out metastasis in cases of known malignancy

Diagnostic Procedures/Surgery

- Fine needle aspiration may lead to false negatives or positives
- Solid lesions require inguinal approach
- Benign lesions
  - Observation
  - Testis-sparing surgery
- Malignant or suspicious lesions
  - Radical orchiectomy, inguinal approach
    - High dissection to internal ring
    - Early vascular control

- Resection of adherent structures
  - Skin
  - Fascia
  - Muscle

Pathologic Findings

- Benign lesions usually need low power H&E
  - Adenomatoid tumor
    - Well circumscribed
    - May involve tunica albuginea
    - Benign appearing cords and cystic tubules lined by eosinophilic cells with small nuclei
  - Papillary cystadenoma
    - Well circumscribed
    - Brown fronds within cystic space
    - May have clear cells that resemble renal cell carcinoma (commonly associated with VHL)
- Malignant lesions may need electron microscopy
  - MM
    - Friable, multicystic within hydrocele
    - Epithelioid, papillary, tubulopapillar pattern
    - Fibrovascular core
  - Rhabdomyosarcoma (RMS)
    - Embryonal in 90%
    - Alveolar
    - Mixed pleiomorphic
  - Desmoplastic round cell tumor (DRCT)
    - Firm, white, often near epididymis
    - Small blue cells in nests and cords
    - Mitotically active
  - Leiomyosarcoma
    - Intersecting bundles of smooth muscle cells
    - Atypical and mitotically active
  - Liposarcoma
    - Large, atypical cells, large nuclei
    - Fibrous septae
    - Lipoblasts present

DIFFERENTIAL DIAGNOSIS

- Epididymal tumors (rare)
  - Adenocarcinoma
  - Cystadenoma
- Proliferative folliculitis
  - Resemble nodular fasciitis
  - Incidental at herniorrhaphy
- Hernia, direct or indirect
- Hydrocele

- Lymphadenopathy
- Metastatic tumor
- Squamous cell carcinoma (scrotal skin)
- Sperm granuloma, usually post-vasectomy
- Testis tumor
- Tunica albuginea cyst
- Vasitis nodosa

TREATMENT

GENERAL MEASURES

- Cystic PT structures are treated with observation or rarely conservative excision
- Solid masses usually require excision
  - Benign: use testicle sparing surgery (TSS)
  - Malignant
    - TNM staging
    - Local excision
      - Adjuvant chemotherapy for RMS
      - Adjuvant local radiation for other sarcomas

MEDICATION

First Line

- Malignant rhabsomyosarcoma (RMS)
  - Vincristine
  - Dactinomycin
  - Cyclophosphamide
    - MESNA for bladder protection

Second Line

N/A

ADDITIONAL TREATMENT

Radiation Therapy

Reserved for local adjuvant or salvage control of malignant PT sarcomas

Additional Therapies

- Secondary resection
  - Local recurrence of benign lesions
  - Local recurrence of malignant lesions if localized, no evidence of metastatic disease, and radiotherapy not given

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Benign lesions

  - Resection is usually curative
  - Fertility can be maintained
- Malignant lesions
  - RMS
    - Favorable prognosis in children
    - Stage I in 60–80%
    - Unfavorable prognosis in adults and children >10 yr
  - DCRT unfavorable prognosis with nodal and pulmonary metastasis
  - Mesothelioma. Aggressive; similar to peritoneal mesothelioma
  - Lipo-/leiomyosarcoma
    - Excellent prognosis but may recur locally and require retreatment
    - Metastases exceedingly rare, reportable

COMPLICATIONS

- General as seen for inguinal surgery:
  - Secondary hernia
  - Infection
  - Hematoma
  - Pain
- Loss of testis after testicular sparing surgery (TSS) (rare)
- Infertility (eg, after excision of bilateral cystadenoma or epididymal masses in VHL)

FOLLOW-UP

Patient Monitoring

- Benign lesions
  - Physical exam semiannual and self-exam yearly
- Malignant lesions
  - Liposarcomas rarely metastasize but can recur locally
  - RMS
    - Interdisciplinary oncologic team (3)
    - Serial imaging
    - 40% metastasize to retroperitoneum
    - Role of RPLND in RMS controversial

CODES

ICD9

- 214.8 Lipoma of other specified sites
- 239.5 Neoplasm of unspecified nature of other genitourinary organs
- 608.89 Other specified disorders of male genital organs

ICD10

- D49.5 Neoplasm of unspecified behavior of other genitourinary organs
- N44.1 Cyst of tunica albuginea testis
- N50.8 Other specified disorders of male genital organs

CLINICAL/SURGICAL PEARLS

- Most common adult benign paratesticular tumor: Lipoma.
- Most common adult malignant paratesticular tumor: Liposarcoma.
- Most common pediatric PT tumor is malignant RMS (rhabdomyosarcoma).
- Cure rate of RMS with multimodality therapy: 90%.

UMBILICAL ABNORMALITIES, UROLOGIC CONSIDERATIONS

Evalynn Vasquez, MD, MBA
Derek Matoka, MD

BASICS

DESCRIPTION

- Umbilical abnormalities result from failure of umbilical ring to close or persistence of umbilical structures
- Abnormalities can be classified as:
  - Mass
  - Infection
  - Persistent drainage
- Most likely to present during the neonatal period or early infancy

EPIDEMIOLOGY

Incidence

- Most common mass at the umbilicus in an infant is granulation tissue
- Umbilical hernia: 10–20% of all infants
  - Increased incidence: Premature infants (up to 75% in infants under 1500 g), females, African descent, Down syndrome, Beckwith–Wiedemann syndrome, hypothyroidism, mucopolysaccharidosis
- Omphalitis is currently extremely rare due to adequate hygiene and the use of topical antibiotics on the umbilical cord
- Persistent remnant of the vitelline duct has 2% incidence
- Urachal remnants are common but often asymptomatic (3% of adult autopsy specimens)
- Patent urachus occurs in $<1/1000$ live births
- Urachal carcinoma: 1 in 5 million cases annually

Prevalence

N/A

PATHOPHYSIOLOGY (1)

- The primitive umbilical cord develops with the anterior abdominal wall during weeks 2–3 of gestation
- Early in gestation, the umbilical cord contains the vitelline duct, allantois, two arteries, and one vein
- The vitelline duct is a connection between the midgut and yolk sac. It involutes in weeks 7–9 and becomes the ligament teres of the liver. This ligament attaches to the inferior portion of the umbilical ring (75%) or the superior aspect (25%)
- The bladder forms from the ventral portion of the cloaca. The bladder descends into the pelvis with the urachus connecting the bladder apex to the umbilicus. The urachus involutes to a fibrous cord becoming the median umbilical ligament
- The anterior abdominal wall progressively closes leaving only an umbilical ring
- Failure of normal development or failure of the vitelline duct, urachus, or umbilical ring to

involute results in umbilical abnormalities
- The urachal remnant is represented by the median umbilical ligament in adults. Urachal remnants: Most common; comprise spectrum of anomalies:
  – Patent urachus (rare, 3 in 1 million): Unobliterated urachus draining urine from the bladder to the umbilicus
  – Urachal sinus: Urachus obliterated at the bladder level, but open sinus remains at the umbilicus. Drainage often is the result of episodic infections of the sinus
  – Urachal cyst: Urachus obliterated proximally and distally, but unobliterated fluid-filled cyst remains in between
  – Infected urachal cysts found in all ages
  – Urachal diverticulum of the bladder: May result from drainage of a urachal cyst to the bladder.
- Vitelline duct remnant (omphalomesenteric duct): Connects fet al midgut to yolk sac
  – Umbilical sinus, vitelline cyst, or Meckel (8%–10% of Meckel have umbilical anomaly)
- Arterial umbilical remnants

ASSOCIATED CONDITIONS
- Volvulus or internal hernia with vitelline abnormalities
- GI bleed: Meckel diverticulum
- Bladder outlet obstruction

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Most umbilical disorders are found antenatally or at birth but can have a delayed diagnosis or be found incidentally if asymptomatic
- Discharge suggests vitelline duct remnant, urachal remnant, or umbilical granuloma
- Umbilical infections are often related to hygiene issues.
  – Home births have a slightly increased incidence of omphalitis.
- Painless, intermittent, self-resolving GI bleed in a young child should raise the suspicion of a Meckel diverticulum.
- Acute onset abdominal pain can suggest incarcerated umbilical hernia, volvulus or internal hernia due to fibrous vitelline remnant, or intussusception of a Meckel diverticulum.
- Urachal tumors are typically silent because of their extraperitoneal location; consequently, the majority of patients exhibit local invasion or metastatic disease at presentation.
- UTI or bladder stone can be associated with a urachal diverticulum.

PHYSICAL EXAM
- Granuloma and umbilical polyp: Small bright red remnant of intestinal or gastric mucosa
- Hernia: Non-tender reducible outpouching through umbilical ring
- Omphalitis: Tender, erythematous, bleeding, and discharge at the umbilicus
- Patent urachus: Clear fluid draining in the newborn period often exaggerated with crying or straining
- Urachal cyst: Asymptomatic and incidentally found unless associated with infection. Patient

may then present with fever, voiding symptoms, midline infraumbilical tenderness, mass, or urinary tract infection. Rarely it can rupture into preperitoneal tissues or the peritoneal cavity
- Urachal sinus: May present in infancy or later with clear drainage or nonspecific periumbilical erythema
- Vesicourachal diverticulum: May present with urinary tract infections
- Vitelline umbilical fistula: Found in newborn period with the appearance of an umbilical stoma with pink, circular, intestinal remnant
- Meckel diverticulum: Asymptomatic unless bowel obstruction from intussusception occurs or GI bleed due to mucosal ulceration from acid secretion. Rule of 2's: 2% of the population, 2 feet from the ileocecal valve, 2 inches in length, 2 types of common ectopic tissue (gastric and pancreatic), 2 yr is the most common age at clinical presentation, 2 times more boys are affected

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis: evidence of hematuria or infection
- Check creatinine of draining umbilical fluid to determine if it could be a patent urachus
- Urine cytology may be positive in cases of urachal carcinoma

Imaging

- Ultrasound: Best tool for initial assessment. It accurately determines anatomy of umbilical structures and evaluates for bladder/small bowel communication
- VCUG: Assess for a urachal remnant and can rule out associated bladder outlet obstruction
- Fistulography/Sinogram: Catheterization of tract and injection of contrast may be difficult and unreliable. Can diagnosis vitelline umbilical fistula which will show communication to small bowel.
- Meckel scan: Specific for gastric mucosal cells and accuracy is greater than 90%
- CT or MRI of abdomen and pelvis with IV and PO contrast
  - Gold standard for diagnosis and staging particularly for cancer
  - Midline, calcified, partially cystic mass with local extension is concerning for but not diagnostic of urachal carcinoma.

Diagnostic Procedures/Surgery

Cystoscopy with biopsy or resection

Pathologic Findings

- Umbilical polyp: Excrescence of vitelline duct mucosa retained in the umbilicus
- 10% of bladder adenocarcinomas arise from a urachal remnant.
  - Only type of bladder cancer more common in women than in men
  - Urachal adenocarcinoma tends to present at an earlier age than other forms of bladder adenocarcinoma
  - Histologically, urachal adenocarcinoma tends to be lower grade with improved overall 5-yr survival
  - Mucin production is found in up to 75% of cases; calcification in 50–70%

DIFFERENTIAL DIAGNOSIS

- Umbilical mass
  - Granuloma/umbilical polyp: Infants
  - Umbilical hernia: All ages
  - Urachal neoplasms: Adults
    - Benign (very rare): Adenomas, fibromas, fibroadenomas, fibromyomas, hamartomas
    - Malignant (very rare, less than 0.5% of all bladder cancers): Most adenocarcinoma
  - Sister Mary Joseph nodule (adults): Umbilical metastasis of primary tumors (if primary is known, usually from genital or GI tract)
  - Others: Dermoid cyst, sebum cyst, spontaneous umbilical fistula from Crohn disease/TB/perforated appendix, urachal carcinoma, and skin cancers such as basal-cell and squamous-cell carcinoma
- Infection
  - Omphalitis
  - Infected urachal cyst
- Drainage
  - Urachal remnant:
    - Patent urachus (50%)
    - Urachal cyst (30%)
    - Urachal sinus (15%)
    - Vesicourachal diverticulum (5%)
  - Vitelline remnant: Meckel diverticulum, vitelline umbilical fistula, fibrous vitelline remnant
  - Endometriosis: Pain and hemorrhagic umbilical discharge during menses

TREATMENT

GENERAL MEASURES

Identify the abnormality and manage accordingly

SURGERY/OTHER PROCEDURES (2,3)

- Granuloma and umbilical polyp (infants): Very difficult to differentiate clinically. Treat with silver nitrate. If there is no response after two or three attempts, surgical excision may be necessary. Pedunculated lesions with a narrow stalk may be managed with ligation of the base with absorbable suture
- Hernia (infants): 1 cm or less, spontaneous closure likely in >90%. Hernias >2 cm typically need surgical correction after 3–4 yr of observation
- Omphalitis (infants): Broad spectrum antibiotics. Surgical debridement may be necessary. There is a high mortality rate and risk of polymicrobial necrotizing fasciitis; mortality of up to 15%
- Patent urachus: Resect entire duct via infra-umbilical incision (in newborns), or transverse mid-hypogastric incision in older children; remove cuff of bladder with specimen
- Urachal remnant: Surgical exploration with excision.
  - If urachal cyst is infected, it may be treated initially with broad spectrum antibiotics and drainage.
  - Complete excision can be performed once infection has subsided. Risk of malignant

degeneration has been reported in the literature.
- Patent vitelline duct/ vitelline umbilical fistula (enteric contents per umbilicus): Surgical exploration with excision needs prompt laparotomy and duct excision to avoid intussusception/volvulus
- Meckel diverticulum: Surgical exploration with excision
- Urachal carcinoma
  - Radical cystectomy or partial cystectomy with wide surgical margins and en-bloc resection of urachal remnant extending from bladder to umbilicus, posterior rectus sheath, and all tissue between medial umbilical ligaments is recommended for lower stage, resectable disease.
  - Partial cystectomy may offer a comparable oncologic outcome and less morbidity to radical cystectomy if tumor is completely resected (4)[C]
  - Failure to resect the umbilicus and positive surgical margins are associated with a worse outcome (5)[B]
- Bilateral pelvic lymph node dissection
  - Should follow the standard template for bladder cancer.
  - May be useful for staging but does not provide any survival advantage.
- Surgical resection is particularly well-suited to a laparoscopic or robotic approach with comparable short-term outcomes.

ADDITIONAL TREATMENT

Radiation Therapy

Limited role for unresectable urachal carcinoma

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Minimal long-term sequelae when managed appropriately
- Urachal carcinoma
  - 5-yr overall survival: 27–80%; about 50% for locally advanced disease
  - Less than 20% for metastatic disease
  - 93% for disease confined to the urachus and bladder after surgical resection with bladder preservation
  - 69% for extravesical and periurachal disease after surgical resection with bladder preservation

COMPLICATIONS

Morbidity related to the abnormality and the specific treatment modality that is utilized

- Urachal Carcinoma

CODES

ICD9
- 553.1 Umbilical hernia without mention of obstruction or gangrene
- 759.89 Other specified congenital anomalies
- 772.3 Umbilical hemorrhage after birth

ICD10
- K42.9 Umbilical hernia without obstruction or gangrene
- P51.9 Umbilical hemorrhage of newborn, unspecified
- Q89.8 Other specified congenital malformations

CLINICAL/SURGICAL PEARLS

- In the newborn, a granuloma is the most common cause of persistent drainage.
- Ultrasound is an accurate, minimally invasive initial imaging modality.
- Umbilical hernias may be seen in up to 20% of infants, but the majority will resolve by 3 yr of life.
- If surgical excision of a urachal remnant is performed, a bladder cuff should be taken if there is involvement of the dome of the bladder.

UNDERACTIVE BLADDER (DETRUSOR UNDERACTIVITY)

Michael J. Amirian, MD
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION

- Detrusor underactivity (DU) often referred to as underactive bladder is a bladder contraction of reduced strength and/or duration
  - Results in prolonged bladder emptying
  - Failure to complete bladder emptying within a normal time span
  - Observed in many neurologic conditions and myogenic failure
- DU is a common cause of lower urinary tract symptoms (LUTS) in both men and women
- A wide range of terminology is currently applied in the literature
  - The only formal definition was from the International Continence Society (ICS) in 2002 was the urodynamic definition of DU along with detrusor acontractility
- Underactive Bladder Syndrome is characterized by urinary symptoms including hesitancy, straining, and incomplete bladder emptying in the absence of anatomic obstruction.

EPIDEMIOLOGY

Incidence

Present in 9–48% of men and 12–45% of older women undergoing urodynamic evaluation for non-neurogenic LUTS (1)

Prevalence

N/A

RISK FACTORS (2)

- Overactive bladder (OAB) may lead to underactive bladder (UAB)
- Diabetes mellitus
- Aging
- Acute Cerebrovascular accident (CVA)
- Multiple sclerosis (MS)
- Parkinson disease
- Injury to spinal cord, cauda equine, and pelvic plexus
  - Pelvic surgery
  - Pelvic and sacral fractures
  - Herniated disc
  - Lesions of pudendal nerve
- Infectious neurologic problems
  - AIDS
  - Neurosyphilis
  - Herpes zoster and herpes simplex
  - Guillain–Barre syndrome
- Medications

- Antimuscarinics, α-receptor antagonists

Genetics

N/A

PATHOPHYSIOLOGY

- Diabetic mellitus leading to diabetic cystopathy
  - Metabolic derangement of Schwann cells
    - Altered metabolism of glucose
    - Ischemia
    - Superoxide-induced, free-radical formation
    - Impaired axonal transport
  - Alteration in physiology of detrusor smooth muscle cell
- Aging
  - Reduction in acetylcholinesterase-positive nerve
    - Reduced parasympathetic innervation
- CVA
  - Cerebellar infarct leading to detrusor areflexia

ASSOCIATED CONDITIONS

OAB syndrome

GENERAL PREVENTION

- Diabetic patients
  - Control blood glucose levels
- Hypertension and hyperlipidemia control
- Smoking cessation

DIAGNOSIS

HISTORY

- History of neurologic injury or medical disorder
- Recurrent episodes of urinary retention
- Lower urinary tract symptoms
  - Straining to urinate
  - Sensation of incomplete bladder emptying
  - Diminished and interrupted urinary stream
  - Urinary hesitancy
  - Rely on abdominal straining to urinate
- Incontinence
  - Overflow, urge, or stress
- Recurrent urinary tract infections

PHYSICAL EXAM

- May reveal a distended bladder
- Suspected or known neurologic injury due to pelvic or sacral injury
  - Testing of sacral dermatomes
    - Assessing perianal sensation

    - Anal sphincter tone
    - Bulbocavernosus reflex
- Neurologic testing
  - Deep tendon reflexes in the lower extremities
  - Clonus
  - Plantar responses

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Beyond routine urinalysis and culture, none specific

Imaging

Upper tract screening if obstruction suspected.

Diagnostic Procedures/Surgery

- Urodynamic evaluation (basis of current ICS definition of UAB)
  - Cystometry
    - Long curve with lack of sensation
    - Low detrusor pressure
  - Electromyography
    - Usually normal
    - May show sphincter denervation and uninhibited sphincter relaxation
- Uroflowmetry
  - Low peak flow
  - Prolonged duration of flow
  - Increased residual urine

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Bladder outlet obstruction
- Detrusor overactivity

TREATMENT

GENERAL MEASURES

- Limited management available (3)
  - No validated, effective oral drugs, no FDA approved medications. All used off label.
- Double void or straining to void
- Avoidance of bladder overdistention
  - Indwelling urinary catheter
  - Intermittent catheterization (preferred)

MEDICATION

First Line

- α-Adrenergic blockers
  - Alfuzosin

  – Doxazosin
  – Terazosin
• Muscarinic receptor agonists
  – Bethanechol, carbachol
• Choline esterase inhibitors
  – Distigmine (Approved outside of US)

Second Line
• Potential therapy
  – Prostaglandin E2
  – Acting on four types of EP receptors
    ◦ Increase detrusor contraction
    ◦ Relax the urethra

SURGERY/OTHER PROCEDURES
• Sacral nerve stimulation and intravesical electrical stimulation
  – Potentially beneficial in select patients
• Invasive surgical reconstruction
  – Latissimus dorsi muscle transposition to restore bladder function

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
• Experimental therapeutics:
  – Stem cell therapy
    ◦ Allow weak detrusor to improve contractility
  – Targeted gene therapy

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
Good prognosis with appropriate bladder management

COMPLICATIONS
• Urinary retention
• Urinary tract infections
• Damage to upper urinary tract

FOLLOW-UP
Patient Monitoring
• Post-void residual
• Uroflowmetry
• Urinalysis and urine culture

Patient Resources

- Underactive Bladder Foundation – www.underactivebladder.org

CODES

ICD9

- 596.59 Other functional disorder of bladder
- 788.21 Incomplete bladder emptying
- 788.99 Other symptoms involving urinary system

ICD10

- N31.8 Other neuromuscular dysfunction of bladder
- R33.8 Other retention of urine
- R39.19 Other difficulties with micturition

CLINICAL/SURGICAL PEARLS

The term DU remains surrounded by ambiguity and confusion with a lack of accepted terminology, definition, and diagnostic methods and criteria.

UNDESCENDED TESTES (CRYPTORCHIDISM)

Julia S. Barthold, MD, FACS

BASICS

DESCRIPTION

- Cryptorchidism, or undescended testis (UDT), is failure of one or both testes to descend or remain descended in a dependent scrotal position.
- Position
  - Intra-abdominal (10–20%)
  - Canalicular: Within inguinal canal
  - Distal to external ring, including prepubic, prescrotal/gliding, superficial inguinal pouch
  - True ectopic: Perineal most common
- Subclassifications
  - Congenital: Testis extrascrotal at birth
  - Acquired: Testis intrascrotal at birth but found in an extrascrotal position at a subsequent time (1)
    - Delayed diagnosis of primary UDT
    - After inguinal surgery
    - After spontaneous postnatal descent (recurrent cryptorchidism)
  - Vanishing: Blind-ending spermatic vessels and vas deferens in a boy initially diagnosed with UDT

EPIDEMIOLOGY

Incidence

- 2–4% of full-term boys
- Up to 30% of premature boys (< 37 weeks gestational age)
- Up to half descend spontaneously in the first 3–6 months of life but some will reascend
- Testes of premature boys are more likely to descend and may take a year or longer

Prevalence

- 1% of boys at 1 year of age
- Up to 4% of boys undergo orchidopexy for UDT during childhood, presumably related to risk of acquired UDT
- Up to half of boys present with acquired UDT

RISK FACTORS

- Increased incidence in families (2)
  - Fathers, brothers, dizygotic twins, monozygotic twins
- Low birth weight: Prematurity or SGA
- Maternal environment
- Retractile testis is a risk factor for acquired UDT in some individuals
  - Unilateral > bilateral
  - Risk of ascent 7–32% (3)
  - Normal testes frequently retractile >6 mo up to puberty; peak at 4 yr

- Environmental exposures?—Antiandrogenic and estrogenic compounds in animal models but weak evidence for etiology in human population

Genetics

- Rare variants of *INSL3* or its receptor *RXFP2*
- Possible association with *AR* or *ESR1* variants
- Likely polygenic/multifactorial

PATHOPHYSIOLOGY

- Failure of complete testicular descent
- Requires normal development and function of the gubernaculum
  - Arises from intermediate mesoderm 1st trimester, enlarges 2nd trimester, migrates and then regresses 3rd trimester-birth
  - Requires stimulation by testicular androgens and INSL3
- Acquired UDTs are frequently located in the superficial inguinal pouch and in most cases represent primary undescended testes not clinically identifiable until a later age

ASSOCIATED CONDITIONS

- Inguinal hernia/patent processus vaginalis
  - 50–90%, increased incidence in younger boys
  - Rarely clinically apparent
- Epididymal anomalies
  - Long-looping most common
  - Detachment of caput
  - Atresia rare
  - Association with patent processus vaginalis
  - Clinical relevance unclear
- Hypospadias
- Abdominal wall defects
  - Prune Belly (triad) syndrome; omphalocele; gastroschisis
- Neurologic and musculoskelet al diseases
  - Myelomeningocele, cerebral palsy
- Component of over 300 syndromes
- Abnormal Leydig cell function
  - Subtle reduction in testosterone (T) and/or increased LH/T ratio
  - Low incidence in nonsyndromic UDT
- Disorders of sex differentiation (DSD)
  - Usually associated with abnormal urethral and/or penile development
  - 46XX congenital adrenal hypoplasia (CAH) with complete penile development; very rare; bilateral non-palpable testes; urgent diagnosis in newborn due to risk of salt wasting

GENERAL PREVENTION

Unknown

DIAGNOSIS

HISTORY

- Family history of UDT
- History of inguinal hernia and/or surgery
- Maternal exposures or illness during pregnancy
- Birth history: Gestational age and birth weight

PHYSICAL EXAM

- Document testicular position at birth
- Assess scrotal development: May be hypoplastic
- Assess penile development
  - Hypospadias
  - Micropenis (>2 SD below mean for age)
  - Ambiguous genitalia (DSD)
- Continue periodic exams to assess for spontaneous testicular descent for at least 6 mo
- Assure maintenance of scrotal position
  - After spontaneous descent
  - Older boys with retractile testes
    - Yearly exam, warm room, warm hands, relaxed child if possible
    - Upright cross-legged position or supine with legs abducted
- Evidence that a nonpalpable testis is absent
  - Intrascrotal "nubbin" = vanishing testis
  - Contralateral testicular hypertrophy (length ≥1.8 cm) (4)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Unilateral nonpalpable testis: No testing
- Bilateral nonpalpable testes
  - Rule out CAH in newborn: Karyotype; electrolytes, 17-OH progesterone
  - Hormone levels: T and gonadotropin levels during postnatal surge at 1–3 mo
    - Low anti-Müllerian hormone (AMH)
    - ± abnormal hCG stimulation test

Imaging

- Imaging rarely indicated (5)
  - US inaccurate to determine position
  - MRI/MRA more accurate but rarely used
- *Potentially* useful in selected cases after referral to specialist
  - Obese boys with a history of palpable testes
  - Failure to identify spermatic vessels after laparoscopy or abdominal exploration

Diagnostic Procedures/Surgery

- Laparoscopy
  - Procedure of choice for localization and determination of status of nonpalpable testis
  - Open internal ring: Distal testis likely
  - Closed internal ring: No vessels: look for high abdominal testis (image); small/atretic vessels suggests distal "vanishing" testis.
  - Retroperitoneal exploration to kidney may be required.

Pathologic Findings

- Testicular biopsy
  - Not standard practice at orchidopexy
  - Reduced spermatogonia numbers in UDT
  - Reduced Ad (adult dark) spermatogonia most predictive of spermatogenic function
  - Leydig cell hypoplasia and/or Sertoli cell degeneration—limited data

DIFFERENTIAL DIAGNOSIS

- Retractile testis
- Vanishing testis: Confirmation of blind-ending spermatic vessels; antenatal torsion, or vascular accident
- True agenesis
  - Rare; ipsilateral failure of Wolffian duct development and Müllerian duct regression

TREATMENT

GENERAL MEASURES

- Observe for spontaneous postnatal descent
  - Identify clinical hernia or torsion
  - Ensure permanent, stable scrotal position by 6 mo of age, then yearly observation
  - Observe longer for descent if prematurity
- Plan surgery at 6–18 mo of age if testis fails to descend to improve testicular growth (6)
- Plan surgery at diagnosis in boys with acquired UDT

MEDICATION

- Hormonal treatment not efficacious (7)
  - hCG injections or LHRH nasal spray (not available in the United States)
  - Slight benefit over placebo; efficacy 15–20%
  - Possible adverse effects: Pigmentation, transient pubic hair, behavior changes, adverse testicular effects
  - Inadequate follow-up to rule out recurrence

SURGERY/OTHER PROCEDURES

ALERT
In cases of nonpalpable testis, the surgeon must identify the spermatic vessels and confirm that they are blind-ending or associated with an intact testis.

- Surgery is treatment of choice (3)
- Approach depends on testis palpability
- Inguinal orchidopexy
  - Standard approach for palpable testis
    - Mobilize testis via inguinal incision
    - High ligation of hernia sac if present
    - Transection of lateral retroperitoneal fascial bands to provide additional length
    - Medial translocation behind epigastric vessels (Prentiss maneuver) rarely needed
    - Higher abdominal counterincision possible if further mobilization needed
    - Placement of testis in sub-Dartos pouch without tension

- Success rate ~95%
- Complications: Testicular retraction; testis, cord or nerve injury; bleeding, infection, recurrent hernia (all rare)

• Primary scrotal orchidopexy (Bianchi)
- Increasingly reported as preferred approach for testes distal to external inguinal ring
  - Mobilization of testis and cremasteric muscle/fascia from cord via scrotal incision
  - Standard fixation in subdartos pouch
  - Best for low testes without associated patent processus vaginalis
  - Repair of hernia through scrotum possible although long-term failure rate uncertain and may be higher (8)
  - Similar success and complication rates as compared to inguinal orchiopexy

• Laparoscopic orchidopexy
- Procedure of choice for abdominal or high canalicular testes near internal ring
  - Laparoscopy for testis(es) localization with two additional lower quadrant ports
  - Mobilization of lateral and medial peritoneal attachments to cord
  - Transaction of peritoneum over cord
  - Transfer of mobilized testis through existing or neo-internal ring and standard fixation in subdartos pouch
- Success rates 72–91%

• Open abdominal orchiopexy
- High inguinal incision; Potentially more limited access to proximal cord
- Mobilization similar to laparoscopic approach
- Success rates 77–86%

• **Fowler-Stephens orchiopexy**
- One- or two-stage procedure via open or laparoscopic approach
- Required for high testis and/or short spermatic vessels
- Maintain vascular supply between vas and spermatic vessels
- Transection of spermatic vessels
- Success rates 80–94%

• Orchiectomy of unilateral UDT
- Consider in high abdominal testis, short vas deferens, hypoplastic testis, adolescent/postpubertal male

• Special considerations
- Testicular biopsy in dysmorphic testis; consider in postpubertal males
- Microvascular autotransplant requires specific expertise; solitary testes in low risk patients
- Subcutaneous testis placement as last resort to maintain endocrine function

ADDITIONAL TREATMENT

Additional Therapies

Adjuvant hormonal therapy may improve germ cell number and/or maturation; long-term efficacy uncertain

ONGOING CARE

PROGNOSIS

- Fertility
  - Abnormal semen analysis: Highly variable in unilateral, 20–50%, common bilateral, 75–100%
- Paternity
  - Conception success essentially normal in unilateral, 90%; reduced in bilateral, 30–50%
- Malignancy: Overall relative risk 2.9–6.5
  - Postpubertal presentation; risk may be decreased by prepubertal orchidopexy
  - Testicular position may influence histology
  - Abdominal: Seminoma more common
  - Scrotal: Nonseminomatous germ cell tumor more common

COMPLICATIONS

- Testicular atrophy; increased risk for abdominal testes
- Torsion risk 10× normal

FOLLOW-UP

Patient Monitoring

- Testicular development and position during peripubertal period
- Counseling regarding potential subfertility
- Testicular self-exam

CODES

ICD9
- 752.51 Undescended testis
- 752.52 Retractile testis
- 752.89 Other specified anomalies of genital organs

ICD10
- Q53.9 Undescended testicle, unspecified
- Q53.11 Abdominal testis, unilateral
- Q55.22 Retractile testis

CLINICAL/SURGICAL PEARLS
- Spontaneous testicular descent is common in the first 6 mo of life but testes may re-ascend.
- Surgery is the standard treatment.
- Testes that appear to be scrotal at birth can be later diagnosed as cryptorchid with potentially increased risk in retractile testes.
- Routine testis exams with well-child visits are indicated.

URACHAL CARCINOMA

Michael O. Koch, MD, FACS
Andrew D. Strine, MD

BASICS

DESCRIPTION

- Urachal carcinoma is a rare non-urothelial malignancy (almost always adenocarcinoma) usually involving the dome of the bladder due to direct extension from the urachal ligament, the structure from which this tumor arises.
- Rare malignancy
  - Less than 1% of all bladder cancers
- Almost exclusively occurs in adults and most commonly in the 4th to 5th decades.
- Adenocarcinoma is the most common histologic subtype.
- Staging is distinct from bladder cancer but not standardized.
  - Sheldon, Mayo (1,2), and Ontario (3) staging systems
- Generally has a poor prognosis due to delayed diagnosis but may be curable with early surgical resection.

EPIDEMIOLOGY

Incidence

1 in 5 million cases annually

Prevalence

Unknown due to its rarity and often asymptomatic nature

RISK FACTORS

None

Genetics

None

PATHOPHYSIOLOGY

- Originates from the urachus.
  - Serves as a communication between the developing bladder and allantois but becomes a fibrous band by 12 weeks of gestation and is recognized as the median umbilical ligament in adults.
  - Composed of urothelium-lined lumen of epithelial origin as well as submucosa and smooth muscle of mesenchymal origin.
    - Any layer may undergo a malignant transformation.
- Locally invades into muscularis propria and perivesical fat with demarcation from urothelium.
- Local extends to space of Retzius, anterior abdominal wall, umbilicus, and peritoneal cavity.
- Metastasizes to pelvic lymph nodes, lungs, liver, and bone.

ASSOCIATED CONDITIONS

Urachal remnants, including patent urachus, urachal sinus, cyst, and diverticulum

GENERAL PREVENTION
None

DIAGNOSIS
HISTORY
- Increasing incidental detection due to routine use of imaging
- Often asymptomatic until more advanced
- Presenting signs and symptoms
  - Hematuria (most common) or mucosuria
  - Abdominal pain
  - Voiding symptoms or urinary tract infection (UTI)
  - Umbilical drainage
  - Omphalitis
  - Umbilical mass

PHYSICAL EXAM
- Palpable urachal mass
  - Large, fixed mass or concurrent ascites may suggest locally advanced, unresectable disease.
- Umbilical drainage or mass that fluctuates in size is more consistent with an infected urachal sinus or cyst.
- Perform a pelvic and rectal examination to evaluate for a gynecologic or rectal malignancy.
- Evaluate for any systemic signs and symptoms of infection and metastatic disease.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Hematologic and chemistry panels
- Urinalysis and urine culture to evaluate for microscopic hematuria and UTI
- Urine cytology to evaluate for a urothelial malignancy
- CA-125 and CA 19-9
  - May be elevated in 40–60% of patients
  - Useful in evaluating the response to systemic therapies

Imaging
- Abdominal ultrasound
  - Often obtained during the initial evaluation and in the pediatric population
  - High specificity for urachal cysts
  - Significant false-positive rate for other urachal lesions
  - Poor characterization of locally advanced disease
- CT or MRI of the abdomen and pelvis with IV and PO contrast
  - Gold standard for diagnosis and staging
  - Midline, calcified, partially cystic mass with local extension is concerning for but not diagnostic of urachal carcinoma.
- Chest x-ray or CT of chest for staging

- Bone scan if advanced disease, bony symptoms, or elevated alkaline phosphatase

Diagnostic Procedures/Surgery

- Cystoscopy with transurethral biopsy or resection
  - Evaluate for intravesical invasion, drop metastases, or metasynchronous bladder cancer
  - Biopsy or resection of tumor and adjacent normal urothelium is recommended but may be difficult due its extravesical location.
  - Any tumor arising from the dome of bladder should be considered urachal in origin until proven otherwise.
- Percutaneous biopsy may be performed but raises a theoretical concern for seeding the biopsy tract.

Pathologic Findings

- A majority (>80%) is adenocarcinoma with glandular features and produces mucin.
  - Similar immunohistochemistry to colonic adenocarcinoma (1)
    - Strong reactivity for 34BE12 and lack of diffuse nuclear reactivity for β-catenin is more suggestive of urachal origin.
  - No immunohistochemical markers to differentiate adenocarcinoma originating from the urachus and bladder
- Other subtypes
  - Sarcoma
  - Squamous-cell carcinoma
  - Urothelial carcinoma
- Pathologic criteria
  - Definitive
    - Tumor located in the dome of bladder or along midline
    - Demarcation between tumor and urothelium
  - Supportive
    - Presence of urachal remnant in tumor
    - Enteric-type pathology
    - Absence of urothelial dysplasia or carcinoma
    - Absence of cystitis glandularis and cystisa
- Favorable (well-differentiated) histology may have a better prognosis than unfavorable (poorly differentiated) histology for similarly staged tumors (3).

DIFFERENTIAL DIAGNOSIS

- Primary bladder lesion
  - Primary bladder cancer of any histologic type at the dome of bladder
  - Secondary malignancy of gynecologic or colorectal origin invading into the bladder
- Periumbilical mass
  - Urachal remnants
    - Patent urachus
    - Urachal cyst
    - Urachal sinus
    - Vesicourachal diverticulum
  - Umbilical hernia

- Urachal neoplasms: Adults
  - Benign (very rare): Adenomas, fibromas, fibroadenomas, fibromyomas, hamartomas
  - Malignant (very rare, less than 0.5% of all bladder cancers): Mostly adenocarcinoma
- Sister Mary Joseph nodule (adults): Umbilical metastasis of primary tumors (if primary is known, usually from genital or GI tract)
- Others: Dermoid cyst, sebum cyst, spontaneous umbilical fistula from Crohn disease/TB/perforated appendix, and skin cancers such as basal-cell or squamous-cell carcinoma

TREATMENT

GENERAL MEASURES

- Typically manifests as locally advanced or metastatic disease.
  - Less than 20% of patients present with stage 1 (no invasion) or 2 (invasion confined to urachus) disease based on Sheldon staging system in most series.
- Management is controversial but typically involves surgical resection.
- Chemotherapy and radiation therapy are generally thought to be less effective and reserved for higher stage disease.

MEDICATION

First Line

- Chemotherapy is typically reserved for unresectable or metastatic disease.
  - No standard regimen established.
  - Regimens using 5-fluorouracil, cisplatin, and either α-interferon or gemcitabine and lucovorin are superior to others.
  - Median overall survival of 20 months reported in patients with at least a partial response or stabilized disease (4)[B].
- No definitive role for neoadjuvant chemotherapy

Second Line

No definitive role but often used as an adjuvant therapy for margin- and node-positive disease as well as recurrences.

SURGERY/OTHER PROCEDURES

- Radical cystectomy or partial cystectomy with wide surgical margins and en-bloc resection of urachal remnant extending from bladder to umbilicus, posterior rectus sheath, and all tissue between medial umbilical ligaments is recommended for lower stage, resectable disease.
  - Partial cystectomy may offer a comparable oncologic outcome and less morbidity to radical cystectomy if tumor is completely resected (3 – 5)[C].
  - Failure to resect the umbilicus and positive surgical margins are associated with a worse outcome (2,4,5)[B].
- Bilateral pelvic lymph node dissection
  - Should follow the standard template for bladder cancer.
  - May be useful for staging but does not provide any survival advantage (1,2)[B].
- Surgical resection is particularly well suited to a laparoscopic or robotic approach with

comparable short-term outcomes.

ADDITIONAL TREATMENT

Radiation Therapy

- Limited evidence
- Occasionally used for unresectable or metastatic disease (with chemotherapy) or as an adjuvant therapy for margin- and node-positive disease as well as recurrences.
- Median overall survival of 19.5 mo and 21 mo reported after radiation therapy alone and radiation therapy with chemotherapy, respectively (1)[B].

Additional Therapies

None

Complementary & Alternative Therapies

None

ONGOING CARE

PROGNOSIS

- Clinical and pathologic staging is the most important predictor of survival (1 – 5)[B].
  - Two staging systems (Sheldon and Ashley) (6) (See Section II: Urachal Carcinoma Staging Systems)
- 5-yr overall survival rates range from 27 to 80%, depending on the series.
  - About 50% for locally advanced disease (1 – 5)[B]
  - Less than 20% for metastatic disease (1 – 4)[B]
  - 93% for disease confined to the urachus and bladder after surgical resection with bladder preservation (5)[B]
  - 69% for extravesical and peri-urachal disease after surgical resection with bladder preservation (5)[B]

COMPLICATIONS

- Bleeding
- Infection
- Injury to surrounding organs
- Urinary leak
- Lymphocele
- Postoperative cardiopulmonary complications, including myocardial infarction, deep vein thrombosis, and pulmonary embolism
- Development of recurrent or progressive disease

FOLLOW-UP

Patient Monitoring

- No standard schedule for oncologic surveillance established
- Adaptation from bladder cancer
  - Radical cystectomy
    - History and physical examination, electrolytes, serum creatinine, and urine cytology every 3–6 mo for 2 yr and then as clinically indicated

- Imaging of the chest, abdomen, and pelvis every 3–12 mo for 2 yr based on risk of recurrence and then as clinically indicated
- Partial cystectomy
  - Same as above
  - Cystoscopy every 3–6 mo for 2 yr and then at increasing intervals as clinically indicated

CODES

ICD9

- 188.7 Malignant neoplasm of urachus
- 198.1 Secondary malignant neoplasm of other urinary organs

ICD10

- C67.7 Malignant neoplasm of urachus
- C79.11 Secondary malignant neoplasm of bladder

CLINICAL/SURGICAL PEARLS

- It is difficult to differentiate between an infection and urachal carcinoma for symptomatic urachal lesions.
- There should be a high clinical suspicion for urachal carcinoma in any adult with an urachal lesion.
- Any tumor arising from the dome of bladder should be considered urachal carcinoma until proven otherwise.
- Surgical management of urachal carcinoma should involve a complete resection of the urachus and umbilicus with wide surgical margins.

URETER AND RENAL PELVIC TUMORS, GENERAL CONSIDERATIONS

Julie M. Riley, MD
Timothy D. Averch, MD, FACS

BASICS

DESCRIPTION

- Tumors of the ureter and renal pelvis are relatively rare.
- Tumors are most often malignant and account for 5% of all urothelial tumors; most commonly TCC (transitional cell carcinoma), also called urothelial cell carcinoma (UCC).

EPIDEMIOLOGY

Incidence

- 1 in 113,333 or ~2400 cases/yr
- 7% of all kidney tumors
- Ureteric TCC account for 1 in every 25 upper-tract tumors
- Males:female = 2:1
- More common in Caucasian population
  - Asians more often have high-grade tumors

Prevalence

Rare <40 yr, peak incidence 6th–7th decade

RISK FACTORS

- Smoking: Risk from 2.6–8.0
  - Increases with higher dose and duration
- History of bladder cancer: 2–25% of patients with bladder cancer develop upper-tract TCC
- Occupational exposure: Similar to bladder cancer; risk from 4.0 to 5.5
  - ~20% of TCCs
  - Disease latency of 30–50 yr
  - Aromatic amines (aniline dyes [color fabrics]), 2-naphthylamine, 4-aminobiphenyl, 4-nitrobiphenyl, 4,4-diaminobiphenyl, 2-amino-1-naphthol, soot from coal, combustion gas, and aliphatic hydrocarbons
  - High-risk jobs: Autoworkers, leather workers, painters, truck drivers, met al workers, machinists, dry cleaners, dental technicians, beauticians, and physicians
- Coffee: Minor contribution, relative risk of 1.3
- Analgesic abuse: All components implicated; highest risk with phenacetin abuse; latency of 25 yr (dose of 10–15 g over 10 yr); tend to be women who present with high-stage tumors. Relative risk: 2.4 for men and 4.2 for women
- Cyclophosphamide: Hemorrhagic cystitis and carcinoma; 9 times increased risk of carcinoma after exposure; latency of 6–13 yr
- Infectious agents: Chronic bacterial infection with calculi and obstruction; increased risk of SCC (squamous-cell carcinoma)

- Balkan nephropathy: Endemic to Bulgaria, Greece, Romania, and Yugoslavia
  - Carcinogenic potential of *Aristolochia fangchi* and *Aristolochia clematis* (plants endemic to the Balkans).
  - Often multiple, bilateral, and indolent tumors
  - Renal-sparing surgery when possible
- Black Foot disease: Vasculopathy in Taiwan; arsenic contamination of water
- Lynch syndrome

Genetics
- Most have no family history of disease
- Certain familial cancer syndromes show an increased incidence of TCC (Lynch type II)
- Familial clustering exists; difficult to determine if related to environmental factors
- Low-grade superficial TCC: *p15* and *p16* loss (chromosome 9p)
- High-grade TCC: *p53* loss (chromosome 17p)
- Amplification and overexpression of genes that code for growth factors or their receptors
  - EGF-R (chromosome 7): Trisomy 7 associated with TCC
  - Erb-2 mutations associated with TCC

PATHOPHYSIOLOGY
- >90% upper tract urothelial tumors are TCCs
  - ~70% ureteral TCCs occur in distal ureter, 25% mid ureter, and 5% proximal ureter.
  - Tumors of the ureter tend to be less invasive and smaller than those of the renal pelvis.
  - Up to 50% of ureteral TCCs are multicentric.
- SCC: 7%; associated with long-term infection, inflammation, and calculi
- Rare malignant tumors include sarcoma, adenocarcinoma, and carcinosarcoma.
- Rare benign tumors include inverted papilloma and fibroepithelial polyp.

ASSOCIATED CONDITIONS
Urothelial carcinoma of the bladder

GENERAL PREVENTION
- Smoking cessation
- Avoid or limit chronic analgesia use.
- Avoid exposure to implicated toxins

DIAGNOSIS

HISTORY
- Age and sex of patient: Peak incidence in mid-60s, male > female
- Hematuria: Most common presenting symptom (75% of patients)
- Dull flank pain due to the gradual distention of collecting system (30% of patients)
- Tobacco use or occupational exposure (up to 20% of TCCs)
- History of analgesia abuse in past: Dose-related effect; phenacetin is most common
- History of recurrent infections and calculi: SCC
- Asymptomatic: Incidental diagnosis in 10–15%
- Rarely, patients present with signs of advanced disease (abdominal or flank mass, anorexia, weight loss, etc.)

PHYSICAL EXAM

Usually normal; flank or abdominal mass with advanced disease

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine analysis: Hematuria (gross or microscopic)
- Cytopathology:
  - Voided specimen: Low sensitivity for upper-tract TCC; ureteral catheterization specimens are more sensitive.
  - Accuracy increases with increasing grade of tumor.

Imaging

- Intravenous pyelogram (IVP):
  - 50–75%: Radiolucent filling defect; irregular and continuous with the wall
  - 10–30% show obstruction or non-visualization of the collecting system, which indicates more invasive disease
  - Assess contralateral kidney for lesion and function
- Retrograde pyelography (RGP): Better visualization than IVP (>75% accuracy)
- Antegrade pyelography:
  - Used only if not possible to visualize collecting system via retrograde approach utilizing a percutaneous nephrostomy tube.
- Computed Tomography Urogram (CTU): Primary imaging study, used for diagnosis and staging of tumors (image)
- Magnetic resonance imaging (MRI): For staging

Diagnostic Procedures/Surgery

- Ureteroscopy (URS) and nephroscopy (image):
  - Diagnostic accuracy of 58–83%.
  - Not accurate for staging TCCs due to difficulty in determining the depth of invasion, particularly renal pelvic TCC
- Brush biopsy:
  - High positive predictive value, overall accuracy of 78%
  - significant risk of bleeding and perforation
- Selective cytology barbotage (repeated injection and aspiration of saline): Localize tumor

Pathologic Findings

- Urothelial carcinoma: Papillary (exophytic) predominate:
  - Slender stalks or endophytic (flat)
  - Invasive or noninvasive
  - Almost no tumors of low malignant potential in the upper tract
- SCC is characterized by sheets of cells with well-defined cell borders, deeply eosinophilic cytoplasm, and focal keratin pearl formation.

DIFFERENTIAL DIAGNOSIS

- Malignant filling defect of ureter and renal pelvis:
  - TCC Urothelial cell carcinoma: The most common malignant cause of upper urinary tract filling defects.

  – Squamous cell carcinoma (SCC)
  – Rare malignant tumors: Adenocarcinoma, sarcoma, angiosarcoma, and carcinosarcoma
  – Renal cell carcinoma (RCC)
• Benign filling defect of the ureter and renal pelvis:
  – Air: Iatrogenic, infectious, or due to fistula
  – Blood clot
  – Fibroepithelial polyp
  – Fungus ball
  – Hemangioma
  – Inflammatory lesions: Granuloma, malakoplakia, tuberculosis
  – Inverted papilloma
  – Radiolucent calculus
  – Rare benign tumors: Leiomyoma, neurofibroma, cholesteatoma
  – Renal or sloughed papilla
  – Extrinsic compression on the ureter
  – Mucus: Urinary diversion patients
  – Protein matrix
  – Ureteritis or pyelitis cystica
  – Vascular impression

TREATMENT

GENERAL MEASURES
• If positive cytology is the only sign of upper tract TCC, close follow-up is required.
• Standard treatment is surgical for most benign and malignant lesions.

MEDICATION
First Line
N/A

Second Line
• Instillation therapy with BCG or mitomycin not proven to increase survival:
  – Appears to be safe
  – May be useful in multiple superficial tumors or bilateral disease
  – Difficult to deliver the agent in adequate doses and dwell time

SURGERY/OTHER PROCEDURES
• Standard treatment is nephroureterectomy (NU): Laparoscopic or open
• Renal-sparing surgery indicated: Solitary kidney, bilateral disease, poor function of contralateral kidney, or low grade and stage
• Survival related to stage and grade of tumor rather than to treatment modality
• Radical NU and excision of bladder cuff
  – 80–90% 5-yr survival (low grade and stage)
  – 30–75% recurrence rate in ureteral stump
  – Radical lymphadenectomy not shown to improve survival
  – Endoscopic approach to bladder cuff resection has slightly higher rate of bladder

recurrence (1)
- Endoscopic treatment (ureteroscopy [URS]) or percutaneous):
  - Indications: solitary kidney, poor renal function, bilateral disease, moderate tumor burden, low-grade, poor surgery candidate
  - Risk of perforation is higher than that in bladder (overall complication rate: 7%)
  - Requires close follow-up due to high recurrence rate (recurrence free survival ~ 20% at 10 yr) (2)
  - Laser ablation in low-grade or multiple tumors
  - Seeding of percutaneous tract is low (0.03%) (3)
- Segmental ureteral resection: Solitary low-grade upper and mid-ureteral lesions:
  - Recurrence rate of 6%; higher if multifocal
- Distal ureterectomy and ureteroneocystostomy: Distal, solitary ureteral lesions
- Benign tumors such as fibroepithelial polyp or inverted papilloma: Endoscopic management

ADDITIONAL TREATMENT

Radiation Therapy

Can be used for advanced tumors not amenable to surgery, with decreased efficacy

Additional Therapies

- Neoadjuvant/adjuvant chemotherapy has not been established as in bladder cancer (3)
  - Cisplatin therapies have been successful

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Recurrence rate reduced with more aggressive resection of tumor:
  - 48% recurrence with nephrectomy
  - 32% with nephrectomy plus partial ureterectomy
  - 24% with nephrectomy plus subtotal ureterectomy
  - 12% with NU
- Prognosis largely unchanged in locally advanced disease for last 20 yr
- Better survival for tumors in renal pelvis than ureteral in T3 or higher disease

COMPLICATIONS

- Obstruction of urinary tract
- Development of metastatic disease

FOLLOW-UP

Patient Monitoring

- Cystoscopy with cytology every 3–6 mo for 2–3 yr, then yearly
- 6-mo CT urogram + chest x-ray, then annually
- URS is more sensitive than radiologic techniques for follow-up of upper-tract TCC

Patient Resources

CODES

ICD9
- 189.1 Malignant neoplasm of renal pelvis
- 189.2 Malignant neoplasm of ureter
- 239.5 Neoplasm of unspecified nature of other genitourinary organs

ICD10
- C65.9 Malignant neoplasm of unspecified renal pelvis
- C66.9 Malignant neoplasm of unspecified ureter
- D49.5 Neoplasm of unspecified behavior of other genitourinary organs

CLINICAL/SURGICAL PEARLS

- Ureteral and renal pelvic tumors are rare.
- Management remains surgical with NU being the gold standard.
- Endoscopic management is becoming more accepted but the risk of under staging and under grading remains.
- Close follow-up is warranted and ureteroscopy remains the most sensitive surveillance test.

URETER AND RENAL PELVIS, SQUAMOUS CELL CARCINOMA

Angela B. Smith, MD
Raj S. Pruthi, MD, FACS

BASICS

DESCRIPTION

- Squamous-cell carcinoma (SCC) of the renal pelvis and ureter is a rare but aggressive tumor characterized by nests of squamous cells with hyperchromatic nuclei and prominent keratin production.
- Most common non-urothelial tumor of the upper urinary tract.

EPIDEMIOLOGY

Incidence

- 0.5–0.8% of all malignant renal tumors (1)[C]
- 6–15% of all upper tract urothelial cancers (4)[C]
- Mean age 61 yr
- Equal incidence male:female (although some series suggest male predominance) (2,3)[C]
- 6× more likely to occur in the renal pelvis than in the ureter

Prevalence

- Prevalence unknown due to rarity of tumor
  - Rare tumor, with case reports in literature

RISK FACTORS

- Chronic inflammation (4)[C]
- Chronic infections associated with (4)[C]
  - Urinary stones
  - Obstruction
- Cyclophosphamide (alkylating agent) shown to increase risk of upper tract SCC

Genetics

- No specific genetic patterns identified
- Possible that DNA ploidy pattern correlates with grade and stage but does not aid prognosis
  - Not definitive; requires further study (3)[C]

PATHOPHYSIOLOGY

- SCC of the renal pelvis and ureter has been shown to be associated with chronic infection and inflammation
  - Presumed that chronic irritation of urothelium leads to squamous metaplasia and subsequent SCC

ASSOCIATED CONDITIONS

- Chronic infections: (4)[C]
  - Genitourinary tuberculosis
  - Struvite stones

  – Chronic pyelonephritis or pyonephrosis
  – Parasitic infection
• Chronic inflammation: (4)[C]
  – Analgesic abuse
  – Prior percutaneous nephrolithotomy
• Horseshoe kidney (3× risk due to stones/infection) (4)[C]
• Renal or ureteral calculi (4)[C]
  – Present in up to 50% of cases
• Bladder cancer history uncommon (3)[C]
  – 5% preceding diagnosis
  – 2% with concomitant bladder cancer

GENERAL PREVENTION

As a rare condition, little evidence exists for prevention of this condition

DIAGNOSIS

HISTORY

• History of chronic renal infections or stones
• Vague abdominal or flank pain
• Gross hematuria
• Local symptoms more common than those with TCC urothelial carcinoma (4)[C]
• Nonspecific symptoms:
  – Anorexia
  – Lethargy
  – Weight loss

PHYSICAL EXAM

• Often no signs on physical exam
• Flank or abdominal mass may be present with advanced disease

DIAGNOSTIC TESTS & INTERPRETATION

Lab

• Urinalysis:
  – Hematuria
  – Pyuria
• Serum chemistries (3)[C]
  – Serum creatinine may be elevated due to tumor infiltration, obstruction, chronic infection, or scarring
  – Paraneoplastic syndrome which may resolve following resection includes:
    ○ Hypercalcemia
    ○ Leukocytosis
    ○ Thrombocytosis

Imaging

• Diagnosis suggested (but not definitive) with radiologic imaging
• Excretory imaging useful (including intravenous pyelogram, CT urogram) and may

demonstrate:
  – Filling defect
  – Solid mass w/ or w/o calcifications
  – Hydronephrosis
• Once pathology confirmed, CT or MRI/MRA necessary for surgical planning
  – Vascular anatomy
  – Presence of metastases
  – Evaluation of contralateral renal unit
  – Size and extent of tumor

Diagnostic Procedures/Surgery

• Cystoscopy to evaluate for lower tract urothelial cancer, selective ureteral cytology
• Retrograde ureteropyelogram and ureteroscopy/pyeloscopy with biopsy essential
  – Often with sessile appearance
  – May have calcifications
• Definitive diagnosis confirmed following nephroureterectomy (see TREATMENT)

Pathologic Findings

• Most moderately or poorly differentiated
• Gross (1)[C]
  – Infiltrating at time of diagnosis
  – Sessile tumor on endoscopy
  – Usually large, necrotic, ulcerated
• Histology (5)[C]
  – Sheets of cells with deeply eosinophilic cytoplasm
  – Large nuclei with prominent nucleoli
  – Focal keratin pearl formation
    ○ Keratin pearls and intercellular bridges may not be apparent in advanced cases

DIFFERENTIAL DIAGNOSIS

• Primary renal neoplasms
  – Renal cell carcinoma
  – Urothelial cancer (TCC) of upper tract
  – Wilms tumor
• Secondary renal neoplasms
  – Lymphoma/leukemia
  – Metastasis to kidney (breast, lung, and others)
• Benign renal masses
  – Xanthogranulomatous pyelonephritis
  – Rare form of chronic pyelonephritis
  – Angiomyolipoma

TREATMENT

GENERAL MEASURES

Surgery (nephroureterectomy) is mainstay of treatment (3)[C]

MEDICATION

First Line

Medical therapy not effective although some patients require broad-spectrum antibiotics in the setting of concurrent infection

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Referent standard treatment is surgical excision (radical nephroureterectomy with excision of bladder cuff) (3)[C]
- Role of retroperitoneal lymph node dissection controversial
- For those patients with infection, pre- and post-operative antibiotics may be required

ADDITIONAL TREATMENT

Radiation Therapy

Occasionally used for adjuvant treatment following surgery; however shown to have little benefit (1)[C]

Additional Therapies

Adjuvant platinum-based chemotherapy appears to have limited benefit (3)[C]

Complementary & Alternative Therapies

No complementary therapies have shown benefit

ONGOING CARE

PROGNOSIS

- Generally poor if found at advanced stage
  - Median survival of 7–14 mo postoperatively (2 – 4)[C]
  - Median 5-yr survival 7.7% (3)[C]
- Tumor stage at diagnosis most important for prognosis (3)[C]
- Grade has been found to add little value (3)[C]

COMPLICATIONS

- Renal insufficiency or failure
- Metastatic disease (3)[C]
  - Regional lymph nodes
  - Lungs
  - Liver
  - Bone

FOLLOW-UP

Patient Monitoring

- Limited data for patient monitoring
- Similar to TCC of upper tract
  - Urine cytology and cystoscopy every 3–4 mo for first 2 yr
  - Value of cystoscopy questionable due to low number of concurrent bladder cancers
- Metastatic workup every 6–12 mo, depending on stage

  – Chest imaging
  – CT abdomen/pelvis
- Monitor renal function periodically

CODES

ICD9

- 189.1 Malignant neoplasm of renal pelvis
- 189.2 Malignant neoplasm of ureter

ICD10

- C65.1 Malignant neoplasm of right renal pelvis
- C65.9 Malignant neoplasm of unspecified renal pelvis
- C66.9 Malignant neoplasm of unspecified ureter

CLINICAL/SURGICAL PEARLS

- SCC of upper tract is the most common non-urothelial cancer of the renal pelvis and ureter.
- A few symptoms manifest, but once hematuria and pain present, often advanced stage.
- Usually presents as advanced disease and has poor prognosis at this stage.
- Nephroureterectomy is standard of care with chemotherapy and radiation of limited benefit.

URETER AND RENAL PELVIS, UROTHELIAL CARCINOMA

Emma F.P. Jacobs, MD
Michael O. Koch, MD, FACS

BASICS

DESCRIPTION

Urothelial carcinoma (formerly known as transitional cell carcinoma or TCC) is an epithelial neoplasm of the ureter, renal pelvis, and calyces

EPIDEMIOLOGY

Incidence

- 5–10% of renal tumors are renal pelvis TCC
- 2–5% of urothelial tumors occur in the upper urinary tract (UUT)
- Peak incidence of 10 per 100,000/yr in 75–79 age group
- Mean age at presentation is 65, seldom appear before age 40 yr.
- Incidence is increasing.

Prevalence

Poor data available given rarity of condition

RISK FACTORS

- Bladder cancer (2–4% lifetime risk of UUT TCC)
  - Stage, grade, multiplicity, ureteral reflux, recurrent CIS after BCG, and TCC close to ureteral orifice all increase likelihood of UUT TCC in patient with bladder TCC
- Contralateral UUT TCC (1.6–6% risk)
- Risk factors shared with bladder TCC:
  - Cigarette smoking (≥3 times risk; only partly declines with smoking cessation)
  - Occupational exposure (≥4 times risk):
    - Aniline dyes, β-naphthylamine, benzidine, coal, coke, asphalt, or tar exposure; chemical, petroleum, or plastics industries
  - Cyclophosphamide:
    - Mesna (Uro-protectant) can be coadministered to neutralize acrolein (urotoxic metabolite)
- Other risk factors specific to UUC TCC:
  - Balkan nephropathy (100–200 times risk):
    - Typically bilateral, multifocal, low-grade
    - May be environmental rather than genetic
  - Analgesic abuse (3.6 times risk):
    - Phenacetin, aspirin, acetaminophen, codeine
    - Papillary necrosis (6.9 times risk):
    - Synergistic with analgesic abuse (20 times risk)
  - Chinese weight-loss herb *Aristolochia fangchi*

Genetics

- Male > Female (3:1)
- White > Black (2:1)
- Lynch II syndrome (HNPCC): Familial syndrome predisposing to GI, endometrial, and UUT neoplasms

PATHOPHYSIOLOGY
- Growth patterns include papillary and nodular
- TMN staging (stage is most important predictor of survival)
  - Stage Ta: Papillary, noninvasive
  - Stage Tis: CIS
  - Stage T1: Invades subepithelial connective tissue
  - Stage T2: Invades muscularis
  - Stage T3: Invades periureteral fat (renal pelvis only, and/or invades beyond muscularis into perinephric fat or the renal parenchyma
  - Stage T4: Invades adjacent organ or through kidney into perinephric fat

ASSOCIATED CONDITIONS
- Bladder TCC: 30–50% risk of developing bladder TCC after UUT TCC
- Balkan nephropathy
- Lynch II syndrome

GENERAL PREVENTION
Avoidance of risk factors

DIAGNOSIS
HISTORY
- Gross hematuria, dull flank pain, acute renal colic, weight loss, anorexia, bone pain
- Social history: Tobacco use, occupational exposures
- Medications: Analgesics (i.e., phenacetin, aspirin), cyclophosphamide, exotic herbs
- Family history: Balkan family, colonic malignancy

PHYSICAL EXAM
- Often asymptomatic
- CVA tenderness
- Flank or abdominal mass

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urine analysis: Gross or microscopic hematuria (60–90% present with hematuria)
- Electrolytes, LFTs normal in absence of urinary obstruction, or metastatic disease
- Voided urine cytology: Low sensitivity for low-grade TCC; better for high-grade, CIS

Imaging
- Intravenous urogram (IVU) or intravenous pyelogram (IVP):—traditional diagnsotic study largely replaced by CT Urograms
- Retrograde pyeloureterography
  - Indications: Contrast allergy, renal insufficiency
  - More sensitive than IVU or computerized tomographic urography (CTU)

  - Use dilute contrast (1/2–1/3).
  - Inject through cone-tip or open-ended catheter to fill entire collecting system (10–15 cc).
  - Avoid contrast extravasation due to overfilling.
- Computerized tomographic urography (CTU):
  - 3D reconstruction image quality is equivalent to IVU for UUT TCC.
  - Can differentiate renal parenchymal mass from extrinsic mass, and TCC from calculus
  - Can evaluate for locoregional or distant metastatic disease
- Ultrasound (US):
  - Can help distinguish stone from tumor in the setting of a fillling defect in the upper urinary tract

Diagnostic Procedures/Surgery

- Cystoscopy: Evaluates lower urinary tract for concomitant TCC
- Ureteroscopy: Provides direct visualization of UUT TCC, aspiration for cytology, cup/basket biopsy, and treatment simultaneously
- Catheterized ureteral or RP washing: 65–73% sensitive
- Ureteroscopic cup/basket biopsy: Most sensitive
- Brush biopsy: 91% sensitive, 88% specific

Pathologic Findings

- Pathologic staging of UUT TCC is difficult due to the limited size of biopsy specimens.
- Staging is predicted by biopsy grade.
- Tumor grade may be a more important prognostic factor than pathologic stage in UUT.
- Sending all biopsies for cytopathologic exam can improve the diagnostic yield (cell block).

DIFFERENTIAL DIAGNOSIS

- TCC is the most common malignant cause of UUT filling defects
- Squamous-cell carcinoma—Often associated with stones and recurrent infections
- Rare malignant tumors (adenocarcinoma, sarcoma, angiosarcoma, and carcinosarcoma)
- RCC—Typically found in conjunction with renal mass; has been reported without associated renal mass as a filling defect in the collecting system
- Benign filling defects of the ureter and renal pelvis:
  - Air: Iatrogenic, infectious, fistula
  - Blood clot
  - Fibroepithelial polyp
  - Fungus ball
  - Hemangioma
  - Inflammatory lesions: Granuloma, malakoplakia, TB
  - Inverted papilloma
  - Radiolucent calculus
  - Rare benign tumors: Leiomyoma, neurofibroma, cholesteatoma
  - Renal papilla—Ectopic or end on
  - Sloughed papilla
  - Extrinsic compression of the ureter
  - Mucous (urinary diversion patients)
  - Protein matrix

- Ureteritis or pyelitis cystica
- Vascular impression

TREATMENT

GENERAL MEASURES (2)

- Surgical excision is gold standard.
  - Preservation of renal unit is preferred when possible (low-grade focal disease) or involving the distal ureter (low- or high-grade disease)

MEDICATION

First Line

- Limited role, benefit has not been consistently demonstrated
  - Topical therapy- BCG, mitomycin, thiotepa
    - Instilled via percutaneous nephrostomy, external urethral catheter, or into bladder with indwelling ureteral stent
    - Typically given for large, multifocal, or residual tumor burden

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Open radical nephroureterectomy (RNU) with en-bloc excision of peri-ureteric bladder cuff:
  - Traditional treatment
  - Provides adequate surgical margins, local control, removes need for ipsilateral ureteroscopic surveillance, provides most accurate staging information
  - Role of lymphadenectomy is unclear
- Laparoscopic RNU
  - Equivalent disease-specific and overall survival compared to open RNU
  - Skin incision positioned to allow for distal ureteral dissection and en-bloc specimen removal
- Nephron-sparing surgery—For locally contained low-grade disease or high-grade disease with overwhelming concern for loss of renal function
  - Segmental ureterectomy
  - Used for noninvasive low-grade TCC of proximal or mid ureter too large for endoscopic ablation
  - Distal ureterectomy with reimplantation
    - Used for distal ureteral TCC to large for endoscopic ablation or high-grade TCC
- Endoscopic treatment
  - Indications include solitary kidney, bilateral disease, poor renal function, moderate tumor burden, low-grade disease, high-risk surgical candidates
  - Retrograde or percutaneous antegrade approach
  - Tumor biopsy with cold-cup or basket
  - Treatment techniques include electrosurgical resection, fulguration, laser ablation
  - Recurrence rates: 33% for ureteral TCC, 31% for renal pelvic TCC

ADDITIONAL TREATMENT

Radiation Therapy
Possible role for adjuvant radiation after complete excision. Studies have been small and collectively inconclusive.

Additional Therapies
- Consider systemic chemotherapy for high-stage or node-positive disease in patient with adequate renal function
  - Standard urothelial agents as used for bladder cancer
    - Methotrexate, vinblastine, doxorubicin, and cisplatin (MVAC)
    - Gemcitabine and cisplatin

Complementary & Alternative Therapies
No accepted therapy

ONGOING CARE

PROGNOSIS
- Overall 5-yr survival based on grade:
  - Grade 1–2: 40–87%
  - Grade 3–4: 0–33%
- 5-yr survival based on stage:
  - Stage Ta, T1, Tis: 60–90%
  - Stage T2: 43–75%
  - Stage T3: 16–33%
  - Stage T4: 0–5%

COMPLICATIONS
Ureteral obstruction, metastatic dissemination

FOLLOW-UP
Patient Monitoring
- If RNU is performed: Cystoscopic surveillance and cytology every 3 mo for 2 yr, then every 6 mo for 2 yr, then yearly thereafter; IVP or CTU yearly
- If nephron-sparing surgery is performed: Ureteroscopic surveillance and cytology every 3 mo until tumor-free, then every 6 mo thereafter; IVP or CTU yearly

CODES

ICD9

- 189.1 Malignant neoplasm of renal pelvis
- 189.2 Malignant neoplasm of ureter

ICD10

- C65.1 Malignant neoplasm of right renal pelvis
- C65.9 Malignant neoplasm of unspecified renal pelvis
- C66.9 Malignant neoplasm of unspecified ureter

CLINICAL/SURGICAL PEARLS

Due to the high distal recurrence rate (33–55%), it is prudent to ensure that the entire ureteral stump is removed at the time of radical nephroureterectomy (RNU).

URETER, INTRAOPERATIVE INJURY

Daniel D. Dugi III, MD
John M. Barry, MD, FACS

BASICS

DESCRIPTION

- Intra-operative injury to the ureter can ocurr during open, laparoscopic, or endoscopic surgery
- May be direct laceration, suture ligation, crush injury, thermal injury, or devascularization
- Lower 1/3 of ureter (within the pelvis) is most commonly injured
- Injury may cause obstruction of kidney if ureter is ligated or urinary extravasation if lacerated
- Due to the proximity to the vagina, some injuries may result in uretero-vaginal fistula

EPIDEMIOLOGY

Incidence

- Most series report 1–5% of pelvic surgeries; highest rates among radical hysterectomy cases (1)[B]
- 1–5% of ureteroscopic surgeries (1)[A]
- Approximately half of iatrogenic injuries occur during gynecologic surgery (2)[B]

Prevalence

N/A

RISK FACTORS

- Pelvic surgery, especially gynecologic, intestinal, urologic surgery, or aorto-iliac vascular surgery
- Laparoscopic surgery may have a higher incidence than open surgery (3)[B]
- Radiation therapy, cancer, prior pelvic surgery, aorto-iliac aneurysm, and inflammatory processes such as endometriosis, Crohn disease, and diverticulitis

Genetics

N/A

PATHOPHYSIOLOGY

- Ureters are anatomically close to the uterus, uterine and ovarian arteries, sigmoid colon and rectum, and iliac arteries, and they are at risk of injury during operations on these organs
- Although retroperitoneal organs, the ureters may become involved with inflammatory processes within the peritoneum

ASSOCIATED CONDITIONS

Any condition leading to pelvic, abdominal, or retroperitoneal surgery

GENERAL PREVENTION

- Awareness of risk of ureteral injury, especially during pelvic surgery
- Prospective identification of ureter during retroperitoneal or pelvic surgery

- Placement of ureteral catheters prior to complex pelvic surgery to aid in identifying ureters and increasing intraoperative recognition of ureteral injury (4)[C]

DIAGNOSIS

HISTORY

Most ureteral injuries are not recognized intraoperatively (3)[A]

PHYSICAL EXAM

- Intraoperative identification and inspection of ureters in cases where they are at risk for injury may help prevent or recognize an intraoperative injury
- Post-operatively, a patient with an unrecognized ureteral injury may develop fever, abdominal distention, flank or abdominal pain, or peritonitis and ileus from urinary extravasation

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Surgical drain fluid with elevated creatinine level confirms urinary extravasation
- Gross or microscopic hematuria may suggest urinary system injury but is non-specific, and its absence does not exclude injury
- Leukocytosis or elevated serum creatinine from renal obstruction or reabsorption of extravasated urine

Imaging

Contrast studies are critical for postoperative diagnosis. CT scan with IV contrast and excretory phase imaging may show urine extravasation or a urinoma

Diagnostic Procedures/Surgery

- Indigo carmine or methylene blue may help identify ureteral injury if dye is seen in the operative field after intravenous or intravesical administration
- Retrograde pyelography can definitively confirm or exclude ureteral injury. This also allows an attempt at placement of a ureteral stent
- Women with leakage of urine per vagina postoperatively may have ureteral or bladder injury. A tampon dye test may help differentiate between the two:
  - Place a Foley catheter.
  - Give oral phenazopyridine hydrochloride 200 mg orally.
  - When the urine in the Foley catheter drainage is orange, place a tampon into the vagina
  - Fill the bladder gently through the Foley with saline containing indigo carmine or methylene blue.
  - Remove the tampon. If the tampon has only orange dye, there is likely a ureteral fistula and no bladder fistula. If there is also blue dye on the tampon, there is likely a bladder fistula.
  - Further diagnostic imaging studies may still be necessary to guide therapy

Pathologic Findings

Diagnosis usually not made pathologically

DIFFERENTIAL DIAGNOSIS

- Unrecognized bladder injury
- Lymphocele
- Hematoma

TREATMENT

GENERAL MEASURES

Intraoperative recognition ensures best possible outcome and the fewest complications

MEDICATION

First Line

Indigo carmine or methylene blue may help identify ureteral injury if dye is seen in the operative field after intravenous or intravesical administration

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Injuries recognized intraoperatively:
  - Ligation injures: Remove suture and inspect for devascularization
  - Partial-thickness, clean lacerations may be closed with fine interrupted absorbable suture if the surrounding tissue has not be devascularized
  - Injuries within the pelvis are usually best repaired by direct reimplantation into bladder, with psoas hitch, if necessary (3)[C]
  - Injuries above the true pelvis (proximal ureter) may be repaired with direct anastomosis if proximal and distal mobilization allows tension-free repair of healthy, well-vascularized edges (3)[C]
  - More complex repairs, such as Boari flap, trans-uretero-ureterostomy, or ileal ureter should be undertaken cautiously in the acute setting
  - In unstable patients, the ureter may be left ligated and a percutaneous nephrostomy tube placed postoperatively to drain the kidney
  - It is best to leave an indwelling ureteral stent
- Injuries recognized postoperatively:
  - If recognized in the first few days to 1 week after initial injury, operative repair is recommended
  - If recognized later, reoperation after resolution of surgical inflammation 6 weeks or more postoperatively is recommended (2)[C]
  - Retrograde ureteropyelography is helpful in diagnosing ureteral injury and allows for attempt at ureteral stent placement in low-grade injuries (2)[C]
  - Small lacerations or partial ligations may heal after a period of ureteral stenting
  - Percutaneous nephrostomy drainage is recommended if ureteral stenting is not possible. This also allows attempt at antegrade ureteral stent placement
  - Optimal duration of ureteral stenting is not known, but 6 wk is reasonable
  - Percutaneous drainage of urinoma is necessary if the urinoma is infected, symptomatic, or does not decrease in size after reliable renal drainage is established

ADDITIONAL TREATMENT

Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Intraoperative recognition and repair usually prevents complication of urine extravasation or renal obstruction
- Ureteroneocystostomy for distal ureteral injuries has an excellent prognosis. Proximal ureteral repair have a higher risk of long-term complications because of compromised blood supply
- Patients who have delayed recognition of injuries have higher rates of complications and more procedures needed to resolve injury than those with injuries recognized intraoperatively (5)[B]

COMPLICATIONS
- Urine leakage from a ureteral injury may lead to urinoma formation and infection or abscess
- Extravasated urine may cause irritation of the intestines and peritoneum and result in pain and/or ileus
- Ureteral stricture and renal obstruction may cause loss of renal function
- Ureterovaginal fistula
- Complications of ureteral injury and repair may result in nephrectomy

FOLLOW-UP
Patient Monitoring
- Perform follow-up imaging of the kidney to assure no obstruction from ureteral stricture. Renal ultrasound can evaluate for hydronephrosis and urinoma and has no radiation.
  - Excretory imaging (i.e., ExU, CT urography, radioisotope renography with furosemide washout) may be indicated in complex circumstances or when hydronephrosis is found by ultrasound.

CODES

ICD9

- 867.2 Injury to ureter, without mention of open wound into cavity
- 997.5 Urinary complications, not elsewhere classified
- 998.2 Accidental puncture or laceration during a procedure, not elsewhere classified

ICD10

- N99.71 Acc pnctr & lac of a GU sys org during a GU sys procedure
- N99.81 Other intraoperative complications of genitourinary system
- S37.10XA Unspecified injury of ureter, initial encounter

CLINICAL/SURGICAL PEARLS

- During mobilization of the ureter, avoid “skeletonization” and include periureteral tissue to better preserve blood supply.
- Repair ureteral injuries and avoid nephrectomy unless the repair will place the patient at risk.
- A cystostomy allows easy access to the ureteral orifice to aid in stent placement during open surgery.

URETER, OBSTRUCTION

Jennifer E. Heckman, MD, MPH
Stephen Y. Nakada, MD, FACS

BASICS

DESCRIPTION

- Ureteral obstruction can be an anatomic or functional blockage of the ureter and further classified as:
  - Congenital or acquired
  - Acute or chronic
  - Benign or malignant
  - Intrinsic or extrinsic
  - Unilateral or bilateral
- Impact of obstruction dependent on:
  - Degree and duration of obstruction
  - Baseline renal function
  - Potential for reversibility
- Associated definitions:
  - Hydronephrosis
    - Dilation of renal pelvis and calyces
    - Can occur with or without obstruction (obstruction may be anywhere in urinary tract, from urethral meatus to calyces)
  - Hydroureteronephrosis
    - Dilation of renal pelvis, calyces, and ureter
  - Obstructive uropathy
    - Impedance to urinary flow anywhere in urinary tract
  - Obstructive nephropathy
    - Renal parenchymal damage from urinary tract obstruction
- Urinary tract infection and sepsis may be superimposed

EPIDEMIOLOGY

Incidence

- No data available in unselected populations
- Etiology-dependent

Prevalence

- Can occur during fet al development, childhood, or adulthood
  - Occurrence increases with increasing age
- Unilateral > bilateral
- Hydronephrosis may be surrogate marker for obstruction
  - Overall prevalence in autopsy series: 3.1% (1)

RISK FACTORS

- Renal or ureteral calculi

- Malignancy
  - Genitourinary
  - Gynecologic
  - Abdominopelvic
- Trauma
- Radiation

Genetics

- No specific associated familial or hereditary disorders, but cause may be congenital
- 30–50% of children with end-stage renal disease have obstructive uropathy associated with congenital anomalies

PATHOPHYSIOLOGY

- Ureter blockage results in elevated ureteral intraluminal pressure
- With increased pressures in proximal tubule and Bowman capsule, glomerular filtration rate (GFR) decreases
- Persistent obstruction leads to decreased renal blood flow and subsequent ischemia and nephron loss
- Three major points of anatomic ureteral narrowing:
  - Ureteropelvic junction (UPJ)
  - Where ureter crosses iliac vessels
  - Ureterovesical junction (UVJ)

ASSOCIATED CONDITIONS

- Congenital
  - Ureterocele
  - Megaureter
  - UPJ obstruction
  - Stricture
- Inflammatory
  - Abscess
  - Amyloidosis
  - Tuberculosis
  - Fungal bezoars
- Malignancy
  - Ureteral cancer
  - Bladder cancer
  - Metastatic disease
- Vascular
  - Aneurysms
  - Aberrant vessels
- Other
  - Urolithiasis
  - Pregnancy
  - Trauma
  - Retroperitoneal fibrosis

GENERAL PREVENTION
Dependent on underlying etiology

DIAGNOSIS
HISTORY
- Presentation reflects underlying etiology
- May be asymptomatic
- Acute obstruction may cause significant pain
  - Ureteral colic
    - Flank pain (proximal obstruction)
    - Pain radiating to ipsilateral groin (distal obstruction)
- Inquire about history of urinary tract infections, renal failure, urolithiasis, malignancy, radiation therapy

PHYSICAL EXAM
- Pyrexia if associated with infection
- Hypertension possible
- Costovertebral angle tenderness
- Abdominal tenderness

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum studies:
  - Creatinine
    - Often elevated, though may be normal in setting of normal contralateral kidney
  - Electrolytes
- Urine studies:
  - Urinalysis
    - May see hematuria, pyuria, or crystals
    - May see elevated pH secondary to nephron destruction in affected kidney
  - Urine electrolytes

Imaging
- Renal ultrasound
  - Screening test of choice (inexpensive, no radiation or contrast required)
  - Can identify parenchymal thickness, urinary tract dilation
- Intravenous pyelogram/excretory urography
  - Provides anatomic and functional information
  - Low false-positive rate
  - Requires contrast (limit use in renal insufficiency)
- Retrograde pyelogram
  - Delineate collecting system anatomy
- Nuclear renal scan
  - Assess relative renal function and degree of obstruction
    - $T_{1/2}$ >20 minutes consistent with obstruction
  - No contrast required

- Computed tomography (urography)
  - Determine location of obstruction
  - Highly sensitive
  - Requires contrast (limit use in renal insufficiency)

Diagnostic Procedures/Surgery

Perform Whitaker test (pressure flow test) in equivocal cases

Pathologic Findings

- Gross
  - Pelviureteric dilation
  - Papillary blunting
  - Cortical and medullary atrophy
  - Parenchymal edema
  - Enlarged, cystic appearance if total obstruction
- Microscopic
  - Collecting duct, tubular, and lymphatic dilation
  - Interstitial edema and fibrosis
  - Tubular basement membrane thickening

DIFFERENTIAL DIAGNOSIS

- Intrinsic
  - Urolithiasis
  - Sloughed papilla
  - Malignancy
- Extrinsic
  - Abdominopelvic tumors
  - Retroperitoneal fibrosis
  - Pregnancy
  - Vascular anomalies
- Anomalous course of ureter (circumcaval, retrocaval)
- Stricture disease (congenital or acquired)
- Inflammatory disorder
- Neuromuscular dysfunction
- In children:
  - Posterior urethral valves (males)
  - UPJ obstruction
  - UVJ obstruction
  - Ectopic ureter
  - Megaureter
  - Ureterocele

TREATMENT

Ureteral obstruction, if high-grade, bilateral, or associated with renal failure or infection warrants urgent decompression

GENERAL MEASURES

- Early recognition important in preventing irreversible renal functional impairment
- Management of acute obstruction directed at establishing drainage
- After initial stabilization and drainage, determine location and cause of obstruction
- Ureteral obstruction does not always require intervention
  - May observe (e.g., terminally ill patient with normal contralateral kidney, normal serum Cr, and electrolytes)
- Supportive care (pain control, correction of electrolyte abnormalities)

MEDICATION

First Line

- Pain management (oral or parenteral)
  - 1st line: Non-steroidal, anti-inflammatory medications
  - 2nd line: Narcotic medications

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Renal drainage:
  - Retrograde ureteral stent placement
  - Percutaneous nephrostomy tube placement
  - Similar health-related quality of life (2)[C]
  - Preferred technique depends on clinical scenario (e.g., stent preferred if uncorrectable coagulopathy, stent not as effective for extrinsic ureteral obstruction) (3)[C]
- After management of acute obstruction, definitive management directed by cause, renal function, and patient condition
  - Urolithiasis
    - Ureteroscopy with laser lithotripsy/stone extraction, percutaneous nephrolithotomy, or extracorporeal shockwave lithotripsy (location- and calculus-dependent)
  - UPJ obstruction
    - Open or laparoscopic pyeloplasty
  - Vascular lesions (e.g., aortic aneurysm)
    - May require urgent operative intervention
- May consider nephrectomy if affected kidney contributes $<10\%$ to global renal function

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Progressive renal damage may occur
- Poor if untreated bilateral obstruction

COMPLICATIONS

- Acute renal failure
- Chronic renal failure
- Postobstructive dieresis in setting of bilateral ureteral obstruction

FOLLOW-UP

Patient Monitoring

- Serum creatinine
- Serum electrolytes
- Renal ultrasound
- Nuclear renal scan

CODES

ICD9

- 591 Hydronephrosis
- 593.3 Stricture or kinking of ureter
- 753.20 Unspecified obstructive defect of renal pelvis and ureter

ICD10

- N13.1 Hydronephrosis w ureteral stricture, NEC
- N13.5 Crossing vessel and stricture of ureter w/o hydronephrosis
- Q62.39 Other obstructive defects of renal pelvis and ureter

CLINICAL/SURGICAL PEARLS

- Hydronephrosis is an anatomic, not functional, diagnosis.
- Renal scan best study if renal function adequate.
- Bilateral ureteral obstruction, ureteral obstruction in a solitary kidney, and ureteral obstruction associated with renal failure or infection warrant immediate renal drainage.

URETER, TRAUMA

Brad Figler, MD
Hunter Wessells, MD, FACS

BASICS

DESCRIPTION

- Owing to its mobility, narrow diameter, and protected location, ureteral injury from external trauma is rare.
- 75% of ureteral injuries are iatrogenic; 18% form blunt trauma and only 7% from penetrating trauma (1).
- Iatrogenic injury is discussed in detail elsewhere (see Section I: "Ureter, Intraoperative Injury").

EPIDEMIOLOGY

Incidence

- Ureteral injuries represent <1% of all genitourinary injuries caused by violent trauma
- Typically result from gunshot wounds
- Blunt trauma and stab wounds responsible for <20% of ureteral injuries
- Typically occurs concomitant with other injuries (chest, retroperitoneal, intraperitoneal, pelvic)

Prevalence

Unknown

RISK FACTORS

- Penetrating injury to the abdomen and low chest/back
- Flexion/extension injuries (esp. children)
- Diagnosis requires high index of suspicion

Genetics

N/A

PATHOPHYSIOLOGY

- Direct injury from penetrating object
- Stretching of ureter as a result of hyperextension of the body
- Compression against transverse process as a result of rapid deceleration
- American Association for the Surgery of Trauma (AAST) Injury Scoring Scale for ureteral trauma (2)

Grade	Description
1	Hematoma only
2	Laceration <50% of circumference
3	Laceration >50% of circumference
4	Complete tear <2 cm of devascularization
5	Complete tear >2 cm of devascularization

ASSOCIATED CONDITIONS

- Small bowel injury
- Colon injury
- Liver injury
- Iliac vessel injury
- Bladder injury

GENERAL PREVENTION
- Avoid high-risk activity
- Seatbelt use

DIAGNOSIS
HISTORY
- Requires a high index of suspicion
- History of urologic condition or surgery
- Mechanism of injury
  - Hyperextension
  - Deceleration
  - Fall from height
  - Primary location of impact
- Presence of hematuria
  - Onset
  - Duration
- Flank pain
- Fever
- Nausea/vomiting

PHYSICAL EXAM
- Entrance/exit wounds
- Gross hematuria
- Flank or lower abdominal tenderness
- Flank bulge
- Abdominal distention

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Hematuria is unreliable; absent in 26% of cases (3)
- Creatinine may (rarely) be elevated due to extravasation and reabsorption of urine or obstruction.

ALERT
Absence of hematuria does not exclude ureteral injury. Clinical suspicion should guide investigation.

Imaging
- Demonstration of extravasation of contrast is the gold standard for the diagnosis of ureteral trauma.
  - Retrograde pyelography is most reliable for diagnosing ureteral injury; often impractical

in trauma patient.
  – CT with IV contrast and delayed images is an acceptable alternative. Most trauma patients have CT scans before being taken to the OR emergently.
  – On table "one-shot" IVP is sometimes performed in the operating room
    ◦ Administration of 2 mg/kg IV contrast with on table x-ray plain film after 10 min
- Medial extravasation of contrast at the level of the UPJ, suggestive of UPJ or renal pelvis injury
- Ureters should opacify to the level of the bladder on delayed imaging to be diagnostic
- Assess for foreign bodies, fluid collection, and hydronephrosis
- Ultrasound is generally not useful, except in demonstrating a urinoma or hydronephrosis.
- MRI not used acutely in the trauma setting

Diagnostic Procedures/Surgery
- Retrograde pyelogram: Useful to verify presence or absence of suspected injury
- Ureteral exploration is highly sensitive
- Probe wounds to establish trajectory

Pathologic Findings
Microvascular injury from high-velocity missiles or thermal injury can extend up to 2 cm beyond evidence of gross injury

DIFFERENTIAL DIAGNOSIS
- Other urinary tract trauma
  – Kidney
  – Bladder
- Contusion
- Renal pelvis laceration
- Ureteropelvic junction avulsion

ALERT
Delay in diagnosis of ureteral injury is a major contributing factor to morbidity in a trauma patient.

TREATMENT

GENERAL MEASURES (1)
- Initial management of the trauma patient employs primary survey, resuscitation stabilization, and
- Minor ureteral injury:
  – Ureteral stenting or
  – Nephrostomy tube
- Some common options for complete ureteral injury
  – Upper third: Uretero-ureterostomy
  – Middle third: Uretero-ureterostomy or Boari flap and reimplantation; normally a staged procedure and not performed acutely.
  – Lower third: Direct reimplantation or psoas hitch or Blandy cystoplasty.
  – Complete ureteral loss: Ileal interposition or autotransplantation as a delayed procedure

ALERT

- With compete ureteral loss employ “Damage Control” first: tie off ureter, place percutaneous nephrostomy.

- Complete UPJ transections will not heal and need open repair
- Partial UPJ injury (laceration) may be successfully treated by primary repair or stent
- Ureteral contusions or proximity gunshot wounds can be treated successfully by stenting

MEDICATION

First Line

Methylene blue and indigo carmine may help identify the site of a ureteral perforation or transection (see Section I: “Ureter, Intraoperative Injury”).

Second Line

Furosemide (20–40 mg IV) can be administered to speed indigo carmine excretion.

SURGERY/OTHER PROCEDURES

- Principles of ureteral repair include:
  - Careful mobilization
    - Preserve adventitia
    - Avoid electrocautery
  - Debridement of nonviable tissue to bleeding
  - Spatulated
  - Tension-free
  - Watertight
  - Mucosa to mucosa
  - Absorbable suture
  - Ureteral stent
  - Closed suction drain
- Blast effect from high-velocity gunshot wound (GSW) may require more extensive debridement.
- When concomitant injuries (particularly pancreatic) are present, consider omental flap to protect the repair.
- Successful methods for ureteric repair are based on injury location.
  - Upper and middle third: Primary repair
  - Lower third: Reimplantation
- Psoas hitch can reduce tension on repair
  - Divide contralateral inferior pedicle
  - Tack posterior bladder to psoas muscle
  - Use multiple longitudinally placed sutures in psoas fascia to avoid femoral nerve injury
- Advanced techniques typically not appropriate in the acute trauma patient
  - Bowel interposition
  - Transureteroureterostomy
  - Autotransplant
  - Boari flap

ADDITIONAL TREATMENT

Radiation Therapy
N/A

Additional Therapies
- Delayed management ("damage control") if patient unstable:
  - Tie off ureter with long suture and place nephrostomy tubes post-operatively
  - Externalize ureters

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
Long-term outcomes not reported in this population, but long-term results of ureteral surgery are excellent (4)

COMPLICATIONS
- Complication rate after repair of traumatic injuries of the ureter: 25%
  - Prolonged leakage is most common
- Delayed complications include
  - Ureteral stricture
  - Retained ureteral stent
  - Renal loss
  - UTI
  - Hydronephrosis

FOLLOW-UP
Patient Monitoring
- Check JP creatinine at least 2 days after abdominal closure. If consistent with serum, consider removing.
- Stent removal 4–6 wk
- Renal scintigraphy with Lasix 2–4 wk after stent removal to document function/drainage

CODES

ICD9

- 867.2 Injury to ureter, without mention of open wound into cavity
- 867.3 Injury to ureter, with open wound into cavity
- 997.5 Urinary complications, not elsewhere classified

ICD10

- N99.81 Other intraoperative complications of genitourinary system
- S37.10XA Unspecified injury of ureter, initial encounter
- S37.19XA Other injury of ureter, initial encounter

CLINICAL/SURGICAL PEARLS

- Diagnosis of ureteral injury requires a high index of suspicion.
- Absence of hematuria does not exclude ureteral injury. Hematuria absent in 25–45% of ureteral trauma.
- Ureteral injury is indicated by extravasation of contrast.
- Primary anastomosis and reimplant with psoas hitch are effective methods for repairing ureteral injuries. More complicated injuries can be managed in a delayed fashion.
- Unstable patients can be managed with temporary drainage followed by delayed management.

URETEROCELE

Ross M. Decter, MD, FRCS
Paul H. Smith III, MD

BASICS

DESCRIPTION

- Ureterocele is a cystic dilation of the terminal/intravesical ureter.
- May be classified based on anatomic location:
  - Intravesical: Contained entirely within the bladder above the bladder neck; seen frequently in single system ureteroceles.
  - Extravesical (Ectopic): Some portion of ureterocele permanently located at the level of the bladder neck or urethra; seen frequently in duplex system ureteroceles.
- Descriptive classification:
  - Cecoureterocele: Ureterocele extends into urethra, but orifice within the bladder
  - Sphincteric
  - Stenotic
  - Sphinctero-stenotic
  - Blind
  - Nonobstructive
- Most ureteroceles are associated with the upper pole of a duplex collecting system and are usually ectopic
- Today many ureteroceles are detected during routine prenatal screening ultrasounds
- When discovered in adults they are rarely of clinical consequence.

EPIDEMIOLOGY

Incidence

1 in 500 to 1 in 4,000

Prevalence

As high as 1 in 500 (autopsy study)

RISK FACTORS

- More common in girls (5–7:1)
- More common in whites
- Bilateral in 10–15% of cases
- Extravesical ureteroceles associated with upper pole of duplex system often diagnosed in infancy or childhood

Genetics

Likely multifactorial inheritance

PATHOPHYSIOLOGY

- Several hypotheses:
  - During embryogenesis, the mesonephric duct and the distal ureteral bud incorporate into the anterior cloaca/urogenital sinus. Chawalla membrane breaks down allowing the

incorporation of the distal ureter into the developing bladder. Incomplete breakdown of Chwalla membrane is thought to be one cause of the ureterocele.
  – Delay in canalization of lumen of ureteral bud is another theory.

ASSOCIATED CONDITIONS
- Duplicated collecting system: 80%
- Single system: 20%
  – Most common type in boys, but uncommon in girls (5%)
- Vesicoureteral reflux (VUR)
  – Ipsilateral lower pole in duplex system: 50–70%
  – Contralateral kidney: 10–30%

GENERAL PREVENTION
Antibiotic prophylaxis in patients at risk for upper-tract infection (VUR or obstruction)

DIAGNOSIS

HISTORY
- Prenatal hydronephrosis
- UTI/sepsis/failure to thrive
- Hematuria
- Bladder outlet obstruction
  – Most common cause of bladder outlet obstruction in newborn girls
- Intralabial mass (prolapsed ureterocele)

PHYSICAL EXAM
- Abdominal mass (hydronephrosis)
- Intralabial prolapsing cystic mass
  – Often appear congested and dusky
  – Smooth-walled appearance helps differentiate from sarcoma botryoides; other causes can include urethral prolapse and urethral caruncle

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum creatinine
- Urinalysis
- Urine culture

Imaging
- Renal/bladder US:
  – Prenatal hydronephrosis
  – Thin-walled intravesical cystic structure or septations in the bladder
  – Hydroureteronephrosis
  – Duplex collecting system with dilated upper pole
- Voiding cystourethrogram (VCUG)
  – Smooth, broad based filling defect near trigone
  – Critical to image during early filling
    - May efface as bladder fills

- Renal scintigraphy
  - DMSA
    - Evaluate renal parenchyma for scarring, differential function
  - MAG-3
    - Evaluate drainage to determine extent of obstruction, differential function
- IVP:
  - Cobra-head sign in the bladder when contrast fills the ureterocele (not usually performed) (1)

Diagnostic Procedures/Surgery
- Cystoscopy
  - Findings vary, but best seen with partially empty bladder

Pathologic Findings
- Abnormal or absent musculature of distal ureter
- Renal dysplasia
  - Seen in ~40–70% of upper-pole moieties with ureterocele; more common in association with extravesical ureteroceles

DIFFERENTIAL DIAGNOSIS
- Bladder polyps
- Ectopic ureter
- Edema
- Mesonephric duct cyst
- Tumor
- Urethral prolapse

TREATMENT

GENERAL MEASURES
Surgical treatment is needed in most cases

MEDICATION
First Line
- Culture directed antibiotics for treatment of UTI/Sepsis
- Antimicrobial prophylaxis until reflux or obstruction repaired in children:
  - Amoxicillin: 5–7 mg/kg/d as neonate
  - Trimethoprim-sulfamethoxazole: 2 mg/kg/d OR nitrofurantoin 1–2 mg/kg/d beyond 2 mo of age

Second Line
Endoscopic incision if acutely septic

SURGERY/OTHER PROCEDURES
- Endoscopic transurethral incision:
  - Usually effective in relieving obstruction
  - Risk of developing reflux in that system
  - Outpatient procedure

- Effective for intravesical and single-system ureteroceles, less so for extravesical ureteroceles (2)[B]
- Can be a temporizing measure until definitive repair (2)[B]

• Formal surgical repair
- Definitive treatment but higher morbidity
- Goals of surgery: Preserve functional renal parenchyma, relieve obstruction, correct reflux
- Upper-pole heminephrectomy if dilated non-functioning upper pole
- Ureteroureterostomy if upper pole is functional and no lower pole reflux
- Ureterocele excision and common sheath reimplatnation if reflux is present (3)[B]

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Observation if asymptomatic; no or mild reflux or obstruction

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Depends on extent of obstruction, infections, and presence or absence of renal dysplasia

COMPLICATIONS

• The major complication in adults and children is ureteral obstruction (4)
• Sepsis, loss of renal function
• Incontinence (primary or secondary)
• Persistent dilation of ureteral stump
• Persistent VUR

FOLLOW-UP

Patient Monitoring

• Renal and bladder US
• VCUG to diagnose/follow-up VUR
• Monitor renal function if bilateral
• Treat UTI

Patient Resources

• MedlinePlus: Ureterocele. http://www.nlm.nih.gov/medlineplus/ency/article/000462.htm

CODES

ICD9

• 593.70 Vesicoureteral reflux unspecified or without reflux nephropathy
• 593.89 Other specified disorders of kidney and ureter
• 753.23 Congenital ureterocele

ICD10

• N13.70 Vesicoureteral-reflux, unspecified
• N28.89 Other specified disorders of kidney and ureter
• Q62.31 Congenital ureterocele, orthotopic

CLINICAL/SURGICAL PEARLS

• Early filling x-rays during VCUG mandatory to enhance detection of ureterocele.
• Choice of treatment driven by acuity of illness, degree of obstruction, VUR, and degree of renal dysplasia.
• Definitive endoscopic treatment most successful for single-system ureteroceles.

URETEROENTERIC ANASTOMOTIC STRICTURE

Chad R. Ritch, MD, MBA
David F. Penson, MD, MPH

BASICS

DESCRIPTION

- Ureteroenteric anastomotic stricture (UE) is typically a benign obstruction of the ureter at the level of the sutured anastomosis following an intestinal urinary diversion
  - Typically benign process that develops 7–18 mo postoperatively (1)
    - most often performed in setting of radical cystectomy and ureteral/bowel anastomosis; therefore, recurrent malignancy must be ruled out (malignant stricture)

EPIDEMIOLOGY

Incidence

- Various series report range of 3–10% (1,2)
  - More common on left (1,2)

Prevalence

N/A

RISK FACTORS

- Surgical technique is the main risk factor
  - Aggressive handling of the ureter leads to stricture formation
    - Avoid stretching, grasping, skeletonization, and tension on the ureter
  - A non-refluxing anastomosis may be more prone to stricture formation than a refluxing anastomosis
  - Suture-line gaps lead to urine leak and predispose to stricture

Genetics

N/A

PATHOPHYSIOLOGY

- Aggressive handling, suboptimal technique devascularizes tissue causing poor blood flow and ischemia.
  - Ischemia interferes with healing of ureteral tissue and causes scarring and stricture formation
    - Urine leakage causes inflammation around anastomotic site
    - Lack of mucosa to mucosa apposition impairs healing

ASSOCIATED CONDITIONS

- Any condition where urinary tract surgery requires urinary diversion using a bowel anastomosis
  - Bladder carcinoma
  - Neurogenic bladder
  - Gynecologic malignancies

- Pelvic exenteration for rectal cancer

GENERAL PREVENTION

- Good surgical technique essential
  - No grasping of ureter with instruments, may crush and devascularize tissue
  - Maintain good blood supply—Avoid skeletonization
  - Minimize stretching and tension
  - Ensure mucosa to mucosa apposition
  - Balance watertight anastomosis with excessively close/tightened suture line
  - Ureteral stent may prevent urine leak

DIAGNOSIS

HISTORY

- Complaints of flank pain or fever and UTI suggestive of pyelonephritis
  - Typically presents 6–18 mo after surgery
    - Chronic as opposed to acute process

PHYSICAL EXAM

- Dull achy pain on palpation of flank
  - May be sharp if associated with infection

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- In the case of unilateral stricture with an unaffected contralateral kidney, often no significant abnormal laboratory findings.
  - May have transient rise in serum Cr
  - A urine analysis or dipstick evaluation may demonstrate elevated leukocyte esterase and white blood cells consistent with inflammation. Presence of urinary nitrites and bacteria may occur with concomitant UTI but should be interpreted with caution due to the presence of bowel in the urinary tract.
  - If bilateral strictures are present or patient has poorly functioning or absent contralateral kidney, patient may present with markedly elevated serum creatinine and acute renal failure (hyperkalemia, marked acidosis)

Imaging

- Renal ultrasound or CT imaging are initial diagnostic modalities of choice
  - Ultrasound cost-effective and highly sensitive for demonstrating obstruction
  - CT imaging with pre- and post-IV contrast dye can provide further anatomic and functional information.
    - More costly than US and risk of radiation exposure and contrast-dye allergy in susceptible patients
    - Some patients may have compromised renal function that precludes the use of IV contrast
  - MRI may also be considered if US unavailable and contraindications to CT imaging
  - If kidney appears atrophic consider renal scan to assess function
    - Poorly functioning kidney (<15%) better served with nephrectomy than UE stricture

repair

Diagnostic Procedures/Surgery

- If hydronephrosis found, consider percutaneous antegrade contrast instillation (nephrostogram) of affected side.
- If ileal conduit urinary diversion, instillation of contrast dye directly into the ileal loop (loopogram) may be considered as alternative to nephrostogram
  - Ileal conduit has refluxing anastomosis so loopogram will demonstrate reflux of contrast up the ureter if hydronephrosis not due to obstruction.
    - If no reflux is demonstrated on loopogram, then cause of hydro is likely stricture
    - Loopogram is less costly and noninvasive compared to nephrostogram
    - Nephrostogram can be therapeutic by providing instant drainage via nephrostomy as well as provide access for endoscopic treatment (see "Treatment")
  - Retrograde pyelogram very difficult due to inability to locate and cannulate ureteroenteric orifice during loop endoscopy

Pathologic Findings

Inflammation and scarring identified on pathologic specimen following open surgical revision and excision

DIFFERENTIAL DIAGNOSIS

- Urine reflux
- Ureteral stone
- Extrinsic compression
- Ureteral kinking
- Recurrent malignancy
- Pyelonephritis
  - Differential can be explored with CT or MR imaging which will provide anatomical detail

TREATMENT

GENERAL MEASURES

- Consider pain relief if obstruction causing hyrdonephrosis and flank pain
  - Rule out and treat UTI if suspected
    - UTI, fever, and presence of obstruction is a medical emergency with increased mortality
    - Treat with urgent decompression via nephrostomy tube and systemic antibiotics
- If patient comfortable and no evidence of infection, then consider elective repair

MEDICATION

First Line

- No therapeutic medications
- Consider narcotics and anti-inflammatories for temporary relief of pain
- If infection noted and patient clinically stable, mildly symptomatic, treat with fluoroquinolone or culture specific antibiotics for 7–14 days
- Asymptomatic infection can be treated prior to elective repair

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Nephroureteral or antegrade ureteral stent placement for temporary relief of obstruction or in the setting of palliative care
- Definitive therapy: Open versus endoscopic repair
  - Decision is based on surgeon experience, prior attempts at repair (primary vs. secondary) and length/complexity of stricture
  - Retrospective series suggest higher success rates with open repair (see below)
  - Indwelling stent for 2–3 wk after repair
- Open surgical repair
  - Recommended for strictures >1 cm and failed endoscopic repairs
  - Success rates of up to 71.4–100% reported for primary open revision (2,3)
  - Difficult procedure with mean reported operative time of 240+ (145–450) min, EBL 300+ (150–500) cc (2,4)
- Endoscopic repair
  - Recommended for stricture <1 cm and primary repairs
  - Typically performed antegrade with Ho:Yag laser or Accucise device (2,5). Balloon dilation less commonly used and may be less efficacious.
  - Success rates of 26–50% reported for primary repair (3 – 5).
  - Secondary or redo endoscopic repair has low success rate (35%) (5)
  - Left side strictures and those >1 cm in length appear more prone to failure after repair (2,5)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- If ureteral stricture very long, ureter devascularized or insufficient length and renal unit still functional consider bowel interposition (ileal ureter)
- If renal scan demonstrates poorly functioning kidney (<15%) consider nephrectomy

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Mean time to failure after open and endoscopic repair are 12 and 5 mo, respectively (3)
  - Left sided and redo repairs are at higher risk for failure

COMPLICATIONS

- Uretero enteric stricture
  - Stone formation
  - Hydronephrosis
  - Renal insufficiency
  - Pyelonephritis
- Open repair: complication rate of up to 40% (2,4)

  - Complications include vascular injury, contralateral ureteral injury, urine leak, damage to diversion bowel segment, bowel injury (2,4).
- Endoscopic repair:
  - Complications are rare, most common is infection (UTI/urosepsis) (2,3,5)

FOLLOW-UP

Patient Monitoring

- Consider renal U/S at 6 weeks following repair
  - If hydronephrosis present consider waiting 2 wk (potential post-op anastomotic edema) and perform repeat imaging with contrast based study to rule out obstruction/failure
    - Reflux may occur following repair so should also rule out as possible cause of hydronephrosis

Patient Resources

See Also (Topic, Algorithm, Media)

- Hydronephrosis/Hydroureteronephrosis, (Dilated Ureter/Renal Pelvis), Adult
- Ureter, Obstruction

CODES

ICD9

- 593.3 Stricture or kinking of ureter
- 867.2 Injury to ureter, without mention of open wound into cavity
- 997.5 Urinary complications, not elsewhere classified

ICD10

- N13.5 Crossing vessel and stricture of ureter w/o hydronephrosis
- N99.89 Oth postprocedural complications and disorders of GU sys
- S37.10XA Unspecified injury of ureter, initial encounter

CLINICAL/SURGICAL PEARLS

- Avoid aggressive handling of the ureter to prevent devascularization and ischemia during urinary diversion operation.
- Ureteral obstruction, fever, and UTI in a patient with a urinary diversion requires emergent treatment with percutaneous drainage.
- Open primary repair of UE stricture has higher success rate than endoscopic repair.
- Open repair is complex procedure best performed in experienced hands.

URETEROPELVIC JUNCTION OBSTRUCTION

Christopher E. Keel, DO
Raju Thomas, MD, MHA, FACS

BASICS

DESCRIPTION

- Ureteropelvic junction obstruction (UPJO) is a restriction of urine flow from the renal pelvis to ureter
- Most common cause of significant dilation of collecting system in fet al kidney

EPIDEMIOLOGY

Incidence

- 1:500–1000 newborns
  - 25% diagnosed by 1 yr, 50% by 5 yr
- Adult presentation usually in 3rd–4th decade

Prevalence

- Left > right side (67%)
- Male > female (>2:1) (1)

RISK FACTORS

- Familial disposition
- Congenital renal anomalies:
  - Contralateral UPJO: 10–40% risk
  - Vesicoureteral reflux (VUR): 0.5–5% risk
  - Renal duplication: 6% risk
  - Horseshoe kidney: 15% risk
  - Ectopic kidney: 35% risk

PATHOPHYSIOLOGY

- Congenital (most common etiology):
  - Intrinsic etiologies:
    - Adynamic ureteral segment due to ureteral smooth muscle maldevelopment; the most common cause of pediatric UPJO
    - Intrinsic stenosis due to inadequate ureteral recanalization during fet al development
    - Persistent valvular mucosal folds
  - Extrinsic etiologies:
    - Crossing accessory lower-pole vessel; most common cause of adult UPJO
    - High ureteral insertion into renal pelvis
    - Horseshoe, ectopic, or malrotated kidney causing kinking at ureteropelvic junction (UPJ)
- Acquired:
  - Severe VUR can cause ureteral tortuosity and kinking at UPJ
  - Inflammation and scarring from trauma, urolithiasis, instrumentation, infected urinoma, retroperitoneal fibrosis

ASSOCIATED CONDITIONS
- 50% associated with another congenital anomaly:
  - Contralateral renal dysplasia or multicystic dysplastic kidney (MCDK)
  - Contralateral UPJO: Most common
  - Horseshoe or ectopic kidney
  - Incomplete renal duplication
  - Unilateral renal agenesis
  - VACTER/VACTERL syndrome
  - Vesicoureteral reflux (9–18%)

GENERAL PREVENTION
None

DIAGNOSIS
HISTORY
- Prenatal/neonatal presentation:
  - Hydronephrosis seen on antenatal US
  - Typically asymptomatic; but occasionally see feeding difficulties, failure to thrive, sepsis
- Childhood presentation:
  - Episodic abdominal complaints or ipsilateral colicky flank pain
  - Cyclic nausea and vomiting
  - Gross hematuria, classically after minor abdominal or flank trauma
  - UTI
- Adult presentation:
  - Episodic ipsilateral colicky flank pain, classically after diuretic or alcohol intake (aka Dietl crisis)
  - Cyclic nausea and vomiting
  - UTI or pyelonephritis

PHYSICAL EXAM
- Prenatal/neonatal or childhood presentation:
  - Palpable abdominal mass
  - Fever, failure to thrive
- Childhood presentation:
  - Costovertebral (CVA) tenderness
  - Palpable abdominal mass in small children
- Adult presentation:
  - CVA tenderness
- Hypertension (HTN): Due to acute pain or activation of renin–angiotensin–aldosterone system

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum BUN and creatinine
- Urine analysis:
  - Microscopic hematuria, rarely gross

  - Trace proteinuria
  - Pyuria and bacteriuria
- Urine culture

Imaging

- Renal US:
  - Most often used as initial screening study in pediatric population
  - Useful to distinguish renal masses and ureterovesical junction obstruction from UPJO
- Defer until 2nd or 3rd day of life to avoid false-negative result secondary to physiologic oliguria
- Computed Tomography (CT):
  - Most commonly employed diagnostic study after neonatal period
  - When IV contrast given, findings include delayed opacification of collecting system, pyelocaliectasis, nonvisualization of ureter, cortical thinning
- Intravenous pyelogram; still occasionally performed
- Diuretic renal scintigraphy (Tc-99mm MAG3):
  - Provides differential renal function
  - $T_{1/2}$ assesses for presence of obstruction:
    - Normal $T_{1/2}$: <10 min
    - Indeterminate $T_{1/2}$: 10–20 min
    - Obstruction $T_{1/2}$: >20 min

Diagnostic Procedures/Surgery

- Cystoscopy with retrograde pyelography:
  - Defines extent of ureteral involvement
  - Allows for placement of temporary ureteral stent to relieve urinary obstruction
  - If available endoluminal ultrasound can define crossing vessels intraoperatively
- Helical CT scan with 3D reconstruction:
  - Allows visualization of collecting system and renal vasculature (crossing vessels)
- Whitaker test (WT): Rarely performed
  - Reserved for equivocal IVP or MAG3
  - Percutaneous catheter with pressure transducer placed in renal pelvis, another placed in bladder via urethra; fluid infused into renal pelvis at 10 cc/min; measure pressure differential:
    - Normal: <15 cm H_2O
    - Equivocal: 15–22 cm H_2O
    - Obstructed: >22 cm H_2O

Pathologic Findings

- Hydronephrosis without hydroureter
- Elevated $T_{1/2}$ >20 min on diuretic MAG3
- Pressure differential >22 cm/H_2O on WT
- Crossing vessel on helical CT scan

DIFFERENTIAL DIAGNOSIS

- Obstructive dilation:
  - Fungal balls
  - Impacted urinary calculus
  - Intraluminal benign or malignant neoplasm
  - Sloughed papilla
- Nonobstructive dilation:
  - Prune belly syndrome
  - Renal or peripelvic cysts
  - VUR
  - Megaureter

TREATMENT

GENERAL MEASURES

- Prevent further deterioration in renal function
- Relieve symptoms of obstruction

MEDICATION

First Line

- Neonatal/newborn presentation:
  - Prophylactic antibiotics to maintain sterile urine:
    - UTI prophylaxis: Ampicillin 25 mg/kg/d as neonates THEN
    - Trimethoprim-sulfamethoxazole 2 mg/kg/d OR nitrofurantoin 1–2 mg/kg/d beyond 2 mo of age
  - Repeat imaging—to monitor for resolution or deterioration of function (2)
- Childhood and adult presentation:
  - No medical therapy appropriate except to treat active infection

SURGERY/OTHER PROCEDURES

- Purpose: Restore renal function
  - Especially in patients with bilateral obstruction, solitary kidney, or poorly functioning contralateral kidney
- Relieve severe symptoms:
  - Percutaneous nephrostomy or ureteral stent
- Treat pyonephrosis if present:
  - Culture-specific antibiotics
  - Percutaneous nephrostomy or ureteral stent may be necessary to ensure adequate drainage of infected urine.
- Expectant treatment:
  - Neonatal hydronephrosis: Obstruction associated with unilateral neonatal hydronephrosis is 15%; a majority of neonates with hydronephrosis can be initially managed nonoperatively.
  - Asymptomatic adults with normal contralateral kidney and significant comorbidities
- Definitive operative treatment:
  - Robotic assisted laparoscopic pyeloplasty
    - Gaining more acceptance and is now becoming the standard approach, even in the

pediatric population, with increasing access to robotic surgical technology (3).
  - Employs the same techniques as those performed both open and laparoscopic
  - Comparative outcomes to open techniques approaching >95%
  - Ease in surgical dissection and suturing techniques, management of associated calculi and crossing vessels, has increased its popularity (4).
  - Offers decreased morbidity, better cosmesis, and quicker return to daily activities
- Laparoscopic pyeloplasty: Success rate >90%; transabdominal or retroperitoneal approach; employs dismembered or Y-V plasty technique;
  - Utilized when robotic technology is not available. Technical demands of laparoscopic suturing techniques is a major drawback.
  - Open pyeloplasty: Procedure of choice in pediatric patients:
    - Dismembered (Anderson-Hynes) pyeloplasty: Most common open technique; success rate >90%; appropriate for high insertion, accessory vessels, massive dilation, long ureteral involvement; excise anatomic and functionally abnormal segment
    - Foley Y-V plasty: Appropriate for high ureteral insertion
    - Spiral or vertical flap: Appropriate for large extrarenal pelvis and long segment of narrowed ureter
    - Ureterocalycostomy: Appropriate for rotational anomalies or reoperation after failed pyeloplasty; partial lower pole nephrectomy is required to prevent anastomotic stenosis.
    - Simple nephrectomy: May be appropriate for ipsilateral poor renal function and normal contralateral renal function, especially if differential renal function <10–15%, extensive stone disease, chronic infection, multiple failed repairs
- Endoscopic procedures: Minimally invasive alternative to open procedures in adults: (5)
  - Antegrade cold-knife incision endopyelotomy: Success rate >60%; requires percutaneous access; nephrostomy tube left indwelling 24–48 hr, ureteral stent left indwelling 6 wk; appropriate for adult patients with stricture <2 cm, UPJO associated with renal calculi, children with secondary UPJO
  - Retrograde ureteroscopic laser incision: Success rate in small series 85–90%; allows direct visualization of incision; requires specialized ureteroscopic equipment and endourologic expertise; ureteral stent left indwelling 6 wk
- Chronic percutaneous nephrostomy or ureteral stent: Reserved for patients who are not candidates for definitive operative treatment

ONGOING CARE

PROGNOSIS

- Prenatal/neonatal presentation:
  - Often does not require definitive operative treatment, due to propensity for self resolution or to remain stable
  - Intervention in severe cases can result in greatly improved renal function
- Childhood and adult presentation:
  - Recent investigations demonstrate excellent long-term success rates with pyeloplasty (>90%) verses 60–70% with endoscopic techniques.

COMPLICATIONS

- Recurrent stricture
  - Usually managed endoscopically or by repeat pyeloplasty
  - Ureterocalycostomy
- Urinary leak/fistula
- Infection
- Rarely sepsis/HTN

FOLLOW-UP

Patient Monitoring

- Expectant management in the neonate:
  - Renal US or MAG3 at 1 mo, followed at 3–6 mo
  - Operative intervention is recommended if >10% difference in renal function, worsening of obstruction or renal function or worsening hydronephrosis
- Postoperative Management
  - Renal US or MAG3 6–12 wk postop
    - 91% of children will have improvement in renal function
    - Adults generally will not improve function but will have improvement in drainage.

CLINICAL/SURGICAL PEARLS

- Purpose is to relieve obstruction and preserve kidney function.
- Open or laparoscopic surgical repair remains the best option for treatment.

URETHRA, ABSCESS (PERIURETHRAL ABSCESS)

H. Henry Lai, MD, FACS
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION

- Urethral abscess is best defined based on the sex of the patient
  - Men: Infection of the male urethra and periurethral tissues, usually associated with urinary infection and urethra stricture disease.
  - Women: Infection of Skene's glands located on the anterior vaginal wall, usually associated with a chronically infected urethral diverticulum.
    - Diagnosis and management of female urethral abscess are discussed in Section I "Urethra, diverticulum, female (Urethral diverticulum)".

EPIDEMIOLOGY

Incidence

Can occur at any age.

Prevalence

- The exact prevalence is not known.
- More likely in diabetics or those with sexually transmitted diseases.
- Recurrent abscess in up to 19% of patients.

RISK FACTORS

- Diabetes mellitus
- Urethral stricture disease
- Frequent urethral instrumentation
- Periurethral bulking agent injection
- Gonorrhea
- HIV
- Previous periurethral abscess

Genetics

N/A

PATHOPHYSIOLOGY

- Periurethral extravasation of infected urine (1).
- Urine extravasation may be caused by:
  - High-pressure voiding behind a stricture
  - Difficult dilation of a stricture, false passage
  - Traumatic urethral instrumentation
- Often localized to the bulbar urethra or spongiosum.
- Once eroded through Buck's fascia, may cause extensive necrosis of the fascia and adjacent tissues, leading to Fournier gangrene.
- Three potential sources of Fournier gangrene:

  - Periurethral
  - Perirectal
  - Subcutaneous
- Fistula may develop in delayed cases following spontaneous abscess rupture
- Common organisms:
  - *Neisseria gonorrhea*
  - *Chlamydia trachomatis*
  - Gram-negative rods
  - Enterococci
  - Anaerobes

ASSOCIATED CONDITIONS (2)
- Diabetes mellitus
- Immunosuppression (eg, HIV)
- Sexually transmitted disease
- Urethral stricture disease
- Urinary tract infection

GENERAL PREVENTION
- Eradicate and prevent sexually transmitted disease
- Sterilize the urine and defer instrumentation if the urine is infected
- Diversion of urine away from the urethra
- Adequate management of urethral stricture:
  - Dilation
  - Internal urethrotomy
  - Urethroplasty and reconstruction
  - Perineal urethrotomy

DIAGNOSIS

ALERT
Failure to recognize and treat a localized periurethral abscess in a male can result in life-threatening necrotizing fasciitis (fournier gangrene), or septic shock.

HISTORY
- Symptoms may include urethral discharge, dysuria, pain, swelling of penis or scrotum, foul smelling urine, fever, chills, weak urine stream, incomplete emptying, urinary frequency, urgency.
- History of urethral stricture and treatment
- Recent history of urethral instrumentation, dilation, catheterization, bulking agent, sling, or other surgery
- History of sexually transmitted disease, pelvic radiation, trauma (risk factors of stricture)
- History of recurrent UTI
- Diabetes, including glycemic control
- Immunosuppression (eg, HIV)
- Prior periurethral abscess and treatment

– Maintain an index of suspicion for neoplasm for recurrent periurethral abscess and stricture

PHYSICAL EXAM

- Evaluate for urosepsis: fever, tachypnea, tachycardia, hypotension, mental status change.
- Palpate penile shaft and perineum for mass, induration, tenderness, fluctuance, or crepitus.
- Fournier gangrene may involve the penis, scrotum, perineum, extending around the rectum, inner thighs, or up the abdominal wall.
- Palpate for a distended bladder (retention).
- Rectal exam to exclude perirectal abscess.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis of the initial urine stream
- Urine culture and sensitivity
- Wound culture, including anaerobic
- Blood culture (sepsis workup)
- BUN, creatinine (renal function, dehydration)
- WBC with differential
- Coagulation profile (sepsis-induced coagulopathy)

Imaging

- CT (look for subcutaneous air, abscesses)
- Retrograde urethrogram:
  – Not recommended during acute phase
  – Look for extravasation, stricture, fistula
- Transrectal ultrasound imaging of prostate: not recommended during acute phase

Diagnostic Procedures/Surgery

- Post-void residual volume (bladder scanner)
- Aspiration of pus when diagnosis is in doubt

Pathologic Findings

- Tissue inflammation, necrosis, fasciitis
- Biopsy may be used to rule out urethral or perianal cancer in rare cases

DIFFERENTIAL DIAGNOSIS (3,4)

- Anasarca (generalized edema) from liver or renal failure
- Carcinoma of perianal glands
- Fournier gangrene
- Perirectal abscess
- Pneumoscrotum after laparoscopy
- Subcutaneous abscess
- Urethral carcinoma
- Urethral diverticulum (in female)

TREATMENT

GENERAL MEASURES

Supportive treatment of other medical issues: diabetes, hypotension, septic shock, or organ failures

MEDICATION

First Line

- Board spectrum antibiotics coverage
  - Cephalosporin and aminoglycoside
    - Such as ceftriaxone 2g IV q24 plus gentamicin 1.5–2 mg/kg loading dose, followed by 5–7 mg/kg IV q24
  - Consider vancomycin (15–20 mg/kg IV q12)

Second Line

Antibiotics are adjusted based on culture sensitivity

SURGERY/OTHER PROCEDURES

- Incision and drainage of abscess with debridement and excision of necrotic tissue.
- May require repeated exploration and debridement as the margin between necrotic tissue and viable tissue becomes more apparent.
- Needle aspiration or endoscopic transurethral incision may be considered in selected cases.
- Wet to dry dressing change twice a day.
- Wound vac placement after debridement if the wound is clean and if wound location permits.
- Exposed testicle may be placed in the scrotum or thigh pouch.
- Skin grafting may be needed to cover skin loss, alternatively secondary closure of wound.
- Biopsy to exclude urethral or perianal cancer.
- Urinary diversion:
  - Suprapubic tube initially
  - Avoid urethral Foley catheter
  - Perineal urethrotomy as a secondary option in patients with severe bladder spasm or when adequate urine drainage has not been achieved.
- Cystoscopy to evaluate urethral stricture disease after complete resolution of infection.
- Definitive management of stricture should be deferred for 6 mo after resolution of abscess.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Variable based on diagnosis and treatment

- Failure to recognize and treat a periurethral abscess in a male can result in life-threatening necrotizing fasciitis (Fournier gangrene) and septic shock.

COMPLICATIONS

- Sepsis, acute renal failure, death (1%) (5)
- Necrotizing fasciitis: Progression to Fournier gangrene
- Extensive genital skin loss
- Recurrent abscess and urinary infection
- Necrosis of corpora spongiosum
- Urethrocutaneous fistula

FOLLOW-UP

Patient Monitoring

- Frequent wound check until healed.
- Monitoring for recurrent stricture (eg, uroflow)
- Periodic evaluation of urine for infection.
- Testing for sexually transmitted disease.

- Urethra, Stricture, Male

CODES

ICD9

- 597.0 Urethral abscess
- 598.9 Urethral stricture, unspecified
- 599.2 Urethral diverticulum

ICD10
- N34.0 Urethral abscess
- N35.9 Urethral stricture, unspecified
- N36.1 Urethral diverticulum

CLINICAL/SURGICAL PEARLS

- In men, urethral abscess is associated with urinary infection, urethral stricture, diabetes, and immunosuppression. In women, it is associated with urethral diverticulum.
- Incision and drainage of abscess may include exploration and debridement of necrotic tissues.
- Board spectrum antibiotics coverage and supportive care.
- Urinary diversion with suprapubic tube are important in the treatment of urethral abscess.
- Early recognition and treatment is key to prevent progression to life-threatening Fournier gangrene and septic shock.

URETHRAL CARCINOMA, GENERAL CONSIDERATIONS

Michael A. Poch, MD
Philippe E. Spiess, MD

BASICS

DESCRIPTION

- Urethral carcinoma is a tumor arising from the lining of the male or female urethra
- Considered a rare cancer (< 1% of all malignancies)
- Urothelial carcinoma is most common histologic type followed by squamous cell carcinoma and adenocarcinoma.

EPIDEMIOLOGY (1)

Incidence

- Incidence (male): 1.6 per 1,000,000
- Incidence (female): 0.6 per 1,000,000
- Incidence is higher in African American patients
- Incidence increases steadily with age, more steeply in men as compared to women peaks at age 75: 7.6/1,000,000

Prevalence

N/A

RISK FACTORS (1)

- Male
  - Chronic inflammation
    - Intermittent catheterization, urethroplasty
  - History of sexually transmitted infection (STI/STD)
    - HPV (condyloma with HVP 16)
  - Urethritis
  - Urethral stricture disease
  - Prior radiation
    - External beam or seed implant
  - Arsenic exposure (adenocarcinoma of bulbar urethra)
  - Urethral stent
- Female
  - Leukoplakia
  - Chronic inflammation/recurrent UTI
  - STI/STD
    - HPV, condyloma
  - Parturition
  - Urethral diverticula

Genetics

Unknown

PATHOPHYSIOLOGY

- Male
  - Anatomic considerations: The male urethra (averages about 20 cm in length), is divided into distal and proximal portions. The distal urethra, which extends distally to proximally from the tip of the penis to just before the prostate, includes the meatus, the fossa navicularis, the penile or pendulous urethra, and the bulbar urethra. The proximal urethra, which extends from the bulbar urethra to the bladder neck, includes distally to proximally the membranous urethra and the prostatic urethraurethra
  - Squamous-cell carcinoma: Occurs in the membranous urethra, bulbar urethra, and penile urethra
  - Urothelial carcinoma: Typically occurs in the prostatic urethra
- Female
  - Anatomicconsiderations: The female urethra is In adults, it is about 4 cm in length and is mostly contained within the anterior vaginal wall.
  - Squamous-cell carcinoma: Occurs at distal 2/3 of female urethra
  - Urothelial carcinoma: Occurs at the proximal 1/3 of the urethra
  - Adenocarcinoma: Occurs in urethra diverticula

ASSOCIATED CONDITIONS

- STI/STD
- Indwelling catheter
- Urethral stricture disease
- Urethral diverticula
- Bladder cancer

GENERAL PREVENTION

- Prevention of STI
- Prevention of traumatic injury leading to stricture disease
- Smoking cessation

DIAGNOSIS

HISTORY

- Urethral bleeding
- Perineal discomfort
- Decrease force of stream
- Urinary frequency
- Urinary urgency
- Dysuria
- Urinary fistulae
- Urinary tract infection
- STI/STD, condyloma history

PHYSICAL EXAM

- Perineal exam
  - Identifies palpable mass in proximal urethra
- Pelvic exam

  – Identifies visual or palpable mass associated with female urethra
- Examination under anesthesia with bimanual exam
- Inguinal exam to evaluate palpable inguinal adenopathy

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis often demonstrates hematuria
- Urine culture
- Urine cytology
  – Sensitivity 55–59%

Imaging

- Urethrography—Aids in the diagnosis of diverticula and/or stricture disease
  – Voiding cystourethrogram (VCUG)
  – Retrograde urethrogram
- Cross sectional imaging identifies local extension
  – MRI of pelvis
    ○ Preferred imaging modality for urethral carcinoma
  – CT scan of pelvis
  – CT thorax and abdomen in patients with invasive disease (rule out metastasis)

Diagnostic Procedures/Surgery

Cystoscopy with biopsy/transurethral resection

Pathologic Findings (2)

- Urothelial carcinoma 50–60%
- Squamous-cell carcinoma 16–25%
  – More common in women, traditionally considered-more prevalent
- Adenocarcinoma 10–16%
- Primary tumor staging based on TNM classification (See also Reference tables: TNM: Urethra Cancer)
  – T—Primary tumor (men and women)
    ○ Tx Primary tumor cannot be assessed
    ○ Tis Carcinoma in situ
    ○ T0 No evidence of primary tumor
    ○ Ta Non-invasive papillary carcinoma
    ○ T1 Tumor invades subepithelial connective tissue
    ○ T2 Tumor invades any of the following structures: Corpus spongiosum, prostate, periurethral muscle
    ○ T3 Tumor invades any of the following structures: Corpus cavernosum, invasion beyond prostatic capsule, anterior vaginal wall, bladder neck
    ○ T4 Tumor invades other adjacent organs
  – N—Regional lymph nodes
    ○ Nx Regional lymph nodes cannot be assessed
    ○ N0 No regional lymph node metastases
    ○ N1 Metastasis in a single lymph node <2 cm in greatest dimension
    ○ N2 Metastasis in a single lymph node >2 cm in greatest dimension or in multiple nodes

- M—Distant metastasis
  - Mx Distant metastasis cannot be assessed
  - M0 No distant metastasis
  - M1 Distant metastasis
- Primary tumor in prostatic urethra:
  - Tx Primary tumor cannot be assessed
  - Tis pu Carcinoma *in situ* in the prostatic urethra
  - Tis pd Carcinoma *in situ* in the prostatic ducts
  - T0 No evidence of primary tumor
  - T1 Tumor invades subepithelial connective tissue (only in case of concomitant prostatic urethral involvement)
  - T2 Tumor invades any of the following structures: Corpus spongiosum, prostatic stroma, periurethral muscle
  - T3 Tumor invades any of the following structures: Corpus cavernosum, beyond prostatic capsule, bladder neck
  - T4 Tumor invades other adjacent organs
- N (Nodes) and M (metastasis) as above

DIFFERENTIAL DIAGNOSIS

- Adenomatous polyp
- Squamous papilloma
- Transitional cell papilloma
- Leiomyoma
- Nephrogenic adenoma
- Amyloidosis
- Urethral caruncle
- Leukoplakia
- Periurethral abscess
- Skene gland, inflammation/adenitis
- Urethral diverticulum
- Urethral fistula
- Urethral stricture
- Malignant neoplasms
  - Adenocarcinoma
  - Melanoma
  - Metastatic disease
  - Skene (paraurethral) gland, adenocarcinoma
  - Squamous-cell carcinoma
  - Urothelial carcinoma

TREATMENT

GENERAL MEASURES (1,3)

Based on pathology, stage, location of tumor

MEDICATION

First Line

- No medical therapy as first-line treatment
- Preoperative cisplatin-based systemic chemotherapy followed by surgery for locally advanced urothelial cancer has demonstrated a survival advantage
- Preoperative chemoradiation followed by surgery for locally advanced squamous-cell carcinoma has demonstrated a survival advantage

Second Line

Adjuvant systemic chemotherapy based on underlying tumor histopathology

SURGERY/OTHER PROCEDURES

- Male
  - Penile urethra
    - Transurethral resection (TUR)
    - Corpus spongiosum—partial penectomy
    - Proximal penile urethra—total penectomy
  - Prostatic urethra
    - TUR + BCG for Ta or Tis
    - Higher stage-radical cystoprostatectomy
  - Bulbomembranous
    - TUR
    - Primary excision with primary anastomosis
    - Cystoprostatectomy with urethrectomy and total penectomy, with possible bilateral pelvic lymph node dissection
    - Locally advanced disease: Excision of pubic rami
- Female
  - Distal
    - Partial urethrectomy or TUR
  - Proximal—often presents at higher stage
    - Anterior pelvic exenteration
    - Pelvic lymph node dissection

ADDITIONAL TREATMENT

Radiation Therapy

- Used as primary therapy for low-stage distal urethral carcinoma in females
  - Primary brachytherapy or external beam
- Used as adjuvant therapy for advanced cancer

Additional Therapies

Ilioinguinal lymphadenectomy only recommended for palpable disease or for high risk disease in the distal urethra

Complementary & Alternative Therapies

None

ONGOING CARE

PROGNOSIS (4)

- Male
  - 5-yr survival: Depends on location, stage, and pathology
- Female
  - 5-yr survival: Depends on location, stage, and pathology
- Complications
  - Associated surgical complications
  - Abscess
  - Cystitis
  - Incontinence
  - Stricture
  - Fistula

FOLLOW-UP

Patient Monitoring

- Q3–6 mo cystoscopy and urine cytology
- Cross sectional imaging to evaluate for local recurrence
- Recurrences often occur early (1–2 yr)

CODES

ICD9

- 189.3 Malignant neoplasm of urethra
- 597.80 Urethritis, unspecified
- 598.9 Urethral stricture, unspecified

ICD10

- C68.0 Malignant neoplasm of urethra
- N34.2 Other urethritis
- N35.9 Urethral stricture, unspecified

CLINICAL/SURGICAL PEARLS

- Urethral cancers appear to be associated with infection with human papillomavirus (HPV), particularly HPV16, a strain of HPV known to be causative for cervical cancer.
- Most urethral cancers are managed surgically.
- Low-grade female distal urethral cancer can be managed with radiotherapy.
- Most locally advanced urethral tumors are best approached by neoadjuvant systemic chemotherapy (±radiotherapy) followed by consolidative surgical resection.
- Outcome strongly correlates with stage

URETHRAL CARUNCLE

Margarita M. Aponte, MD
Victor W. Nitti, MD, FACS

BASICS

DESCRIPTION

- Urethral caruncle is a benign tumor consisting of friable mucosa at the posterior edge of the urethral meatus in females.
- Most are asymptomatic.
- Most common in postmenopausal females.

EPIDEMIOLOGY

Incidence

- Most common benign tumor of the female urethra.
- Occurs more frequently in postmenopausal women.
- Uncommon in childbearing years.
- Extremely rare in children.

Prevalence

Common in postmenopausal elderly women

RISK FACTORS

- Postmenopausal vaginal atrophy
- Chronic irritation to the urethral meatus

Genetics

No known genetic association

PATHOPHYSIOLOGY

- Mucosal ectropion of posterior urethral wall secondary to retraction of an atrophic vagina due to decreased estrogens
- Appears unrelated to any viral etiology
- Some cases may be related to the autoimmune phenomena of IgG4-associated disease

ASSOCIATED CONDITIONS

Vaginal atrophy

GENERAL PREVENTION

Prevention of vaginal atrophy

DIAGNOSIS

HISTORY

- Determine menopausal status, as more common in postmenopausal females
- Incidental finding on pelvic exam in asymptomatic women
- Light bleeding or spotting on underwear
- Microscopic hematuria

- Vaginal irritation
- Occasional dyspareunia
- Voiding or obstructive symptoms infrequent
- Tenderness is infrequent

PHYSICAL EXAM
- Erythematous, soft, friable mass seen protruding from a segment of the urethral meatus and palpated on vaginal inspection
- Usually reddish, occasionally may appear blue or black
- Usually located at the ventral (posterior) urethral meatus
- May be tender to palpation
- Usually $<$1–2 cm

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- There are no diagnostic lab tests
- Urine analysis may show RBCs or epithelial cells
- Urine cytology may identify malignancy but it is unrelated to the urethral caruncle

Imaging

Usually not required, may be visualized on MRI

Diagnostic Procedures/Surgery
- Urethroscopy: May help delineate extent of lesion and may be performed in the work up of microscopic hematuria
- Biopsy: Excisional or incisional.
  - Not usually required for diagnosis, but indicated if mass is suspicious for malignancy, it increases in size or fails to respond to topical estrogen cream.

Pathologic Findings
- Papillomatous, granulomatous, and angiomatous varieties
- Histologic:
  - Connective tissue containing many inflammatory cells and blood vessels and covered by an epithelial layer
  - Evidence of necrosis, inflammation, and hemorrhage may be present.
- Transitional or stratified squamous epithelium
- 2% of caruncles have associated malignancy
- Case reports of intestinal heterotopia (1)[C]

DIFFERENTIAL DIAGNOSIS
- Urethral prolapse:
  - Evagination of urethral mucosa
  - Typically circumferential
  - Seen in women of all ages (prepubertal through postmenopausal); caruncle is almost exclusively seen in post-menopausal females
- Malignancy:
  - Urethral carcinoma:
    - Uncommon

- Peak incidence 5th–7th decade
- Usually a firm, nontender, indurated mass
- Irritative and obstructive voiding symptoms may be associated
- Bleeding from urethra or on toilet tissue is more typical.
- Four subtypes of urethral carcinoma: Squamous cell, transitional cell, adenocarcinoma, melanoma (2)[B].

– Lymphoma
– Intestinal metaplasia

• Periurethral glans abscess
• Urethral polyp: Pediatric equivalent of urethral caruncle
• Urethral syndrome
• Urethral condyloma
• Urethral varices
• Thrombosis of urethral vein:
– Bluish, swollen, very tender lesion in similar location to caruncle
• Other causes of postmenopausal bleeding: Cervical, ovarian, uterine pathology

TREATMENT

GENERAL MEASURES

• Most urethral caruncles are asymptomatic and do not require definitive treatment.
• Conservative management with sitz baths, topical estrogen creams, topical anti-inflammatory agents should be used in the majority of patients.
• Excessive or persistent bleeding of obstructive voiding symptoms may prompt treatment.
• If there is any doubt concerning the diagnosis, biopsy should be performed.

MEDICATION

First Line

• Topical estrogen: Apply cream 0.3 mg daily for 2 weeks then decrease to twice a week for maintenance.
– Due to minimal absorption, progesterone is not usually needed.
• Anti-inflammatory medications for mild discomfort, PO, or topical.

Second Line

Systemic estrogen replacement

SURGERY/OTHER PROCEDURES

• Excision:
– Outpatient procedure performed under local anesthesia with or without sedation
– Remove the entire caruncle and approximate the ventral urethral meatal mucosa to the vaginal epithelium
• Ligation (3)[C]:
– Outpatient procedure performed under local anesthesia
• Cryoablation
• Laser fulguration

ADDITIONAL TREATMENT

Radiation Therapy
Applicable only for certain distal urethral malignancies and not for urethral caruncle

Additional Therapies
Sitz baths may alleviate discomfort.

Complementary & Alternative Therapies
None

ONGOING CARE

PROGNOSIS
Excellent

COMPLICATIONS
Urethral stricture or meatal stenosis with surgical excision

FOLLOW-UP
Patient Monitoring
- None specific
- Routine gynecologic follow-up as this is a benign lesion

Patient Resources
Urology Care Foundation: Benign Urethral Lesions.
http://www.urologyhealth.org/urology/index.cfm?article=93

CODES

ICD9

- 599.3 Urethral caruncle
- 627.3 Postmenopausal atrophic vaginitis
- V49.81 Asymptomatic postmenopausal status (age-related) (natural)

ICD10

- N36.2 Urethral caruncle
- N95.2 Postmenopausal atrophic vaginitis
- Z78.0 Asymptomatic menopausal state

CLINICAL/SURGICAL PEARLS

- Urethral caruncles occur most frequently in postmenopausal women.
- Most are asymptomatic and do not need treatment.
- Biopsy is indicated if there is a suspicion for malignancy.
- Topical estrogen is the first-line treatment.
- Surgical intervention should be reserved for patients with larger symptomatic lesions or who fail conservative therapy.

URETHRAL DISCHARGE

Ryan Cleary, MD
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION

- Urethral discharge is abnormal fluid (not urine or semen) released through the urethra most commonly as a result of increased local inflammation.
  - Inflammation secondary to infection, neoplasm, trauma, or local irritation
- Most common symptom of a sexually transmitted infection (STI/STD) in men and most commonly a manifestation of urethritis.
- Appearance of the fluid is commonly characterized as purulent or mucopurulent; scant, watery, or mucoid; or bloody.

EPIDEMIOLOGY

Incidence

Gonorrhea (a common cause of urethral discharge) in men reported to the CDC: 98.7 per 100,000 men

Prevalence

N/A

RISK FACTORS

- Male sex
- Urinary tract infection
- Recent instrumentation or catheterization
- Urothelial carcinoma
- Urethral mass
- Benign prostatic hypertrophy
- Unprotected sexual intercourse

Genetics

N/A

PATHOPHYSIOLOGY (1)

- Urethritis
  - *Neisseria gonorrhea*
    - May present as urethritis, epididymitis, proctitis, or prostatitis
    - Male—Purulent discharge, dysuria
    - Female—Usually asymptomatic, but may have pelvic discomfort, dysuria, dyspareunia
  - Non-gonococcal (*Chlamydia trachomatis, Mycoplasma, Ureaplasma urealyticum*)
    - Chlamydia—Frequently asymptomatic, may present with urethritis, epididymitis, or prostatitis. Gonorrhea may coexist.
    - 25% of women are symptomatic and can have a mucopurulent cervical discharge.
    - 40% of untreated women will develop pelvic inflammatory disease (PID). PID is

associated with infertility and ectopic pregnancy.
  - *Trichomonas vaginalis*
    - Male—Present with urethritis but often asymptomatic.
    - Female—Malodorous, yellow-green vaginal discharge with vulvar irritation.

ASSOCIATED CONDITIONS

With STI coinfection is common (ie, gonorrhea and chlamydia)

GENERAL PREVENTION

- For STI:
  - Abstinence
  - Female and male condoms
  - Education and awareness of risky behavior

DIAGNOSIS

HISTORY

- Age, sex, and duration?
  - Males are more likely to have discharge from a venereal cause
  - STIs are most common in the 15–24–yr-old age group
  - Venereal or traumatic cause is more likely to have acute onset while chronic inflammation or tumor is usually insidious
- Obtain thorough sexual history to discover risk of STI/STD
  - Sex with men, women, or both?
  - Oral, vaginal, or anal intercourse
  - Condom usage
  - How many partners in last month?
  - History of STI/STD
  - Dyspareunia?
- Ask the time since onset, any inciting events, quality or character, quantity, prior treatments, associated symptoms
- History of irritative or obstructive voiding symptoms
  - Hematuria, dysuria, frequency, urgency, incontinence, post void dribbling, straining, incomplete emptying
    - Hematuria noted at beginning, middle or total hematuria, or end of stream helps localize bleeding source to urethra, bladder or upper tracts, or prostate
    - Frequency and urgency can indicate an acute inflammatory response
    - Incontinence can indicate a diverticular source
    - Straining and incomplete emptying indicate obstructive cause
- History of perineal, scrotal, or penile pain
  - Assists in localizing source of discharge
- Any vaginal symptoms?
  - Vaginal mass, discharge, or irritation can indicate presence of urethral diverticulum
- Past medical and surgical history
  - Gonorrhea can have systemic effects
  - Reactive arthritis (arthritis, conjunctivitis, and urethritis) often presents initially with

urethral complaints Prior urethral surgery such as sling for incontinence of artificial urinary sphincter. Erosion of prosthetic material can cause discharge.

- Other symptoms
  - Constitutional symptoms indicate systemic process (fevers, chills, fatigue)
  - In women clearly delineate urethral discharge form vaginal discharge.

PHYSICAL EXAM

- Men
  - Request the patient avoid urination before being examined.
  - Genital skin exam to evaluate for evidence of trauma, ulcers, rashes, abrasions, or masses
  - If no discharge is seen, the urethra should be gently massaged from the ventral part of the penis toward the meatus.
  - Examination of testicles and spermatic cord, scrotum, and inguinal lymph nodes
- Women
  - Genital skin exam to evaluate for evidence of trauma, ulcers, rashes, abrasions, masses, or fissures
  - External genitalia inspection
  - Palpation of urethra for mass, fluctuance, or discharge
  - Bimanual exam to evaluate for tenderness, mobility, and masses

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis
  - Positive leukocyte esterase on first void urine is diagnostic of urethritis.
- Gram stain of discharge
  - >5 WBCs/oil immersion field $\rightarrow$ Urethritis
  - Presence of gram $(-)$ intracellular diplococci on gram stain is 99% specific and 95% sensitive for gonococcal urethritis
  - Negative gram stain does not rule out gonococcal urethritis
  - When gonococcal urethritis is suspected and investigatory tests cannot confirm the diagnosis, consider *Neisseria meningitidis* infection (2).
- Repeated nucleic acid amplification testing (NAAT) is the most sensitive test for chlamydia and gonorrhea.
  - Vaginal, endocervical, or urethral swab or first catch urine from men or women
  - Additional PCR-based genotyping is necessary to differentiate lymphogranuloma venereum (LGV) from chlamydia.
    - LGV is caused by specific strains of Chlamydia (L1, L2, L3).
- CBC if evidence of systemic involvement
- BMP if concern for obstruction from prostatic enlargement

Imaging

- If the cause of the discharge is unclear additional imaging
- Men
  - Scrotal ultrasound
  - Renal/bladder ultrasound
  - CT abdomen and/or pelvis

  - MRI pelvis
- Women
  - Pelvic ultrasound (transabdominal or transvaginal)
  - Renal/bladder ultrasound
  - CT abdomen and/or pelvis
  - MRI pelvis

Diagnostic Procedures/Surgery

- Cystourethroscopy
  - Normally needed for more atypical presentations and if discharge persists in spite of adequate medical therapy
  - Evaluate for mass, erythema, false passage, stricture, or diverticulum of urethra
  - Inspect prostate for friability, vascularity, hypertrophy, narrowing, and areas of visual fluctuance

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Inflammatory causes
  - Gonococcal urethritis
  - Non-gonococcal urethritis
    - *Chlamydia trachomatis*
    - *Mycobacterium genitalium*
    - *Trichomonas vaginalis*
    - *Ureaplasma urealyticum*
  - Urethral diverticulum
  - Trichomoniasis
  - TB
  - Periurethral abscess
  - Reactive arthritis (Previously called Reiter syndrome)
- Masses
  - Urethral tumor
  - Urethral caruncle
  - Urethral hemangioma
  - Urethral condyloma
  - Urethral carcinoma
- Trauma/iatrogenic
  - Acute external force
  - Recent instrumentation
  - Recent catheterization
  - Eroded urethral sling or implanted prosthesis
- Mucosal hyperemia
  - Benign Prostatic Hypertrophy often can have initial hematuria due to dilated prostatic vessels (3).

TREATMENT

GENERAL MEASURES

Cause of discharge dictates treatment

MEDICATION

First Line

- Gonococcal and non-gonococcal urethritis
  - Azithromycin 1 g PO × 1 or doxycycline 100 mg PO BID × 7 days plus ceftriaxone 125 mg IM × 1 or cefixime 400 mg PO × 1 is first-line empiric therapy
- Trichomoniasis
  - Metronidazole 2 g PO × 1 or 250 mg TID × 7 days
- Reactive arthritis
  - NSAIDs, methotrexate, cyclosporine, and sometimes corticosteroids
- BPH
  - 5α-reductase inhibitors can be used for refractory prostatic bleeding

Second Line

Please refer to the CDC's published Sexually Transmitted Diseases Treatment Guidelines 2010 for updates and alternatives

SURGERY/OTHER PROCEDURES

- Urethral mass
  - Often surgical excision is preferred approach
  - Urethral carcinoma can be treated effectively with surgical excision—better control with anterior involvement in males (vs. posterior)
  - Diverticulum requires diverticulectomy
- Trauma
  - Radiographic interrogation of anatomy
  - Retrograde urethrogram, cystogram, cystoscopy, CT cystogram
  - Urethral injuries can be repaired surgically after several months of recovery

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

For STI/STD consider screening and treating partner

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

N/A

COMPLICATIONS

- Urethral stricture

- Local spread to other genitourinary organs – cystitis, prostatitis, epididymitis, orchitis
- Abscess formation in urethra, prostate, epididymis, or testicle
- Systemic infection
- Local invasion or metastasis of malignant lesion
- Recurrent pain

FOLLOW-UP

Patient Monitoring

Follow-up is dictated by any associated findings and etiology of discharge

Patient Resources

- Medline Plus: Gram stain of urethral discharge.http://www.nlm.nih.gov/medlineplus/ency/article/003749.htm

- Urethral Carcinoma, General Considerations
- Urethral Condyloma
- Urethral Diverticulum
- Urethral Hemangioma
- Urethritis, Gonococcal and Non-gonococcal

CODES

ICD9

- 098.0 Gonococcal infection (acute) of lower genitourinary tract
- 788.1 Dysuria
- 788.7 Urethral discharge

ICD10

- A54.01 Gonococcal cystitis and urethritis, unspecified
- R30.0 Dysuria

- R36.9 Urethral discharge, unspecified

CLINICAL/SURGICAL PEARLS

- Character, color, and acuity of discharge can usually direct diagnosis.
- Urethral discharge is the most common symptom of an STI/STD in men.
- Carcinoma of the urethra must be ruled out in the presence of bloody urethral discharge.

URETHRAL DIVERTICULA, FEMALE

Alana M. Murphy, MD

BASICS

DESCRIPTION

- A urethral diverticula is an out-pocketing off the urethra between the submucosal layer and the periurethral fascia
- Often contains a collection of urine and/or pus
- Usually connects to the urethra through a neck or ostium
- Classic symptoms are dysuria, dyspareunia, and post-void dribbling

EPIDEMIOLOGY

Incidence (1)

- Depends on avidity with which it is sought
- Mean age at surgery ~48 yr

Prevalence

- *Difficult to determine true prevalence*
- *1–3% asymptomatic women*

RISK FACTORS

Some series have demonstrated a higher prevalence in African American women compared to Caucasian women

Genetics

No known genetic risk factors

PATHOPHYSIOLOGY

- Congenital female urethral diverticula are uncommon
- Most common theory regarding adult female diverticula (2)
  - Infection or obstruction of periurethral glands
  - Obstruction or abscess formation leads to cyst-like cavity
  - Diverticulum is contained within periurethral fascia

ASSOCIATED CONDITIONS

- Urinary incontinence
- Dyspareunia
- Dysuria
- Storage or voiding symptoms
  - Occasional urinary retention

GENERAL PREVENTION

No known method of prevention

DIAGNOSIS

HISTORY

- Classic 3 Ds (rare for all 3 to be present):
  - Dysuria: Pain during voiding
  - Dribbling (incontinence): Typically due to urine leaking from the diverticulum, patient may also have concomitant stress and/or urgency incontinence
  - Dyspareunia: Pain with intercourse
- Nonspecific complaints are common:
  - Frequency/urgency
  - Hematuria
  - Palpable or visible vaginal lump/bulge
  - Periurethral pain
  - Recurrent UTIs
  - Voiding symptoms or urinary retention
- May be an incidental finding

PHYSICAL EXAM

- Inspect the anterior vaginal wall:
  - Some diverticula are visible as a suburethral mass
  - Assess bladder neck mobility
  - Observe for stress incontinence
  - Assess for point tenderness suburethrally, which may be the only sign of a urethral diverticulum.
- If a suburethral mass is noted:
  - Classic sign: Compressing the mass expresses urine or pus from urethral meatus.
  - If the mass does not compress, consider:
    - Vaginal wall cyst
    - Obstructed (noncommunicating) diverticulum
  - Induration suggests stone or cancer
- Evaluate for other pelvic pathology

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine analysis, urine culture
- Preoperative tests appropriate to patient's age and medical condition

Imaging

- Magnetic resonance imaging (MRI) (3)
  - Diverticulum has high signal intensity on T2-weighted imaging
  - Most accurate diagnostic test
  - Does not require the patient to void
  - Shows noncommunicating diverticula
  - Helps surgical planning
  - Shows size, extent, location, and presence of filling defects
- Voiding cystourethrogram (VCUG):
  - Advantage: Less costly than MRI, allows assessment of other causes of voiding symptoms (ie, closed bladder neck)
  - Disadvantages compared to MRI:

    - More invasive
    - Patient must be able to void
    - Less sensitive for diagnosis
    - Less anatomic detail
- Positive-pressure double-balloon urethrogram:
  – Less sensitive than MRI
  – More sensitive than VCUG
  – Requires special radiology expertise
- Ultrasound (US): Highly operator-dependent
  – Intraurethral or transvaginal

Diagnostic Procedures/Surgery

- Cystoscopy:
  – Much less sensitive than VCUG or MRI
  – Ostium usually in mid-urethra at 5–7 o'clock
  – Main value: Rule out other pathology
- Urodynamics (UDS):
  – Not mandatory in straightforward cases
  – Useful if the patient has incontinence or voiding difficulty
  – Fluoroscopic UDS: Combines VCUG with lower-tract functional evaluation

Pathologic Findings

- *Histology of epithelium may be:*
  – *Transitional*
  – *Stratified squamous*
  – *Columnar*
  – *Cuboidal*
  – *Absent (wall just fibrous tissue)*
- *May have carcinoma* (4)
  – *Adenocarcinoma more common than transitional or squamous cell*
- *Diverticulum may contain stones*

DIFFERENTIAL DIAGNOSIS

- Benign neoplasms
  – Leiomyomas:
    - Increased prevalence in females aged 30–50 yr
  – Skene gland cyst or abscess
    - Associated with meatal deviation
  – Gartner duct cyst
  – Ectopic ureterocele
  – Urethral prolapse or caruncle
  – Vaginal wall cyst
- Malignant neoplasms:
  – Primary urethral carcinoma; more common in females:
    - Squamous cell (80%)
    - Transitional cell (15%)

- Adenocarcinoma (4%)
- Melanoma (1%)

– Rarely and adenocarcinoma can arise in a urethral diverticulum or in Skene gland

TREATMENT

GENERAL MEASURES

- No treatment is necessary if the patient is asymptomatic
  – Patient must understand the small risk that the diverticulum may harbor neoplastic cells
- Little is known about the natural history of untreated diverticula
- Antibiotics and analgesics may control symptoms
- With significant symptomatology, surgical excision is best

MEDICATION

First Line

- Antibiotics (eg, trimethoprim/sulfamethoxazole)
- Analgesics (eg, phenazopyridine), and antispasmodics (eg, oxybutynin) may control mild symptoms
- Surgical excision should be considered if medications are required for symptoms

Second Line

If first-line medications do not alleviate symptoms, then surgical excision is appropriate

SURGERY/OTHER PROCEDURES

- Transvaginal excision and reconstruction is the most common operation.
- Key principles of excision include:
  – Well-vascularized anterior vaginal wall flap
  – Preserve periurethral fascia
  – Excise diverticulum completely
  – Watertight, tension-free urethral closure
  – Avoid overlapping suture lines
  – Close dead space
  – Multiple layer closure (consider Martius flap)
  – Adequate bladder drainage with a urethral catheter ± suprapubic catheter
  – Antimuscarinics can be used to prevent bladder spasms
- Perform simultaneous anti-incontinence procedure (fascial sling) for stress urinary incontinence (SUI) if:
  – Stress incontinence is present before surgery
  – Patient desires concomitant treatment

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- If untreated, natural history is not well known
- Reported surgical success rates 70–99%

COMPLICATIONS

- Related to the diverticulum:
  - Stones
  - Carcinoma: Adenocarcinoma, transitional cell, squamous cell
  - Recurrent UTIs
  - Dysuria
  - Dyspareunia
  - Urinary incontinence
  - Storage or voiding symptoms
- Related to the surgery:
  - Infection
  - Bleeding
  - Urinary incontinence
  - Recurrent diverticulum
  - Urethrovaginal fistula
  - Urethral stricture or necrosis
  - Bladder or ureteral injury
  - Vaginal scarring or narrowing

FOLLOW-UP

Patient Monitoring

- VCUG after surgery at the time of catheter removal
- History and genitourinary exam on follow-up visits
- Additional studies if indicated based on history and exam findings

Patient Resources

http://www.urologyhealth.org/urology/index.cfm?article=110

- R30.0 Dysuria

CLINICAL/SURGICAL PEARLS
- Classic symptoms include dysuria, dyspareunia, and post-void dribbling.
- Definitive management requires transvaginal excision with a multilayer closure.

URETHRAL MASS

Bic N. Cung, MD
Jack H. Mydlo, MD

BASICS

DESCRIPTION

- Urethral masses may be palpable; they are often visualized on cystoscopy or other imaging modalities.
- In females the most common differential includes: urethral caruncle, periurethral/Skene duct cyst, urethral prolapse, ectopic ureterocele, urethral diverticulum, vaginal wall cyst (Müllerian and Gartner duct), and urethral and vaginal malignancy.
- In men inflammatory lesions such as Lichens Sclerosis (LS) or Balanitis Xerotica Obliterans (BXO), periurethral abscess and malignancy can be commonly seen.

EPIDEMIOLOGY

Incidence

- Incidence of urethral mass unknown
- With respect to urethral malignancy:
  - African Americans twice as likely of developing primary urethral cancer as whites
  - Primary urethral cancer at least twice as common in males as in females (1).
  - Most common from 5th to 7th decades of life.

Prevalence

N/A

RISK FACTORS

- Malignancy:
  - Chronic inflammation may increase risk of malignancy.
  - History of bladder cancer may suggest urethral recurrence.
  - HPV-16 infection has been linked to urethral carcinoma in males (2).
- Benign mass
  - Chronic UTIs may suggest anatomic problem such as diverticuli.

Genetics

None

PATHOPHYSIOLOGY

- Anatomic considerations: The male urethra (averages about 20 cm in length), is divided into distal and proximal portions. The distal urethra, which extends distally to proximally from the tip of the penis to just before the prostate, includes the meatus, the fossa navicularis, the penile or pendulous urethra, and the bulbar urethra. The proximal urethra, which extends from the bulbar urethra to the bladder neck, includes distally to proximally the membranous urethra and the prostatic urethra
  - Lymphatic drainage varies according to region:
    - Distal urethra drains to superficial and deep inguinal lymph node (LN).

- Proximal urethra drains to external iliac, obturator, and internal iliac LNs in pelvis.
- Sex accessory glands. These can be the source of infection due to obstruction of their secretory ducts.
  - Prostate
  - Glans Littre
  - Cowper gland

• Anatomicconsiderations: The female urethra is In adults, it is about 4 cm in length and is mostly contained within the anterior vaginal wall.
- Lymphatic drainage varies according to region:
  - Distal 1/3 urethra drains to superficial or deep inguinal LN.
  - Proximal 2/3 urethra drains to external iliac, internal iliac, and obturator (deep pelvic LN).
- Mucus glands
  - Skene gland: Mucus-producing gland that opens into distal urethra; homologous to the prostate glands in males. It can be the site of infection, cysts, or diverticuli.

ASSOCIATED CONDITIONS
None

GENERAL PREVENTION
Safe sexual practices can prevent STDs and decrease risk of inflammatory/infectious conditions.

DIAGNOSIS
HISTORY
• Age and sex of patient
- Malignancy more common >50

• Prior history of bladder cancer may suggest urethral recurrence, particularly in men
• Sexual history:
- Genital warts, gonorrhea may predispose to malignancy.

• Lower urinary tract symptoms:
- Frequency, urgency, hematuria, or dysuria may be associated with stricture or malignancy.
- Obstructive voiding symptoms such as weak stream, straining, and dribbling

• History of UTIs:
- May be associated with urethral diverticulum

PHYSICAL EXAM
• General exam: Assess for lower extremity edema.
• Lymph node assessment:
- Metastatic disease from the distal urethra can involve the superficial inguinal LN.

• External genitalia: Examine for lesions for condyloma acuminatum.
• Urethral exam:
- Carefully palpate full length of lesion.
  - Palpate for abscess or areas of tissue necrosis
- Note location, number, consistency, degree of fixation.

  - Careful bimanual exam to assess for extent of local invasion and involvement of bladder if malignancy is suspected.
  - Inspect meatus for discharge, mass, or stricture.
  - Compression or stripping of a diverticulum in females may express purulent discharge.
- Inspect perineum for fistulous tracts.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine analysis
- Urine culture
- Urine cytology
- Urethral swab: Culture for gonorrhea, Chlamydia, and TB

Imaging

- Ultrasound to evaluate urethral stricture, diverticulum, and foreign body.
- VCUG can help diagnose urethral diverticulum.
- Retrograde urethrogram (RUG) to assess for location and length of urethral stricture.
- Pelvic MRI or CT to assess for urethral diverticulum, metastasis to the pelvic and inguinal LN, evidence of corporal invasion by carcinoma.
  - Pelvic MRI often considered imaging study of choice for urethral neoplasms.

Diagnostic Procedures/Surgery

- Cystoscopy allows direct visualization of the mass and allows for biopsy.
- Percutaneous aspiration of fluctuant mass may provide fluid for cytology and culture.
- Needle biopsy may provide tissue for diagnosis for deep lesions.
- Open surgical biopsy for diagnosis.

Pathologic Findings

Based on specific diagnosis

DIFFERENTIAL DIAGNOSIS

- Depends on clinical presentation and age of patient:
  - Children are more likely to have congenital disease
  - Young adults are more likely due to trauma or STI/STDs
  - Older adults are at greater risk for primary or metastatic malignancy.
- Congenital conditions:
  - Benign fibroepithelial polyp
  - Retention cysts of Cowper gland ducts
  - Ectopic ureterocele
  - Urethral diverticulum
    - The 3 Ds: **d**ysuria, **d**yspareunia, **d**ribbling
- Inflammatory:
  - Stricture disease secondary to gonococcal urethritis
  - Periurethral abscess
  - Accessory gland cysts/abscesses
  - condylomata acuminata
  - TB

- Lichens Sclerosis (LS) or Balanitis Xerotica Obliterans (BXO)
  - Most common cause of meatal stenosis in adults
- Traumatic:
  - Stricture disease secondary to injury; hematoma, foreign body
- Benign neoplasms:
  - Hemangioma
  - Adenomatous polyps
  - Squamous papilloma
  - Transitional cell papilloma
  - Leiomyomas:
    - Increased prevalence in females aged 30–50 yr.
  - Inverted papilloma
    - Type I benign, type 2 higher malignant potential and requires follow-up.
  - Polypoid urethritis
    - Most commonly seen in patients with chronic catheter use.
  - Nephrogenic adenoma
  - Amyloidosis
  - Skene (paraurethral) gland, inflammation/adenoma/abscess
  - Urethral caruncle:
    - More common in postmenopausal women
- Malignant neoplasms:
  - Primary urethral carcinoma, more common in females.
    - Squamous cell (80%)
    - Transitional cell (15%)
    - Adenocarcinoma (4%)
    - Melanoma (1%)
    - Clear cell adenocarcinoma has been associated with urethral diverticulum.
    - Skene (paraurethral) gland adenocarcinoma
    - Metastatic disease
- Miscellaneous conditions
  - Urethral prolapsed:
    - Interlabial, well-circumscribed mass most common in African American females aged 5–7 yr, postmenopausal women is the 2nd most common group.
    - Stone impacted in urethra or dierticulum
    - Foreign body
- Mass in corporal body in male:
  - Metastatic deposit
  - Fibrosis of corporal body from priapism or trauma
  - Peyronie disease plaque
  - Penile prosthesis
- Vaginal wall mass:
  - Leiomyoma
  - Vaginal wall cyst:
    - Gartner duct cysts

TREATMENT

GENERAL MEASURES

- Management is directed by the pathologic findings.
  - Cystoscopic exam with biopsy will usually provide the diagnosis.
  - Imaging and bimanual exam will provide staging information in the case of malignancy.
- In cases with locally advanced disease, multimodality therapy using chemotherapy with radiation is sometimes used.
- Condyloma of the urethra: Intraurethral 5-FU cream, biopsy with fulguration/laser ablation.
- Urethral mucosal prolapsed: Estrogen and anti-inflammatory cream.
- Infectious etiologies: Antibiotic specific to offending organism

MEDICATION

First Line

N/A

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Urethral stricture:
  - Dilation
  - Internal urethrotomy
  - Urethroplasty
- Urethral prolapsed:
  - Excision
- Urethral diverticulum:
  - Excision
- Benign neoplasm:
  - Biopsy for diagnosis
  - Excision, fulguration, laser ablation.
- Malignant neoplasms:
  - Male urethra: Partial or total urethrectomy, possible penectomy with perineal urethrostomy.
  - Female urethra: Total urethrectomy.
  - Cystectomy necessary for high-grade lesions near bladder neck for both males and females.
  - In females, this includes an anterior exenteration (urethrectomy, cystectomy with pelvic lymphadenectomy, hysterectomy with salpingectomy, and anterior vaginal wall).
  - Inguinal and pelvic LN dissections are based on location of lesions.

ADDITIONAL TREATMENT

Radiation Therapy

- May be indicated in some cases of urethral cancer to decrease local recurrence.
- In women, radiation therapy using brachytherapy and external beam radiation combination is a suitable alternative.

Additional Therapies

Cisplatin-based chemo therapy has a role in the adjuvant and neo-adjuvant setting for advance disease (3).

Complementary & Alternative Therapies

Combination of chemotherapy, radiation therapy, and surgery is recommended for advanced female urethral cancer.

ONGOING CARE

PROGNOSIS

- Depends on etiology of mass
- Neoplasms:
  - Males
    - Survival dependent on grade and stage of tumor.
    - Anterior urethral carcinoma of lower grade has best survival and posterior urethral carcinoma of higher grade has worst survival.
  - Distal urethral carcinoma in females of low stage has 70–90% cure rates with surgery.
  - Proximal urethral carcinoma in females are more likely of high stage and has poor prognosis, $<20\%$ 5-yr survival.

COMPLICATIONS

- Dependent on pathology and treatment
- Urethral stricture: Complications secondary to instrumentation and treatment of urethral mass.

FOLLOW-UP

Patient Monitoring

- Cystourethroscopy and urine cytology every 6 mo for urethral carcinoma.
- Urethral condyloma require urethroscopy and retreatment for disease eradication.

Patient Resources

CODES

ICD9

- 189.3 Malignant neoplasm of urethra
- 223.81 Benign neoplasm of urethra
- 599.84 Other specified disorders of urethra

ICD10

- C68.0 Malignant neoplasm of urethra
- D30.4 Benign neoplasm of urethra
- N36.8 Other specified disorders of urethra

CLINICAL/SURGICAL PEARLS

- Many benign and malignant urethral masses can present with similar constellation of symptoms.
  - Cystoscopic examination and biopsy are often necessary to confirm diagnosis.
- Draining fistulas of the penis and perineum should alert suspicion of malignancy.

URETHRAL SQUAMOUS-CELL CARCINOMA

Zachary L. Smith, MD
S. Bruce Malkowicz, MD, FACS

BASICS

DESCRIPTION

Squamous-cell carcinoma (SCC) of the urethra is a malignancy arising from the native squamous lining of the male and female urethra.

EPIDEMIOLOGY

Incidence

- Incidence is higher in African American patients as compared to their white counterparts.
  - White males: 0.58 per 1,000,000
  - African American males: 2.3 per 1,000,000
  - White females: 0.43 per 1,000,000
  - African American females: 0.69 per 1,000,000
- Incidence increases steadily with age, more steeply in men as compared to women (1).

Prevalence

N/A

RISK FACTORS

- Male urethral SCC:
  - Chronic irritation after clean intermittent catheterization (CIC)
  - History of sexually transmitted infection (STI): Nearly 25% of patients with urethral carcinoma will give history of STIs.
  - Urethritis
  - Urethral stricture disease ($\geq$50% of patients).
  - HPV
  - History of external beam radiation therapy
- Female urethral SCC:
  - Leukoplakia
  - Chronic irritation
  - Parturition
  - Human papilloma virus
  - Viral infections
  - Recurrent urinary tract infections
  - Possibly urethral diverticula: 4% of female urethral carcinoma is found within the diverticulum.

Genetics

- Possibility raised for aberrations in chromosomes Y, 2, 3, 4, 6, 7, 8, 11, and 20 (2).
- Notably, there have been no abnormalities described in chromosomes 9 and 17, those largely responsible for the development of urothelial carcinoma.

PATHOPHYSIOLOGY

- Male urethral SCC:
  - Occurs in the male membranous urethra (80% SCC), bulbar urethra (80% SCC), and penile urethra (90% SCC).
- Female urethral SCC:
  - Occurs in the distal 2/3 of the female urethra.
- Both male and female urethral carcinoma spread via direct local extension and via lymphatics:
  - Anterior urethra drains to superficial and deep inguinal nodes.
  - Posterior urethra drains to pelvic lymph nodes.

ASSOCIATED CONDITIONS

- Condyloma acuminatum
- History of STIs
- Presence of indwelling catheter
- Urethral diverticula
- Urethral stricture disease

GENERAL PREVENTION

Prevention of STIs with the use of barrier protection such as condoms

DIAGNOSIS

HISTORY

- Particular attention must be made to risk factors and associated GU conditions.
- Male urethral SCC:
  - Urethral bleeding
  - Perineal discomfort
  - Decreased force of stream
  - Urinary urgency or frequency
  - Dysuria
  - Urinary fistulae
  - Chronic irritation (CIC, history of urethroplasty)
- Female urethral SCC:
  - Urethral bleeding
  - Palpable urethral mass
  - Urinary urgency or frequency
  - Induration of urethra or anterior vaginal wall

PHYSICAL EXAM

- Examiner should evaluate for potential mass arising from urethra:
  - Formal pelvic exam for female patients
  - Perineal exam (to evaluate proximal urethra) in male patients
- Particular attention should be given to the inguinal exam, as 20–30% of patients present initially with nodal metastases to the inguinal chain.
- Exam under anesthesia at time of cystoscopy including bimanual palpation of genitalia, urethra, rectum, and perineum helpful to determine extent of disease

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis
- Urine culture
- Urine polymerase chain reaction for *Neisseria gonorrhoeae* and *Chlamydia trachomatis*
- Cytology of 1st voided urine

Imaging

- Retrograde urethrogram/voiding cystourethrogram (RUG/VCUG):
  - Evaluates entire urethra
  - Aids in assessment for stricture disease, urinary fistulae, or urethral diverticula
- Cross-sectional imaging (CT or MRI):
  - Aids in the determination of local involvement, spread to regional lymphatics, or invasion of contiguous structures
  - MRI particularly helpful for assessment of corporal involvement
  - CT urography provides evaluation of upper urinary tract drainage and presence or absence of upper urinary tract neoplasia (more critical in patients with urethral urothelial carcinoma)

Diagnostic Procedures/Surgery

- Cystoscopy with biopsy or transurethral resection:
  - Gold standard in histologic diagnosis of urethral carcinoma
  - Cystoscopic appearance of fungating growth extending into urethral lumen
- Sigmoidoscopy/colonoscopy if concern for involvement of GI tract based upon physical exam or imaging
  - Particularly important in cases of urethral adenocarcinoma to rule out a GI primary source

Pathologic Findings

Fungating tumor with varied cytologic differentiation ranging from well-differentiated lesions producing keratohyaline pearls to anaplastic giant-cell tumors

ALERT

The clinician must have a very high index of suspicion when considering urethral carcinoma, considering the often insidious and nonspecific nature of the patient's complaints.

DIFFERENTIAL DIAGNOSIS

- Condyloma acuminatum
- Benign neoplasms:
  - Hemangioma
  - Adenomatous polyps
  - Squamous papilloma
  - Urothelial cell papilloma
  - Leiomyomas
    - Increased incidence in females aged 30–50 yr
  - Polypoid urethritis
  - Nephrogenic adenoma

  - Amyloidosis
  - Urethral caruncle: More common in postmenopausal women
- Leukoplakia
- Periurethral abscess
- Skene's (periurethral) gland, inflammation/adenitis
- Urethral diverticulum
- Urethral fistula
- Urethral stricture
- Malignant neoplasms:
  - Primary urethral carcinoma:
    - Squamous cell
    - Urothelial cell
    - Adenocarcinoma
    - Melanoma
    - Clear-cell adenocarcinoma has been associated with urethral diverticulum.
    - Skene (periurethral) gland adenocarcinoma
    - Metastases

TREATMENT

GENERAL MEASURES

- Treatment decisions based on sex, stage, and location of tumor
- TNM staging (See Reference tables: TNM: Urethra Cancer)

MEDICATION

First Line

- Localized disease:
  - The precise role for chemotherapy in the treatment of localized urethral SCC is poorly defined; however, chemotherapy not considered 1st-line treatment
- Advanced disease:
  - Preoperative chemotherapy (or chemoradiotherapy) has been shown to be of benefit over surgical resection alone.
    - Cisplatin-based poly-chemotherapeutic regimens should be used.

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Male bulbomembranous urethral SCC (3):
  - Early lesions have been treated successfully with transurethral resection or local excision with end-to-end urethral anastomosis.
  - Radical excision offers best chance at cure, with radical cystoprostatectomy, total penectomy, bilateral pelvic lymphadenectomy recommended.
  - With locally advanced disease, consider en-bloc excision to include the pubic rami and urogenital diaphragm.
- Male penile urethral SCC (3):

- Transurethral resection, fulguration, or local excision may be employed for superficial low-grade tumors.
- For tumors invading the corpus spongiosum, partial penectomy with a 2-cm margin is treatment of choice if localized to the distal half of the penis
- With involvement of the proximal penile urethra, total penectomy is required to obtain an adequate margin of excision.
- Ilioinguinal lymphadenectomy is indicated only in presence of palpable disease, as there has been no documented benefit of prophylactic lymphadenectomy.

• Distal female urethral carcinoma (3):
- Tumors of the distal urethra tend to be low-stage with cure rates of 70–90% with local excision alone.
- External beam radiation therapy is also therapeutic option for distal female urethral carcinoma.

• Proximal female urethral SCC (3):
- Far more likely to extend into the anterior vaginal wall and bladder
- Requires anterior exenteration with wide resection of the vagina; pelvic lymph node dissection is often required to achieve negative surgical margins.

ADDITIONAL TREATMENT

Radiation Therapy

• Localized disease:
- Male urethral SCC:
  - Few series of radiation therapy for patients with early-stage lesions of the anterior urethra who refuse surgery
  - Possible role in palliation, with occasional adjuvant use with extensive resection
- Female urethral SCC:
  - Low-stage distal lesions can be treated with external beam radiation, brachytherapy, or combined therapy with 5-yr survival rates approaching 75%.
  - Although there appears to be some role to adjuvant external beam or brachytherapy in the treatment of locally advanced female proximal urethral carcinoma, the precise role of radiation therapy remains unclear.

• Advanced disease:
- While surgical resection remains standard of care, preoperative radiation therapy combined with cisplatin-based chemotherapy regimens have been shown to give remarkable results in comparison to surgical resection alone.

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

• Male urethral carcinoma (4):
- 5-yr overall survival (OS): 42.3%

  – 5-yr OS (superficial disease): 83.3%
  – 5-yr OS (invasive disease): 35.7%
  – 5-yr OS (anterior urethra): 69.1%
  – 5-yr OS (bulbar urethra): 44.7%
- Female urethral carcinoma (5):
  – 5-yr OS: 32%
  – 5-yr OS (low-stage): 78%
  – 5-yr OS (high-stage): 33%
  – 5-yr OS (anterior urethra): 54%
  – 5-yr OS (posterior urethra): 25%

COMPLICATIONS

- Abscess
- Cystitis
- Incontinence
- Urethral stricture
- Urinary fistula

FOLLOW-UP

Patient Monitoring

- Vast majority of recurrences occur within 1–2 yr following definitive therapy.
- Surveillance is not well established, but routine cystoscopy and urinary cytology for 1–2 yr, with increasing interval between surveillance cystoscopy in the absence of recurrence seems reasonable

CODES

ICD9
- 189.3 Malignant neoplasm of urethra
- 598.9 Urethral stricture, unspecified
- V12.09 Personal history of other infectious and parasitic diseases

ICD10
- C68.0 Malignant neoplasm of urethra
- N35.9 Urethral stricture, unspecified
- Z86.19 Personal history of other infectious and parasitic diseases

CLINICAL/SURGICAL PEARLS
- Primary urethral SCC is a rare entity.
- Surgical excision is the mainstay of treatment.
- Distal tumors tend to be less advanced and more amenable to localized treatment.
- Proximal tumors tend to have a worse prognosis and require more aggressive treatment.
- Preoperative chemoradiotherapy may be used in advanced disease.

URETHRAL STRICTURE, MALE

Brad Figler, MD
Hunter Wessells, MD, FACS

BASICS

DESCRIPTION

- A urethral stricture is a narrowing of the caliber of the anterior or posterior urethra. Progressive scarring can cause voiding symptoms possibly urethral obstruction.
- True stricture of the female urethra is very rare.

EPIDEMIOLOGY

Incidence

Unknown

Prevalence

- Urethral strictures in Medicare: 4.5k/100k men
- Urethral strictures in VA: 274/100k men
- Posterior urethral injury in 6% of pelvic fractures and 15% of severe pelvic fractures

RISK FACTORS

- Sexually transmitted infections (STIs) (sexually transmitted diseases [STDs]), particularly gonorrhea
- Increasing age
- Some data from Medicare suggests black Americans may have higher stricture rates
- Recurrent infection
- Previous TURP or radical prostatectomy
- Catheterization (usually prolonged)
- Urethral instrumentation
- Trauma (straddle injury or pelvic fracture)
- Lichen sclerosis/balanitis xerotica obliterans (BXO)
  - A chronic skin disease that shows a predilection for the anogenital area and may cause anterior urethral stenosis (1)
  - Reported as the most common cause of meatal stenosis.
- Hypospadias, with or without prior repair

Genetics

No known associations

PATHOPHYSIOLOGY

- Anterior urethral strictures
  - Compromised viability of corpus spongiosum secondary to trauma, inflammation or ischemia
- Posterior urethral strictures
  - Pelvic fracture-associated urethral injury and related distraction defects
  - Scarring following TURP or radical prostatectomy

ASSOCIATED CONDITIONS
- Trauma
- STD/STI
- Urethral instrumentation
- BPH
- Prostate cancer
- Lichen sclerosis/BXO

GENERAL PREVENTION
- Limited urethral instrumentation
- Appropriately sized instruments for transurethral procedures
- STD/STI prevention and early treatment (gonorrhea most common)

DIAGNOSIS
HISTORY
- Voiding symptoms
  - Hesitancy
  - Reduced stream
  - Post void dribbling
  - Spraying or split stream
  - Incontinence
  - Retention
- Prior surgery
  - Transurethral surgery or manipulation
  - Hypospadias repair
- Trauma
- STD/STI
  - Urethral discharge
- Recent or remote urinary tract infection
- Prostatitis
- Lichen sclerosis/BXO
- Urinary retention

PHYSICAL EXAM
- Palpable bladder with retention
- Lichen sclerosis/BXO
  - Hyperkeratosis, meatal stenosis
  - Thickened foreskin with glandular adhesion
- Examination of foreskin
- Abundance and quality of penile skin
- Palpable fibrosis of corpus spongiosum
- Evidence of discharge

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis, urinary culture

- Gonorrhea swab
- Uroflowmetry
  - Significant strictures will have flow rates <10 mL/s (normal, >20 mL/s)
- Post void residual urine to evaluate for retention

Imaging
- RUG (anterior urethra)
- VCUG or antegrade urethrography through suprapubic catheter (posterior urethra)
- Sonography

Diagnostic Procedures/Surgery
Urethroscopy with flexible cystoscope or hysteroscope may be helpful

Pathologic Findings
- Fibrotic narrowing composed of dense collagen and fibroblasts.
- Squamous metaplasia is common

DIFFERENTIAL DIAGNOSIS
- Benign or malignant prostatic obstruction
- Urethral carcinoma
- Urethral abscess
- Functional bladder disorder

TREATMENT

GENERAL MEASURES
- Often detected with episodic urinary retention or with the inability to pass a catheter
- Treatment depends on stricture location, length, caliber, and whether previous treatment was attempted
- No role for primary medical management of urethral stricture disease

MEDICATION

First Line
Urinary tract infections should be treated before any intervention

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Dilation and direct vision internal urethrotomy (DVIU)
  - Dilation, cold DVIU, laser DVIU equivalent results
  - Minimally invasive and easy to perform
  - Effective for short (<1 cm), large caliber (>15 Fr) strictures in which dilation or DVIU have not been previously attempted
  - Use sparingly in long, narrow or refractory strictures; these will not be cured with DVIU
  - Techniques
    - Dilation: Balloon, sounds, filiform, and followers
    - DVIU: Incise at 12:00 to limit bleeding
    - For balloon and DVIU, wire helpful

- 18-French Foley catheter for 48–72 h
- Urethroplasty: Anterior
  - Short strictures (≤2 cm) amenable to excision and primary anastomosis
  - Long strictures (>2 cm) require substitution with flap or graft
  - Long strictures with narrow segment may need combination of resection and substitution (augmented anastomosis)
  - Long strictures that are diffusely narrow may need staged urethroplasty with substitution (Johanson urethroplasty)

- Urethroplasty: Posterior
  - Typically, excision and reapproximation required
  - Techniques used to bridge defect:
    - Urethral mobilization
    - Corporal separation
    - Inferior pubectomy
    - Supracrural rerouting
- Grafts
  - Buccal mucosa widely used; favorable outcomes
  - No difference in success rates with ventral/dorsal graft position
- Lichen sclerosis urethral reconstruction
  - One-stage or staged repairs using oral mucosa grafts are the most recommended

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Intermittent catheterization for 3–6 mo in select cases may improve patency rates
- Suprapubic placement is selected cases with inability to pass catheter or postoperatively following open repair
- Urolume™ stent approved for short bulbar urethral strictures; no longer manufactured
- Memokath™ stent may be useful after dilation or DVIU; not currently approved in the United States (2).

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Dilation/DVIU:
  - 75% long-term success rate for short (<1 cm), wide-caliber (>15-French) and non-refractory stricture
  - Minimal long-term efficacy for long, narrow or refractory stricture
- Urethroplasty
  - 90–95% long-term success rate for excision and primary anastomosis
  - 85% long-term success rate for substitution urethroplasty

COMPLICATIONS

- Immediate
  - UTI
  - Bleeding
  - Urinary leak and/or fistula
  - Lower extremity compartment syndrome
- Delayed
  - Postoperative erectile dysfunction may occur, but recovers by 3 mo
  - Stress incontinence is rare, but can occur if internal and external sphincters are damaged —either prior to or at time of urethroplasty
  - Post-void dribbling
  - Bleeding
  - Urethrocutaneous fistula
  - Penile curvature

FOLLOW-UP

Patient Monitoring

- Recurrence most likely within 1 yr
- Uroflowmetry, PVR, and AUA-SS sufficient to monitor for recurrence; cystoscopy optional

Patient Resources

- MedlinePlus: Urethral Stricture.http://www.nlm.nih.gov/medlineplus/ency/article/001271.htm

CLINICAL/SURGICAL PEARLS
- Direct vision internal urethrotomy (DVIU) is effective for short, wide-caliber, non-refractory strictures; otherwise non-curative.
- Excision and primary anastomosis for strictures <2 cm.
- Buccal mucosa is excellent graft; success rate similar for dorsal or ventral graft position.
- Recurrences most likely within 1 yr.
- Flow/PVR and AUA-SS sufficient for monitoring postoperatively.

URETHRAL TRAUMA (ANTERIOR AND POSTERIOR)

Lee C. Zhao, MD, MS
Allen F. Morey, MD, FACS

BASICS

DESCRIPTION
- Injury that disrupts the watertight integrity of the urethra, typically in male patients.
- Injury to the urethra in women is less common.

EPIDEMIOLOGY
Incidence
- Occurs in 10% of pelvic fractures
- Estimate 10–20% of anterior urethral stricture from external trauma

Prevalence
N/A

RISK FACTORS
- Pelvic fracture
- Perineal straddle injury
- Urethral instrumentation

PATHOPHYSIOLOGY
- Anterior urethra injuries
  - Less common due to mobility of anterior urethra and protection of the bulbospongiosus
  - Penile fracture (often intercourse related) can cause anterior urethral injury
  - Penile constriction bands
  - Penetrating trauma (gunshot, stabbing)
- Posterior urethra
  - More common due to fixed location of urethra within urogenital diaphragm; the combination of straddle fractures with diastasis of the sacroiliac joint has the highest risk of urethral injury
  - Pelvic fracture
  - Straddle injuries
- Penetrating can injure both anterior and posterior urethra
  - Gunshot wound, stab
- Iatrogenic
  - False passage: instrument or catheter
  - Catheter placement in patient with urethral stricture
  - Chronic indwelling catheters
  - Transurethral surgery using oversized resectoscopes

ASSOCIATED CONDITIONS
- Pelvic fracture
- Pelvic hematoma

- Bladder injury
- Vaginal injury

GENERAL PREVENTION
- Seat belts
- Careful instrumentation of the urethra to prevent iatrogenic injury

ALERT
- The amount of urethral bleeding does not correlate with the degree of injury.
- Pain with urination or inability to void is highly suggestive of urethral disruption in the trauma patient.

DIAGNOSIS

HISTORY
- Description of trauma and mechanism of injury
- Voiding history
  - Retention
  - Hematuria

PHYSICAL EXAM
- Classic clinical triad:
  - Bloody urethral discharge
  - Inability to urinate
  - Palpably full bladder
- Blood at meatus:
  - 37–93% of patients with posterior urethral injury
  - Greater than 75% of patients with anterior urethral (AU) injury.
- Ecchymosis and swelling limited to penile shaft
  - Anterior urethral injury confined by Buck fascia
- Butterfly hematoma
  - Violation of Buck fascia, hematoma confined by Colles fascia
- DRE: High riding prostate may be hard to detect due to associated pelvic hematoma and may not be reliable for urethral disruption
- Vaginal laceration is often associated with urethral injury
- Vaginal introitus blood is present in more than 80% of pelvic fractures and coexisting urethral injury (1).

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CBC, electrolytes, BUN, creatinine
- Urinalysis

Imaging
- Retrograde urethrography
  - 30-degree oblique position with bottom leg flexed at knee and top leg straight.
  - Place Foley catheter into fossa navicularis, inflate balloon with 2–3 mL
  - Injection of ~25 mL of contrast into urethra

  – Extravasation of contrast indicates the location of the tear
  – Complete injury usually has no contrast flow into the bladder
• CT is inadequate to evaluate urethral trauma
  – Generally obtained for staging of associated injuries

Diagnostic Procedures/Surgery
Flexible cystoscopy

DIFFERENTIAL DIAGNOSIS
• Urethral injury: contusion, complete, partial
• Injury to bladder neck, ureter
• Penile corporal injury
• Labial/vaginal injury

TREATMENT

GENERAL MEASURES
• Perform retrograde urethrogram (RUG) prior to placement of Foley catheter; avoid urethral instrumentation until urethral imaging if the patient is stable.
• If catheter has already been placed, do not remove it. Perform pericatheter RUG with pediatric feeding tube or angiocatheter
• Establish prompt urinary drainage in patients with pelvic fracture associated urethral injury as typically unable to void and undergo aggressive resuscitation
• Urethral injury confirmed by:
  – Extravasation on RUG or VCUG
  – Cystoscopy
• Classification of urethral injury can guide treatment decisions
  – EAU Classification of blunt urethral injury (1)[C]:
    ◦ Grade I: stretch injury
    ◦ Grade II: contusion
    ◦ Grade III: partial disruption
    ◦ Grade IV: complete disruption
    ◦ Grade V: complete or partial disruption of posterior urethra with associated tear of the bladder neck, rectum or vagina

MEDICATION
First Line
• Analgesics as needed
• Antibiotics

Second Line
N/A

SURGERY/OTHER PROCEDURES
• Pelvic fracture and posterior urethral injury
  – Place large bore suprapubic catheter (16-Fr Foley) using percutaneous peel-away sheath
  – We advise against using small pigtail suprapubic catheters
  – For complex injuries with associated bladder trauma, open suprapubic tube placement

with bladder inspection is suggested. Place suprapubic tube (SPT) in patients undergoing ORIF for pelvic fracture (24 Fr, high on bladder and tunneled through skin away from hardware)
  - Open surgical realignment should be avoided due to high risk of erectile dysfunction, incontinence
  - Primary endoscopic realignment may be attempted but has a success rate of 25% (2)[B], but may delay the ultimate curative therapy for this condition. In our experience, traumatic strictures tend to be short and dense, and refractory to endoscopic treatment. Success rates for open anastomotic urethroplasty are greater than 90%.
  - In women, primary open repair is recommended for disruption of the urethra with associated tear of bladder neck and vagina (3)[C] due to risk of incontinence and vesicovaginal fistula
- Penetrating trauma
  - Immediate reconstruction is highly successful
    - High velocity projectile creates blast effect, making immediate reconstruction less reliable
- Iatrogenic urethral injury: Place indwelling Foley for 7 days, followed by voiding cystourethrogram

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Repeated endoscopic treatment of traumatic urethral strictures may lead to longer strictures (4)[B].
- In an unstable trauma patient, a cautious attempt can be made to pass a urethral catheter.
  - If there is any a difficulty a suprapubic catheter can be placed and a retrograde urethrogram performed later (1).

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Posterior urethral injury:
  - Low rate of incontinence in patients with competent bladder neck
- Anterior urethral injury: Good prognosis after primary repair

COMPLICATIONS

- Urethral stricture
- Fistulas
- Incontinence
- Erectile dysfunction

FOLLOW-UP

Patient Monitoring

- Recovery often complicated by other orthopedic and neurologic injuries
- Anterior urethral injury:
  - If primary repair has been performed, catheter should be kept in place for 2–3 wk with follow-up VCUG
- Posterior urethral injury:
  - If endoscopic alignment has been performed, the suprapubic tube should be kept in place for at least one week after removal of urethral Foley. Most endoscopic alignment will fail at 1 wk
  - Perform reconstructive procedures at 4–6 mo

CODES

ICD9

- 599.70 Hematuria, unspecified
- 867.0 Injury to bladder and urethra, without mention of open wound into cavity
- 867.1 Injury to bladder and urethra, with open wound into cavity

ICD10

- R31.9 Hematuria, unspecified
- S37.30XA Unspecified injury of urethra, initial encounter
- S37.33XA Laceration of urethra, initial encounter

CLINICAL/SURGICAL PEARLS

- Retrograde urethrography is considered the gold standard for evaluating urethral injury.
- Most pelvic fracture associated injuries occur in the posterior urethra.
- Posterior urethral injury should be managed with suprapubic catheter and delayed definitive repair.
- When placing a suprapubic catheter, should use a large bore Foley catheter placed via a peel away sheath.
- Urethral injury in women associated with bladder neck or vaginal injury should be repaired primarily.
- Anastomotic repair of traumatic strictures has a high success rate.

URETHRITIS, GONOCOCCAL AND NONGONOCOCCAL

Daniel C. Parker, MD
Jack H. Mydlo, MD

BASICS

DESCRIPTION

- Gonococcal urethritis (GU) and nongonococcal urethritis (NGU) are urethral infections characterized by dysuria and urethral discharge
  - Both types are STDs/STI
    - *Neisseria gonorrhoeae* (gram-positive diplococci) on culture/gram stain differentiates GU from NGU
    - *Chlamydia trachomatis* is the most common cause of NGU

EPIDEMIOLOGY

Incidence

- Estimated 820,000 new cases of gonococcal urethritis
  - Most common reportable disease in the United States
- Over 3 million cases of non-gonoccal urethritis annually
- Both GU and NGU are belived to be significantly under repprted

Prevalence

- Gonococcal urethritis: 100.8 per 100,000 population
  - Rate has increased among all gender/racial/ethnic groups since 2009 some data suggests NGU is increasing

RISK FACTORS

- Individuals aged 15–24 yr at highest risk
- African Americans
- Sexual Activity
  - Risk of infection is 10% for men after a single exposure
  - Multiple sexual partners

Genetics

No heritable form of transmission

PATHOPHYSIOLOGY

- GU
  - Caused by *N. gonorrhoeae*
    - Coinfection with Chlamydia 4–35%
    - Incubation is 3–10 days
- NGU
  - *Chlamydia trachomatis* most common (25–60%)
  - Mollicutes*: Ureaplasma urealyticum, Mycoplasma hominis, Mycoplasma genitalium* in up to 40% of cases
  - *Trichomonas vaginalis*, CMV, and HPV have been reported

  – Incubation period is 7–21 days
- Both types acquired during sexual intercourse
- Urethritis is a difficult diagnosis in women because copious discharge may not be present; the hallmark is dysuria and frequency.

ASSOCIATED CONDITIONS
- Other STDs/STI
- Pendulous urethral stricture
- Epididymitis/orchitis

GENERAL PREVENTION
- GU and NGU
  – Proper use of male and female condoms, if multiple sexual partners

DIAGNOSIS

HISTORY
- GU and NGU
  – Systemic symptoms are rare
  – Important information to gather
    - Relationship to sexual activity (when/type)
    - Number of episodes
    - Number of sexual partners
    - Nature of sexual relations
    - Severity of symptoms
    - Characteristics of dysuria and urethral discharge
- NGU
  – Urethral discharge
    - Usually mild to moderate, clear or whitish fluid
  – Dysuria
    - Mild burning with urination or absent
- GU
  – Urethral discharge
    - Usually purulent, green/yellow/white, and copious
  – Dysuria
    - Usually moderate to severe burning with urination
    - May present as urethral itching

PHYSICAL EXAM
- GU and NGU
  – Pendulous urethra may be tender to palpation
  – Abdomen and flanks palpated for tenderness, masses, and bladder distention
  – Scrotal contents examined for testicular/epididymal size, consistency, and tenderness
  – Digital rectal exam (DRE) for prostate size, tenderness, and consistency

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine analysis
  - Obtain 1–4 h after voiding
  - ≥15 PMN leukocytes per HPF of spun sediment in the first-void urine specimen
  - Positive leukocyte esterase on urine dip in the absence of UTI suggests urethritis
  - Up to 30% of patients with urethritis will not have WBC in the urine
- Urethral smear for gram stain and culture
  - Calcium alginate swab inserted 1–2 cm into urethra best to obtain 1–2 hours after voiding
  - Culture plated on Thayer-Martin media for GU
- Sensitivity of DNA targeted assays is improving (1)[A]
  - Nucleic Acid Amplified Test (NAAT) of urine—first 10–30 cc voided
  - NAAT available for: C trachomatis and N gonorrhoeae. Labs can also test for Mycoplasma, Ureaplasma, and Trichomonas vaginalis but these assays are no commonly performed since they are very costly and may not alter the recommended antibiotic regimen

Imaging

Typically not necessary

Diagnostic Procedures/Surgery

Cystourethroscopy with dilation of pendulous urethra may be indicated for chronic cases resulting in urethral stricture.

Pathologic Findings

Urethral inflammation

DIFFERENTIAL DIAGNOSIS

- GU
- NGU
  - *Chlamydia trachomatis*
  - *Mycobacterium genitalium*
  - *Trichomonas vaginalis*
  - *Ureaplasma urealyticum*
- Uncommon infectious causes: TB, adenovirus, uropathogenic *Escherichia coli* (unprotected anal intercourse), herpes simplex, cytomegalovirus
- Urethral diverticulum
- Periurethral abscess
- Reactive urethritis (Formerly Reiter syndrome) associated with conjunctivitis, arthritis, and tenosynovitis
  - No growth on culture
  - Minimal number of leukocytes in urethral smear or urinalysis
- Miscellaneous: Urethral irritation from detergents, body soap, lotions, spermicides, contraceptives, manipulation, and/or foreign body insertion.

TREATMENT

GENERAL MEASURES

- Cases are reportable to health department.
- Sexual intercourse should be avoided until cure.

- Sexual partners within 60 days of diagnosis or symptoms should be evaluated and treated.
- Dual treatment for both *N. gonorrhoeae* and *C. trachomatis* is recommended.

ALERT
The CDC now recommends against the use of quinolones and oral cephalosporins for treatment of gonococcal urethritis in the US due to widespread bacterial resistance (2)[A].

MEDICATION

First Line

- GU
  - CDC recommends dual therapy for GU and NGU
  - Ceftriaxone 250 mg IM once
    - Efficacious in 99% of cases
    - Also treat for NGU (Chlamydia)
- NGU
  - Azithromycin 1 g PO once, or doxycycline 100 mg PO b.i.d. for 10–14 days

Second Line

- GU
  - Cefixime 400 mg PO once
  - Azithromycin 2 g PO once for pregnant women or cephalosporin allergy.
- NGU
  - Erythromycin 500 mg PO q.i.d. for 7 days
  - Ofloxacin 300 mg PO b.i.d. for 10–14 days

SURGERY/OTHER PROCEDURES

Surgery typically not indicated

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Patient education
  - Proper use of condoms and safe sexual practice
  - Reduce number of sexual partners
  - Evaluation and treatment of sexual partners at risk (3)[A]

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Generally good prognosis with treatment for both GU and NGU
  - Systemic manifestations of gonococcal dissemination are rare today:
    - Arthritis
    - Dermatitis

- Meningitis
- Endocarditis

COMPLICATIONS

- GU
  - Periurethritis
    - May lead to abscess
  - Urethral fibrosis
    - May lead to stricture
  - Epididymitis/orchitis
    - May lead to testicular atrophy or infertility
  - Prostatitis
    - May lead to abscess
- NGU
  - Emotional sequelae are common
    - Fear of loss of sexual function or guilt may produce depression
  - Epididymitis and/or nonbacterial prostatitis
  - Usually does not cause severe physical complications in men

FOLLOW-UP

Patient Monitoring

- GU and NGU
  - Post therapy culture and urethral smear to confirm response to therapy

Patient Resources

- CDC. STD fact sheets. http://www.cdc.gov/std
- MedlinePlus: Urethritis. http://www.nlm.nih.gov/medlineplus/ency/article/000439.htm

CODES

ICD9

- 098.0 Gonococcal infection (acute) of lower genitourinary tract
- 099.40 Unspecified other nongonococcal urethritis [NGU]
- 131.02 Trichomonal urethritis

ICD10

- A54.01 Gonococcal cystitis and urethritis, unspecified
- A59.03 Trichomonal cystitis and urethritis
- N34.1 Nonspecific urethritis

CLINICAL/SURGICAL PEARLS

- GU is caused by the gram-positive diplococci *Neisseria gonorrhoeae*.
- NGU is most commonly caused by *Chlamydia trachomatis*.
- Up to 35% of cases of GU are coinfected with chlamydia.
- The CDC recommends simultaneous treatment for *both* GU and NGU in patients presenting with urethritis.
- Sexual partners within 60 days of diagnosis or symptom onset should be evaluated and treated.

URGENCY, URINARY (FREQUENCY & URGENCY)

Jessica M. DeLong, MD
Kurt A. McCammon, MD, FACS

BASICS

DESCRIPTION

- Urgency is the complaint of a sudden compelling desire to void that is difficult to defer while frequency is the complaint by a patient that he or she voids too often
- Urgency:
  - Urgency is the most common symptom of overactive bladder (OAB).
  - Urge incontinence is involuntary leakage of urine preceded by the above symptom (1).
- Frequency:
  - There is no minimum number of voids.
  - Nocturia is the complaint of waking at night to void one or more times.
- These are classified as storage symptoms.

EPIDEMIOLOGY

Incidence

Not well known; one study showed 9.2%

Prevalence

Estimates vary

RISK FACTORS

- Dependent upon etiology
  - Older age

Genetics

N/A

PATHOPHYSIOLOGY

- Inflammation/irritation
  - Infection, malignancy, urinary lithiasis, etc.
- Neurogenic
- Myogenic (2)
- Polyuria
- Idiopathic

ASSOCIATED CONDITIONS

- Bladder outlet obstruction
- Diverticulosis
- Dysfunctional voiding
- Interstitial cystitis (IC)/painful bladder syndrome (PBS)
- OAB
- Urinary tract infection (UTI)

- Vaginitis

GENERAL PREVENTION

- Treat any underlying condition (eg, UTI)
- Maintain good voiding habits and regular bowel pattern

DIAGNOSIS

HISTORY

- Use validated questionnaires when possible
  - International prostate symptom score (IPSS), IPSS-QOL
  - Urgency sensation scale
- Irritative voiding symptoms:
  - Urgency, frequency, urge incontinence, nocturia
- Obstructive voiding symptoms:
  - Hesitancy, slow stream, post-void dribbling, retention
  - Consider causes of bladder outlet obstruction
- Other medical history
  - Stone disease
  - Malignancy such as bladder cancer
- Symptoms of infection
- Episodes of gross hematuria
- Bowel habits
- Sexual function
- Current medications
  - Diuretics, alpha blockers
- Tobacco use
- Family history
- Pregnancy is normally associated with urinary frequency
- Voiding diary, nature, and volume of fluid intake

PHYSICAL EXAM

- In males:
  - External genital exam to evaluate for phimosis, evidence for lichen sclerosis (LS), urethral discharge or mass
  - Digital rectal exam (DRE) to:
    - Evaluate prostate size, nodularity
    - Assess for rectal mass or fecal impaction
    - Assess perineal sensation, bulbocavernosus reflex, anal sphincter tone
- In females:
  - Pelvic exam to:
    - Assess for mass, pelvic floor support
    - Detect stress urinary incontinence (SUI by employing Valsalva manuever
    - Assess urethral lesions or discharge
- General exam for peripheral edema
- Focused neurologic exam

- Mental status exam
- Motor deficits, gait stability
- Sensory deficits, reflexes

• Abdominal exam
- Palpable mass (retention, fibroids, etc.)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

• Urine analysis (UA): Exclude other pathology
- Specific gravity
- Presence of leukocyte esterase (LE), nitrates, and pyuria suggests UTI
- Microhematuria necessitates further work up
  - Cystoscopy, triphasic CT
- Glucose: Assess for diabetes
- Protein: Assess for medical renal disease
  - Obtain culture if UA suggestive of infection
- Urinary cytology to rule out urothelial carcinoma

Imaging

• Renal/bladder ultrasound (US):
- If bladder outlet obstruction (BOO) suspected (ie, elevated PVR)
- If renal insufficiency

• Dedicated pelvic US (female):
- If adnexal mass or uterine abnormality noted on pelvic exam

• KUB may be appropriate initial study if stones are suspected

• CT:
- If hematuria, triphasic CT is standard of care
- If stones suspected, non-contrast CT

ALERT
If UA suggests infection or hematuria, appropriate evaluation is key.

Diagnostic Procedures/Surgery

• Check post void residual (PVR)

• Cystoscopy:
- If hematuria or persistent problems
  - May detect bladder pathology (tumor, calculus), BOO

• Urodynamics (UDS):
- If conservative therapy fails
- Can help define treatment options and evaluate for neurogenic component

Pathologic Findings

Dependent upon etiology

DIFFERENTIAL DIAGNOSIS

• Inflammation—UTI, urethritis

• Radiation cystitis

• IC/PBS

- Trauma—local or neurologic
- Foreign body
- Neurologic condition (ie, spina bifida, spinal cord injury, neuropathy)
- Neoplasm—urologic or nonurologic by local extension
  - Urothelial carcinoma, especially CIS, often causes urinary frequency
- Urolithiasis
- Polyuria
- Drugs—diuretics, irritants
- Gynecologic-vaginitis, pregnancy

TREATMENT

GENERAL MEASURES

- Based on underlying etiology
  - Treat UTI with appropriate antibiotics
  - Initiate appropriate workup and management of hematuria
- In general, treatment is divided into:
  - Conservative (behavioral)
  - Pharmacotherapy
  - Surgery

MEDICATION

First Line

- Choice based on etiology
- Antimuscarinics are used to inhibit detrusor contractions by competitively inhibiting muscarinic cholinergic receptors. Common side effects: dry mouth and constipation. Maximal effect after 3 mo
  - Oxybutynin
    - 5 mg PO TID; XL 15 mg daily-BID
    - Transdermal patch 3.9 mg/d: may be good option to avoid cognitive side effects
  - Trospium 20 mg PO BID; XR 60 mg PO daily
  - Tolterodine 1–2 mg PO BID
  - Darifenacin 7.5–15 mg PO daily
  - Solifenacin 5–10 mg PO daily
- β-3 adrenergic receptor antagonist: A newer drug; induces detrusor relaxation
  - Mirabegron 25–50 mg PO daily
- α-Blockers are used to decrease outflow obstruction due to prostatic hypertrophy. Common side effects: dizziness, retrograde ejaculation
  - Tamsulosin 0.4 mg PO qhs
  - Alfuzosin 10 mg PO daily
  - Terazosin start 1 mg PO qhs, titrate up to 20 mg
  - Doxazosin start 1 mg PO daily titrate to 8 mg
  - Silodosin 8 mg PO daily
- 5-α-reductase inhibitors are used to lower DHT in men with prostates >40 cc. Are synergistic with α-blockers and take 6–12 mo for maximum effect:

- Finasteride 5 mg PO daily
- Dutasteride 0.5 mg PO daily

Second Line

- PDE5 inhibitors
  - Documented efficacy for men with lower urinary tract symptoms (LUTS)/OAB
    - FDA approved for signs and symptoms of BPH with our without erectile dysfunction
- Imipramine
  - No good quality RCTs
- Estrogens (vaginal superior to systemic) may be beneficial for post-menopausal women
  - Contraindicated if history of venous thromboembolism (VTE), breast cancer

SURGERY/OTHER PROCEDURES

- Intravesical botulinum toxin A (onabotulinumtoxinA) injection
  - If refractory to pharmacologic therapy
  - Decreases bladder contraction
  - Clean intermittent catheterization (CIC) may be necessary postoperatively
- Sacral neuromodulation: Interstim® implantation
  - Stimulation of S3 afferent nerve
  - 2-stage procedure; revision rates 7–33%
  - Not recommended in neurogenic voiding dysfunction, elderly
- Correction of BOO
  - Transurethral resection of prostate (TURP); transurethral incision of prostate (TUIP)
- Correction of pelvic floor prolapse in females
- If fails all other therapy and associated with incontinence can consider bladder augmentation or urinary diversion

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Behavioral therapy is first-line
  - Bladder training may include biofeedback and pelvic floor physical therapy
  - Timed voiding
  - Kegel exercises may be of benefit

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Generally a long-term problem; dependent on etiology

COMPLICATIONS

Common side effects of pharmacotherapy include dry mouth and constipation

FOLLOW-UP

Patient Monitoring

- Depends upon etiology, treatment, response
  - Often periodic visit with voiding diary, uroflow, PVR

Patient Resources

MedlinePlus: Frequent or urgent urination.
http://www.nlm.nih.gov/medlineplus/ency/article/003140.htm

- Incontinence, Urinary, Adult Female
- Lower Urinary Tract Symptoms (LUTS)
- Neurogenic Bladder
- Overactive Bladder (OAB)
- Painful Bladder Syndrome/Interstitial Cystitis (PBS/IC)
- Prostate, Benign Hyperplasia/Hypertrophy (BPH)
- Prostatitis, General

CODES

ICD9

- 596.51 Hypertonicity of bladder
- 788.41 Urinary frequency
- 788.63 Urgency of urination

ICD10

- N32.81 Overactive bladder
- R35.0 Frequency of micturition
- R39.15 Urgency of urination

CLINICAL/SURGICAL PEARLS

- Hematuria warrants appropriate workup. May be a presentation of genitourinary malignancy.
- Anticholinergics are contraindicated in patients with untreated narrow-angle glaucoma.

- Combination of antimuscarinics plus alpha blockers may be better than either alone for men with LUTS (3).
- Use anticholinergics with caution in elderly patients, as cognitive effects may be pronounced.
- Use of intravaginal estrogen for postmenopausal women may worsen incontinence.

URINARY RETENTION AFTER STRESS URINARY INCONTINENCE SURGERY IN FEMALES

Bradley C. Gill, MD, MS
Sandip P. Vasavada, MD, FACS

BASICS

DESCRIPTION
- Inability to void spontaneously following surgery for stress urinary incontinence
- Voiding with Valsalva or straining following surgery for stress urinary incontinence
- Procedure performed may be either midurethral sling or retropubic urethropexy

EPIDEMIOLOGY
Incidence
- Estimated 3–11% for midurethral sling
- Estimated 3–7% for retropubic urethropexy

Prevalence
- More common with retropubic or transvaginal slings than transobturator slings
- Likely more common with synthetic than biologic sling materials
- Episodes are generally transient and last days to weeks but resolution up to 3 mo can occur

RISK FACTORS (1)
- Weak detrusor contraction or incomplete voiding preoperatively
- Procedure done with “tension” rather than “tension free” placement
- Inability to urinate or elevated post-void residual postoperatively

PATHOPHYSIOLOGY
- Iatrogenic urethral obstruction by extrinsic compression
- Retropubic suspension can cause urethral “kinking”
- Tension-free vaginal tape has lowest rate of retention
- Retention is frequently self-limited and will resolve within 6–12 wk following anti-incontinence surgery

ASSOCIATED CONDITIONS
- Bladder diverticulum
- Cystocele
- Cystolithiasis
- Detrusor hypocontractility
- Recurrent urinary tract infections
- Urethral stricture

DIAGNOSIS

HISTORY
- Details of retention

  - Timing of symptom onset with regard to surgery
  - Duration of symptoms and consistency with voiding
  - Associated with discomfort, distention, or incontinence
- Urologic conditions
  - Detrusor hypocontractility on urodynamic studies
  - Episodes of cystolithiasis
  - Recurrent urinary tract infections
  - Cystocele
- Urologic interventions
  - Intra-detrusor botulinum toxin injections
  - Previous midurethral sling or urethropexy
- Other interventions
  - Abdominopelvic surgery, radiation, or injury
  - Spine surgery or injury
- Current medications
  - Antimuscarinics or anticholinergics
  - Alpha adrenergic agonists
- Diabetes mellitus

PHYSICAL EXAM

- Visual inspection of the abdomen and suprapubic area
- Abdominal palpation with attention to the suprapubic area
- Visual inspection of external genitalia for discharge or bleeding
- Speculum examination
  - Swelling or bulging anterior vaginal wall
  - Incisional discharge or bleeding
  - Cystocele
- Palpation of external genitalia, vaginal sidewalls, and pelvic floor muscles
  - Urethral or anterior vaginal wall bulging or tension
  - Tension and mobility of surgically placed sling or sutures
  - Pelvic floor muscle tension, spasm, or tenderness

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Renal function panel
- Serum electrolytes
- Blood counts

Imaging

- Bladder volume ultrasound
- Residual bladder volume after decompression

Diagnostic Procedures/Surgery

- Catheterization only if easily passable with indwelling left temporarily
- Cystoscopy if catheterization not possible with guide wire placement

DIFFERENTIAL DIAGNOSIS

- Bladder diverticulum
- Detrusor hypocontractility
- Occult urinary retention or incomplete emptying
- Sling placed under too much tension
- Neurogenic bladder
- Diabetic cystopathy
- Cystocele
- Medication

TREATMENT

GENERAL MEASURES (2,3)

- Catheterization and observation of iatrogenic obstruction
  - Trial of intermittent self-catheterization to observe for resolution
  - Temporary indwelling catheter with office visits for trails of voiding
  - Cystoscopy and guidewire placement if catheterization not possible
  - Consider operative intervention if no resolution within 3 mo
- Emergent bladder drainage for an impassable urethra
  - Operative sling incision pending anticipated delay for arranging surgery
  - Suprapubic aspiration and drainage at bedside
  - Percutaneous nephrostomy tubes if no other options are possible
- Careful urethral dilation may be considered soon after surgery
- Evacuation of hematoma if suspected as etiology of urethral compression

MEDICATION

First Line

N/A

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Elective bladder diverticulectomy as indicated
- Transvaginal retropubic urethrolysis if more conservative measures fail

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Excellent considering multiple options

- Major risk is incontinence recurrence
  – 15–20% recurrence of stress urinary incontinence symptoms

COMPLICATIONS
- Infection
- Urethral/bladder injury
- Recurrent incontinence

FOLLOW-UP

Patient Monitoring
- Office follow-up every 7–14 days for trials of voiding if an indwelling catheter placed
- Standard postoperative follow-up if a surgical intervention is pursued

Patient Resources

N/A

CODES

ICD9
- 599.60 Urinary obstruction, unspecified
- 788.29 Other specified retention of urine
- 997.5 Urinary complications, not elsewhere classified

ICD10
- N36.8 Other specified disorders of urethra
- N99.89 Oth postprocedural complications and disorders of GU sys
- R33.8 Other retention of urine

CLINICAL/SURGICAL PEARLS

- Think about how sling vectors impact function.
- Many cases will resolve themselves with time.
- If consistently occurring change the technique.

URINARY RETENTION, ADULT FEMALE

Mary K. Powers, MD
Raju Thomas, MD, MHA, FACS

BASICS

DESCRIPTION

- Urinary retention is the inability to properly empty the urinary bladder. It can be further classified as acute and chronic.
  - *Acute retention of urine* is defined by the International Continence Society (ICS) as a painful, palpable or percussable bladder, when the patient is unable to pass any urine (1).
  - *Chronic retention of urine* is defined by the ICS as a non-painful bladder, which remains palpable or percussable after the patient has passed urine. Such patients may be incontinent (1).
- Females can void with low detrusor pressures and valsalva, making diagnosis more complicated than the old adage "high pressure, low flow"

EPIDEMIOLOGY

Incidence

Occurs in 2.7–23% of women, most commonly after anti-incontinence surgery

Prevalence

Usually self-limited

RISK FACTORS

- Anti-incontinence surgery (eg, urethral slings)
- Diabetes
- Neurologic conditions
- Psychological conditions

Genetics

N/A

PATHOPHYSIOLOGY (2)

- Kinking or stricture of the urethra depending on procedure performed or anatomy
- Cases of neurologic complications include detrusor acontractility versus detrusor sphincter dyssynergia
- Diabetes mellitus, causing low detrusor tone

ASSOCIATED CONDITIONS

- Chronic constipation
- Multiple sclerosis (MS)
- Pelvic organ prolapse (POP)
- Spinal cord injury
- Stress urinary incontinence

GENERAL PREVENTION

- Avoidance of anti-incontinence surgery or optimization of patient selection and/or surgical technique
- Quick detection of neurologic conditions

DIAGNOSIS

HISTORY

- Complaints of frequency, decreased force of stream, urgency or urge incontinence, or UTI are indicative of bladder outlet obstruction (BOO)
- Feeling of vaginal bulge
- History of stroke, diabetes, MS, Parkinson's disease, "back problems," neurologic conditions, depression
- Chronic narcotic medication use
- Chronic constipation
- Use of psychotropic medication

PHYSICAL EXAM

- Examine abdomen to evaluate any prior surgeries
- Bladder distension
- Pelvic examination:
  - Urethral hypermobility, cystocele, pelvic organ prolapse, diverticulum, vaginal/pelvic mass, rectal prolapse, or rectocele
- Motor/sensory tone to rule out neurologic disorder
- Stress urinary incontinence (or overflow incontinence)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis
- Urine culture
- Complete metabolic panel

Imaging

- Ultrasound:
  - Measure post-void residual urine
  - Look for hydronephrosis
- MRI of brain/spinal cord in young females with new onset voiding symptoms (MS, occult spinal dysraphism)

Diagnostic Procedures/Surgery

- Videourodynamics show high pressure, low flow state with closed bladder neck in primary BOO, "spinning top"
  - Flow rate less than 12 mL/s with maximum detrusor pressure of 20 cm H_2O
  - Uroflow—"saw tooth" pattern. Does not distinguish between BOO and decreased detrusor function
  - EMG of sphincter to assess for sphincter/detrusor coordination
- Cystoscopy to assess for stones, eroded material, diverticulum, extrinsic mass, stricture, or kinking

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Iatrogenic (26%)—most commonly following anti-incontinence surgery.
  - 2–8% of women require reintervention.
  - Retropubic suspension can cause urethral "kinking"
  - Tension-free vaginal tape has lowest rage of retention
  - Retention is frequently self-limited and will resolve within 6–12 wk following anti-incontinence surgery
    - Manage with catheterization or clean intermittent catheterization
- Anatomic:
  - Urethral stricture (13%)
  - Ectopic ureterocele
  - Urethral diverticulum (3%)
  - Urethral malignancy
  - Bladder neck obstruction
  - Pelvic organ prolapse (24%)
- Dysfunctional Voiding (5%)
  - Pseudomyotonia—severe spasticity of sphincter without nerve stimulation (rare)
  - Fowler syndrome—young women without neurologic disease. Highly responsive to neuromodulation.
    - Higher incidence of depression and polycystic ovarian syndrome
- Neurologic
  - Detrusor sphincter dyssynergia (5%)
- Pharmacologic
  - Anticholinergic, opioid, and other narcotic medications
    - Antihistamines
    - Anticholinergics: Atropine, belladonna, benztropine, mesylate, cyclic antidepressants, phenothiazines, ipratropium bromide
    - Antispasmodics
    - Tricyclic antidepressants
    - α-Agonists: Cold preparations, ephedrine derivatives, amphetamines
    - Narcotics
    - Detrusor muscle relaxants: Tolterodine, trospium, oxybutynin, solifenacin, hyoscyamine
    - NSAIDS
- Psychogenic
- Myogenic (eg, detrusor acontractility)

TREATMENT

GENERAL MEASURES (3)
- Treatment based on underlying cause
- Stop medications predisposing to retention
- Evaluation and management of chronic constipation/bowel dysfunction

- Foley catheterization vs. clean intermittent catheterization (preferred) to manage acute retention

MEDICATION

First Line

- Alpha-adrenergic blockade can be useful in patients with dysfunctional voiding
  - Tamsulosin: 0.4 mg daily
  - Doxazosin: 1–4 mg daily
  - Terazosin: 1–5 mg daily
  - Prazosin: 1–5 mg daily

Second Line

- Baclofen for patients with neurologic causes of dysfunctional voiding
  - 5 mg TID, increase 15 mg/d q3 days, max. 80 mg/d divided TID/QID

SURGERY/OTHER PROCEDURES

- For iatrogenic causes, intervention should be postponed for a period of 12 wk to allow for stabilization of symptoms
  - Urethrolysis is the gold standard, circumferentially free the urethra
    - Recurrence or development of stress incontinence high as 30%
  - Bladder neck incision/resection has mixed result in primary bladder neck obstruction, caution not to cut too deep and develop fistulas
  - Refractory strictures can undergo reconstruction with vaginal flap

ADDITIONAL TREATMENT

Radiation Therapy

NA

Additional Therapies

- Urethral dilation for urethral strictures. Caution because this can lead to fibrosis and is falling out of favor.
- Clean intermittent catheterization may be best choice for patients with acontractile bladder
- Constipation management
  - Colace 100 mg 1 tab by mouth BID
  - Magnesium citrate 250 mL PO

Complementary & Alternative Therapies

Concurrent evaluation and management by gastroenterology

ONGOING CARE

PROGNOSIS

- Depends on the etiology
  - Iatrogenic retention following slings has a good success rate with urethrolysis up to 92%
  - α-Blockade shows 50% improvement in PVR, symptoms, and flow rate

COMPLICATIONS

- Urethrolysis can lead to development of stress incontinence
- Bladder neck incision can lead to incontinence, vesicovaginal fistula, or need for repeat

procedures
- Urethral dilation can cause recurrent stricture and fibrosis

FOLLOW-UP

Patient Monitoring

- Repeat urodynamic studies are recommended if problem persists
- Videourodynamics should be done if concern for bladder neck obstruction
- Neurologic evaluation if new diagnosis of MS, Parkinson's disease

Patient Resources

National Kidney and urologic diseases information clearinghouse.

CODES

ICD9

- 598.9 Urethral stricture, unspecified
- 788.20 Retention of urine, unspecified
- 788.29 Other specified retention of urine

ICD10

- N35.9 Urethral stricture, unspecified
- R33.8 Other retention of urine
- R33.9 Retention of urine, unspecified

CLINICAL/SURGICAL PEARLS

- There are multiple causes of urinary retention in females; urodynamics can help distinguish causes.
- In young females with new onset voiding complaints must rule out diabetes or neurologic diagnosis such as MS.
- Pelvic organ prolapse is a major cause of retention.

URINARY RETENTION, ADULT MALE

Amar J. Raval, MD
Akhil Das, MD, FACS

BASICS

DESCRIPTION

- Urinary retention is the inability to properly empty the urinary bladder. It can be further classified as acute and chronic.
  - ***Acute retention of urine*** is defined by the International Continence Society (ICS) as a painful, palpable, or percussable bladder, when the patient is unable to pass any urine (1).
  - ***Chronic retention of urine*** is defined by the ICS as a non-painful bladder, which remains palpable or percussable after the patient has passed urine. Such patients may be incontinent (1).

EPIDEMIOLOGY

Incidence

Incidence increases with age in males (~10% in men aged 70 yr)

Prevalence

Exact prevalence is difficult to estimate

RISK FACTORS

- General: Diabetes, herpes zoster, drugs, psychogenic, neurologic disease, bladder calculus, recent surgery (especially with epidural or spinal anesthesia), groin surgery such as hernia repair, prostate brachytherapy, stroke, pelvic trauma
- Elderly men: BPH, prostate cancer, history of retention, urologic procedures or instrumentation, medications, prostatitis, urothelial carcinoma (rare cause)
- Recent inguinal/pelvic surgery (ie, hernia)
- Medications:
  - Antihistamines
  - Anticholinergics: Atropine, belladonna, benztropine, mesylate, phenothiazines, ipratropium bromide
  - Antispasmodics
  - Tricyclic antidepressants
  - α-Agonists: Cold preparations, ephedrine derivatives, amphetamines
  - Narcotics
  - Detrusor muscle relaxants: Tolterodine, trospium, oxybutynin, solifenacin, hyoscyamine
  - NSAIDS

Genetics

- Increased risk of moderate-to-severe symptoms in men with positive family history
  - Some BPH thought to be inherited in pattern consistent with autosomal dominant pattern

PATHOPHYSIOLOGY

- Most commonly occurs in patients with preexisting bladder outlet obstruction or with a

known history of neurologic voiding dysfunction.
- Infection, bleeding, or over distension is the usual precipitating event.
- Drainage of bladder results in prompt symptomatic relief.
- Although acute retention is usually thought of as painful, in certain circumstances pain may not be a presenting feature.
  - When due to prolapsed intervertebral disc, post partum, or after regional anaesthesia such as an epidural anesthetic.
  - The retention volume should be significantly greater than the expected normal bladder capacity.
  - In patients after surgery, due to bandaging of the lower abdomen or abdominal wall pain, it may be difficult to detect a painful, palpable, or percussible bladder (1).

ASSOCIATED CONDITIONS
- Diabetes
- Disease of prostate
  - BPH
  - Prostate cancer
  - Prostatitis
- Neurologic conditions
  - Neurogenic bladder
  - Multiple sclerosis
  - Cerebrovascular accident
  - Parkinson disease
  - Spinal cord injury
  - Demyelinating disorders
- UTI
- Recent hernia or other surgery

DIAGNOSIS
HISTORY
- Acute retention: Sudden onset of the inability to void more than small volumes of urine
  - Associated with an uncomfortable sensation and a distended bladder
- Chronic retention: Longstanding inability to completely void, with occasionally large PVRs, but not usually associated with discomfort.
  - Common symptoms include frequency, urgency, overflow incontinence, and weak urinary stream
- Retention may suggest infection or BPH:
  - Symptoms of bladder outlet obstruction: Weak stream, hesitancy, incomplete voiding, dribbling.
  - Symptoms of irritative voiding: Frequency, urgency, dysuria, nocturia
- Previous urinary retention
- Urologic procedure/instrumentation resulting in scarring, stricture, or clot retention.
- STDs
- Strictures
- Medication use

- Recent gross hematuria, resulting in clot retention.
- Pain: Bone pain and weight loss suggest prostate cancer.
- Spinal cord injury or pelvic trauma.
- Recent surgery, especially in those with spinal or epidural anesthesia.
- Diabetes mellitus

PHYSICAL EXAM

- Palpable abdominal mass
  - Assess for severe urgency and/or pain on suprapubic palpation
- DRE
  - Symmetrically enlarged prostate suggests BPH
  - Nodularity suggests cancer
  - Boggy, tender prostate suggests prostatitis
- Complete neurologic exam if suspicion for a neurologic etiology exists
  - Anal (S2) and levator muscle tone (S3–S4)
  - Check sensation over the penis (S2), perianal area (S2–S3), outside of the foot (S2), sole (S2–S3), and large toe (S3)
  - Suspect spina bifida or meningomyelocele when extremity findings do not parallel perineum findings, ie, absent sensation and tone in feet but partial tone or sensation in perineum
- Examine genitalia for rashes or lesions, ie, herpes zoster flare

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Chemistry: BUN and creatinine may be abnormal in retention especially if hydronephrosis is present
  - Increased post obstructive diuresis risk with post renal obstructive renal failure
- Urinalysis and culture
  - Leukocyte esterase or nitrite positivity with pyuria suggests infection
  - Hematuria suggestive of infection, tumor, or calculi
- PSA usually not checked acutely due to false positive with prostatitis, recent prostate surgery, etc.

Imaging

- Bedside bladder scan
  - Post void residual (PVR) can be obtained and useful for diagnosis of acute and chronic urinary retention
- Renal/bladder US
  - Can be obtained if diagnosis uncertain
  - Can delineate hydronephrosis and/or bladder wall thickening
- CT of abdomen/pelvis
  - Can delineate bladder calculi, prostate size, hydronephrosis, bladder wall thickening, obstructing masses, and foreign bodies
- Retrograde urethrogram
  - Obtained if history of pelvic trauma with new onset urinary retention to rule out urethral injury

Diagnostic Procedures/Surgery

- Foley catheter placement for bladder drainage is diagnostic and curative
- Cystoscopy for definitive diagnosis or acutely to place catheter
- Urodynamic studies
  - Uroflowmetry, cystometrogram, electromyography, urethral pressure profile, pressure flow studies

DIFFERENTIAL DIAGNOSIS

- Generally either bladder outlet obstruction or bladder dysfunction:
  - Anatomic:
    - Penis: Phimosis, paraphimosis, meatal stenosis, foreign-body constriction
    - Urethra: Tumor, foreign body, calculus, urethritis, stricture, clot retention, hematoma
    - Prostate: BPH, prostate cancer, bladder neck contracture, prostatitis, prostatic infarction
  - Trauma
    - Urethral disruption
  - Neurologic
    - Motor paralytic: Spinal shock, spinal cord syndromes, ie, spina bifida, meningomyelocele
    - Sensory paralytic: Tabes dorsalis, diabetes, multiple sclerosis, and pernicious anemia
    - Syringomyelia, myasthenia gravis
    - Herpes zoster, poliovirus
    - Herniated disks
  - Drugs: see “Risk Factors”

TREATMENT

GENERAL MEASURES

- Acute retention: Catheterization for decompression
  - In men with BPH, consider immediate α-blocker therapy to improve likelihood of successful catheter removal
  - Some consider suprapubic tube (SPT) superior in the management of short-term retention
- Chronic retention: Clean intermittent catheterization preferred over long-term indwelling catheter
- Definitive management may involve medications, surgical intervention, or chronic catheterization strategies
- Urodynamic studies may be required to establish diagnosis
- Treatment should be directed toward cause, with goal of preventing future episodes
- Antibiotics as indicated for infection
- Decrease or stop medications that can contribute to voiding dysfunction

MEDICATION

First Line

- Most medications are used for BPH; may also help with transient postoperative retention (2).
- α-Adrenergic blockers: Relax prostatic/bladder neck smooth muscle tone, most useful for acute retention
  - Alfuzosin 10 mg/d

  - Doxazosin start 1 mg/d to max. 8 mg
  - Silodosin 8 mg/d
  - Tamsulosin start 0.4 mg to max. 0.8 mg
  - Terazosin start 1 mg/d to max. 20 mg
- Side-effects: syncope, orthostasis, retrograde ejaculation, asthenia, and nasal congestion
- 5α-reductase inhibitors: Reduce prostatic volume, longer-term effects
  - Finasteride or dutasteride
  - Side-effects: Decreased libido and sexual dysfunction
  - Reduce PSA by ~50% and correction should be used when evaluating risk for cancer
- Combination therapy (α-adrenergic blocker + 5α-reductase inhibitor)
- Tadafil 2.5–5 mg/d FDA approved to treat both lower urinary tract symptoms (LUTS) and erectile dysfunction (ED)

Second Line

- Bethanechol (10–50 mg PO tid–qid)
  - Direct cholinergic stimulant; increases detrusor tone
  - Indicated for the treatment of acute postoperative and postpartum nonobstructive (functional) urinary retention and for neurogenic atony of the urinary bladder with retention
  - Side effects: Diarrhea, nausea, bronchospasm, hypotension, tachycardia, seizure

SURGERY/OTHER PROCEDURES

- If catheter placement fails, bedside or intraoperative cystoscopy can be performed:
  - Cystoscopy is usually diagnostic and can delineate urethral stricture, a false passage, bladder neck contracture, and obstructing prostatic tissue.
  - Once bladder is entered under direct vision, a wire can be placed and dilations sequentially performed. The wire can then be used to allow passage of a Council tip catheter.
- If cystoscopy is unsuccessful, consider SPT placement
  - Open SPT preferable in patients with history of multiple abdominal surgeries
  - If no prior surgery, place SPT via percutaneous approach

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- >30% of patients with an episode of urinary retention will recur if untreated
- Prevention of recurrence underscores management decisions

COMPLICATIONS

- Bladder rupture in acute urinary retention; usually associated with trauma.
- Relief of chronic prolonged obstruction may result in post-obstructive diuresis or major hemorrhage secondary to bladder mucosal disruption or tearing of bladder vessels, hematuria may require evacuation of clots.
- Significant hypotension may occur secondary to vaso-vagal response.
- Longstanding, untreated urinary retention can lead to reflux nephropathy and permanent voiding dysfunction.

FOLLOW-UP

Patient Monitoring

- Monitoring of electrolyte imbalance and fluid resuscitation for post obstructive diuresis (>200 mL/h).
- Patient with signs of infection or impaired renal function should be admitted and observed.

Patient Resources

National Kidney and Urologic Diseases Information Clearinghouse (NKUDIC).

CLINICAL/SURGICAL PEARLS

In chronic retention clean intermittent catheterization (CIC) is preferred over long-term indwelling catheter.

URINARY RETENTION, PEDIATRIC

Dana A. Weiss, MD
Douglas A. Canning, MD, FACS

BASICS

DESCRIPTION

- Urinary retention is the inability to properly empty the urinary bladder. Can be acute or chronic partial or complete.
  - Acute
    - Uncommon in children
    - Acute onset of inability to void for over 12 h
    - Associated with uncomfortable often painful sensation and distended bladder.
  - Chronic
    - Inability to void over long period of time
    - Usually asymptomatic

EPIDEMIOLOGY

Incidence

Not reported

Prevalence

2:1 boys:girls

RISK FACTORS

- Acute onset
  - Surgery, narcotic use, immobility, urinary tract infection (bacterial or viral), local inflammation (balanitis, meatal stenosis, labial adhesions, cellulitis), constipation, incarcerated inguinal hernia, acute neurologic inflammatory processes, invasive mass, drug related
- Chronic
  - Dysfunctional voiding, Hinman syndrome (non-neurogenic neurogenic bladder), lazy bladder syndrome, spina bifida, reduced mental status, benign obstructing mass, locally invasive mass, posterior urethral valves, prune belly syndrome

Genetics

Genes related to underlying etiology

PATHOPHYSIOLOGY

- Obstruction
  - External compression, intrinsic obstruction by valve, stone, stricture, etc.
- Neurogenic bladder
- Inflammation/infection
  - Effect on brain/meninges (encephalitis, meningitis), spinal cord (transverse myelitis), nerve roots (radiculitis), peripheral nerves (neuritis)
- Constipation (1)

  - Distended rectum displaces bladder and trigone anteriorly, impairing bladder outflow. Impairment of urethrovesical and sacral reflexes from rectal distension.
- Drug related
  - Disruption of autonomic balance between bladder and proximal urethra

ASSOCIATED CONDITIONS
- Dysfunctional elimination syndrome
- Neurologic inflammatory disorders: Transverse myelitis, Guillain–Barré syndrome, encephalitis
- Neurologic neoplasms: neuroblastoma, ependymoma, Ewing sarcoma
- Benign neurologic abnormalities: Tethered cord
- Inflammatory conditions
- Obstructive processes
  - Posterior urethral valves, prune belly syndrome, urethral strictures, foreign body, or stones

GENERAL PREVENTION
Early education of proper voiding habits (drinking water, voiding 6–8 times per day, avoiding constipation).

DIAGNOSIS

HISTORY
- Recent events, including surgery
- Subtle neurologic changes
- History of constipation
- History of hematuria, dysuria
- Recent medications

PHYSICAL EXAM
- Palpable mass (bladder)
- External genitalia exam
  - Meatal stenosis, phimosis, balanoposthitis; labial adhesions, prolapsed urethra
- Spine and lower back
  - Sacral dimple, sacral tuft
- Motor and sensory exam
- Digital Rectal exam
  - Tone
  - Mass

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis
- Urine culture
- Electrolytes
  - Creatinine, potassium, magnesium

Imaging

- Renal bladder ultrasound (RBUS), pelvic ultrasound
- MRI spine (if no other etiology identified)
- Voiding cystourethrogram (VCUG) if concern for PUV, stricture (wait until urine culture negative prior to study)
- Retrograde urethrogram

Diagnostic Procedures/Surgery
- Urodynamic evaluation
- Cystoscopy

Pathologic Findings
Based on etiology

DIFFERENTIAL DIAGNOSIS
- Obstruction
  - Tumor
  - Benign mass (fibroepithelial polyp)
  - Urethral valves (posterior or anterior)
  - Urethral stone
  - Prolapsing ureterocele
  - Urethral stricture
  - Paraurethral cyst
  - Hydrometrocolpos
- Inflammation
  - Cystitis (bacterial or viral) (2)
  - Bacterial
    - Gram positive
    - Gram negative
  - Viral
    - Herpes simplex virus (HSV)
    - Varicella Zoster virus (VZV)
    - Cytomegalovirus (CMV)
    - Epstein Barr Virus (EBV)
  - Eosinophilic cystitis
  - Prostatic abscess
- Neurogenic dysfunction
  - Neuropathic bladder
    - Myelomeningocele
    - Sacrococcygeal teratoma
    - Prune belly syndrome
    - Tethered spinal cord
  - Detrusor sphincter dyssynergia
- Other
  - Constipation
  - Adverse drug effect
  - Trauma

– Electrolyte abnormalities (hypermagnesemia) (1)

TREATMENT

GENERAL MEASURES

- Empty bladder with catheter
- Initiate clean intermittent catheterization until resolution.
- Complete workup based upon findings on history and physical exam
- For chronic retention, after complete workup to rule out pathologic cause, begin behavioral modification (increase water intake, increasing voiding attempts to every 3 h, treat constipation)

MEDICATION

First Line

- Polyethylene Glycol 3350 for constipation/dysfunctional elimination syndrome
  - 0.5–1.5 g/kg daily, max. dose 17 g/d.
    - Use only in children older than 6 mo

Second Line

- α-Blockers (3,4)
  - Smooth muscle relaxation and decreased bladder outlet resistance:
    - Doxazosin <6 yr 0.5 mg daily
    - Doxazosin >6 yr 1 mg daily
- Steroids for inflammatory processes (2)
  - Very seldom used. Stress dose steroids.

SURGERY/OTHER PROCEDURES

- In acute setting, place urethral catheter
- If unable to place catheter, place suprapubic cystostomy tube.
- For posterior urethral valves, perform cystoscopy, transurethral incision of valves.
- For urethral stones, cystoscopy and laser lithotripsy or basket extraction (may require antegrade and retrograde approach).
- For obstructing fibroepithelial polyp, transurethral resection possible, vs. open cystotomy and excision.
- For obstructing prolapsing ureterocele, incision of ureterocele may leave obstructing tissue. May require excision of ureterocele and bladder neck reconstruction.
- Urethral stricture—based on length
- For significant detrusor sphincter dyssynergia, may benefit from botulinum toxin injection into urethral sphincter vs. urethral dilation

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Behavioral modification
  - Timed voiding
  - Increased water intake

– Pelvic floor relaxation

Complementary & Alternative Therapies
Biofeedback program for dysfunctional elimination syndrome

ONGOING CARE

PROGNOSIS
Based upon etiology.

COMPLICATIONS
- Bladder rupture in acute urinary retention; usually associated with trauma
- Postobstructive diuresis after relief of acute retention
- Urinary tract infection from stasis of chronic retention
- Chronic retention with high detrusor pressure can lead to renal impairment
- Missed diagnosis of malignant cause of urinary retention

FOLLOW-UP
Patient Monitoring
- Monitor for post-obstructive diuresis after drainage. May require fluid replacement in neonates
- Follow uroflow and post-void residual after treatment

Patient Resources
National Kidney and Urologic Diseases Information Clearinghouse (NKUDIC).
http://kidney.niddk.nih.gov/kudiseases/pubs/UrinaryRetention/

CODES

ICD9

- 596.0 Bladder neck obstruction
- 599.0 Urinary tract infection, site not specified
- 788.20 Retention of urine, unspecified

ICD10

- N32.0 Bladder-neck obstruction
- N39.0 Urinary tract infection, site not specified
- R33.9 Retention of urine, unspecified

CLINICAL/SURGICAL PEARLS

- Urinary retention in a newborn must be closely evaluated with RBUS and VCUG to rule out posterior urethral valves, ureterocele, and urethral atresia.
- Young boys presenting with acute urinary retention should undergo DRE to rule out prostatic or bladder rhabdomyosarcoma.

URINARY TRACT INFECTION (UTI), ADULT FEMALE

Duane R. Hickling, MD
Victor W. Nitti, MD, FACS

BASICS

DESCRIPTION

- Urinary tract infection (UTI) in a female is defined as a symptomatic urothelial inflammation secondary to bacterial adhesion and internalization within the urinary tract.
- Most common human bacterial infection.
- Tremendous economic impact
  - ~ $3.5 billion annually in the United States.
- Possibility of progression to urosepsis
- Anatomical: Lower (confined to bladder and/or urethra) vs. upper (involving the ureters and/or kidneys)
- Complicated: Structural or functional abnormality, or if immunosuppressed (See Section I in "Urinary tract infection (UTI), complicated, adult")
- Recurrence (rUTI): 3 or more culture positive infections within 12 mo
  - Reinfection: Different infecting uropathogen, negative culture between infections or infection occurs >2 wk after successful treatment
  - Persistence: Recurrence within 2 wk of treatment and identical uropathogen
- Asymptomatic bacteriuria: 2 consecutive midstream urine specimens with isolation of the same bacterial strain in quantitative counts $\geq 10^5$ in the absence of symptoms

EPIDEMIOLOGY

Incidence

- 13,320 cases per 100, 000 adult women/yr (1)
- 44% have at least 1 rUTI in 12 mo
- 5% more than 3 rUTIs in 12 mo
- Bacteriology of female UTI (2):
  - Ambulatory: *Escherichia coli* (74.2%), *Klebsiella pneumonia* (6.2%), *Enterococcus species* (5.3%), *Streptococcus agalactiae* (2.8%), *Proteus mirablis* (2.0%), and *Staphylococcus saprophyticus* (1.4%)
  - Nosocomial: *E. coli* (65.5%), *Enterococcus* species (8.0%), *K. pneumonia* (8.0%), *Klebsiella oxytoca* (8.9%), *P. mirablis* (2.2%), *Pseudomonas aeruginosa* (1.8%)
  - Nursing home: *E. coli* (46.6%), *Enterococcus* species (11.4%), *Proteus mirabilis* (10.1%), *K. pneumonia* (9.7%), *Pseudomonas aeruginosa* (3.2%)

Prevalence

53,067 cases per 100,000 adult women (1)

RISK FACTORS

- Behavioral factors
  - Sexual intercourse, spermicide use, barrier contraceptives, recent antibiotic use, dysfunctional voiding

- Anatomic Variations
  - Perineal and urethral anatomy is thought to be important only in absence of other risk factors
  - Urinary tract obstruction: Medullary sponge kidney, calyceal diverticula, ureteral obstruction, ureteropelvic junction obstruction, vesicoureteric reflux, primary bladder neck, urethral stricture, or benign prostatic hyperplasia
- Physiologic Factors
  - Diabetes mellitus
    - 1.2–2.2-fold increased risk
    - Theories: Hyperglycosuria, increased glycosylation of uroplakin Ia, less effective urinary glycoproteins, and impaired bladder contractility and emptying (diabetic cystopathy)
  - Pregnancy
    - Prevalence of bacteriuria is similar to non-gravid females
    - However, 22–35% progression to pyelonephritis. Secondary to hydronephrosis of pregnancy
  - Neurologic diseases
    - Detrusor-external sphincter dyssynergia
  - Other: Alternations in toll-like receptors, anti-microbial peptides (defensins and cathelicidin), anti-bacterial adherence factors (eg, Tamm–Horsfall protein) and growth factors (eg., TGF-β1 and VEGF
  - Postmenopausal female
    - Atrophic vaginitis, decreased levels of lactobacilli, incontinence, cystocele, elevated post-void residual

Genetics

- Positive female family history strongly predictive of UTI
- Greater binding of uropathogenic coliforms
  - ABH blood group non-secretor status
  - P1 status
- Alterations in HSPA1B, CXCR1&2, TLR2&4, and TGF-β1 genes

PATHOPHYSIOLOGY

- Routes of infection:
  - Ascending (majority)
    - From extra urinary sources such as the distal gut or vaginal epithelium (majority)
  - Hematogenous (rare)
    - Increased with ureteral obstruction
    - Staphylococcus bacteremia or Candidal fungemia
  - Quiescent intracellular reservoirs
    - Dormant uropathogenic bacteria residing within urothelial cells
    - Evade host immune responses and can emerge at any given time to reinfect host
- Adherence and internalization
  - Mediated via bacterial FimH and terminal mannose units of host uroplakin Ia

ASSOCIATED CONDITIONS

- Postmenopausal

- Diabetes mellitus
- Urolithiasis
- Anatomic or function abnormalities of the urinary tract

GENERAL PREVENTION
- Avoidance of spermicidal products and barrier contraceptives
- Although hygiene, pericoital voiding, hydration has not been shown to be uniformly effective in UTI prevention women are encouraged to clean perineum wiping front to back and should empty bladder before, and after intercourse

DIAGNOSIS
HISTORY
- UTI signs/symptoms: General malaise, frequency, urgency, urge incontinence, dysuria, suprapubic pain pressure, cloudy urine, foul smelling urine, hematuria
- Pyelonephritis: Fever, chills, flank pain
- Negatively predictive: Vaginal discharge, foul vaginal odor, pruritus, urethral discharge
  - Suggestive of vaginitis or urethritis
- Review previous UTI episodes: Number, frequency, temporal associations (eg, sexual activity), results of documented urine cultures, treatment, and treatment efficacy
- Medical/surgical history: Childhood UTIs, structural/functional abnormalities, immunocompromise, recent hospitalization, genitourinary manipulation/surgery
- Gynecologic history: Menstrual cycle, birth control, menopausal status, STI/STD's, pelvic organ prolapse

PHYSICAL EXAM
- Vital signs: Hemodynamic instability can be associated with pyelonephritis/urosepsis
- Abdominal exam: Suprapubic tenderness, bladder distension suggestive of urinary retention
- Costovertebral angle tenderness with pyelonephritis
- Pelvic exam:
  - Assessment of vaginal epithelium
  - Vaginal discharge
  - Pelvic organ prolapse
  - Urethral abnormalities:
    - Diverticulum: Suburethral tenderness, cystic mass, and/or expression of urethral discharge
    - Skene's gland infection: Expression of discharge from Skene's gland duct

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis
  - Leukocyte esterase
    - Sensitivity 68–98%
    - Specificity 59–96%
    - Positive predictive value 19–86%
    - Negative predictive value 91–97%
  - Nitrite

    - Sensitivity 19–45%
    - Specificity 95–98%
    - Positive predictive value 50–78%
    - Negative predictive value 82–89%
  - Leukocyte esterase and nitrite
    - Sensitivity 35–84%
    - Specificity 98–100%
    - Positive predictive value 84%
    - Negative predictive value 98%
- Microscopy
  - Bacterial counts $>30{,}000$ cfu/mL for detection
  - ≥ 1 bacteria per hpf (uncentrifuged urine) correlates to $\geq 10^5$ cfu/ml via culture
  - Pyuria: ≥ 10 WBCs/hpf
- One study has suggested that midstream urine generally is not indicated in the treatment of healthy premenopausal women with presumptive cystitis.
  - Cultures can be complicated by the potential for contamination of the voided urine specimen by periurethral organisms (enterococci and group B streptococci), which cannot be distinguished from bladder organisms.

Imaging

- Generally unnecessary; obtain if suspect complicated UTI
  - Indications: persistent fever (72 h after initiation of treatment), suspected urolithiasis (urine pH ≥ 8.0, history of calculi, very severe flank pain), unexplained/persistent hematuria, bacterial persistence, analgesic abuse, urinary retention
  - First line: renal ultrasound
  - CT $\pm$ intravenous contrast: alternative for further evaluation or renal abscess, renal mass, or urolithiasis

Diagnostic Procedures/Surgery

- Cystoscopy not necessary unless hematuria, bacterial persistence, recurrent UTIs
- Urodynamic testing: urinary retention, voiding dysfunction, neurologic disease

Pathologic Findings

Cystoscopy: generalized erythema and edema of urothelium

DIFFERENTIAL DIAGNOSIS

- Urothelial malignancy: Persistent microscopic or gross hematuria, lower urinary tract symptoms recommendation is for cystoscopy and CT urogram
- Urolithiasis
- Vaginitis: Vaginal discharge, odor, pruritus, dyspareunia
- Urethritis: Urethral discharge, dysuria, pruritus, STI history
- Painful bladder syndrome: Characterized by bladder pain with filling that is alleviated with voiding, chronic frequency, and urgency

TREATMENT

GENERAL MEASURES

- Empiric antimicrobials ideally started after urine specimen collected
  - Adjust to urine C + S if necessary
- NSAIDs for discomfort

MEDICATION

First Line

- Acute UTI
  - Algorithm outlines an approach to choosing an optimal empiric antimicrobial for uncomplicated cystitis (3,4)
  - If complicated UTI, urine specimen should be collected prior to treatment and treatment duration should be adjusted to 10–14 days
  - If patient is systemically unwell/urosepsis consider broad spectrum IV antimicrobials such as 2nd- or 3rd-generation cephalosporins ± urinary tract imaging

Second Line

- Prevention:
  - Intravaginal estrogen in post-menopausal women: Creams, suppositories, vaginal ring
  - Methenamine salts: Hydrolyzed to ammonia and formaldehyde in urine (bacteriostatic)
    - Cochrane review: Only short-term efficacy
    - Improved efficacy with vitamin C
  - D-mannose: Fim H inhibitor; no clinical studies
  - Antimicrobials for recurrent UTI
    - Self-start therapy: Start 3-day course after onset of symptoms; contact provider if symptoms persist beyond 48 h
    - Postcoital prophylaxis (See Section II)
    - Continuous prophylaxis

SURGERY/OTHER PROCEDURES

- Rarely indicated unless the following present:
  - Obstruction and urosepsis: Stent or percutaneous nephrostomy tube (PCNT)
  - Renal abscess drainage: Percutaneous drainage
  - Urethral diverticulum
  - Emphysematous pyelonephritis: Drainage or nephrectomy

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

- Cranberry supplements
  - Some data to suggest cranberry supplements are effective at preventing rUTI (relative risk 0.62; 95% CI 0.49–0.8) (4)
  - Twice daily dosing more effective

ONGOING CARE

PROGNOSIS

- Typically will have prompt symptomatic response to antimicrobial therapy
- Recurrence can occur

COMPLICATIONS

Urosepsis, pyonephritis, renal abscess, emphysematous cystitis or pyelonephritis (diabetic or immunocompromised patients)

FOLLOW-UP

Patient Monitoring

- Routine follow-up urine cultures not recommended
- Annual chest x-ray when using nitrofurantoin prophylaxis long-term

Patient Resources

CLINICAL/SURGICAL PEARLS

Always consider urolithiasis with UTI when flank pain is severe.

URINARY TRACT INFECTION (UTI), ADULT MALE

Patricia Lewandoski, MD
Akhil Das, MD, FACS

BASICS

DESCRIPTION

- A urinary tract infection (UTI) is a male is an inflammatory response of urothelium to bacterial invasion with associated bacteriuria and pyuria (1)
- Defined by source of infection:
  - Cystitis: Infection of bladder; dysuria, frequency, urgency, suprapubic pain, hematuria.
  - Isolated cystitis in men rare, usually associated with prostatitis or pyelonephritis
  - Pyelonephritis: Infection of kidney; chills, fever, flank pain ± symptoms of cystitis
  - Prostatitis infection or inflammation of prostate; acute or chronic; either bacterial or nonbacterial based on NIH classification (see Section I: "Prostatitis, General")
  - Urethritis: Infection of urethra
- Defined as uncomplicated or complicated
  - Uncomplicated: Isolated infection or reinfection in a healthy young male with normal urinary tract; urethritis or prostatitis
  - Complicated: Infection associated with:
    - Structurally abnormal urinary tract (eg, bladder outlet obstruction/BPH), or
    - Functionally abnormal urinary tract (eg, neurogenic bladder)
    - Impaired host defense (eg, immunosuppression/diabetes)
    - Increased bacterial virulence
- Most UTIs in men are complicated.
- Defined based on chronicity:
  - Unresolved: UTI that has not responded to antimicrobial treatment
  - Recurrent: UTI that occurs after complete resolution (proven by negative culture after complete antimicrobial course) of previous UTI
- Reinfection: A recurrent UTI from reintroduction of bacteria into previously sterilized urine
- Bacterial persistence: A recurrent UTI due to a source of bacterial colonization (eg, infected stone, prostate, or foreign body)
- Other definitions (and suggested therapies):
  - Emphysematous cystitis/emphysematous pyelonephritis: Complicated UTIs associated with gas in bladder wall or renal parenchyma; typically found in diabetes; gas-forming organisms and obstruction (in pyelonephritis); treated with parenteral antimicrobials; pyelonephritis may require nephrectomy
  - Xanthogranulomatous pyelonephritis:
    - Chronic renal infection associated with obstruction, nephrolithiasis; massively enlarged, nonfunctioning kidney; presenting signs of flank pain, fever, and persistent bacteriuria
- Asymptomatic bacteriuria in men:
  - 10^2 CFU/mL of single organism from cath specimen or 10^5 CFU/mL from single clean catch in men without symptoms of UTI

– Treatment recommended only prior to urologic procedures (2)[C]
- Prophylaxis in those at risk (ie, spinal cord injury or other cause for indwelling catheter) is not recommended; treat only when symptomatic.

EPIDEMIOLOGY

Incidence

12.6/1000 person years (if prostatitis included as UTI) (3)[C]

Prevalence

- Increases with age to >10% in men aged >65 yr
- Asymptomatic bacteriuria in elderly men approaches 60–80%.

RISK FACTORS

- Risk factors for complicated UTI:
  – Male gender
  – Elderly
  – Diseases: Diabetes mellitus; recent UTI, immunosupressive disease or diseases requiring the use of immunospsuppression such as steroids
  – Recent antimicrobial use
  – Indwelling urinary catheter
  – Recent urologic intervention or hospital infection
  – Urinary tract obstruction (eg, BPH, urethral stricture disease); urinary stasis
  – Urinary calculi
  – Uncircumcised
  – Spinal cord injury
  – Unprotected anal intercourse
  – History of childhood UTI

Genetics

Certain individuals (including those with HLA-A3) prone to recurrent UTIs have increased epithelial cell receptivity for uropathogenic *Escherichia coli*.

PATHOPHYSIOLOGY

- UTI occurs via 1 of 3 routes (1):
  – Ascending: Via inoculation of urethra/urethral catheter with bowel flora: Most common
  – Hematogenous seeding of kidney
  – Lymphatic spread
- Males are more resistant to UTI than females due to longer urethra, antibacterial nature of prostatic fluid, drier periurethral environment.
- UTIs occur as a result of interaction between host defense mechanisms and bacterial virulence:
  – Inherent host defense mechanisms:
  – Urinary flow helps decrease retrograde infection; conversely, residual urine/obstruction increases risk of infection
  – Urine: Urea, pH, organic acids help prevent growth; glucose provides environment conducive for bacterial growth and increases risk of infection
  – Bladder: Host recognition of bacteria, with innate immune response against infection;

exfoliation of infected urothelial cells
  – Infection of urinary tract involves attachment of bacterium to the host's epithelium.
  – Adherence of bacteria to urothelial cells necessary for infection; some virulent bacteria have type 1 pili (mediate attachment to cells); pyelonephritis bacteria contain P pili
- Common community-acquired uropathogens: *E. coli* (most common), *Proteus*, *Klebsiella pneumonia*, *Enterococcus faecalis*, *Staphylococcus saprophyticus*
- Common nosocomial uropathogens: *E. coli*, *Klebsiella*, Enterobacter, Citrobacter, *Serratia*, *Pseudomonas*, *Enterococcus faecalis*, *Providencia*, *S. epidermidis*

ASSOCIATED CONDITIONS
See "Risk Factors."

GENERAL PREVENTION
Maintenance of low residual urine clearing any foreign bodies (catheters, stones)

DIAGNOSIS
HISTORY
- Assess for any of risk factors listed above.
- Workup of recurrent UTI, inquire about risk factors and obtain a complete and thorough culture history of involved bacteria, treatment course, and documented evidence of clearance of bacteria.

PHYSICAL EXAM
- Obtain vital signs to assess severity of infection, presence of systemic disease.
- Assess for suprapubic pain, flank pain, and urethral discharge and rectal exam for tenderness and fluctuance.
- Uncircumcised: May increase risk of infection

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urine analysis: Quality of specimen grossly assessed by presence (poor) or absence (good) of squamous cells
- Microscopic analysis for bacteria: False-positive from foreskin contamination if poor-quality specimen; false-negative if 10^2–10^4 bacteria/mL (too few to be seen under slide)
- Dipstick: WBC must be present for infection but WBC without bacteriuria may be present with stones, indwelling stent, tuberculous infection
  – Nitrite: Bacterial reduction of nitrate in urine
  – Leukocyte esterase: Presence of WBC
  – Sensitivity of nitrite and leukocyte esterase positivity varies greatly; does not replace microscopic analysis for bacteria
- Culture: Midstream clean catch: Reduce bacterial contamination of culture in uncircumcised men by retracting foreskin and cleansing
  – 10^2–10^3 CFU/mL in dysuric male with pyuria is indicative of infection (clean catch).
- For lower UTI, consider localization studies (see Section I: "Prostatitis, General").

Imaging
- Recommended in most men to rule out complicated infection, if not responding to therapy,

in patients with rapid recurrent infection and found to have bacteria susceptible to antimicrobial used (i.e., persistence), when obstruction suspected
- CT urogram or MRI: Provide excellent detail, evidence of urinary tract abnormalities, stones, or foreign bodies, among others

Diagnostic Procedures/Surgery
- Cystoscopy: Same indications as listed under "Imaging"; allows direct visualization of bladder to assess for foreign body, ectopic ureters, diverticula, stones, or other abnormalities
- PVR: Should be considered in men with BPH, voiding dysfunction; high residual with stasis increases risk of infection
- Localization studies: Selective cultures from each kidney via ureteral catheterization and prostatic cultures are helpful in identifying source of bacterial persistence.

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Urgency, frequency, dribbling, and dysuria can be symptoms of prostatitis.
- Prostatitis:
  – NIH Class I: Acute bacterial prostatitis, sudden onset
  – NIH Class II: Chronic bacterial prostatitis; Insidious onset, relapsing, recurrent UTI
- For cystitis: Interstitial cystitis vs. urethritis
- For pyelonephritis: Pancreatitis vs. appendicitis vs. diverticulitis vs. acute focal/multifocal nephritis

TREATMENT

GENERAL MEASURES
- Maintain adequate hydration/good hygiene.
- Remove urinary catheters as soon as possible to prevent catheter associated UTI

MEDICATION
First Line
- Antimicrobial therapy for UTI in men is extrapolated from data for treatment of women. (see Section I: "Prostatitis, General")
- If severe infection or toxicity is present, CT should be obtained to rule out obstructive pyelonephritis; if found, decompression is critical.
- Common oral antimicrobials (1):
  – Trimethoprim-sulfamethoxazole: Inexpensive, covers staphylococci, streptococci, and most gram-negatives except *Pseudomonas*
  – Fluoroquinolones: More expensive (levofloxacin > ciprofloxacin), cover staphylococci and most gram-negatives including *Pseudomonas*
- Common parenteral antimicrobials:
  – Ampicillin: Covers streptococci, enterococci, *E. coli, Proteus*; addition of β-lactamase inhibitor covers *Klebsiella and Haemophilus*; no pseudomonal coverage; good 1st-line IV drug

  - Gentamicin: Staphylococci, most gram-negatives including *Pseudomonas*; augments ampicillin for coverage in pyelonephritis
- For cystitis (1)[C]:
  - Take into account local resistance profiles
  - No controlled trials; antimicrobials based on local resistance patterns, previous culture
  - Further tailored to culture sensitivities
  - Duration: For most men with complicated infections, treat for at least 10 days
- In complicated UTI, obtain culture during therapy and 1–2 wk after therapy is complete to document clearance.
  - For uncomplicated UTI, longer-duration treatment (>7 days) has no association with a reduced risk for early or late recurrence compared to shorter treatment (≤7 days)
- For pyelonephritis (1)[C]:
  - For men, pyelonephritis is a complicated UTI and outpatient therapy is initiated only after treatment of complicating factors is initiated.
  - Renal/perirenal abscess: Suspected if indolent/recurrent fever >72 h and/or persistently positive culture despite therapy; CT when suspect; if small abscess antimicrobial treatment; if large (>3 cm) abscess or perinephric abscess: percutaneous drainage
- Outpatient therapy:
  - Fluoroquinolone (7 days) is more effective than trimethoprim-sulfamethoxazole (14 days)
  - Tailor antimicrobial to culture sensitivities.
  - If no improvement, use IV therapy
- Inpatient therapy:
  - IV fluoroquinolone or ampicillin + gentamicin or 3rd-generation cephalosporin
  - Duration without bacteremia: 2–3 days IV then 10–14 days PO antimicrobial
  - Duration with bacteremia: 7 days IV, then 10–14 days appropriate PO antimicrobial
- Repeat cultures on therapy and 10–14 days after completion of course should be negative; if positive, continue a 14-day specific regimen

Second Line

Abscesses in the upper urinary tract or prostate often require percutaneous drainage.

SURGERY/OTHER PROCEDURES

- As needed for cause of recurrent UTI, such as stone, foreign body, or enlarged prostate.
- Transurethral resection (TUR) (unroofing procedure) or percutaneous drain may be required for prostatic abscess.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

Cranberry juice: No male evidence (4)[B]

ONGOING CARE

PROGNOSIS

When appropriate antimicrobial therapy is chosen, complicating factors are identified and treated, and close follow-up is achieved with documentation of clearance of infection, a good prognosis is expected.

COMPLICATIONS

- Sepsis
- Upper urinary tract infections with abscess formation can cause loss of renal function.

FOLLOW-UP

Patient Monitoring

Follow-up culture, post void resideual urine (PVR) and adassessment of lower urinary tract symptoms (LUTS)

Patient Resources

CODES

ICD9
- 590.80 Pyelonephritis, unspecified
- 595.9 Cystitis, unspecified
- 599.0 Urinary tract infection, site not specified

ICD10
- N12 Tubulo-interstitial nephritis, not spcf as acute or chronic
- N30.90 Cystitis, unspecified without hematuria
- N39.0 Urinary tract infection, site not specified

CLINICAL/SURGICAL PEARLS
- Most UTIs in men are considered complicated and require a longer course of antibiotics.
- UTI-related prostatitis requires a minimal of 7 days of treatment.

URINARY TRACT INFECTION (UTI), CATHETER-ASSOCIATED (CAUTI, CA-UTI)

Jeremy N. Reese, MD, MPH
Timothy D. Averch, MD, FACS

BASICS

DESCRIPTION

- Catheter-associated urinary tract infection (CAUTI/CA-UTI) is defined as an infection occurring in a person whose urinary tract is currently catheterized or has been catheterized within the previously 48 h.
- May refer to indwelling urethral or suprapubic catheters as well as routine intermittent catheter use.

- Catheter-associated asymptomatic bacteriuria (CA-ASB) is the presence of bacteria in the urinary tract without signs or symptoms of infection.
- CA-UTI and CA-ASB are often not distinguished from each other in reported cases of catheter associated bacteriuria and may result in inappropriate antibiotic use contributing to antimicrobial resistance and adverse event reporting to governmental agencies.
  - UTIs are the most common type of healthcare-associated infection reported to the National Healthcare Safety Network (NHSN).

EPIDEMIOLOGY

Incidence

- CA-UTI is the most common nosocomial infection in the United States, accounting for 40% of hospital-acquired infections and over 80% of the 900,000 cases of bacteriuria annually.
- 15–25% of hospitalized patients have a urethral catheter inserted during their stay
- Incidence of CA-bacteriuria is thought to be 3–8% per catheter-day, with 3.1–7.4 CA-UTIs per 1000 urinary catheter days reported in US intensive care units
- Cost: $1006 per episode of CA-UTI

Prevalence

5–10% of long-term care facility patients are managed with indwelling or intermittent catheterization, accounting for >100,00 patients in the United States at any given time

RISK FACTORS

Duration of catheter use, placement outside operating room, open drainage system, female sex, diabetes mellitus, renal insufficiency, and inappropriate use (discussed below)

Genetics

N/A

PATHOPHYSIOLOGY

- Urethral catheterization is most important predisposing factor for nosocomial UTI
  - Disrupted mucosa exposes new binding sites for bacteria allowing for growth of less virulent organisms

- Indwelling catheter may introduce bacteria at time of insertion, allowing ascension of uropathogens into bladder at time of insertion and then later via intra- and extra-luminal spread
  - 2/3rd of identified pathogens are extraluminally acquired vs. 1/3rd intraluminally acquired
- Bacterial adhesions and production of exopolysaccharides allow for replication on the catheter surface and formation of biofilms
  - Short-term catheter use tends to be associated with a single organism, whereas longer catheter use is associated with polymicrobial growth
  - Biofilms protect bacteria from antimicrobials and host immune response, facilitating spread of antimicrobial resistance genes
- *Escherichia coli* is most common isolate, as well as *Klebsiella*, *Serratia*, Citrobacter, Enterobacter, *Pseudomonas*, *Staphylococcus*, and *Enterococcus*.
  - *Providencia*, *Morganella*, and *Proteus* species more commonly isolated from long-term catheters

ASSOCIATED CONDITIONS

Spinal cord injury, neurogenic bladder, urinary incontinence, sacral or perineal wounds, prolonged immobilization

GENERAL PREVENTION

- Limiting use of urinary catheters, aseptic insertion, early discontinuation of catheter use, use of pre-sealed closed drainage systems, maintaining drainage bag below level of bladder (1) [A]
  - Absolute indications include: urinary retention, accurate measurement of urine output in critically ill patients, prolonged general or spinal anesthetic, following selected urologic or gynecologic procedures, comfort care
- Application of institutional reminders such as nurse or electronic-based reminders, automatic stop-orders, use of reminder stickers or dated collection bags, requirement of physician order to place and maintain catheters
- No trials support use of: antimicrobial or chemical prophylaxis, routine catheter irrigation, antimicrobial use in drainage bag, antibiotic use at time of routine catheter exchange or removal
  - Routine screening for CA-ASB should be avoided (1)[A]
- Alternatives to indwelling urethral catheters
  - Condom catheters provide alternative to short-term catheter use in men with low-post void residuals
  - Urethral and suprapubic catheters have similar rates of CA-UTI, although suprapubic catheters are often more comfortable, spare urethral catheterization, and are easier to exchange
  - Intermittent catheterization significantly reduces rates of CA-ASB and is associated with higher patient satisfaction
- Healthcare providers should clean their hands with soap and water or use an alcohol-based hand rub before and after touching catheters.
- Avoid disconnecting the catheter and drain tube.

- The catheter is secured to the leg to prevent pulling on the catheter.
- Avoid twisting or kinking the catheter.
- Keep the bag lower than the bladder to prevent urine from backflowing to the bladder.
- Empty the bag regularly. The drainage spout should not touch anything while emptying the bag.

DIAGNOSIS

HISTORY

- CA-UTI: Patients with signs and symptoms of UTI with current or recent (<48 h) indwelling urinary catheter or routine intermittent catheter use
  - Symptoms may include chills, rigors, altered mental status, malaise, flank pain, and pelvic discomfort
  - Patients with a recently removed catheter may report dysuria, urinary urgency and/or frequency
  - Spinal cord injury patients may report increased spasticity, autonomic dysreflexia and/or sense of uneasiness

PHYSICAL EXAM

- A few physical exam findings are reliable to diagnose CA-UTI but may include suprapubic and/or costovertebral angle tenderness, hematuria, or fever
- Foul-smelling and/or cloudy urine have not been shown to be significant clinical predictors of CA-UTI
  - Encourage hydration if no other clinical indicators of infection and reassess thereafter

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CA-UTI: Patients with signs and symptoms of UTI with current or recent (<48 h) indwelling urinary catheter or routine intermittent catheter use with cultures growing >103 cfu/mL (1)[A]
- CA-ASB is defined as cultures growing >105 cfu/mL WITHOUT signs or symptoms or UTI (1)[A]
- Urine specimen should be sent for culture prior to initiation of antimicrobials (1)[A]
- Catheters should be replaced, if still indicated, and a culture should obtained from newly placed catheter (1)[A]
- If catheter can be discontinued, a midstream voided specimen should be used for culture (1)[A]
- Pyuria on urinalysis is not sufficient to diagnose CA-UTI or CA-ASB, but its absence can exclude infection (1)[A]

Imaging

- Not routinely indicated
- May be necessary in cases of suspected complicated UTI such as concern for urolithiasis, foreign body, abscess, emphysematous infection, or vesicoureteral reflux

Diagnostic Procedures/Surgery

- Not routinely indicated

- Urodynamic studies may be useful to determine necessity of routine catheterization, particularly in spinal cord injury (SCI) population
- For patients with long-term catheter use (eg, SCI, neurogenic bladder population), routine cystoscopy has been suggested for cancer detection due to increased risk of both transitional cell and squamous-cell carcinomas
  - Lifetime bladder malignancy incidence ranges from 0.39% to 2.4% in published retrospective reviews of SCI patients

Pathologic Findings

Pathology is not routinely performed

DIFFERENTIAL DIAGNOSIS

- In patients presenting with fever, rigors, altered mental status, and other non-specific symptoms, all other sources of infection must be ruled out as CA-ASB is diagnosed in >85% of patients with long-term catheter use
- Bladder tumor: Hematuria must be worked up, given increased risk of malignancy from long-term catheter use
- Bladder calculus: Associated with chronic urinary stasis
- Local inflammation: Vaginitis, urethritis, interstitial cystitis

TREATMENT

GENERAL MEASURES

- Prevention through early removal of urinary catheters is best preventative treatment
- Routine screening for and treatment of CA-ASB should be avoided (1)[A]
- Optimal duration of therapy is unknown, but typically ranges from 3 to 21 days depending on severity of symptoms (eg, cystitis, pyelonephritis, associated abscess, or bacteremia)
  - Most literature suggests 7–14 days of therapy for CA-UTI (1)[A]
  - 3-day regimen suggested in younger woman (<65 yr) in whom a catheter was recently removed (1)[B]
- Catheters placed >2 wk prior should be exchanged at time of diagnosis (prior to cultures being sent) to improve antimicrobial penetration and reduce bacterial concentrations (1)[A]
- When possible, antibiotic therapy should be culture driven to avoid exposure to additional antimicrobial agents

MEDICATION

First Line (2,3)

- Given incidence of polymicrobial colonization as well as involvement of both gram-positive and -negative organisms, no 1st-line agent can be recommended.
- Serious infections must be covered with broad-spectrum antibiotics and narrowed based on culture sensitivity patterns.
- Treatment of minor infections should be delayed until culture sensitivities are available to guide antimicrobial selection

Second Line

N/A

SURGERY/OTHER PROCEDURES

Rarely indicated, but may be necessary in cases of encrusted catheters, emphysematous, or abscess forming infections (see Section I: UTI, complex, adult)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

- Antimicrobial coated catheters may delay detection of CA-ASB in short-term catheter use (<1 wk) (1)[B].
- Methenamine salts may reduce CA-ASB and CA-UTI in short-term catheter use (<1 wk) (1) [C].
- Cranberry products have not been shown to be effective in the prevention or treatment of infection in CA-UTI population (1)[A].
- Catheter irrigation has not been shown to prevent or treat CA-ASB or CA-UTI (1)[A].

ONGOING CARE

PROGNOSIS

- Generally good (4)
- Patient hospitalization lengths and costs are elevated when diagnosed with CA-ASB or CA-UTI
- Mortality rate among hospitalized patients with bacteremic UTI is ~13%; however, <1% of CA-ASB results in bacteremia.

COMPLICATIONS

Patients with indwelling catheter experience increased rates of bacteremia, upper tract inflammation and infection, catheter obstruction, urinary stone formation, fistula formation, urethral erosion, incontinence, and bladder cancer

FOLLOW-UP

Patient Monitoring

- Institutional education on indications for catheter use and reminder systems for early catheter removal such as nursing protocols, electronic reminders, chart and collection bag stickers
- Attention to and staff education to urologically essential catheters (eg, radical prostatectomy, etc)

Patient Resources

CODES

ICD9

- 041.49 Other and unspecified Escherichia coli [E. coli]
- 599.0 Urinary tract infection, site not specified
- 996.64 Infection and inflammatory reaction due to indwelling urinary catheter

ICD10

- B96.20 Unsp Escherichia coli as the cause of diseases classd elswhr
- N39.0 Urinary tract infection, site not specified
- T83.51XA Infect/inflm reaction due to indwell urinary catheter, init

CLINICAL/SURGICAL PEARLS

- Advise against routine screening for CA-ASB due to increasing antimicrobial resistance and inappropriate use.
- Most important prevention is adherence to indications for catheter use and prompt removal when no longer indicated.
- When catheter use is unavoidable, it should be aseptically inserted, maintained with closed drainage system and removed as early as possible.

- When infection is suspected, culture specimen should be sent from a newly placed catheter or midstream voided specimen.
- Treatment should be driven by culture sensitivities and typically last 7–14 days.

URINARY TRACT INFECTION (UTI), COMPLICATED, ADULT

Steve Dong, MD
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION

- Complicated urinary tract infection (UTI) occurs in adults with functional or structural abnormalities of the genitourinary system who develop an infection. Associated abnormalities can include:
  - Structurally abnormal urinary tract (eg, BPH, kidney stones)
  - Functionally abnormal urinary tract (eg, neurogenic bladder, vesicoureteric reflux)
  - Impaired host defense (eg, immunosuppression/diabetes)
  - Increased bacterial virulence, multidrug-resistant organism
  - Children and pregnant women
  - Hospital-acquired infection (1)
- Patients with complicated UTI are more likely to harbor multiresistant pathogens, and whose infections are more difficult to eradicate (2).

EPIDEMIOLOGY

Incidence

- UTI accounts for 7 million physician visits annually and 100,000 hospital admissions.
- Complicated UTI is a wide spectrum; its incidence depends on age, sex, host, and environmental factors.

Prevalence

- For men, the lifetime prevalence of UTI is 14 per 100. Compared to women which is 53 per 100.
- The prevalence of asymptomatic bacteriuria, which makes host at risk for symptomatic episodes of complicated UTI
  - Patients with indwelling catheter: Approaches 100% based on timing.
  - Elderly nursing home residents: 50%
  - Patients with neurogenic bladder managed by clean intermittent catheterization: 30–40% (Table 1).

RISK FACTORS

- Male gender
- Elderly
- Hospital associated infection
- Pregnancy
- Diseases: Diabetes mellitus; history of recent UTI; diseases that cause immunosuppression or require treatment with immunosuppressive agents such as steroids
- Recent antimicrobial use
- Indwelling urinary catheter
- Recent urologic intervention

- Urinary tract obstruction (eg, kidney stones, benign prostatic hypertrophy [BPH], urethral stricture disease)
- Spinal cord injury with neurogenic bladder
- Azotemia caused by intrinsic renal disease

Genetics

- Six genes in humans have found to be associated with host response to infection predispose them to UTI
  – HSPA1B, CXCR1 & 2, TLR2, TLR4, TGF-β1

PATHOPHYSIOLOGY

- Primary UTI occurs via 1 of 3 routes (1):
  – Ascending by inoculation of urethra/urethral catheter with bowel flora: Most common
  – Hematogenous seeding of kidney
  – Lymphatic spread
- Structural, functional, or metabolic abnormalities allow infection of more uncommon pathogens, and increase the rate of therapy failure
- *Escherichia coli*, accounts for only approximately half of infections with complicated UTI, compared to uncomplicated (75–95%)
- A broader range of organisms can seen in complicated UTI, include *Proteus mirabilis* and *Klebsiella pneumoniae* as well as *Pseudomonas*, *Serratia*, *Providencia,* enterococci, staphylococci, and fungi (3)

ASSOCIATED CONDITIONS

- Diabetes mellitus (10%)
- Renal failure
- Multiple sclerosis
- Spinal cord injury

GENERAL PREVENTION

- Proper infection control practice in health care facilities to avoid contact transfer of resistant organisms between patients.
- Avoid over-treatment of asymptomatic bacteruria
- For patients with spinal cord injury, maintain a low bladder pressure to prevent reflux, ascending infections, and progression to renal failure. Monitoring of bladder pressure and function can be done with urodynamics testing
- Prevention of complicated UTI with long-term prophylaxis in at risk adult population is not recommended due to the emergence of resistant organisms (4)

DIAGNOSIS

HISTORY

- Assess for any of risk factors listed above.
  Clinical presentation may or may not be associated with clinical symptoms (eg, dysuria, urgency, flank pain, fever)
- Clinical presentation may vary from severe obstructive pyelonephritis with imminent urosepsis to catheter associated UTI, which disappears once the catheter is removed.

- Patients with spinal cord injuries can present with bladder, leg spasms, or autonomic dysreflexia.
- Patients with multiple sclerosis may present with fatigue or worsening neurologic function.
- Fever without localizing findings is a common presentation of UTI in patients with chronic indwelling catheters.

PHYSICAL EXAM

- Check vital signs to assess severity of infection, presence of systemic disease.
- Assess for suprapubic pain, flank pain, urethral discharge rectal exam for tenderness
- Evaluate for anatomical abnormalities, such as the presence of a nephrostomy tube, or an ileal conduit

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis
  - Pyuria is almost always present
  - Unless the collecting system is obstructed
  - White cell casts suggest a renal origin
- Urine culture is positive for a UTI with the following:
  - $\geq 10^5$ cfu/mL in mid-stream sample
  - $\geq 10^4$ cfu/mL in a straight catheter urine sample

Imaging

- Is recommended in patients suspected of complicated infection, especially in those not responding to therapy for 48–72 h, in patients with rapid recurrent infection and found to have bacteria susceptible to antimicrobial used (ie, persistence), when obstruction suspected, as well as history of kidney stones or has symptoms of renal colic
- Renal Ultrasound
  - For patients who could not be exposed to radiation
  - Cheap and readily available
  - Best to evaluate for hydronephrosis
  - Lack details and sensitivities of other imaging modalities
- Computed tomography (CT) urogram
  - The study of choice
  - Most sensitive in detecting abnormalities and able to delineate the extent of disease. Has 3 phases
    - No contrast—evaluate for renal or ureteral calculi, gas-forming infections, hemorrhage
    - Contrast—detect areas lacking perfusion due to infection induced ischemia
    - Delayed phase—detect for any filling defects such as fungus ball
- Magnetic resonance imaging (MRI)
  - Has no advantage over CT except in patients who wants to avoid contrast and radiation (3)

Diagnostic Procedures/Surgery

- Urologic evaluation is often necessary in the setting of a complex UTI
- Urinary obstruction associated with UTI must be relived emergently. e.g. placing a ureteral stent or nephrostomy tube for a obstructing ureteral calculus, or placing a Foley catheter for

urethral stricture.
- Cystoscopy allows direct visualization of bladder to assess for foreign body, ectopic ureters, diverticula, stones, or other abnormalities that could be a nidus for infection
- Post-void residual (PVR): Should be considered in men with baseline voiding symptoms; high residual with stasis increases risk of infection
- Localization studies: Selective cultures from each kidney via ureteral catheterization and prostatic cultures are helpful in identifying source of bacterial persistence.

Pathologic Findings
- In acute pyelonephritis—polynuclear leukocytes are seen throughout renal tubules, may form casts that can be seen in an urinalysis
- In chronic pyelonephritis, both lymphocytes and plasma cells are the predominant cells.

DIFFERENTIAL DIAGNOSIS
- For cystitis: Interstitial cystitis vs. urethritis
- For pyelonephritis:
  - Pancreatitis vs. appendicitis vs. diverticulitis vs. acute focal/multifocal nephritis
  - Urolithiasis

TREATMENT

GENERAL MEASURES

If severe infection or toxicity is present, CT should be obtained to rule out obstructive pyelonephritis; if found, decompression is critical.

MEDICATION

First Line
- Common oral antimicrobials:
  - Fluoroquinolones: More expensive (levofloxacin > ciprofloxacin), cover staphylococci and most gram-negatives including *Pseudomonas*
  - Trimethoprim-sulfamethoxazole: Resistance is often seen, therefore not recommended for empiric therapy (3)
- Commonly parenteral antimicrobials:
  - For those who have hemodynamic instability, or cannot tolerate oral therapy, or for patients with suspected resistant organisms
  - Gentamicin: Can cover Staphylococci, most gram-negatives including *Pseudomonas*; augments ampicillin for coverage in pyelonephritis
  - Cephalosporin
  - Carbapenem
  - Aminopenicillin PLUS a β-lactam inhibitor. Aminopenicillin by itself (eg, ampicillin) is not recommended for empiric therapy (3)
- For complicated pyelonephritis (1,5)
  - Renal/perirenal abscess is suspected if indolent/recurrent fever >72 h and/or persistently positive culture despite antimicrobial treatment; CT when suspect; if small renal abscess, then antimicrobial treatment; if large (>3 cm) renal abscess or perinephric abscess, then percutaneous drainage

– Inpatient therapy is recommended:
  - IV fluoroquinolone or ampicillin + gentamicin or 3rd-generation cephalosporin (3)
  - Duration without bacteremia: 2–3 days IV then 10–14 days PO antimicrobial
  - Duration with bacteremia: 7 days IV, then 10–14 days appropriate PO antimicrobial

Second Line

- Colistin: Reserved for extended-spectrum β-lactamase (ESBL)-producing bacteria that are resistant to gentamycin and carbapenems.
- Tigecycline: Has activity against ESBL-bacteria, but is unstable in urinary tract.

SURGERY/OTHER PROCEDURES

As needed for cause of complicated UTI, such as stone, foreign body, or enlarged prostate

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

Cranberry juice and products have not been shown to reduce the risk of complicated UTI.

ONGOING CARE

PROGNOSIS

When appropriate antimicrobial therapy is chosen, complicating factors are identified and treated, and close follow-up is achieved with documentation of clearance of infection, a good prognosis is expected.

COMPLICATIONS

- More likely to occur in patients with comorbidities
- Acute complicated pyelonephritis can progress to emphysematous pyelonephritis, renal abscess, perinephric abscess, or papillary necrosis.
- Infections can spread to cause bone and joint infection, or endocarditis
- Renal failure in patients with spinal cord injury with recurrent sepsis

FOLLOW-UP

Patient Monitoring

Repeat urine cultures must be obtained because patients with complicated UTI are more at risk for recurrent infection

CODES

ICD9
- 592.0 Calculus of kidney
- 599.0 Urinary tract infection, site not specified
- 600.01 Hypertrophy (benign) of prostate with urinary obstruction and other lower urinary tract symptoms (LUTS)

ICD10
- N20.0 Calculus of kidney
- N39.0 Urinary tract infection, site not specified
- N40.1 Enlarged prostate with lower urinary tract symptoms

CLINICAL/SURGICAL PEARLS

- Complicated UTI can have a wide range of atypical presentations, eg, MS patients with neurologic decompensation, spinal cord injury patients with spams or autonomic dysreflexia, or nursing home patient who has indwelling Foley with fever should be suspected of UTI.
- CT should be considered the imaging of choice, and with a low threshold with any history of stone, flank pain, or pyelonephritis not improving or persistent positive culture.
- Presence of obstruction on imaging requires urgent decompression.

URINARY TRACT INFECTION (UTI) COMPLICATED, PEDIATRIC

Christopher J. Long, MD
Douglas A. Canning, MD, FACS

BASICS

DESCRIPTION

- A complicated urinary tract infection (UTI) is an infection in the presence of abnormalities of metabolism, GU structure, or function
- There is an increased risk of therapy failure and patient morbidity and mortality.
- For recurrent UTI:
  - Unresolved: Incompletely treated infection
  - Reinfection: Infection by another organism
  - Persistent infection: Seeding from another site (ie, abscess)

EPIDEMIOLOGY

Incidence

- Highest incidence < 2-yr-olds
- Males/females < 1-yr-olds: 3–4%/2% develop UTI
- Males more likely to develop UTI in the first year of life then shifts to female predominance

Prevalence

Has not been delineated for each particular subpopulation/risk factor in the pediatric population

RISK FACTORS

- Previous UTI: 26% recur within 3 mo
- Metabolic abnormalities: Diabetes, pregnancy
- Impaired host response: Transplant, chemotherapy, HIV
  - Neonates < 90 days: Impaired immunity
- Structural anomalies
  - Calculi, renal cysts, abscess, pyelonephritis, bladder diverticulum
  - Urinary diversion, bladder augmentation
  - Posterior urethral valves, reflux, prune belly, bladder exstrophy, urogenital sinus
- Uncircumcised males 10× risk of UTI
- Neurogenic bladder
- Intermittent catheterization: Increases rate of bacteriuria
  - Single use, sterile catheters show no benefit

Genetics

- Polymorphisms of the interleukin-8 (IL-8) cytokine and decreased receptor expression increase risk for developing pyelonephritis
- Blood group antigen phenotype has been shown to play a role in UTI resistance
- Familial susceptibility to UTI
- Autosomal dominant inheritance of vesicoureteral reflux

- African Americans less likely to develop UTI when compared to whites, Hispanics

PATHOPHYSIOLOGY
- Fecal seeding of the perineum allows ascending infection of the GU tract
- Biofilm formation on stents or catheters
- Increased bladder pressure
  - Decreased bladder capacity
  - Compromised Foley catheter drainage
  - Dysfunctional voiding
- Bacteriology of *E. coli* increase affinity for GU tract: P fimbriae and MRHA (mannose-resistant hemagglutination)

ASSOCIATED CONDITIONS
- Urinary stasis increases risk of UTI
- Stents or catheters located within the GU tract act as a nidus for bacterial colonization
- Surgically correctable conditions of the GU tract
- Spina bifida (1)

GENERAL PREVENTION
- Antibiotic prophylaxis
  - Low-dose daily antibiotic
  - Healthy children have no proven benefit
  - Benefit for anatomic abnormality such as severe VUR
- Consider circumcision in boys <12 mo of age with GU tract anomalies
- Consider correction of vesicoureteral reflux (VUR) in females approaching puberty for increased risk of pyelonephritis during pregnancy
- Treatment of constipation and dysfunctional voiding

DIAGNOSIS

HISTORY
- Vague in infants and nonverbal children: Fever, irritability, poor feeding, vomiting, diarrhea, abdominal distention, new onset incontinence, jaundice.
- Older children: Dysuria, incontinence, voiding dysfunction, lower abdominal pain, enuresis
- Neurogenic bladder: Adominal pain, new onset back pain, new or worsening incontinence, pain with catheterization or urination, malodorous or cloudy urine
- Presence and severity of fever
- Previous UTIs and how documented (urine analysis, culture, how culture was obtained).
- Urinary stream, voiding history
- Previous GU/GI surgery
- Family history of infections and/or GU anomalies
- Prenatal history including ultrasounds

PHYSICAL EXAM
- Clinical signs of urosepsis
- Palpable bladder or kidneys, bladder or flank tenderness
- Foul smelling urine

- External genital anomalies: Labial adhesions, evidence of previous genital surgery
- Circumcision status

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Blood work: CBC, BMP, c-reactive protein (CRP), erythrocyte sedimentation rate (ESR), procalcitonin
  - Procalcitonin, CRP, ESR correlate with systemic illness and suggest pyelonephritis/sepsis
- Diagnosis: 2 or more symptoms, >100,000 CFU/mL of a single organism, and >10 WBC/HPF on urine microscopy
- Urinalysis (UA)
  - Leukocyte esterase, nitrite
  - Microscopy: WBC, bacteria
- Urine culture: obtained with UA
  - Consider lower threshold (>50,000 CFUs per mL) PLUS pyuria ± bacteriuria in some cases

Imaging

- Renal and bladder ultrasound: Assess hydronephrosis or incomplete bladder emptying
- Voiding cystourethrogram if not already performed
  - Document test of cure prior to study
- Renal cortical scan: Rule out scarring or pyelonephritis
  - Consider Gallium scan for complicated cases

Diagnostic Procedures/Surgery

- Catheterized or midstream specimen is preferred depending upon patient age
  - Suprapubic aspiration has highest accuracy but increases morbidity for patients
  - Bagged specimen not recommended
- Cystoscopy is rarely indicated
  - Can document bladder diverticulum, stones, etc., as source of UTI
- Specific intervention for GU anomalies (ie, treatment of reflux) once therapy is completed

Pathologic Findings

- *Escherichia coli* is the most common isolated organism although less so compared to uncomplicated UTI (45–51%)
- *Proteus, Pseudomonas,* and *Candida* are more commonly identified in complicated UTI
- Infants <90 days; *Enterococcus* and *Listeria* are most common organisms

DIFFERENTIAL DIAGNOSIS

- Younger children (<24 mo) presenting with fever: otitis media, gastroenteritis, upper respiratory tract infection
- Stone disease
- Urethritis
- Dysfunction voiding/elimination syndrome
- Pregnancy
- Appendicitis
- Bladder outlet obstruction

- Epididymitis
- Abuse

TREATMENT

GENERAL MEASURES (2,3)

- Antibiotic therapy after urine culture obtained
- Oral antibiotic therapy vs. IV antibiotics dependent upon severity of infection
  - Stratify by presence or absence of fever, concern for urosepsis, elevated WBC, etc.
- Duration of therapy 7–14 days
- Increased rate of resistant organisms

MEDICATION

First Line

- 3rd-generation cephalosporin ± aminoglycoside
  - Cefotaxime: 50–180 mg/kg/d (q4–6h)
  - Ceftriaxone: 50–75 mg/kg/d (q12–24h)
  - Ceftazidime: 90–150 mg/kg/d (q8–12h)
  - Aminoglycoside (gentamicin, tobramycin): 7.5 mg/kd/d (q8h)
    - *Enterococcus* resistance to 3rd-generation cephalosporins

Second Line

- Fluoroquinolones
  - Ciprofloxacin: 20–40 mg/kg/d (q8h)
    - Concern for cartilage damage limits its use in pediatric populations
- Carbapenem
- Combination therapy:
  - Aminoglycoside plus β-lactam inhibitor
  - Aminoglycoside plus fluoroquinolone

SURGERY/OTHER PROCEDURES

- Circumcision in boys with GU anomaly
- Correction of urologic anomaly if possible
- Removal of urinary stents or catheters if possible
- Video urodynamics to assess bladder emptying in particular if history of neurogenic bladder

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies (5)

- Targeted therapy for voiding dysfunction
  - Timed voiding, biofeedback
  - Anticholinergic medications for small, overactive bladder
- Pelvic floor therapy for detrusor sphincter dyssynergia
- Consider supressive antibiotics in selected cases: Nitrofurantoin 1–2 mg/kg PO daily, Sulfamethoxazole/trimethoprim (SMZ-TMP) 5–10 mg/kg SMZ,1–2 mg/kg TMP PO daily (Do not use nitrofurantoin or sulfa in children <6 weeks); Trimethoprim 1–2 mg/kg PO daily.

Ampicillin or amoxicillin not recommended due to resistance

Complementary & Alternative Therapies (4)

- Ensure adequate hydration
- At home urine tests for families for early detection of UTI
- Breast feeding has been shown to confer protection during immune compromised neonatal period
- Cranberry juice/supplements show little, if any, benefit in the adult population; no data in children
- Probiotics have not been shown to prevent UTI

ONGOING CARE

PROGNOSIS

- Dependent upon severity of infection (febrile vs. afebrile, pyelonephritis, degree of subsequent renal scarring)
- While a single UTI rarely has long term sequelae, recurrent infections place the kidney at increased risk for damage

COMPLICATIONS

- Urosepsis
- Pyelonephritis
- Hypertension (HTN)
- Loss of renal function, progression of renal scarring
- Compromise of renal transplant

FOLLOW-UP

Patient Monitoring

- Document test of cure with repeat urine culture
- Yearly blood pressure assessment
- Consider nephrology referral

Patient Resources

- Urinary Tract Infection, Pediatric
- Urinary Tract Infection (UTI), Complicated, Pediatric Image
- Vesicoureteral Reflux, Pediatric

CODES

ICD9

- 590.80 Pyelonephritis, unspecified
- 599.0 Urinary tract infection, site not specified
- 771.82 Urinary tract infection of newborn

ICD10

- N12 Tubulo-interstitial nephritis, not spcf as acute or chronic
- N39.0 Urinary tract infection, site not specified
- P39.3 Neonatal urinary tract infection

CLINICAL/SURGICAL PEARLS

- Complicated UTIs can lead to increased patient morbidity and mortality.
- Treatment plan should be tailored to the specific underlying contributing factors leading to UTI development.
- Prompt initiation of broad spectrum antibiotics after urine culture is obtained with subsequent tailoring of antibiotic therapy based on bacteria sensitivities is recommended in cases suspicious for urosepsis.
- Maintain a high degree of suspicion for potentially surgically correctable causes. Corrrection will likely decrease UTI risk.

URINARY TRACT INFECTION (UTI), PEDIATRIC

Kathleen Kieran, MD, FAAP, FACS
Christopher S. Cooper, MD, FAAP, FACS

BASICS

DESCRIPTION

- A urinary tract infection (UTI) represents inflammatory changes in the urinary tract caused by the presence of an infectious agent
- Spectrum of severity, from local infection to systemic changes/urosepsis

EPIDEMIOLOGY

Incidence

- 180,000 children annually will develop UTI in the United States
- 0.7% of all pediatric office visits each year (3.5–5% of emergency department visits)
- Overall 2% of febrile infants, 5% of all infants:
  - 21% of uncircumcised male infants
  - 5% of female infants
  - 2.3% of circumcised male infants

Prevalence

Prevalence is variable and closer to an adult level as age groups increase

RISK FACTORS

- Previous UTI:
  - ~25% of infants with a symptomatic UTI will have a recurrence
  - Older females may have a 40–60% risk of recurrent infection
- Immunosuppressive states, including diabetes, chemotherapy, and steroid use
- Anatomic and functional abnormalities of the urinary tract which predispose to urinary stasis:
  - Vesicoureteral reflux, ureterocele, ureteropelvic junction obstruction, bladder diverticula, posterior urethral valves
  - Neurogenic bladder, dysfunctional voiding/elimination behaviors (eg, constipation)
- Urologic instrumentation (catheters)
- Older children: Sexual activity
- Circumcision (1):
  - Uncircumcised males <1 yr of age have the highest rate of UTI of all gender and age groups (10 times higher than circumcised males)
  - AAP has stopped short of endorsing routine circumcision, but acknowledges apparent protective effect against UTIs and penile cancer
  - Consider circumcision in infant males with UTI

Genetics

- Incompletely understood
- Multifactorial, including altered carbohydrate secretion antigens on cell surface molecules

which may increase bacterial adherence

PATHOPHYSIOLOGY

- Usually ascending infections, although hematogenous spread can be seen in infants or immunocompromised populations
- Colonization of female introitus or male preputial epithelium with intestinal flora
- The most common pathogen *is Escherichia coli* (~85%)
- Other uropathogens include *Klebsiella, Proteus, Enterobacter, Citrobacter*, *Staphylococcus saprophyticus*, and *Enterococcus*
- Viral (eg, adenovirus, BK virus) and fungal *(Candida*) infections may be seen in immunocompromised patients
- Both humoral and cellular responses result in inflammation of the urinary tract
- Bacterial virulence factors include O antigen (part of lipopolysaccharide), K antigen (part of capsule), and P fimbriae contributes to bacterial ascent to the upper tracts, even in the absence of reflux

ASSOCIATED CONDITIONS

- Dysfunctional elimination including incontinence, holding or retention of urine, and constipation increase risk of UTI
- Immunocompromise
- Structural abnormalities of the GU tract

GENERAL PREVENTION

- Good voiding/elimination habits
- Treatment of constipation
- Identification and treatment of underlying urologic conditions which may predispose to urinary stasis

DIAGNOSIS

HISTORY

- Vague in infants:
  - Symptoms: Fever, irritability, poor feeding, vomiting, diarrhea, abdominal distention, foul-smelling urine
  - Older children may complain of dysuria, incontinence, changes in voiding habits, flank or abdominal pain, enuresis
- Presence, severity, and duration of fever
- Previous UTIs and how documented (eg, culture, urinalysis, symptoms)
- Prenatal history including prenatal ultrasounds
- Previous GU/GI surgery
- Family history of infections and/or GU anomalies

PHYSICAL EXAM

- Specific findings in infants are rare; may see fever, failure to thrive, jaundice, or lethargy
- Older children may have suprapubic, flank, abdominal and/or upper quadrant tenderness
- CVA tenderness suggests pyelonephritis
- A scrotal exam will help rule out epididymitis

- Careful external genital exam to rule out trauma, local irritation, urethral discharge, phimosis, and anatomic abnormalities
- Circumcision status
- Palpable abdominal or flank mass (eg, severe hydronephrosis or distended bladder)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine analysis (2):
  - Microscopic exam after dipstick urine analysis increases the test's sensitivity and specificity. It can also yield clues to contamination (epithelial cells)
  - Positive leukocyte esterase (indicates WBCs in the urine) is up to 95% sensitive in children with symptoms
  - Positive nitrite (many gram-negative bacteria produce this substance) has a sensitivity of 30–45%, but a specificity that nears 100%
  - Combined positive nitrite-leukocyte esterase 80–90% sensitive and 60–98% specific
  - >10 WBCs per HPF on an unspun specimen or >5 WBCs on a spun sediment is usually indicative of infection
  - Identification of bacteria on Gram stain has a sensitivity and specificity better than that of a dipstick evaluation for nitrite and leukocyte esterase
- Urine culture is the gold standard to diagnose UTI (2):
  - >100,000 CFU/mL on a voided or catheterized specimen, and any bacteria on a suprapubic aspirate is generally considered a positive culture
  - Lower colony counts in symptomatic children, or growth of pathogenic bacteria (eg, *Klebsiella, Pseudomonas*) should also be treated
  - In non-toilet trained children, >50,000 CFU/mL of a single pathogen is also consistent with UTI
- Blood tests are unreliable in diagnosing UTI
- Asymptomatic bacteriuria (no symptoms, <5 WBC/hpf, but positive culture) should prompt treatment if a pathogenic organism is present

Imaging

- The need for and timing of imaging following UTI remains controversial; it is not required in the acute setting, but may be indicated at follow-up
  - Consider evaluating all children <5 yr after their 1st documented UTI; and all girls, regardless of age, with febrile or recurrent infections, particularly with voiding dysfunction
  - Renal/bladder US should be considered following a febrile UTI
  - Need for and timing of VCUG is controversial: The American Academy of Pediatrics (AAP) recommends VCUG after second febrile UTI unless there is a suspicion of underlying anatomic abnormality (3), while most pediatric urologists recommend VCUG following first febrile UTI
- 40% of children with a single febrile UTI have VUR
- Absence of clinical improvement after 48 h of appropriate treatment should raise concern for structural or functional abnormalities
- DMSA scan may reveal renal inflammation in acute pyelonephritis and/or scarring from previous infections

- Older girls with recurrent cystitis in the absence of voiding dysfunction should be evaluated with pre- and post-void renal and bladder sonography (4)
- In toilet-trained children in whom voiding dysfunction may be a factor, assessment of voiding patterns (eg, uroflow) may be helpful

Diagnostic Procedures/Surgery

None specific, though cystoscopy may be performed for associated conditions or chronic infections as indicated

Pathologic Findings

- Cystitis and pyelonephritis are generally associated with inflammatory response
- Renal scarring may be manifested by architectural changes including collagen deposition and glomerular loss

DIFFERENTIAL DIAGNOSIS

- UTIs present similarly to other infections:
  - Bacteremia and sepsis
  - Epididymitis
  - Gastroenteritis
  - Sexual abuse
  - STD/STI in a sexually active child
  - Vaginitis
- Also consider: Appendicitis, diabetes, dysfunctional voiding/elimination, pregnancy in postpubertal females, urolithiasis, urinary obstruction

ALERT

Findings suggestive of an STI/STD infection should raise concern for sexual abuse

TREATMENT

GENERAL MEASURES

- Initial, empiric treatment should be based on clinical suspicion of UTI as well as reliability of patient and family
- As the symptoms are often vague, a high index of suspicion must be maintained to ensure early detection of pyelonephritis
- Hospitalization might be required based on patient age and clinical status, although infants >2 mo and nontoxic children with suspected pyelonephritis can be treated as outpatients as long as compliance is not an issue
- Children with asymptomatic bacteriuria may not require treatment with antibiotics if the urinary system is otherwise normal

MEDICATION

ALERT

- In children, use 7–14 day treatment course (<7 days has been shown to be inferior).
- Fluoroquinolones should not be a 1st-line choice and are limited to resistant organisms.
- Nitrofurantoin has poor tissue penetration and should not be used for suspected pyelonephritis.

- Age of child and comorbid conditions should be considered when selecting antibiotics.

First Line

- Infants <2 mo (IV therapy preferred)
  - Ampicillin Neonates <7 d. 50–100 mg/kg/24 h IV ÷ q8h Term infants.75–150 mg/kg/24 h ÷ q6–8h IV Children >1 mo. 200 mg/kg/24 h ÷ q6h IM or IV
  - Gentamicin Infants <7 d <1200 g. 2.5 mg/kg/dose q18–24h.Infants >1200 g: 2.5 mg/kg/dose q12–18h. Infants >7 d: 2.5 mg/kg/dose IV q8–12h. Children: 2.5 mg/kg/d IV q8h; ↓ w/ renal Insufficiency
  - 3rd-generation cephalosporin
- Cefixime: 8 mg/ kg/d PO ÷ daily-bid; ↓ w/ renal impairment
- Cefdinir: 7 mg/kg PO bid or 14 mg/kg/d PO; ↓ in renal impairment
- Ceftibuten: 9 mg/kg/d PO; ↓ in renal impairment; take on empty stomach (susp)
- Children >2 mo
  3rd-generation cephalosporin: Cefixime, Cefdinir, Ceftibuten
- Children <2 yr of age should be treated with therapeutic doses (IM, IV, PO, or combination)
- School-aged children without systemic signs may be treated with an oral broad-spectrum antibiotic such as SMZ-TMP, nitrofurantoin
- Appropriate to start broad-spectrum antibiotics while awaiting culture results (5)

Second Line

Antibiotic course should be tailored by comorbidities, age, and local bacterial resistance patterns

SURGERY/OTHER PROCEDURES

- May be indicated following resolution of infection if child has specific urinary abnormalities predisposing to or exacerbating effects of urinary tract infection (eg, obstruction, VUR)
- Surgical correction of reflux is aimed at protecting upper tracts and is associated with a decrease in the number of febrile UTIs

ADDITIONAL TREATMENT

- In children with UTI and dysfunctional voiding/elimination behaviors, improvement in the latter will often result in fewer recurrent UTIs
- Regular (eg every 2 h) voiding
- Avoidance of constipation

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

- Cranberries may be effective in decreasing bacterial adherence, but there are no specific recommendations for children at present
- Probiotics may favorably alter gastrointestinal flora, but again there are no specific recommendations for use

ONGOING CARE

PROGNOSIS

- Most children do not have any long-term sequelae from a single UTI
- Prompt, efficacious treatment can prevent systemic sequelae
- Recurrence is common, especially in those with anatomic/functional abnormalities
- Identification of predisposing and comorbid factors may help prevent recurrent UTI

COMPLICATIONS

- Renal insufficiency/failure: Renal scarring in ~8% of children overall
- Urosepsis

FOLLOW-UP

Patient Monitoring

- If scarring is present, consider a nephrology consult to monitor for evaluation of HTN, proteinuria, and renal insufficiency
- Patients with a history of UTI may be more likely to develop UTIs and toxemia during pregnancy (CITE)

Patient Resources

National Kidney and Urologic Diseases Information Clearinghouse (NKUDIC).

CODES

ICD9

- 041.49 Other and unspecified Escherichia coli [E. coli]
- 599.0 Urinary tract infection, site not specified

- 771.82 Urinary tract infection of newborn

ICD10

- B96.20 Unsp Escherichia coli as the cause of diseases classd elswhr
- N39.0 Urinary tract infection, site not specified
- P39.3 Neonatal urinary tract infection

CLINICAL/SURGICAL PEARLS

- A high index of suspicion is often required for an accurate diagnosis of UTI, especially in nonverbal children.
- Treatment of the acute infection should be tailored to the child's age, comorbidities, and clinical condition, as well as local antibiotic resistance patterns and culture results.
- Surgical intervention is undertaken when conservative management is unlikely to prevent further UTIs and/or protect the kidneys.
- Patients with recurrent febrile infections, VUR, and/or kidney scarring should be followed carefully for development of renal disease.

UROLITHIASIS, ADULT, GENERAL

Margaret S. Pearle, MD, PhD, FACS
Jodi A. Antonelli, MD

BASICS

DESCRIPTION

- Concretion that occurs in the urinary tract
- May be asymptomatic but can also be associated with mild to severe symptoms

EPIDEMIOLOGY

Incidence

- Peak incidence: 4th–6th decades of life
- More common in Caucasians than in Hispanics, Asians, or African Americans
- More common in men; increasing in women

Prevalence

- Prevalence in US adults is 8.8% (10.6% for men, 7.1% for women) (1)[A]
- Prevalence gradient increases from North to South and West to East

RISK FACTORS

- Personal or family history
- Hot, arid, or dry climate
- Obesity and weight gain
- Low fluid intake, dehydration
- Diets high in sodium, animal protein, oxalate
- Comorbidities: chronic diarrheal states, GI surgery, gout, diabetes, recurrent UTIs hyperparathyroidism, cystinuria, type 1 renal tubular acidosis, sarcoidosis
- Anatomic anomalies: Ureteropelvic junction obstruction, horseshoe kidney, caliceal diverticula, medullary sponge kidney

Genetics

- Multiple genetic polymorphisms may contribute to calcium stone formation
- Heritable disorders: Primary hyperoxaluria, cystinuria, Lesch–Nyhan syndrome, xanthinuria, type I renal tubular acidosis

PATHOPHYSIOLOGY

- Most common stone—calcium oxalate (60%)
- Calcium (Ca) stones—occur in settings of hypercalciuria, hyperoxaluria, hyperuricosuria, hypocitrituria
- Hypercalciuria—urine Ca >200 mg/d
  - Absorptive hypercalciuria—Increased intestinal absorption of Ca
  - Renal hypercalciuria—Impaired renal reabsorption of Ca
  - Resorptive hypercalciuria—Primary hyperparathyroidism, rare cause is sarcoidosis
- Hyperoxaluria—Urine oxalate >40 mg/d
  - Primary hyperoxaluria—Excess endogenous oxalate production

  - Enteric hyperoxaluria—Increased intestinal absorption of oxalate
  - Dietary hyperoxaluria—Overindulgence in oxalate-rich foods, Ca restriction, excess vitamin C supplementation, reduced *Oxalobacter formingenes* (oxalate-degrading intestinal flora)
- Hyperuricosuria—Uric acid (UA) >600 mg/d
  - Causes: excess animal protein intake, gout, myelproliferative disorders
  - Urine pH <5.5—Uric acid or calcium stones
  - Urine pH >5.5—Ca oxalate stones
- Hypocitriuria—Urine citrate <320 mg/d
  - Citrate inhibits Ca stone formation
  - Low urine citrate occurs in states of acidosis—Renal tubular acidosis, chronic diarrhea
- Uric acid stones—Radiolucent
  - Congenital causes—Disorders of renal tubular urate transport, disorders of UA metabolism
  - Acquired causes—Obesity, high animal protein intake, volume depletion
- Cystine stones
  - Cystinuria—Inherited disorder of impaired renal absorption of cystine
- Infection stones—Composed primarily of magnesium, ammonium, and phosphate
  - Alkaline urine produced by urease-splitting bacteria—*Proteus* (most common), *Klebsiella*, *Pseudomonas*, *Staphalococcus*
- Miscellaneous stones
  - Xanthine—Radiolucent, inherited disorder of the enzyme (XDH) that catalyzes xanthine to UA, another cause—high-dose Allopurinol use
  - Ammonium acid urate—Associated with laxative abuse, inflammatory bowel disease (IBD), ileostomies
  - Matrix—Typically radiolucent, associated with infection, may contain protein
  - Medication-related—Indinavir (not visible on x-ray or CT), triamterene (radiolucent), topiramate, and carbonic anhydrase inhibitors (calcium phosphate stones)
- Stones in pregnancy
  - Overall risk similar to non-gravid women
  - Majority occur in 2nd–3rd trimester
  - Physiologic hydronephrosis may promote crystallization through urinary stasis
  - Hypercalciuria is enhanced by placental production of vitamin D

ASSOCIATED CONDITIONS

- Chronic diarrheal states: GI surgery: gastric bypass/banding, small bowel resection
- Hyperparathyroidism
- Gout
- Sarcoidosis
- Primary hyperoxaluria
- Cystinuria
- Type I renal tubular acidosis
- Medullary sponge kidney

GENERAL PREVENTION

- Hydration
- Dietary limitation of animal protein (all types), sodium, and oxalate (chocolate, nuts,

brewed tea, spinach, rhubarb, potatoes, beets); maintenance of recommended daily allowance of calcium (~1 g)
- Keep vitamin C intake low

DIAGNOSIS

HISTORY
- Can be asymptomatic
- Personal/family history of kidney stones
- Gross hematuria
- Pain—Flank, abdomen, ipsilateral groin
  - Renal colic—Pain in flank/abdomen that occurs in waves
  - Acute colic may suggest obstruction
- Nausea/vomiting—may suggest obstruction

PHYSICAL EXAM
- Can be unremarkable
- Elevated heart rate and blood pressure—pain
- Febrile, tachycardic, hypotensive
- Abdominal/CVA tenderness
- Costovertebral angle tenderness

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis—Microhematuria, pyuria
- Crystalluria—Hexagonal (cystine), coffin-lid (MAP), dumbell (Ca oxalate monohydrate)
- Leukocytosis/leukopenia—Inflammation and/or infection
- Elevated serum creatinine—Bilateral obstruction or solitary kidney

Imaging
- Non-contrast CT of abdomen and pelvis—Gold standard to identify urinary stones
  - Low-dose protocol limits radiation exposure
  - Provides additional anatomic information: Hydronephrosis, kidneys and other viscera
- Plain radiography: Not as sensitive or specific as CT for stones, useful for follow-up
- Ultrasound—Often difficult to visualize adult ureters, first-line for pregnant women, consider transvaginal ultrasound for pregnant women
- Intravenous pyelogram (IVP)—Assesses anatomy of collecting system, renal function, obstruction; limited availability, must give IV contrast; CT urography generally replaces this
- MRI—Poor for stones of all types; some value in pregnant women but data are limited

Diagnostic Procedures/Surgery
Endoscopic procedures are both diagnostic and therapuetic

Pathologic Findings
Stone analysis—Ca oxalate monohydrate or dihydrate, Ca phosphate, uric acid, cystine, struvite, matrix, mixed

DIFFERENTIAL DIAGNOSIS
- Any of the following causes may be confused with pain related to urolithiasis:

- Vascular: Abdominal aortic aneurysm, mesenteric ischemia
- Gastrointestinal: Appendicitis, bowel obstruction, cholecystitis/biliary colic, constipation, diverticulosis/diverticulitis, gastritis, pancreatitis, peptic ulcer
- Gynecologic: Ectopic pregnancy, tubo-ovarian abscess, ovarian torsion/cyst rupture
- Musculoskelet al—Back pain
- Urologic: Pyelonephritis, urinary tract infection, sloughed renal papilla, ureteropelvic junction obstruction

TREATMENT

GENERAL MEASURES

ALERT
Fever, leukocytosis/leukopenia, tachycardia, hypotension, tachypnea, bacteriuria, and/or pyuria with upper tract stone is life-threatening; treat with renal decompression (ureteral stent or nephrostomy tube)

- Conservative therapy
  - Hydration, analgesia, medical expulsive therapy (best evidence for alpha-blockers)
  - % passage with conservative measures
    - 80%—Stone 2–3 mm
    - 50%—Stone 4–5 mm
    - 20%—Stone 7–8 mm
  - Strict instructions to return for fevers, worsening pain, unable to tolerate oral fluids
- Relative indications for intervention
  - Large stone burden—Staghorn or partial staghorn or large ureteral stone
  - Stone location—Renal pelvis, ureter
  - Concern for infection; severe pain
  - Unable to tolerate oral fluids
  - Renal deterioration, solitary kidney
  - Repeated presentations to emergency room

MEDICATION

First Line

- Analgesia—anti-inflammatory (ibuprofen, ketorolac), acetaminophen, narcotic
- Antibiotics
  - Infection or positive urine culture (Empiric ciprofloxin, adjust based on culture results)
  - Prophylactic
    - Lower tract: Cysto stone manipulation
      - *Fluoroquinolone or Trimethoprim sulfamethoxazole
    - Upper tract: Percutaneous renal surgery:
      - *1st/2nd-generation cephalosporin, aminoglycoside + metronidazole or clindamycin
    - Upper tract: Ureteroscopy (all patients) or ESWL with risk factors
      - * Fluoroquinolone or trimethoprim sulfamethoxazole
- Medical expulsive therapy
  - α-Blockers: Increase stone passage, reduce time to stone passage, reduce pain

- Tamsulosin 0.4 mg PO QD (2)[A]

- Directed at metabolic abnormality
  - Hypercalciuria: Thiazide or thiazide-like diuretic with potassium citrate/chloride (avoids hypokalemia)
    - Hydrochlorothiazide: 50 mg/d or 25 mg BID
    - Chlorthalidone: 25–50 mg/d
    - Indapamide: 1.25–2.5 mg/d
  - Low urine pH, low citrate
    - Potassium citrate: 20–60 mEq/d in 2–3 divided doses with meals to desired level of urinary citrate
  - Cystinuria: Tiopronin 200 mg BID and titrate to 200–300 BID or TID with potassium citrate or sodium bicarbonate (goal urine pH of 7.5).
  - Uric acid: Allopurinol 100–300 mg/d if dietary measures fail to reduce elevated serum UA
  - Dissolution therapy
    - Alkalinize urine with potassium citrate 40–60 mEq individed doses or sodium bicarbonate 1300 mg BID
      *Uric acid: Goal urine pH of 6.5
      *Cystine: Maintain urine pH >7.0–7.5

Second Line

Antiemetics if colic is associated with nausea

SURGERY/OTHER PROCEDURES

- Preoperative urine culture should be negative or appropriately treated prior to surgery
- Excorporeal shockwave lithotripsy (ESWL)—70% successful with 1 treatment, best when stones <2 cm in the kidney (not lower pole) and proximal ureter
- Ureteroscopy with laser lithotripsy (URS)—80–90% successful for ureteral stones and kidney stones <1.0 cm
- Percutaneous nephrolithotomy (PCNL)—large (≥2 cm) renal or proximal ureteral stones
- Ureteral calculi (3)[A]
  - <10 mm—surveillance, URS, or SWL
  - ≥10 mm—URS or SWL
- Renal calculi
  - <2 cm—SWL (not lower pole), URS, PCNL
  - ≥2cm—PCNL is treatment of choice

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Avoid future episodes: Hydration (≥2 L/24 h)

Complementary & Alternative Therapies

None

ONGOING CARE

PROGNOSIS

- First-time stone-formers have a 50% chance of recurrent calculi within 5 yr
- Dietary modifications and medical therapy tailored to metabolic abnormality can prevent recurrence in 75% of patients and reduce new stone formation in 98% of patients

COMPLICATIONS

- Potential renal function deterioration after 4–6 wk of untreated urinary tract obstruction
- Surgical treatment of urinary stones carries risks of bleeding, infection, injury to urinary tract (ie, ureteral strictures, ureteral perforation)
- Pneumothorax and/or hydrothorax can occur with percutaneous renal access (especially above the 12th rib)

FOLLOW-UP

Patient Monitoring

- Low risk—Inactive stones, first-time formers without risks (family history, GI/bone disease, gout, obesity, diabetes)
  - – Screening evaluation—Diet/medical history, serum studies (Cr, K, CO_2, Ca, P, UA, iPTH), stone analysis, urine culture or
  - – Conservative therapy
- High risk—Recurrent/active formers, children/adolescents, solitary kidney, first-time former with risks listed above
  - – Screening evaluation as above
  - – Two 24-h urine collections

CODES

ICD9

- 592.0 Calculus of kidney
- 592.1 Calculus of ureter
- 592.9 Urinary calculus, unspecified

ICD10

- N20.0 Calculus of kidney
- N20.1 Calculus of ureter
- N20.9 Urinary calculus, unspecified

CLINICAL/SURGICAL PEARLS

- The most important measure to avoid future stones is adequate hydration ($\geq$2 L/d).
- Upper urinary tract stone with UTI requires decompression with stent or nephrostomy tube.
- Preoperative urine culture should be negative or treated prior to definitive surgical treatment.
- Medical management can significantly reduce risk of future stones.
- Urinary stones in a solitary kidney should be treated aggressively.

UROLITHIASIS, CALCIUM OXALATE/PHOSPHATE

John J. Pahira, MD

BASICS

DESCRIPTION

- Deposition of calcium salts in the urinary tract may result in a urinary calculus.
- Ca oxalate in its pure form or mixed with Ca phosphate (hydroxyapatite) is the most common type of calculus in industrialized countries.

EPIDEMIOLOGY

Incidence

- US annual stone incidence: 16.4/10,000
- Male > Female (3:1–2.0)
- Age of peak incidence: 20–40 yr
- 1 in 8 men, 1 in 20 women lifetime risk
- Stone incidence by composition: Ca oxalate 30–56%; mixed Ca oxalate and Ca phosphate: 11–31%

Prevalence

- 10–15% US prevalence of stones
- Lifetime prevalence of kidney stone disease is estimated at 1–15%, with the probability of having a stone varying according to age, gender, race, and geographic location.

RISK FACTORS

- See also Section II: "Urolithiasis, Risk Factors"
- Intrinsic: Polygenic defect; hypercalciuria inherited as autosomal dominant trait; white males; other illnesses: (IBD, etc.), elevated PTH, medullary sponge kidney, recurrent UTI
- Anatomic: UPJ obstruction, horseshoe kidneys
- Extrinsic risk factors: Geography/climate
- Diet: Elevated dietary protein, oxalates, refined sugars, and Ca, and low fiber intake; high salt intake increases Urinary Calcium (UCa)
- Water intake: Low consumption increases risk
- Occupation: Sedentary occupations

Genetics

- Ca oxalate: Multifactorial; hypercalciuria an autosomal dominant trait
- Idiopathic hypercalciuria: 5–10% of normals and 30–60% with Ca nephrolithiasis
- Familial tendency to form stones

PATHOPHYSIOLOGY

Hypercalciuria may be heterogeneous.

- Normocalcemic hypercalciuria (idiopathic hypercalciuria): 30–60% of Ca oxalate stones
- AH: Intestinal hyperabsorption of Ca:
  - Hypercalciuria: Increased filtered load and decreased renal tubular reabsorption due to decreased PTH

- Renal loss of Ca compensates for absorption, maintains normal (SCa)
  - Hypercalciuria: >4 mg/kg weight/24 hr on random diet (>250 mg/24 hr), *OR* >200 mg/24 hr after 1 wk diet to 400 mg Ca and 100 mEq Na/d (1)
  - AH type I: Uncommon, most severe form; persistent hypercalciuria >250 mg/24 hr on random diet or restricted diet with normal SCa and normal or slightly decreased PTH level; 2-hr fasting UCa normal.
  - AH type II: Most common, mild form; hypercalciuria >250 mg/24 hr on random diet but normo-calciuria on Ca/Na-restricted diet, normal SCa and PTH
  - AH type III: Vitamin D–dependent hypercalciuria, renal phosphate "leak"; low serum phosphate, elevated urinary phosphate, and Ca-enhanced Vitamin D_3 synthesis by the kidney leads to increased intestinal Ca absorption
- Renal hypercalciuria (renal leak):
  - Impaired renal tubular reabsorption of Ca; decreased in SCa; elevated PTH; elevated vitamin D_3, and increased intestinal hyperabsorption
  - SCa normal, mild secondary elevated PTH
  - UCa elevated on both random and restricted diets; 2-hr fasting UCa elevated
- Resorptive hypercalciuria:
  - Primary elevated PTH; elevated SCa and UCa secondary to increased PTH secretion, causing excessive resorption of bone and an increased intestinal absorption of Ca due to increased PTH and increased renal synthesis of vitamin D3
  - 2-hr fasting UCa is elevated
- Unclassified hypercalciuria:
  - Hypercalciuria with normal SCa, normal PTH, and elevated 2-hr fasting UCa
  - Na cellulose phosphate may help distinguish AH by eliminating problem of inadequate dietary preparation prior to fast and load Ca studies; renal hypercalciuria by reducing the suppressive effect of absorbed Ca on parathyroid stimulation
- Other causes Ca oxalate stones:
  - Hyperuricosuria (urinary uric acid >600 mg/24 hr); only abnormality in 10% of Ca stones; up to 40% of Ca stone-formers with other physiochemical abnormalities
  - May initiate Ca oxalate stones by direct induction of heterogeneous nucleation of Ca oxalate crystals, or by absorption of certain macromolecular inhibitors
- Hyperoxaluria:
  - Urinary oxalate >45 mg/24 hr
  - Mild hyperoxaluria (45–80 mg/24 hr) is as important a risk factor for idiopathic Ca oxalate stones as hypercalciuria and is found in 37% of patients with Ca oxalate stones
  - Activity of stone disease correlates better with level of urinary oxalate than Ca.
  - Most common: Intestinal hyperabsorption of oxalate: Intestinal resection (enteric hyperoxaluria), IBD, celiac, gastric/small bowel resection; JI bypass
  - Bile salts and fatty acids increases large-bowel oxalate absorption.
  - Fat malabsorption causes Ca to complex with bile acids and form Ca soap, which decreases free Ca in the intestinal lumen, which can complex with oxalate, and decrease oxalate for absorption.
  - Stone formation due to hyperoxaluria but also contributed to by low-volume urinary output, low citrate secondary to hypokalemia, chronic metabolic acidosis

  - Low magnesium levels may be secondary to intestinal malabsorption.
  - Primary hyperoxaluria type I:
    - Autosomal recessive, defect of AGT
    - Elevated urinary oxalic, glycolic, glyoxylic acids
    - Clinically, nephrocalcinosis, tissue deposition of oxalate, and renal failure, with death by age 20 yr if untreated
    - 2/3 have undetectable AGT on liver biopsy; glyoxylate oxidized to oxalate
  - Primary hyperoxaluria type II:
    - Rare (21 cases) deficiency of d-glycerate dehydrogenase and glyoxylate reductase
    - Elevated urinary oxalate and glycerate; nephrocalcinosis and renal failure
  - Dietary hyperoxaluria:
    - Excess oxalate-rich foods (dark green vegetables, tea, nuts, concentrated fruit juices, chocolate); vitamin C >1000 mg/d
  - Pyridoxine (vitamin B_6) deficiency, ethylene glycol toxicity, hepatic conversion to glycoaldehyde and glycolic acid, methoxyflurane anesthesia, converted in liver to oxalate
  - Hypocitraturia:
    - Citrate <220 mg/24 hr; sole abnormality in 10%; 15–60% with other Ca stones causes
    - Acidosis most important factor in hypocitraturia; decreases urinary citrate secondary to increased renal tubular reabsorption and decreased synthesis
    - Causes of metabolic acidosis: IBD, chronic diarrhea; thiazide-induced hypokalemia, and intracellular acidosis; purine-rich diet (high acid-ash); strenuous exercise (lactic acid); RTA (type I, distal); increased Na intake. UTI with bacteria-degrading citrate decreases urinary Ca salts by forming soluble complexes with Ca.
- Hypomagnesuria:
  - Urinary Mg <50 mg/24 hr; coexists with hypocitraturia in 2/3 and with low urine volume (<1 L/24 hr) in 40%
  - Pathogenesis is not known; may be dietary (IBD and malabsorption)

ASSOCIATED CONDITIONS
IBD, chronic pancreatitis, chronic diarrhea, elevated PTH, medullary sponge kidney, UTIs

GENERAL PREVENTION
See “General Measures” below

DIAGNOSIS
HISTORY
- See “Flank Pain” and “Urolithiasis, General.”
- Review stone history, family history, and the intrinsic and extrinsic risk factors noted earlier

PHYSICAL EXAM
See “Flank Pain” and “Urolithiasis, General.”

DIAGNOSTIC TESTS & INTERPRETATION
Lab (1)
- Abbreviated protocol for low-risk single-stone formers (history, dietary habits, basic metabolic panel including Ca, PTH, and uric acid, urinalysis/pH, radiologic imaging, stone

analysis)
- A comprehensive metabolic evaluation (with Ca fast/ load test) in recurrent stones and increased stone risk can be replaced by a simple evaluation (metabolic panel and 1–2 24-hr urines):
  – 24-hr urine (volume, Ca, Cr, oxalate, citrate, Na, phosphate, magnesium, pH, uric acid, sulfate)
  – Data best on a diet at least 1 month after stone passage or 1 wk after IVP studies
  – D/C drugs that may affect the tests (vitamins, antacids, diuretics, allopurinol, etc.)

Imaging
- CT: Most sensitive
- US, KUB, Excretory Urography (ExU)
- MRI not useful for calcifications/urinary calculi

Diagnostic Procedures/Surgery (2)
- In deciding which stone-formers require a metabolic evaluation consider the following:
  – 80–90% have predisposing urinary abnormality or underlying disease identified.
  – Treatment program is to be maintained for life.
  – 50–60% patients pass only 1 stone/lifetime.
  – Involve your patient in the decision to perform a workup; explain risk and benefits.
- Criteria for metabolic evaluation:
  – Anatomic abnormality; family history of stones; history of gout or major stone complications; history of metabolic stone (uric acid or cystine), infection stone (struvite), pure Ca phosphate stone (RTA or elevated PTH)
  – Metabolically active (x-ray evidence of new stone or stone growth in the past year or the documented passage of a new stone or gravel)
    - Osteoporosis or pathologic skelet al fracture
    - Recurrent stone formation
    - Renal insufficiency
    - Significant number of risk factors
    - Solitary kidney; age at onset <20 yr

Pathologic Findings
- Stone analysis: Varying percent composition from Ca oxalate and/or Ca phosphate
- Crystals: Ca oxalate monohydrate (dumbbell/hourglass), Ca oxalate dehydrate (envelope/bipyramidal), Ca phosphate-apatite (amorphous)

DIFFERENTIAL DIAGNOSIS
- Hypercalcemia: Primary elevated PTH, RTA, vitamin D excess, immobilization, sarcoidosis, metastatic malignancies, milk-alkali syndrome, hyperthyroidism, myxedema, adrenal insufficiency, furosemide administration
- See: “Section I Filling Defect-Upper Urinary Tract.”
- See: Section I “Flank Pain”

TREATMENT

GENERAL MEASURES

- Treat active UTI.
- Medical expulsion therapy for a symptomatic ureteral stone (1)[C] (See "Urolithiasis, General")
- Prevention tailored to patient need.
- 1st-time stone-formers at low risk for recurrence should follow a conservative approach.
- Conservative treatment is appropriate for all stone-forming patients, regardless of cause.
- High fluid intake, daily urine output of 2 L; Na and oxylate restriction
- Restrict protein (8 oz meat/chicken/fish/day)
- Vitamin C <2 g/d
- Avoid excess Ca intake. 1 serving with each meal acceptable; avoid late at night
- Ca citrate: "Stone-friendly" supplement
- Avoid stone-provoking drugs: Vitamin D, antacids, furosemide, uricosurics, triamterene

MEDICATION (3)

First Line

- Absorptive hypercalciuria type I:Thiazide (not a selective therapy for AH as does not decrease intestinal Ca; limited long-term effect):
  – Hydrochlorothiazide 25–50 mg b.i.d.
  – Consider K citrate (20 mEq b.i.d.)
  – Alternates: Indapamide 1.25–2.5 mg/d or chlorthalidone (25–50 mg/d):
  – Restrict dietary oxalate, Na to 2000 mg/d
  – Magnesium supplementation
- AH type II: Moderate Ca restriction (600 mg/d or 1–2 servings dairy/d); Na restriction; thiazide if not effective; K citrate supplementation
- AH type III: orthophosphate (Neutra-Phos-K) 250–500 mg tid/qid
- Renal hypercalciuria: Thiazide to increase tubular Ca reabsorption; hydrochlorothiazide 25–50 mg b.i.d.; Indapamide 1.25–2.5 mg/d, Chlorthalidone 25–50 mg/d, K citrate supplementation (Polycitra K syrup 15–30 mL b.i.d.; Polycitra K crystals 1 packet b.i.d.; Urocit K 10–20 mEq b.i.d.); Na restriction (2 g Na diet; keep urinary Na <100 mg/d)
- Hyperuricosuric Ca nephrolithiasis: Increase fluid intake; reduce dietary purine (eg, red meat); urinary alkalization (pH 6.5–7.0), K citrate; reduce endogenous uric acid production (allopurinol 300 mg/d); if serum uric acid >8 mg/dL, or if urinary uric acid >800 mg/24 hr
- Hypocitraturic Ca nephrolithiasis: K citrate, increases intracellular pH, which increases citrate production
- Hyperoxaluria: High fluid intake; low-oxalate diet; (see http://ohf/diet.html) K citrate (60–120 mEq/d), Ca supplementation (Ca citrate, TUMS); therapy to control diarrhea. Fish oil and probiotics may help reduce oxalate excretion.
- Type I RTA: K citrate

Second Line

Absorptive hypercalciuria type I: Na cellulose phosphate out of favor (GI effects); use if UCa >500 mg/d; 2nd line only

SURGERY/OTHER PROCEDURES

See "Urolithiasis, Adult, General."

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Untreated recurrence for Ca oxalate stones: 10% at 1 yr, 35% at 5 yr, 50% at 10 yr
- Medical therapy: Decreases new stone formation; remission >80%, and >90% recurrence reduction

COMPLICATIONS

- Obstructing calculus: sepsis and/or progressive renal damage.
- Un-obstructing calculus: May sometimes grow and cause obstruction, deterioration of renal function.

FOLLOW-UP

Patient Monitoring

- Provide patients with appropriate written dietary hand-outs
- Patients with recurrent stones on medical therapy require periodic monitoring:
  - Urine analysis, urine pH
  - Serum chemistry if warranted
  - 24-hr urine collection
  - KUB, US, or CT

CODES

ICD9

- 275.40 Unspecified disorder of calcium metabolism
- 592.0 Calculus of kidney
- 592.9 Urinary calculus, unspecified

ICD10

- E83.52 Hypercalcemia
- N20.0 Calculus of kidney
- N20.9 Urinary calculus, unspecified

CLINICAL/SURGICAL PEARLS

- A family history of nephrolithiasis is important risk when deciding on a metabolic work-up.
- A slight increased PTH is best indication of renal leak hypercalciuria with normal SCa and persistent hypercalciuria on a restricted diet.
- When starting on a thiazide for hypercalciuria, it is important to check serum calcium in 2–4 wk to rule out an occult hyperparathyroidism.
- Accurate 24 hr urinary uric acid cannot be done until the patient is placed on urinary alkalization as acidic urine can cause uric acid to precipitate out of solution causing underestimation.

UROLITHIASIS, CYSTINE, AND CYSTINURIA (HYPERCYSTINURIA)

Anthony J. Tracey, MD, MPH
Raju Thomas, MD, MHA, FACS

BASICS

DESCRIPTION

- Cystinuria is caused by an autosomal recessive error of transepithelial transport involving the intestine and the kidneys. Cystine lithiasis is the clinical result of crystallization and stone formation in the urinary tract.
  - Excessive urinary excretion secondary to reduced tubular absorption of cystine disulfate (1).
  - There is a transport defect of dibasic amino acids including cystine, ornithine, lysine, and arginine (COLA). (See also Section I: "Urolithiasis, Pediatric.") (1)
- Cystine stones form when concentrations rise above the saturation point (roughly 250 mg cystine per liter of urine)
- Cystinuria accounts for about 1–2% of adult and 6–8% of pediatric nephrolithiasis (1)
- Historically, three types of cystinuria have been recognized in humans—type I, type II, and type III—on the basis of levels of urinary cystine in obligate heterozygotes; however, this classification correlates poorly with molecular findings; newer genetic classification is available (see below).
- Cystinuria is distinct from cystinosis, which is intracellular cystine accumulation leading to the Fanconi syndrome and progressive renal failure

EPIDEMIOLOGY

Incidence

- For patients with cystinuria:
  - One new stone formation per patient per year
  - An average of one surgical procedure every 3 yr
  - 7 surgical procedures for nephrolithiasis by middle age (2)
  - Average age at first stone diagnosis was 12.2 yr
  - Mean number of stone episodes of 0.42 and 0.21 per year occurring in men and women, respectively.

Prevalence

- Homozygous: 1 in 15,0000 in the United States
- Heterozygous: 1 in 20–200 in the United States
- Libyan Jews: 1 in 2,500 (3)
- Cystinuria is more common in Caucasians
- Cystine stones are common in the second or third decade of life
- 20% of these patients develop calculi in childhood

RISK FACTORS

Family history (See genetics)

Genetics

- Identification of genetic mutations that cause cystinuria have led to a new classification system based on genotype that is more accurate than the prior phenotypic one.
- Mutations in 2 genes, *SLC3A1* and *SLC7A9* (3)
- Recent classification by International Cystinuria Consortium (ICC) to account for the chromosomal localization of the mutation:
  - Type A (SLC3A1 gene is located on chromosome 2p16.3-p21)
  - Type B (SLC7A9 gene is located on chromosome 19q12-13.1)
  - Type AB (both chromosomes)
- Homozygotes exhibit urinary cysteine levels as high as 2000 µmol/g of creatinine
- Heterozygotes do not form stones; urinary excretion <100 mg/d
- Autosomal recessive complete; urinary excretion 250–1,400 mg/d
- Autosomal recessive incomplete; urinary excretion 100–300 mg/d (1)

PATHOPHYSIOLOGY

- Cystine is a homodimer of the amino acid cysteine.
  - Cystinurics have impaired renal cystine transport, with decreased proximal tubular reabsorption of filtered cystine resulting in increased urinary cystine excretion with the consequence of cystine urolithiasis.
- Clinical consequences present only when crystals precipitate (low cystine solubility at normal urinary pH values).
- Cystine stone formers have slightly lower creatinine clearance than other types of stone formers.

ASSOCIATED CONDITIONS

- Defective renal acidification
- Hypercalciuria 19%
- Hypertension
- Hyperuricosuria 22%
- Hypocitraturia 44%
- Urolithiasis

GENERAL PREVENTION

- Create high urine volume (>1.5 L/m^2/d) to reduce the urinary concentration of cystine to below its solubility limit (200–300 mg/L)
- Alkalize urine to pH of >7.5 (3–4 mEq/kg/d potassium citrate/bicarbonate, in 3–4 divided doses. Alkaline urine increases solubility of cysteine) (1)
- Restrict sodium and protein.

DIAGNOSIS

HISTORY

- Stones in childhood (3)
- Family history of stones (3)
- The presentation of a large branched calculi

PHYSICAL EXAM

CVA tenderness may be present with active stone disease

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine is screened for cystine using the cyanide-nitroprusside test (positive = purple hue) with cystine >75 mg/L)
  - Cyanide converts cystine to cysteine; this binds nitroprusside then binds resulting in a purple color usually in <10 min.
- If positive, a 24-hr urine quantitative test is performed.
  - Normal cystine excretion is 30 mg/d (0.13 mmol/d),
  - Cystinurics >400 mg/d (1.7 mmol/d) (1).
- Heterozygotes for cystinuria and with the Fanconi syndrome, excrete <250 mg/d (1 mmol) and usually do not form stones.
- Urine microscopy: Hexagonal or benzene crystals, which are pathognomonic of cystinuria.
  - Microscopic crystalluria is present in 26–83% of patients.
  - Can also be seen in cystinosis
- Cystine capacity: A highly specialized assay that measures the ability of urine to take up additional cystine from a preformed solid phase reaction (under saturation, or "positive cystine capacity") or to give it up to the solid phase (supersaturation, or "negative cystine capacity")
  - May help guide drug dosing and treatment

Imaging

- CT scan of abdomen without contrast
  - Preferred imaging modality
- KUB may show stones with a fuzzy gray appearance (1)
  - Stones are less radiopaque than calcium stones but usually well seen
- Renal ultrasonography
  - More economical than CT scan for monitoring the growth of renal calculi
  - Indicated for children and frequent stone formers to reduce radiation (2)

Diagnostic Procedures/Surgery

N/A

Pathologic Findings

Renal biopsy is not usually performed. However, renal pathology may include plugging of the Ducts of Bellini with cystine crystals, tubular dilation, and focal fibrosis.

DIFFERENTIAL DIAGNOSIS

- Other forms of urolithiasis (calcium oxylate, uric acid, etc.)
- Any of the following may be confused with pain related to urolithiasis:
  - Vascular: Abdominal aortic aneurysm, mesenteric ischemia
  - Gastrointestinal: Appendicitis, bowel obstruction, cholecystitis/biliary colic, constipation, diverticulosis/diverticulitis, gastritis, pancreatitis, peptic ulcer
  - Gynecologic: Ectopic pregnancy, tubo-ovarian abscess, ovarian torsion/cyst rupture
  - Musculoskelet al: Back pain

- Urologic: Pyelonephritis, urinary tract infection, sloughed renal papilla, ureteropelvic junction obstruction

TREATMENT

GENERAL MEASURES

- For existing calculi treatment is similar to other stones based on clinical indication
- Extracorporeal shockwave lithotripsy has been discouraged for stones >1 cm by some authors (2)
  - Cysteine stones are often not well fragmented by ESWL (extracorporeal shock wave lithotripsy)
  - Multiple treatments are usually required
- Algorithm for Patients with Renal cystine stones:
  - Percutaneous nephrolithotripsy (PNL) for cystine renal calculi larger than 15 mm in diameter
  - Ureteroscopy effective for cysteine ureteral stones and for select renal cystine calculi
  - Laparoscopic pyelolithotomy may also be possible for stones in favorable locations of the ureter or renal pelvis.
  - ESWL monotherapy for cystine renal calculi 15 mm or smaller (High failure rate)

MEDICATION

First Line

See general prevention

Second Line

- Use chelating agents (bind cystine) only if the conservative methods do not work
- These increase cystine solubility in urine via formation of a more soluble mixed-disulfide bond
- These medications have potentially serious side effects and must be monitored.
  - α-Mercaptopropionylglycine (Thiola, Tiopronin)
    - Most frequently used cystine-binding agent
    - Dosage start at 100 mg, orally two times per day, doses titrated to achieve urinary concentrations of cystine less than 250 mg/L urine.
    - Side effects include asthenia, GI distress, rash, joint aches, and mental status changes
    - Better tolerated than d-penicillamine
  - d-penicillamine (Cuprimine)
    - binds with cystine to yield a disulfide more soluble than cystine
    - Typically start therapy at 250 mg per day and titrate to effect
    - Significant side effects: nephrotic syndrome, dermatitis, and pancytopenia.
  - Captopril: Potential alternative
    - More favorable side effect profile: Fatigue, hypotension, and chronic cough
    - No long-term clinical trials demonstrate the effectiveness of captopril in preventing recurrent cystine stone formation

SURGERY/OTHER PROCEDURES

See General Measures above

ADDITIONAL TREATMENT

Radiation Therapy

NA

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- One study reported 1.22 stone episodes per year (2)
- The medical compliance of patients with cystinuria can be poor.
- A few patients are able to achieve and maintain targeted goals of medical intervention
  - 15% achieved and maintained therapeutic success, as defined by urine cystine concentration less than 300 mg/L.
  - 42% achieved therapeutic success but subsequently had failure at an average of 16 mo
- Rare Kidney Stone Consortium has developed a registry and will lead further efforts in managing cystinuria

COMPLICATIONS

- Studies report 1.22 stone episodes per year
- Chronic pyelonephritis—19%
- Renal impairment—Approximately 70%
- Risk for nephrectomy—10–20%
- End-stage renal failure—5%
- Hypertension—10%
- Mental illness and mental retardation (2)

FOLLOW-UP

Patient Monitoring

- Patients should have frequent clinical, radiologic, and laboratory surveillance
  - Patients should follow a diet low in protein and sodium chloride
  - Urinary pH level, and check first-morning urine for cystine crystals (2)
  - Regularly check renal function
  - RBC counts, WBC counts, and platelet counts should be monitored for patients on d-penicillamine and tiopronin (2).
  - KUB and renal ultrasound should be routine
- Surveillance:
  - Annually perform 24-hr urine testing and imaging for patients with stable disease (2)
  - Multidisciplinary approach early in disease
    - Nephrologists
    - Renal dietitians

CODES

ICD9

- 270.0 Disturbances of amino-acid transport
- 592.9 Urinary calculus, unspecified

ICD10

- E72.01 Cystinuria
- N20.9 Urinary calculus, unspecified

CLINICAL/SURGICAL PEARLS

- Cystine stones are often not well fragmented by ESWL and may be considered for cystine renal calculi < 15 mm.
- Consider PCNL for cystine renal calculi larger than 15 mm in diameter.
- Ureteroscopy effective for cystine ureteral stones and for select renal cystine calculi.

UROLITHIASIS, PEDIATRIC, GENERAL CONSIDERATIONS

Gregory E. Tasian, MD, MSc
Douglas A. Canning, MD, FACS

BASICS

DESCRIPTION

- Urolithiasis can be found anywhere in the urinary tract of a child.
- Urolithiasis is much less common in children than adults
  - Urolithiasis is an increasingly common disease of childhood.
- The most commmon stones in children are calcium (calcium oxalate and calcium phosphate), uric acid, Struvite and cysteine.

EPIDEMIOLOGY

Incidence

- In adolescents, the incidence of nephrolithiasis has increased 6–10% per year over the last 20 yr (1,2).
- White > African American
- Male = Female
- Increased incidence in the Southwest United States.

Prevalence

The prevalence is unclear.

RISK FACTORS

- When a metabolic evaluation is performed, an abnormality can be identified in 40–50% of children.
  - Most common metabolic abnormalities are hypercalciuria and hypocitraturia.

PATHOPHYSIOLOGY

- Urine contains inhibitors of crystallization and thus can sustain large concentrations of solute (eg, Ca, uric acid) in a metastable state; however, perturbations of the equilibrium between inhibitors and promoters of stone formation may destabilize the urine to a point where solute cannot be held in solution and spontaneous nucleation occurs.
- Infection:
  - Urea-splitting organisms produce urease, which catalyzes the hydrolysis of urea.
  - Magnesium ammonium phosphate (struvite) and calcium phosphate stones
  - Urine is alkaline due to urease.
  - Most often present in patients with an anatomic abnormality that leads to chronic infection (neurogenic bladder, reflux, obstruction, etc.)
- Anatomic:
  - Ureteropelvic/vesical obstruction
  - Neurogenic bladder
  - Previous bladder neck surgery
- Hypercalciuria:

- Renal: Impaired tubular reabsorption of calcium causes increased parathyroid hormone release, which normalizes serum calcium.
- Absorptive: Increased absorption from intestines causes decreased parathyroid hormone and therefore decreased calcium tubular reabsorption:
  - Type 1: Severe
  - Type 2: Mild
- Resorptive (exceedingly rare):
  - Results from primary hyperparathyroidism
  - Elevated PTH and serum calcium, low serum phosphorous, high urine calcium
- Iatrogenic (medications): Loop diuretics (furosemide), corticosteroids, methylxanthines (theophylline, aminophylline)
- RTA: Inability to acidify urine in response to an acid load:
  - Metabolic acidosis; high urine pH
  - Type I (distal) most common: Disorder of hydrogen ion excretion that leads to bone demineralization and thus hypercalciuria
  - Most common stone is calcium phosphate, which results from hypercalciuria, hypocitraturia, and elevated urine pH

- Uric acid stones/hyperuricosuria:
  - Rare in children; high purine intake, uricosuric drugs (probenecid, sulfinpyrazone, allopurinol), renal tubular disorders, cyanotic congenital heart disease, hemolysis, and myeloproliferative disorders
  - Lesch–Nyhan syndrome and type I glycogen storage disease: Increased uric acid
- Cystinuria: Autosomal recessive disorder of amino acid transport; impaired reabsorption of cystine
- Hyperoxaluria:
  - Primary types I and II are rare autosomal recessive disorders with hepatic enzyme defects
  - Secondary: Excessive intake of ethylene glycol, ascorbic acid, methoxyflurane, or increased intestinal absorption due to bowel disease/resection, gastric bypass

ASSOCIATED CONDITIONS

- Bartter syndrome
- Cystinuria
- Diabetes, obesity, and sugary drinks are associated with an increased risk of nephrolithiasis in adults. These risk factors have not been well studied in children.
- Distal RTA
- Gout (Hypoxanthine-guanine phosphoribosyl transferase deficiency and phosphoribosyl pyrophosphate synthetase superactivity) is rare in children unless associated with a genetic disorder
- Hyperparathyroidism
- Hypervitaminosis D
- Intestinal malabsorption (Crohn disease, bowel resection, cystic fibrosis)
- Ketogenic diet (high-fat, low-carbohydrate)
- Medications (furosemide, acetazolamide, protease inhibitors, and anticonvulsants such as topiramate and zonisamide).
- Primary hyperoxaluria

- Prolonged immobility
- Recurrent UTIs
- Rickets (associated with Dent disease and hereditary hypophosphatemic rickets with hypercalciuria)
- Tetany (familial hypomagnesemia with hypercalciuria and nephrocalcinosis and autosomal dominant hypocalcemic hypercalciuria)
- Urinary tract abnormalities (spina bifida, horseshoe kidney, UPJ obstruction, VUR)
- William syndrome

GENERAL PREVENTION
- Maintain adequate hydration and fluid volume
- Treat underlying disorders (anatomic or metabolic)

DIAGNOSIS
HISTORY
- Patient: Prematurity, medications, dietary habits, fluid consumption, malignancies, previous intestinal disorder/surgery, hematuria
- Family: Cystinuria, primary hyperoxaluria, RTA, uric acid lithiasis
- Abdominal/flank pain ± nausea/vomiting

PHYSICAL EXAM
- Hypertension associated with acute pain or obstruction
- Occasional abdominal or flank tenderness
- Growth charts may identify decreased growth patterns associated with certain childhood diseases associated with stones(cystic fibrosis, distal RTA, hyperoxaluria, etc.).

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Acute Episode: Urinalysis
  - Macroscopic or microscopic hematuria is found in 85% of children with nephrolithiasis (3).
- Metabolic evaluation
  - Following the resolution of the acute stone episode, obtain at least one 24-hr urine collection in children who are toilet-trained
  - Analyze for calcium, oxalate, uric acid, sodium, citrate, creatinine levels, volume, pH, and cystine. It is essential to evaluate the results with respect to weight and creatinine level to accurately interpret the results.
  - Hypercalciuria is defined by a urinary calcium excretion of greater than 4 mg/kg over 24 hr while ingesting a routine diet.
  - Urine creatinine excretion (normal 15–25 mg/kg/d) is useful in assessing the adequacy of the urine collection.
  - Urine calcium—creatinine ratios (UCa/Cr) from a spot urine sample should be obtained in children who have not been toilet-trained.
    - Except for neonates, there is an inverse relationship between age and UCa/Cr.
    - At approximately 5 years of age, UCa/Cr approaches 0.21, the upper limit of normal for adults (4).

Imaging
- Ultrasound: Reliable when it identifies a kidney stone, but it has only moderate sensitivity particularly for stones in the mid-ureter.
- CT: Accurate but delivers ionizing radiation, concerns for increased cancer risk, particularly with exposure at young ages
- A reasonable approach is to use US as the initial study. A non-contrast CT is indicated in children with persistent symptoms of nephrolithiasis and a non-diagnostic US.

Diagnostic Procedures/Surgery
N/A

Pathologic Findings
- Stone analysis to determine composition
- Calcium oxalate stones are most common, followed by calcium phosphate.
- The prevalence of struvite, cystine, and uric acid stones is each $<10\%$.

DIFFERENTIAL DIAGNOSIS
See Section I: “Urolithiasis, Adult, General.”

TREATMENT
GENERAL MEASURES
- Indications for surgery: fever in the presence of an obstructing stone, pain refractory to oral analgesics, acute kidney injury, and an obstructing stone in a solitary kidney.
- Evaluate all children for underlying metabolic disorder.
- Goal is to decrease stone-promoting risk factors (urinary calcium, sodium, oxalate, uric acid, and low urine volume), and increase protective factors (urine pH, citrate, magnesium)
- Hydration:
  - Water preferred; avoid caffeine, sodium, and sugary drinks (sports drinks)
- Dietary modifications when applicable

MEDICATION
First Line
- Should a trial of spontaneous passage be indicated, appropriate oral analgesics are important (ie, narcotics).
- Tamsulosin may increase passage of distal ureteral stones in children (5).

Second Line
- Hypercalciuria:
  - Hydrochlorothiazide:
    - 1–2 mg/kg/d in children
    - 25–100 mg/d in adults
- Hypocitraturia
  - Potassium citrate
    - 2–4 mEq/kg/d
    - adults 30–90 mEq/d
- Uric acid stones:
  - Limit dietary sodium

- Alkalinization of urine to pH >6.5:
- Allopurinol (decrease uric acid production) 200 mg/d

• Cystinuria:
- Create high urine volume (>1.5 L/m^2/d)
- Chelating agents (bind cystine):
  - Thiola
  - D-penicillamine

• Hyperoxaluria:
- Limit sodium and oxalate-rich foods (eg, spinach, rhubarb, nuts, tea, bran, strawberries)
- Supplemental citrate, magnesium, phosphorous (stone inhibitors)

SURGERY/OTHER PROCEDURES

• The optimal management based on the size, location, and presumptive stone composition, as well as the age, size, and health of the patient.

• Extracorporeal Shock Wave Lithotripsy (ESWL)
- Renal/proximal ureteral stones, <1 cm, all ages
- Use for distal stones not well defined
- Success rate depends upon many variables:
  - Stone size and location, energy utilized, density of stone, anatomic abnormalities
- Complications
  - Subcapsular hematoma: Self-limiting
  - Interstitial fibrosis: Insignificant unless multiple procedures
  - Injury to surrounding organs:

• Ureteropyeloscopy:
- Rigid and flexible endoscopes permit access to almost all areas of the collecting system in nearly all children:
- Pre-placement of stent is sometimes necessary to passively dilate the ureter.
- Access sheaths (with/without pre-stenting) facilitate procedures requiring multiple endoscope passes.
- All forms of lithotripsy are safe; holmium laser most effective

• Percutaneous nephrolithotomy (PCNL):
- Appropriate for large intrarenal/proximal ureteral stones:
- Also failed primary procedures (SWL, ureteroscopy), and with associated anatomic abnormalities (congenital, acquired, etc.)
- Access at same time as or prior to surgery:
- Sheath size as small as possible to allow for success of procedure and to accommodate flow of irrigant around scope
- Renal access: best access to stone burden.
  - Multiple tracts are safe.
  - Irrigation (saline): Warmed for children
- Postoperative management: Appropriate drainage; chest x-ray in recovery room (upper pole access)
- Complications:
  - Bleeding: Place tube (traction if necessary); embolize if significant
  - Perforation/extravasation: If significant, stop procedure and place nephrostomy tube

- Infection: Appropriate antibiotics; confirm patency of tube/stent
- Pleural effusion/pneumothorax: Chest tube, needle drainage
- Intestinal injury: Expectant management; colostomy tube

• Open/laparoscopic pyelolithotomy (rare): Large pelvic/staghorn stones

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

Adequate hydration to dilute urine

ONGOING CARE

PROGNOSIS

• Up to 50% of children will develop recurrent stones within 10 yr of initial occurrence, which is similar to rates in the adult population.
• The odds of recurrence is up to 5× higher in children with an identifiable metabolic abnormality.

COMPLICATIONS

Obstruction, infection, lost productivity, impaired renal function

FOLLOW-UP

Patient Monitoring

• Repeat 24-hr urine 3–4 mo after instituting therapy and if stone recurs after initial stabilization.
• Assess periodically for stone growth or new stone disease with US.

Patient Resources

National Kidney and Urologic Diseases Information Clearinghouse (NKUDIC).
http://kidney.niddk.nih.gov/kudiseases/pubs/stoneschildren/

CODES

ICD9

- 275.49 Other disorders of calcium metabolism
- 592.0 Calculus of kidney
- 592.9 Urinary calculus, unspecified

ICD10

- E83.52 Hypercalcemia
- N20.0 Calculus of kidney
- N20.9 Urinary calculus, unspecified

CLINICAL/SURGICAL PEARLS

- Kidney stones can occur at any age, even in premature infants.
- Most occur in teens, with teen girls having the highest incidence in adolescents.

UROLITHIASIS, RENAL

Aaron G. Boonjindasup, MD, MPH
Raju Thomas, MD, MHA, FACS

BASICS

DESCRIPTION

- Renal urolithiasis refers to kidney stones within the kidney itself (parenchyma, calyces or renal pelvis. The majority of stones inthe urinary tract have their origin in the kidney.
- Renal urolithiasis is a significant cause of patient renal morbidity and a major source of medical costs in the UnitedStates.
- Calcium oxalate stones most common; also uric acid, struvite (magnesium ammonium phosphate), calcium phosphate, cystine, etc.

EPIDEMIOLOGY

Incidence

- Estimated to be 10–15% in the United States
- Males are affected 2–3× more than females
- Peak incidence: 4th–6th decades
- More common in Southeast, Southwest, and Northwest United States.
- Increasing incidence with increased obesity
- Accounts for 7–10 of every 1000 hospital visits

Prevalence

Highest prevalence in Caucasians

RISK FACTORS

- Calcium stone formation
  - Dietary excess
  - Hyperparathyroidism
  - inappropriate loss of calcium in urine through renal tubules
  - Excessive intestinal absorption
  - Inadequate levels of stone inhibitors in urine
  - Sarcoidosis
  - Multiple myeloma
  - Leukemia
- Uric acid stone formation
  - Purine excess
  - Gout
  - Myeloproliferative disorders
  - Chronic dehydration
  - Lesch–Nyhan syndrome
  - Ingestion of uricosuric drugs
- Struvite stones
  - UTI with urease-splitting organisms (*Proteus*, *Klebsiella*, etc.)

- Alkalinizes urine and magnesium ammonium phosphate crystallization
- Cystine stones
  – Inherited disorder of renal tubular reabsorption of cysteine (See Urolithiasis, Cystine)

Genetics

- In general, urolithiasis associated with polygenic defect and partial penetrance
  – Cystinuria: Homozygous recessive
- Renal tubular acidosis (RTA): Inherited

PATHOPHYSIOLOGY

- Supersaturation: Urine oversaturated with certain types of crystal, which then is precipitated out of solution.
  – Saturation level is variably pH dependent based on crystal type
- Inhibitor deficiency: Inhibitors may limit crystal growth and aggregation
  – Urinary citrate and magnesium are inhibitors
- Non-infection stones: Calcium oxalate, calcium phosphate (brushite, carbonate apatite), uric acid
- Infection stones: Magnesium ammonium phosphate (struvite), carbonate apatite, ammonium urate
- Genetic defects: Cystine, xanthine, 2,8-dihydroxyadenine (DHA)
- Drug stones: Indivavir, triamterene, others

ASSOCIATED CONDITIONS

- Congenital malformations or anatomic variations of kidney, collecting system, ureter, or bladder may predispose patient to urolithiasis due to stasis and/or impaired urine drainage
- Crohn disease
- Dehydration
- Gout
- Inflammatory bowel disease
- Intestinal bypass
- Medullary sponge kidney
- Renal tubular acidosis

GENERAL PREVENTION

- Decreased sodium intake
- Diuretics
- Encourage fluid intake; avoid dehydration
- Increase urinary citrate
- Reduce dietary protein (purine) if at-risk
- Restrict oxalate consumption

DIAGNOSIS

HISTORY

- Acute onset of severe pain
  – Partially obstructive stones have more chronic, mild to moderate pain
  – Pain radiates to groin or lower abdomen

- Gross hematuria
- Previous history of kidney stones or UTIs
- Family history of urolithiasis
- Changes in urination patterns

PHYSICAL EXAM
- CVA tenderness
  - Moderate, deep tenderness in flank radiating to groin
  - Great tenderness suggests pyelonephritis
- Fever present if associated infection

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urinalysis
  - Microscopic hematuria
    - Unless complete obstruction
    - Crystalluria may provide important information regarding the type of calculus.
  - Pyuria
    - May suggest concomitant UTI
- Urine gram-stain and culture
  - Authors opinion: Catheterized urine specimen should be collected for urinalysis, gram-stain, and culture in all female patients under consideration for surgical intervention
- CBC
  - Leukocytosis: Suggests secondary infection
- Basic metabolic profile
  - Elevated creatinine
    - May be present if bilateral obstruction present
  - Calcium level
  - Glucose: Impaired glycemic control in patients with diabetes especially in setting of infection

Imaging
- Non-contrast low-dose helical computed tomography (CT)
  - Rapid study
  - 1st-line test with acute renal colic
  - Can determine degree of hydronephrosis, size, and location of stones
- Intravenous pyelogram (IVP)
  - Requires IV contrast
  - Delayed x-rays needed if high-grade obstruction present
  - Some stones radiolucent—not visible on IVP
  - Can provide some assessment of renal function
- Ultrasound
  - Non-invasive, 1st-line evaluation for in patients at risk for X-ray exposure
    - Children, pregnant females
    - Operator-dependent
  - Difficult to visualize ureter in adult

- Resistive index (>0.7) suggestive of obstruction in the setting of acute obstruction
- Ureteral Jets—Presence does not rule out partial obstruction

Diagnostic Procedures/Surgery

- Retrograde pyelography
  - Invasive
  - Can assist concomitant surgical management

Pathologic Findings

- Hydronephrosis
  - Note degree and anatomic location of obstruction
  - Perinephric stranding on CT

DIFFERENTIAL DIAGNOSIS

- Abdominal aortic aneurysm
- Appendicitis
- Bowel obstruction
- Gastritis, pancreatitis, peptic ulcer
- Mesenteric ischemia
- Musculoskelet al back pain
- Pyelonephritis, urinary tract infection
- Cholecystitis or biliary colic
- UPJ obstruction
- Sloughed renal papilla

TREATMENT

ALERT

The presence of pyuria, fever, leukocytosis, or bacteriuria suggests the possibility of a urinary infection and the potential for an infected obstructed renal unit or pyonephrosis. Such a condition is potentially life-threatening and should be treated as a surgical emergency.

GENERAL MEASURES

- Hydration and adequate pain control
- Patients with likelihood of spontaneously passing a stone (<4–5 mm in size) in the absence of indication for surgical intervention may be sent home with analgesics and a trial of medical expulsive therapy (MET); (hydration, analgesia, symptomatic relief)
  - Should be instructed to return if pain worsens, or severe vomiting or fever
  - Likelihood of spontaneous stone passage is related to location and size of stone
  - Stones 2–3 mm: 80% probability of passing
  - Stones 4–5 mm: 50% probability of passing
  - Stones 7–8 mm: 20% probability of passing
  - Stones >1 cm: unlikely to pass spontaneously
- Controversy exists regarding maximum period of observation for partially obstructing stone without development of significant irreversible renal dysfunction; generally, within 4–6 wk.

- Indications for intervention:
  - Fever and/or infection
  - Intractable pain
  - Unable to tolerate oral fluid and at risk for dehydration
  - Progressive renal deterioration; obstruction of solitary functioning kidney
- All urinary tract infections should be treated with culture-sensitive antibiotics prior to surgical treatment

MEDICATION

First Line (1,2)

- Patients with evidence of active UTI should be treated with broad-spectrum antibiotics (eg, ampicillin and gentamicin, 3rd-generation cephalosporin).
- Antiemetic if acute colic is associated with nausea and vomiting.
- Medical expulsive therapy (MET):
  - α-Blockers (ie, terazosin, tamsulosin) or calcium-channel blockers (eg, nifedipine) can relax musculature of the ureter and lower urinary tract and can reduce pain associated with stone passage (tamsulosin 0.4 mg PO QD).
- Uric acid stones and cystine stones can be dissolved with medical therapy; calcium stones and struvite stones cannot be dissolved:
- Uric acid stones: Alkalinize urine with potassium citrate or bicarbonate, to maintain urinary pH between 6.5 and 7.0:
  - Urinary pH >7.5 can precipitate calcium phosphate with resulting stone formation.
  - May dissolve up to 1 cm per month
- Cystine stones: see Urolithiasis, Cystine

Second Line

N/A

SURGERY/OTHER PROCEDURES (3)

- Primary goal is to achieve maximal stone clearance with minimal morbidity.
- Patients with active UTI/sepsis: Obstructed kidney is drained by placement of ureteral stent or percutaneous nephrostomy tube.
- Preoperative urine culture should document no infection before stone removal:
- Calculi in kidney: Ureteroscopy vs. ESWL with or without stent placement (>1 cm)
- >2 cm: Percutaneous nephrolithotomy or if >1.5 cm in lower pole.
- Shock-wave lithotripsy (SWL)
  - Intrarenal calculus <2 cm
  - Relative contraindications
    - Stone > 2 cm
    - Within dependent or obstructed portions of collecting system
    - Body habitus/obesity that inhibits imaging and targeting of the stone
    - Lower pole stone
    - Uncorrected coagulopathy or recent anticoagulant use
- Ureteroscopy
  - Used for lower pole stones or stones resistant to SWL
  - Effective for treatment of cystine, calcium oxalate monohydrate, and brushite stones

- Percutaneous nephrolithotomy (PCNL)
  - Stones >2 cm; no bleeding diathesis or obesity
  - Staghorn calculi
- Laparoscopic and robotic stone surgery for large non-branching calculi
- "Sandwich technique"
  - SWL in combination with other modality

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

NA

Complementary & Alternative Therapies

NA

ONGOING CARE

PROGNOSIS

- The most important measure to avoid future stone episodes is increased fluid intake.
- Once patient has initial incident, 50% chance that in 5 yr will have recurrent calculus.
- Produce >2 L of urine/day
- 24-hr urine collection for metabolic analysis
- Stone fragment chemical analysis should be performed when possible
- Metabolic workup after 2nd episode

COMPLICATIONS

- Pyelonephritis
- Renal deterioration
- renal abscess formation
- Surgery carries standard risks of bleeding, infection, ureteral stricture.
- Pneumothorax with nephrostomy access

FOLLOW-UP

Patient Monitoring

- Oral hydration to make 2–2.5 L of urine/day
- Diet low in protein and sodium intake
- Dietary modification and medical intervention tailored to underlying metabolic abnormality can prevent recurrence of stones in 75% patients and significantly reduce new stone formation in up to 98% of patients.
- Restriction of oxalate-rich foods such as chocolate, nuts, soybeans, rhubarb, spinach, sweet potatoes, beets.
- Maintenance of adequate intake of dietary calcium

CLINICAL/SURGICAL PEARLS

Renal stones >1 cm are unlikely to pass spontaneously.

UROLITHIASIS, STAGHORN

Brian M. Benway, MD
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION

- Staghorn calculi are branched stones that occupy a large portion of the collecting system. Typically, they fill the renal pelvis and branch into several or all of the calices.
- Partial staghorn: Fills some but not all of the collecting system
- Complete staghorn: Fills nearly the entire collecting system
- Can be comprised of any of the following stone types, with struvite and calcium carbonate apatite the most commonly seen:
  - Struvite (magnesium ammonium phosphate)
  - Calcium carbonate apatite
  - Cystine
  - Uric acid
  - Calcium oxalate
  - Calcium phosphate
- Some literature refers to staghorn calculi as "coral calculi" or "coral nephrolithiasis" based on its characteristic shape.

EPIDEMIOLOGY

Incidence

- Not well-defined, with conflicting studies
- More common in women than in men

Prevalence

N/A

RISK FACTORS

- Chronic indwelling catheter
- Chronic infection
- Dehydration
- Metabolic disorders (hypercalciuria, cystinuria, hyperoxaluria)
- Neurogenic bladder
- Ureteral obstruction or reflux
- Urinary diversion

Genetics

N/A

PATHOPHYSIOLOGY

- Staghorn calculi are most frequently composed of mixtures of magnesium ammonium phosphate (struvite) and/or calcium carbonate apatite
  - These are also commonly referred to as "infection stones"

- Strong association with urinary tract infection caused by specific organisms that produce the enzyme urease that promotes the generation of ammonia and hydroxide from urea.

- Cystine or uric acid (pure form or mixed) can sometimes grow in a “staghorn” or branched configuration, but calcium oxalate or phosphate stones only rarely grow in this configuration.
- Urinary stasis due to obstruction or smooth muscle paralysis due to endotoxins
- Infection with urea-splitting organisms
  – Often harbored inside stones
  – Produce urease—hydrolyzes urea into ammonia, bicarbonate, and carbonate
    - *Proteus*
    - *Pseudomonas*
    - *Klebsiella*
    - *Staphylococcus*
    - *E. coli*
    - *Mycoplasma*
    - *Yeast*

ASSOCIATED CONDITIONS
- Chronic urinary tract infections
- Urinary tract obstruction
- Urinary diversion
- Neurogenic bladder

GENERAL PREVENTION
- Hydration
- Treatment of urinary tract infections
- Elimination of stones prior to evolution into staghorn calculus

DIAGNOSIS
HISTORY
- Often asymptomatic
- Discovered incidentally on imaging
- Recurrent or persistent urinary tract infection
- Fever, malaise, weight loss
- Renal insufficiency
- Flank pain
- Hematuria
- Neurogenic bladder
- Urinary diversion
- Metabolic disorders

PHYSICAL EXAM
- Costovertebral angle tenderness
- Rarely, palpable mass

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- CBC
- Basic metabolic panel
- PTT/INR
- Urinalysis and culture
  - pH >7.0 may indicate urea-splitting infection
  - Culture may demonstrate commonly associated bacteria
  - Persistence of a species may indicate a stone harboring infection

Imaging
- May be seen on KUB or ultrasound
- CT is gold-standard
  - Provides clear information on stone location and configuration
  - Evaluates cortical thickness
  - Can identify excluded calyces and calyceal diverticula
  - Provides information on location of surrounding structures
  - Aids selection of access site(s)

Diagnostic Procedures/Surgery
Diagnosis is made based on imaging studies

Pathologic Findings
- Gross pathology—calculus material
- Microscopic evaluation of crystals aids in determination of stone composition

DIFFERENTIAL DIAGNOSIS
- Blood clot
- Fibroepithelial polyp
- Fungus ball
- Granuloma
- Hemangioma
- Malakoplakia
- Renal cell carcinoma and other renal malignancy
- Tuberculosis
- Upper tract carcinoma (urothelial, other)
- Xanthogranulomatous pyelonephritis (XGP)

TREATMENT

GENERAL MEASURES
- Culture-specific antibiotic therapy
- Relief of obstruction in anticipation of later intervention (stent, percutaneous nephrostomy tube)
- Observation is associated with significant morbidity, including renal deterioration and septic events. Only appropriate for patients who would not tolerate definitive intervention

MEDICATION
First Line

Culture-specific antibiotics

Second Line

- Acetohydroxamic acid
  - May reduce recurrence of struvite stones
  - Inhibits bacterial urease, decreasing urinary ammonia production
  - Adult dose: 12 mg/kg/d PO, 3–4 times a day on empty stomach. 1.5 g/d maximum.
  - Pediatric dose: 10 mg/kg/day titrated
  - May have severe side effects including deep venous thrombosis, myelosuppression, hepatotoxicity, palpitations, edema, nausea, vomiting, diarrhea, headache, loss of taste sensation, hallucinations, rash, abdominal discomfort
  - Must follow CBC and liver functions
  - Contraindicated in patients with severe renal insufficiency (serum creatinine >2.5 mg/dL)

SURGERY/OTHER PROCEDURES

- Goal is complete elimination of stone burden
- Percutaneous nephrolithotomy (PCNL) is gold-standard (1)
- Shockwave lithotripsy (SWL) is not recommended as monotherapy for most staghorn calculi
- If combination SWL and PCNL or "sandwich" therapy is performed, PCNL should be the last intervention
- SWL monotherapy can be considered for small stones (<500 mm^2), provided a ureteral stent or nephrostomy tube is placed. May also be used in pediatric patients.
- Open surgery is not commonly performed. May be used in extraordinary cases where clearance is not expected within a reasonable number of less-invasive procedures
- Nephrectomy for kidneys with negligible function or Xanthogranulomatous pyelonephritis (XGP)
- Dissolution may be effective in carefully selected patients, but has the potential for significant side effects. It is not presently included in the guidelines for staghorn management.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Prophylactic antibiotics to suppress UTI

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Observation associated with significant risk of renal deterioration (28–48%) (2,3)
- Good prognosis for patients who are rendered stone-free

COMPLICATIONS

- Observation

  - Death
  - Functional renal loss
  - Pyelonephritis
  - Sepsis
- Intervention
  - Anesthesia complications
  - Death
  - Hematoma
  - Hemorrhage
  - Injury to colon, liver, spleen
  - Pneumothorax/hydrothorax
  - Upper tract injury
  - Urinary fistula
  - Urinoma

FOLLOW-UP

Patient Monitoring

- KUB and ultrasound at regular intervals
- Urinalysis and culture
- Consider metabolic evaluation (serum studies, 24-hr urine study)

Patient Resources

- N12 Tubulo-interstitial nephritis, not spcf as acute or chronic
- N20.0 Calculus of kidney
- N39.0 Urinary tract infection, site not specified

CLINICAL/SURGICAL PEARLS

- Staghorn calculi are large branching renal calculi most often associated with urinary tract infections.
- Observation carries a high risk of morbidity, including renal deterioration and sepsis.
- Percutaneous nephrolithotomy is the gold-standard for treatment.

UROLITHIASIS URETERAL

Mohamed S. Ismail, MBChB, MRCS, PhD
Francis Xavier Keeley, Jr., MD, FRCS

BASICS

DESCRIPTION

- Ureteral urolithiasis refers to a stone present in the ureter.
- Ureteral stones usually pressent with severe colicky pain that radiates from the loin (flank) to the groin as the stone passes to the lower ureter. Ureteral stone can cause obstructive uropathy as well as urosepsis which are a clinical emergency.
- Stone composition:
  - Calcium oxalate 85%
  - Uric acid 5–10%
  - Calcium phosphate and oxalate 10%
  - Struvite (infection stones) 2–20%
  - Cystine 1%

EPIDEMIOLOGY

Incidence

- The incidence of ureteral stones is increasing worldwide
- 116 affected individuals per 100,000 in the United States
- Peak incidence reported age ranging from 40 to 49 yr
- Prevalence rates decrease in women over age 59 yr and men over age 69 yr
- 2.3% for women and 7% for men
- White > Hispanics > Asian > Blacks

Prevalence

The prevalence of stone disease in the United States is 5.2% which has doubled since the 1960s.

RISK FACTORS

- Genetic and environmental factors
- Diet and climate have the most significant impact on the prevalence
- Males are 3 times more affected than females
- Diet: Dehydration, high animal protein, high salt diet, vitamin D (too much?), vitamin C and (low?) calcium consumption
- Obesity, metabolic syndrome
- Previous history of stone formation
- Urinary tract infection: urease producing bacteria such as Proteus
- Family history: 3 times normal risk
- Drugs: Chemotherapy, corticosteroids
- Hot climate

Genetics

- Stone formation is common in Caucasian and Asians.
- 25% of kidney stone patients report a family history of stone disease
- Familial renal tubular acidosis and cystinuria predispose for stone formation

PATHOPHYSIOLOGY

- Supersaturation: The urine is supersaturated with salts when the concentration of the salt exceeds its solubility product (K_{sp}). Beyond this point crystallization start to form. The concentration at which crystallization occurs is called formation product (K_f).
- Supersaturation depends on urinary PH, ionic strength, solute concentration, and complexation.
- Inhibitors of crystallization: The presence of inhibitors allows urine to hold more solute in solution, inhibiting stone formation
  - Calcium oxalate: Absorptive hypercalciuria, resorptive hypercalciuria, renal hypercalciuria, hypercalcemia, hyperuricosuria, hyperoxaluria, hypocitraturia, enteric hyperoxaluria
  - Uric acid stones: Gout, myeloproliferative disorders, idiopathic uric acid stones, chemotherapy
  - Calcium phosphate and oxalate stones: Distal renal tubular acidosis
  - Struvite stones: Occur as a result of infection with urease-producing bacteria that breakdown urea into ammonia
  - Cystine stones: Occur in patients with cystinuria an autosomal recessive disorder resulting in reduced absorption of cystine from the proximal tubules
  - Medication stones (rare): Triamterene, indinavir.

ASSOCIATED CONDITIONS

- Primary hyperparathyroidism
- Medullary sponge kidney/nephrocalcinosis
- Distal (type 1) renal tubular acidosis
- Chronic diarrheal states: GI surgery: gastric bypass/banding, small bowel resection
- Gout
- Sarcoidosis
- Primary hyperoxaluria
- Cystinuria

GENERAL PREVENTION

- Adequate hydration
- Low protein diet
- Reduce dietary salt
- Allopurinol for uric acid stones
- Alkalinization of urine using potassium citrate
- Restrict oxalate consumption

DIAGNOSIS

HISTORY

- Acute onset colicky pain that radiates from the loin to the groin

- Patient moves around trying to find a comfortable position
- Lower ureteral stone pain may radiate to the tip of the penis
- Microscopic haematuria and very rarely macroscopic haematuria
- Previous history of renal stones
- Urinary frequency, urgency, and urinary incontinence are associated with lower ureteral stones

ALERT
Obstructed infected kidney is a clinical emergency.

PHYSICAL EXAM
- The most important aspect of examination of patient with ureteral stone is core body temperature.
- Abdominal examination may reveal tenderness.
- Urosepsis is associated with high temperature, low blood pressure, and tachycardia.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CBC to test for underlying infection (See General Measures).
- Serum creatinine to detect renal impairment.
- Urine analysis: To check for hematuria, nitrite, and leukocytes.
  – Up to 30% of patients with ureteral stones have no blood in their urine.

Imaging
- Computed tomography: Non-contrast spiral CT is the imaging of choice for patient with suspected ureteral stone.
- Intravenous urography: Can document renal anatomy.
- X-ray KUB: Only in radio opaque stones. Most practical for conservative management.
- Ultrasound:
  – Operator dependent. Very useful in pregnancy, patients with contrast allergy and children. Can miss small kidney stones. Normal examination does not rule out ureteral stone since hydronephrosis is a relatively late finding.
- MR urography: May be used to diagnose Ureteral stones due to ureteral dilatation, but stones usually not well seen. Cost and availability also limit its routine use.

Diagnostic Procedures/Surgery
Retrograde pyelography: Occasionally used in the diagnosis. Is used in conjunction with ureteroscopy.

Pathologic Findings
Depend on stone composition

DIFFERENTIAL DIAGNOSIS
- Abdominal aortic aneurysm
- Acute appendicitis
- Acute cholecystitis
- Pancreatitis
- Peritonitis

- Pyelonephritis
- Renal cell carcinoma
- Upper-tract TCC
- Ureteropelvic junction obstruction

TREATMENT

GENERAL MEASURES

- Ureteral calculi which are associated with renal impairment and/or signs of infection are indication for emergency treatment with broad-spectrum antibiotics and decompression of the renal tract.
- Infected stones warrant close observation to limit morbidity and mortality. Systemic inflammatory response syndrome (SIRS) is the earliest manifestations of the continuum leading to sepsis and shock and these patients require intensive monitoring. These criterion for SIRS include 2 or more of the following (1):
  - Temperature $>38^{\circ}C$ or $<36^{\circ}C$
  - Heart rate >90 BPM
  - Respiratory rate >20 breaths/min
  - WBC $>$ 12,000/mm^3 or $<4000/mm^3$ or $>10\%$ bands
- Mortality is improved with decompression of an infected system (ureteral or percutaneous nephrsotomy tube [PCNT]) (2).
- Watchful waiting: Small ureteral stones will pass spontaneously and do not require any intervention (see rate of spontaneous stone passage).
- Indication of conservative management:
  - Stone size less than 10 mm
  - Well-controlled pain
  - No clinical evidence of infection
  - Adequate renal function reserve
- Spontaneous passage of stone depends on the stone size, shape, location, and associated ureteral edema
  - 68% of stones 5 mm or less pass spontaneously
  - 47% of stones 6–10 mm in diameter
  - $>$ 10 mm unlikely will pass
- Average stone passage time is 3 wk, stone has not passed within 2 mo is unlikely to pass.

MEDICATION

First Line

- Pain control: Nonsteroidal anti-inflammatory drugs, or opiate analgesia.
- Antiemetics: If the acute pain is associated with nausea and vomiting.
- Treat dehydration and avoid excessive fluid intake as it may increase discomfort.
- Broad-spectrum empiric antibiotic in the presence of infection, modified based on culture
  - 3rd-generation cephalosporin, or a fluoroquinolone (ciprofloxacin, levofloxacin)
  - Aminoglycoside or a carbapenem with high rate of fluoroquinolone resistance.
  - For hospital-acquired urosepsis following urologic interventions, an antipseudomonal 3rd-generation cephalosporin or piperacillin/β-lactamase inhibitor in combination with an

aminoglycoside or a carbapenem.
- Ureteroscopy: Fluoroquinolone, trimethoprim sulfamethoxazole, or aminoglycoside ± ampicillin or 1st/2nd-generation cephalosporin or amoxicillin/clavulanate (3).
- Percutaneous nephrolithotomy (PCNL): 1st/2nd-generation cephalosporin, or aminoglycoside + metronidazole or clindamycin or aminoglycoside/sulbactam or fluoroquinolone (3)

Second Line
- Medical expulsive therapy: α1-adrenergic adrenoceptor blockers (such as tamsulosin) cause smooth muscle relaxation and increase spontaneous stone passage rate by 1/3. However, it is not licensed yet for this purpose. It is contraindicated in the presence of infection.
- Oral chemolysis: High fluid intake and alkalinization of urine with potassium citrate is indicated in uric acid and cystine stones.

SURGERY/OTHER PROCEDURES
- Extracorporeal shock wave lithotripsy (ESWL): Using ultrasound shock wave to fragment the stone. The efficacy is related to the stone size and location. The clearance rate for stone <10 mm in the upper ureter is >80%
- Ureteroscopy and endoscopic lithotripsy: Has a higher clearance rate for upper ureteral stones >10 mm and all mid Ureteral and distal ureteral stones compared to ESWL.
- There are no significant differences between ESWL and ureteroscopy and the use of either treatment depend on local resources.
- Other treatment modalities such as percutaneous nephrolithotomy, open ureterolithotomy, laparoscopic ureterolithotomy are rarely used.
- The presence of infection requires emergency management Antibiotics with urinary diversion (stent or PCNT).

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Prevention of further stone formation (see general prevention)

Complementary & Alternative Therapies

No alternative or complementary medications have been shown to be beneficial

ONGOING CARE

PROGNOSIS
- The prognosis of ureteral calculi is excellent.
- Patient with recurrent stone formation needs metabolic workup.

COMPLICATIONS
- Infection, bleeding, and pneumothorax are the complications of the treatment
- Multiorgan failure
- Renal impairment
- Urosepsis

FOLLOW-UP

Patient Monitoring

- Patient is followed to detect any further stone formation
- Prevention measures to avoid further stone formation (see general prevention)
- Patients with septic stone picture require at least 14 days of culture appropriate antibiotics

Patient Resources

CODES

ICD9

- 592.1 Calculus of ureter
- 599.0 Urinary tract infection, site not specified
- 599.60 Urinary obstruction, unspecified

ICD10

- N13.9 Obstructive and reflux uropathy, unspecified

- N20.1 Calculus of ureter
- N39.0 Urinary tract infection, site not specified

CLINICAL/SURGICAL PEARLS

- In the setting of an infected obstructing ureteral calculus, there is no significant difference in outcome whether stented or treated by percutaneous drainage.
- Recent studies suggest that in unstable patients with very large stone burdens percutaneous drainage may be preferred.

UROLITHIASIS, URIC ACID

Aaron G. Boonjindasup, MD, MPH
Raju Thomas, MD, MHA, FACS

BASICS

DESCRIPTION
- Urinary stones that are composed primarily of uric acid and can be found anywhere in the urinary tract.
- Uric acid usually precipitates in acidic urine.

EPIDEMIOLOGY
Incidence
Account for 5–10% of all urinary tract stones

Prevalence
1/1000 adults

RISK FACTORS
- Persistent acidic urine is most important pathogenic factor.
- Strenuous exercise, dehydration
- Bowel related:
  - Crohn disease, regional ileitis
  - Ulcerative colitis, ileostomy, short bowel syndrome
- Hyperuricosuria, gout
  - Uric acid nephrolithiasis occurs in 10–25% of patients with gout
- Purine gluttony
- Inborn errors of metabolism
  - Lesch–Nyhan syndrome
    - Hypoxanthine guanine phosphoribosyl transferase deficiency (HGPRT)
  - Phosphoribosylpyrophosphate synthetase overactivity
  - Glucose-6-phosophate deficiency
- Myeloproliferative states
  - Neoplasia
  - Leukemia
  - Hemolytic anemia
  - Chemotherapy
- Decreased urinary volume
- Diabetes associated with metabolic syndrome

Genetics
Autosomal dominant for familial variant

PATHOPHYSIOLOGY (1)
- Uric acid crystallization caused by the supersaturation of urine with respect to undissociated uric acid.

- Free uric acid is 20× LESS soluble in urine than urate salt.
- At a pH of 5.35, ½ of the uric acid is a urate salt and ½ is free uric acid.
- At pH of 6.5, 90% of the uric acid is soluble.
- Uric acid may serve as a nidus.
  - Calcium oxalate stone formation
- Acute and chronic nephropathy due to uric acid crystals in renal tubules
  - May be related to hyperuricemia or gout
- Uricase—enzyme that converts uric acid to allantoin
  - Allantoin—10 to 100× more soluble in urine than uric acid
- Relationship between obesity, diabetes, and the metabolic syndrome
  - Causes of low urinary pH.
  - Low urinary pH in turn is the major urinary risk factor for uric acid stones
- High plasma uric acid (UA) is a precipitating factor for gout and renal calculi as well as a strong risk factor for metabolic syndrome and cardiovascular disease.

ASSOCIATED CONDITIONS

- Obesity with insulin resistance (metabolic syndrome)
  - High waist circumference and BMI are associated with higher insulin resistance and leptin production; both reduce uric acid excretion.
- Myeloproliferative disorders
- Congenital disorders
  - Lesch–Nyhan syndrome
- Gout
- Inflammatory bowel disease

GENERAL PREVENTION

- Low purine diet in at-risk population
- Encourage fluid intake

DIAGNOSIS

HISTORY

- Acute presentation of urolithiasis
  - Pain, fever, chills, nausea, vomiting
- Purine gluttony
  - Diet high in red meats, fish, poultry
- Dehydration
  - Poor urine output
  - Poor urine volume
- Gout
  - Up to 20% of patients will have uric acid calculi
- Family history of uric acid stones
- Short bowel syndrome, inflammatory bowel disease, ileostomy
- History of myeloproliferative disorders

PHYSICAL EXAM

Costovertebral angle (CVA) tenderness

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum uric acid level may be normal or elevated
  - >380 μmol/L or 6.4 mg/100 mL
  - Latent hyperuricemia may require purine loading test
- Urinalysis
  - pH: Acidic. Generally <5.8
  - Crystals: Coffin-lid crystals
- 24-h urine collection for uric acid
  - Volume <2 L/d
  - pH <6.0
  - Uric acid >4.0 mmol/d
  - Can often underestimate the total amount of uric acid of pH drops lower than 5.5

Imaging

- Non-contrast abdominal spiral computed tomography (CT): Gold standard
- Plain x-ray Kidneys, ureters, bladder (KUB)
  - Uric acid stones are often RADIOLUCENT (noncalcified); plain film often not useful
- Renal ultrasound
- Intravenous (IV) urogram

Diagnostic Procedures/Surgery

- Stone analysis
- 24-hr urine collection for uric acid

Pathologic Findings

- Long-term deposition of crystals in the renal parenchyma can cause chronic urate nephropathy.
- Microtophi cause giant-cell inflammatory reaction
  - Proteinuria
  - Inability of the kidney to concentrate urine
- May have orange appearance when viewed endoscopically

DIFFERENTIAL DIAGNOSIS

- Other renal calculi
  - Calcium oxalate monohydrate
  - Calcium oxalate dehydrate
  - Cysteine
  - Struvite
- Filling defect if IV urogram is obtained
  - Urothelial neoplasm
  - Blood clot
  - Fungus ball
  - Sloughed renal papilla
  - Stricture
- Bladder calculi
  - 50% consist of uric acid

TREATMENT

GENERAL MEASURES (2)

ALERT
- During alkalinization, do not allow urinary pH to chronically rise above 7.0.
- This may cause precipitation of other urinary calcium salts (heterogenous nucleation/epitaxy).

- Acute renal colic should be treated accordingly (see Section I "Urolithiasis, adult, general considerations")
- Uric acid stones are often amenable to medical therapy
  - Low-protein/low purine diet
  - >2 L fluid intake/day
  - Alkalinization of urine
- Medical therapy should only be initiated in moderately symptomatic or asymptomatic patients

MEDICATION

First Line (3)

- Potassium citrate 30–60 mEq/d
  - Urine alkalinization
  - Goal is pH between 6.0 and 7.0
    - Do not exceed 7.0, may precipitate other stones
  - May require 3–4 mo to dissolve stone
  - Requires patient to monitor urine pH daily with Nitrazine paper or pH paper
- Sodium bicarbonate 650 mg q6–8h
  - May cause high sodium load

Second Line

- Allopurinol 100–600 mg/d
  - Hyperuricemia or urinary uric acid secretion >100 mg/d
  - Inhibits conversion of hypoxanthine and xanthine to uric acid
  - Use if failed urine alkalinization
  - Add to PO alkalinization
  - SE: Skin rash, fever, acute attack of gout

SURGERY/OTHER PROCEDURES

- Dependent on size and position of stone
  - Extracorporeal shock wave lithotripsy (ESWL)
  - Ureteroscopy with lithotripsy
  - Percutaneous nephrolithotomy
- Rarely
  - Open/laparoscopic nephrolithotomy
  - Alkaline irrigation via nephrostomy tube

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Treat underlying illness
- Evaluate for and treat gout if elevated serum uric acid
- Correct metabolic syndrome though diet and weight reduction
- Febuxostat a relatively new xanthine oxidase inhibitor (80 mg daily) has been used in the management of hyperuricemia in patients with gout with limited information on uric acid stones. It can reduce uric acid excretion.

Complementary & Alternative Therapies

- Foods rich in urate should be restricted in patients with uric acid stone disease.
- The intake of urate should not exceed 500 mg/d.

ONGOING CARE

PROGNOSIS

Dependent on etiology and stone characteristics

COMPLICATIONS

- Sepsis
- Obstructive nephropathy

FOLLOW-UP

Patient Monitoring

- Urinalysis
  – pH, crystals, red blood cells (RBCs)/white blood cells (WBCs)
- Follow stone size with US or low-dose CT every 3–6 mo on medical therapy

Patient Resources

- Urology Care Foundation: Kidney and Ureteral Stones. http://www.urologyhealth.org/urology/index.cfm?article=148

CODES

ICD9

- 274.11 Uric acid nephrolithiasis
- 592.0 Calculus of kidney
- 790.6 Other abnormal blood chemistry

ICD10

- E79.0 Hyperuricemia w/o signs of inflam arthrit and tophaceous dis
- N20.0 Calculus of kidney
- N20.9 Urinary calculus, unspecified

CLINICAL/SURGICAL PEARLS

- Common conditions that increase the risk of uric acid stone formation: gout, chronic diarrhea, diabetes, and metabolic syndrome.
- Uric acid stones are often radiolucent (noncalcified); therefore, plain film often not useful.
- Non-contrast abdominal spiral computed tomography (CT) is considered the gold standard for imaging urolithiasis including uric acid stones.
- The metabolic syndrome causes low urinary pH which in turn is a major urinary risk factor for uric acid stones.
- Alkalinization can dissolve uric acid calculi.

UROSEPSIS

Christopher Amling, MD, FACS
Nick Cowan, MD

BASICS

DESCRIPTION

- Sepsis is the systemic inflammatory response syndrome (SIRS) with associated infection, and urosepsis identifies the source of the infection as originating somewhere in the urinary tract.
- International Sepsis Definitions Conference definitions:
  - SIRS: 2 or more of the following:
    - Temperature >38°C or <36°C
    - Heart rate >90 beats/min
    - RR >20 breaths/min or $PaCO_2$ <32 mmHg
    - WBC >12,000 cells/mL or <4,000 cells/mL or >10% bands
  - Sepsis:
    - SIRS in response to a suspected or proven infection
  - Severe sepsis: Sepsis-induced tissue hypo-perfusion or organ dysfunction (any of the following thought to be due to infection):
    - Sepsis induced hypotension
    - UOP <0.5 mL/kg/hr for more than 2 hr despite adequate resuscitation
    - Lactate above upper limits normal
    - Acute mental status changes
    - Platelets <100,000 cells/mL
    - Acute lung injury/ARDS
  - Septic shock: Sepsis-induced hypotension despite adequate fluid resuscitation, along with signs of hypoperfusion
- Differentiate SIRS and sepsis
  - Noninfectious processes (such as acute pancreatitis) may also be complicated by tissue injury secondary to the inflammatory system.
  - SIRS refers to the dysregulated host inflammatory response in the absence of infection.
  - It is essential to distinguish an underlying disease (infection or non-infection) and the host response (sepsis or SIRS).
- It is estimated that UTIs account for 5% of severe sepsis cases.

EPIDEMIOLOGY

Incidence

- Sepsis occurs in >1.6 million patients in the United States annually, with an estimated incidence of 240 cases per 100,000 population.
- Patients aged ≥65 yr account for nearly 60% of all episodes of severe sepsis.

Prevalence

N/A

RISK FACTORS

- Advanced age (≥65 yr)
- Diabetes, malignancy, immunosuppression, cachexia, immunodeficiency, alcoholism
- Obstructive uropathy: BPH, prostate cancer, stricture, urolithiasis, neurogenic bladder disorders, retroperitoneal masses and fibrosis, sloughed papilla, endometriosis
- Abnormal/congenital anatomy: ureteropelvic junction obstruction, polycystic kidneys, ureterocele, vesicoureteral reflux, phimosis
- Inflammatory/infectious diseases:
  - Pyelonephritis, acute bacterial prostatitis, renal abscess, perinephric abscess, epididymo-orchitis, Fournier gangrene
- Precipitating interventional/nosocomial events resulting in bacteremia and subsequent urosepsis:
  - Indwelling catheters, urologic instrumentation/surgery such as prostate biopsy, transurethral surgery

Genetics

Genetic factors are known to be major determinants of susceptibility to death from infectious disease.

PATHOPHYSIOLOGY

- Sepsis is a systemic, deleterious host response to infection leading to severe sepsis and septic shock.
- The most common etiology of urosepsis is secondary to a bacterial infection with *Escherichia coli, Proteus* sp., *Enterobacter* and *Klebsiella* sp., *and Pseudomonas aeruginosa*
- Obstruction in an infected urinary tract further contributes to the development of sepsis.
- Primary initiator of gram-negative bacteria septic shock is endotoxin, a lipopolysaccharide component of the bacterial cell membrane.
- Exotoxins released by some bacteria can initiate septic shock:
  - However, the bacteria themselves and cell wall components are primarily responsible for the development of septic shock.
- The intravascular activation of inflammatory systems results in overproduction of cytokines such as tumor necrosis factor (TNF) and IL-1.

ASSOCIATED CONDITIONS

- Acute pyelonephritis
- Lower UTI
- Urolithiasis
- Urologic procedure/instrumentation

GENERAL PREVENTION

- Urine culture and appropriate antibiotic coverage prior to urologic procedure
- To further reduce incidence of nosocomial UTI: remove Foley as soon as it is no longer needed, use aseptic insertion technique, maintain unobstructed flow, use closed urinary drainage systems (1)[B].

DIAGNOSIS

HISTORY

- A thorough history should be obtained, with emphasis on identifying the primary etiology:
  - Classic presentation of fevers, chills, followed by hypotension seen in only ~30% of patients.
- A history of hydronephrosis, urolithiasis, flank pain, UTIs, immunocompromised status, urinary retention, and recent urologic instrumentation/procedure is common.
- Evaluate for mental status changes.

PHYSICAL EXAM

- Emphasis on identifying the primary source of the infection
- Most common findings: Hyper thermia, hypothermia, tachycardia, tachypnea, and hypotension
- Earliest signs of sepsis may be increased respiratory rate with respiratory alkalosis.
- Examine for all urologic and non-urologic sources of bacteremia:
  - Purulent subcutaneous fluid collections; chest exam; costovertebral angle tenderness; abdominal or suprapubic tenderness; examine of the scrotum, testis, perineum; prostatic fluctuance; extremities for tenderness or swelling.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC with differential: Usually shows elevated WBC count with elevated neutrophil count.
  - Patients may also have neutropenia
- Basic metabolic panel (BMP), liver finction tests (LFT's), lactate: May show evidence of end-organ dysfunction
- Blood, urine, and wound culture with a Gram stain for preliminary identification:
  - If possible obtain 2 sets of blood cultures before starting empiric antibiotics
  - Specific organisms causing sepsis are identified in about half of patients

Imaging

- Obtain based on presumptive initiating event and clinical symptoms
  - US can quickly evaluate for hydronephrosis
  - CT scan can evaluate for stones, fluid collections and gas within tissues

Diagnostic Procedures/Surgery

Diagnostic procedures should be tailored to identifying the initiating event.

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Upper urinary tract source:
  - Emphysematous pyelonephritis
  - Pyelonephritis, pyonephrosis
  - Renal and perirenal abscess
  - Xanthogranulomatous pyelonephritis
- Lower urinary tract source:
  - Acute bacterial prostatitis
- External genitalia:

- Epididymitis/orchitis
- Fournier gangrene
- Pyoderma gangrenosum
- Testicular abscess

• Common non-urologic causes of sepsis:
- Central lines
- Empyema, pneumonia
- Endocarditis, mediastinitis
- Prosthetic device infection
- Intra-abdominal processes: Pancreatic infection, cholecystitis, cholangitis, peritonitis, diverticular/appendiceal/tubo-ovarian abscess
- Septic arthritis
- Soft-tissue infection

• Noninfectious conditions that mimic sepsis:
- Acute adrenal insufficiency
- GI bleed
- Myocardial infarction
- Pancreatitis
- Pulmonary embolus
- Transfusion reactions

TREATMENT

GENERAL MEASURES

• Early goal-directed therapy, "Rivers protocol":
- Goal MAP ≥65 mmHg, CVP 8–12 mmHg, UOP ≥0.5 mL/kg/hr
- Start empiric IV antibiotics (ABX) within 1 hr. of recognition of severe sepsis or septic shock
- Volume expansion with isotonic fluids
- Supplemental oxygen with or without intubation and assisted ventilation if indicated
- Vasoactive drugs to achieve hemodynamic goals (norepinephrine preferred to dopamine)
- Maintain glycemic control
  - Keep glucose <180 mg/dL as intensive glycemic control (80–110 mg/dL) has shown either no change or increased mortality, and increased rates of hypoglycemia (2)[A]

ALERT
Autopsy studies in persons who died in the ICU show that the failure to diagnose and treat infections with antibiotics or surgical drainage is the most common avoidable error.

MEDICATION

First Line (3)

• Broad-spectrum antibiotic coverage (against both gram-positive and gram-negative bacteria) should be instituted immediately.

• Nosocomial urosepsis monotherapy:
- Piperacillin/tazobactam, imipenem, or meropenem

  – Add vancomycin if MRSA a concern
• Monotherapy for urosepsis due to aerobic gram-negative bacilli:
  – Aztreonam: 2 g IV q6–8h; max 8 g/d
  – Levofloxacin: 500 mg IV q24h
  – 3rd-generation cephalosporins:
    ◦ Ceftriaxone: 1–2 g IV q12–24h
    ◦ Cefotaxime: 2 g IV q6–8h
    ◦ Ceftazidime: 500 mg IV q8–12h
  – 4th-generation cephalosporin:
    ◦ Cefepime: 2 g IV q12h
• Monotherapy for suspected enterococci (*E. faecalis*) urosepsis: Ampicillin or vancomycin (penicillin-allergic).
• Community-acquired urosepsis infection:
  – Levofloxacin, aztreonam, or an aminoglycoside plus ampicillin
• Fournier gangrene:
  – Piperacillin/tazobactam 3.375 IV q6h, add vancomycin 1 g IV q12h if MRSA suspected
  – Imipenem: 500–1,000 mg IV q6h for polymicrobial coverage.
  – Clindamycin: 600–900mg IV q8hr for anaerobic coverage if *Clostridia* are suspected (to block toxin production)

Second Line
• Reassess antimicrobial regimen daily and deescalate when sensitivity results are available.
• Switch to PO ABX when clinically stable for at least 48 hr and usually complete a 7–10 day course based on the cause of the infection.

SURGERY/OTHER PROCEDURES
• Patients should undergo surgical drainage of purulent collections, debridement of necrotic tissue, and relief of urinary tract obstruction.
• Retrograde ureteral catheterization and percutaneous nephrostomy effectively relieve obstruction and infection due to ureteral calculi
  – Neither modality has demonstrated superiority in promoting a more rapid recovery

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
• Definitive correction of any correctible factors when patient stabilized
• Corticosteroid use in sepsis is complex and current data do not show improved survival in severe sepsis

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
• Mortality rates associated with severe sepsis and septic shock are 25–30% and 40–70%,

respectively.
- Factors associated with a higher risk of mortality from sepsis: Fever, WBC count, serum creatinine, diabetes mellitus, lactate, and albumin.

ALERT
Mortality rate decreased by 42% when early goal-directed therapy achieved within the first six hours for severe sepsis and septic shock.

COMPLICATIONS
Renal insufficiency, hepatic dysfunction, end organ failure, cardiac events, death

FOLLOW-UP
Patient Monitoring
- Patient should be continued on appropriate ABX coverage for 7–10 days, longer if needed.
- Repeat cultures can be obtained to ensure treatment is adequate.

Patient Resources
International Sepsis Forum: Understanding Sepsis.

CODES

ICD9

- 599.0 Urinary tract infection, site not specified
- 785.52 Septic shock
- 995.92 Severe sepsis

ICD10

- N39.0 Urinary tract infection, site not specified
- R65.20 Severe sepsis without septic shock
- R65.21 Severe sepsis with septic shock

CLINICAL/SURGICAL PEARLS

- Early goal-directed therapy guided by invasive monitoring (mean arterial pressure [MAP], central venous pressure [CVP] and urine output [UOP]) within the first 6 hours after recognition or sepsis.
- Blood culture x2 prior to antibiotics if possible.
- Start empiric ABX within 1 hour of recognition of severe sepsis or shock.
- Initial fluid resuscitation with crystalloid.

UROSTOMY PROBLEMS

Edouard J. Trabulsi, MD, FACS

BASICS

DESCRIPTION

- Urostomy is an incontinent urinary diversion and relies on an external appliance (pouching system) for the collection of urine.
- Urostomy can be made of either small or large intestine, with the distal ileum being the most common bowel segment used:
  - Also called ileal conduit, cutaneous ureteroileostomy if made up of ileum
  - Colon conduit, if made up of segment of large bowel.
  - Very rarely, a urostomy can consist of the ureters being directly anastomosed to the skin (cutaneous ureterostomies). These are uncommon in adults but are sometimes performed in children.
- Complications of the abdominal urinary stoma (urostomy) are the most common problem encountered in the postoperative period in patients undergoing urinary diversion.

EPIDEMIOLOGY

Incidence

- 2.8–19% of patients develop stomal stenosis with ileal conduits.
- 10–20% of patients with colon conduits develop stenosis.
- Parastomal hernia:
  - Occurs in 2–6.6% of patients with loop ileostomies
  - Rare with end stomas (1–4%)
  - More commonly occur with loop stomas (4–20%)
- Nearly all patients will have a stomal-related complication at some point.

Prevalence

N/A

RISK FACTORS

- Obesity
- Chronic cough
- Wound infection
- Abdominal distension
- Malnutrition
- Immunosuppression/steroid use
- Poor surgical technique
- Lack of proper stomal care
- Warm weather, excessive sweating, oily skin may cause the skin barrier adhesive to loosen
- Weight gain or loss can alter the topography of the stoma itself and the surrounding skin that may affect the security of the face plate adherence

Genetics

N/A

PATHOPHYSIOLOGY

- A pouching system (also called an appliance) collects the urine that exits from the stoma:
  - 2 styles of pouching systems are available:
    - Both include an adhesive faceplate, flange, skin barrier, or wafer (the part that sticks to the skin), and a urine collection pouch.
    - 1-piece pouches fused to skin barrier.
    - 2-piece systems have a face plate and a pouch that can be removed from the barrier.
- Patients should be encouraged to empty the pouch as needed but at least every 2–4 hr.
- The faceplate and system should be changed if there is leakage or every 4–7 days depending on individual patient characteristics.
- A properly constructed stoma usually protrudes ~1.5 cm from the abdominal wall:
  - Initially, a properly constructed stoma will be somewhat edematous. It will reduce slightly in size over several weeks following surgery. This means that the initial hole in the faceplate may change as the edema resolves.
  - The stoma is ideally not placed near a skin fold and is sufficiently far from the incision that the appliance will adhere and not leak.
- Early complications usually relate to impaired vascular supply (1):
  - Stomal necrosis can result in retraction, with a flush ostomy that is difficult to apply an appliance to.
- Early stomal retraction can be caused by an insufficient length of bowel segment or improper technique in securing and eversion of the stoma.
- Stomas stenosis: with or without obstruction:
  - Reported in 2.8–19%
  - May be asymptomatic, painful, or cause appliance fit problems
  - Stomal stenosis is less for loop stoma than end stomas.
  - Multifactorial causes: Fascial or muscular constriction, ischemia, and retraction allowing skin edges to overgrow opening (hyperkeratosis)
- Parastomal Hernia:
  - Gap between the intestinal segment forming the stoma and the surrounding fascia
  - Factors include obesity, malnutrition, chronic cough, wound infection.
  - Placement of the intestinal segment through the rectus fascia minimizes the risk of herniation.
  - Stomas placed lateral to the rectus fascia are more likely to develop a parastomal hernia (2.8% in rectus fascia vs. 21% lateral to rectus fascia).
  - Most parastomal hernias worsen with time.
- Poorly fitting appliances can cause social embarrassment and skin irritation and breakdown:
  - Urine contact (alkaline) with the skin can cause stomal encrustation, stomal epithelization, and eventual stenosis due to hyperkeratosis.
  - Unless contraindicated, maintaining the urine in an acid state is more protective of the skin (see below).
  - Peristomal skin problems can occur frequently and early after surgery.
- Irritative adhesives
- Fungal infections: redness and pruritus.

- Bleeding from portal HTN
- Urine pH:
  - Most fruits and vegetables: alkalinized urine.
  - Meats and cereals: acidic urine.
  - Unless contraindicated, keep urine in acidic pH range; protects skin, limits the deposition of urine crystals in and around the stoma.
- Calcifications and small stones due to exposed staples usually pass spontaneously

ASSOCIATED CONDITIONS
- Congenital anomalies such as exstrophy or myelodysplasia
- Urothelial carcinoma
- Urethral carcinoma

GENERAL PREVENTION
- Parastomal skin care can reduce bleeding, stomal stenosis, and dermatitis.
- Surgical technique ensuring a properly formed stoma in an appropriate location based on the abdominal wall contours
- Proper site location by an experienced stoma nurse preoperatively takes into account many variables, including the contour of the abdomen in the sitting and standing positions and the type of belts and garments worn by the patient.
- Proper selection of pouching system:
  - Compatibility with abdominal contours
  - Proper sizing of the pouch opening to minimize urine exposure on the skin
  - The opening on the adhesive skin barrier should be no more than 1/8-inch larger than the stoma to help keep urine off the skin.
- Emptying pouch appropriately such that excessive weight of the pouch will not disrupt the skin adhesion (usually when about 1/3 full)
- When changing the faceplate, the patient should learn to gently push the skin away from the sticky barrier rather than pulling the barrier off the skin.
- An acidic urine will be more protective of the peristomal skin than alkaline urine.

DIAGNOSIS

HISTORY
- Timing of diversion
- Weight change; may alter the fit of the faceplate
- Review the care of the stoma and appliance:
  - Frequency of face plate change
  - Frequency of emptying the collection pouch
- Complaints of parastomal skin lesions, bleeding, or dermatitis
- Problems with the adhesives, paste, tape, or pouch material

PHYSICAL EXAM
- Peristomal skin lesions:
  - Irritative parastomal lesions that are manifested by hypopigmentation, hyperpigmentation, and skin atrophy
  - Erythematous erosive lesions that are macular, scaling with loss of epidermis

– Pseudo-verrucous appear wartlike
- Minor bleeding from the exposed mucosa is common. Significant bleeding can be seen in cases of ileal conduit varices.
- Examine for evidence of parastomal herniation: Defect along fascial region of urostomy usually redicible
- Stomal stenosis or hyperkeratosis:
  – Calibrate ostomy with a sterile catheter if stomal stenosis present.
- Note presence of urinary crystals on the skin.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Usually not necessary

Imaging

- Not usually necessary. However, in the setting of severe stomal stenosis or prolapse, CT or US may identify dilation of the intestinal segment or evidence of hydronephrosis.
- Loopogram to identify if there is reflux or obstruction of the ureters with prolapse or parastomal herniation.

Diagnostic Procedures/Surgery

Calibration of the stoma with a red rubber catheter and determination if there is retained urine may be useful.

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Cutaneous allergic reaction or fungal infection
- Parastomal hernia
- Peristomal skin breakdown
- Stomal bleeding, prolapse, retraction, stenosis

TREATMENT

GENERAL MEASURES

- Proper initial surgical technique will minimize short- and long-term stomal problems.
- Proper stomal care and problem-solving is often accomplished by consultation with a certified ostomy care health provider:
  – Wound, Ostomy and Continence Nursing Certification Board (WOCNCB) provides certification in ostomy nursing
- A proper pouching system should have the following characteristics:
  – Secure, leak-proof seal that lasts 3–7 days
  – Protective of the skin around the stoma
  – Nearly invisible when covered with clothing
  – Easy to put on and take off
- Convex-style appliances can sometimes compensate for a retracted or flush stoma:
  – Many styles and adhesive types may offer options to correct many fit problems.
- A 1-piece urostomy system tends to be more flexible that a 2-piece unit; may help with

stomas that are near a deep abdominal fold or crease.
- Ostomy belts can sometimes help with securing the appliance in place and minimize mechanical disruption of the system.
- Gently trimming peristomal hair may help with face plate adherence.
- Allergic reaction to adhesive or other components can be addressed by switching to another product.
- Urine crystals on the skin or stoma (whitish gritty particles) are caused by alkaline urine:
  – Cranberry juice in place of citrus juices (citrus juices make the urine more alkaline)
  – Consider vitamin C daily
  – Some acid ash foods (make urine acidic) include: Most meats, breads and cereals, cheese, corn, cranberries, eggs, macaroni, nuts, pasta, prunes, fish, and poultry.
  – A 1:1 dilution of water and white vinegar applied with a cloth moistened with the mixture will dissolve the crystals.
- A pouch cover can help keep the skin beyond the skin barrier dry and reduce the incidence of superficial fungal infections where the pouch hangs down and contacts the skin.

MEDICATION

First Line
- Antifungal agents: Nystatin or miconazole powder lightly applied twice a day in cases of superficial fungal infection
- Severe allergic reactions to adhesive or appliance may require topical steroids short-term.

Second Line

N/A

SURGERY/OTHER PROCEDURES
- Surgical repair for parastomal hernias:
  – High likelihood of recurrence with or without relocation of the fascial opening. Suprafascial synthetic mesh wrap may decrease recurrence.
  – Period of conservative management appropriate; Laparoscopic repair reported
- Surgical revision for stomal stenosis
- Surgical revision of retracted stoma
- Liposuction reported to correct inverted stoma in obese patients
- Looposcopy to remove calculi

ADDITIONAL TREATMENT

Radiation Therapy

Some limited reports of radiation to treat stomal stenosis–related hyperkeratosis

Additional Therapies

Formally trained wound and ostomy care nurses or a nure with extensive experience can often help resolve many issues.

Complementary & Alternative Therapies

Asparagus and seafood may cause increased odor. Hydration helps limit odors in general.

ONGOING CARE

PROGNOSIS

Very good when intervention is applied in a timely fashion to prevent irreversible upper tract deterioration from stomal stenosis.

COMPLICATIONS

- Recurrent stomal stenosis
- Recurrent parastomal hernia
- Recurrent skin irritation from poor ostomy care
- Appliance leakage

FOLLOW-UP

Patient Monitoring

- Stomal wound care
- Cancer surveillance as per protocol

Patient Resources

- Wound, Ostomy and Continence Nursing Society. http://www.wocn.org/?page=patients

- Urostomy Problems Image

CODES

ICD9

- 553.29 Other ventral hernia without mention of obstruction or gangrene
- 997.5 Urinary complications, not elsewhere classified

ICD10

- K43.5 Parastomal hernia without obstruction or gangrene
- N99.531 Infection of other stoma of urinary tract
- N99.538 Other complication of other stoma of urinary tract

CLINICAL/SURGICAL PEARLS

- Urostomy difficulties are common.
- A urostomy that is flush with the skin causes significant skin excoriation and complications, so attempt to have the stoma protrude at least 1–2 cm above the skin when creating it in the OR.
- A convex stoma appliance can be helpful for stoma issues.

VAGINAL MESH EROSION

Jessica M. DeLong, MD
Kurt A. McCammon, MD, FACS

BASICS

DESCRIPTION

- Mesh erosion is 1 of the major complications of prolapse surgery conducted by transvaginal approach.
- Currently, most common mesh used for pubovaginal sling (PVS) and pelvic organ prolapse (POP) repair is polypropylene mesh
- Most sling erosions diagnosed 1–18 mo postoperatively (mean 9 mo)
- Most common and consistently reported mesh-related complication for POP (1)
- May occur in isolation or in combination with urethral or bladder erosion
- Note: More specific term may be "vaginal extrusion"

EPIDEMIOLOGY

Incidence

- 0.012–23% for midurethral slings; varies widely in literature (2)
- Wide variation with POP repair as well
  - Attributed to type of synthetic material used
  - Older synthetic materials had higher risk of extrusion due to intrinsic properties

Prevalence

- Unknown; increasing over time with increasing use of mesh
- Likely underreported

RISK FACTORS

- Patient factors
  - Estrogen deficiency
  - History of local radiation
  - Early resumption of intercourse
- Operative factors
  - Use of tightly woven, large-diameter mesh
  - Excessive sling tension or mesh too loose
  - Perforation of urethra or bladder
  - Inadequate vaginal closure
  - Superficial mesh placement

Genetics

N/A

PATHOPHYSIOLOGY

- Not completely understood. Theories:
  - Subclinical infection
  - Poor wound healing

– Iatrogenic injury/technical error (3)

ASSOCIATED CONDITIONS
- Stress incontinence
- POP
- Cystocele

GENERAL PREVENTION
- Perform intraoperative cystoscopy to minimize risk of urinary tract erosion
- Appropriate patient selection
- Rigorous surgical technique

ALERT
Be familiar with FDA warnings regarding risks of intravaginal mesh & counsel patients appropriately.

DIAGNOSIS

HISTORY
- Determine timing, details of initial surgical procedure and type of mesh used
- Patients often present with storage symptoms, vaginal discharge, pelvic pain/dyspareunia, UTI
- May complain of de novo lower urinary tract symptoms (LUTS)
- Delay in presentation is common
- Sexual activity/sexual function

PHYSICAL EXAM
- Pelvic exam
  – Localize sites of pain
  – Palpate for exposed mesh
  – Note discharge, if present
- Abdominal exam
  – Assess for tenderness, suprapubic pain if retropubic sling placed

DIAGNOSTIC TESTS & INTERPRETATION
Lab
Urine analysis

Imaging
Usually not indicated

Diagnostic Procedures/Surgery
- Cystoscopy
  – Perform if concern for urethral or bladder involvement
- Urodynamics may be of value to assess lower urinary tract function
- Check PVR if concern for retention

Pathologic Findings
Inflammation, fibrosis

DIFFERENTIAL DIAGNOSIS
- Urethral mesh erosion
- Bladder mesh erosion
- UTI

TREATMENT

GENERAL MEASURES
- In general treatment is divided into:
  - Conservative
  - Surgical
- Some patients may be observed with reasonable success

MEDICATION
First Line
- Culture specific antibiotic course if UTI present
- Vaginal estrogen cream
  - May be effective for small erosions
  - Apply small amount to tip of index finger, apply vaginally 2–3 times/wk
    - Contraindicated if history of deep venous thrombosis (DVT), estrogen-responsive cancer

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Transvaginal excision
  - Only exposed mesh vs. entire mesh
- Primary reapproximation of tissue over exposed mesh (4)
- Martius flap interposition at the discretion of the surgeon

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Unclear in literature
  - Recurrent SUI is common and may be alleviated by repeat PVS placement
    - Generally autologous material preferred
  - Pain may not be corrected with mesh removal
- Expectant management may be successful in up to 42% of patients
- However, a recent multicenter review of the topic indicated that the majority of women who

present for management of synthetic mesh complication after POP or SUI surgery have severe complications that require surgical intervention, with a significant proportion requiring >1 surgical procedure (5).

COMPLICATIONS

- Voiding dysfunction after surgical management of synthetic sling erosion is common (3)
- Sexual dysfunction, male and female dyspareunia
- Persistent pain
- Vesicovaginal fistula formation
- Recurrent stress urinary incontinence (SUI)
  - Can place 2nd pubo vaginal sling (PVS)

FOLLOW-UP

Patient Monitoring

- Depends upon treatment
  - If patient observed, will need follow-up exams
  - If mesh excised, patient should return if bothersome symptoms

Patient Resources

www.fda.gov—health notification regarding use of surgical mesh for POP and SUI

CODES

ICD9

• 599.84 Other specified disorders of urethra
• 629.31 Erosion of implanted vaginal mesh and other prosthetic materials to surrounding organ or tissue
• 996.39 Other mechanical complication of genitourinary device, implant, and graft

ICD10

• N36.8 Other specified disorders of urethra
• T83.711A Erosion of implnt vag prstht mtrl to surrnd org/tiss, init
• T85.628A Displacement of other specified internal prosthetic devices, implants and grafts, initial encounter

CLINICAL/SURGICAL PEARLS

• Erosion commonly presents with vaginal discharge, discomfort; urgency, urge urinary incontinence, and irritative voiding symptoms.
• Preoperative counseling is key; inform patients about risks and benefits of mesh use.
• Good physical exam is key to early detection.

VAGINITIS/VULVOVAGINITIS

Debra L. Fromer, MD
Drew A. Freilich, MD

BASICS

DESCRIPTION

- Vaginitis is infection or inflammation of only the vagina. Vulvovaginitis involves both the vagina and vulvar areas
- The spectrum of conditions that cause vulvovaginal symptoms such as itching, burning, irritation, and abnormal discharge (1)
- Can be infectious, noninfectious (chemical or irritants), or hormonal
- Bacterial vaginitis (BV) is the most common cause of vaginal discharge in women of childbearing age

EPIDEMIOLOGY

Incidence

7.4 million cases of BV annually in USA

Prevalence

- Among women with vulvovaginitis symptoms, prevalences are (1):
  - BV: 22–50%
  - Candidiasis: 17–39%
  - Trichomoniasis: 4–35%

RISK FACTORS

- Depends on etiology
- Risk factors for BV include new sex partner, multiple partners, and douching (2)
- Risk factors for vulvovaginitis candidiasis (VVC) (3):
  - Recent use of antibiotics
  - Corticosteroids
  - Diabetes mellitus
  - Immunosuppression
  - Pregnancy
- Risk for any STD is increased with:
  - Number of partners
  - Number of partners' partners
  - Unprotected sexual contact

Genetics

Evolving data supporting potential genetic predisposition

PATHOPHYSIOLOGY

- Depends on etiology
  - BV: Normal vaginal *Lactobacillus* are replaced with anaerobic bacteria, *Gardnerella vaginalis* and *Mycoplasma hominis* (some of these are normal vaginal flora; their

overgrowth leads to BV)
  – VVC: Overgrowth of *Candida*
  – Trichomonas and other STIs: Infection with organism
  – Atrophic vaginitis: Lack of estrogen

ASSOCIATED CONDITIONS

STI/STD's are often associated with other STI/STD's

GENERAL PREVENTION

- Avoid local irritants such as perfumed soaps and shower gels, wipes, powders, and sprays
- Wash external skin with water alone or mild soap
- Avoid tight clothing
- For STIs, treat partners as applicable
- Avoid douching, a risk factor for BV
- For trichomoniasis and other STIs:
  – Latex male condoms
  – Abstain from sexual contact, or be in a long-term mutually monogamous relationship with an uninfected partner

DIAGNOSIS

HISTORY

- Potential predisposing factors:
  – Prior vaginitis
  – Antibiotic use
  – Pregnancy
  – Diabetes
  – Sexual intercourse
  – Method of contraception
  – STI history
  – Response to prior treatment
  – Any current treatments that have been self-administered (OTC products)
- Symptoms of current condition:
  – Duration
  – Itching, burning
  – Color, consistency, and odor of discharge

PHYSICAL EXAM

- Inspect the vulva, vagina, and cervix for:
  – Erythema or skin lesions
  – Degree of estrogenization
  – Discharge
  – Foreign body (eg, forgotten tampon)
  – Friable cervix: Consider *Chlamydia* or gonorrhea
- Inspect the vulva, vagina, and cervix for:
  – BV: White or gray, homogeneous, thin, coats the vaginal walls, can have fishy odor
  – *Candida*: White, thick, curdy, not malodorous

  - Trichomonas: Yellow or yellow-green, malodorous, can be profuse and frothy
  - Cervicitis: Purulent, comes from cervix
  - Extensive condyloma can cause discharge
- Palpate for tenderness:
  - Vulvar tenderness without discharge suggests atrophic vaginitis, vulvodynia, or dermatologic condition

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine analysis and culture if dysuria is present
- Evaluate discharge by wet mount and KOH:
  - Put a drop of discharge on a glass slide
  - Add a drop of saline to the discharge, add cover slip, and look under microscope for *Trichomonas* and clue cells (BV)
  - Repeat with another slide, using a drop of 10% KOH instead of saline.
  - "Whiff test": Fishy smell (amine odor) immediately after KOH application suggests BV.
    - Wait 2 min for KOH to dissolve most of the cells. Yeast cells or hyphae remain undissolved.
- Clinical diagnosis of BV (Amsel criteria) requires the presence of ≥ 3 of the following:
  - Homogeneous, thin, white discharge that smoothly coats the vaginal walls
  - Vaginal pH $>$ 4.5 (sample from midvagina)
  - Positive amine test (aka whiff test) (fishy odor before or after addition of 10% KOH)
  - Presence of clue cells on microscopic exam
- Diagnosis of candidiasis:
  - Hyphae or yeast cells on KOH or wet mount
  - If *Candida* suspected but not seen on KOH or wet mount, send discharge for yeast culture
- Diagnosis of trichomoniasis:
  - See organisms on wet mount about 60% sensitive (1,2)
  - FDA-approved point-of-care tests have sensitivity $>83\%$ and specificity $>97\%$ (2)
    - Affirm VP III (45 min for result)
    - OSOM Trichomonas Rapid Test (10 min)
  - Culture is most accurate test for trichomonas ($\sim 98\%$)
- Indications for *Chlamydia*/Gonorrhea testing (1):
  - Purulent discharge
  - Discharge has leukocytes (>10 WBC on microscopy) without trichomonads
  - Friable cervix; symptoms of PID (pelvic pain, fever)
  - Patient in high-risk group for STIs
  - NAAT (nucleic acid amplification testing) should be used for diagnosing *Chlamydia trachomatis* and *Neisseria gonorrhoeae* with cervicitis

Imaging

Rarely indicated

Diagnostic Procedures/Surgery

- Vaginal sidewall pH can help with diagnosis:
  - Premenopausal: normal pH 4–4.5

- BV: pH >4.5
- Trichomoniasis: pH 5–6
- Candidiasis: pH 4–4.5

– Postmenopausal: normal pH >4.7

• Biopsy may be indicated for vulvar dermatologic disorders or to rule out cancer. Not needed in most cases

Pathologic Findings

Based on organism

DIFFERENTIAL DIAGNOSIS

• The most common vaginal infections that cause discharge are:
  – Bacterial vaginosis (BV)
  – Vulvovaginitis Candidiasis (VVC)
  – Trichomoniasis
  – Cervicitis due to *Chlamydia* or gonorrhea can present with discharge
  – Group A *Streptococcus* (very rare)
• Noninfectious etiologies:
  – Atrophic vaginitis
  – Ectropion
    - May normalize vaginal discharge volume
    - Normalize physiologic presence of endocervical glandular tissue on the cervix.
    - More common with estrogen–progestin contraceptives and with pregnancy.
  – Foreign body (ie, retained tampon)
  – Allergies and irritants: Contraceptives, douches, perfumes, soaps, laundry detergents, panty liners, etc.
  – Vulvar dermatologic conditions
  – Vulvodynia

TREATMENT

GENERAL MEASURES

• See “General Prevention.”
• Attempt to identify specific cause based on history, lab testing to target treatment
• Correct underlying conditions if possible

MEDICATION

First Line

• Bacterial vaginosis (2,5):
  – Metronidazole 500 mg PO BID for 7 days
  – Metronidazole gel 0.75%; 1 applicator (5 g) per vagina every day for 5 days
  – Clindamycin cream 2% 1 applicator (5 g) per vagina at bedtime for 7 days
• Uncomplicated VVC:
  – Multiple topical azole regimens, or single PO dose 150 mg fluconazole
    - All have similar results
    - Fluconazole has many drug interactions.

- Complicated VVC (2): (< 5% of women)
  - Defined as severe disease (extensive erythema, edema, excoriation, fissures), recurrent disease, not *Candida albicans*, uncontrolled diabetes, debilitation, immunosuppression, or pregnancy, > 4 per year
  - Start with same drugs but give longer courses (7–14 days).
  - If azoles fail, use 600 mg of boric acid in a gelatin capsule, per vagina daily for 2 wk
- Trichomonas (2):
  - Metronidazole or tinidazole 2 g single dose PO (tinidazole is equivalent or superior) (2)
  - Gel is much less effective than PO dose.
- Cervicitis: Azithromycin 1 g PO single dose OR Doxycycline 100 mg PO BID for 7 days
  - Consider concurrent treatment for gonococcal infection if prevalence of gonorrhea is high in the patient population (Ceftriaxone 250 mg IM 1 dose)
- Atrophic vaginitis: Topical estrogen is effective; several forms can be used

Second Line

- BV (2):
  - Clindamycin ovules 100 mg per vagina at bedtime for 3 days
  - Clindamycin 300 mg PO BID. for 7 days
- VVC: No 2nd-line treatments described (2)
- Trichomoniasis: Metronidazole 500 PO BID for 7 days (2)

Pregnancy Considerations

- Bacterial vaginosis (1,2)
  - BV in pregnancy is associated with preterm birth and postpartum endometriosis
  - However only proven benefit of treating symptomatic BV in pregnancy is reduction in symptoms
  - Trial results inconsistent for screening/treating asymptomatic high-risk patients
  - USPSTF recommends not screening for BV in low or average risk for preterm birth
  - BV treatment in pregnancy (2):
    - Metronidazole 500 mg PO BID for 7 days
    - Metronidazole 250 mg PO TID for 7 days
    - Clindamycin 300 mg BID for 7 days
    - Topical clindamycin should not be used in the 2nd half of pregnancy
- VVC: If pregnant, the only recommended treatment is topical azole for 7 days (2)
- Trichomoniasis in pregnancy is associated with adverse outcomes, but no strong evidence that treatment improves outcomes, therefore(1, 2):
  - No need to screen
  - Do treat women who have symptoms
  - Metronidazole is pregnancy category B and OK for 2 g single PO dose
  - Tinidazole is pregnancy category C
  - With both drugs, stop breast-feeding.

SURGERY/OTHER PROCEDURES

N/A

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Partners should be notified and examined if chlamydia, gonorrhea, or trichomoniasis found
- For atrophic vaginitis, if estrogen cannot be used, moisturizers and lubricants may help

Complementary & Alternative Therapies

For *Candida*, no evidence for lactobacilli, yogurt, garlic, tea tree oil, a low-carbohydrate diet, or desensitization to *Candida* species antigen (1); but minimal evidence for atrophic vaginitis.

ONGOING CARE

PROGNOSIS

Depends on etiology

COMPLICATIONS

Inflammation from trichomonas, gonococcal urethritis, chlamydial urethritis, and nongonococcal, nonchlamydial urethritis might facilitate HIV transmission to her partner (3)

FOLLOW-UP

Patient Monitoring

- BV is not thought to be a STD (4):
  - No follow-up needed if symptoms resolve (2)
  - Partner notification not needed/partner treatment does not improve the outcome
- Candidiasis (2):
  - No follow-up needed unless symptoms persist or recur within 2 mo
  - No partner treatment, unless he has balanitis or if she has frequent recurrences
- Trichomoniasis (2):
  - Treat partners and avoid sexual contact until both partners have completed treatment and are asymptomatic
  - Consider follow-up screening as >17% relapse within 3 mo

CODES

ICD9

- 112.1 Candidiasis of vulva and vagina
- 131.01 Trichomonal vulvovaginitis
- 616.10 Vaginitis and vulvovaginitis, unspecified

ICD10

- A59.01 Trichomonal vulvovaginitis
- B37.3 Candidiasis of vulva and vagina
- N76.0 Acute vaginitis

CLINICAL/SURGICAL PEARLS

- Pelvic pain and fever are red flags for pelvic inflammatory disease.
- Avoid alcohol with metronidazole until 24 hr after last dose (72 hr for tinidazole) as it can cause nausea.
- Clindamycin cream may weaken latex condoms and diaphragms for 5 days after use.
- Consider delaying breast-feeding 12–24 hr after metronidazole and 72 hr for tinidazole.

VARICOCELE, ADULT

Samuel Ohlander, MD
Craig S. Niederberger, MD, FACS

BASICS

DESCRIPTION

- Varicocele is an abnormal dilation of the pampiniform plexus of veins situated within the spermatic cord
- Can be asymptomatic, cause discomfort and may impact spermatogenesis.
- Clinical grading of varicoceles:
  - Subclinical: Nonpalpable
  - Grade I: Small, not grossly visible, palpated only during Valsalva
  - Grade II: Moderate size, not grossly visible, easily palpated in standing position without Valsalva
  - Grade III: Large and grossly visible while standing
- Only palpable are clinically relevant
- If prior to puberty or unilateral right varicocele, suggests underlying pathology (See Varicocele, Pediatric)

EPIDEMIOLOGY

Incidence

- Decrease in incidence with increasing body mass index (BMI)
- Increased (3–8x) among 1st-degree relatives with varicocele (1)

Prevalence

- 15% of males
- Majority left sided (75–90%), 33% bilateral
- Seen in 35–40% of men presenting with primary infertility vs. 70–80% with secondary infertility (infertility after previously conceiving a child)
  - Not causative of infertility in the majority of men

RISK FACTORS

- Congenital absence of valves in spermatic vein
- Acquired incompetence of valves, extrinsic compression increasing intravascular pressure (eg, retroperitoneal pathologic process)

Genetics

Ongoing area of research

PATHOPHYSIOLOGY

- Varices
  - Due to absent or incompetent venous valves in spermatic veins allowing retrograde flow
  - May be congenital or acquired
  - Thought to be due to right-angle insertion of left spermatic vein into left renal vein resulting in turbulent flow and increased intravascular back pressure

  - Extrinsic compression
    - Mass
    - "Nutcracker effect": Left renal vein compressed between superior mesenteric artery and the aorta producing elevated left gonadal vein pressures
- Infertility due to varicoceles:
  - Poorly defined, many theories
    - Increased intratesticular temperature compared to controls (0.6–0.8 C)
    - Loss of countercurrent testicular cooling mechanism
    - Elevated temperature reduces testosterone synthesis by Leydig cells, injures germinal cell membranes, alters protein metabolism, and reduces Sertoli cell function
    - Increased testicular hypoxia and oxidative stress due to impaired venous drainage (possibly affecting Leydig cells, DNA fragmentation)
    - Reflux of gonadotoxic renal and adrenal metabolites
  - Can alter spermatogenesis
  - Decreased sperm quality (concentration, motility, morphology, DNA integrity)

ASSOCIATED CONDITIONS
- Infertility
- Testicular atrophy
- Rarely, tumor, renal vein thrombus

GENERAL PREVENTION
None

DIAGNOSIS

ALERT
Acute onset suggests obstruction of renal or gonadal vein (possibly secondary to tumor).

HISTORY
- Infertility
- Pain
  - Most asymptomatic
  - Dull ache, heavy sensation, sensation of increased heat
  - Increases with activity (including intercourse), standing, and with Valsalva
  - Relieved by recumbency

PHYSICAL EXAM
- Gold standard for diagnosis
  - Examine in a warm room after patient has been standing for 10 min
  - Examine with patient supine and standing upright, with performing Valsalva while in upright position
  - Palpation described as "bag of worms"
  - See subheading "Basics, description" for grading

DIAGNOSTIC TESTS & INTERPRETATION
Lab

- Semen analysis (SA)
  - 2–3 days of sexual abstinence prior to collection
  - "Stress pattern" on SA
  - Concentration <20 million/mL; motility $<60\%$; morphology $<14\%$ strict normal forms (oligoasthenoteratospermia or OAT)
- FSH >4.5 & OAT indicates varicocele may be impacting sperm production

Imaging

- Radiographic testing should only be used when presence is uncertain on physical exam (eg, obesity), recurrence is suspected, or varicocele is present after treatment. (2)[C]
- Ultrasound:
  - Helps exclude other intrascrotal pathology
  - Varicocele defined as dilation of pampiniform plexus veins with Valsalva to caliber of >3 mm with and/or reversal of flow with Valsalva during color Doppler
- Internal spermatic venography:
  - Potentially diagnostic and therapeutic
  - Only used for recurrent varicoceles
  - Invasive
- Abdominal imaging if renal or other retroperitoneal mass suspected of causing varicocele

Diagnostic Procedures/Surgery

Venography, as described above

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Spermatic cord mass:
  - Adenomatoid tumor of the cord
  - Epidermoid cyst
  - Epididymitis/epididymo-orchitis
  - Fibrous pseudotumor
  - Hernia
  - Hemangioma
  - Hydrocele/hydrocele of the cord
  - Inguinal lymphadenopathy
  - Leiomyoma
  - Malignant tumor (liposarcoma, rhabdomyosarcoma, leiomyosarcoma, malignant histiocytoma)
  - Metastasis
  - Polyorchidism
  - Sarcoid
  - Sperm granuloma
  - Spermatocele
  - Testis tumor
  - Undescended/retractile testicle
  - Vasitis and vasitis nodosa (typically associated with epididymitis)

ALERT
Suspect renal or retroperitoneal tumor if varicocele is exclusively right sided or remains engorged when the patient is placed in the supine position.

TREATMENT

GENERAL MEASURES

- Subclinical varicoceles have questionable impact on fertility, and repair may not improve fertility rates (3)[B]
- NSAIDs and ice may provide symptomatic relief
- Indications for treatment of infertile male (should meet all criteria):
  - Varicocele palpable on exam
  - Man with abnormal semen parameters or abnormal sperm function tests
  - Couple with known infertility
  - Female has normal or potentially treatable cause of infertility
  - Treatment will enable natural pregnancy or less invasive assisted reproductive techniques (ART) eg, intrauterine insemination (IUI)
- Surgical varicocelectomy significantly improves semen parameters in infertile men with palpable varicocele and abnormal semen parameters (4)[A].
- Pain from symptomatic varicocele or testicular atrophy (>15–20%) are also indications for repair

MEDICATION

First Line

Pain: Analgesics (eg, NSAIDs) usually not durable therapy

Second Line

None

SURGERY/OTHER PROCEDURES

- Surgical treatment successfully eliminates over 90% of varicoceles
- Bilateral repair warranted when varicoceles are noted on both sides in presence of elevated FSH and testicular hypotrophy
- Operative intervention classified by anatomic site of varix ligation and surgical technique
- Anatomic site of ligation:
  - Subinguinal microsurgical: The standard in recent years, incision over the cord below the external ring
    - Number of veins requiring ligation is greater
    - Microscope and Doppler to protect spermatic artery and lymphatics
    - Recurrence rates ~1%
    - Hydrocele rates <1%
  - Inguinal: Inguinal incision, ligation of spermatic veins within inguinal canal
    - Allows for concurrent hernia repair
    - Recurrence rates up to 16%
    - Hydrocele rate up to 30% if nonmicrosurgical
  - Scrotal: The transcrotal approach is considered obsolete

- Retroperitoneal (Palomo or high ligation): Muscle splitting incision, exposure of spermatic vessels with or without preservation of spermatic artery
  - Mass ligation permitted due to presence of collateral arterial circulation (vasal, cremasteric artery)
  - Recurrence rates 15–25%
  - Hydrocele rate ~7%
- Surgical technique:
- Open with or without magnification:
  - Magnification preferred to spare arteries and lymphatics, and allow ligation of small venous tributaries
  - Subinguinal or inguinal microscopic varicocelectomy offers the best overall outcome (5) [A]
- Laparoscopic:
  - High ligation
  - Recurrence rates <2%
  - Hydrocele rate 5–8%
  - 5% of patients experience transient anterior thigh numbness

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Interventional radiology:
- Used as a 2nd-line therapy for those who fail surgery
- Venography with access through the femoral or internal jugular vein
- Occlusion therapy (sclerotherapy, embolization)
- Quicker recovery (3–4 days) but higher recurrence rate (up to 27%)

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- See “Surgery/Other Procedures” for recurrence rates of individual techniques
- Pain or relief of pain typically immediate after recovery from surgery

COMPLICATIONS

- See “Surgery/Other Procedures” for treatment specific complication rates
- Hydrocele
- Recurrence
- Testicular artery injury
- Nerve injury
- Testicular atrophy

FOLLOW-UP

Patient Monitoring

- Varicocele recurrence:
  - Typically evident within 6–13 mo
- Infertility:
  - Semen analysis (SA) at 3-mo intervals; semen should be monitored for at least 1 yr or until pregnancy has been achieved
  - Young men with varicocele and normal SA should be followed with testis size SA and FSH every 1–2 yr

CODES

ICD9

- 456.4 Scrotal varices
- 752.89 Other specified anomalies of genital organs

ICD10

- I86.1 Scrotal varices
- Q64.8 Other specified congenital malformations of urinary system

CLINICAL/SURGICAL PEARLS

- Majority of varicoceles are left sided (75–90%) with diagnosis by physical exam.
- Subclinical (nonpalpable) varicoceles have questionable impact on fertility, and repair may not improve fertility rates.
- Suspect renal or retroperitoneal tumor if varicocele is acute in onset, exclusively right sided or remains engorged when the patient is placed in the supine position.
- Subinguinal microscopic varicocelectomy offers the best overall outcome, though approach should depend on surgeon comfort.

VARICOCELE, PEDIATRIC

Hyeyoung Lee, MD, MS
Harry P. Koo, MD, FAAP, FACS

BASICS

DESCRIPTION

A pediatric varicocele is defined as an abnormal dilatation of the internal spermatic veins in the pampiniform plexus of the spermatic cord in a male generally <18 yr of age. Usually asymptomatic; may cause testicular hypotrophy

EPIDEMIOLOGY

Incidence

- Reported frequency of varicoceles in adolescent boys is ~16%, developing as a result of testicular enlargement and concomitant increased blood flow in puberty
- Actual incidence may be underestimated and detected later during evaluation of infertility in adulthood

Prevalence

- 8–16% of adolescent males but unusual in prepuberty
- 90% left sided
- 1–7% right sided
- 2% bilateral
- No racial, cultural, or geographic predilection
- More common in tall, thin males

RISK FACTORS

- Increased height, and relatively low weight and body mass index
- Congenital incompetence or absence of valves of internal spermatic vein
- Acquired incompetence of valves, extrinsic compression increasing intravascular pressure (eg, inguinal hernia repair, retroperitoneal pathologic process)
- May be associated with generalized venous abnormality

Genetics

- Varicocele prevalence as high as 67% has been reported in sons of fathers with varicocele
- Risk of varicocele in 1st-degree relatives is 4–8 times higher, suggesting genetic susceptibility (1)

PATHOPHYSIOLOGY

- Unique angle of left spermatic vein entering the left renal vein compared to right spermatic vein entering IVC
- Left spermatic vein is 8–10 cm longer than the right
- "Nutcracker" phenomenon of left renal vein passing between aorta and superior mesenteric artery
- Erect posture (no varicocele in four-legged animals)
- Different mechanisms are hypothesized to cause testicular insult

- Hyperthermia:
  - Increased testicular arterial blood flow interferes with countercurrent heat exchange
  - Increased testicular temperature affects enzymatic reactions
  - Decreased proliferation and increased apoptosis of germ cells
  - Heat shock protein A2, oxidative stress patterns, calcium channels, and DNA fragmentation affected
- Testicular hypotrophy: Significant testicular volume loss in 30–70% of adolescents with a varicocele:
  - Most rapid growth of testis between ages 11 and 16 yr
  - Testicular hypotrophy reversible in 90% of patients after varicocelectomy
- Venous stasis:
  - Possible oxygen depletion in testis
  - Human studies do not support theory
- Adrenal/renal reflux:
  - Theory of toxic exposure to testis from reflux of adrenal and renal metabolites
  - Data inconclusive
- Endocrine imbalance:
  - Abnormal response in patients with varicocele to GnRH stimulation
  - Unclear how it affects future fertility or hypotrophy

ASSOCIATED CONDITIONS

Secondary causes can include retroperitoneal tumor, renal mass with renal vein extension, renal vein thrombosis, retroperitoneal fibrosis

GENERAL PREVENTION

None

DIAGNOSIS

HISTORY

- Usually asymptomatic, associated pain reported in 2–11%
- Symptomatic dull ache or fullness in scrotum, worsened with activity
- Occasional testicular pain due to venous congestion
- Change in size with position or Valsalva
- Found after routine pediatric physical exam

PHYSICAL EXAM

- Examine patient upright and supine, with and without Valsalva
- Grading criteria:
  - Grade 0: Subclinical, not visible or palpable, only detected by ultrasound (US)
  - Grade I: Palpable only with Valsalva
  - Grade II: Palpable but not readily visible
  - Grade III: Visible through scrotal skin
- Check patient in supine position—idiopathic varicoceles may disappear, while secondary varicoceles persist if caused by tumor, especially on right side
- “Bag of worms” superior to testicle
- Negative transillumination

- Examine for bilateral varicocele and lymphedema
  - If present, rule out secondary varicocele
- Testicular exam:
  - Visual inspection
  - Orchidometer—Prader vs. disk to determine testicular volume of each testicle and the comparison between the two testes
    - Prader orchidometer: Consists of 12 solid ellipsoid testis-shaped models ranging in volume from 1 to 25 mL (1–6, 8, 10, 12, 15, 20, and 25 mL), against which the testis is compared
    - Disk or Takihara orchidometer: Series of 15 punched-out elliptical rings; volumes ranging from 1 to 30 mL (1–6, 8, 10, 12, 14, 16, 19, 22, 26, and 30 mL)
  - 2 cc or 20% size discrepancy suggests testicular hypotrophy
  - Testicular hypotrophy is correlated with poor semen quality

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Semen analysis: Can be performed if Tanner stage 5 or >18 yr old
- Response to GnRH stimulation: Not useful for surgical decision making

Imaging

- Scrotal US
- Color Doppler US can detect subclinical varicoceles that are not palpable
  - Decrease in volume of 2 cc or 20% size warrants intervention
  - Spermatic vein diameter >2 mm in standing position with Valsalva is noted in up to 96% of boys with grade III varicocele
  - Lambert formula: 0.71 (length × width × depth on US measurement)

Diagnostic Procedures/Surgery

Diagnosis confirmed by physical exam ± US

Pathologic Findings

- Leydig cell atrophy is known to be associated with high levels of luteinizing hormone (LH) and follicle-stimulating hormone (FSH) and low testosterone levels
- Endothelial proliferation and basement membrane thickening in venules and capillaries
- Germ cell maturation arrest and sloughing, ultrastructural changes in Sertoli cells, Leydig cell atrophy to hyperplasia have been described in testicular biopsy specimens (2)

DIFFERENTIAL DIAGNOSIS

- Epididymal cyst (spermatocele)
- Hydrocele:
  - Communicating
  - Scrotal
  - Spermatic cord
- Inguinal hernia
- Lipoma of cord
- Paratesticular rhabdomyosarcoma

TREATMENT

GENERAL MEASURES

- Management is either observation or surgical intervention
- Nonoperative treatment can be proposed when the patient or guardian fully understands the need for lifelong follow-up and the potential for progressive subfertility
- Surgical indications in the pediatric population:
  - 2 cc or 20% size discrepancy between testicles based on US or orchidometer measurements
  - Symptomatic
  - Bilateral varicoceles
  - Abnormal semen analysis
  - Solitary testis with varicocele

MEDICATION

First Line

N/A

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Surgical technique based on comfort and experience of surgeon
- Techniques described in more detail in Section I: "Varicocele, Adult"
- 50–75% of patients demonstrate catch-up growth, not necessarily meaning improved semen quality
- Testicular artery sparing:
  - Doppler can help identify
  - Preferred in adults because of concerns with infertility
  - Should be considered in adolescents
- Laparoscopic:
  - Retroperitoneal or transperitoneal
  - High ligation of vessels (Palomo)
  - Closer to left renal vein; usually fewer veins to ligate
  - Laparoscopy offers magnification, facilitating artery/lymphatic sparing
  - Single port laparoscopic approach provides excellent cosmesis
- Subinguinal/inguinal microsurgical:
  - Provides facilitated artery and lymphatic sparing
  - Low risk of hydrocele
  - Time consuming
- Radiographic embolization:
  - Limited data in children and adolescents, less successful than open or laparoscopic approach
  - Significant radiation exposure
  - Generally reserved for recurrent/persistent varicocele

ADDITIONAL TREATMENT

Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
No definitive evidence that adolescents with varicocele will have impaired fertility in future or that surgical correction will improve/prevent infertility

COMPLICATIONS
- Recurrence or persistence of varicocele:
  – 1–35% depending on technique (3)
- Postoperative hydrocele (1–9%)
- Testicular atrophy
- Failure of catch-up growth
- Possible decreased fertility

FOLLOW-UP
Patient Monitoring
- If asymptomatic and no testicular size discrepancies, observe with biannual or annual exams
- If postsurgical, assess for testicular catch-up growth and hydrocele formation after 3 mo with US. Then monitor biannually or annually

Patient Resources
- Urology Care Foundation: Varicoceles

See Also (Topic, Algorithm, Media)
• Infertility, Urologic Considerations
• Spermatic Cord Mass and Tumors
• Varicocele, Adult

CODES

ICD9
• 456.4 Scrotal varices
• 459.81 Venous (peripheral) insufficiency, unspecified
• 752.89 Other specified anomalies of genital organs

ICD10
• I86.1 Scrotal varices
• I87.8 Other specified disorders of veins
• Q64.8 Other specified congenital malformations of urinary system

CLINICAL/SURGICAL PEARLS

• Varicocele is found in 8–16% of adolescents.
• Genetic susceptibility, thin and tall body habitus, and venous abnormalities increase the risk of varicocele.
• Surgical treatment is indicated if testicular hypotrophy, bilateral varicocele, abnormal semen analysis or symptoms.
• Laparoscopic and open suprainguinal varicocelectomy are almost equally effective.
• Microsurgical approach minimizes risk of hydrocele development.

VAS DEFERENS, CONGENITAL ABSENCE

Pravin K. Rao, MD

BASICS

DESCRIPTION

- Congenital absence of the vas deferens in males can be bilateral (CBAVD) or unilateral (CUAVD)
- Primarily relevant to infertility evaluation
- Absence of the vas deferens interrupts transport of sperm beyond testis/epididymis
- Often accompanied by poor development of epididymides and seminal vesicles (SVs), causing low-volume ejaculate.
- Diagnosis is made by physical exam
- CBAVD present in >98% of cystic fibrosis (CF) patients
- CBAVD
  - Always azoospermic (bilateral obstruction)
- CUAVD
  - Can be azoospermic due to unidentified contralateral defects or testis failure
  - More often (-) CFTR mutations (vs. CBAVD)
  - Higher incidence renal anomalies (vs. CBAVD)

EPIDEMIOLOGY

Incidence

- 65–98% of men with CF
- 1.3% of all infertile men

RISK FACTORS

- CF
- Family history of CF or CBAVD
- See associated conditions

Genetics

- Most common: Mutations of cystic fibrosis transmembrane conductance regulator (CFTR)
- CFTR:
  - Chromosome 7
  - Causes spectrum of conditions ranging from AVD to clinical CF
  - Mutations of both chromosomes necessary for clinical CF or CBAVD
  - Mutations appear to have incomplete penetrance (1)[B]
  - Single chromosome mutations = carrier
  - "Severe" vs. "Mild" mutations
- CF patients
  - ~88% have severe mutation of both chromosomes
  - ~11% have severe mutation on 1 CFTR gene and mild on the 2nd (2)[B]
- CBAVD without clinical CF

- ~88% carry 1 severe mutation and 1 mild mutation
- ~12% carry mild mutations on both (Claustres 2000)

- Genetics of CUAVD less understood
  - Most CUAVD thought to be due to embryologic defect (non-CFTR)
  - Some men with CUAVD do have CFTR mutations (3)[B]
  - Some may be due to unidentified CFTR mutation or other genetic factor(s)

PATHOPHYSIOLOGY

- CFTR
  - Glycosylated transmembrane protein
  - Function: Chloride channel
  - Sites:
    - Lungs, liver, pancreas, intestines
    - Vasa deferentia/GU tract
- CFTR mutation
  - Point mutations most common in CF
  - Altered chloride transport
  - Thick, viscous secretions
    - Multisystem disease in CF
    - Obstruction/degeneration of vasa vs. agenesis.
- Vas deferens is a derivative of mesonephric (Wolffian) duct.
  - Wolffian abnormalities often seen with AVD
    - Seminal vesicle (SV) hypoplasia or absence
    - Causes low-volume ejaculate.
    - See: Associated Conditions

ASSOCIATED CONDITIONS

- CF
  - CBAVD is considered the mildest manifestation of CFTR disease spectrum
  - CF is most severe
  - Nearly all CF patients have CBAVD
- Genitourinary abnormalities
  - Renal agenesis
  - Abnormalities of mesonephric structures
    - Ejaculatory ducts
    - SVs
- Low testicular volume
  - Seen more commonly when CFTR mutations not detected (4)[B]
  - May indicate primary testicular cause

GENERAL PREVENTION

CFTR screening of both partners can help assess and manage risk of CF and CBAVD for offspring

DIAGNOSIS

HISTORY

- Medical history
  - Presence of associated conditions
- Patients usually asymptomatic except for infertility
- Screen for other causes of infertility/azoospermia
  - Developmental/puberty history
    - Testicular descent
  - Sexual function, libido
    - Hypogonadism, testis failure
- Screen for CF manifestations
  - Sinopulmonary symptoms
  - GI/digestive problems

PHYSICAL EXAM

- Findings in AVD
  - Absent vas deferens (bilateral/unilateral)
  - Absent or hypoplastic body/tail of epididymis
  - Present caput epididymis, often dilated
- Considerations:
  - Evaluate for skip lesions
  - Check for other causes of infertility
    - Varicocele
    - Atrophic testis
- Normal in CBAVD:
  - Testis size (>3.5 cm length, 2–3 cm diameter)
  - Digital rectal exam
    - Prostate usually normal
    - SVs usually nonpalpable/hypoplastic; may be cystic

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Potential semen analysis findings:
  - Low volume (<1.5 cc)
  - Azoospermia if bilateral obstruction
  - Acidic pH (decreased basic SV fluid)
  - Seminal fructose might be negative
  - Presence of sperm rules out bilateral obstruction
- Postejaculatory urinalysis
  - Evaluates for retrograde ejaculation
  - Part of evaluation for low-volume azoospermia
- CFTR genetic mutation screen
  - Assesses for mild vs. severe mutations
  - Can prove, but not exclude, a congenital form of CF
  - Risk is difficult to predict with some rare CFTR mutations
  - Negative CFTR screen reduces, but does not eliminate, risk of being a carrier
    - Thus, suggest screening in female partner

- CFTR screening for partner
  - Helps guide genetic counseling regarding CF risk for offspring

Imaging

- Renal ultrasound
  - For all men with vasal agenesis
  - Evaluates for renal anomalies/agenesis
  - Optional if CFTR mutation detected
    - Renal anomalies rare
- Transrectal ultrasound (TRUS)
  - Part of evaluation for low-volume azoospermia
  - Not necessary with CBAVD
  - Evaluates for ejaculatory duct obstruction
  - Normal findings:
    - Vasal diameter: 0.3–0.5 cm
    - SV width: 0.3–1.5 cm
    - SV length: 1.4–4.6 cm
    - Ejaculatory duct diameter: <0.1 cm
  - Optional: Aspiration of dilated SVs
    - Ejaculatory Disturbances
- Vasography (see below)

Diagnostic Procedures/Surgery

- Vasography
  - Fluoroscopic injection of contrast material
  - Assesses patency of vas/vasa
  - Only done at time of planned microsurgical reconstruction of ejaculatory duct(s), due to risk of damage/obstruction at vassal entry point
  - Of limited utility in CBAVD since reconstruction usually not an option

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Spermatogenic failure causing azoospermia
  - Congenital/genetic causes
    - Y chromosome microdeletions
    - Sex chromosome abnormalities (XXY male)
    - Undescended testes
  - Gonadotoxin exposure
    - Chemotherapy
    - Radiation
    - Environmental
  - Varicocele
- Obstruction causing azoospermia
  - Inflammatory or infectious causes
    - Sexually transmitted infections

    - Tuberculosis
  - Vasal obstruction/vasectomy
  - Epididymal obstruction
  - Ejaculatory duct obstruction
- Poor development of accessory sex organs causing low-volume ejaculate
  - Hypogonadotropic hypogonadism
  - Pituitary tumor
  - Disorders of sexual differentiation
- Respiratory infections and male infertility can also be due to primary ciliary dyskinesis
  - This condition is characterized by immotile sperm and situs inversus

TREATMENT

GENERAL MEASURES

- Infertility treatment requires assisted reproductive techniques (ART)
- Sperm retrieval techniques
  - See Surgery, below
- Donor semen
  - Intrauterine insemination
  - IVF/ICSI
- Consider referral for genetic counseling regarding CF risk for offspring

MEDICATION

First Line

- Medications used only to treat other conditions found on evaluation (eg, hypogonadism)
  - Clomiphene citrate
  - Avoid exogenous testosterone if patient is planning to use his own sperm for ART
    - Suppresses endogenous gonadotropins and testosterone/sperm production

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Sperm retrieval for ART
  - Testicular sperm extraction (TESE)
  - Testicular sperm aspiration (TESA)
  - Microsurgical epididymal sperm aspiration (MESA)
  - Sperm can be used for IVF or ICSI

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Besides association with CF/CFTR disease spectrum, no other known detriment to health
- Fertilization and pregnancy rates with ART in obstructive azoospermia are most closely tied to female factors.

COMPLICATIONS

CF or CBAVD in offspring

FOLLOW-UP

Patient Monitoring

CODES

ICD9

- 606.0 Azoospermia
- 606.9 Male infertility, unspecified
- 752.89 Other specified anomalies of genital organs

ICD10

- N46.01 Organic azoospermia

- N46.8 Other male infertility
- Q55.4 Other congenital malformations of vas deferens, epididymis, seminal vesicles and prostate

CLINICAL/SURGICAL PEARLS

Low-volume ejaculate in CBAVD and CUAVD is usually due to poor development of accessory sex organs (SVs).

VASECTOMY AND POSTVASECTOMY PAIN SYNDROME

Christopher L. Starks, MD
Edmund S. Sabanegh, Jr, MD

BASICS

DESCRIPTION

- Vasectomy is a surgical procedure that creates a disruption of the vas deferens leading to permanent male sterilization
  - Vasectomy is the safest, least expensive, and most reliable form of sterilization (1,2)
- Postvasectomy pain syndrome: Poorly understood and largely unpredictable chronic testicular pain >3 mo duration after vasectomy
  - Variable constellation of symptoms including but not limited to orchalgia, pain with daily activities, and pain with intercourse/ejaculation

EPIDEMIOLOGY

Incidence

- Vasectomy
  - Number of vasectomies performed each year is ~175,000–500,000
- Postvasectomy pain syndrome
  - 15–33% of men may experience persistent mild or troublesome testicular discomfort following vasectomy with 4% experiencing significant long-term testicular pain (orchalgia)
  - Long-term pain requiring some kind of intervention or surgical therapy occurs in up to 1 in 1,000 vasectomized men

Prevalence

~5% of couples of reproductive ages rely on vasectomy for contraception

RISK FACTORS

N/A

Genetics

N/A

PATHOPHYSIOLOGY

- Vasectomy
  - Vasectomy involves disrupting the vas deferens via suture ligation, electrocautery, clips, and/or fascial interposition
  - Vasectomy disrupts the blood–testis barrier
    - Antisperm antibodies in 60–80% of men
    - Does not appear to result in cell-mediated immunity
- Postvasectomy pain syndrome
  - Proposed mechanisms:
    - Increased pressure on the testicle and epididymis
    - High pressure may cause blowouts of sperm resulting in tender sperm granulomas and

epididymal regions
- Nerve entrapment
- Fibrosis

ASSOCIATED CONDITIONS
N/A

GENERAL PREVENTION
No preoperative factors have been identified in the postvasectomy pain syndrome

DIAGNOSIS

HISTORY
- Vasectomy
  - A careful history ensuring that the patient understands that this is a permanent method of sterilization should occur
  - A directed history including previous scrotal and inguinal surgery
- Postvasectomy pain syndrome
  - Mean time to onset of pain reported as 2 yr
  - Symptoms associated with postvasectomy pain syndrome include:
    - Persistent pain in the groin, testicle, or epididymis
    - Pain with an erection and/or engaging in sexual activity
    - Pain with ejaculation
    - Decreased libido and/or erections

PHYSICAL EXAM
- Prevasectomy
  - Ideally a preprocedure consultation should occur in person
  - Detailed physical exam performed to ensure the vas deferens are easily palpable
  - Patients with unusual scrotal sensitivity or anatomy may be identified, and may be recommended for procedure with sedation
- Postvasectomy pain syndrome
  - Physical exam commonly reveals fullness/tenderness at the proximal vas, epididymis, or at a granuloma site
  - Evidence of sperm granuloma
  - Epididymal tenderness or other masses
  - Examine for evidence for groin hernia

DIAGNOSTIC TESTS & INTERPRETATION
Lab
N/A

Imaging
- Postvasectomy pain syndrome
  - Usually not necessary
  - Ultrasound imaging can confirm epididymal engorgement, thickening, or nodularity

Diagnostic Procedures/Surgery
N/A

Pathologic Findings

- Vasectomy
  - Routine histologic exam of excised vas segment is not required
  - Analysis of testicular histology after vasectomy demonstrates dilatation of the seminiferous tubules, interstitial fibrosis, and reductions in the seminiferous cell population

DIFFERENTIAL DIAGNOSIS

- Postvasectomy pain syndrome
  - Hydrocele
  - Infection (eg, epididymitis)
  - Inguinal hernia
  - Intermittent testicular torsion
  - Nerve injury or entrapment
  - Psychogenic causes
  - Referred pain
  - Testicular or paratesticular neoplasm
  - Varicocele

TREATMENT

ALERT
Patients must be fully informed that an alternative form of birth control must be used immediately after vasectomy and until a semen analysis is clear.

GENERAL MEASURES

- Vasectomy
  - A minimally invasive or “no-scalpel vasectomy” technique should be used
  - Methods of performing vasectomy are based upon surgeon preference. These include:
    - Excision of a portion of the vas
    - Clips vs. suture ligation of vas ends
    - Cautery of mucosa
    - Interposition of the vas ends between fascia (may reduce recanalization)
- Postvasectomy pain syndrome
  - Conservative therapies are the mainstay: Scrotal support, activity limitation, sitz baths, ice-packs

MEDICATION

First Line

- Postvasectomy pain syndrome
  - Antibiotics
    - Empirically often used with no documented benefit in the absence of obvious infection
  - Nonsteroidal anti-inflammatory medication
    - Prolonged course (>3 mo) suggested before employing more aggressive approaches (see below)

Second Line
Tricyclic antidepressants and neuroleptic medication (eg, gabapentin) can be considered

SURGERY/OTHER PROCEDURES
- Postvasectomy pain syndrome
  - With the failure of long-term conservative management, more invasive treatments: Sperm granuloma excision, denervation of the cord, open-ended vasectomy, epididymectomy, and orchiectomy may be considered
  - With pain localized to a sperm granuloma on physical exam, granuloma excision with occlusion of vas with intraluminal cautery usually relieves the pain and reduces the risk of recurrence
    - In 1 study up to 50% were pain free following epididymectomy
    - Epididymectomy renders the vasectomy completely irreversible and may jeopardize the blood supply to the testes, which can result in ischemic atrophy
    - Vasectomy reversal: There are no controlled trials, but reversal may offer best chances of significant improvement (50% pain free in 1 series). The drawback is that fertility is restored (3)

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
- Postvasectomy pain syndrome
  - Men with intractable symptoms might benefit from a multidisciplinary team approach involving a urologist and a pain-clinic specialist, including a psychologist
  - Many men with chronic orchalgia also had signs of major depression or chemical dependencies (4)
  - Spermatic cord blocks
  - Local intralesional steroids
  - Transrectal injections into the region of pelvic plexus (5 mL bupivacaine and methyl prednisolone) have been used to manage cases of chronic orchalgia and may be considered as salvage therapy in refractory cases (5)
  - Neuromodulation and the use of testosterone have also been reported in this setting (6)

Complementary & Alternative Therapies
- Vasectomy
  - Patients should continue other means of contraception if they do not desire permanent sterilization

ONGOING CARE
PROGNOSIS
- Vasectomy
  - Patients are instructed that vasectomy does not work immediately
  - They should use contraception and consider themselves fertile until a postvasectomy semen analysis (PVSA) is negative

  - Even once vas occlusion is confirmed, the risk of preventing pregnancy is not 100% reliable. Risk of pregnancy is 1 in 2,000 for men who have PVSA showing azoospermia or rare nonmotile sperm
  - Repeat vasectomy is needed in $<1\%$
- Despite counseling, up to 5% of men will change their mind postvasectomy and request a vasectomy reversal

COMPLICATIONS

- Bleeding/hematoma: $\sim$1–2%
- Infection: $<1\%$
- Symptomatic sperm granuloma: $<1\%$
- Postvasectomy pain syndrome: 15–33%

FOLLOW-UP

Patient Monitoring

- PVSA should be a fresh uncentrifuged semen sample and should be examined within 1–2 hr of ejaculation
- PVSA can be made by the patient between 8–16 wk after vasectomy
- Acceptable PVSA show azoospermia or only rare nonmotile sperm
- Vasectomy should be considered a failure if motile sperms are present at 6 mo

CODES

ICD9

- 338.18 Other acute postoperative pain
- 608.89 Other specified disorders of male genital organs
- V26.52 Vasectomy status

ICD10

- G89.18 Other acute postprocedural pain
- N50.8 Other specified disorders of male genital organs
- Z98.52 Vasectomy status

CLINICAL/SURGICAL PEARLS

- A minimally invasive approach to accessing the vas (ie, no scalpel vasectomy) should be used.
- There are a variety of methods and techniques that can be used to disrupt the vas bilaterally including excision, clips, suture ligation, cautery, and fascial interposition.
- There are rare complications from vasectomy including hematoma and postvasectomy pain syndrome.

VESICOURETERAL REFLUX, ADULT

Sanjay S. Kasturi, MD

BASICS

DESCRIPTION

- Vesicoureteral reflux (VUR) is defined as retrograde passage of urine from the bladder into the ureter and/or renal pelvis and calyces
- VUR in the presence of bacteria is a risk factor for pyelonephritis and may lead to upper-tract pathology. It may be unilateral or bilateral, primary or secondary
- A more common problem in children, it can be associated with significant morbidity in adults and may be an uncommonly unrecognized cause of hypertension (HTN) in this population

EPIDEMIOLOGY

Incidence

- 5% of adults have VUR
- Female > male

RISK FACTORS

- 85% of childhood reflux occurs in girls; likely to be similar in adults
- Family history of VUR
- Conditions that predispose to secondary VUR (eg, neuropathic bladder)

Genetics

Having a parent or sibling with VUR increases the risk of childhood VUR

PATHOPHYSIOLOGY

- Primary VUR (1)
  - Failure of development or breakdown of the distal ureteral antireflux mechanism
  - Normally, the distal 4–5 cm of the ureter courses through the muscular wall of the bladder before reaching the bladder trigone
  - This tunnel prevents reflux of urine
  - Congenital deficiency of the intravesical tunnel is the most common etiology
- Secondary VUR
  - Disorders that cause elevated intravesical pressure: BPH, spinal cord injury, MS, and other neurologic diseases
  - Patients who have undergone urinary diversion (ileal conduit) or bladder replacement (orthotopic neobladder, catheterizable diversions) commonly have VUR
  - Bacterial cystitis can often cause transient ureteral reflux due to inflammation
  - Genitourinary TB can cause the ureteral orifices to become fixed and relatively patulous
- International Reflux Study Committee classifies VUR into 5 grades:
  - Grade I: Reflux partly up to the ureter
  - Grade II: Reflux up to the pelvis and calyces without dilatation; normal calyceal fornices
  - Grade III: Same as grade II, but with mild dilatation and tortuosity of the ureter and

minimal blunting of the fornices
  – Grade IV: Moderate dilatation and tortuosity of the ureter, pelvis, and calyces; complete blunting of fornices
  – Grade V: Gross dilatation and tortuosity of the ureter, pelvis, and calyces; absent papillary impressions in the calyces
- Mild reflux: Grades I and II
- Moderate reflux: Grade III
- Severe reflux: Grades IV and V
- Reflux associated with diversions such as ileal conduit is considered to be low pressure with minimal long-term damage to upper tracts.

ASSOCIATED CONDITIONS
- See causes of high bladder storage pressure mentioned above
- Typically seen in refluxing anastomosis: Neobladders, ileal conduits, renal transplantations

GENERAL PREVENTION
None; Long-term renal damage can be limited by appropriate prevention of infection and management of secondary cause of VUR

DIAGNOSIS

HISTORY
- History of VUR in childhood
- Family history of VUR
- Recurrent UTIs
- Simple cystitis leading to fever and flank pain suggestive of pyelonephritis
- Lower urinary tract voiding symptoms, suggesting outlet obstruction or neuropathic bladder

PHYSICAL EXAM
- CVA tenderness with pyelonephritis
- Digital rectal exam for BPH
- Palpable bladder
- Neurologic impairment
- HTN (if renal compromise)

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Blood testing is not necessary, except for severe cases in which renal function should be evaluated
- Proteinuria (if renal compromise)
- Urine analysis and culture should demonstrate the presence of infection if the patient is symptomatic:
  – Between infections, the urine will often be normal

Imaging
- US can show hydroureteronephrosis dependent on severity of VUR
- VCUG: Definitive test for identifying and grading the severity of reflux. It may also point toward the cause of VUR

- A nuclear medicine cystogram (indirect VCUG):
  – Can be performed with MAG3
  – Provides less anatomic information than the VCUG but does not require catheterization

Diagnostic Procedures/Surgery

Video urodynamic studies combine the information provided by the VCUG with physiologic information on bladder filling and voiding

Pathologic Findings

- Renal lesions (scarring) can be associated with higher grades of reflux
- Chronic scarring may, over time, cause HTN

DIFFERENTIAL DIAGNOSIS

- Other causes of flank (loin) pain and infection (eg, renal colic, ureteropelvic junction obstruction) (see Section I: "Flank Pain")
- Other causes of hydroureteronephrosis or ureteral obstruction (See Section I: "Hydronephrosis/Hydroureteronephrosis [Dilated Ureter/Renal Pelvis], Adult")

TREATMENT

GENERAL MEASURES

- Treatment of secondary VUR is directed at the primary cause (management of BPH, treatment of UTI, etc.)
- Early treatment of cystitis can prevent progression to pyelonephritis

MEDICATION

First Line

- Patients with recurrent UTI may benefit from prophylactic antibiotics
- Primary asymptomatic adult VUR does not otherwise require ongoing medical therapy as risk of progressive renal impairment is low
- Pregnant women with known VUR should be given antibiotic prophylaxis until delivery (eg, amoxicillin 250 mg/d PO) (2)

Second Line

- Secondary VUR may benefit from medical treatment of underlying cause:
  – Anticholinergic preparations in detrusor overactivity
  – α-Blockade or 5α-reductase inhibition in bladder outlet obstruction

SURGERY/OTHER PROCEDURES

- Primary VUR rarely requires surgical intervention in adults; however, where indicated procedures include:
  – Endoscopic treatment: Injection of bulking agents below the ureteral orifice:
    ◦ Initial results are good; however, long-term follow-up is scant
  – Several agents have been used for endoscopic correction of VUR:
    ◦ Polytetrafluoroethylene (Teflon)
    ◦ Cross-linked bovine collagen, dextranomer/hyaluronic copolymer (Deflux)
    ◦ Since the FDA approval of Deflux in 2001, this has been the most commonly used injectable agent for VUR

– Ureteric reimplantation can be undertaken transvesically, extravisually, or by a combination of both:
  ◦ Some common techniques include: Cohen cross-trigonal, Politano–Leadbetter, Lich–Gregoir (extravesical) reimplantations

ADDITIONAL TREATMENT

Additional Therapies

Additional therapeutic options in the treatment of the underlying condition for secondary VUR include intradetrusor botulinum toxin and sacral neuromodulation

Complementary & Alternative Therapies

Some data suggest cranberry juice and live-culture yogurt can be effective in preventing UTI

ONGOING CARE

PROGNOSIS

Depends on underlying etiology and severity of VUR

COMPLICATIONS (3,4)

- Chronic pyelonephritis
- Reflux nephropathy
- Renal impairment rare in primary VUR unless pre-existing from childhood, but can be encountered in secondary VUR
- UTI
- Urolithiasis

FOLLOW-UP

Patient Monitoring

- Medical follow-up is unnecessary in patients without HTN or proteinuria, unless the patient develops recurring infections, at which point repeat workup is needed
- Patients with intrinsic renal disease due to prior reflux (in childhood) require follow-up of BP, creatinine, and urine protein

CLINICAL/SURGICAL PEARLS

Women with VUR tend to present with infections, while men tend to present with HTN and proteinuria.

VESICOURETERAL REFLUX, PEDIATRIC

Angela M. Arlen, MD
Kathleen Kieran, MD, FAAP, FACS
Christopher S. Cooper, MD, FAAP, FACS

BASICS

DESCRIPTION

- Vesicoureteral reflux (VUR) is the retrograde flow of urine from the bladder into the ureter and/or kidney
- Primary VUR occurs in the absence of underlying lower urinary tract dysfunction
- Secondary VUR is associated with abnormally increased pressures or anatomy in the bladder or urethra

EPIDEMIOLOGY

Incidence

- Incidence is ~1% (1)[C]
- 30% in those with a febrile UTI
- 16.2% in those with prenatal hydronephrosis
- VUR detection varies with indication for radiographic evaluation, eg, 31% of children with UTIs and 17.2% of those without sonographic renal abnormalities had VUR (1)[C]

Prevalence

N/A

RISK FACTORS

- Caucasian race
- Younger age
- Female
- Family history
- Conditions associated with VUR secondary to anatomic anomalies: Bladder exstrophy, prune belly syndrome, ureteral duplication
- Obstructing bladder pathologies can create hostile and excessive storage and emptying pressures that eventually overwhelm a normal antirefluxing intramural flap–valve mechanism: Posterior urethral valves, myelodysplasia
- Severe voiding dysfunction

Genetics

- Likely autosomal dominant with incomplete penetrance
- Seen in 27–51% of siblings of children with VUR; up to 100% in identical twins
- Seen in 50–66% of children of parents with VUR

PATHOPHYSIOLOGY

- The normal ureter enters the bladder at an oblique angle through the bladder wall; with bladder filling on contraction, the ureter is compressed and retrograde flow of urine (reflux) is prevented

- Primary VUR is associated with a functionally shortened submucosal tunnel
- Secondary VUR occurs in the setting of abnormal lower urinary tract function with resulting increase in bladder pressures
- VUR is graded on a scale of I–V:
  - I: Ureter only
  - II: Renal pelvis and calyces without dilatation
  - III: Renal pelvis and calyces with calyceal blunting
  - IV: Renal pelvis and calyces with ureteral tortuosity
  - V: Severe ureteral tortuosity

ASSOCIATED CONDITIONS

- Primary VUR: Hydronephrosis, UTI, bladder/bowel dysfunction
  - Also ipsilateral or contralateral renal anomalies: Ureteral duplication, ureteral ectopia, ureterocele, lulticystic dysplastic kidney (MCDK) or ureteropelvic junction (UPJ) obstruction
- Secondary VUR: All of the above, as well as neurogenic bladder, posterior urethral valves, prune belly syndrome, bladder exstrophy

GENERAL PREVENTION

- Primary VUR: None
- Secondary VUR: Optimizing lower urinary tract function to prevent elevated pressure and decreased bladder compliance

DIAGNOSIS

HISTORY

- Typically asymptomatic
- Frequently found on evaluation of patients with history of hydronephrosis, pyelonephritis, or UTIs
- Obtain careful history of UTI and other infections, fevers, abdominal or flank pain, dysuria, elimination habits
- Review antenatal imaging, gestational course, postnatal growth and development

PHYSICAL EXAM

- Complete physical exam for baseline functional information
- Neurologic exam for spina bifida
- Abdominal and pelvic exam:
  - Palpable kidneys secondary to hydronephrosis
  - Palpable bladder secondary to incomplete emptying
  - CVA tenderness
  - Suprapubic tenderness
  - Circumcision status in males
- Poor somatic growth seen in some patients with renal insufficiency
- Blood pressure should be compared with age-adjusted normative values
- Identify or exclude causes of secondary VUR, eg, neurogenic bladder

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Voided specimen urine for assessment of proteinuria, evidence of infection
  - Catheterized urine samples are more accurate for diagnosis of infection but are more costly and invasive; collect in patients with high index of suspicion based on voided sample or in patients with history of VUR
- Cultures sent only when urinalysis or clinical presentation is suspicious for infection
- Serum creatinine and electrolytes are not routinely checked unless significant sonographic anomalies in renal units, history of multiple febrile UTIs, or significant renal scarring on radionuclide imaging; evaluate at initial diagnosis and again only when substantial change in clinical condition
- Annual CBC appropriate in patients taking daily sulfamethoxazole or nitrofurantoin

Imaging

- Voiding cystourethrogram (VCUG) or radionuclide cystogram
- Renal ultrasound and nuclear medicine scan may suggest presence of VUR but are not sensitive or specific enough for definitive diagnosis
- Renal ultrasound utilized to help define upper tract anatomy, eg, hydronephrosis or duplicated systems, assess quality of renal parenchyma, ensure adequate renal growth
- Renal scintigraphy (DMSA scan) is the gold standard for detection of renal scarring
  - Differential renal function
  - Diagnosis of acute pyelonephritis/scarring

Diagnostic Procedures/Surgery

- Uroflowmetry to screen for abnormal voiding pattern in toilet-trained children may be useful
- Urodynamics to evaluate bladder compliance and function in children with secondary VUR
- Routine cystoscopy is avoided, but can be considered preoperatively to further evaluate duplication, diverticula, or ureteral ectopia

Pathologic Findings

Patients with reflux nephropathy and renal scarring may have increased deposition of collagen and scar tissue in the renal parenchyma

DIFFERENTIAL DIAGNOSIS

- Should be based on the abnormal symptom or clinical finding that prompted the evaluation
  - UTI: Dysuria, lower tract infection vs. pyelonephritis
  - Hydronephrosis: Physiologic hydronephrosis, ureterovesical junction obstruction, ureteropelvic junction obstruction, congenital megaureter
  - Always consider secondary causes when evaluating for VUR

TREATMENT

GENERAL MEASURES

- Counsel parents on pathophysiology and natural history of VUR: Causes, comorbid conditions, potential sequelae, likelihood of resolution, risks and benefits of alternative treatment plans
- Spontaneous resolution of primary reflux is common and depends on initial grade of reflux,

gender, age, voiding dysfunction, presence of renal scarring, and timing of VUR on VCUG
- Goal of intervention is to prevent renal scarring, recurrent febrile UTI, and long-term complications such as hypertension and renal insufficiency

MEDICATION

First Line

- Prophylactic daily antibiotics to keep urine sterile, preferentially given at bedtime to maximize urinary retention
  - <2 mo age: Amoxicillin 20 mg/kg/d
  - ≥ 2 mo of age: Trimethoprim–sulfamethoxazole 2 mg/kg/d (concentrates in urine); nitrofurantoin is an alternative, but liquid is expensive and bad tasting

ALERT
American Academy of Pediatrics (2011): meta-analysis of 6 randomized controlled studies demonstrated no difference in rates of UTI between patients taking prophylactic antibiotics and those not taking prophylactic antibiotics (2)[A].

- Findings met strenuous objection from pediatric urology community based on multiple methodologic flaws
- Majority of urologists continue to endorse prophylactic antibiotics in patients being followed conservatively, and consider exceptions case by case

Second Line

- Management of elimination habits:
  - Constipation: Encourage daily soft bowel movement, consider polyethylene glycol, probiotics
  - Urinary urgency and/or urge incontinence refractory to behavioral modification: Addition of an anticholinergic (eg, oxybutynin)

SURGERY/OTHER PROCEDURES

- Surgical intervention recommended for persistent VUR, worsening renal function, recurrent UTIs (3)[A]
- May be performed endoscopically or via open approach
  - Tailor approach to clinical presentation, medical history, anatomy, shared goals of clinician and patient
- Endoscopic intervention:
  - Benefit of using natural orifice, avoiding incision/scar; typically same-day surgery
  - Success rate dependent on surgeon, reflux grade, and bulking agent; typically 70–85%
  - Injection of bulking agent in and around ureteral orifice
  - Only 1 currently in use in US: Deflux, Salix (dextranomer–hyaluronic acid copolymer)
- Ureteral reimplantation:
  - Higher success rate (95–99%)
  - Can be performed via intra- or extravesical approach
  - Laparoscopic/robotic approaches have success rates comparable to open
- If VUR persists after either approach, surgery may be repeated
  - These patients must be vigorously evaluated for secondary cause of VUR, such as dysfunctional elimination

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Treatment of constipation and voiding dysfunction, including adherence to a bowel regimen, increased hydration and a timed voiding schedule is mandatory in children with VUR and elimination dysfunction
- Selective use of anticholinergic medications

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Overall resolution rate according to grade:
  - Grade I: Over 90%
  - Grade II: 70–80%
  - Grade III: 50–60%
  - Grade IV: 10–30%
  - Grade V: <10%
- Likelihood of resolution depends on many factors: Age, gender, laterality, reflux grade, volume of bladder at onset of reflux, presence/absence of voiding dysfunction (4)[B]
- Online neural network available: http://godot.urol.uic.edu/urocomp/svm_vur.html (5)[B]
- Bladder and bowel dysfunction shown to decrease and delay resolution
- Ureteral duplication associated with delay in time to resolution, but not significantly with changes in overall resolution rate

COMPLICATIONS

- Renal insufficiency
  - Reflux nephropathy most common cause of renal failure in children, often associated with renal scarring
    - Scarring occurs from infection in renal parenchyma; prophylactic antibiotics keep urine sterile
    - May manifest as hypertension, proteinuria, elevated serum creatinine, decreased GFR
    - Severe cases may progress to chronic renal insufficiency and end-stage renal disease
  - Dysplastic renal parenchyma
    - Increased risk with high-grade VUR
    - Sonography, serial creatinine, proteinuria, blood pressure checks may help identify these patients

FOLLOW-UP

Patient Monitoring

- Patients with VUR:
  - Annual complete physical exam with blood pressure check and urinalysis (proteinuria, infection)

  – Serial imaging: No consensus on interval, but general agreement of renal ultrasound and cystography every 1–2 yr
- After surgical correction or spontaneous resolution:
  – Annual blood pressure check and urinalysis (proteinuria, infection)
  – Use of routine sonography is debated
  – VCUG or nuclear cystography should be considered with symptoms of pyelonephritis or new sonographic abnormalities
- Siblings of children with VUR should undergo renal ultrasonography; VCUG reserved for cases of symptoms or ultrasound abnormalities (6)[A]

CODES

ICD9

- 593.70 Vesicoureteral reflux unspecified or without reflux nephropathy
- 753.5 Exstrophy of urinary bladder
- 756.71 Prune belly syndrome

ICD10

- N13.70 Vesicoureteral-reflux, unspecified
- Q64.10 Exstrophy of urinary bladder, unspecified
- Q79.4 Prune belly syndrome

CLINICAL/SURGICAL PEARLS

- VCUG should be performed in children with febrile UTI and non–toilet-trained infants with UTI, and in other children as clinically indicated.
- All children with VUR should be assessed for dysfunctional elimination to reduce the likelihood of UTI.

VON HIPPEL–LINDAU DISEASE/SYNDROME

Jed-Sian Cheng, MD, MPH
Gennady Bratslavsky, MD

BASICS

DESCRIPTION

- Von Hippel–Lindau (VHL) disease is a multisystem autosomal dominant neoplastic syndrome with a predisposition to develop:
  - Clear cell renal cell carcinoma (ccRCC) and cystic lesions
  - Pancreatic neuroendocrine tumors (NET) and cystic lesions
  - Pheochromocytomas
  - Central nervous system (CNS) hemangioblastomas
  - Retinal angiomas
  - Endolymphatic sac tumors (ELST)
  - Cystadenomas of the epididymis (males) or broad ligament (females)

EPIDEMIOLOGY

Incidence

Rare: 1 in 35,000 live births

Prevalence

Prevalence in USA: About 7,000 people

RISK FACTORS

- Inheritance of a mutated VHL allele
- No gender or racial predilection

Genetics

- Autosomal dominant inheritance pattern
- *VHL* is a tumor suppression gene on chromosome 3p25–26 (3)
- Affected individuals inherit 1 copy of a mutated VHL from the affected parent
- The loss or mutation of the 2nd (initially normal) allele in the cell leads to tumor formation (mechanism known as a 2-hit model)
- Present technology identifies the mutated gene in 100%

PATHOPHYSIOLOGY

- Mutated VHL leads to aberrant VHL protein (pVHL)
- Abnormal pVHL is unable to target hypoxia inducible factor (HIF) for degradation
- Accumulation of HIF protein upregulates downstream genes such as *VEGF, GLUT-1, PDGF, TGF-α, Epo,* and many others, leading to tumor formation

ASSOCIATED CONDITIONS

- Multifocal and bilateral ccRCC in 50%
- Renal cysts seen in up to 70%
- Pheochromocytomas in about 20%

  - Extra-adrenal pheochromocytomas in $<5\%$
- CNS hemangioblastomas in 75%
- Retinal angiomas in 50–55%
- Pancreatic NET in 15–20%
- Pancreatic cysts are seen in up to 60%
- ELST in 5–10%
- Papillary cystadenomas of the epididymis or broad ligament in $<5\%$
- VHL-associated lung cysts/tumors in $<1\%$
- VHL-associated ovarian tumors in $<1\%$

GENERAL PREVENTION
- Close surveillance of affected individuals and timely intervention
- Genetic screening of family to initiate early surveillance

DIAGNOSIS

HISTORY
- Family history of RCC or pheochromocytoma, CNS or pancreatic surgeries, hearing or vision problems is often elicited
- Patients may present with ≥ 1 symptoms related to the organ involved
- Renal tumors and cysts:
  - Usually detected incidentally or during screening by imaging in VHL patients
  - May present with hematuria, flank pain, abdominal fullness, weight loss, cachexia in advanced disease
- Pheochromocytoma:
  - Headaches, palpitations, episodic sweating, anxiety attacks, personality changes
  - Severe hypertension (HTN) leading to hemorrhagic stroke
  - Rarely may present with weight loss, cachexia, bone pain, or cough in setting of metastatic disease
  - May be asymptomatic
- CNS hemangioblastomas:
  - Often asymptomatic
  - Headaches, vertigo, ataxia, vomiting, wide-based gait, sensory loss, seizures
  - Size and location of the lesion(s) often determine symptoms
- Retinal angiomas:
  - Blurred or decreased vision, eye pain
  - If undetected, may present with blindness
- Pancreatic NET and cysts:
  - Most are asymptomatic
  - Diarrhea, steatorrhea, and diabetes may occur if pancreas is replaced by cysts
  - Early satiety if pancreatic cysts are large and compressing the stomach
  - Bone pain and painless jaundice in rare cases of extrinsic compression of the biliary system or metastatic disease
- ELST:
  - Hearing decrease or loss, tinnitus, vertigo
- Cystadenomas of epididymis:

– Scrotal or testicular tenderness or mass

PHYSICAL EXAM

- Careful urologic, neurologic, and ophthalmologic exam can often help with diagnosis of VHL
- ccRCCs:
  – Undetected unless large in size
  – May cause marked varicocele
  – Occasionally, skin lesions or jaundice may be appreciated in metastatic RCC
- Pheochromocytoma:
  – HTN, tachycardia, arrhythmias
- CNS hemangioblastomas:
  – Nystagmus, papilledema, loss of proprioception, and sensory deficits
- Retinal angiomas:
  – Decreased visual acuity, characteristic retinal hemangiomas, and retinal detachment
- Pancreatic NET:
  – Undetected on exam unless large in size, metastatic, or causing obstruction
- ELST:
  – Decrease or loss of hearing
- Papillary cystadenomas of the epididymis:
  – Paratesticular tenderness and palpable epididymal masses

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Elevated plasma and urine catecholamines are seen in patients with pheochromocytoma:
  – Norepinephrine or normetanephrine are most commonly elevated in VHL patients
  – Other catecholamines may also be elevated
- Similar to sporadic ccRCC:
  – Hypercalcemia, erythrocytosis, anemia, or elevated liver function tests (LFTs) may be seen as paraneoplastic lab abnormalities
- Elevated erythropoietin levels or erythrocytosis may be seen with CNS involvement

Imaging

- Brain and spine magnetic resonance imaging (MRI) for detection of CNS hemangioblastomas and ELSTs
- Abdominal imaging: Ultrasound (US) in children, and computed tomography (CT) or MRI in adults for detection of renal or pancreatic masses, as well as adrenal and extra-adrenal pheochromocytomas
- Metaiodobenzylguanidine scan (MIBG) scan is helpful in localizing active pheochromocytoma
- Chest CT or MIBG may be helpful for extra-abdominal pheochromocytomas

Diagnostic Procedures/Surgery

- Genetic testing
- Occasionally, the glucagon stimulation test or clonidine suppression for pheochromocytoma

Pathologic Findings

- ccRCCs:

  – Usually multifocal and bilateral
  – May be several hundreds of gross and microscopic lesions in a single kidney
  – Most commonly Fuhrman nuclear grade II
  – Cysts commonly lined by clear cells
- Pheochromocytoma:
  – Encapsulated and vascular
  – Frequently multifocal and bilateral
  – Microscopic: Nests of cells in round clusters
- CNS hemangioblastomas:
  – Solitary or multiple lesions in cerebellum, spinal cord, brainstem, or cerebrum
  – Benign vascular lesions
- Pancreatic NET:
  – Usually multifocal intermixed with cysts
  – May metastasize to liver or bones unless resected in timely manner
  – Well-demarcated, unencapsulated nodules
  – Microscopic: Nests of polygonal cells with vesicular nuclei
- ELST:
  – Locally aggressive; usually slow growing
  – Microscopic: Low-grade papillary adenocarcinomas
- Papillary cystadenomas of the epididymis or the broad ligament:
  – Benign lesions
  – Well circumscribed but unencapsulated
  – Microscopic: Papillary and tubular architecture with a fibrous stroma

DIFFERENTIAL DIAGNOSIS
- Metastatic RCC or other primary
- Multiple endocrine neoplasia type 2 (MEN-2)
- Non-VHL familial bilateral multifocal RCC
- Other familial types of hereditary renal carcinoma syndromes
- Polycystic kidney disease
- Sporadic form of bilateral RCC
- Succinate dehydrogenase B (SDHB) deficiency syndrome in the presence of pheochromocytoma and renal masses

TREATMENT

GENERAL MEASURES
- Vigilant surveillance of kidneys, adrenals, pancreas, retina, brain, and spinal cord are the most important measures for timely intervention
- Surgery is still the mainstay of VHL treatment
- Nephron-sparing surgery is recommended when the largest solid tumor reaches 3 cm in the largest dimension

MEDICATION
First Line
- No VHL-specific medical treatment

- Treatment directed to address immediate presenting symptoms (eg, antihypertensives in patients presenting with pheochromocytoma)
- Other agents may be necessary for the management of related diseases such as RCC
- Preoperative blockade in a patient with a known pheochromocytoma
  - National Cancer Institute (NCI) regimen: Phenoxybenzamine 10 mg BID and metyrosine 250 mg TID for 2 wk preop

Second Line

N/A

SURGERY/OTHER PROCEDURES

- ccRCC:
  - Dozens of tumors may be resected in a single setting with adequate renal preservation
  - To minimize renal ischemia, most of the surgery is performed without hilar clamping
  - Select patients may benefit from laparoscopic or robotic surgery
  - Prior renal surgery or ablation makes surgery more challenging and increases morbidity
  - Bilateral nephrectomies and renal transplantation may be a valid option for occasional patients
- Pheochromocytoma:
  - Laparoscopic, robot-assisted, or open partial adrenalectomies are performed to preserve maximal adrenal function and avoid steroid dependence (1)
- Pancreatic NET:
  - Resection is the most definitive treatment
  - The type of surgical resection and procedure is determined by tumor size and location
- ELSTs or hemangiomas: Surgical resection
- Retinal angiomas: Laser ablation or cryotherapy

ADDITIONAL TREATMENT

Radiation Therapy

Occasional stereotactic irradiation of the metastatic disease or CNS hemangioblastomas not amendable to surgical resection

Additional Therapies

- A few clinical trials are presently in progress for treatment of VHL-associated tumors
- Genetic counseling, ophthalmology, neurosurgery, and otolaryngology support as needed

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Much depends on the stage of the renal lesions at presentation
- Growth rate similar to sporadic counterpart of about 3 mm on average per year
- No metastasis with solid RCC lesions <3 cm (2)
- Metastatic potential of RCC lesions increases with increase in the size of the lesion, with up to 50% metastasis in those with tumors >6 cm
- Pancreatic NET also increase metastatic potential with increase in size

COMPLICATIONS

- Hypertensive crisis resulting in hemorrhagic stroke
- Severe neurologic deficit or paralysis
- Blindness
- Metastatic disease from either RCC, pheochromocytoma, or pancreatic NET

FOLLOW-UP

Patient Monitoring

- Radiographic surveillance is performed every 1–2 yr with CT or MRI for kidneys, adrenal, pancreas; and MRI for brain or spinal cord
  - More frequent for faster-growing lesions
- Ophthalmology exams yearly
- Otology exams every 5 yr
- Pediatric considerations
  - Yearly ophthalmologic exam from birth
  - Yearly urinary catecholamines from age 2 yr
  - Yearly abdominal US from age 10 yr
- Pregnancy considerations
  - Higher risk of miscarriage with active pheochromocytoma
  - Treatment of pheochromocytoma is preferred before pregnancy or early in the pregnancy

CODES

ICD9

- 189.0 Malignant neoplasm of kidney, except pelvis
- 209.60 Benign carcinoid tumor of unknown primary site
- 759.6 Other hamartoses, not elsewhere classified

ICD10

- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- D3A.8 Other benign neuroendocrine tumors
- Q85.8 Other phakomatoses, not elsewhere classified

CLINICAL/SURGICAL PEARLS

Suspect VHL in a patient with strong family history of RCC or pheochromocytoma, CNS or pancreatic surgeries, hearing or vision problems.

WILMS TUMOR (NEPHROBLASTOMA)

Jonathan S. Karpelowsky, MD, PhD
Grahame H.H. Smith, MBBS

BASICS

DESCRIPTION

- Wilms tumor (nephroblastoma) is the most common primary malignant renal tumor in childhood
- Represents 6% of all childhood cancers
- Most present in children with abdominal mass
- Symptoms may include pain, hypertension, or hematuria
- Wilms tumor is considered a pediatric renal tumor, but does rarely occur in adults

EPIDEMIOLOGY

Incidence

- 6% of all childhood tumors
- 80% of cases occur in age <5
- 7% bilateral (present at mean age 2.5)
- 12% multifocal within a single kidney
- Rare >10 yr and <6 mo
- Median age 3.5 yr

Prevalence

8 per million children every year

RISK FACTORS

- Increased frequency in children with:
  - Beckwith–Wiedemann syndrome: 1 in 10 children develop a tumor of the liver, adrenal cortex, or kidney
  - Hemihypertrophy (2% risk)
  - Denys–Drash syndrome
  - WAGR syndrome (Wilms tumor/aniridia/genitourinary anomalies/mental retardation syndrome), (30% risk)
  - Perlman syndrome
  - Sotos syndrome (2–3% risk)
- Presence of nephrogenic rests:
  - 1% of kidneys on infant postmortems
  - 35% of unilateral Wilms
  - Almost 100% of bilateral Wilms
- Higher risk in African American compared to Caucasians for Wilms tumor
- Lower risk in Asians compared to Caucasians

Genetics

- WT1 (11p13): Denys–Drash and WAGR syndromes

- WT2 (11p15): Beckwith–Wiedemann syndrome
- FWT1 (17q), FWT2 (19q): Familial; 1–2% of cases
- 16q, loss of long arm in 20% of cases
- 1p, loss of short arm in 10% of cases

PATHOPHYSIOLOGY
- An embryonal tumor marked by proliferation of metanephric blastema composed of 3 cell types: Blastemal, stromal, epithelial
- Histology: Favorable vs. unfavorable (ie, anaplasia pre- or postchemotherapy and blastemal predominant histology postchemotherapy)
- Anaplasia seen in 5%

ASSOCIATED CONDITIONS
- Congenital anomalies in 15% of Wilms tumors
- GU anomalies: Renal anomalies, cryptorchidism, hypospadias, ureteral duplication, ambiguous genitalia (4%)
- Hemihypertrophy (3%)
- Aniridia (1%)
- Denys–Drash syndrome (male pseudohermaphroditism, renal mesangial sclerosis, renal failure)
- WAGR syndrome
- Beckwith–Wiedemann syndrome (macroglossia, organomegaly, hemihypertrophy)
- Other: Perlman syndrome, Sotos syndrome, Simpson–Golabi–Behmel syndrome

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Abdominal mass
- Fever, anorexia, weight loss
- Hematuria

PHYSICAL EXAM
- Most common presentation is abdominal mass
- HTN: 20–25% from activation of RAAS (renin-angiotensin-aldosterone system)
- Occasionally present as acute abdomen or with hypotension from tumor rupture

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CBC: Anemia, polycythemia
- Liver function tests
- BUN, creatinine
- Serum calcium
- Urine analysis: 25% with microhematuria
- Coagulation studies to assess for an acquired von Willebrand disease

Imaging

- Abdominal US: Initial study and if there is any concern about intravascular extension
- CT of abdomen and chest: To detect smaller lesions in either renal unit not detected by US; chest imaging to evaluate for pulmonary metastasis
- Bone scan: If history of bone pain or elevated alkaline phosphatase or serum Ca

Diagnostic Procedures/Surgery

- National Wilms Tumor Study Group (*NWTSG*)/Children's Oncology Group (COG), recommends surgical excision or biopsy, followed by adjuvant treatment
- SIOP (International Society of Pediatric Oncology) treatment involves preoperative chemotherapy followed by surgery. Histology and staging are potentially altered but the tumor response to chemotherapy is noted and aids in risk stratification
- Percutaneous biopsy is not recommended

Pathologic Findings

- Gross: Tan or grayish, fleshy tumor with a pseudocapsule
- Microscopic (3 features): Stromal (immature spindle cells and can have muscle cartilage or fat), epithelial (recapitulates kidney with glomeruli and tubules), and blastemal (undifferentiated cells)
- Venous invasion in up to 20%; usually single tumor; 7% bilateral and 12% multifocal
- Histology relates to final outcome:
  - Favorable (95%)
  - Unfavorable (Anaplasia) (5%): Nuclear enlargement (>3-fold), hyperchromasia, abnormal mitoses. Unfavorable marker of chemoresistance

DIFFERENTIAL DIAGNOSIS

- Clear cell sarcoma
- Rhabdoid tumor
- Neuroblastoma
- Multilocular cystic nephroma
- Mesoblastic nephroma
- Multicystic dysplastic kidney
- Renal cell carcinoma
- Renal medullary carcinoma

TREATMENT

GENERAL MEASURES

- Multimodality therapy combining surgery, chemotherapy, and radiation
- Treatment decisions based on staging
- Staging relies on anatomic extent of tumor (no genetic, histologic, or biomarkers); higher stages have worse prognosis and require more aggressive therapy
- 2 systems currently used, the NWTSG/COG and SIOP; they are difficult to compare directly due to the fact that NWTSG/COG is a prechemotherapy staging and SIOP post-neoadjuvant therapy:
  - NWTSG/COG: Commonly used in USA and Canada; based on surgical evaluation prior to chemotherapy

– SIOP: Commonly used in Europe, based on surgical findings following chemotherapy

MEDICATION

First Line

- SIOP studies favor preoperative chemotherapy for 6 wk with dactinomycin plus vincristine following which surgery is undertaken and the tumor response to chemotherapy and the residual histology, ie, if is blastemal predominant will risk stratify further therapy
- Chemotherapy recommendations based on NWTSG/COG, which is given adjuvantly postoperatively
- Children <24 mo and with a specimen weight of <550 g and favorable histology are being considered under study for surgery only and no chemotherapy
- Pulse-intensive dactinomycin plus vincristine (18 wk) for:
  – Stage I: Favorable histology, age >2 yr, or tumor <550 g
  – Stage I: Anaplasia
  – Stage II: Favorable histology
- Pulse-intensive dactinomycin, vincristine, and doxorubicin (24 wk) for:
  – Stages III–IV: Favorable histology
  – Stages II–IV: Focal anaplasia
  – Stage V: Doxorubicin, vincristine, cyclophosphamide, etoposide
  – Stages II–IV: Diffuse anaplasia (1)

Second Line

The optimal salvage chemotherapy regimen is unknown. Recurrent/persistent tumors have been treated with cyclophosphamide, ifosfamide, carboplatin, etoposide, and cisplatin combinations

SURGERY/OTHER PROCEDURES

- Choose incision that provides adequate exposure: Transabdominal, thoracoabdominal, chevron
- Unilateral tumor:
  – Radical nephrectomy
  – Contralateral exploration not needed if not seen on adequate preoperative imaging
  – Lymph node: Sample perihilar, pericaval, and para-aortic nodes; excise suspicious nodes minimum of 3–5 nodes
- Bilateral tumor:
  – Biopsy not initially required
  – Reimage 6 wk after chemotherapy; if <50% response consider open bilateral biopsy, if >50% response then continue therapy to 12 wk and then aim for nephron sparing surgery
  – Renal preservation is key to avoid renal failure; important for patient with syndromes at high risk for metachronous disease
- Tumor spillage:
  – Local: Percutaneous anterior/posterior percutaneous biopsy; open incisional biopsy (stage III)
  – Peritoneal spillage or tumor thrombus spillage is more extensive (stage III)
- Local invasion: Usually can be resected en masse; if not, biopsy and treat with chemotherapy

ADDITIONAL TREATMENT

Radiation Therapy

- Stage III favorable histology and stages II–III focal or diffuse anaplasia:
  - Abdominal/flank irradiation 10.8 Gy
- Stage IV favorable histology and stage IV focal or diffuse anaplasia:
  - Abdominal/flank irradiation 10.8 Gy
  - Lung radiation 12 Gy with lung metastasis on chest x-ray or CT only metastasis not responding to therapy (CT only metastasis that respond to chemotherapy and have no loss of heterozygosity can have pulmonary radiotherapy omitted)

Additional Therapies

Ongoing studies of NWTSG/COG to assess modifying treatment based on risk stratification

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- 5-yr overall survival: 90%
- 4-yr postnephrectomy overall survival:
  - Favorable histology:
    - Stage I: 98%
    - Stage II: 96%
    - Stage III: 95%
    - Stage IV: 90%
  - Unfavorable histology:
    - Stage I: 83%
    - Stage II: 81%
    - Stage III: 72%
    - Stage IV: 37%
    - Stage V: 55%
- Unfavorable histology: 12% of patients, but 50% of deaths
- Prognostic factors: Histology, stage, patient age (younger better prognosis, but less significant today due to improved treatments)
- Future treatment will include 1p and 16q loss of heterozygosity in the risk and treatment stratification

COMPLICATIONS

- Surgical:
  - Bowel obstruction (5.1%)
  - Hemorrhage (1.9%)
  - Wound infection (1.9%)
  - Vascular injuries (1.4%)
  - Injuries to other visceral organs (1%)
- Medical:
  - Renal impairment

    - 1% chance from surgical, chemotherapy, and/or radiation
    - Increased in bilateral disease with radiation
    - Unilateral disease risk in Denys–Drash
  - Cardiotoxicity
    - Congestive heart failure in patients treated with doxorubicin; dose dependent
  - Hepatotoxicity
    - Vincristine and dactinomycin; dose related
  - Secondary malignancies
    - Highest risk in patients treated with both doxorubicin and radiation; occur in radiation field; mean 16.1-yr post therapy
- Radiation:
  - Short stature, muscle atrophy, scoliosis
  - Highest risk in age <1
  - Thyroid disease and mammary tissue damage in chest radiation
  - Pregnancy complications increased in females receiving high-dose abdominal radiation

FOLLOW-UP

Patient Monitoring

- Screen patients with aniridia, hemihypertrophy, and Beckmann–Wiedemann syndrome with abdominal US every 3–4 mo to age 7
- 1% of children develop contralateral Wilms within 6 yr of 1st diagnosis
- Majority of Wilms tumor recurrence occurs within 2 yr of nephrectomy
- Favorable histology, <24 mo, and tumor weight <550 g
  - Chest x-ray, abdominal US every 3 mo for 1st 2 yr after diagnosis, then every 6 mo for 1 yr, then yearly for 2 yr
- All others:
  - Chest x-ray 6 wk and 3 mo after surgery; then every 3 mo for 15 mo, every 6 mo for 18 mo, and yearly for 2 yr
  - Abdominal US every 3 mo for 2 yr, then every 6 mo for 3 yr

CODES

ICD9
- 189.0 Malignant neoplasm of kidney, except pelvis
- 253.0 Acromegaly and gigantism
- 759.89 Other specified congenital anomalies

ICD10
- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- E22.0 Acromegaly and pituitary gigantism
- Q87.3 Congenital malformation syndromes involving early overgrowth

CLINICAL/SURGICAL PEARLS

An asymptomatic abdominal mass is the most common manifestation of Wilms tumor.

SECTION II

Short Topics: A to Z

Section Editors: Deborah T. Glassman, MD
Alana M. Murphy, MD

11β-HYDROXYLASE (CYP11B1) DEFICIENCY

DESCRIPTION Comprises 5–8% of congenital adrenal hyperplasia (CAH) cases. Autosomal recessive disorder that manifests as childhood hypertension, hypokalemia, and muscle weakness. Low plasma renin activity is a hallmark. A deficiency in 11β-hydroxylase leads to low cortisol levels, high adrenocorticotropic hormone levels, and adrenal hyperplasia. Afflicted females are virilized and may have male-appearing genitalia. Males may be hyperdeveloped. Diagnosed by high levels of deoxycorticosterone and/or 11-deoxycortisol in serum or their tetrahydro-metabolites in a 24-hr urine. (See also Section I: "Disorders of Sexual Development [DSD]"; Section II: "Congenital Adrenal Hyperplasia.")

TREATMENT

- Oral hydrocortisone (10–20 mg/m^2/d)
- Refractory hypertension treated with spironolactone, amiloride, and/or calcium channel blockers
- Surgical correction of ambiguous genitalia in females
- Prenatally treated with steroid administration to mother

REFERENCE

White PC. Steroid 11 beta-hydroxylase deficiency and related disorders. *Endocrinol Metab Clin North Am.* 2001;30(1):61–79.

2,8-DIHYDROXYADENINE (2,8-DHA) UROLITHIASIS

DESCRIPTION Adenine phosphoribosyltransferase (APRT) deficiency is a defect of purine metabolism and is inherited as an autosomal recessive trait. APRT is a salvage enzyme that catalyzes the conversion of adenine to adenosine monophosphate. The APRT deficiency results in adenine accumulation with oxidation by xanthine dehydrogenase (XDH) to 2,8-dihydroxyadenine (2,8-dihydroxyadenine or 2,8-DHA) then excreted in urine. This compound is extremely insoluble and its crystallization can lead to stone formation and renal failure. The diagnosis is based on stone analysis by infrared spectroscopy or exam of urine, which may reveal typical 2,8-DHA crystals.

TREATMENT

The crystallization of 2,8-DHA and subsequent renal damages may be prevented with allopurinol therapy, a xanthine oxidase inhibitor.

REFERENCE

Bouzidi H, Lacour B, Daudon M. 2,8-dihydroxyadenine nephrolithiasis: From diagnosis to therapy. *Ann Biol Clin (Paris)*. 2007;65(6):585–592.

21-HYDROXYLASE (CYP21A2) DEFICIENCY

DESCRIPTION Responsible for >90% of CAH cases. This enzyme deficiency leads to low cortisol levels and high ACTH level, leading to adrenal hyperplasia. It is the most common cause of female pseudohermaphrodism. Most have aldosterone deficiency, which can lead to fatal salt wasting. Untreated patients are tall as children but short as adults. Untreated

females may have secondary amenorrhea or polycystic ovarian syndrome. Males may have small testes with precocious secondary sexual characteristics. Diagnosed by elevated 17α-hydroxyprogesterone levels in serum with ACTH stimulation test. (See also Section I: "Disorders of Sexual Development [DSD]"; Section II: "Congenital Adrenal Hyperplasia.")

TREATMENT

- Oral hydrocortisone (10–20 mg/m^2/d)
- 9α-fluorohydrocortisone for salt wasters
- Surgical correction of ambiguous genitalia in females
- Prenatally treated with steroid administration to mother

REFERENCE

White PC, Bachega TA. Congenital adrenal hypoplasia due to 21 hydroxylase deficiency: From birth to adulthood. *Semin Reprod Med.* 2012;30(5):400–409.

5α-REDUCTASE DEFICIENCY

DESCRIPTION An autosomal recessive disorder characterized by a 46XY male with external female phenotype at birth, normally developed wolffian structures, and bilateral testes residing outside the abdominal cavity. The primary etiology is the loss of dihydrotestosterone (DHT) during fet al development. Hypoplasia or absence of the prostate and a blind-ending vagina are common. Virilization occurs at puberty. Diagnosed by normal-to-high male plasma testosterone levels, abnormal ratios of serum testosterone to DHT, or abnormal ratios of urinary 5α- to 5β-steroid metabolites. (See also Section I: "Disorders of Sexual Development [DSD].")

TREATMENT

- Male gender assignment: Genital reconstruction and supplemental androgen
- Female gender assignment: Orchiectomy, estrogen/progesterone therapy, and vaginoplasty

REFERENCE

Cheon CK. Practical approach to steroid 5-alpha-reductase type 2 deficiency. *Eur J Pediatr.* 2011;170(1):1–8.

AARSKOG SYNDROME (FACIODIGITOGENITAL SYNDROME)

DESCRIPTION A malformation syndrome carried by both an X-linked and an autosomal dominant form. Primary diagnostic criteria include short stature, hypertelorism, short nose with anteverted nares, maxillary hypoplasia, a crease below the lower lip, mild interdigital webbing, clinodactyly, and shawl scrotum. Cardiac abnormalities are also reported. There is no specific treatment.

REFERENCE

ABDOMINOPERINEAL RESECTION (APR), UROLOGIC CONSIDERATIONS

DESCRIPTION Commonly performed for rectal cancers in which the rectum, anus, and a portion of the sigmoid colon are removed (also known as Miles resection or abdominal perineal proctosigmoidectomy). The extensive pelvic dissection can lead to a number of urologic problems. Urinary retention and urinary incontinence represent 2 distinct urologic complications after abdominoperineal resection (APR). Injury to detrusor branches of the pelvic nerve can cause detrusor denervation and urinary retention. In addition, injury to intrapelvic branches of the pelvic and pudendal nerves to the urinary sphincter can result in intrinsic sphincter deficiency (ISD) and urinary incontinence. Impotence and urinary retention can occur in males; urinary incontinence and altered sexual function may occur in females, secondary to removal of the anterior vaginal wall. Damage to the ureters is not uncommon during the procedure.

TREATMENT

- Stent placement preoperatively may help in identifying the ureters.
- Intermittent catheterization for retention; TURP or other bladder outlet procedure may be considered preoperatively in men with BPH.
- Impotence managed with penile prosthesis, vacuum device, or intracorporal therapy.

REFERENCE

Lange MM, van de Velde CJ. Urinary and sexual dysfunction after rectal cancer treatment. *Nat Rev Urol.* 2011;8(1):51–57.

ABRAMS–GRIFFITHS NOMOGRAM

DESCRIPTION Bladder outlet obstruction can be defined only by pressure–flow measurement. The Abrams–Griffiths nomogram is an easy method of classifying these data to distinguish between the presence or absence of obstruction. Using the values for maximal flow and the corresponding voiding detrusor pressure, a point can be plotted on the nomogram that determines whether the bladder outlet is obstructed, unobstructed, or equivocally obstructed. For those that fall in the equivocal zone, further criteria for the mean slope of the pressure–flow plot and the minimal voiding detrusor pressure are used to determine whether obstruction is present. The nomogram has shown excellent prognostic value in multiple studies in predicting the outcome of outlet reduction procedures. Although the Abrams–Griffiths nomogram is somewhat simplistic, none of the more complex methods of pressure–flow analysis has been shown to be a better predictor of treatment outcome to date. (See also Section II: “Pressure–Flow Studies” and “Urodynamics, Indications, and Normal Values.”)

REFERENCE

Lim CS, Abrams P. The Abrams-Griffith nomogram. *World J Urol.* 1995;13:34.

ACETAMINOPHEN ABUSE, UROLOGIC CONSIDERATIONS

DESCRIPTION 1–2% of patients with acetaminophen overdose present with renal

insufficiency. Proposed mechanisms for etiology are uncertain, but may involve increased cytochrome P-450, prostaglandin synthetase, and N-deacetylase enzymes. Although clinical management rarely leads to renal biopsy, histopathologic specimens would most likely show proximal tubule epithelial cell necrosis. A urinalysis can differentiate acetaminophen nephrotoxicity from hepatorenal syndrome (HRS) or prerenal azotemia. If acetaminophen nephrotoxicity is the etiology of renal insufficiency, a urine sediment would have granular casts with variable hematuria or pyuria. Urine sodium would typically be >20 mmol/L, compared to <10 mmol/L with HRS. Onset of renal insufficiency ranges from 1–8 days (peak 3–16 days). The return to baseline renal function may take approximately 1 mo with a 1% chance of requiring dialysis. There is no clear relationship between acetaminophen dose and nephrotoxicity.

TREATMENT

- N-acetylcysteine has a clear role in preventing liver necrosis but not in the treatment of acetaminophen nephrotoxicity.
- Treatment focuses on supportive care, including management of volume status, blood pressure, and electrolyte balance.

REFERENCE

Mazer M, Perrone J. Acetaminophen-induced nephrotoxicity: Pathophysiology, clinical manifestations, and management. *J Med Toxicol.* 2008;4:2–6.

ACQUIRED RENAL CYSTIC DISEASE

DESCRIPTION The development of renal cysts in patients with long-standing ESRD or severe chronic renal insufficiency. The cause is not known, but an accumulation of toxins unfiltered by dialysis is theorized. Usually asymptomatic, it can present with abdominal pain or hematuria. It is more common in males, and there is a 3–6 times greater incidence of renal cell carcinoma (RCC) compared to the general population (individual risk 4–7%). In dialysis-related RCC, neoplastic cells of acquired cystic disease-associated RCC are positive for alpha-methylacyl-CoA racemase (AMACR), but negative for cytokeratin (CK) 7. Tumors tend to be very aggressive, with a high incidence of metastasis. Risk increases with increased time on dialysis. (See also Section I: “Renal Cysts [Intrarenal, Peripelvic and Parapelvic].”)

TREATMENT

- Close follow-up for early detection of malignancy (periodic imaging)
- Renal transplantation can reverse growth of cysts, but malignancy can still occur

REFERENCE

Farivar-Mohseni H, Perlmutter AE, Wilson S, et al. Renal cell carcinoma and end stage renal disease. *J Urol.* 2006;175(6):2018–2020.

ACROSOME REACTION ASSAY

DESCRIPTION The acrosome is a membrane-bound organelle covering the anterior 2/3 of the sperm head. This organelle contains numerous enzymes whose release, termed the acrosome reaction, is required for penetration of the hard zona pellucida of the ovum. It is

hypothesized that human sperm bind to the ovum, after which the acrosome reaction is induced by 1 or more of the zona pellucida glycoproteins. Abnormalities of any aspect of this reaction may be a source of male-factor infertility. Transmission electron microscopy, although the procedure of choice to detect acrosome reaction defects, is labor-intensive and expensive. This test may be recommended in cases of profound abnormalities of head morphology or in the setting of unexplained infertility in patients with poor IVF pregnancy rates. (See also Section II: "Semen Analysis, Technique, and Normal Values.")

REFERENCE

Agarwal A. Assessing sperm function. *Urol Clin North Am.* 2008;35(2);157–171.

ACTINOMYCOSIS, RENAL

DESCRIPTION Actinomycosis is a chronic granulomatous infection caused by a gram-positive anaerobic *Actinomyces* bacteria, usually *A. israelii.* No pathognomonic findings are common; it can reach the kidney by hematogenous spread or instrumentation. Fibrosis and fistulas are common. The infection can present as sepsis with negative urine culture. Imaging can reveal renal abscesses and hydronephrosis, and the condition has been typically diagnosed postoperatively due to a renal mass prompting nephrectomy; it is diagnosed by gram-positive organisms on stain and prolonged incubation of bacteria. Microscopic exam of the organism can appear as yellow bodies called sulfur granules.

TREATMENT

- Nephrectomy of involved renal unit is usually necessary
- Aggressive antibiotic therapy with long-term penicillin followed by doxycycline and ciprofloxacin

REFERENCE

Dhanani NN, Jones DM, Grossman HB. Medical management of renal actinomycosis. *J Urol.* 2004;171(6 Part 1):2373–2374.

ACUTE KIDNEY INJURY (AKI), DEFINITIONS

DESCRIPTION Acute renal failure (ARF) has been defined as the abrupt loss of kidney function resulting in the retention of urea and other nitrogenous waste products and in the dysregulation of extracellular volume and electrolytes. While this loss in kidney function is detected by elevated serum creatinine, several problems are associated with the use of this measure to quantitatively define ARF, particularly the lack of consensus in the quantitative definition. The Acute Dialysis Quality Initiative (ADQI) has proposed a graded definition of ARF called the RIFLE criteria. The Acute Kidney Injury Network modified the RIFLE criteria to include less severe ARF, a time constraint of 48 hr, and to allow for correction of volume status and obstructive causes of ARF prior to classification. The Acute Kidney Injury Network uses the term acute kidney injury (AKI) to represent the spectrum of ARF. The proposed diagnostic criteria for AKI are: An abrupt (<48 hr) increase in creatinine concentration of ≥ 0.3 mg/dL (26.4 mmol/L) from baseline, a percentage increase in the serum creatinine $\geq 50\%$, or oliguria of <0.5 mL/kg/h for >6 hr. (See also Section I: "Acute kidney Injury,

Adult (Renal Failure, Acute), Acute Kidney Injury, Pediatric (Renal Failure, Acute); Section II "Rifle Criterion for Acute Renal Injury.")

REFERENCE

ADENOFIBROMA, METANEPHRIC, PEDIATRIC

DESCRIPTION Metanephric adenofibroma is a very rare benign tumor 1st described as nephrogenic adenofibroma by Hennigar and Beckwith in 1992. This tumor appears to affect predominantly young people (mean, 14 yo; range, 20 mo–35 yo). The most common symptom is hematuria, but a significant proportion of patients are asymptomatic. Polycythemia is a peculiar incidental finding that resolves after resection of the tumor. The radiologic appearances are nondiagnostic and indistinguishable from other solid pediatric renal tumors, particularly Wilms tumor. Histologically, this tumor is characterized by proliferation of benign-appearing mesenchymal cells surrounding multifocal nodules of immature epithelial cells. The latter cells show differentiation toward glandular and papillary structures. The mesenchymal component of metanephric adenofibroma closely resembles congenital mesoblastic nephroma in cytologic appearance. At present, all metanephric adenofibroma lesions should be excised to establish diagnosis, but no further adjuvant therapy is required.

Palese MA. Metanephric stromal tumor: A rare benign pediatric renal mass. *Urology.* 2001;58:462.

ADRENAL ANGIOMYOLIPOMA

DESCRIPTION Angiomyolipoma arising the adrenal is very rare with only a few reported in the literature. They are usually asymptomatic, diagnosed incidentally, and much more common in the kidney. Histologically it consists of mature fat cells, smooth muscle fibers, and thin-walled blood vessels. Management is identical to any adrenal mass: Assessment of functional status of the tumor with surgery if the patient is symptomatic or lesion is >5 cm (risk of malignancy and possibly bleeding). (See also Section I: "Adrenal Mass" and Section II: "Adrenal; Myelolipoma [Adrenal Myolipoma].")

REFERENCE

Yener O, Özçelik A. Angiomyolipoma of the right adrenal gland. *ISRN Surg.* 2011;2011:102743.

ADRENAL CALCIFICATIONS

DESCRIPTION Adrenal calcifications may be the result of hemorrhage (secondary to trauma, venous thrombosis, stress, or bleeding diatheses), infection (usually granulomatous

diseases), or may be associated with different tumors. Necrosis and calcification are more common in association with adrenal carcinoma but are not diagnostic. Bilateral calcified adrenal glands may be seen in adrenal insufficiency or secondary Addison disease. Calcifications may be detected on MRI because of their susceptibility artifact but are much better appreciated on CT images.

REFERENCE

Kenney PJ, Stanley RJ. Calcified adrenal masses. *Urol Radiol.* 1987;9:9–15.

ADRENAL CYSTS AND PSEUDOCYSTS

DESCRIPTION A rare (0.064–0.18% on autopsy studies) condition, more often detected on imaging. Most are asymptomatic. These cysts can cause GI discomfort, pain if large, and even an acute abdomen with rupture or infection. Four major types are recognized: Endothelial, pseudocyst, epithelial, and parasitic, in order of decreasing incidence. Parasitic cysts arise primarily from *Equinococcus granulosus* infection. Adrenal pseudocysts are thought to result from infarction or hemorrhage of a cyst or tumor.

TREATMENT

- >3.5 cm: Aspiration for fluid analysis and cytology to rule out malignancy
- <3.5 cm: Observe with serial imaging (US or CT or MRI).

REFERENCE

Sebastiano C, Zhao X, Deng FM, et al. Cystic lesions of the adrenal gland: Our experience over the last 20 years. *Hum Pathol.* 2013;44(9):1797–1803.

ADRENAL CYTOMEGALY

DESCRIPTION Found infrequently in children and adults and considered a benign mass lesion, the condition is seen often in Beckwith–Wiedemann syndrome. Other possible associations include hemolytic disease of the newborn, erythroblastosis fet alis, and congenital rubella. It is characterized by the presence of large polyhedral cells with eosinophilic granular cytoplasm and enlarged nuclei in the adrenal cortex. Adrenal cytomegaly rarely forms cysts. This condition is thought to be a degenerative process but not a malignancy, possibly caused by a physiologic condition that demands increased functional capacity and proliferation of adenocytes.

REFERENCE

Noguchi S, Masumoto K, Taguchi T, et al. Adrenal cytomegaly: Two cases detected by prenatal diagnosis. *Asian J Surg.* 2003;26(4):234–236.

ADRENAL HEMORRHAGE

DESCRIPTION Adrenal hemorrhage (AH) is a collection of blood producing a mass effect in 1 or both adrenal glands, with or without adrenal necrosis and insufficiency. It occurs in up to 30% of selected neonatal intensive care patients, 14–22% of newborns at autopsy, and up to 15% at autopsy of adult patients dying in shock. Signs and symptoms include fever, flank

or abdominal pain, tachycardia, nausea, vomiting, respiratory distress, and weakness. Unilateral AH may be an incidental finding during imaging. AH may result from multiple mechanisms: Stress, sepsis (Waterhouse–Friderichsen syndrome), anticoagulation-related hypotension, vascular spasm, adrenal venous thrombosis, or heparin-associated thrombocytopenia.

Workup may show dropping hemoglobin and electrolyte abnormalities (hyponatremia, hyperkalemia in 56% of bilateral AH).

TREATMENT

Includes replacement of fluids, electrolytes, and blood if anemia is significant. Patients should be started on steroid replacement if adrenal insufficiency is suspected. Surgical exploration may be necessary for uncontrollable hemorrhage, uncertain diagnosis, or if abscess formation is suspected.

REFERENCE

Simon DR, Palese MA. Clinical update on the management of adrenal hemorrhage. *Curr Urol Rep.* 2009;10(1):78–83.

ADRENAL HYPOPLASIA

DESCRIPTION Reduced ACTH production can result in hypoplasia of the adrenal gland (secondary adrenal hypoplasia); this can occur as a result of lack of pituitary trophic signaling, such as in pituitary agenesis. Congenital adrenal hypoplasia (primary) is an inherited disorder, with several forms identified. The major form of adrenal hypoplasia is X-chromosome linked and traced to the DAX-1 (AHCH) gene. This gene is in close proximity to other genes encoding for glycerol kinase and Duchenne muscular dystrophy (both associated with adrenal hypoplasia). Hypogonadotrophic hypogonadism is also a common finding. It typically presents in the neonatal period or with adrenal crisis (dehydration, hyponatremia, hyperkalemia, hypotension, hypoglycemia). Disorders of the external genitalia may include micropenis, undescended testes, or hypospadias. It can be detected by biochemical testing (serum cortisol, corticotropin-releasing hormone (CRH) stimulation test, etc.). Antenatal maternal estriol screening can also detect adrenal hypoplasia. Treatment is replacement of adrenal hormones.

Diagnosis must be made early, or it can be fatal secondary to salt wasting.

REFERENCE

Ferraz-de-Souza B, Achermann JC. Disorders of adrenal development. *Endocr Dev.* 2008;13:19–32.

ADRENAL INCIDENTALOMAS

DESCRIPTION Incidentally discovered adrenal lesions – called “adrenal incidentalomas” – are by-products of increased availability and use of advanced imaging. Adrenal masses are found in approximately 4% of patients undergoing abdominal CT scans, and the prevalence increases with age. Most are nonfunctional, benign adenomas. It is important to consider 2 questions in the evaluation of an adrenal incidentaloma: Whether it is functioning and

whether it is malignant. Differential diagnosis includes benign nonfunctioning adenoma; cyst/pseudocyst; hormonally active tumors such as pheochromocytoma, primary hyperaldosteronism, and Cushing disease (nodular hyperplasia); myelolipoma and malignancies including adrenocortical carcinoma; or metastasis from lungs, breast, colon, kidney, melanoma, or lymphoma. Incidentaloma <4 cm are likely benign. A 1-mg dexamethasone suppression test and measurement of plasma-free metanephrines is recommended for all patients with an adrenal incidentaloma, as well as a serum potassium and plasma aldosterone concentration-plasma rennin activity ratio for patients with hypertension. (See also Section I: "Adrenal Mass.") (Image ☼)

TREATMENT

- Surgical removal is indicated with hormonally active tumors, as well as any tumors >6 cm.
- Observation is warranted for any mass <4 cm and nonfunctioning. A repeat CT 6–12 mo after the initial study is reasonable for follow-up.

REFERENCE

Grumbach MM, Biller BM, Braunstein GD, et al. Management of the clinically inapparent adrenal mass (incidentaloma). *Ann Intern Med.* 2003;138(5):424–429.

ADRENAL METASTASES

DESCRIPTION The 4th most common site of metastatic tumor spread. Common metastases include breast (most common), lung, kidney, stomach, pancreas, and melanoma. (See also Section I: "Adrenal Mass.")

REFERENCE

Gittens PR Jr, Solish AF, Trabulsi EJ. Surgical management of metastatic disease to the adrenal gland. *Semin Oncol.* 2008;35(2):172–176.

ADRENAL MYELOLIPOMA (ADRENAL MYOLIPOMA)

DESCRIPTION Referred to as *myolipoma* and *myelolipoma* in the literature, this rare, usually nonfunctioning lesions are composed of adipose and hematopoietic cells may represent extramedullary hematopoiesis. It is rarely metabolically active (Cushing or Conn syndrome) and usually asymptomatic, except when very large or if hemorrhage occurs. They mostly occur in the adrenal glands, but extra-adrenal myelolipomas have been reported (presacral, retroperitoneum). It can be diagnosed radiographically and is more typically incidentally discovered at imaging or autopsy. Ultrasound shows a highly echogenic mass. CT demonstrates focal densities near that of fat (Hounsfield units of –30 to –115). MRI T1-weighted images demonstrate high signal intensity, whereas T2-weighted images are moderately intense. The main diagnostic similarity is well-differentiated liposarcoma. (See also Section I: "Adrenal Mass.")

TREATMENT

Excision if symptomatic or if diagnosis cannot be confirmed radiographically or on needle biopsy.

REFERENCE

Nabi J, Rafiq D, Authoy FN, et al. Incidental detection of adrenal myelolipoma: a case report and review of the literature. *Case Rep Urol.* 2013;2013:789481. doi: 10.1155/2013/789481.

ADRENAL ONCOCYTOMA

DESCRIPTION Oncocytic neoplasms of the adrenal gland, unlike that of the kidney, are rare with only 147 cases described. 80–90% of lesions are nonfunctional and only 10–20% of lesions show malignant elements. Typically occurs from 27–72 yr of age. More common in women (2.5:1 compared to men) and the left adrenal gland (3.5:1 compared to the right). Histologically, lesions are highly granular and eosinophilic due to an abundance of mitochondria. Grossly, they are large, well-rounded, and encapsulated with an average diameter of 8 cm (2–20 cm). When cross sectioned, they have a brown, yellow, or mahogany appearance. All tumors >6 cm should be excised. Percutaneous biopsy of an indeterminate mass has 73% sensitivity. Resection of the adrenal lesion can be performed either laparoscopically or using an open technique. If benign, the prognosis is excellent; if malignant, there is a 20–35% 5-yr survival rate. (See also Section I: "Adrenal Mass.")

REFERENCE

Mearini L, Del Sordo R, Costantini E, et al. Adrenal oncocytic neoplasm: A systematic review. *Urol Int.* 2012;1–9.

ADRENALITIS

DESCRIPTION An inflammation of the adrenal gland that can lead to primary adrenal insufficiency (Addison disease), which accounts for 80% of cases. Tuberculosis is the 2nd leading cause, with the balance made up by fungal infections, hemorrhage, metastatic neoplasms, sarcoidosis, amyloidosis, and adrenal leukodystrophy. Autoimmune adrenalitis can be associated with thyroiditis, diabetes mellitus, pernicious anemia, vitiligo, hypoparathyroidism, and mucocutaneous candidiasis (autoimmune polyendocrine syndrome type 1, also known as candidiasis-hypoparathyroidism-Addison disease-syndrome), or with autoimmune polyendocrine syndrome type 2 (also known as Schmidt syndrome). HIV with opportunistic CMV adrenalitis accounts for an increasing number of cases. (See also Section I: "Adrenal insufficiency, acute (adrenal crisis) and "Addison Disease.")

TREATMENT

- Replacement of adrenal and other hormones, as necessary
- Treatment of underlying cause

REFERENCE

Perry R, Kecha O, Paquette J, et al. Primary adrenal insufficiency in children: Twenty years experience at the Sainte-Justine Hospital, Montreal. *J Clin Endocrinol Metab.* 2005;90(6):3243.

ADRENOCORTICAL DISEASE, PRIMARY PIGMENTED NODULAR

DESCRIPTION Primary pigmented nodular adrenocortical disease (PPNAD) is a rare ACTH independent form of Cushing syndrome, accounting for <1% of Cushing syndrome patients. Hypercortisolism is resistant to a dexamethasone suppression test. Typically, bilateral adrenal glands are involved with gross appearance of multiple nodules of varying sizes and pigmented colors. Histologically, the nodules are circumscribed, unencapsulated, and comprised of polygonal cells with an eosinophilic appearance. 25% of patients manifest Carney complex, which includes spotty skin pigmentation, endocrine tumors, and neuroendocrine tumors. Treatment requires bilateral adrenalectomy as unilateral and partial adrenalectomy has resulted in recurrence. (See Section I: "Cushing Disease and Syndrome.")

REFERENCE

Manipadam M, Abraham R, Sen S, et al. Primary pigmented nodular adrenocortical disease. *J Indian Assoc Pediatr Surg.* 2011;16(4):160–162.

ADRENOGENITAL SYNDROME

DESCRIPTION This is the most common cause of disorders of sexual development (DSD) (formerly ambiguous genitalia), caused by an inborn error of metabolism involving cortisol synthesis. At fault is a defect in any 1 of 5 enzymes involved in the cortisol biosynthetic pathway (21-hydroxylase, 11-hydroxylase, 3-hydroxysteroid dehydrogenase, 20.22-desmolase, or 17-hydroxylase), which may result in CAH. Usually presents with an autosomal recessive inheritance. (See also Section I: "Disorders of Sexual Development [DSD]"; Section II: "Congenital Adrenal Hyperplasia.")

SYNONYMS

- CAH
- Female pseudohermaphrodite
- Male pseudohermaphrodite

COMPLICATIONS

- For untreated females:
  - Premature pubic and axillary hair development
  - Rapid somatic maturation, premature epiphyseal closure, short adult stature
  - No breast development or menstruation until excessive androgen production is suppressed
- For untreated males:
  - Sexual and somatic precocity within 1st 2 yr of life
  - Premature epiphyseal closure, short adult stature
- Untreated males and females with salt-losing variant:
  - Progressive weight loss, dehydration within 1st few weeks of life

TREATMENT

- Early diagnosis with ascertainment of correct sex and prevention of salt wasting and metabolic consequences
- Steroid replacement with cortisone, fluorohydrocortisone as needed
- Surgical genital reconstruction may be necessary early in life, based on specific findings

ADRENOLEUKODYSTROPHY

DESCRIPTION Rare, X-linked recessive metabolic disorder occurring in boys, and characterized by adrenal atrophy and widespread, diffuse cerebral demyelination. It produces mental deterioration, corticospinal tract dysfunction, and cortical blindness. There is lab evidence of adrenal cortical dysfunction. 2 phenotypes, with onset in childhood or young adulthood, exhibit hypogonadism. Death inevitably occurs within months of onset. A defect is theorized in peroxisomes, which handle long-chain fatty acids. *Lorenzo's oil* (a mixture of glyceryl trioleate and glyceryl trierucate oil) has been tried in this disease, with some delay in neurologic symptoms. Bone marrow transplantation is under study.

SYNONYM
Formerly Schilder disease

REFERENCE
Moser HW, Moser AB, Hollandsworth K, et al. "Lorenzo's oil" therapy for X-linked adrenoleukodystrophy: Rationale and current assessment of efficacy. *J Mol Neurosci.* 2007;33(1):105–113.

AGING MALE SURVEY

DESCRIPTION The Aging Male Survey (AMS) is a questionnaire developed to detect hypogonadism in adult men. It has 3 domains: Psychological, Somato-vegetative, and sexual. The minimum and maximum scores are 5 and 25, respectively, for the Psychological and Sexual domains and 7 and 35 for the Somato-vegetative domain. The higher the score, the more severe the symptoms. The AMS has been shown to have a sensitivity (83%) and specificity (39%) similar to those of the shorter ADAM Survey. (See also Section I: "Andropause [Late Onset Male Hypogonadism]" and Testosterone, Decreased [Hypogonadism; Section II: "Androgen Deficiency in the Aging Male [ADAM] and ADAM Survey.")

REFERENCE
Moore C, Huebler D, Zimmermann T, et al. The Aging Males Symptom Scale (AMS) as outcome measure for treatment of androgen deficiency. *Eur Urol.* 2004;46:80–87.

AL GHORAB CORPORAL SHUNT

DESCRIPTION A surgical treatment for the management of priapism refractory to penile irrigation. A small transverse incision is made on the dorsum of the glans. A section of septum between the glans spongiosa and the corpora cavernosa is removed to create a shunt. (See also Section I: "Priapism" and Section II "Al Ghorab Corporal Shunt With Burnett "Snake" Maneuver.)

REFERENCE

AL GHORAB CORPORAL SHUNT WITH BURNETT "SNAKE" MANEUVER

DESCRIPTION A modification of the Al Ghorab distal corporal-glanular shunt for priapism. The Burnett "snake" modification involves passing a 7/8 Hegar dilator through the amputated distal tips of the corpora cavernosa bilaterally. The dilator is passed to the proximal limit of the corpora cavernosum laterally on each side to avoid urethral injury. Milking of ischemic blood and clot is performed until bright red blood is visualized. A study of 10 patients with a mean follow-up of 7 mo reported that 8 men had no recurrence of priapism. Of the 6 men who had normal erectile function preoperatively, 2 had partial erectile function postoperatively.

ALAGILLE SYNDROME

DESCRIPTION An autosomal dominant disorder associated with abnormalities of the liver, heart, eye, skeleton, and kidneys. A characteristic facial appearance is also seen. Renal abnormalities are not specific but include dysplasia and renal failure. This autosomal dominant disorder is mapped to chromosome 20; it is treated by renal replacement therapy as needed.

SYNONYM

Alagille–Watson syndrome

REFERENCE

Hartley JL, Gissen P, Kelly DA. Alagille syndrome and other hereditary causes of cholestasis. *Clin Liver Dis.* 2013;17(2):279–300.

ALKALINE PHOSPHATASE, UROLOGIC CONSIDERATIONS

DESCRIPTION As an enzyme produced in many tissues, such as bone, liver, placenta, and intestine, alkaline phosphatase can monitor the progression of metastatic cancer to bone (such as prostate cancer). (Bone source can be distinguished from other sources by its heat lability compared with other forms.) This test has also been recommended by some authors as a useful tool for monitoring seminoma.

REFERENCE

ALKAPTONURIA

DESCRIPTION An inherited inborn error of metabolism of phenylalanine and tyrosine metabolism wherein homogentisic acid (HGA) accumulates in the body and is excreted in a large amount in the urine. If allowed to stand, the urine gradually turns dark (black urine disease). Alkali can accelerate this process. Ochronosis (deposition of a bluish-black pigment noted in the connective tissue) may lead to arthropathy. Of urologic interest, renal failure occurs, rarely, with long-standing disease. Even more rarely, HGA stones can occur. It is caused by a single gene defect, causing absence of HGA oxidase. It is treated by dietary restriction of phenylalanine and tyrosine and large doses of ascorbic acid; otherwise, treatment is symptomatic.

SYNONYM

Black urine disease

REFERENCE

Kazancioglu R, Taylan I, Aksak F, et al. Alkaptonuria and renal failure: a case report. *J Nephrol.* 2004;17(3):441–445.

ALLOPURINOL HYPERSENSITIVITY SYNDROME (AHS)

DESCRIPTION 2% of patients treated with allopurinol will develop minor adverse reactions, including drug eruption, pruritic maculopapular exanthema or minor vasculitis, which often disappear after cessation of treatment. In contrast, AHS is life threatening and includes at least 2 of the following major criteria:

- Deteriorating renal function
- Acute hepatocellular injury
- Cutaneous rash including erythema multiforme (EM), generalized maculopapular exanthema, generalized exfoliative dermatitis (GED), or Steven–Johnson syndrome/toxic epidermal necrolysis (SJS/TEN)

Diagnostic criteria may also include 1 of the above and at least 1 of the following minor criteria:

- Fever
- Eosinophilia
- Leukocytosis

TREATMENT

Febuxostat alternative for patients with AHS

ALOPECIA GENITALIUM

DESCRIPTION A poorly understood and clinically insignificant condition marked by the loss

and subsequent regrowth of pubic hair, possibly due to tight fitting undergarments.

REFERENCE

Pavona, NA. Alopecia genitalium: Personal observation. *Tech Derm Urol.* 1981;10:24.

α-(ALPHA) FETOPROTEIN

DESCRIPTION A single-chain glycoprotein (MW 70,000) that primarily aids in the management of testicular cancer. It is normally produced by the liver, yolk sac, and GI tract of the fetus; its half-life is 5 (3.5–6) days. Serum *α*-fetoprotein (AFP) levels are normally elevated in the 1st 8 mo of life. The normal adult level is <8 ng/mL; this can be elevated in 38% of cases of embryonal cell carcinoma, 64% of teratocarcinoma, and in yolk sac tumors. Other reasons for elevation include neuroblastoma, hepatoblastoma (hepatoma), hepatocellular, neural tube defects, fet al death, ataxia-telangiectasia, and some cases of benign hepatic disease.

ALPORT DISEASE/SYNDROME

DESCRIPTION Alport disease/syndrome consists of hereditary nephritis, high-frequency neural hearing loss, and ocular abnormalities. It can present as hematuria, proteinuria, or uremia. Family history is crucial in diagnosis. The nephritis is progressive, usually resulting in renal failure by the 3rd decade. Males are more severely affected. It is caused by a genetic mutation on a single locus on the X chromosome, with altered type IV collagen production. Treat with renal replacement therapy, as needed.

REFERENCE

Gregory MC, Terreros DA, Barker DF, et al. Alport syndrome—clinical phenotypes, incidence, and pathology. *Contrib Nephrol.* 1996;117:1–28.

ALSTRÖM–EDWARDS SYNDROME

DESCRIPTION A progressive autosomal recessive genetic disorder affecting multiple organ systems. It may be detected at birth or in early childhood. Clinically, patients with Alström syndrome develop cone–rod dystrophy leading to eventual blindness, have sensorineural deafness, and normal intelligence. Patients develop obesity, endocrine disturbances such as type 2 diabetes mellitus, dilated cardiomyopathy, and progressive renal and hepatic failure. Alström syndrome is caused by specific mutations in the *ALMS1* gene, located at chromosome 2p13. No specific treatment is available for infertility; renal replacement therapy is indicated as needed.

SYNONYM

Alström syndrome

REFERENCE

ALZHEIMER DISEASE, UROLOGIC CONSIDERATIONS

DESCRIPTION Alzheimer disease is the principal cause of dementia in the elderly patient population. The urologic manifestations include urinary incontinence, overactive bladder, and erectile dysfunction (ED). Patients may be difficult to treat due to limited cooperation with the treatment plan; toileting schedules can help with early incontinence episodes. Often considered a cuae of "functional" urinary and fecal incontinence. Current theories regarding the etiology of Alzheimer disease revolve around cortical cholinergic loss. This may also make the treatment of urologic manifestations even more difficult by limiting the use of anticholinergic agents. Rule out other correctable causes before ascribing urinary tract problems to this disease specifically. (See Section I: "Incontinence, Urinary, Adult Male"; Section I: "Incontinence, Urinary, Adult Female.")

REFERENCE

Resnick NM, Yalla SV, Laurino E. The pathophysiology and clinical correlates of established urinary incontinence in frail elderly. *N Engl J Med.* 1989;320:1–7.

AMBIGUOUS GENITALIA

DESCRIPTION DSD (Disorders of sexual development) refers to a child born with a congenital discrepancy between external genitalia, gonadal, and chromosomal sex. In 2006, consensus conference stated that the potentially pejorative terms "pseudohermaphrodite," "hermaphrodite," and "intersex" be replaced by the more appropriate diagnostic category "DSD." It is recognized that some DSDs present with abnormalities of the external genitalia (ambiguous genitalia). These abnormalities that prompt evaluation occur in approximately 1 in 4,500 live births. These findings may include may include micropenis, clitoromegaly, bilateral cryptorchidism, perineal hypospadias with bifid scrotum, posterior labial fusion, phenotypic female appearance with a palpable gonad (with or without inguinal hernia) hypospadias and unilateral nonpalpable gonad as a few examples. (See also Section I: "Disorders of Sexual Development [DSD]" and Section II: "Androgen Insensitivity Syndrome [AIS]"; or "Androgen Resistance Syndrome, Complete [CAIS] and Partial [PAIS].")

AMERICAN ASSOCIATION FOR THE SURGERY OF TRAUMA (AAST) ORGAN SEVERITY SCALES: GENITOURINARY INJURIES

DESCRIPTION Numerous classifications of traumatic injuries exist, but the most widely

used and accepted classification was developed by the American Association for the Surgery of Trauma's Organ Injury Scaling Committee. (See also Section I: "Bladder Trauma; Penis, Trauma; Renal Trauma, adult; Ureter, Trauma; Urethra, Trauma.")

REFERENCE

Santucci RA, et al. Validation of the American Association for the Surgery of Trauma organ injury severity scale for the kidney. *J Trauma.* 2001;50(2):195–200.

AMINOACIDURIA

DESCRIPTION Excretion of an overabundance of amino acids in the urine, most often due to an inborn error of metabolism. Aminoaciduria is found in association with renal tubular acidosis, Fanconi syndrome, and other primary renal tubular disturbances. It may also occur secondary to other diseases that affect the kidney, such as diabetes mellitus (DM) and diabetes insipidus (DI).

REFERENCE

Neithercut WD, Spooner RJ, Hendry A, et al. Persistent nephrogenic diabetes insipidus, tubular proteinuria, aminoaciduria, and parathyroid hormone resistance following long term lithium administration. *Postgrad Med J.* 1990;66(776):479–482.

AMMONIUM CHLORIDE LOADING TEST

DESCRIPTION An acid loading test to rule out distal renal tubular acidosis. Performed by giving 0.1 g/kg ammonium chloride oral solution over 45 min after a 6-hr fast. 100 mL of water are given every hour during the test. Urine pH is measured hourly for 4 hr. Serum bicarbonate values are taken at hours 2 and 4 to ensure adequate acidification (<16 mmol/L). The normal result is urine pH <5.4; distal RTA exists if pH >5.4. (See also Section II: "Renal Tubular Acidosis.")

REFERENCE

Weger W, Kotanko P, Weger M, et al. Prevalence and characterization of renal tubular acidosis in patients with osteopenia and osteoporosis and in nonporofic controls. *Neprhol Dial Transplant.* 2000;15(7):975–980.

AMMONIUM URATE UROLITHIASIS

DESCRIPTION Extremely rare form of stone disease ($<0.5\%$), endemic in countries with poor nutrition and in patients with Crohn disease. In contrast to uric acid stones, these grow only in urine with pH <6.5. Caused mostly by infection, usually mixed with struvite stones.

TREATMENT

- Clear infection and increasing urine output to >2.5 L/d.
- Chemolitholysis is not possible, and surgical intervention may be necessary. Encourage a balanced diet.

AMSTERDAM AND BETHESDA CRITERIA FOR LYNCH SYNDROME

DESCRIPTION Criteria have been developed to aid in the diagnosis of hereditary nonpolyposis colorectal cancer (HNPCC or Lynch syndrome). Lynch syndrome caused by a germline mutation in a mismatch repair gene and associated with tumors exhibiting microsatellite instability (MSI), is characterized by an increased risk of colon cancer and cancers of the endometrium, ovary, stomach, small intestine, hepatobiliary tract, urinary tract (upper tract urothelial carcinoma), brain, and skin. Originally developed in 1991, they have been modified several times with the most current version referred to as Bethesda Criteria.

- **Amsterdam II Criteria (Revised International Collaborative Group on Hereditary Nonpolyposis Colorectal Cancer [HNPCC] Criteria 1998)** 3 or more relatives with HNPCC-associated cancer (colorectal cancer or cancer of the endometrium, small bowel, ureter, or renal pelvis) plus all of the following:
  - 1 affected patient should be a 1st-degree relative of the other 2;
  - 2 or more successive generations should be affected;
  - Cancer in 1 or more affected relatives should be diagnosed before the age of 50 yr;
  - Familial adenomatous polyposis should be excluded in any cases of colorectal cancer;
  - Tumors should be verified by pathologic exam.
- **Revised Bethesda Criteria (2003)** Just 1 these criteria need to be met:
  - Diagnosed with colorectal cancer before the age of 50 yr;
  - Synchronous or metachronous colorectal or other HNPCC-related tumors (which include stomach, bladder, ureter, renal pelvis, biliary tract, brain [glioblastoma], sebaceous gland adenomas, keratoacanthomas and carcinoma of the small bowel), regardless of age;
  - Colorectal cancer with a high-microsatellite instability morphology that was diagnosed before the age of 60 yr;
  - Colorectal cancer with 1 or more 1st-degree relatives with colorectal cancer or other HNPCC-related tumors. 1 of the cancers must have been diagnosed before the age of 50 yr (this includes adenoma, which must have been diagnosed before the age of 40 yr);
  - Colorectal cancer with 2 or more relatives with colorectal cancer or other HNPCC-related tumors, regardless of age

ANAL SPHINCTER TONE AND SENSATION, UROLOGIC CONSIDERATIONS

DESCRIPTION Anal sphincter tone is a vital part of the GU evaluation, especially in a

person with new-onset urinary incontinence. Normal anal sphincter tone is a function of somatic fibers traveling over S2–S4 in the pudendal nerve. A hypoactive sphincter suggests a lower motor neuron lesion, whereas a hyperactive sphincter may be an upper motor neuron lesion. The loss of voluntary contraction of the sphincter suggests interruption of centrally directed fibers somewhere between the motor strip of frontal cortex and the pudendal nerve. The bulbocavernosus reflex (BCR), which is widely used in evaluating urinary incontinence and ED, requires anal sphincter contraction in response to squeezing the glans of penis.

ANDERSON-HYNES PYELOPLASTY

DESCRIPTION Used to treat ureteropelvic junction (UPJ) obstruction. The UPJ is excised, and excess renal pelvis is removed. The widely spatulated ureter is reanastomosed to the renal pelvis with interrupted chromic sutures, and the excess renal pelvis is closed with simple or running suture. After nephrostomy, a ureteral stent is placed. (See also Section I: "Ureteropelvic Junction Obstruction.")

ANDREWS PROCEDURE (HYDROCELE)

DESCRIPTION A technique described in 1907 where the hydrocele sac at the superior portion of the tunica vaginalis is incised 2–3 cm. This step is followed by eversion of the edges of the tunica vaginalis, which is wrapped around the cord structure.

SYNONYM

Bottle Operation

ANDROGEN DEFICIENCY IN THE AGING MALE (ADAM) AND ADAM QUESTIONNAIRE

DESCRIPTION Previously referred to as andropause, this has more recently been described as ADAM. The onset of ADAM is unpredictable, and its manifestations are subtle and variable. It is associated with a decrease in testosterone, but also with decreased growth hormone, melatonin, and dehydroepiandrosterone (DHEA). Clinical manifestations include fatigue, depression, decreased libido, and erectile dysfunction (ED), as well as changes in cognition

and mood. The ADAM questionnaire is a screening tool to detect late-onset hypogonadism, with a sensitivity and specificity of 88% and 60%, respectively, compared with serum-bioavailable testosterone levels. A positive answer represents yes to questions 1 or 7 or to any 3 other questions.

The Androgen Deficiency in Aging Male (ADAM) Questionnaire		
Yes	No	1. Do you have a decrease in libido (sex drive)?
Yes	No	2. Do you have a lack of energy?
Yes	No	3. Do you have a decrease in strength and/or endurance?
Yes	No	4. Have you lost height?
Yes	No	5. Have you noticed a decreased enjoyment of life?
Yes	No	6. Are you sad and/or grumpy?
Yes	No	7. Are your erections less strong?
Yes	No	8. Have you noticed a recent deterioration in your ability to play sports?
Yes	No	9. Are you falling asleep after dinner?
Yes	No	10. Has there been a recent deterioration in your work performance?

ANDROGEN DEPRIVATION SYNDROME (ADS)/METABOLIC SYNDROME

DESCRIPTION Long-term androgen deprivation therapy (ADT), for the treatment of prostate cancer, results in hypogonadism and increased risk of type 2 diabetes mellitus. Furthermore, death from cardiovascular disease (CVD) is the most common cause of prostate cancer–related death in these men. ADS is a spectrum of adverse effects: Hot flushes, impotence, loss of libido, emotional lability, anemia, hyperglycemia, increased triglycerides and cholesterol, muscle atrophy, decreased muscle strength, testicular atrophy, osteoporosis, depression, anxiety, malaise, fatigue, and memory difficulties. *Metabolic syndrome* defined by the NIH Adult Treatment Panel III criteria is also part of this spectrum and may include abdominal obesity, hyperglycemia, hypertriglyceridemia, elevated HDL cholesterol, and hypertension. Treatment of the metabolic syndrome includes:

- Management of underlying causes (overweight/obesity and physical inactivity): Weight management, increased physical activity
- Treat lipid and nonlipid risk factors if they persist despite these lifestyle therapies: Treat hypertension; use aspirin for coronary heart disease (CHD) patients to reduce prothrombotic state; treat elevated triglycerides and/or low HDL; monitor blood sugars.

ANDROGEN INSENSITIVITY SYNDROME (AIS; OR ANDROGEN RESISTANCE SYNDROME), COMPLETE (CAIS) AND PARTIAL (PAIS)

DESCRIPTION Androgen insensitivity is a disorder of androgen action and a common form of 46,XY DSD. Mutations in the androgen receptor lead to variable defects in virilization or infertility in 46,XY males with testes and normal testosterone formation. Clinical presentation ranges from phenotypic women with decreased or absent axillary and pubic hair (complete androgen insensitivity syndrome [CAIS]) through individuals with partial androgen insensitivity (PAIS), including women with partial virilization, to phenotypic men with variable defects in virilization to men with isolated infertility An X-linked recessive disorder with a prevalence range from 1 in 20,400 genetic males to 1 in 99,000 genetic males. The typical mode of presentation is in an adolescent female who has breast development with a pubertal growth spurt but has not had her menarche with little or no axillary and pubic hair. Insensitivity can be complete insensitivity or partial. (See also Section I: "Disorders of Sexual Development [DSD]" and Section II: "Ambiguous Genitalia.")

Clinical Features of Complete Androgen Insensitivity Syndrome

Karyotype	46, XY
Inheritance	X-linked recessive; mutations in AR gene
Genitalia	Female with blind vaginal pouch
Wolffian duct derivatives	Often present, depending on mutation type
Müllerian duct derivatives	Absent or vestigial
Gonads	Testes
Habitus	Scant or absent pubic and axillary hair; breast development and female habitus at puberty; primary amenorrhea
Hormone and metabolic profile	Increased LH and testosterone levels; increased estradiol (for male reference range); FSH levels often normal or slightly increased. Resistance to androgenic and metabolic effects of testosterone

Management of complete (severe) androgen insensitivity relates primarily to the optimal timing of gonadectomy. Because the testes produce estradiol, which results in appropriate changes for the female phenotype, it is considered by many preferable to leave the testes in situ until puberty is complete. In partial androgen insensitivity, the external genitalia may be ambiguous at birth, but the prototypic phenotype is characterized by perineoscrotal hypospadias, micropenis, and a bifid scrotum. The testes may also be undescended.

Clinical Features of Partial Androgen Insensitivity Syndrome	
Karyotype	46, XY
Inheritance	X-linked recessive; mutations in AR gene
External genitalia	Ambiguous with blind vaginal pouch, undermasculinized, isolated hypospadias, normal male with infertility (mild AIS)
Wolffian duct derivatives	Often normal
Müllerian duct derivatives	Absent
Gonads	Testes (usually undescended)
Habitus	Decreased to normal axillary and pubic hair, beard growth, and body hair; gynecomastia common at puberty
Hormone and metabolic profile	Increased LH and testosterone concentrations; increased estradiol (for men); FSH levels may be normal or slightly increased
	Partial resistance to androgenic and metabolic effects of testosterone

REFERENCE

Hughes IA, Deeb A. Androgen resistance. *Best Pract Res Clin Endocrinol Metab.* 2006;20(4):577–598.

ANDROGEN/ANABOLIC STEROID ABUSE

DESCRIPTION Androgens are steroid hormones that include testosterone and its derivatives, including androstenedione, DHT, and dromostanolone. In the medical realm, androgens at physiologic doses treat androgen deficiency due to hypothalamus, pituitary, or testis disorder of genetic or acquired etiology. The use of androgens at supra-physiologic doses greatly enhances muscle strength, size, and performance, thus promoting its abuse most notably in power sports and body building. While banned by all major sports organizations, androgen abuse is rampant and has been linked to several high-profile athletes. Androgen abuse is a frequent cause of male infertility by suppression of Leydig cell production of testosterone, which results in deficient spermatogenesis. Abnormalities in sperm motility and morphology are commonly seen, and usually recover spontaneously within 4 mo after cessation of abuse.

Dohle GR, Smit M, Weber RF. Androgens and male fertility. *World J Urol.* 2003;21(5):341–345.

ANGIOKERATOMA OF FORDYCE (PENILE AND SCROTAL ANGIOKERATOMAS)

DESCRIPTION Vascular malformation of subepidermal blood vessels with an overlying epidermal proliferative reaction. Capillary ectasia is present in the papillary dermis. Typically, numerous dark red to blue dome–shaped papules are linearly arranged on the scrotum and, less commonly, on the penis. In women, 1 larger vulvar papule is typical.

Usually asymptomatic, but can cause annoying bleeding either spontaneously or with scratching or intercourse. The etiology is not known but possibly related to increased regional venous pressure; some believe an association with varicocele exists. Typically seen in older patients; these are distinct from congenital scrotal hemangiomas (see Section II: "Scrotum, Hemangioma.")

TREATMENT
Electrosurgery and lasers are effective, but rarely necessary.

REFERENCE
Schiller PI, Itin PH. Angiokeratomas: An update. *Dermatology.* 1996;193(4):275–282.

ANGIOLYMPHOID HYPERPLASIA, PENILE

DESCRIPTION A subtype of a broad class of histiocytoid hemangiomas in which 4 features are found: (1) Vacuolated histiocytoid cells, (2) tumor vessels that are thick-walled or capillaries consisting only of histiocytoid endothelial cells, (3) interstitial eosinophils, and (4) lymphoid infiltrates. These are usually confined to the skin of 1 area of the body.

SYNONYMS
- Pseudopyogenic (or atypical pyogenic) granuloma
- Inflammatory angiomatous nodule
- Subcutaneous angioblastic hyperplasia with eosinophilia
- Epithelioid hemangioma
- Intravenous atypical vascular proliferation

TREATMENT
Local surgical excision or laser (CO_2) ablation.

REFERENCE
Allen PW, Ramakrishna B, MacCormac LB. The histiocytoid hemangiomas and other controversies. *Pathol Ann.* 1992;27(Pt 2):51–87.

ANGIOMYXOMA, PERINEAL

DESCRIPTION Benign lesion of the pelvic soft tissue, but may very rarely metastasize. Characterized by slow, infiltrative growth. May present as mass in the pelvis. Histologically, demonstrates wavy collagen fibrils related to the myxoid change. Multiple prominent blood vessels are also seen. It occurs mainly in females and can be quite locally aggressive, with frequent local recurrence. Treatment is through wide local excision with close postoperative monitoring.

REFERENCE
Hong RD, Outwater E, Gomella LG. Aggressive angiomyxoma of the perineum in a man. *J Urol.* 1997;157(3):959–960.

ANGIOSARCOMA, GENITOURINARY

DESCRIPTION A very rare malignancy that grossly appears as a well-circumscribed mass or diffusely fungating tumor that may involve any organ. Microscopically, angiosarcoma shows numerous vascular channels. It stains positively for factor VIII immunohistochemically. These sarcomas can be widely metastatic and have persistent local recurrence. Bladder angiosarcoma has been reported postradiation for treatment of other malignancies; chronic lymphedema, foreign bodies, and other toxins have been implicated.

TREATMENT

- Radical resection of affected area (penectomy, cystectomy with diversion)
- Lymph node dissection for presence of lymphadenopathy
- Adjuvant radiation may be useful; chemotherapy for adjuvant or metastatic disease is not usually effective

REFERENCE

Wu X, Chen Z, Ji H, et al. Angiosarcoma of the penis: A case report and literature review. *Int Urol Nephrol.* 2012;44(5):1341–1343.

ANOGENITAL INTRAEPITHELIAL NEOPLASIA

DESCRIPTION Genital warts are caused by human papilloma virus (HPV), a DNA-containing virus that is spread by direct skin-to-skin contact; 100 different types of HPV exist, and over 30 types can infect the genital area. Risk factors for acquiring HPV include multiple sexual partners, early age at onset of sexual intercourse, and having a sexual partner with HPV. Most infections are subclinical and asymptomatic. Anogenital HPV infection is common in HIV-infected men who have sex with men. These patients have a strongly increased risk of HPV-induced anal cancer and its precursor lesion, anal intraepithelial neoplasia (AIN), and a moderately increased risk for penile cancer. Many of these men also have penile intraepithelial neoplasia (PIN), a penile cancer risk factor. Some authors recommend that all HIV positive men who have sex with men be screened for PIN. (See also Section I: "HIV/AIDS, Urologic Considerations" and Section II "HPV (Human Papilloma Virus), Urologic Considerations.")

REFERENCE

Kreuter A, Brockmeyer NH, Weissenborn SJ, et al. Penile intraepithelial neoplasia is frequent in HIV-positive men with anal dysplasia. *J Invest Derm.* 2008;128, 2316–2324.

ANORGASMIA, FEMALE

DESCRIPTION Part of female orgasmic disorder, anorgasmia describes the absence of orgasm following a normal sexual excitement phase. A DSM-IV diagnosis, patients can have marked distress and difficulty in interpersonal situations. Treatment includes behavioral therapy and reduction in anxiety, such as directed masturbation, desensitization, sex education, education regarding communication skills, and Kegel exercises. Pharmaceutical therapies have not currently proven uniformly beneficial (See Section I: "Dyspareunia, Female" and "Sexual Dysfunction, Female.")

REFERENCE

Meston C, Hull E, Levin RJ, et al. Disorders of orgasm in women. *J Sexual Med.* 2004;1:66–68.

ANTERIOR URETHRAL VALVES

DESCRIPTION Much less common than posterior urethral valves, this condition is characterized by obstruction of the anterior urethra, usually associated with a urethral diverticulum. It is caused by a diverticulum acting as valves, although cusps without diverticulum have been reported. It usually presents with voiding symptoms or bulging diverticulum on the ventral shaft with voiding. Diagnosed by VCUG and renal ultrasound. Retrograde urethrogram may miss the valve. It may be associated with reflux, but less so than with PUV. Renal deterioration is less common than with PUV.

TREATMENT

- Foley catheter if azotemia occurs
- Endoscopic valve fulguration or single-stage urethroplasty if urethra is adequate
- Staged urethroplasty for large diverticulum
- Vesicostomy for reflux or persistent azotemia

REFERENCE

Routh JC, McGee SM, Ashley RA, et al. Predicting renal outcomes in children with anterior urethral valves: A systematic review. *J Urol.* 2010;184(4 Suppl):1615–1619.

ANTIANDROGEN WITHDRAWAL SYNDROME (FLUTAMIDE WITHDRAWAL SYNDROME)

DESCRIPTION A decrease of PSA levels occurs in 15–40% of patients upon withdrawal of nonsteroidal antiandrogen in those treated for advanced prostate cancer with total androgen blockade that is rarely durable. This is possibly caused by a mutation in the androgen receptor, which then acts to stimulate growth of tumor when bound by the agent. Initially reported for flutamide, but bicalutamide and nilutamide have also shown this effect. This effect should be sought before adding other more cytotoxic agents to patients with castrate resistant prostate cancer, and could partially explain the activity of some salvage therapies.

REFERENCE

Miyamoto H, Rahman MM, Chang C. Molecular basis for the anti-androgen withdrawal syndrome. *J Cell Biochem.* 2004;91(1):3–12.

ANTISPERM ANTIBODIES

DESCRIPTION Antisperm antibodies develop when a disruption occurs in the blood–testis barrier; they may be a cause of infertility. Causes can include ductal obstruction (ie, vasectomy), infection, cryptorchidism, and varicocele, but are often idiopathic. Serum antisperm antibody levels are not as useful as antibodies in the semen, which can be measured by immunobead testing. The higher the percentage of sperm binding to the bead, the lower the probability of pregnancy. Scoring varies by lab, but normal is generally considered to be $<10\%$ of sample binding to the bead. Condoms, antibiotics, steroids, and sperm washing have all been utilized, with variable results. Presently, assisted reproductive

techniques (ARTs) such as in vitro insemination are most effective. (See also Section I: "Infertility"; Section II: "Semen Analysis, Abnormal Findings and Terminology"; "Semen Analysis, Technique and Normal Values.")

APHTHOUS ULCER, EXTERNAL GENITALIA

DESCRIPTION Aphthae are localized, painful, shallow, round to oval ulcers often covered by a gray fibromembranous slough and surrounded by an erythematous halo. Complex aphthosis involves almost constant, multiple, oral or oral and genital aphthae. Those involving both oral and genital aphthae are termed *bipolar aphthosis* (BA) of Neumann. Most specialists consider bipolar aphthosis to be a forme fruste of Behçet disease (BD). The prevalence of genital aphthae in BD varies from 60–90% in various reports. Genital aphthae are most commonly seen in male patients on the scrotum and in female patients on the vulva. In females, genital aphthae tend to be larger and deeper, sometimes even leading to perforations. Genital aphthae, especially those that are larger, may be confused with STDs; a common misdiagnosis is genital herpes or Donovanosis. (See also Section I: "Penis, Cutaneous Lesion" and Section II: "Behçet Disease" and "Genital Ulcers.")

APPENDIX TESTIS AND APPENDIX EPIDIDYMIS, TORSION

DESCRIPTION The appendix testis, historically known as the hydatid of Morgani, is a vestigial remnant of the müllerian duct in the paratesticular region. It is present in >90% of testes at autopsy. It is usually located on the superior aspect of the testis and attached to the tunica vaginalis. Grossly it appears polypoid or a sessile nodule, typically 2–4 mm in length. It can undergo torsion and cause acute scrotum. In children, this torsion is the most common cause of an acute scrotum. This condition is characterized by the "blue dot sign." It is difficult to clinically distinguish between testicular torsion and torsion of the appendix testis or epididymitis. Diagnosis is made by scrotal ultrasound.

The appendix epididymis is also referred to as the "vestigial caudal mesonephric collecting tubule." It is present in 35% of autopsy cases and on ultrasound is seen in 18% of cases. Grossly it appears as a pedunculated spherical or elongated structure arising from the antero-superior head of the epididymis. It may also undergo torsion and cause an acute scrotum that must be differentiated from testicular torsion.

Torsion of these testicular and epididymal appendages are benign conditions but must be differentiated form testicular torsion which can lead to ischemia and infarction of the testicle if not recognized and treated promptly. Epididymitis is very rare in this age group and the urinalysis is negative. Most cases occur in children between the ages of 7 and 14 yr. Pain

onset is usually acute and unlike cases of testicular torsion, nausea, and vomiting may not be present.

3 elements serve to predict testicular torsion: Pain <6 hr, absent cremasteric reflex, and diffuse testicular tenderness. In the absence of any of these elements, none of the subjects had testicular torsion; when all 3 elements present, 87% had testicular torsion. A paratesticular nodule at the superior aspect of the testicle, with or without the characteristic "blue-dot appearance" seen with the scrotal skin pulled over the lesion, is pathognomonic. The blue-dot is present in only 21% of cases and may not be easily seen in children with pigmented skin.

Color Doppler transscrotal ultrasound is the imaging modality of choice for evaluation of the acute scrotum. With torsion of an appendage, testicular blood flow is usually normal. Ultrasonography can distinguish torsion of a testicle and torsion of an appendix testis or appendix epididymis. Nuclear scanning has limited utility.

If the likelihood of a torsed appendage is high, it can be managed conservatively. If these is any doubt as to the diagnosis surgical exploration is indicated to limit the risk of testicular loss with a missed testicular torsion. The necrotic tissue of the testicular or epididymal appendix causes no significant damage to the surrounding structures other than the inflammation and discomfort. Most cases are managed conservatively. Scrotal discomfort gradually resolves over the next 1–2 wk. Limit activity initially and the use of scrotal support and ice can help initially. Nonsteroidal anti-inflammatory medications usually provide symptomatic relief. (See also Section I: "Torsion, Testis or Testicular/Epididymal Appendages" and "Torsion, Testis or Testicular/Epididymal Appendages Images.")

ARISTOLOCHIC ACID (FANG CHI)

DESCRIPTION Aristolochic acid is a toxin found in plants of the genus *Aristolochia*, a vine widely known as birthwort and contained in herbal remedies used to treat a variety of ailments such as arthritis, gout, and inflammation. Certain Chinese herbal medicines contain this toxin. In 2001, the US Food and Drug Administration warned consumers of the dangers of aristolochic acid-containing herbs, and regulations established in the Europe Union in 2004 effectively banned the substance. However, Internet sites still sell the processed drug or source plant, which remains legal in China and several other countries. Associated with end-stage renal disease (ESRD) and upper tract urothelial carcinoma. Several studies have revealed the carcinogenic potential of aristolochic acid contained in *Aristolochia fangchi* and *Aristolochia clematis* (plants endemic to the Balkans). Balkan Endemic Nephropathy has been linked to consumption of bread grain with seeds from the weed *Aristolochia clematitis*. Moreover, the vine has been found to be an environmental carcinogen through the contamination of food supplies of farming villages in the Balkans, where *Aristolochia* grows wildly in the local wheat fields. A meta-analysis of eight studies reported a pooled odds ratio of 5.97 (95% CI: 2.78–12.84) for aristolochic acid related UTUC. The lower dose confidence

limit for aristolochic acid related ESRD is 0.42 g cumulative aristolochic acid exposure. The plant contains a set of highly toxic nitrophenolate derivatives that exhibit a powerful mutagenic action. The aristolochic acid derivative d-aristolactam causes a specific mutation in the p53 gene at codon 139. This mutation is very rare in the nonexposed population and is predominant in patients with nephropathy due to Chinese herbs or Balkan endemic nephropathy who present with upper tract urothelial carcinoma. Genome-wide sequencing has allowed a link between aristolochic acid exposure directly to an individual getting cancer. (See also Section II: “Balkan Nephropathy.”)

ARTERIOVENOUS FISTULA (AVF), RENAL (OR ARTERIOVENOUS MALFORMATION [AVM])

DESCRIPTION Renal AVF or AVM are uncommon lesions. They can be congenital, acquired, or idiopathic. Most (70%) are iatrogenic and occur as a result of renal biopsy, blunt or penetrating trauma, inflammation, malignancy, or renal surgery. Congenital fistulas account for ~20% and are often found under the mucosa, accounting for the bleeding presentation. The right kidney is more often involved than the left, and women twice as often as men. May rarely present as a renal mass. The peak incidence occurs in patients 30–40 yo. Acquired or idiopathic lesions are usually aneurysmal. Congenital renal AVF frequently causes hematuria. Symptoms can include abdominal bruit, hypertension, headache, and palpitation. Indications for treatment include progressive increase in the size of the fistula, recurrent or persistent hematuria, and hemodynamic effects (cardiac decompensation, hypertension, high-output heart failure). Arteriography is the gold standard for evaluating renal AVF (demonstrating simultaneous visualization of major arteries and veins). Doppler US is a good screening tool. CT or MRI angiography can usually demonstrate the lesion adequately. Endovascular techniques are used even for giant aneurysms with AVFs. For small renal AVFs, macroparticules or methyl cyanoacrylate glue should be used. For larger fistulas, coils or detachable balloons are used. With any concerns for the possibility of systemic and pulmonary embolism, high-flow AVF should be managed by open resection or ligation.

ARTIFICIAL INSEMINATION (AI)

DESCRIPTION The process by which semen is introduced into the female reproductive tract by artificial means, for the purpose of improving the chance for conception in fertile couples with patent tubes. Variations include controlled ovarian hyperstimulation, intrauterine insemination (IUI), direct interperitoneal insemination (DIPI), a combination of IUI and DIPI,

fallopian tube sperminfusion (FSI), and peritoneal oocyte and sperm transfer. Other related means of improving fertility include in vitro fertilizations (IVFs), such as zygote intrafallopian transfer (ZIFT) and tubal embryo stage transfer (TEST) techniques.

ASK-UPMARK KIDNEY

DESCRIPTION These are small kidneys with areas of normal architecture separated by grooves overlying dilated calices without pyramids. The parenchyma of the grooved areas contain thyroid-like tubules and lack glomeruli. Cause is unknown, but vesicoureteral reflux and ascending infection have been implicated. They are typically unilateral and associated with vesicoureteral reflux, and commonly present as malignant hypertension, but cases of nonmalignant hypertension and recurrent UTIs occur. Nephrectomy of the affected side for refractory hypertension is the treatment.

SYNONYM

Segmental renal hypoplasia

REFERENCE

Zezulka AV, Arkell DG, Beevers DG, et al. The association of hypertension, the Ask-Upmark kidney and other congenital abnormalities. *J Urol.* 1986;135(5):1000–1001.

ASOPA HYPOSPADIAS REPAIR

DESCRIPTION The dorsal preputial foreskin's inner rectangular graft is tubularized to form the neourethra, and the outer opposing skin, which shares the same blood supply, serves as the outer penile shaft skin cover.

REFERENCE

Wacksman J. Use of the Hodgson XX (modified Asopa) procedure to correct hypospadias with chordee: Surgical technique and results. *J Urol.* 1986;136(6):1264–1265.

ASPERGILLOSIS, GENITOURINARY

DESCRIPTION Only *Candida* infections are more common opportunistic infections in the urologic population than aspergillosis. It affects patients with diabetes and malignancy, and immunosuppressed patients (HIV, renal transplant). It can cause renal parenchymal disease or obstructive uropathy. The prostate has been a rare site of infection. Renal aspergilloma or pseudotumor has been reported in patients with AIDS. Urine cultures can be negative, but aspiration and cytology can demonstrate typical septated hyphae. Therapy is systemic amphotericin B and at least 3 mo of itraconazole, or voriconazole. Amphotericin B irrigations into the involved renal unit have been used to supplement systemic therapy. Direct instillation of amphotericin B into the urinary pelvis through a ureteral catheter or nephrostomy tube has been the most successful approach to therapy. Through a retrograde

ureteral catheter instillation of a solution of amphotericin (50 mg/L in sterile water) is infused at 40 mL/h. Shade the solution to limit degradation. Monitor pressure with a pop-off mechanism at 20-cm water. (See also Section I: "Fungal Infections, Genitourinary.")

REFERENCE

Wise GJ, Freyle J. Changing patterns in genitourinary fungal infections. *AUA Update Series* . Volume XVI, Lesson 1, 1997.

ASPERMIA

DESCRIPTION A condition of no ejaculate, which should be differentiated from *azoospermia,* where an ejaculate is present but the sperm are absent from the fluid. (See also Section I: "Infertility, Urologic Conside-rations" and "Ejaculatory Disturbances (Delayed, Decreased, or Absent)"; Section II: "Semen Analysis, Technique, and Normal Values"; Section II: "Semen Analysis, Abnormal Findings, and Terminology.")

CAUSES

- Complete bilateral obstruction of ejaculatory duct
- Congenital anorchidism, imperforate anus, and other congenital anomalies
- Medication (chlorpromazine, α-blockers, methyldopa, imipramine)
- Radical prostatectomy (RP)
- Retrograde ejaculation; failure of seminal emission
- Surgical (bladder neck dysfunction secondary to TURP, TUIP, retroperitoneal lymph node dissection)

REFERENCE

Zorn B, Virant-Klun I, Stanovnik M, et al. Intracyto-plasmic sperm injection by testicular sperm in patients with aspermia or azoospermia after cancer treatment. *Int J Androl.* 2006;29(5):521–527.

ASSISTED REPRODUCTIVE TECHNOLOGY (ART)

DESCRIPTION ART includes all fertility treatments in which both eggs and sperm are handled. Although the Centers for Disease Control and Prevention does not include treatments in which only sperm are handled, there are various methods of sperm retrieval as defined below:

- Percutaneous epididymal sperm aspiration (PESA): Aspiration of sperm from epididymis percutaneously
- Microsurgical epididymal sperm aspiration (MESA): Done by open surgery
- Testicular sperm aspiration (TESA): Done percutaneously
- Testicular sperm extraction (TESE): Done through open biopsy of testicular tissue
- Intrauterine insemination (IUI) or Artificial insemination (AI): Also not ART by strict definition; however these are methods for fertility performed during ovulation by inserting a catheter into the cervical os and injecting concentrated sperm into the uterus, thereby bypassing the cervical mucous barrier.

The following are classical methods of ARF:

- Gamete intrafallopian transfer (GIFT): Oocytes and semen are retrieved, the semen is concentrated, then both are placed into the fallopian tube by laparoscopy.
- In vitro fertilization (IVF): Fertilization by either incubating sperms with oocytes or by injecting a single live sperm into an oocyte with a micropipette (called intracytoplasmic sperm injection [ICSI]). The resultant embryo is transplanted to the uterus or fallopian tube with a catheter through the cervix.
- ZIFT: After IVF of an egg, the resultant embryo is placed into the fallopian tube laparoscopically, instead of through the cervix.

ASTHENOSPERMIA

DESCRIPTION A general term for defects in sperm movement, usually a decrease in sperm motility to <50–60% of normal. It can be detected on semen analysis and can be a cause of male factor infertility. (See also Section I: "Infertility, Urologic Considerations"; Section II: "Semen Analysis, Abnormal Findings, and Terminology.")

CAUSES

- Antisperm antibodies
- Hypoandrogenic state
- Idiopathic
- Immotile cilia (Kartagener syndrome and immotile cilia syndrome)
- Infection
- Partial ejaculatory duct obstruction (EDO)
- Varicocele (most common surgically correctable abnormality)

TREATMENT

- Aimed at offending agent (ie, antibiotics for infection, sperm washing for antibodies, varicocelectomy)
- Interest has been noted in vitamins C and E and other free-radical scavengers
- ARTs

REFERENCE

Meacham RB, et al. Male infertility. In: Gillenwater JY, Grayhack JT, Howards SS, Duckett JW, eds. *Adult and Pediatric Urology*. 3rd ed. St. Louis, MO: Mosby, 1996.

ATHLETIC HEMATURIA

DESCRIPTION Hematuria, microscopic, or gross, can be noted in athletes engaged in high-intensity or long-duration exercise. Usually benign in course. Repeated episodes of hematuria may cause anemia in some athletes. Theorized causes include foot-strike hemolysis, renal ischemia, release of a hemolyzing factor, direct trauma to bladder or kidney, dehydration, myoglobinuria, increased circulation, and NSAIDs. Treatment includes adherence to sensible training guidelines and hydration.

SYNONYMS
- Sport-related hematuria
- Exercise-induced hematuria

REFERENCE

ATOPIC DERMATITIS (ECZEMA), UROLOGIC CONSIDERATIONS

DESCRIPTION Also called eczema, disseminated neurodermatitis, atopic eczema, and Besnier prurigo, this chronic pruritic eczematous condition affects characteristic sites. In adults, the genitalia is a common site. Patients present with itching, excoriation, edema, erythema, and scaling. As the disease progresses, the skin undergoes lichenification (thickening). The cause is unknown, but there is a familial association with this and other atopic diseases (allergic rhinitis, asthma).

TREATMENT
Topical corticosteroids such as triamcinolone 0.1% BID; nighttime sedation with antihistamines or other agent. Treat stress and remove irritants (soaps, solvents, fabrics made of wool or nylon).

REFERENCE
Edwards L, Lynch PJ. In: Sams WM, et al., eds. *Principles and Practice of Dermatology*. New York, NY: Elsevier, 1998:960–961.

ATTENTIVE DIGITAL RECTAL EXAM

DESCRIPTION Utilized to obtain prostatic secretions in urine to identify DNA, RNA, protein, and metabolite based biomarkers for the detection of prostate cancer. Clinical studies have identified PCA3 and TMPRSS2:ERG fusion transcripts as promising RNA markers for cancer detection and possibly prognosis. A “light prostatic massage” should be performed, including firm pressure to depress the gland by 1 cm. A total of 3 strokes per lobe should be performed from base to apex and from lateral to median line. (See Attentive digital rectal exam [DRE] Image ☼)

REFERENCE

ATYPICAL ADENOMATOUS HYPERPLASIA OF THE PROSTATE (ADENOSIS)

DESCRIPTION Some lesions can be confused with low-grade prostate cancer on small-needle biopsy samples. The differential diagnosis of these confusing pseudoneoplastic lesions includes atypical adenomatous hyperplasia of the prostate (AAH), sclerosing adenosis, postatrophic hyperplasia, basal cell hyperplasia, and others that must be differentiated from

low-grade prostatic carcinoma. Histologically, AAH is a crowded focus of small glands. It has not yet been definitively associated with an increased risk of prostate cancer. AAH is no longer considered a premalignant lesion but rather a benign small glandular process of the transition zone that simulates acinar adenocarcinoma. It is recommended to stain for 34βE12, which detects basal cell–specific CK. If basal cell staining is present, this helps to rule out carcinoma. Although the biologic significance of AAH is uncertain, its light microscopic appearance and immunophenotype allow it to be distinguished from carcinoma in most cases. The lesion appears to be distinct from atypical small acinar proliferation prostate (ASAP), which appears to be more associated with prostate cancer. In AAH, rebiopsy is not usually indicated. (See also Section II: "Atypical Small Acinar Hyperplasia, Prostate (ASAP)"; Section II: "Postatrophic Hyperplasia of the Prostate Gland.")

SYNONYMS

- Small gland hyperplasia
- Atypical adenosis
- Atypical small acinar hyperplasia

REFERENCE

Armah HB, Parwani AV. Atypical adenomatous hyperplasia (adenosis) of the prostate: A case report with review of the literature. *Diagn Pathol.* 2008;3:34.

ATYPICAL SMALL ACINAR PROLIFERATION, PROSTATE (ASAP)

DESCRIPTION Prostate needle biopsies occasionally contain cells identified as ASAP that are suspicious for but not diagnostic of malignancy. About 2% of contemporary prostate needle biopsy specimens contain collections of small acini that are suspicious for cancer but that fall below the diagnostic threshold and are often reported as "ASAP suspicious for but not diagnostic of malignancy." Prostate cancer has been identified in specimens from subsequent biopsies in up to 60% of cases of ASAP, indicating this finding is a significant predictor of cancer. Identification of ASAP (with or without high-grade PIN) warrants repeat biopsy for concurrent or subsequent invasive prostate carcinoma. (See also Section I: "Prostatic Intraepithelial Neoplasia"; Section II: "Atypical Adenomatous Hyperplasia and Postatrophic Hyperplasia of the Prostate.")

REFERENCE

AUA (AMERICAN UROLOGIC ASSOCIATION) SYMPTOM INDEX FOR BPH

DESCRIPTION Also called the *BPH symptom index*, and the AUA symptom score or AUA-SS this standardized instrument assesses the degree of lower urinary tract symptoms (LUTS) due to BPH in men, as well as guides response to treatment. Originally developed by the AUA, it is now used widely used. (See Section VII: Reference tables: AUA Symptom Index/International Prostate Symptom Score [I-PSS].) The AUA Index consists of 7 questions that assess emptying, frequency, intermittency, urgency, weak stream, and straining, with

each graded on a score of 0–5. Scores can range from 0–35. The index currently categorizes symptoms as:

- Mild (score ≤7)
- Moderate (score 8–19)
- Severe (score 20–35)

The International Prostate Symptom Score (I-PSS) is identical to the AUA index, except that it adds a single question to assess the quality of life based on the patient's perception of the problem. This is scored from 0 (or "delighted") to 6 (or "terrible").

It is suggested that patients with mild symptoms (AUA-SS ≤7) and patients with moderate or severe symptoms (AUA-SS ≥8) who are not bothered by their symptoms (ie, symptoms do not interfere with daily activities) should be managed by watchful waiting, although a wide range of patients with bothersome moderate to severe symptoms prefer this strategy as well. Today, most patients undergo medical management (α-blockers with or without 5α-reductase inhibitors or 5α-reductase alone prior to any surgical intervention). Surgical options include TURP, transurethral incision of the prostate, open prostatectomy, or minimally invasive therapies (such as transurethral microwave thermotherapy, transurethral needle ablation, and water-induced thermotherapy). (See also Section II: "International Prostate Symptom Score [I-PSS]"; Section VII: "AUA Symptom Index for BPH/I-PSS.")

AZOOSPERMIA

DESCRIPTION The absence of viable sperm on semen analysis and a documented cause of male factor infertility. Azoospermia can be obstructive or nonobstructive. When 1st noted, the sample should be centrifuged and the pellet examined for the presence of sperm. If present, a workup for oligospermia should be performed. A postejaculate urine analysis should be obtained to rule out retrograde ejaculation (ie, the urine contains significant numbers of sperm, 10–15/HPF). If absent, a physical exam for the presence of vas deferens and hormone studies are indicated. Treatment is based on the underlying cause. (See also Section I: "Infertility, Urologic considerations"; Section II: "Semen Analysis, Abnormal Findings, and Terminology.")

CAUSES

- Congenital absence of vas deferens
- Ductal obstruction
- Germ cell failure
- Gonadotoxins
- Hypogonadotropic hypogonadism
- Idiopathic
- Testicular failure (Klinefelter syndrome)

REFERENCE

Practice Committee of American Society for Reproductive Medicine in collaboration with

Society for Male Reproduction and Urology. Evaluation of the azoospermic male. *Fertil Steril.* 2008;90(5 Suppl):S74–S77.

BACK PAIN, UROLOGIC CONSIDERATIONS

DESCRIPTION The differential diagnosis of back pain includes several potential urologic etiologies:

- Cauda equina syndrome is a surgical emergency. Common findings are bladder dysfunction (especially urinary retention) and saddle anesthesia, in addition to sciatica and weakness
- Endocrine: Adrenal hyperplasia or infarction
- Gynecologic: Neoplasm of uterus or ovary, dysmenorrhea, salpingitis, uterine prolapse
- Infectious: Osteomyelitis, subarachnoid or spinal abscess, tuberculosis, meningitis, basilar pneumonia
- Mechanical: Pregnancy, obesity, fatigue, scoliosis
- Medication: Tadalafil-incidence of back pain and/or myalgia in 9.4% in patients receiving tadalafil 10 mg; 8.3% in patients receiving tadalafil 20 mg, and 3.7% in placebo-treated patients.
- Neoplastic: Myeloma, Hodgkin disease, carcinoma of pancreas or adrenal, metastatic neoplasm from breast, prostate, lung
- Renal: Hydronephrosis, calculus, neoplasm, renal infarction, pyelonephritis
- Trauma: Injury to bone, joint, internal organs, or ligament

BALANITIS XEROTICA OBLITERANS/LICHEN SCLEROSIS ET ATROPHICUS

DESCRIPTION BXO (Balanitis Xerotica Obliterans) is an inflammatory lesion of the glans and foreskin, now considered to be synonymous with lichen sclerosis et atrophicus (LSA). The term BXO is used when the skin of the genitalia is affected. BXO can cause itching and decreased sensitivity in the head of penis, but the hallmark is urethral meatal stenosis or distal urethral stricture. Differential diagnosis includes leukoplakia, Bowen disease (BD), erythroplasia of Queyrat, or squamous cell carcinoma (SCC) of the glans or preputial skin; biopsy is necessary to confirm the absence of malignancy. (See also Section I: “Penis, Cancer, General Considera-tions” and “Penis, Cutaneous Lesion.”)

TREATMENT

- Local therapy with steroid, estrogen, or testosterone cream
- Surgical therapy with circumcision (when appropriate) and flap reconstruction of fossa navicularis for severe cases; meatal or urethral dilation rarely gives durable response

REFERENCE

BJU Int. 2011;108(Suppl 2):14–19.

BALANITIS, ZOON (PLASMA CELL BALANITIS)

DESCRIPTION Also called *balanoposthitis chronica circumscripta plasma cellularis* and *plasma cell balanitis*. Can be confused clinically with erythroplasia of Queyrat. Grossly, it appears as a shiny, glazed-red macular erythematous lesion with multiple, pinpoint, bright red "cayenne pepper" spots. Histologically, a subepidermal inflammatory infiltrate of plasma cells and dermal red cell extravasation is present. No malignant transformation is reported. Proposed etiologies include *Mycobacterium smegmatis*, heat, poor hygiene, or constant friction. Treated by circumcision.

REFERENCE

BALKAN NEPHROPATHY

DESCRIPTION An interstitial nephropathy endemic to the Balkan Republics of Yugoslavia, Bulgaria, and Romania, and that afflicts mainly the middle-aged rural populations. It is slowly progressive, and may eventually end in ESRD. Anemia, proteinuria, and hypertension can be severe. Renal biopsy has no specific markers for the disease. Balkan endemic nephropathy is caused by eating bread that is contaminated with a toxin called aristolochic acid, which comes from a plant called Aristolochia. Balkan endemic nephropathy can occur in multiple family members, but it is not an inherited condition. A strong association with increased incidence of upper tract transitional cell carcinoma (TCC) has been documented, although bladder TCC incidence is normal. Treatment involves aggressive surveillance for TCC and renal replacement therapy, as necessary. (See also Section II: "Aristolochic acid [fang chi].")

REFERENCE

Stefanovic V, Polenakovic M. Fifty years of research in Balkan endemic nephropathy: Where are we now? *Nephron Clin Pract.* 2009;112(2):51–56.

BANFF CLASSIFICATION, TRANSPLANT REJECTION

DESCRIPTION A classification method developed in 1993 for standardization of criteria in the histologic diagnosis of renal allograft rejection. The Banff classification characterizes renal biopsy findings into a scheme that outlines possible clinical approaches to manage the rejection. (See also Section I: "Transplant Rejection, Renal.")

REFERENCE

Solez K, Racusen LC. The Banff classification revisited. *Kidney Int.* 2013;83(2):201–206.

BARCAT-REDMAN HYPOSPADIAS REPAIR

DESCRIPTION In a modification of the Mathieu procedure, this repair mobilizes the posterior urethral plate and splits the glans in addition to the parameatal flap. The full-

thickness parameatal and urethral plate grafts are tubularized together and laid to rest in the new urethral groove.

REFERENCE

Snodgrass WT. Hypospadias. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders, 2012:3503–3536.

BARIATRIC SURGERY, UROLOGIC CONSIDERATIONS

DESCRIPTION Jejunoileal bypass, the 1st bariatric procedure, produced severe hyperoxaluria secondary to steatorrhea. Modern bariatric surgery utilizes gastric restrictive procedures and sometimes bypass of variable amounts of small intestine, such as a Roux-en-Y gastric bypass and biliopancreatic diversion. Modern bariatric surgery is associated with less malabsorption compared to jejunoileal bypass; however, contemporary bariatric bypass patients continue to have hyperoxaluria, hypocitruria, and lower urine volumes, which result in an increased risk of calculus formation.

REFERENCE

Tasca A. Metabolic syndrome and bariatric surgery in stone disease etiology. *Curr Opin Urol.* 2011;21:129–133.

BARTTER SYNDROME

DESCRIPTION Congenital abnormality that usually presents in childhood with metabolic acidosis, hyperreninemic hyperaldosteronism, and hypokalemia. Presenting symptoms are muscle weakness, polyuria, and sometimes growth retardation. Patients are normotensive. Renal biopsy reveals juxtaglomerular hyperplasia. Defective platelet aggregation and decreased vascular responsiveness to pressors are also noted. Pathophysiology includes decreased sodium transport in the thick ascending loop of Henle; decreased vascular responsiveness and increased prostaglandin secretion may also play a role. This condition is incurable; potassium supplementation, prostaglandin synthesis inhibitors, aldosterone antagonists, and ACE inhibitors can help greatly to ameliorate symptoms.

REFERENCE

Fremont OT, Chan JC. Understanding Bartter syndrome and Gitelman syndrome. *World J Pediatr.* 2012;8(1):25–30.

BASHFUL BLADDER (PARURESIS, SHY BLADDER SYNDROME, "PEE-SHY")

DESCRIPTION This is the inability to urinate with others present, such as in a public restroom. It is a relatively common disorder but little is understood about the phobia. According to DSM-IV TR, this disorder is classified as social phobia.

REFERENCE

Hammelstein P, Soifer S. Is "shy bladder syndrome" (paruresis) correctly classified as social phobia? *Anxiety Disord.* 2006;20(3):296–311.

BCG REFRACTORY TRANSITIONAL CELL CARCINOMA (TCC)

DESCRIPTION TCC that recurs after treatment with intravesical BCG treatment. Failure of initial intravesical therapy may be managed by further intravesical therapy or cystectomy, with more aggressive therapy indicated for high-risk patients having superficial invasion (T1), high-grade lesions or concomitant carcinoma in situ (CIS). Patients with high-risk features who fail a 2nd course of BCG have a very high risk of progression to muscle-invasive TCC. In addition, relapses after ≥ 2 courses of BCG appear to be associated with poor outcomes, despite subsequent aggressive therapy. Several different salvage therapies, including intravesical interferon alone or in combination with BCG, valrubicin, mitomycin C, gemcitabine, and other chemotherapeutic agents, as well as photodynamic therapy, have been described for BCG failures. Salvage therapies have poor response rates, however, and radical cystectomy remains the "gold standard" for the salvage of failed intravesical therapy in high-risk patients. (See Also Section I: "Bladder Cancer, General.")

BCL-2, UROLOGIC CONSIDERATIONS

DESCRIPTION The protein product of the gene bcl-2 acts as an apoptosis-blocking agent. It appears to be required for normal morphogenesis of the kidney, and may be unimportant as a prognostic factor in RCC. It is seen in higher levels in prostatic intraepithelial hyperplasia but is variable in prostate cancer. Levels increase during XRT. Expression is increased in high-grade bladder tumors.

REFERENCE

King ED, Matteson J, Jacobs SC, et al. Incidence of apoptosis, cell proliferation and bcl-2 expression in transitional cell carcinoma of the bladder: Association with tumor progression. *J Urol.* 1996;155(1):316–320.

BECKWITH–WIEDEMANN SYNDROME

DESCRIPTION This condition is characterized by macroglossia, abdominal wall defects, adrenal cytomegaly, and neonatal hypoglycemia. Other characteristic features include gigantism, earlobe creases and pits, facial nevus flammeus, and prominent eyes with infraorbital creases. Neonatal hypoglycemia is frequent, of which Wilms tumor, adrenal cortical carcinoma, and hepatoblastoma are most common. Mental retardation is not associated. Most cases are sporadic, but a genetic cause related to mutation or deletion of imprinted genes within the chromosome 11p15.5 region. The mode of inheritance of BWS is complex. Possible patterns include autosomal dominant inheritance with variable expressivity, contiguous gene duplication at 11p15, and genomic imprinting resulting from a defective or absent copy of the maternally derived gene. Several lines of evidence suggest that BWS may be caused by relative overexpression of the maternally imprinted IGF2 gene. Some suggest a slightly increased risk in babies born by assisted reproduction. Close follow-up early

in life is recommended for tumor surveillance as 1 of the most ominous findings is the increased risk of neoplasia. In 1 series the majority of tumors were Wilms tumors (67%), followed by hepatoblastomas (11%), rhabdomyosarcomas (5%), and neuroblastomas (4%).

SYNONYM
EMG syndrome (exomphalos, macroglossia, and gigantinism)

REFERENCES
Online Mendelian Inheritance in Man; http://www.omim.org/entry/130650. Accessed March 1, 2014.
Weng EY, Mortier GR, Graham JM Jr. Beckwith-Wiedemann syndrome. An update and review for the primary pediatrician. *Clin Pediatr.* 1995;34(6):317–326.

BEER NEPHROURETERECTOMY

DESCRIPTION Refers to a retroperitoneal 2-incision approach to a nephroureterectomy through a flank and a separate Gibson or a midline Czerny incision.

REFERENCE
Bergman H, Lockhart J. Surgery of the ureteral stump. In: Kaufman JJ, eds. *Current Urologic Therapy*. Philadelphia, PA: Saunders, 1986:212–214.

BEER POTOMANIA

DESCRIPTION A hypo-osmolality syndrome of beer drinkers, usually with hyponatremia. Patients with beer potomania have a history of significant beer drinking, often long term, in conjunction with a poor diet. This may occur because beer has very little sodium and no protein, and the condition is potentially augmented by the possibility of inappropriate antidiuretic hormone (ADH) secretion.

TREATMENT
Fluid restriction, ICU monitoring, and serial serum sodium levels, with slow correction of hyponatremia.

REFERENCE
Sanghvi SR, Kellerman PS, Nanovic L. Beer potomania: An unusual cause of hyponatremia at high risk of complications from rapid correction. *Am J Kidney Dis.* 2007;50:673–680.

BEHÇET DISEASE

DESCRIPTION This is a multisystem vasculitis that is most active during young adulthood syndrome characterized by oral and genital ulcers (vulvar and penile), uveitis, vascular involvement (venous thrombosis, vasculitis), and nonmucous membrane skin lesions of unknown etiology. Lesions on the genitalia are herpetiform and can be painful. Other genital ulcers, such as syphilis, herpes, and chancroid, must be ruled out 1st. Genital ulcers are treated with local moisture-retaining dressings, topical anesthetics, and steroids. Rebamipide is used to treat aphthous ulcers. For severe mucocutaneous lesions, immunosuppressive systemic agents (corticosteroids, azathioprine, pentoxifylline, dapsone, interferon-alfa,

colchicine, and thalidomide) have demonstrated benefit.

REFERENCE

Emmi G, Silvestri E, Squatrito D, et al. Behçet's syndrome pathophysiology and potential therapeutic targets. *Intern Emerg Med.* 2014;9(3):257–265.

BELLINI DUCT CARCINOMA (COLLECTING DUCT CARCINOMA)

DESCRIPTION A variant of RCC in which the cell of origin is the collecting duct. Very few cases are reported in literature. Immunohistochemically, the lesion stains with high–molecular-weight keratin and lectin. Histologically, cells demonstrate intracyto-plasmic mucicarminophilic material, which is not seen in RCC. Radical nephrectomy for localized disease is the treatment of choice. Chemotherapy is used (interferon-α–based) for metastatic disease. (See also Section I: "Renal Mass.") (Image ☼)

REFERENCE

Kassouf W, Binsaleh S, Cohen DD, et al. Bellini duct carcinoma with ovarian metastasis. *Can J Urol.* 2004;11(6):2461–2462.

BELT PROCEDURE

DESCRIPTION Named for Dr. Elmer Belt, who described his technique for performing radical perineal prostatectomy in 1939. Dr. Belt described a new approach to the prostate through the perineum, between the longitudinal fibers of the rectum and the circular fibers of the external anal sphincter. This approach dramatically decreased blood loss. However, Dr. Belt also recommended leaving behind the apex of the prostate to achieve better urinary control, and opening the anterior layer of the Denonvillier fascia during the dissection.

REFERENCE

Belt E, Albert CE, Surber AC Jr. A new anatomic approach in perineal prostatectomy. *J Urol.* 1939;41:482–497.

BENCHEKROUN ILEAL VALVE

DESCRIPTION A hydraulic ileal valve is used as the continence mechanism in ileal or ileocecal reservoirs. As the reservoir fills, increased pressure occurs in the valve, which is created by invaginating an ileal segment that then serves as the efferent continent limb.

REFERENCE

McKiernan JM, et al. Continent urinary diversion. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders, 2012:2450–2478.

BERGER DISEASE (IgA NEPHROPATHY)

DESCRIPTION Sometimes referred to as "idiopathic immunoglobulin A nephropathy," this condition was 1st described by Berger and Hinglas in 1968. As the most common primary glomerulonephritis, it exhibits a wide variation in manifestation, ranging from a benign,

indolent course to rapidly progressive renal failure. Commonly presents with hematuria, proteinuria, and abnormal urine sediment. Diagnosed by renal biopsy demonstrating IgA deposits in the mesangium on immunofluorescence staining.

TREATMENT

- Recent promise seen in corticosteroids, fish oil, and ACE inhibitors
- Renal transplant for cases of renal failure

REFERENCE

Cheng J, Zhang X, Tian J, et al. Combination therapy of ACE inhibitor and an angiotensin receptor blocker for IgA nephropathy: A meta-analysis. *Int J Clin Pract.* 2012;66(10):917–923.

BERGMAN SIGN

DESCRIPTION In urologic radiography, the Bergman sign occurs when the ureter is dilated immediately below a neoplasm, rather than collapsed, as below an obstructing stone, thus showing a chalice shape. Retrograde pyelography demonstrates an irregular ureteral filling defect with complete obstruction and distal ureteral dilation, producing the chalice appearance; a ureteral catheter tends to curl in this segment. The Bergman sign is pathognomonic for neoplasm.

REFERENCE

Bergman H, ed. *The Ureter.* 2nd ed. New York, NY: Springer-Verlag; 1981.

β-hCG (HUMAN CHORIONIC GONADOTROPIN)

DESCRIPTION Glycoprotein with a molecular weight of 38,000 and a half-life of 2 days. It is produced normally by the syncytiotrophoblast cells in pregnancy. hCG is composed of 2 subunits, α and β. The β-subunit is identical to a subunit of LH. Urologic uses include staging and follow-up of testicular cancer (elevated in 100% of choriocarcinoma, 7% of seminoma, 60% of embryonal carcinomas). Has been produced by urothelial tumors and secreting polyembryoma. Therapeutically can be given exogenously to stimulate Leydig cells in secondary hypogonadism and facilitate descent of undescended testicles when administered over several weeks. Typical regimen is 500–2,500 U IM 2 times a week for 4 wk. The hCG test is used to diagnose anorchia in underscended testicles; a failure to increase testosterone after administration suggests anorchia. (See also Section I: “Testis, Cancer, General”; Section I: “Testis, Nonseminomatous Germ Cell Tumors, General.”)

REFERENCE

Bower M, Rustin GJ. Serum tumor markers and their role in monitoring germ cell cancers of the testis. In: Vogelzang NJ, et al., eds. *Comprehensive Textbook of Genitourinary Oncology.* 2nd ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2000.

BETHANECHOL SUPERSENSITIVITY TEST

DESCRIPTION A historical variation of urodynamic testing wherein bethanechol was

administered subcutaneously 20 min before testing. Usually considered when normal bladder contraction is weak or absent. If positive, a rise in filling pressure of >20 cm of water and a shift in the filling curve to the left are noted. A positive test represents bladder denervation. No change during the test represents myogenic damage.

REFERENCE

Snyder JA, Lipsitz DU. Evaluation of female urinary incontinence. *Urol Clin North Am.* 1991;18(2):197–209.

BEZOARS (FUNGUS BALLS)

DESCRIPTION Fungal infections of the kidney occur most commonly in the setting of diabetes, immunosuppression, urinary obstruction, or indwelling urinary catheters or stents. Most commonly *Candida* species such as *C. albicans* and *tropicalis* are involved. Other fungi such as *Torulopsis glabrata* and *Aspergillus* may cause renal infections, although less commonly. These infections can cause the formation of fungal balls or bezoars, which can be seen on imaging as a renal pelvic mass or filling defect and may cause obstruction; in the bladder, they may cause irritative voiding symptoms. Urinary tract imaging in the setting of candiduria (funguria) is needed in patients who have persistent candiduria and are at increased risk of bezoars (diabetics or other urologic abnormalities). Urinary tract fungal bezoars are managed with a combination of surgical and medical therapy. (See also Section I: "Fungal Infections, Genitourinary"; Section II: "Funguria.")

TREATMENT

- Treat medically until endoscopic procedure to remove the bezoar has been accomplished, symptoms have resolved, and cultures are negative
- Candida bezoars: Fluconazole (200–400 mg/d [3–6 mg/kg/d] PO)
- Alternative regimen: Amphotericin B (0.5–0.7 mg/kg/d IV) with or without flucytosine (100 mg/d PO divided into 4 doses)
- Aspergillosis bezoars: Use voriconazole load: 6 mg/kg q12h for 2 doses; then maintenance of 4 mg/kg q12h
- With upper tract involvement, amphotericin B mixed 50 mg/L of sterile water by ureteral catheter, or nephrostomy can be considered

REFERENCE

Pappas PG, Kauffman CA, Andes D, et al. Clinical practice guidelines for the management of candidiasis: 2009 update by the Infectious Diseases Society of America. *Clin Infect Dis.* 2009;48:503.

BIFID RENAL PELVIS

DESCRIPTION A term for incomplete ureteral duplication. Bifid renal pelvis indicates that the confluence of 2 separate pyelocalyceal systems is located at the UPJ. If the confluence is inferior to the UPJ but superior to the entry into the bladder, then this would be termed bifid ureters (Image ☼).

REFERENCE

Decter R. Renal duplication and fusion anomalies. *Pediatric Urol.* 1997;44;1323–1341.

BIFID SCROTUM

DESCRIPTION A congenital anomaly in which the scrotal folds are completely separate. This is generally seen in conjunction with other anomalies, and may be present in CAH and 5α-reductase deficiency, almost always associated with hypospadias.

REFERENCE

Palmer JS. Genitourinary manifestations in boys and girls associated with genetic diseases. *J Men's Health Gend.* 2006;3(1):71–79.

BIOFEEDBACK, UROLOGIC CONSIDERATIONS

DESCRIPTION Any method of training the body while receiving feedback on the specific function being trained. Biofeedback ranges from "low tech" (eg, vaginal cones for incontinence) to expensive electronic systems (utilizing EMG or pressure probes). Biofeedback is applied in urology for improvement of urinary incontinence, generally by strengthening pelvic floor muscles, and for treatment of dysfunctional voiding. Biofeedback has also been used to teach patients to stop uninhibited detrusor contractions, teach relaxation of the pelvic floor and promote normal voiding in children.

REFERENCE

Bø K, Kvarstein B, Nygaard I. Lower urinary tract symptoms and pelvic floor muscle exercise adherence after 15 years. *Obstet Gynecol.* 2005;105:999–1005.

BIOFILM, UROLOGIC CONSIDERATIONS

DESCRIPTION When microorganisms adhere to the surface of a urologic device (catheter, ureteral stent, implant) and create a matrix of extracellular polymeric substance. Biofilms provide resistance to antimicrobial agents by preventing penetration through the film and thereby limiting access to bacteria. Bacteria protected by a biofilm can also have poor expression of antimicrobial binding proteins and activation of intrinsic resistance genes. Biofilm bacteria can typically withstand 1,000–1,500× the concentration of antimicrobial agents utilized to kill nonfilm bacteria. Numerous strategies to avoid biofilm formation are currently being researched. Options include modifying biomaterial surface properties, antibiotic-impregnated material and frequent changes of foreign bodies when suitable.

REFERENCE

BIOTHESIOMETRY, PENILE

DESCRIPTION A simple, inexpensive method of testing the vibratory sensitivity threshold when evaluating neurogenic causes of impotence. It is performed by measuring vibratory thresholds, usually in at least 3 different areas of the body, such as the medial malleolus,

fingertips, and glans penis. Probably not as accurate and reproducible as other forms of neurologic testing, such as tibial-evoked potentials, pudendal-evoked potentials, and BCR latency. (See also Section I: "Erectile Dysfunction/Impotence, General.")

REFERENCE

Bemelmans BL, Hendrikx LB, Koldewijn EL, et al. Comparison of biothesiometry and neuro-urophysiological investigations for the clinical evaluation of patients with erectile dysfunction. *J Urol.* 1995;153(5):1483–1486.

BIRT–HOGG–DUBé SYNDROME

DESCRIPTION Birt–Hogg–Dubé (BHD) syndrome is a rare, autosomal dominant disorder 1st described in 1977. It is caused by germline mutations in the BHD (FLCN) gene that lies within the chromosomal band 17p11.2 and encodes for a tumor-suppressor protein, folliculin. Folliculin is highly expressed in a variety of tissues, including the skin, kidney, and lung (stromal cells and type I pneumocytes). BHD syndrome is the cutaneous triad of fibrofolliculomas (hamartoma of the hair follicle), trichodiscomas, skin tags, and a propensity for renal tumors. The renal tumors are often chromophobe RCC, oncocytoma, or hybrids of these tumors. However, many will develop clear cell tumors as well. These tumors are more likely to be multiple and bilateral. (See also Section I: "Renal Cell Carcinoma, General.")

REFERENCE

BITES TO PENIS, ANIMAL, AND HUMAN

DESCRIPTION Bites to the penis can result in significant morbidity. Of animal bites, the most common is the dog bite. These can be potentially severe, with deep tissue destruction. In the cases of animal bites, patients tend to present early, and usually the wound can be closed after copious irrigation and any necessary debridement is performed. Broad-spectrum antibiotics should be administered for polymicrobial contamination and, in the case of dog bites, penicillin-VK may be given to treat *Pasteurella multocida,* which may be present in 20–25% of bites. Human bites tend to present later and pose a significant risk for infection. These should be copiously irrigated, broad-spectrum antibiotics should be administered, and wound closure is generally avoided. (See also Section I: "Penis, Trauma.")

BK VIRUS, UROLOGIC CONSIDERATIONS

DESCRIPTION A common member of the human polyoma DNA virus, with a seropositivity rate of 60–100% of the general population; it rarely presents any symptoms in immunocompetent hosts, and is not known to cause malignancy. During states of immunosuppression (eg, chemotherapy, AIDS, transplantation), this virus can reactivate and

become a significant pathogen. BK virus often affects the urinary tract, with infections of the kidney and bladder being most common due to affinity to urothelial cells. In kidney transplant recipients, it can cause tubulointerstitial nephritis and ureteral stenosis. It has been shown to cause nephropathy in AIDS patients. BK virus has been found in the urine of immunosuppressed patients (viruria) having hemorrhagic cystitis (0.5–5 mo after bone marrow transplantation), causing both life-threatening hematuria and dysuria, as well as asymptomatic infections. Other causes of hemorrhagic cystitis in the differential include cyclophosphamide toxicity and adenovirus infection. The urine cytology–detectable abnormality of polyomavirus-infected cells is an enlarged nucleus with a single large basophilic intranuclear inclusion known as a "decoy cell"; this appears to be the best diagnostic test. Viral urine cultures and PCR are not useful in the diagnosis. It is named after the 1st patient (B.K.) in whom the virus was identified. (See also Section I: "Cystitis, Hemorrhagic [Infectious, Noninfectious, Radiation]" and "Immunocompromised Patients, Urologic Considerations.")

REFERENCE

Sukov WR, Lewin M, Sethi S, et al. BK virus-associated nephropathy in a patient with AIDS. *Am J of Kidney Dis.* 2008;51(4):15–18.

BLACK-WATER FEVER

DESCRIPTION Black-water fever is a clinical entity characterized by acute intravascular hemolysis, classically occurring after the introduction of quinine for treatment of malaria. It is a rare but serious condition, in which hemolysis and anemia produce characteristically dark-colored urine. The condition has become rare since 1950, when quinine was replaced by chloroquine. Currently, it has reemerged from increased reutilization of quinine because of the development of resistance to chloroquine. Treatment of black-water fever is supportive, including stopping the offending drug, blood transfusion for severe anemia, and a short course of steroids. (See Section II: "Malaria, Urologic Considerations.")

REFERENCE

Tombe M. Images in clinical medicine. Hemoglobinuria with malaria. *N Engl J Med.* 2008;358(17):1837.

BLADDER AGENESIS

DESCRIPTION Rare and usually lethal congenital abnormality that has been reported in <20 living patients. Associated abnormalities include renal agenesis, retroiliac ureters, crossed fused renal ectopia, malrotation of the gut, colonic duplication, anal atresia, intraperitoneal iliac arteries, and bicornuate uterus. It is caused by a urogenital sinus abnormality during wk 5–7 of development.

TREATMENT

- Separation of urinary and fecal stream
- Other reconstructive surgeries as appropriate

REFERENCE

Kaefer M, Adams MC. Penis and bladder agenesis in a living male neonate. *J Urol.* 1997;157(4):1439–1440.

BLADDER AUGMENTATION

DESCRIPTION Bowel segments are most commonly used to improve bladder capacity and manage poorly compliant bladders. The goal is to protect upper urinary tract drainage and maintain renal function. Augmentation cystoplasty is utilized mainly in patients with disorders of the neurologic system (eg, spinal cord injury [SCI], multiple sclerosis [MS], myelodysplasia). Modifications with bladder neck reconstruction and/or addition of continent channels (Mitrofanoff or Monti channels) can be utilized to facilitate both continence and ease in drainage. Complications associated with bladder augmentation include failure to adequately improve bladder capacity, metabolic disturbances, mucous plugging, urinary tract infections, bladder calculi, vesicoureteral reflux, bladder perforation, and malignancy (usually adenocarcinoma most commonly located at the region of the anastomosis).

REFERENCE

Biers S, Venn SN, Greenwell TJ. The past, present, and future of augmentation cystoplasty. *BJU Int.* 2011;109:1280–1293.

BLADDER CANCER, INTRAVESICAL AGENTS

DESCRIPTION Either immunotherapy agents, such as BCG, or chemotherapy agents, such as mitomycin C, are instilled directly into the bladder for the treatment of either carcinoma in situ or high-grade superficial urothelial carcinoma. Adjuvant intravesical chemotherapy regimens have been shown to decrease recurrence rates but no clear improvement in overall progression has been documented. Patients who fail intravesical therapy should be evaluated for extirpative treatment. (See also Section I: “Bladder Cancer, General,” “Bladder Cancer, Nonmuscle-Invasive Bladder Cancer [Ta, T1],” and “Bladder Cancer, Urothelial, Superficial Carcinoma In Situ (CIS) (NMIBC).”)

Agent	Description	Dose	Use	Efficacy	Considerations
Chemotherapy					
Mitomycin c	Alkylating agent-prevention of tumor cell implantation, adjunct therpy post TUR	40 mg/20 mL saline	Adjuvant within 6 hr of TUR resection ideal as single dose, maintenance dose not reduce risk	Recurrence 36.7–48.4%	Avoid dermal exposure and avoid if perforation is suspected
Anthracyclines (doxorubacin, epirubicin, valrubicin, adriamycin)	Alkylating agent-prevention of tumor cell implantation, adjunct therpy post TUR	Epirubicin 80 mg/50 mL saline	Similar to mitomycin but epirubicin has superior shelf life in comparison to mitomycin c		
Thiotepa	Alkylating agent-prevention of tumor cell implantation, adjunct therpy post TUR	30 mg/50 mL saline	Single adjuvant dose and then single dose every 3 mo up to 1 yr	No difference in comparison to no adjuvant therapy	Low–molecular-weight increases risk of absorption and bone marrow dyscrasia. Largely abandoned
Immunotherapy					
BCG**	Live attenuated of *Mycobacterium bovis*	Induction 6-wk course plus maintence for 3 yr (3-wk course at 3, 6, 12, 18, 24, 30, 36 mo)	Utilized in high-risk nonmuscle invasive bladder cancer after TUR has healed (CIS, high-grade Ta, T1)	Recurrence 16–40% and progression 4.4–40%	Only 16% of people will complete full 3-yr maintenance course secondary to toxicity
Interferon alpha	Glycoprotein	10 million–100 million units	Best reported use in BCG failure in combination with BCG	CIS 37% at 12 mo and 47% at 24 mo	Majority of failures within 4 mo of initial treatmemt
Salvage therapies					
Valrubicin	Analog of doxarubacin		Utiliztion in BCG refractory or patients refusing radical cystectomy	BCG refractory patients 21% complete response	
Gemcitabine	Deoxycytidine analog	1,000–2,000 mg	BCG failure	20–75% recurrence free survival	

**FDA Approved for bladder cancer.

REFERENCE

BLADDER CANCER, UROTHELIAL, MICROPAPILLARY

DESCRIPTION Micropapillary (MP) bladder cancer is a uncommon variant of urothelial carcinoma, accounting for 0.7–12% of all bladder cancers. This variant has an aggressive profile and is largely resistant to intravesical BCG. The majority of patients, approximately 2/3, have advanced T3/4 staging upon radical cystectomy and 50% have pN+ disease. Median 10-yr survival is 31%, in contrast to 53% for patients with non-MP urothelial carcinoma. Treatment should include early radical cystectomy (Image ☼).

REFERENCE

Wang J, Boorjian SA, Cheville JC, et al. Outcomes following radical cystectomy for micropapillary bladder cancer versus pure urothelial carcinoma: A matched cohort analysis. *World J Urol.* 2012;30:801–806.

BLADDER CHORIOCARCINOMA

DESCRIPTION Primary choriocarcinoma of the bladder is exceedingly rare. Only 7 cases are described in the literature. Most cases present with hematuria and may also have gynecomastia. Metastases and β-hCG elevation were seen in the majority of reported cases. A full metastatic workup including scrotal exam and ultrasound are mandatory. 3 of the 7 cases were treated with resection and then chemotherapy, and all 3 showed good response (1 patient died of pulmonary embolus during therapy), the other 4 patients died of the disease.

(See also Section I: “Bladder Cancer, General.”)

REFERENCE

Hanna NH, Ulbright TM, Einhorn LH. Primary choriocarcinoma of the bladder with the detection of isochromosome 12p. *J Urol.* 2002;167(4):1781.

BLADDER CONTRACTILITY INDEX (BCI)

DESCRIPTION A urodynamic variable. BCI = $PdetQ_{max}$ + $5Q_{max}$ (Q_{max} is the maximum flow rate and $PdetQ_{max}$ is the detrusor pressure at maximum flow). Poor detrusor contractility is defined as BCI <100, normal contractility is BCI between 100 and 150, and strong bladder contractility is BCI >150.

REFERENCE

Abrams P. Bladder outlet obstruction index, bladder contractility index and bladder voiding efficiency: three simple indices to define bladder voiding function. *BJU Int.* 1999:84(1):14–15.

BLADDER DIVERTICULUM

DESCRIPTION A bladder diverticulum is a herniation of the vesical mucosa through the detrusor muscle. Bladder diverticula may be congenital or acquired. Most acquired diverticula are associated with long-standing bladder outlet obstruction (high intravesical pressures) and are most commonly seen in older men with benign prostatic hypertrophy or other forms of bladder outlet resistance; it is rare in women. The condition usually evolves from bladder wall trabeculation, to cellule, and finally a diverticulum, typically located on the lateral wall and rarely at the dome. Since the acquired diverticuli have no muscle wall components, they do not empty well and cause urinary stasis with increased risk of infection, stones, and urothelial carcinoma (intradiverticular tumors have a prevalence of 1–10%). The lack of a muscular wall makes urothelial carcinoma more likely to extend outside the bladder early. Congenital bladder diverticula are uncommon and occur almost exclusively in boys. When next to the ureteral orifice (Hutch diverticula), this can result in vesicoureteric reflux on that side. Treatment usually involves correction of the outlet obstruction to reduce high-pressure voiding. Diverticulectomy (open or laparoscopic) can be performed for recurrent infection or bladder calculi. Treatment for cancers within diverticula may include transurethral resection (can be complicated by narrow ostia and thin diverticular wall), laser ablation, diverticulectomy, partial cystectomy, and radical cystectomy with or without intravesical therapy (Image ☼).

REFERENCE

Zeman PA, et al. Lower urinary tract symptoms. In: Siroksy MB, et al., eds. *Handbook of Urology*. 3rd ed. Philadelphia, PA: Lippincott; 2004.

BLADDER EARS

DESCRIPTION Transient bladder outpouchings into the inguinal ring of male infants <6 mo

old. This close association of the bladder with the internal ring resolves spontaneously. Inguinal herniorrhaphy in male infants can result in significant bladder damage if bladder ears are present. The condition is differentiated from bladder diverticula by absence of a definable neck.

REFERENCE

Redman JF, Jacks DW, O'Donnell PD. Cystectomy: A catastrophic complication of herniorrhaphy. *J Urol.* 1985;133(1):97–98.

BLADDER FILLING DEFECTS

DESCRIPTION Filling defect on a contrast study of the urinary bladder (cystography) may be the result of:

- Air: Artifactual, postinstrumentation, vesicoenteric fistula
- Benign tumor: Prostatic enlargement, inverted papilloma, endometriosis
- Blood clot
- Calculus
- Congenital: Ureterocele
- Extrinsic compression by pelvic organ or mass, pelvic lipomatosis
- Fungus ball (bezoar)
- Infective, inflammatory: Inflammatory edema
- Instruments (catheters), foreign body
- Malignant tumor: Bladder and prostate malignancy, tumors invading urinary bladder from contiguous organs (eg, uterus, colon)
- Radiologic artifact: Fold in nondistended bladder

See also Section I: "Bladder calculi (vesical calculi)" and Section II: "Bladder Mass, Differential Diagnosis." (Image ☼)

BLADDER HEMANGIOMA

DESCRIPTION A bladder anomaly most often associated with Klippel–Trenaunay syndrome (extensive port wine stains on extremities), bladder hemangioma is a rare, benign tumor. It presents with gross hematuria, at times severe. Bladder hemangiomas may be solitary or multiple.

TREATMENT

- Endoscopic treatment with Nd:YAG laser ablation
- Partial cystectomy can be required for large lesions or uncertainty in diagnosis

REFERENCE

Kato M, Chiba Y, Sakai K, et al. Endoscopic neodymium:yttrium aluminium garnet (Nd:YAG) laser irradiation of a bladder hemangioma associated with Klippel-Weber syndrome. *Int J Urol.* 2000;7(4):145–148.

BLADDER HERNIA

DESCRIPTION Most are found in the inguinal or femoral region and are often associated

with bladder outlet obstruction in men. It is estimated that up to 4% of all inguinal hernias can contain some degree of bladder herniation. Rarely, massive herniation may be found, with significant portions on the bladder and distal ureter descending into the scrotum; bladder infarction and obstruction has been reported. In women, herniation of the bladder into the anterior vaginal wall is technically a cystocele. Treatment is repair of inguinal hernia, with reduction of bladder herniation. Bladder outlet obstruction should be identified and treated in males as this may contribute to the original herniation and subsequent recurrences.

SYNONYM
Scrotal cystocele

REFERENCE
Bisharat M, O'Donnell ME, Thompson T, et al. Complications of inguinoscrotal bladder hernias: A case series. *Hernia.* 2009;13(1):81–84.

BLADDER HYPOPLASIA

DESCRIPTION Lack of urinary bladder development, leading to inadequate function and storage capacity. Hypoplasia is caused either the failure of production or storage of urine, or from complete bypass of the bladder. Causes include urogenital sinus abnormalities, severe epispadias, bilateral renal agenesis, severe renal dysplasia, and bilateral ureteral ectopia. Bladder reconstruction with bowel segments can be attempted.

REFERENCE
Frimberger DC, Kropp BP. Bladder Anomalies in Children. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders, 2012:3381.

BLADDER, INFLAMMATORY PSEUDOTUMOR

DESCRIPTION A benign spindle cell lesion in patients who have not had surgery (as opposed to postoperative spindle cell nodule). Most patients are from 20–50 yo and present with gross hematuria. The lesion is nodular or pedunculated, but some may be sessile and invade the muscularis propria. This is a benign lesion, but it must be differentiated from myxoid sarcomatoid carcinoma and myxoid leiomyosarcoma. Resection is the treatment.

REFERENCE

BLADDER LEIOMYOMA

DESCRIPTION Though very rare, it is the most common mesodermal tumor of the bladder, constituting 0.5% of all bladder neoplasms. Usually incidentally discovered, though if large or pedunculated may present with bladder outlet obstruction. Seen more commonly in females. Generally homogeneous and smoothly marginated on ultrasound and CT. MRI better and shows the submucosal origin, usually has low T2 and intermediate T1 signal.

TREATMENT

- Pedunculated lesions are amenable to transurethral resection
- Sessile or large tumors may require partial cystectomy

REFERENCE

Goel R, Thupili CR. Bladder leiomyoma. *J Urol.* 2013; Epub ahead of print.

BLADDER, LYMPHOMA

DESCRIPTION In lymphoma, involvement of the bladder is usually secondary to systemic disease. Primary lymphoma of the bladder is rare, and carries an excellent prognosis. Most patients are female in the 7th–8th decades. Patients typically present with gross hematuria. The tumors can be single or multiple, sessile or papillary. Most common types are large-cell and small cell lymphocytic lymphoma and further classified as MALT (extranodal marginal zone B-cell lymphoma) lymphomas thought to result from chronic inflammation. Many patients in recent series have chronic cystitis. Radiotherapy has been the treatment of choice for localized lymphoma; otherwise, systemic therapy is undertaken if the bladder is not the primary site.

REFERENCE

Kempton CL, Kurtin PJ, Inwards DJ, et al. Malignant lymphoma of the bladder: Evidence from 36 cases that low-grade lymphoma of the MALT-type is the most common primary bladder lymphoma. *Am J Surg Pathol.* 1997;21(11):1324–1333.

BLADDER MASS, DIFFERENTIAL DIAGNOSIS

Malignant	Benign
Urothelial carcinoma (TCC)	Inverted papilloma
Squamous cell carcinoma	Nephrogenic adenoma
Adenocarcinoma	Leiomyoma
Small cell (neuroendocrine) tumor	Hemangioma
Sarcoma	Granulomas
Sarcomatoid tumors	Abscess
Melanoma	Bladder diverticulum
Metastatic disease	Inflammatory pseudotumor
	Filling defect due to: calculi, air, clot, foreign body, fungus ball

(See also Section II: "Bladder Filling Defect" and "Bladder Wall Thickening.") (Image ☼)

REFERENCE

Abol-Enein H. Nonurothelial cancer of the bladder. *Urology.* 2007;69(1 Suppl):93–104.

BLADDER, METASTASIS TO

DESCRIPTION The bladder may become involved by tumors by direct extension (most commonly) or metastatic spread. The most common locally invasive are colon, prostate, rectum, and cervix. Distant metastasis to the bladder include stomach, skin, lung, breast, and rarely melanoma. These metastasis are almost always solitary and are often located in the bladder neck or trigone. Lymphoma can be metastatic or primary and secondary involvement by leukemia has been reported.

REFERENCE

BLADDER NECK CONTRACTURE

DESCRIPTION Scarring and stenosis of the bladder neck occur most commonly as a postoperative complication of transurethral resection of the prostate or radical prostatectomy at the site of vesicourethral anastomosis. Bladder neck contracture may lead to decreased urinary flow, high-pressure voiding, urinary retention, urinary tract infections, and incontinence. Factors associated with this complication include urinary leak at the anastomosis, poor mucosal approximation, suture retraction, ischemia, or foreign bodies such as surgical clips. Postoperative radiation may contribute. Radiation monotherapy can cause contracture with the presentation from 12–36 mo after completion. Management consists of dilation, endoscopic incision (laser, cold cut, electrosurgical) or resection, and, in severe cases, open repair utilizing a Y–V plasty. Occasionally, intermittent self catheterization may be needed to maintain patency.

REFERENCE

Blumenthal KB, Sutherland DE, Wagner KR, et al. Bladder neck contractures related to the use of Hem-o-lok clips in robot assisted laparoscopic radical prostatectomy. *Urology*. 2008;72(1):158–161.

BLADDER NECK HYPERTROPHY

DESCRIPTION Hypertrophy of the bladder neck is often seen in conjunction with BPH and may lead to obstructive symptoms and dysfunctional high-pressure voiding. Pure bladder neck hypertrophy has also been implicated in chronic pelvic pain syndrome (CPPS) and may respond best to α-adrenergic blockade. (See also Section I: “Bladder Outlet Obstruction [BOO].”)

REFERENCE

Hruz P, Danuser H, Studer UE, et al. Non-inflammatory chronic pelvic pain syndrome can be caused by bladder neck hypertrophy. *Eur Urol.* 2003;4:106–110.

BLADDER, NEUROFIBROMA

DESCRIPTION A rare benign tumor of the nerve sheath from overgrowth of Schwann cells, these lesions originate in the bladder from ganglia in the wall. They can present in childhood as obstruction or voiding symptoms. Malignant degeneration is rare. The condition is sporadic or related to neurofibromatosis. Conservative resection, as needed, is the usual treatment. With severe obstruction or intolerable symptoms, cystectomy may be needed.

REFERENCE

Salvitti M, Celestino F, Gerocarni Nappo S, et al. Diffuse ganglioneuromatosis and plexiform neurofibroma of the urinary bladder: An uncommon cause of severe urological disease in an infant. *J Pediatr Urol.* 2013;9(3):e131–e133.

BLADDER OUTLET OBSTRUCTION INDEX (BOOI)

DESCRIPTION Based on the International Continence Society (ICS) nomogram for identifying bladder outlet obstruction during urodymamic evaluation. The ICS nomogram categorizes patients with LUTS into obstructed, equivocal (or slightly obstructed) or unobstructed based on the maximum detrusor pressure during voiding versus the maximum flow rate.

$$BOOI = PdetQ_{max} - 2Q_{max}$$

$PdetQ_{max}$ is the maximum detrusor pressure at peak flow and Q_{max} is the maximum flow rate.

Patients are obstructed if the BOOI is >40, equivocal if the BOOI is 20–40, and unobstructed if the BOOI is <20.

BLADDER PAIN/INTERSTITIAL CYSTITIS SYMPTOM SCORE (BPIC-SS)

DESCRIPTION BPIC-SS is a questionnaire to select bladder pain syndrome/interstitial cystitis patients for clinical trials. It may have a role in clinical practice in the future. It consists of 8 questions divided into broad areas: Urge to urinate, urinary frequency, and bladder pain and pressure. For the scoring, a single score is created by summing all 8 items to create a total score ranging from 0–38.

Bladder Pain/Interstitial Cystitis Symptom Score (BPIC-SS)

Concept	Item
Urge to urinate	In the past 7 days, how often did you still feel the need to urinate just after you urinated?
	In the past 7 days when you urinated, how often was it because of pain in your bladder?
	In the past 7 days, how often did you urinate to avoid pain in your bladder from getting worse?
Urinary frequency	In the past 7 days, how bothered were you by frequent urination during the daytime?
	In the past 7 days, how bothered were you by having to get up during the night to urinate?
Bladder pain and pressure	In the past 7 days, how often did you have a feeling of pressure in your bladder?
	In the past 7 days, how often did you have pain in your bladder?
	Select the number that describes your worst bladder pain in the past 7 days.

Modified from Humphrey L, et al. *European Urology.* 2012;61(2):271–279.

BLADDER, PARAGANGLIOMA

DESCRIPTION Exceedingly rare tumor, with 15% being malignant. Accounts for 10% of extra-adrenal pheochromocytomas. Catecholamine release is sometimes triggered by voiding, bladder distention, defecation, or intercourse. Typical symptoms are those of a pheochromocytoma (diaphoresis, paroxysmal hypertension, palpitations, headaches, syncope). The lesion may arise from embryonic nests of chromaffin cells in the sympathetic plexus of the detrusor muscle. Cystoscopy should be accompanied by adrenergic blockade; routine biopsy should be avoided. Transurethral resection is considered inadequate, since most lesions involve the entire thickness of the bladder wall. Treatment for smaller lesions consists of partial cystectomy with pelvic lymph node dissection. Radical cystectomy is recommended with large tumors or if lymphatic involvement is present.

REFERENCE

Dahm P, Gschwend JE. Malignant non-urothelial neoplasms of the urinary bladder: A review. *Eur Urol.* 2003;44(6):672.

BLADDER, PHEOCHROMOCYTOMA

DESCRIPTION Similar to pheochromocytomas in other areas of body; 10% are malignant. They are thought to arise from paraganglionic cells in bladder, usually around the trigone. Most are hormonally active and can present with hypertension during bladder emptying and filling. Can appear as a submucosal tumor on cystoscopy. Late metastasis can occur, so long-term follow-up is warranted.

TREATMENT

- Partial cystectomy is the treatment of choice
- TUR may cause a hypertensive crisis

BLADDER SARCOMA (LEIOMYOSARCOMA/RHABDOMYOSARCOMA)

DESCRIPTION Types of sarcoma that have been described in the bladder include angiosarcoma, leiomyosarcoma, rhabdomyosarcoma, liposarcoma, chondrosarcoma, and osteosarcoma. These, combined, account for <1% of all malignant tumors of the bladder. They usually present with hematuria or voiding symptoms. Sarcomas of the bladder are rare aggressive malignancies. Leiomyosarcoma is the most common malignant mesenchymal tumor that arises in the bladder of adults. It occurs more frequently in men. On histology, parallel bundles of spindle cells are seen. The mainstay of treatment is aggressive excision (4–

5 cm margins), but even with such treatment the 5-yr disease-specific survival is 62%. Rhabdomyosarcomas are most common in young children. Embryonal rhabdomyosarcomas in children characteristically produce polypoid lesions in the base of the bladder, and is known as *sarcoma botryoides*. For pediatric rhabdomyosarcoma, a multimodal approach utilizing surgery, radiation, and chemotherapy is employed, with improving rates of bladder preservation and improving prognosis. Metastatic disease treatment consists of resection, radiation, and chemotherapy with single-agent (doxorubicin or ifosfamide). (See also Section I: "Bladder Cancer, General"; Section I: "Rhabdomyosarcoma, Pediatric [Sarcoma Botryoides].")

BLADDER SMALL CELL CARCINOMA (OAT CELL, SIGNET RING)

DESCRIPTION Neuroendocrine or small cell carcinoma is an aggressive malignancy derived from either neuroendocrine or pluripotent cells. This tumor most commonly arises in the lung, but may occur in multiple locations including the bladder and less frequently the prostate. Neuroendocrine tumor of the bladder is rare, with ~286 cases reported in the English literature. It can be seen alone or in combination with other tumor types, most frequently TCC. Small cell carcinoma of the bladder presents as any other bladder tumor, most frequently with hematuria. The diagnosis is made pathologically. The tumor usually presents as muscle-invasive disease (94% in 1 series), and often with metastatic disease (67% in same series). Most common sites of metastases are to lymph nodes, liver, bone, lung, and brain. Due to the high rate of early dissemination, chemotherapy is the mainstay of treatment, with radical cystectomy often performed afterward. The tumor also appears responsive to combined chemotherapy and radiation. Prognosis is generally worse than for urothelial carcinoma. (See also Section I: "Bladder Cancer, General.") (Image ☼)

SYNONYMS

- Small cell carcinoma
- Neuroendocrine tumor
- Oat cell carcinoma

TREATMENT

- Partial or radical cystectomy
- Platinum-based chemotherapy has achieved partial regression

REFERENCE

BLADDER, TEARDROP

DESCRIPTION Diffuse pelvic pathology can compress the bladder into a teardrop configuration on various imaging studies, such as excretory urography or cystogram. Causes include pelvic lipomatosis, pelvic hematoma, pelvic adenopathy, and enlarged pelvic vasculature (usually caused by vena cava obstruction). Occasionally, a muscular patient with a hypertrophied iliopsoas muscle can exhibit this finding.

REFERENCE

Amis ES, Newhouse JH, eds. *Essentials of Uroradiology*. 1st ed. Boston: Little, Brown; 1991:287–288.

BLADDER TRABECULATION AND CELLULES

DESCRIPTION Trabeculation is a cystoscopic description of hypertrophy of smooth muscle bundles in the muscularis propria layer of the bladder wall, which occurs over time due to high-pressure voiding in the setting of bladder outlet obstruction. The obstruction may be due to anatomic obstruction such as benign prostatic hyperplasia (BPH) in the adult or posterior urethral valves in the child, or to neurogenic dysfunction such as detrusor sphincter dyssynergia. It is a manifestation of increased collagen deposition in the bladder wall. More extreme degrees of trabeculation are termed “cellules.” These small pockets are caused when the bladder mucosa is pushed between the collagen and muscle fibers of the bladder wall. Cellules may progress to form an acquired bladder diverticulum. (See also Section II: “Bladder Diverticulum.”) (Image ☼)

BLADDER, VILLOUS ADENOMA

DESCRIPTION This tumor has a histologic appearance identical to villous adenoma of the colon. It can also be seen in the urachus. Cystoscopically, it appears exophytic and papillary. Histologically, a mucous-secreting epithelium with goblet cells is seen. It is treated by transurethral resection with possible cystectomy, if invasion is suspected.

REFERENCE

Channer JL, Williams JL, Henry L. Villous adenoma of the bladder. *J Clin Pathol*. 1993;46(5):450–452.

BLADDER WALL CALCIFICATION, DIFFERENTIAL DIAGNOSIS

DESCRIPTION Bladder wall calcification is a relatively uncommon finding. The differential includes:

- Amyloidosis
- Bilharzia (urinary schistosomiasis)
- Cyclophosphamide-induced cystitis
- Encrusted cystitis
- Mitomycin C intravesical treatment
- Tuberculosis
- Urothelial carcinoma

REFERENCE

BLADDER WALL THICKENING, DIFFERENTIAL DIAGNOSIS

DESCRIPTION Bladder wall thickening can be seen on US, CT, or MRI. The differential includes:

- Bacterial/viral cystitis
- Bilharzial infection (urinary schistosomiasis)
- Bladder cancer (urothelial carcinoma, nonurothelial carcinoma)
- Bladder fistula (Crohn disease, diverticulitis)
- Hemorrhagic cystitis
- High-pressure storage/voiding (eg, bladder outlet obstruction, neurogenic bladder)
- Systemic lupus erythematosus
- Tuberculosis (Image ☼)

BLASTOMYCOSIS, GENITOURINARY

DESCRIPTION *Blastomyces dermatitidis* is endemic in the Ohio, Mississippi, and Missouri river basins. It is an opportunistic infection in immunocompromised patients, particularly associated with prolonged steroid use (>2 mo), HIV, solid tumors treated with radiation or chemotherapy, and end-stage renal and hepatic disease. GU blastomycosis tends to involve the prostate and epididymis, and produces voiding complaints. Genitourinary disease may be seen in 20–30% of disseminated infections. Prostatic abscess can be seen. Up to 30% can have epididymal involvement. GU blastomycosis is a manifestation of systemic disease; it has been reported to be transmitted by sexual relations to the GU system of the partner. Diagnosis may be made by isolation of fungus from the urine, semen, or tissue. Detection of blastomyces A antigen by immunodiffusion may be helpful in diagnosis. Other serologic testing with enzymeimmnoassay and radioimmunoassay have high sensitivity (85–88%) and specificity (100%).

TREATMENT

- Standard therapy for disseminated infection is long-term amphotericin B

- Long-term ketoconazole (12 mo) at 400 mg/d may be effective for prostatitis/epididymitis
- Itraconazole may be effective in focal uncomplicated infections

BLEOMYCIN TOXICITY

DESCRIPTION Used in combination chemotherapy for testicular cancer as well as cervical, ovarian, SCC, and lymphoma, induces single- and double-strand breaks in DNA called *scission*. Pulmonary fibrosis (fibrosing alveolitis) is a potentially lethal toxicity; it can develop 1–6 mo after treatment and has been reported to occur beyond 6 mo. Bleomycin may also cause hypersensitivity pneumonitis and nodular pulmonary densities. Skin changes, alopecia, and stomatitis are common. Vascular toxicity, anaphylaxis, and Raynaud phenomenon have been reported. Clinical indications of pulmonary toxicity may include any of the following: Cough (nonproductive), dyspnea, pleuritic chest pain, fever, tachypnea, rales, lung restriction, and hypoxemia. Renal insufficiency is a risk factor for bleomycin toxicity (80% eliminated by the kidney).

TREATMENT

- Discontinue drug with suspected bleomycin-induced injury; steroids may help some cases.
- Attention to minimizing oxygen concentration and hydration status during surgery is essential.

REFERENCE

Fyfe AJ, McKay P. Toxicities associated with bleomycin. *J R Coll Physicians Edinb*. 2010;40(3):213–215.

BLUE DIAPER SYNDROME

DESCRIPTION Defect in tryptophan absorption in which the urine contains indoles, giving it a blue color. Similar to Hartnup disease, a chronic course is usual. Hypoplasia of the optic disc and abnormal eye movements have also been reported.

SYNONYMS

- Familial hypercalcemia with nephrocalcinosis and indicanuria
- Tryptophan malabsorption

TREATMENT

Low-tryptophan diet; no treatment known for underlying defect

REFERENCE

Chen Y, Wu L, Xiong Q. The ocular abnormalities of blue diaper syndrome. *Metab Pediatr Systemic Ophthalmol*. 1991;14(3–4):73–75.

BLUE DOT SIGN

DESCRIPTION A blue discoloration seen through the scrotal wall when the testes are tented against the skin. Indicates the presence of torsion of appendix testes or appendix epididymis. Should be assessed during the evaluation of scrotal pain or swelling. The torsed appendix may swell to the size of the testicle itself. If torsion of the cord can be ruled out by palpation of the unequivocally normal testicle, appendiceal torsion can be observed. (See also Section I: "Torsion, Testis or Testicular/Epididymal Appendages.")

REFERENCE

Dresner ML. Torsed appendage. Diagnosis and management: Blue dot sign. *Urology*. 1973;1(1):63–66.

BLUE NEVUS (MELANOSIS), UROLOGIC CONSIDERATIONS

DESCRIPTION Benign melanotic lesion of the prostate that must be differentiated from malignant melanoma. It is usually an incidental finding after TURP. In prostate, the term *blue nevus* has been used when melanin is confined to ovoid or elongated melanocytes in the stroma, whereas the term melanosis has been used for those prostatic lesions that have melanin in both the stromal melanocytes and glandular epithelium. It has been reported in lesions with adenocarcinoma.

REFERENCE

Muzaffar S, Aijaz F, Pervez S, et al. Melanosis of the prostate: A rare benign morphological entity. *Br J Urol*. 1995;76(2):265–266.

BOARI-OCKERBLAD FLAP

DESCRIPTION After appropriate bladder mobilization, a tonguelike flap of bladder based on the ipsilateral superior vesicle artery is incised. The base of the flap should be at least 4 cm, while the tip should be at least 3 cm. The tubularized flap is then anchored to the psoas minor tendon, and either direct or tunneled anastomosis with the ureter is then performed. Useful to reimplant the ureter when there is loss of the distal ureter.

REFERENCE

Nakada SY, Hsu T. Management of Upper Urinary Tract Obstruction. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2012:1122–1168.

BODY MASS INDEX (BMI), UROLOGIC CONSIDERATIONS

DESCRIPTION The BMI is defined as the weight (in kilograms) divided by the height (in meters^2). BMI is used to categorize obesity (see table). Higher BMI carries many increased health risks, including diabetes and coronary artery disease. Obesity and elevated BMI have many detrimental effects and associations in urology. Elevated BMI has been shown to be an independent risk factor for incontinence in females and for adverse outcomes in prostate cancer. BMI has been clearly correlated with incidence and risk of formation of renal calculi in both men and women. It has been implicated in ED, with reduction of BMI correlating with

increased IIEF score. Increased BMI as a marker of obesity implies increased difficulty in many open, laparoscopic, and percutaneous procedures. A BMI calculator from the NIH is available online at: http://www.nhlbisupport.com/bmi/. (See also Section II: "Obesity, Urologic Considerations.")

Classification of Overweight and Obesity by BMI

	Obesity Class	BMI (kg/m^2)
Underweight		<18.5
Normal		18.5–24.9
Overweight		25.0–29.9
Obesity	I	30.0–34.9
Obesity	II	35.0–39.9
Extreme obesity	III	≥40

REFERENCES

BONE MARROW/STEM CELL TRANSPLANTATION, UROLOGIC CONSIDERATIONS

DESCRIPTION High-dose chemotherapy regimens used for bone marrow transplantation and stem cell transplantation are accompanied by multiple toxic side effects. The most common urologic complication is hemorrhagic cystitic (HC), with an incidence ranging from 7–68%. HC is commonly seen in a dose dependent manner after the administration of cyclophosphamide and ifosfamide. Both medications have the same metabolite, acrolein. HC can further be caused by busulfan, pelvic irradiation, thrombocytopenia, and the presence of a urinary viral infection (adenovirus, BK virus, cytomegalovirus [CMV], polyoma virus). Early onset HC tends to be due to acrolein exposure, late HC is associated with viral etiologies. Other possible urologic sequelae of high-dose chemotherapy exposures include bladder fibrosis, fistula, bladder contracture, chronic urinary tract infections, pyuria, and secondary malignancies. A preventative measure for HC is premedication with 2-mercaptoethane sodium sulfonate (Mesna) and hydration. Catheter drainage and continuous bladder irrigation may limit acrolein exposure to bladder urothelium. Tumor lysis syndrome and uric acid stone development are also possible.

BONE METASTASIS, UROLOGIC CONSIDERATIONS

DESCRIPTION Bone metastasis is a common problem in urologic malignancies. Prostate cancer has a predilection to metastasize to bone but bone metastasis from renal cell

carcinoma, urothelial carcinoma, and adrenocortical carcinoma is also seen. An elevated alkaline phosphatase suggests bone lesions. The diagnosis often involves a radionucleotide bone scan with confirmatory imaging study and possibly a biopsy. Bone metastases are associated with pain (which may be severe), pathologic fractures, and possible spinal compression (often referred to as skelet al-related events or SRE). These lesions often require treatment independently from the primary tumor. Options for treatment include chemotherapy, surgery, and external beam radiation. Radiation therapy is often highly successful at controlling local bony symptoms and radioisotopes such as strontium-89 are useful for palliation of more extensive bone metastasis. Radium 223 (Xofigo) an α-emitter has been approved for bony metastatic prostate cancer and can improve quality of life and extend survival in metastatic castrate resistant prostate cancer. In prostate cancer in particular, bisphosphonate therapy such as zolendronic acid, and osteoclast targeting agents such as denosumab are used to prevent progression and skelet al-related complications and may be effective at preventing occurrence of bone metastases (Image ☼).

BONE MINERAL DENSITY, UROLOGIC CONSIDERATIONS

DESCRIPTION Prolonged ADT for prostate cancer is associated with decreased bone mineral density (BMD) and osteoporosis, leading to disabling skelet al fractures. Bisphosphonate therapy (zoledronic acid, alendronate, others), smoking cessation, weight-bearing exercise, and vitamin D and calcium supplementation can help improve BMD during androgen ablation therapy. (See also Section II: “Osteoporosis and Osteopenia, Urologic Considerations.”) Some recommend that BMD should be monitored during androgen-deprivation therapy using BMD scans (dual-energy x-ray absorptiometry or DEXA):

- T-score: The number of standard deviations (SDs) by which the patient’s bone mass falls above or below the mean peak bone mass for a 30-yr-old healthy adult. For every 1 SD decrease in T-score, relative risk of fracture increases ~1.5–2.5-fold
- WHO interpretation of T-scores: Normal: ≥–1; Osteopenia: –1 to –2.5; Osteoporosis ≤–2.5; Severe osteoporosis: ≤–2.5 and ≥1 fracture

REFERENCE

Ryan CW, Huo D, Stallings JW, et al. Lifestyle factors and duration of androgen deprivation affect bone mineral density of patients with prostate cancer during 1st year of therapy. *Urology*. 2007;70(1):122–126.

BONE SCAN, UROLOGIC CONSIDERATIONS

DESCRIPTION The radionucleotide bone scan is a sensitive test for bone metastases and is obtained during the initial staging or in the setting of recurrent or metastatic disease in urologic malignancies (prostate, urothelial, renal, and adrenocortical carcinomas). A standard

bone scan is generally performed by acquiring multiple images of the skeleton 3–4 hr after IV injection of ^{99m}technetium-labeled methylene-diphosphonate (MDA). Due to low specificity, if a lesion is identified, particularly when solitary, further investigation is necessary using confirmatory testing. This may be done with plain radiographs, CT, or MRI. Bone scans are extensively used in prostate cancer to detect and follow bone metastases. In prostate cancer patients with extensive bony metastasis, the bone scan may have a "super scan" appearance, in which the focal lesions coalesce to produce diffusely increased uptake. An increase in the contrast between bone and background soft tissue and faint or absent renal images are the typical appearances seen on a "super scan." (Image ☼)

BONNEY TEST (MARSHALL TEST)

DESCRIPTION A clinical test used for >50 yr for the diagnosis of stress incontinence and for the selection of patients for incontinence surgery. As originally described, the test consists of 2 parts:

- The patient coughs with a full bladder, and simultaneous urine loss from the urethra is visually confirmed.
- The examiner elevates the bladder neck with a finger on either side of the urethra while the patient coughs again.
- If the patient is then continent, the test is considered positive and the patient is thought to have an anatomic defect correctable by surgical elevation of the bladder neck. Bonney cautioned that the fingers must be carefully placed to avoid compressing the urethra in the midline.

The contemporary clinical utility of the test has been questioned by many clinicians.

BORS-COMARR CLASSIFICATION OF VOIDING DYSFUNCTION

DESCRIPTION Based on observations noted with spinal cord injury patients. The system takes into account 3 main factors:

- Anatomic location of the lesion (upper motor neuron, lower motor neuron)
- Completeness of the lesion (partial vs. complete SCI)
- Presence of residual urine, which would mean "unbalanced," according to the definition
- Best applied to patients with a complete neurologic lesion after spinal shock has resolved

REFERENCE

BOSNIAK CLASSIFICATION OF RENAL CYSTS

DESCRIPTION Classification system to differentiate renal cystic masses visualized on CT as benign or malignant. Cysts are graded on scale from I–IV, with grade I having typical appearance of benign simple cyst, and grade IV having appearance of RCC. Classification is based on homogeneity and complexity of cystic fluid, presence or absence of septations, calcifications, or solid components; and the density of cystic fluid as determined by Hounsfield units. (See also Section II: "Renal Cysts," Section II: "Renal Mass.")

- Category I: Benign simple cysts; thin walls without septa, calcifications, or solid components; water density and no contrast enhancement. No further imaging needed.
- Category II: Benign cysts with a few thin septa; the wall or septa may contain fine calcification and sharp margins, are nonenhancing, and usually measure <3 cm.
- Category IIF: Well-marginated and may have thin septa or minimal smooth thickening of the septa or wall, which may contain calcification that may also be thick and nodular; no contrast enhancement. Includes totally intrarenal nonenhancing lesions >3 cm. These require follow-up (designated by the "F" designation).
- Category III: Indeterminate cysts with thickened irregular or smooth walls or septa; enhancement present. 40–60% are malignant (cystic RCC and multiloculated cystic RCC). Other class III lesions are benign and include hemorrhagic cysts, infected cysts, and multiloculated cystic nephroma. Surgery is recommended, although additional imaging by MRI or with biopsy is supported by some clinicians.
- Category IV: Risk of malignancy is 85–100%. Characteristics of category III cysts plus they contain contrast-enhancing soft tissue components that are adjacent to and independent of the wall or septum. Surgery is recommended (Image ☼).

BOURNE TEST

DESCRIPTION A diagnostic test for the detection of enterovesical or colovesical fistulas. Radiographs are taken of centrifuged urine samples, which are obtained immediately after a barium enema. In 1 series of 10 patients, in 7 of the 10, the Bourne test was the only positive evidence of an otherwise occult colovesical fistula later proven at surgery.

REFERENCE

Lawrence C, Shaffer HA Jr, Bickston SJ. Image of the month. Bourne test, enterovesical fistulas. *Gastroenterology*. 2003;125(2):291, 641.

BOWENOID PAPULOSIS

DESCRIPTION Bowenoid papulosis is an uncommon skin lesion affecting the genitals, groin, and perianal areas of young, sexually active adult men and women. The histology appearance resembles Bowen disease. BP is rarely invasive and may even regress spontaneously, thus conservative treatments are often adequate. The natural history of the disease is unknown, but the lesions usually follow a benign clinical course, and spontaneous regression is

observed. Evolution of the lesions to invasive carcinoma is rare. The papules are asymptomatic, discrete, small (averaging 4 mm in diameter), flat, reddish violaceous or brown, often coalescent, and usually have a smooth, velvety surface. Many patients have a history of genital infection with viral warts or herpes simplex. Genital warts are primarily caused by HPV types 6 and 11. Treatment should be conservative. Individual lesions can be adequately treated by excision, cautery, cryoablation, or laser surgery, much as ordinary warts, without the need for wide surgical margins. Alternatively, lesions may be treated for 3–5 wk with 5% 5-fluorouracil cream or imiquimod cream QOD.

BOYARSKY GUIDELINES FOR BPH

DESCRIPTION To provide reproducible guidelines for the severity of symptoms of prostatism, BPH, and LUTS, scored questionnaire formats have been developed. Traditional assessment tools include the Madsen–Iversen Point System and the Boyarsky Guidelines. These have been generally replaced by the AUA or I-PSS questionnaires, but are used in several ongoing follow-up studies of BPH therapies.

REFERENCE

Boyarsky S, Jones G, Paulson DF, et al. A new look at bladder neck obstruction by the Food and Drug Administration regulators: Guidelines for investigation of benign prostatic hypertrophy. *Trans Am Assoc Genitourinary Surg.* 1976;68:29–32.

BOYCE NEPHROTOMY (ANATROPHIC NEPHROLITHOTOMY)

DESCRIPTION The longitudinal anatrophic nephrotomy takes advantage of a nearly avascular plane in the kidney (Brödel white line), which can be used to remove staghorn calculi (Boyce anatrophic nephrolithotomy). The incision site in the lateral posterior surface of the kidney can be accurately identified by injecting indigo carmine in the posterior renal artery branch. Once the capsule is incised, the parenchyma is divided with the blunt end of the knife in the proper plain. Traditionally used for staghorn calculi.

BRACHYTHERAPY SEED EMBOLUS

DESCRIPTION Brachytherapy is used to treat prostate cancer via image-guided implantation of radioactive seeds of iodine^{125} or palladium^{103}. These seeds, when placed into periprostatic tissue, have been noted to migrate, at times entering the prominent periprostatic veins and traveling centrally. Multiple investigations have yielded varying rates of seed displacement and embolization ranging from 0.7–55% of all cases. The most common target organ is the

lung, but reports of coronary artery and hepatic emboli exist through a patent foramen ovale. The iodine^{125} seed measures 4.5 mm in length and 0.8 mm in diameter and, due to its small size, is more frequently involved in embolization. Because of their size, these emboli are often asymptomatic and are diagnosed incidentally on imaging studies. 2 concerns regarding this process are possible injury to the end organ, especially in cases of patent foramen ovale, and diminution of the radiation dose to the prostate.

REFERENCE

Nguyen BD. Cardiac and hepatic seed implant embolization after prostate brachytherapy. *Urology*. 2006;68(3):673.

BRAIN METASTASIS, UROLOGIC CONSIDERATIONS

DESCRIPTION Brain metastatic disease can be seen with several urologic malignancies, most commonly with renal cell carcinoma and germ cell tumors (GCT). They generally are poor prognostic indicators. Patients may be asymptomatic with occult disease or display neurologic symptoms such as headache, nausea, and vomiting, mental status changes, seizures, or focal signs. Patients presenting with urologic tumors and neurologic signs should be worked up for brain metastases. CT scan is generally quick and readily available, but MRI has higher sensitivity and is better at distinguishing metastases from other intracranial processes. Due to their high impact on quality of life, these often require prompt treatment usually via radiation therapy or surgical removal.

REFERENCE

Nguyen TD. Brain metastasis. *Neurol Clin*. 2007;25(4):1173–1192.

BRENNER TUMORS

DESCRIPTION These are tumors of variable malignant potential of the ovary. Extraovarian and testicular origins have been reported, and they usually present as an ovarian mass. Light microscopy demonstrates distinctive nests of transitional cells indistinguishable from urothelium. Classified as typical, metaplastic, proliferating, or malignant, these lesions usually stain for carcinoembryonic antigen (CEA). Theorized origin is from a metaplastic process of coelomic epithelium. Usually, surgical removal is used to assess malignant potential.

BRICKER URETERAL ANASTOMOSIS

DESCRIPTION A direct ureteral-to-small bowel end-to-side refluxing anastomosis incorporating full-thickness ureteral and intestinal wall. It is used in ileal conduit construction.

REFERENCE

Dahl DM, McDougal WS. Use of intestinal segments in urinary diversion. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2012:2411–2449.

BRIGHAM SLING (URETHROPEXY)

DESCRIPTION Used to treat stress incontinence in women. A combined endoscopic needle sling procedure that utilizes a rectus fascial strip placed at the bladder neck through a vaginal incision. The fascial sling is held in place with needles placed through the anterior abdominal wall, similar to the Stamey and Raz suspension needle procedures. (See also Section I: "Incontinence, Urinary, Adult Female.")

REFERENCE

Loughlin KR. The Brigham sling. *Contemp Urol*. 1998;10:69–75.

BRINK SCORE

DESCRIPTION A digital test of pelvic muscle strength for evaluation of a pelvic muscle exercise program. Factors of perceived pressure, alteration of the vertical plane, and time were combined to form a 7-point scale. Currently used in pelvic floor physical therapy regimens.

REFERENCE

Brink CA, Wells TJ, Sampselle CM, et al. A digital test for pelvic muscle strength in women with urinary incontinence. *Nurs Res*. 1994;43:352–356.

BRITISH TESTICULAR TUMOR CLASSIFICATION

DESCRIPTION Used mainly in Great Britain, and based on the concept that all nonseminomatous tumors represent displaced, nonorganized embryonic blastomeres and are therefore teratomas. Disparate lesions are classified under a common category. The World Health Organization classification is used in most of the rest of the world.

REFERENCE

Ulbright TM. Neoplasms of the testes. In: Bostwick D, ed. *Urologic Surgical Pathology*. 1st ed. St. Louis, MO: Mosby; 1997.

BRONCHOGENIC CYST, RETROPERITONEAL

DESCRIPTION Bronchogenic cysts are congenital abnormalities arising from remnants of the primitive foregut, which gives rise to the respiratory diverticulum. Generally asymptomatic and benign, these lesions are often incidentally discovered. The true prevalence is unknown due to their asymptomatic nature. Retroperitoneal location is exceedingly rare with only approximately 60 cases reported in the literature. Most retroperitoneal bronchogenic cysts are located near the left adrenal gland or peripancreatic. Anatomopathologic criteria include pseudostratified, ciliated columnar epithelium with cartilage, smooth muscle or seromucous glands. May become larger over time due to continued epithelial secretion. Infection, perforation, hemorrhage, and malignant

degeneration are possible and surgical extirpation is recommended. Definitive diagnosis can only be made histopathologically. (See also Section I: “Retroperitoneal Masses, Fluid, and Cysts.”)

REFERENCE

Govaerts K, Van Eyken P, Verswijvel G, et al. A bronochognic cyst, presenting as a retroperitoneal cystic mass. *Rare Tumors*. 2012;4(1):e13.

BRUNN BUDS AND NESTS (VON BRUNN NESTS)

DESCRIPTION Variant of bladder epithelium, noted in 80–90% of normal bladders. Brunn buds are an invagination of surface epithelium into the lamina propria. Brunn nests represent a further invagination within the lamina propria and are a more progressed form of a Brunn bud. Cystitis cystica is thought to result from a Brunn nest that closes over on itself, forming a cyst. May become involved with urothelial carcinoma; controversy exists as to whether radical or conservative therapy is indicated if these lesions are involved by TCC.

Dinney CP, Ramirez EI, Swanson DA, et al. Management of transitional cell carcinoma involving von Brunn’s nests. *J Urol*. 1995;153:944–949.

BRUSHITE (CALCIUM MONOHYDROGEN PHOSPHATE)

DESCRIPTION A type of calcium phosphate calculus of the kidney. Brushite stones are particularly dense and are 2nd only to cysteine stones in their resistance to fragmentation. Calcium phosphate is the most common type of stone seen in distal renal tubular acidosis (type 1). On metabolic evaluation, primary calcium phosphate stone formers tend to have higher urine volumes, and higher calcium and lower citrate excretion than do idiopathic calcium oxalate formers. (See also Section I: “Urolithiasis, Adult, General”; Section II: “Urolithiasis, Calcium Oxylate/Phosphate.”)

REFERENCE

BTA TESTING (BTA AND BTA STAT URINE TEST)

DESCRIPTION The BTA test (Bard; Redmond, Washington) is a latex agglutination assay. It qualitatively detects high–molecular-weight basement membrane complexes, present when tumor cells become invasive and undergo proteolytic degradation. A comparison of BTA with bladder wash cytology reported a higher sensitivity of BTA (54% vs. 23%); however, BTA was associated with a high false-positive rate (specificity 9%). A multicenter trial demonstrated sensitivities of 40% and 16% for BTA and urine cytology, respectively.

The initial BTA test had 2 limitations: It was a latex agglutination test, and it yielded high false-positive rates. Consequently, the new BTA stat test was developed; it is a monoclonal antibody immunoassay that detects the presence of newly identified human complement factor H-related protein (hCFhrp). A study of BTA stat reported higher sensitivity compared

with cytology. BTA stat has also had higher sensitivity compared with the BTA test (58% vs. 44%). The specificity of BTA stat was reported as 72% for benign genitourinary disease and 95% in healthy volunteers. The main advantage of the BTA test is that it can simply be performed in an office setting and provides rapid results.

BULBOCAVERNOSUS REFLEX

DESCRIPTION Used as a means of evaluating sacral neurologic integrity. The reflex is commonly elicited by touching the labium minus lateral to the clitoris or squeezing the glans penis and observing for anal contraction. Afferent limb of reflex arc is the pudendal nerve, efferent limb is via the inferior hemorrhoidal branch of the pudendal nerve. Reflex is integrated at the S2–S4 cord level. Relevant urologically for its innervation of the bladder outlet and in erectile function and ejaculation.

REFERENCE

Wester C, Fitzgerald MP, Brubaker L, et al. Validation of the clinical bulbocavernosus reflex. *Neurourol Urodyn*. 2003;22(6):589–591.

BULKING AGENTS, INJECTABLE

DESCRIPTION Injections of various agents (synthetic and natural) have been used in urology to treat conditions such as vesicoureteral reflux, intrinsic sphincter deficiency (ISD), and stress urinary incontinence (SUI). Some products that have been used in the United States are listed here. Collagen is no longer available but is included in the table due to its widespread use in the past. A recent study in elderly patients with SUI noted improvement in incontinence after bulking therapy. In contrast to earlier reports, side effects due to injections were few and mild. Coaptite, macroplastique, and durasphere are actively used for SUI in the United States. Only Deflux is still used for VUR in the United States. (See also Section I: “Incontinence, Urinary, Adult Male”; Section I: “Incontinence, Urinary, Adult Female”; Section I: “Vesicoureteral Reflux, Pediatric”; and Section II: “STING Procedure.”)

Table: Bulking Agents, Injectable

Material	Brand Name	Description
Combination of calcium hydroxylapatite (CaHA) particles and a sodium carboxymethylcellulose carrier gel	Coaptite	CaHA is a principle component of human bone and tooth and has been used in multiple orthopedic and dental applications. It is demonstrated biocompatible and safe. Causes fibroblast infiltration rather than heterotopic ossification. The carrier gel suspends the CaHA particles and degrades over several months.
Polytetrafluoroethylene	PTFE (Teflon)	The small size of particles (90% $<40\ \mu m$) allows them to be phagocytosed, which can result in distant migration and granuloma formation. Not FDA approved for incontinence (migration risk).
Glutaraldehyde cross-linked bovine collagen	GAX-Collagen	Highly purified 35% suspension of bovine collagen (95% type I collagen and 1–5% type III collagen). Does not cause granuloma formation or migration to distant body sites. Begins to degrade in 12 wk; completely degraded in 19 mo, but the injected material transforms into living connective tissue.
Pyrolytic carbon-coated zirconium beads	Durasphere	Nonresorbable pyrolytic carbon-coated zirconium beads are much larger (212–500 μm) than either PTFE or silicone polymers and are transferred in a 2.8% β-glucan water-based gel. Durasphere is more viscous than collagen, and its injection was more technically demanding.
Ethylene vinyl alcohol (EVOH)	Tegress	Permanently implanted nonpyrogenic, injectable bulking agent (EVOH dissolved in DMSO). The resulting mixture is 8% EVOH in DMSO. After injection into tissue, the DMSO diffuses away, resulting in the EVOH precipitating into a complex cohesive. Spongiform mass. This phase transformation takes place rapidly (within 60s), and this effect creates increased tissue bulk.
Silicone polymers	Macroplastique	Textured polydimethylsiloxane macro particles ($>100\ \mu m$) suspended in a bioexcretable carrier hydrogel of polyvinylpyrrolidone (povidone) in which the solid particle content is 33% of the total volume.
Dextranomer microspheres	Deflux	Viscous gel of dextranomer microspheres (50 mg/mL) in a carrier gel of nonanimal stabilized hyaluronic acid, constituting a biocompatible and biodegradable implant. The dextranomer microspheres range from 80–250 μm (average 130 μm). The hyaluronic acid acts mainly as a carrier, leaving the dextranomer microspheres at the implant site.

BULLOUS PEMPHIGOID

DESCRIPTION A dermatologic condition thought to be autoimmune related. The condition is more common in men and in patients >60 yr of age. Although variable in clinical presentation, a preliminary nonbullous phase is usually characterized by severe pruritus and nonspecific skin changes, followed by formation of confluencing vesicles and marked erythema of the skin. Immunohistochemical evaluation of the skin biopsy shows IgG deposition along the skin basement membrane. Commonly used medications are anti-inflammatory agents (eg, corticosteroids, tetracyclines, dapsone) and immunosuppressants (eg, azathioprine, methotrexate, mycophenolate mofetil, cyclophosphamide). Most patients require therapy for 6–60 mo.

BUN (BLOOD UREA NITROGEN), INCREASED/DECREASED

DESCRIPTION Blood urea nitrogen (BUN) is a product of dietary protein metabolism. It is produced in the liver and cleared by the kidneys. The serum BUN level depends on both the rate of production and the rate of renal clearance. In renal failure, BUN and creatinine levels generally increase. Factors that might increase BUN include drugs (lithium, diuretics, aminoglycosides, corticosteroids), GI bleeding, prerenal azotemia, renal disease (diabetic nephropathy, pyelonephritis, glomerulonephritis), and obstructive nephropathy. Factors that lower BUN include liver disease, malnutrition and low-protein diets, 3rd-trimester pregnancy, celiac disease, and acromegaly. BUN along with sodium is thought to be responsible for the solute diuresis (postobstructive diuresis) that results after relief of renal obstruction.

BURCH COLPOSUSPENSION

DESCRIPTION The pubocervical fascia at the level of the bladder neck is fixed to Cooper's ligament bilaterally, usually through a Pfannenstiel incision and a retropubic exposure. It is used in treatment of stress incontinence in women.

REFERENCE

Burch JC. Urethrovaginal fixation to Cooper's ligament for correction of stress incontinence, cystocele, and prolapse. *Am J Obstet Gynecol.* 1961;81281–81290.

BUSCHKE-LOWENSTEIN TUMOR

DESCRIPTION Nonmalignant penile or perineal lesion, which may be large and exophytic. May cause urethral erosion and fistulas. Can be very locally invasive and mistaken grossly for SCC. Microscopically, broad rete pegs, filled with benign squamous cells and surrounded by a layer of inflammatory cells, are noted. A possible role of HPV 6 and 11 in the development is theorized. Treatment is by local excision after proven diagnosis. (See also Section I: "Condylomata Acuminata (Venereal Warts)"and "Penis, Lesion.")

SYNONYMS

- Verrucous carcinoma
- Giant condyloma acuminata

1994;37(9):950–957.

BYAR FLAPS

DESCRIPTION The penile prepuce is split dorsally and transferred ventrally, yielding redundant ventral skin (Byars flaps) to be used in 2nd-stage hypospadias repair.

REFERENCE

Snodgrass WT. Hypospadias. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2012:3503–3536.

CALCIFICATIONS, ABDOMINAL AND PELVIC

DESCRIPTION Abdominal and pelvic calcifications are a common finding on plain radiographs and CT. The differential is very broad and includes renal, ureteral and bladder calculi, vascular calcifications (arthrosclerosis and phleboliths), calcified tumors, lymph nodes, seminal vesicles, vas deferens, and infectious processes (TB) (Image ☼).

REFERENCE

O'Connor OJ. Imaging of hematuria. *Radiol Clin North Am.* 2008;46(1):113–132.

CALCIFICATIONS, BLADDER

DESCRIPTION Bladder calcifications on CT or plain radiograph:

- Intraluminal: Bladder calculi, 7% of bladder urothelial carcinomas may be calcified and appear as small stones, encrusted cystitis, foreign body, iatrogenic (postop sutures, retained prostate chips, catheter fragments, hair [due to chronic self-catheterization], following intravesical BCG or mitomycin)
- Bladder wall: Infections (tuberculosis, schistosomiasis), squamous cell carcinoma, cyclophosphamide-induced cystitis, prior radiation treatment, amyloidosis

REFERENCE

O'Connor OJ. Imaging of hematuria: *Radiol Clin North Am.* 2008;46(1):113–132.

CALCIFICATIONS, PROSTATE

DESCRIPTION Calcifications within the prostate are fairly common and can be detected in over 50% of older men. In 1 series of normal men calcifications were found in 23.1% of men aged 20–29 yr compared with 83% for men aged 60–69 yr. Prostatic calculi in childhood are rare. On Doppler imaging they create a prominent "twinkle" artifact. Prostatic calculi usually coexist with prostatitis or BPH in elderly men. It is unclear whether prostatic calculi independently cause LUTS. The prostatic stones are usually located between adenoma and the compressed prostatic tissue sometime referred to as the "surgical capsule" of the gland. Many prostatic stones appear to be calcified proteinaceous bodies called corpora amylacea. Corpora amylacea have no clinical significance, and even if dense or clumped, they are usually not palpable. Primary or endogenous calculi are said to be formed in acini from corpora amylacea. Secondary or exogenous calculi are formed in the prostatic and ejaculatory ducts. Prostatic utricle cysts can also calcify or contain multiple stones.

Prostatic calculi quite often are asymptomatic. Prostatic calcifications are not found more frequently in men with prostatitis but larger calcifications are more likely to be associated with LUTS. However, these calcifications can be a nidus for chronic bacterial infections in some men as many are surrounded by biofilm.

Radiation oncologists have explored the use of prostate calcifications as naturally occurring fiducial markers. The relationship between prostate cancer and calcifications has not been confirmed. Extensive calcifications can be seen after some cases of cryotherapy of the prostate and with tuberculous involvement of the prostate. (See also "Prostate Utricle Calcification.")

Zackrisson B, Hugosson J, Aus G. Transrectal ultrasound anatomy of the prostate and seminal vesicles in healthy men. *Scand J Urol Nephrol.* 2000;34(3):175–180.

CALCIFICATIONS, RENAL

DESCRIPTION May represent calcified renal calculi or calcified cystic or solid renal neoplasms. RCC is detectable on plain radiography and calcified ~8–18% of the time. Other possible etiologies for renal calcifications include papillary tip calcifications, calcified renal pelvis TCC, nephrocalcinosis, calcified renal artery, and tuberculosis (Image ☼).

REFERENCE
O'Connor OJ. Imaging of hematuria. *Radiol Clin North Am.* 2008;46(1):113–132.

CALCINOSIS, IDIOPATHIC SCROTAL

DESCRIPTION Occurs in pre-existing epidermal cysts or in the dermis without cysts. Usually affects young men. Multiple cysts (>50) are not uncommon. Calcifications range in size from a few millimeters to 3 cm. They may represent epidermal cysts that have, over time, lost their normal wall and calcified. Surgical excision is curative if symptomatic.

REFERENCE
Ro JY, et al. Chapter 15: Penis and scrotum. in urologic surgical pathology. In: Bostwick DG, Cheng L eds. 2nd ed. Philadelphia, PA: Mosby Elsevier; 2008.

CALCIPHYLAXIS

DESCRIPTION Calciphylaxis, also known as calcific uremic arteriolopathy, is a rare cutaneous-systemic disease seen with advanced chronic kidney disease. The classical clinical picture is a necrotic and progressive skin ulcer (reticular pattern), primarily in the lower legs and susceptible to local infection. It is a product of mural calcification and occlusion of cutaneous and subcutaneous arteries and arterioles. Calciphylaxis has been reported to occur in 1–4.5% of patients in dialysis, mostly in hemodialysis, with preponderance in patients who are obese, diabetic, present liver disease, are using systemic corticosteroids or have a calcium-phosphate product of >70 mg^2/dL. Calciphylaxis is reported to be a lethal complication with an estimated 1-yr survival rate of .8%. Mortality is usually reported as a result of local and systemic infections and sepsis. Sodium thiosulfate has been proposed as therapy for calciphylaxis with improvements with reduction of pain, inflammation, and healing of lesions (Image ☼).

CALCIUM LOAD AND FAST STUDIES

DESCRIPTION Tests performed to evaluate hypercalciuria in stone-formers. 1 method is to place patients on a low-calcium, low sodium diet for 1 wk. A fast is performed from 9 PM–9 AM. At 7 AM, the patient empties his bladder. This urine is discarded. 600 mL of distilled water is then consumed. Urine is collected from 7 AM–9 AM. At 9 AM, 1 g of calcium is consumed, and urine is collected from that point until 1 PM. Urine samples are analyzed for calcium, creatinine, and cAMP. Results can then differentiate between absorptive hypercalciuria, renal hypercalciuria, and hyperparathyroidism. On a normal diet, 24-hr urinary calcium levels are considered <300 mg/d (7.5 mmol/d) in men and <250 mg/d (6.25 mmol/d) in women. (See also Section I: "Urolithiasis, Adult, General"; Section I: "Urolithiasis, Calcium Oxylate/Phosphate"; Section II: "Hypercalciuria [Absorptive, Renal and Resorptive].")

REFERENCE

Rivers K, Shetty S, Menon M. When and how to evaluate a patient with nephrolithiasis. *Urol Clin North Am*. 2000;27(2):203–213.

CALCIUM SUPPLEMENTATION AND UROLITHIASIS

DESCRIPTION Oral calcium supplementation may be used for a variety of conditions, including osteoporosis. Because calcium carbonate and calcium phosphate are widely used but poorly absorbed from the intestinal tract, these can increase urinary calcium excretion and promote calcium oxalate/phosphate stone disease. Calcium citrate (Citracal) has 950 mg of calcium citrate and 200 mg of elemental calcium in each tablet and increases urinary calcium excretion. However, this formulation also increases urinary citrate excretion, which potentially offsets the lithogenic potential of the calcium supplement–induced hypercalciuria. If calcium supplementation is to be considered to prevent osteoporosis, calcium citrate preparations should be used. In women with a history of stone disease, consider a 24-hr urine collection to identify those who will become or remain hypercalciuric while on calcium supplementation. In patients who are normocalciuric while receiving calcium citrate, no further intervention is necessary. In those patients found to be hypercalciuric, treatment with thiazide diuretics or slow-release potassium phosphate can be used.

CAMEY I AND II ORTHOTOPIC URINARY DIVERSION

DESCRIPTION In the Camey I procedure, a 40-cm segment of the midportion of the ileum is chosen for an orthotopic urinary diversion that can reach the urethra. A LeDuc antireflux ureteral ileal anastomosis is carried out on each end of the ileal segment. In the Camey II version, the initial Camey I diversion is modified by using 65 cm of ileum, which is detubularized along its antimesenteric border. It is folded into a U-shape configuration, the adjoining sides of the U are sutured, and the resulting bowel is then folded again to create a pouch anastomosed to the urethra with a LeDuc ureteral anastomosis.

REFERENCE

Lilien OM, Camey M. 25-year experience with replacement of the human bladder (Camey procedure). *J Urol.* 2002;167(2 Pt 2):1161–1167.

CANAL OF NUCK HYDROCELE AND CYST (FEMALE HYDROCELE)

DESCRIPTION In the female, the labia majora are homologous to the scrotum in the male. The labia majora contain the terminal portion of the round ligaments of the uterus and an obliterated remnant of peritoneum similar to the tunica vaginalis, which may persist as the canal of Nuck. A hydrocele (fluid collection) may rarely form in the canal of Nuck.

CANDIDIASIS—CUTANEOUS, EXTERNAL GENITALIA

DESCRIPTION *Candida albicans,* the most common *Candida* fungus; rarely colonizes normal skin. Risk factors include the elderly, damaged skin, diabetes, broad-spectrum antibiotic use, steroids, pregnancy, and immunosuppression. Can involve warm, moist areas such as distal urethra, scrotum, inguinal region, glans penis of uncircumcised male and cause itching, burning, discharge, dryness, and dysuria in females (vulvovaginitis). Vesicopustules that enlarge and rupture can progresses to maceration and erythema. There are distinct red borders, often with satellite lesions with vaginal discharge being white and thick. Microscopic exam of scrapings or discharge with potassium hydroxide or Gram stain reveals hyphae/pseudohyphae. (For systemic candida, see Section I: “Fungal Infections, Genitourinary.”)

TREATMENT

- Keep affected areas dry and exposed to air
- Men: Topical Nystatin 100,000 U/d, miconazole cream QID
- Women vulvovaginitis: Oral fluconazole (single 150-mg dose) or topicals such as Nystatin 100,000–200,000 U/d for 1–2 wk

Clotrimazole troches or cream 100 mg/d for
3–7 days, others
More severe infections may require long-term
ketoconazole

CAPTOPRIL TEST

DESCRIPTION As a functional test for renovascular hypertension, plasma renin activity (PRA) is measured before and 1 hr after the administration of 25 mg of captopril. The test is considered positive if all of the following occur: Postcaptopril PRA >12 ng/mL/h, an absolute increase in PRA >10 ng/mL/h, and a 400% increase in baseline PRA (150%

increase if the baseline PRA was >3 ng/mL/h). A positive captopril test points to renovascular hypertension. The test has a sensitivity of ~74% and a specificity of 89%. All diuretics and ACE inhibitors must be discontinued 1 wk prior to the test, and a normal or light-sodium diet is necessary.

CARCINOID TUMORS, GENITOURINARY

DESCRIPTION Very rare in the GU tract, carcinoid tumors have been described in the kidneys, ovaries, uterine cervix, urethra, testes, and bladder, and may have associated carcinoid syndrome. They are usually 5-hydroxyindoleacetic acid and argentaffin positive on special staining. Electron microscopy demonstrates granules similar to Kulchitsky cells. Primary treatment is surgical excision.

REFERENCE

Kaplan AL, Margolis DJ, Said J, et al. Primary carcinoid tumor of urinary bladder discovered on pelvic magnetic resonance imaging. *Urology*. 2012;80(5):55–57.

CARCINOSARCOMA, BLADDER

DESCRIPTION Rare tumor exhibiting elements of epithelial and mesenchymal origin. These usually are bulky, fast growing, invasive tumors. Epithelial elements are typically TCC, but they can be any of the other tumor types. Mesenchymal elements are usually spindle cells with evidence of chondroid, osteoid, smooth muscle, or rhabdomyoblastic differentiation. Usually presents with painless, gross hematuria.

TREATMENT

- Transurethral resection or radical cystectomy, as appropriate
- Chemotherapy and radiotherapy for metastatic disease, but outcomes are poor (Image ☼)

REFERENCE

Orsatti G, Corgan FJ, Goldberg SA. Carcinosarcoma of urothelial organs: Sequential involvement of urinary bladder, ureter, and renal pelvis. *Urology*. 1993;41(3):289–291.

CARCINOSARCOMA, PROSTATE

DESCRIPTION Very rare tumor, similar to the carcinosarcoma of the bladder. These tumors are mixtures of epithelial and sarcomatous elements. The epithelial element in the prostate, however, is adenocarcinoma. Most differentiate from collision tumors, which are separate coexisting tumors of differing cell types. True carcinosarcomas have an intermixture of cells in the same tumor. Has been described following radiation therapy. Treatment is RP, if organ-confined.

CARNEY SYNDROME (CARNEY COMPLEX)

DESCRIPTION Also called familial myxoma, the syndrome is characterized by skin pigmentary abnormalities, myxomas, endocrine tumors or overactivity, and schwannomas. Primary pigmented nodular adrenocortical disease or PPNAD, which causes Cushing syndrome, is the most frequently observed endocrine tumor in Carney Complex or CNC, occurring in approximately 25%. Pale brown to black lentigines are the most common presenting feature of CNC and typically increase in number at puberty. Cardiac myxomas occur at a young age. Large-cell calcifying Sertoli cell tumors (LCCSCTs) are observed in 1/3 of affected males within the 1st decade and in almost all adult males. It is an autosomal dominant disorder. Carney complex gene 1 is the regulatory subunit 1A of protein kinase A (PRKAR1A) located at 17q22–24 and is present in about 60%. Prognosis depends on malignant spread of tumors.

TREATMENT
Open-heart surgery for cardiac myxomas; surgical excision of cutaneous and mammary myxoma; bilateral adrenalectomy for Cushing syndrome; transsphenoidal surgery for pituitary adenoma; surgery for cancerous thyroid adenomas; orchiectomy for boys with LCCSCT and gynecomastia to avoid premature epiphyseal fusion and induction of central precocious puberty; surgery to remove primary and/or metastatic psammo-matous melanotic schwannomas (*PMS*) of the spine

REFERENCE

CARNEY TRIAD

DESCRIPTION Syndrome of tumors affecting at least 5 organs, the stomach, the lung, the paraganglionic system, the adrenal and the esophagus. Generally seen in young females; 80% of patients present before age 30 and 85% are females. Gastrointestinal stromal tumors (GISTs) of the stomach, lung chondroma, paraganglioma, adrenal adenoma, pheochromocytoma, and esophageal leiomyoma are syndrome-defining tumors. Of the classic triad, GIST is the most common presenting lesion (75%), followed by lung chondroma (15%) and paraganglionic tumor (10%). 1/5 of patients had a clinically nonfunctioning adrenal tumor. Generally accepted as a genetic disorder, it is not familial and the genetic etiology is unknown.

REFERENCE

Carney JA. Carney triad. *Front Horm Res*. 2013;41:92–110.

CARUNCLE, URETHRAL

DESCRIPTION An inflammatory lesion of the distal female urethra that usually presents as an asymptomatic urethral mass in the postmenopausal woman. Usually reddish in appearance and covered by mucosa, the lesion protrudes from the urethral meatus. The lesion may thrombose or necrose and may present with spotting of the underwear or even pain. Treatment may involve local estrogen replacement or simple excision. Excision should be considered for any atypical-appearing lesions as pathologically significant lesions such as melanoma have been known to mimic this lesion. (See also Section I: “Urethra, Mass.”)

REFERENCE

CASALE PROCEDURE

DESCRIPTION A variation of the Yang–Monti ileal tube, which is often too short to reach from the bladder to the skin surface. This procedure produces a long (12 cm) catheterizable tube (12–16 Fr) from a short (3.5 cm) segment of bowel, usually ileum. It was designed to take the place of the appendix as a continent channel for intermittent catheterization of the bladder utilizing the Mitrofanoff principle. To increase the canal length, as may be necessary in obese children, Casale used an initial segment that is twice as long, partially split in the middle, and then opened the segment in a spiral fashion on opposite sides to make a longer strip that can be tubularized in continuity. The long-term results of the Casale tube are comparable to those of the appendix and Yang–Monti tube in terms of durability, continence, and complication rate (Image ☼).

REFERENCE

Casale AJ. A long continent ileovesicostomy using a single piece of bowel. *J Urol*. 1999;162(5):1743–1745.

CAT-EYE SYNDROME

DESCRIPTION Also called *Schmid–Fraccaro syndrome*, a rare, congenital syndrome with features of coloboma of the iris and anal atresia with fistula, downslanting palpebral fissures, preauricular tags and/or pits, frequent occurrence of heart and renal malformations, and normal or near-normal mental development. The urologic abnormalities reported include various renal malformations, eg, absence of 1 or both kidneys, hydronephrosis, supernumerary kidneys or renal hypoplasia, chronic pyelonephritis, horseshoe kidney, hydronephrosis, and vesicoureteral reflux, and an associated additional chromosome 22. Close monitoring for possible pyelonephritis is warranted.

REFERENCE

Cat Eye Syndrome. Online Mendelian Inheritance in Man. http://omim.org/entry/115470, Accessed March 1, 2014.

CAUDA EQUINA SYNDROME

DESCRIPTION A term applied to the clinical picture resulting from compression of the cauda equina (or "horse tail") formed by nerve roots caudal to the level of spinal cord termination. This includes perineal sensory loss, loss of anal and urethral sphincter control, and loss of erections. The most common causes include posterior, central lumbar disc herniation, spinal stenosis, tumor, and trauma. Cauda equina syndrome is present in 1–5% of all prolapsed lumbar disks. Characteristically, the affected patient has an acontractile detrusor with no bladder sensation, and often an inactive sphincter EMG. Treatment consists of surgical relief of pressure, although the neurologic deficit can be permanent. On follow-up urodynamics, an acontractile detrusor and variable EMG activity may persist.

REFERENCE

Mauffrey C, Randhawa K, Lewis C, et al. Cauda equina syndrome: An anatomically driven review. *Br J Hosp Med (Lond)*. 2008;69(6):344–347.

CAUDAL REGRESSION SYNDROME

DESCRIPTION First described by Duhamel in 1961, this syndrome is caused by disordered embryogenesis during the 4th–5th wk of gestation. It features a wide array of abnormalities centering on the anorectal, urogenital, and lower spine areas. Severe cases demonstrate fusion of the lower limbs, sacral agenesis, imperforate anus, and absent GU tract (except gonads). In less severe cases, imperforate anus and/or sacral agenesis is seen. These, in turn, are associated with voiding dysfunction. Vesicoureteral reflux is also quite common. Managing the myriad problems requires a multidisciplinary approach.

SYNONYMS

- Caudal dysplasia sequence
- VACTER/VACTERL syndrome

CAVERNOSOGRAPHY

DESCRIPTION A test used to evaluate veno-occlusive leak in erectile dysfunction. It is performed by the injection of contrast material into the corpora cavernosa after the injection of a pharmacologic agent, such as papaverine, to stimulate erection. Any visualized leakage of contrast material outside the corpora could be a defect in the veno-occlusive mechanism. Typical leak points include the glans, corpus spongiosum, superficial or deep dorsal veins, and cavernous and crural veins.

REFERENCE

Hsu GL, Hsieh CH, Wen HS, et al. Penile venous anatomy: An additional description and its clinical implication. *J Androl*. 2003;24(6):921–927.

CAVERNOSOMETRY

DESCRIPTION A test used to evaluate veno-occlusive leak in ED. Performed by 1st stimulating erection, either by saline infusion into the corpora or injection of a pharmacologic agent. Intracorporeal pressure measurements are then recorded. The inability to raise intracorporeal pressure to levels equal to systolic blood pressure or a rapid drop of pressure after cessation of infusion is indicative of veno-occlusive dysfunction.

REFERENCE

Vardi Y, Glina S, Mulhall JP, et al. Cavernosometry: Is it a dinosaur? *J Sex Med.* 2008;5(4):760–764.

CECIL URETHRAL STRICTURE REPAIR

DESCRIPTION The stricture is 1st excised, and the defect is closed with urethral skin. In the 2nd stage, a neourethra is created by tabularizing the ventral penile skin, as described by Thiersch. The penis is then buried in a mid-line scrotal incision. In the 3rd stage, the penis is freed from the scrotum, using scrotal skin to cover the ventrum of the penis, and the scrotum is primarily closed.

REFERENCE

Devine CJ, Devine PC. Operations for urethral stricture. In: Novick AC, et al., eds. *Stewart's Operative Urology*. Baltimore, MD: Williams & Wilkins; 1989:650–680.

CECOURETEROCELE

DESCRIPTION A ureterocele is a congenital saccular dilatation of the terminal portion of the ureter. Cecoureteroceles are elongated beyond the ureterocele orifice by tunneling under the trigone and the urethra and represent a subtype of ureterocele.

REFERENCE

Smith EA, Parrott TS. The unsuspected cecoureterocele. *J Urol.* 1994;152(1):182–184.

CELLO SCROTUM

DESCRIPTION A published factitious medical condition in which a cello player irritates the scrotum. Admitted as a "hoax" condition in 2009.

REFERENCE

Murphy E, Murphy JM. Cello scrotum confession. Murphy's lore. *BMJ*. 2009;338:b288.

CEREBRAL PALSY, UROLOGIC CONSIDERATIONS

DESCRIPTION Cerebral palsy is a broad term describing a generally nonprogressive brain dysfunction occurring perinatally (up to age 3 yo by some definitions) with the consequence of long-term cerebral dysfunction. The etiology is thought to involve injury, infection, or a period of anoxia. The range of symptoms is broad, from mild mental retardation to severe developmental and motor delay. Surprisingly little is written on the exact urologic

manifestation of cerebral palsy, and even the incidence of urologic dysfunction is unclear. In some series, up to 36% of patients with cerebral palsy had lower urinary tract dysfunction. In another series, the most common symptoms included incontinence (74%), frequency (56%), and urgency (37%). The most common urodynamic findings were detrusor overactivity (DO) (87% of those undergoing urodynamics), with 25% of these exhibiting apparent striated sphincter dyssynergia. (See also Section I: "Neurogenic Bladder, General Considerations.")

REFERENCE

Ozturk M, Oktem F, Kisioglu N, et al. Bladder and bowel control in children with cerebral palsy: Case-control study. *Croat Med J*. 2006;47(2):264–270.

CERVICAL CANCER, UROLOGIC CONSIDERATIONS

DESCRIPTION Iatrogenic complications regarding cervical cancer treatment are well documented. If pelvic exenteration is performed, urinary diversion is obligatory. Radical hysterectomy has risks of ureteral and bladder damage, which may result in a fistula. Radiation therapy also can be morbid, with radiation cystitis, ureteral stricture, and fistula possibly resulting. The increased risk of bladder cancer after radiation therapy is controversial. (See also Section VII: "TNM Staging.")

REFERENCE

Magerina JF. Complication of irradiation and radical surgery for gynecologic malignancies. *Obstet Gynecol Surv*. 1993;48(8):571–575.

CHANCROID

DESCRIPTION An STD/STI caused by *Haemophilus ducreyi* and relatively uncommon in the United States but a common STD/STI in developing countries. The combination of a painful genital ulcer and tender suppurative inguinal adenopathy suggests the diagnosis of chancroid. *H. ducreyi* is a gram-negative coccobacilli and resembles a "school of fish" on Gram stain (clumping in long parallel strands). Incubation is 4–10 days and the ulcer is 1–2 cm, nonindurated, purulent, and ragged with painful adenopathy in over 50%. Sites include the distal penis in men and labia and vagina in women. Diagnosis is based on clinical findings. No FDA-cleared PCR test for *H. ducreyi* is available in the United States, but such testing can be performed by clinical labs that have developed their own PCR test and have conducted a CLIA verification study. A probable diagnosis of chancroid, for both clinical and surveillance purposes, can be made if all of the following criteria are met: (1) the patient has 1 or more painful genital ulcers; (2) the patient has no evidence of *Treponema pallidum* infection by darkfield exam of ulcer exudate or by a serologic test for syphilis performed at least 7 days after onset of ulcers; (3) the clinical presentation, appearance of genital ulcers and, if present, regional lymphadenopathy are typical for chancroid; and 4) a test for HSV performed on the ulcer exudate is negative.

TREATMENT

Recommended treatment is a single dose of azithromycin 1 g PO or ceftriaxone 250 mg IM or ciprofloxacin 500 mg PO BID × 3 days (contraindicated if pregnant or lactating) or

erythromycin base 500 mg PO TID for 7 days. (See also Section I: "Sexually Transmitted Infections [STIs] and Sexually Transmitted Diseases [STDs], General.")

REFERENCE

Centers for Disease Control and Prevention. Sexually Transmitted Diseases Treatment Guidelines, 2010. *MMWR Recomm Rep*. 2010;59 (No. RR-12):1–110.

CHARCOT-BOETTCHER CRYSTALS AND FILAMENTS

DESCRIPTION A normal ultrastructural component of human Sertoli cells observable with electron microscopy. Can be used to establish Sertoli origin in atypical sex cord-stromal tumors.

REFERENCE

Jarzembowski JA, Lieberman RW. Pediatric sex cord-stromal tumor with composite morphology: A case report. *Pediatr Dev Pathol*. 2005;8(6):680–684.

CHARGE ASSOCIATION

DESCRIPTION CHARGE refers to the association of coloboma, congenital heart disease, choanal atresia, retarded growth and development, structural brain abnormalities, and ear anomalies. Of urologic interest is the association with genital hypoplasia secondary to low androgen levels. Mostly sporadic, but a familial form has been reported. It is theorized to originate during a developmental error of neural crest elements at about the 6th wk.

Early management of sensory defects is important. Androgen replacement is used for genital hypoplasia.

REFERENCE

CHEMOTHERAPY TOXICITY, UROLOGIC CONSIDERATIONS

DESCRIPTION All chemotherapeutic agents have potentially significant toxicities and side effects. For the urologic surgeon, certain toxicities may be more commonly encountered. Both commonly used chemotherapeutic regimens for urothelial carcinoma, methotrexate/vinblastine/adriamycin/cisplatinum and gemcitabine/cisplatinum have significant nephrotoxicity, which can be problematic for older patients or patients with renal insufficiency or malignant ureteral obstruction. Bleomycin, used for nonseminomatous germ cell tumors as part of the bleomycin, etoposide, cisplatinum (BEP) regimen causes pulmonary toxicity. If postchemotherapy retroperitoneal lymphadenectomy is necessary, the anesthetist should be counseled to avoid high inspired oxygen concentrations and minimize crystalloid fluid resuscitation, as these factors may exacerbate bleomycin-related pulmonary toxicity. Cyclophosphamide may cause hemorrhagic cystitis because of its toxic downstream metabolite, acrolein, which is excreted into the urine. Administering the agent Mesna decreases this toxicity. Cyclophosphamide also increases the risk of subsequent bladder cancer up to 9-fold. (See also Section II: "Bleomycin Toxicity.")

CHLAMYDIA SEXUALLY TRANSMITTED DISEASE

DESCRIPTION Chlamydia is the most common bacterial STD in the world. Although often asymptomatic (up to 70% in women), it may cause urethritis, cervicitis, pelvic inflammatory disease (PID) in women, and prostatitis and epididymitis in men. In young sexually active males, it is the most common cause of epididymitis. *Chlamydia trachomatis* is an intracellular bacterium and does not grow in standard urine culture preparations. Nucleic acid amplification test by PCR of urine specimen is an effective diagnostic and screening tool. Alternatively, specialized cultures of urethral or cervical swabs can be performed. Treatment with azithromycin 1 g PO as a single dose or doxycycline 100 mg BID for 7 days is standard treatment. In pregnancy, erythromycin base 500 mg QID for 7 days is a safe alternative. Screening of sexual partners is recommended. (See also Section I: “Sexually Transmitted Diseases [STDs], General.”)

REFERENCE
Centers for Disease Control and Prevention. Sexually Transmitted Diseases Treatment Guidelines, 2010. *MMWR Recomm Rep.* 2010;59 (No. RR-12):1–110.

CHRISTMAS TREE BLADDER

DESCRIPTION A radiologic change in the bladder wall caused by detrusor muscle hypotrophy and fibrosis as a result of detrusor-sphincter dyssynergia. Also called *pinecone appearance.*

REFERENCE
Genitourinary system and retroperitoneum. In: Mettler FA, ed. *Essentials of Radiology*. 2nd ed. Philadelphia, PA: Saunders; 2005.

CHRONIC KIDNEY DISEASE (CKD)

DESCRIPTION The Kidney Disease Improving Global Outcomes (KDIGO) organization developed updated clinical practice guidelines in 2012 to provide guidance on the evaluation, management, and treatment of chronic kidney disease (CKD) in adults and children who are not receiving renal replacement therapy (see table). CKD is defined as the presence of kidney damage (usually detected as urinary albumin excretion of ≥ 30 mg/day, or equivalent) or decreased kidney function (defined as estimated glomerular filtration rate [eGFR] < 60 mL/min/ 1.73 m^2) for 3 or more months, irrespective of the cause. The persistence of the damage or decreased function for at least 3 mo is necessary to distinguish CKD from acute kidney disease (AKI). The term “end-stage renal disease” (ESRD) generally refers to CKD treated with either dialysis or transplantation. Identifying the cause of kidney disease (eg,

diabetes, drug toxicity, auto-immune diseases, urinary tract obstruction, kidney transplantation) enables specific therapy directed at preventing further injury. In addition, the cause of kidney disease has implications for the rate of progression and the risk of complications. The purpose of CKD staging is to guide management (risk for progression and complications of CKD). (See also Section I: "Chronic Kidney Disease, Adult [Renal Failure, Chronic]."")

Revised Chronic Kidney Disease (CKD) Classification Based Upon Glomerular Filtration Rate and Albuminuria

GFR Stages	GFR (mL/min/1.73 m^2)	Terms
G1	>90	Normal or high
G2	60–89	Mildly decreased
G3a	45–59	Mildly to moderately decreased
G3b	30–44	Moderately to severely decreased
G4	15–29	Severely decreased
G5	<15	Kidney failure (add D if treated by dialysis)
Albuminuria Stages	**AER (mg/d)**	**Terms**
A1	<30	Normal to mildly increased (may be subdivided for risk prediction)
A2	30–300	Moderately increased
A3	>300	Severely increased (may be subdivided into nephrotic and nonnephrotic for differential diagnosis, management, and risk prediction)

The cause of CKD is also included in the KDIGO revised classification but is not included in this table. GFR: glomerular filtration rate; AER: albumin excretion rate; CKD: chronic kidney disease; KDIGO: Kidney Disease Improving Global Outcomes. (Reproduced with permission from Wolters Kluwer: Levey, AS and Inker LA. Definition and staging of chronic kidney disease in adults in UpToDate.com. Accessed March 2, 2014.)

CHRONIC PELVIC PAIN SYNDROME/CHRONIC PROSTATITIS (CPPS/CP) IN MALES

DESCRIPTION Chronic pelvic pain syndrome (CPPS) is a diagnosis that can be made in either a man or a woman. Guidelines define CPPS/CP in males as CPP for at least 3 of the preceding 6 mo in the absence of other identifiable causes. Older terms used include prostatodynia and abacterial prostatitis.

- Males: Guidelines define CPPS as CPP for at least 3 of the preceding 6 mo in the absence of other identifiable causes. Sometimes referred to as chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS) is a clinical syndrome. The symptomatology is based on urologic symptoms and/or pelvic pain or discomfort. While the term "prostatitis" is often used it is unclear to what degree the prostate is the cause of symptoms. Nonbacterial prostatitis occurs in men with no history of urinary tract infection and negative bacterial cultures of urine and prostatic fluid. The inflammatory type (NIH III A. Chronic prostatitis/pelvic pain syndrome, inflammatory) presents with GU or rectal pain or voiding symptoms; the prostatic fluid contains inflammatory cells. Men with the noninflammatory type (NIH IIIB. Chronic prostatitis/pelvic pain syndrome, noninflammatory), whose prostatic fluid has no leukocytes, have similar symptoms, but pelvic pain is usually the predominant complaint. (See Section I: "Prostatitis, Chronic, Nonbacterial, Inflammatory [NIH CP/CPPS III A]";

Section I: “Prostatitis, Chronic Nonbacterial, Noninflammatory [NIH CP/CPPS III B]”; Section II: “Pelvic Pain, Male.”)

TREATMENT

- Empiric 8–12 wk course of antibiotics
- Consider prostatic massage, if no response
- High-dose α-blockers (Flomax, Cardura, Hytrin)
- Anti-inflammatory agents, lifestyle changes, stress reduction, holistic therapies

REFERENCE

Nickel JC, Shoskes DA, Wagenlehner FM. Management of chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS): The studies, the evidence, and the impact. *World J Urol.* 2013;31(4):747–753.

CHRONIC PELVIC PAIN SYNDROME (CPPS) IN FEMALES

DESCRIPTION CPPS is a diagnosis that can be made in either a man or a woman. In women it is pain of at least 6-mo duration. The pain location is below the umbilicus and is usually severe enough to result in functional disability or need treatment. See table for causes. The best treatment plan for CPP is based upon shared decision making by the clinician and patient. A combination of treatments may be the optimal approach. (See also “Section I: Pelvic Pain, Female.”)

Conditions Associated with Chronic Pelvic Pain in Women
Gynecologic
Endometriosis
Chronic pelvic inflammatory disease
Pelvic adhesions
Pelvic congestion (pelvic varicosities)
Adenomyosis
Ovarian remnant syndrome
Residual ovary syndrome
Leiomyoma
Endosalpingiosis
Neoplasia
Fallopian tubal prolapse (posthysterectomy)
Tuberculous salpingitis
Benign cystic mesothelioma
Postoperative peritoneal cysts
Mental health issues
Somatization
Substance abuse
Physical and sexual abuse
Depression
Sleep disorders
Urinary tract
Interstitial cystitis/painful bladder syndrome
Recurrent urinary tract infection
Urethral diverticulum
Chronic urethral syndrome
Neoplasia
Radiation cystitis
Gastrointestinal tract
Irritable bowel syndrome
Inflammatory bowel disease and other causes of colitis
Diverticular colitis
Chronic intermittent bowel obstruction
Neoplasia
Chronic constipation

CHRONIC PROSTATITIS SYMPTOM INDEX (CPSI)/NIH-CPSI (NATIONAL INSTITUTES OF HEALTH CPSI)

DESCRIPTION The National Institutes of Health Chronic Prostatitis Symptom Index (NIH-CPSI), a reliable validated instrument developed by the NIH Chronic Prostatitis Collaborative Research Network to aid in the quantification of chronic prostatitis symptoms. The NIH-CPSI

is intended for clinical practice as well as research protocols. The instrument contains 9 questions. The major domains relate to pain (location, severity, frequency), the nature of voiding (irritative and obstructive symptoms), and the impact of prostatitis on quality of life. The goal of this multi-institutional collaborative effort was to define and measure the symptoms of chronic prostatitis and their impact on the daily lives of patients. The test is self-administered and can be completed in 5 min. Higher scores indicate worse outcomes in all domains, with a possible maximum score of 43. (See also Section I: "Prostatitis, Chronic Nonbacterial, Inflammatory & Noninflammatory (NIH CP/CPPS III A and B)," "Prostatitis, General" and "Section VII: Reference Tables: National Institutes of Health (NIH) Chronic Prostatitis Symptom Index [CPSI].").

REFERENCES

Litwin MS, McNaughton-Collins M, Fowler FJ Jr, et al. The National Institutes of Health chronic prostatitis symptom index: development and validation of a new outcome measure. Chronic Prostatitis Collaborative Research Network. *J Urol.* 1999;162:369–375.

CHURG-STRAUSS SYNDROME

DESCRIPTION Also called *allergic angiitis and granulomatosis*, this is a vasculitis characterized by extravascular microscopic granulomas in the lungs, heart, GI tract, and skin. Histologically, necrosis and intense eosinophilic infiltration accompanied by histiocytes are seen. Both necrotizing and eosinophilic granulomatous vasculitis usually involve small arteries and veins, often with a history of atopy. Patients present with fever and weight loss. Eosinophilia, anemia, and an elevated ESR are found. The prostate may be involved by the granulomatous process. Treatment involving corticosteroids with cytotoxic drugs is being investigated.

CHYLOCELE

DESCRIPTION Also called *filarial hydrocele*, chylocele is a cyst-like collection of lymphatic fluid/drainage into the tunica vaginalis around the testis. The fluid is usually described as milky and contains leukocytes. This may result from lymphatic disruption secondary to diseases such as filariasis. Filariasis affects 120 million people in >80 countries and is caused by *Wuchereria bancrofti,* which is transmitted by mosquitoes. Chyloceles usually do not resolve after needle aspiration and require the underlying cause to be surgically or medically addressed. Freedom from infection at the time of surgery is critical for a favorable outcome. (See also "Section I: Scrotum and Testicle, Mass.")

TREATMENT

- Vertical scrotal incision with complete excision of tunica vaginalis sac
- Orchiectomy and chordectomy for severe cases

- Medical treatment of filariasis (diethylcarbamazine, ivermectin, albendazole)

REFERENCE

DeVries CR. The role of the urologist in the treatment and elimination of lymphatic filariasis worldwide. *BJU Int.* 2002;89(S1):37–43.

CIRCUMCISION, FEMALE

DESCRIPTION Female genital cutting, also known as female circumcision or genital mutilation, is a culturally determined practice, predominantly performed in parts of Africa and Asia. The World Health Organization classified female genital cutting into 4 types of procedures.

- Type I consists of excision of the prepuce, with or without excision of part or all of the clitoris.
- Type II involves clitoridectomy and partial or total excision of the labia minora.
- Type III, or infibulation, includes removing part or all of the external genitalia and reapproximation of the remnant labia majora, leaving a small neointroitus.
- Type IV involves other forms of injuries to the genital region including pricking, piercing, stretching, burning, scraping, or any other manipulation of external genitalia.

Short-term urologic problems with the procedure include urethral edema and urinary retention potential. Long-term problems include dysmenorrhea, dyspareunia, fibrosis, keloids, sebaceous cysts, vulvar abscesses, infertility, and difficulty with pelvic exams, coitus, and vaginal delivery. Urologic issues include chronic UTI, voiding difficulties, urethral strictures, meatal obstruction meatitis, and urinary crystals.

REFERENCE

Nour NM. Female genital cutting (circumcision). In UpToDate.com, Accessed March 8, 2014.

CISPLATIN TOXICITY

DESCRIPTION Cisplatin is a very commonly used antitumor agent with significant adverse effects. Administered in urology for urothelial carcinoma and testicular cancer, its nephrotoxicity is cumulative and dose-dependent, and commonly limits use. Other significant effects include myelosuppression, ototoxicity, GI disturbances, and neurotoxicity. (See also Section II: “Chemotherapy Toxicity, Urologic Considerations.”)

TREATMENT

- Amifostine has been used to limit toxicity.
- Use of other platinum-based compounds may decrease toxicity while maintaining efficacy.

CLITORAL LENGTH

DESCRIPTION Anatomically the clitoris is composed of the glans clitoris and the crura, its

dimensions are generally independent of BMI, age, and height. Average length of the glans clitoris is 5.1 +/– 1.4 mm. Total average clitoral length from the tip of the glans to the insertion of the crura on the pubis is 16.0 +/– 4.3 mm. Multiparous women have slightly larger clitoral dimensions than nulliparous women with a total length on average 0.9 mm greater and a glans length 0.5 mm greater. (See also Section II: "Clitoromegaly.")

REFERENCE

Verkauf BS, Von Thron J, O'Brien WF, et al. Clitoral size in normal women. *Obstet Gynecol.* 1992;80(1):41–44.

CLITORAL PRIAPISM

DESCRIPTION A rare condition that is associated with an extended duration of clitoral erection due to local engorgement of clitoral tissue causing clitoral or vulvar pain. The prolonged erection is not associated with sexual stimulation, and can last from minutes to days. It has been associated with medications: α-blockers, inhibitors of serotonin reuptake (SSRI antidepressants), and non-SSRI antidepressants and with TCC obstructing venous and lymphatic outflow. Stopping the offending agent can result in resolution within 24–72 hr. Other treatments reported: Imipramine, NSAIDs, ice packs, opiates, and, rarely, intracavernous injection of adrenaline. (See also Section II: "Clitoromegaly.")

REFERENCE

Gharahbaghian L. Clitoral Priapism with No Known Risk Factors. *West J Emerg Med.* 2008;9(4):235–237.

CLITOROMEGALY

DESCRIPTION Enlargement of the clitoris is most commonly see in newborns. When noted, the practitioner must consider the possibility of intersex issues. The condition may be so severe as to appear as a normal male penis, although chordee is also usually present. Virilization is most commonly secondary to CAH. The underlying cause must be addressed. (See also Section I: "Disorders of Sexual Development [DSD]"; Section II: "Congenital Adrenal Hyperplasia.")

REFERENCE

Rink RC, Kaefer M. Surgical management of disorders of sexual differentiation, cloacal malformation, and other abnormalities of the genitalia in girls. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2012:3629–3666.

CLONIDINE SUPPRESSION TEST

DESCRIPTION A test sometimes used to rule out pheochromocytoma. Clonidine (0.3 mg) is administered and plasma norepinephrine levels are then measured. Those patients with essential hypertension with an elevation of norepinephrine levels will experience a 50% decrease in this catecholamine level. Patients with pheochromocytoma will not be suppressed. Patients should not be taking diuretics, β-blockers, or tricyclic antidepressants; α-blockers do not interfere with the test.

REFERENCE

CLOSTRIDIUM DIFFICILE COLITIS, UROLOGIC CONSIDERATIONS

DESCRIPTION Also known as *pseudomembranous enterocolitis*, this is a potentially life-threatening infection of the colon due to overgrowth of *C. difficile*. It can be precipitated by antibiotic therapy – most commonly fluoroquinolones, clindamycin, cephalosporins, and penicillins – but any antibiotic can be implicated. This suppression of normal bowel flora by antibiotics and overgrowth of *C. difficile* has been reported in association with bowel preparation prior to elective surgery, as well as in addition to the use of antibiotics for any indication. Watery diarrhea and abdominal pain are the main symptoms of *C. difficile* infection, but it can range from the asymptomatic carrier state, diarrhea with colitis, or pseudomembranous colitis (endoscopic evidence of "pseudomembranes"), to severe life-threatening disease with toxic megacolon. Low-grade fever and leucocytosis are common. It is diagnosed by classic endoscopic findings, culture of organism, or detection of toxin in stool. Enzyme immunoassay (EIA) allows the direct detection of *C. difficile* toxin and is the test of choice.

TREATMENT

- Removal of antibiotic therapy. If antibiotic therapy is essential, attempt to use an agent with lesser likelihood of causing *C. difficile* overgrowth (aminoglycosides, macrolides, sulfonamides, tetracycline, or vancomycin).
- Metronidazole (500 mg TID or 250 mg QID) is recommended as initial treatment of less severe cases. If needed, IV metronidazole 500 mg q8h; treat for 10–14 days with follow-up toxin assay.
- Alternatively, oral vancomycin 125 mg QID.

REFERENCE

Kelly CP, LaMont JT. *Clostridium difficile*: More difficult than ever. *N Engl J Med*. 2008;59:1932–1940.

CLOT RETENTION

DESCRIPTION The culmination of visible blood in the urine that has formed clots within the bladder. The presence of blood clots impede the outflow of urine via the urethra and result in urinary obstruction. If not addressed emergently, clot retention can lead to pain, abdominal distension, hydroureteronephrosis, and bladder rupture.

TREATMENT

- Bedside insertion of urinary catheter for drainage and evacuation of blood clots
- May require operative cystoscopy and treatment of underlying cause of hematuria
- Correction of blood coagulation disorders

REFERENCE

Hicks D, Li C. Management of macroscopic hematuria in the emergency department. *EMJ*. 2007;24:385–390.

COBB COLLAR

DESCRIPTION Congenital narrowing of the bulbar urethra that can present with hematuria, UTI, or weak stream. Endoscopy and retrograde urethrogram reveal a bulbar urethral narrowing. The obstructing membrane is located just distal to the external sphincter and is reinforced by a fold extending from the verumontanum. Treatment is endoscopic resection.

SYNONYMS
- Moerman rings
- Congenital obstructive posterior urethral membrane

TREATMENT
Endoscopic resection

REFERENCE
Dewan PA, Keenan RJ, Morris LL, et al. Congenital urethral obstruction: Cobb's collar or prolapsed congenital obstructive posterior urethral membrane (COPUM). *Br J Urol*. 1994;73(1):91–96.

COBRA HEAD SIGN

DESCRIPTION The radiologic appearance on an intravenous urogram (IVU) of an intravesical ureterocele of a single ureter in an adult, also called *spring onion sign*. The dilated ureterocele, filled with contrast material, protrudes into the bladder, which is also filled with contrast material, but is separated from it by a thin radiolucent halo. The ureterocele might be congenital or acquired, as in cases of trauma or inflammation.

REFERENCE
Nussbaum AR, Dorst JP, Jeffs RD, et al. Ectopic ureter and ureterocele: Their varied radiographic manifestations. *Radiology*. 1986;159:227–235.

COCCIDIOMYCOSIS, GENITOURINARY

DESCRIPTION Outbreaks of *Coccidioides immitis* infection are common when people are exposed to dust that contains the spore. An opportunistic infection more common in patients <5 and >50 yo, it is associated with AIDS, steroid use, and chemotherapy for malignancy. After pulmonary inoculation, the patient can develop erythema nodosum (valley bumps or valley fever). Chest radiographs demonstrate infiltrates with cavitation. Serologic tests are available to help establish the diagnosis. Disseminated disease involves the kidney in up to 65%, the adrenal in 16–32%, and the prostate in 6%. Renal coccidiomycosis may cause similar changes, as seen in renal TB (moth-eaten calyces, infundibular stenosis, ureteral stricture, and calcifications). Prostatic infection with occasional abscess and scrotal infections with fistulas have been reported. Epididymal and prostatic involvement can demonstrate necrotizing and nonnecrotizing granulomas. Therapy includes up to 2 g of amphotericin, with 1 year of ketoconazole (200 mg/d).

REFERENCE

Wise GJ, Freyle J. Changing patterns in genitourinary fungal infections. *AUA Update.* Vol. XVI, Lesson 1, 1997.

COHEN ("CROSS-TRIGONAL") URETERAL REIMPLANTATION

DESCRIPTION Through a transvesical approach, the ureter is mobilized from its hiatus and delivered through a submucosal tunnel to the contralateral side of the trigone. A cross-trigonal reimplantation is then carried out by reanastomosing the ureter to the bladder.

REFERENCE

Khoury AE, Bagli DJ. Vesicoureteral Reflux. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2012:3267–3309.

COITAL INCONTINENCE (COITAL LEAKAGE/INTERCOURSE INCONTINENCE)

DESCRIPTION Recent attention has focused on loss of urine during intercourse termed "coital incontinence." Loss of vaginal fluids during sexual activity is not well studied and the term "female ejaculation" has become a popular term. Although the exact pathophysiology is poorly understood this phenomenon may include urinary incontinence during sexual activity. In 1 series 60% of women with a history of urinary incontinence reported urinary leakage during intercourse. Coital incontinence is considered in the spectrum of stress urinary incontinence (SUI) and pelvic organ prolapse by some authors. Urethral sphincter incompetence has also been suggested as part of the pathophysiology. Many women with detrusor overactivity (DO) leak during sex; however, the potential role of associated urethral incompetence needs further investigation. Quality of life appears negatively impacted by this condition. (See also Section I: "Incontinence, Urinary, Adult Female and Section II; "Ejaculation, Female.")

COLLECTING SYSTEM DUPLICATION, COMPLETE

DESCRIPTION Duplicated collecting systems (also known as duplex collecting systems) can be defined as renal units containing 2 pyelocaliceal systems that are associated with a single ureter or with double ureters. The 2 ureters empty separately into the bladder or fuse to form a single ureteral orifice. Associated problems include upper-pole hydronephrosis from stenosis, ectopic insertion of the upper-pole ureter, ureterocele of the upper-pole ureter, and reflux involving the lower pole. Duplex collecting systems can be unilateral or bilateral and can be associated with obstruction, reflux, and infection. Caused by early ureteral bud bifurcation or the occurrence of 2 ureteral buds from the wolffian duct during renal

embryogenesis.

REFERENCE

Glassberg KI, Braren V, Duckett JW, et al. Suggested terminology for duplex systems, ectopic ureters and ureteroceles. *J Urol*. 1984;132(6):1153–1154.

COLON AND RECTAL CANCER, UROLOGIC CONSIDERATIONS

DESCRIPTION Colorectal cancer may present as locally invasive lesions that involve the bladder and/or prostate. En-bloc resection (pelvic exenteration) of the bladder and rectum/colon is sometimes indicated. In colorectal malignancies, a 7–12% incidence of locoregional extension into the adjacent organs has been reported, with the bladder as the most commonly involved organ. In women, the interposition of the uterus between the colon and bladder makes the incidence lower. In cases of more proximal colon cancers, ureteral and renal involvement may require localization with ureteral catheters. After extensive colorectal dissection, erectile and bladder dysfunction may occur secondary to disruption of the pelvic plexus up to 70% of the time. (See also Section I: “Neurogenic Bladder, General” and Section VII: “TNM.”)

REFERENCE

Calpista A, Lai S, Agostini A, et al. Functional urological complications after colorectal cancer surgery. *Pelviperineology*. 2007;26(1):38–40.

COLUMN OF BERTIN, HYPERTROPHIED

DESCRIPTION A normal anatomic structure of the kidney, which, if enlarged, can be mistaken for a renal mass. It normally appears as granular material in the renal sinus, which is simply cortex. The column of Bertin is located between the pyramids. (See also Section II: “Renal Pseudotumors.”)

REFERENCE

COMPARTMENT SYNDROME, UROLOGIC CONSIDERATIONS

DESCRIPTION Compartment syndrome, defined by the rise of pressure in a tissue compartment compromising circulation, can result in devastating consequences, especially in the urologic setting. Reports of compartment syndrome leading to rhabdomyolysis, renal failure, and limb loss have been reported with the dorsal lithotomy position, flank position during open or laparoscopic procedures, prolonged reconstructive pediatric procedures, and urethral and perineal surgeries. Recently there has been an increase in reports relating to robotic prostatectomy. In abdominal compartment syndrome, a Foley catheter can be used to provide continuous abdominal compartment pressure readings.

The etiology of compartment syndrome is multifactorial and prevention is the mainstay of treatment. Positioning and other efforts to prevent acute lower extremity compartment

syndrome include limiting the time of leg elevation, positioning the leg below the level of the atrium and postoperative monitoring of patients at risk. Pulse oximetry to detect hypoperfusion has been reported. The 6 "Ps" associated with compartment syndrome are: Pain out of proportion based on exam, paresthesia, pallor, paralysis, pulselessness, and pressure. Fasciotomy may be necessary to relive pressure and restore extremity perfusion. Although debated, measured compartment pressure of 30 mm Hg is a generally accepted indication for lower extremity fasciotomy. (See also Section I: "Rhabdomyolysis.")

COMPULSIVE MASTERBATION

DESCRIPTION Masturbation is the deliberate stimulation of the genitalia in order to achieve sexual arousal. Compulsive masturbation, like all compulsive behaviors, may be included in the spectrum of anxiety disorders. Compulsive behaviors are meant to reduce anxiety, fear, worry, or apprehension. Patients with compulsive disorders are unable to inhibit their behaviors, even after they become maladaptive, regardless of consequences. Most frequently seen in patients with psychiatric disorders such as autism, schizophrenia, and personality disorders. May be seen with dementia and Parkinson disease.

REFERENCE

Calabro RS, Galì A, Marino S, et al. Compulsive masturbation and chronic penile lymphedema. *Arch Sex Behav*. 2012;41(3):737–739.

CONDYLOMATA LATA

DESCRIPTION Also called *flat condyloma*, these moist or mucous papules are found in the skin folds of syphilis patients and reflect the secondary stage of syphilis. They secrete serous fluid and can be covered by a layer of epidermal debris. They represent the hematogenous spread of spirochetes. (See also Section I: "Syphilis.") (Image ☼)

TREATMENT

- Single dose of penicillin G (benzyl penicillin) 2.4 million units IM *OR*
- IM ceftriaxone 1,000 mg/d for 10 days *OR*
- Oral tetracycline 500 mg QID for 14 days *OR*
- Oral doxycycline 100 mg BID for 14 days

REFERENCE

Lautenschlager S. Cutaneous manifestations of syphilis: Recognition and management. *Am J Clin Dermatol*. 2006;7(5):291–304.

CONGENITAL ADRENAL HYPERPLASIA (CAH)

DESCRIPTION The adrenal cortex secretes 2 compounds, DHEA and androstenedione, that require conversion to testosterone in peripheral tissues for their androgenic effects. CAH represents a group of autosomal-recessive, inherited metabolic errors, each characterized by a deficiency or total lack of a particular enzyme involved in the biosynthesis of cortical steroids, particularly cortisol. Steroidogenesis is then channeled into other pathways, leading to increased production of androgens, which accounts for virilization. Simultaneously, the deficiency of cortisol results in increased secretion of ACTH, resulting in adrenal hyperplasia. Certain enzyme defects may also impair aldosterone secretion, adding salt wasting to the virilizing syndrome. The most commonly recognized forms are 21-hydroxylase deficiency (>90%) and 11-hydroxylase deficiency (5–8%). The spectrum of presentation is substantial, resulting from the compound heterozygosity and multiple etiologies in this disease continuum. Phenotypic manifestations include ambiguous genitalia (CAH is the most common reason in newborns), clitoromegaly, labioscrotal fusion, and hypospadias. Clinical CAH subtypes include (1) salt wasters (virilization and aldosterone deficiency), (2) simple virilizers (virilization without salt wasting), and (3) nonclassic patients (no virilization or wasting). In the salt-wasting variant, symptoms begin weeks after birth with weight loss, failure to thrive, vomiting, dehydration, and life-threatening adrenal crisis. In virilizers, sexual precocity is the hallmark of disease. Diagnosis is often made from markedly elevated levels of serum 17-hydroxyprogesterone and progesterone (with 21-OH deficiency), but may also present as elevated 11-deoxycortisol and 11-DOC (with 11-OH deficiency). (See also Section I: "Disorders of Sexual Development [DSD]"; Section II: "11β-hydroxylase (CYP11B1) deficiency and 21-Hydroxylase (CYP21A2) Deficiency.")

Congenital Adrenal Hyperplasia: Features for Each Enzyme Defect

Feature	21-Hydroxylase Deficiency	11β-Hydroxylase Deficiency	17α-Hydroxylase Deficiency	3β-Hydroxysteroid Deficiency	Lipoid Hyperplasia	Aldosterone Synthase Deficiency
Incidence	1:15,000	1:100,000	Rare	Rare	Rare	Rare
Defective gene	CYP21	CYP11B1	CYP17	HSD3B2	StAR	CYP11B2
Chromosomal localization	6p21.3	8q24.3	10q24.3	1p13.1	8p11.2	8q24.3
Ambiguous genitalia	+ (female)	+ (female)	+ (male) Absent puberty (female)	+ (male) Mild in female	+ (male) Absent puberty (female)	No
Acute adrenal insufficiency	+	Rare	No	+	++	Salt wasting only
Hormones:						
Glucocorticoids	Reduced	Reduced	Reduced	Corticosterone normal	Reduced	Normal
Mineralocorticoids	Reduced	Increased	Reduced	Increased	Reduced	Reduced
Androgens	Increased	Increased	Reduced	Reduced (male) Increased (female)	Reduced	Normal
Elevated hormonal metabolite	17-Hydroxy-progesterone	DOC, 11-deoxycortisol	Corticosterone, DOC	DHEA, 17Δ^5-pregnenolone	None	Corticosterone, 18-OHB
Blood pressure	Decreased	Increased	Decreased	Increased	Decreased	Decreased
Potassium	Increased	Decreased	Increased	Decreased	Increased	Increased

DOC, deoxycorticosterone; DHEA, dehydroepiandrosterone; 18-OHB, 18-hydroxycorticosterone.

TREATMENT

- Monitor for severe, life-threatening salt wasting and dehydration in the 1st wk of life. Follow electrolytes.
- Monitor for adrenal crisis.
- Determination of etiology (measure 17-hydroxyprogesterone, ACTH, cortisol, 11-DOC, DHEA)

- Genetic analysis (karyotype, FISH for SRY region)
- Sex assignment. Girls with classic CAH typically undergo reconstructive surgery, usually clitoroplasty and vaginoplasty.
- Glucocorticoid replacement therapy: Hydrocortisone 12–18 mg/m^2/d infants. In older children, dexamethasone 0.25–0.50 mg at bedtime. Stress dose increases for illness or surgery to avoid adrenal crisis.
- Mineralocorticoid replacement fludrocortisone 0.05–0.20 mg/d

CONGENITAL NEPHROSIS/NEPHROTIC SYNDROME

DESCRIPTION Congenital nephrotic syndrome is a rare condition affecting children from birth to the 3rd month of life. Familial incidence occurs as an autosomal recessive mode of inheritance. This disease is seen most frequently in Finland (1:8,000 live births). Clinical manifestations include wide anterior and posterior fontanelles, generalized edema, abdominal distention, anasarca, and malnutrition. Characteristic lab findings include proteinuria, hypoalbuminemia, and hyperlipidemia. Long-term survival is dependent on the correction of nutritional deficits and renal transplantation.

REFERENCE

Ramirez-Seijas F, Granado-Villar D, Cepero-Akselrad A, et al. Congenital nephrotic syndrome. *Intern Pediat.* 2000;15(2):121–122.

CONSTIPATION, UROLOGIC CONSIDERATIONS

DESCRIPTION Constipation is associated with bladder storage symptoms and increased risk of urinary tract infections. Urodynamic studies in children with functional constipation have revealed detrusor overactivity (DO) and small bladder capacity, both of which improve with improved bowel function. In addition, the same holding behavior that leads to functional constipation often alters bladder habits as well, as seen with dysfunctional elimination syndrome. Treatment of bowel dysfunction alone can resolve chronic recurrent UTI and urinary incontinence in some children. It is important to rule out neurologic and bowel disease as causes of constipation before making the diagnosis of functional constipation. (See also Section I: “Dysfunctional Elimination Syndrome.”)

TREATMENT

- Diet changes
- Laxatives, stool softeners
- Toilet schedules

CONTACT DERMATITIS, UROLOGIC CONSIDERATIONS

DESCRIPTION Contact dermatitis is caused by an external irritant or allergen, and the patient complains of itching and burning or stinging. The findings are inflammation, scaling, and crust formation. Extreme reactions can result in blistering and necrosis. Allergic agents typically induce dermatitis after repeated contact with the skin.

CAUSES
- Common irritant agents cause immediate symptoms and include industrial chemicals, soaps, cleansing products, spermicides and lubricants, perfumes, urogenital secretions, and feces.
- Sensitizing agents for the genital skin include cleansing agents and disinfectants, lubricants and emollients, spermicides and other topical ointments, perfumes and fragrances, latex and other types of rubber, clothing, dyes, poison ivy (direct contact or indirect contact from the hand), met als such as nickel, and sanitary napkins.

TREATMENT
- Attempt to identify and remove the offending agent from contact with the skin.
- Topical corticosteroids, emollients, and antihistamines give symptomatic relief. Severe allergic contact dermatitis may require oral corticosteroids.
- Severe reactions (rarely) may require debridement and grafting.
- Patch testing of uninvolved skin to common antigens is often helpful.

CONTRAST-INDUCED NEPHROPATHY (CIN)

DESCRIPTION An acute and usually reversible form of acute kidney injury following the administration of radiocontrast media. Onset is often 12–24 hr after the contrast study, with renal recovery typically beginning within 3–5 days; it is nonoliguric. The process behaves as a clinical acute tubular necrosis (ATN) with decreased GFR and increased FENa. Risk factors include renal insufficiency (Cr >1.5 mg/dL, GFR <60 mL/min), diabetes, heart failure, dehydration, and multiple contrast studies within 72 hr. The mechanisms of the injury are thought to be renal vasoconstriction with resulting medullary hypoxemia and direct cytotoxic effects of contrast material. Older agents are hyperosmolar and ionic and carry a higher risk of nephrotoxicity, whereas newer agents are iso-osmolar and nonionic and have a lower risk of renal injury. (See also Section I: “Contrast allergy and reactions” and Section II: “Nephrogenic Systemic Fibrosis/Fibrosing Dermatopathy.”)

TREATMENT

- Preventative:
  - Avoid contrast material if possible; consider alternative imaging modalities such as ultrasound or CT/MRI without contrast
  - Avoid dehydration and NSAIDs, as both increase renal vasoconstriction
  - IV saline or sodium bicarbonate (154 mEq/L in D_5W, 3 mL/kg/h 1 hr prior, 1 mL/kg/h 6 hr following) before and after the administration of contrast
  - Antioxidant acetylcysteine [600–1,200 mg PO BID] 1 day prior and following contrast study
  - Use low- or iso-osmolal contrast agents and avoid frequent repeat dosing intervals of contrast (ie, <48 hr).
- Contrast-induced nephropathy diagnosed following a procedure should be managed as ATN:
  - Do not biopsy kidney; injury is usually transient.
  - Carefully control fluid and electrolyte balance; hemodialysis is usually unnecessary.
  - Avoid further nephrotoxic insults and/or medications.

REFERENCE

Asif A, Epstein M. Prevention of radiocontrast-induced nephropathy. *Am J Kidney Dis.* 2004;44:12.

CORDONNIER AND NESBIT URETERAL ANASTOMOSIS

DESCRIPTION A direct ureteral colonic refluxing anastomosis incorporating full-thickness ureteral and intestinal wall.

REFERENCE

Dahl DM, et al. Use of intestinal segments and urinary diversion. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2011:2411–2449.

CORPORA AMYLACEA (CA)

DESCRIPTION Small, round, ovoid bodies, lamellar in structure, located in the alveoli of the prostate. Composed of lecithin, albumin, and nitrogenous substances, they may precipitate around sloughed and degenerated prostatic epithelial cells. Recently noted is a high prevalence of calcium phosphate in the form of hydroxyapatite. CAs become more common with age, and act as the nidus for the development of prostatic calculi formation. Although often observed histologically to be associated with inflammation, the contribution of CA to prostatitis-related symptoms of unknown etiology or to prostate carcinogenesis remains unclear.

REFERENCE

Sfanos KS, Wilson BA, De Marzo AM, et al. Acute inflammatory proteins constitute the organic matrix of prostatic corpora amylacea and calculi in men with prostate cancer. *Proc Natl Acad Sci U S A*. 2009;106(9):3443–3448.

CORTICAL NECROSIS, ACUTE (RENAL CORTICAL NECROSIS)

DESCRIPTION Acute cortical necrosis is a rare form of acute renal failure (ARF) characterized by necrosis of the cortex with sparing of the medulla. It is thought to be the result of selective arterial spasm of the cortical vasculature with continued perfusion of the renal medulla via the medullary arterioles. Pathologically, necrosis of the glomeruli, tubules, and arterioles occurs. A cortical rim sign can be seen on contrast-enhanced CT scan, indicating spared perfusion of the renal capsule. Factors that can predispose a patient to acute cortical necrosis include shock, placental abruption, peritonitis, transfusion reaction, pancreatitis, and toxins. (See also Section I: "Renal Failure, Acute.")

REFERENCE

Wilck EJ, Gerard PS. Acute cortical necrosis. *Urology*. 1997;49(3):116.

COSTOVERTEBRAL ANGLE TENDERNESS

DESCRIPTION Costovertebral angle (CVA) tenderness is a clinical sign elicited by percussion of the CVA and often accompanied by symptoms of flank pain. The CVA is defined by the area formed by the 12th rib and vertebral column. CVA tenderness is a manifestation of renal capsular distension resulting in innervation of afferent T11–L2 nerve roots. Common causes include pyelonephritis, perirenal abscess, urolithiasis, acute hydronephrosis, renal artery occlusion, and renal vein thrombosis. (See also Section I: "Flank Pain.")

REFERENCE

Follin SA. *Professional Guide to Signs & Symptoms*, 5th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2006.

COUGH STRESS TEST

DESCRIPTION The cough stress test involves filling the patient's bladder to at least 300 mL or to subjective fullness. The patient is then asked to cough as the physician directly visualizes the urethral meatus. The test can be performed with the patient in an upright position or in dorsal lithotomy on an exam table (supine stress test). If urine leakage is noted, the test is positive. The cough stress test has been compared with other more sophisticated testing methods (multichannel urodynamic studies) and has demonstrated good sensitivity and specificity. This test can be used not only as part of the clinician's physical exam, but as an outcome measure after treatment.

REFERENCE

Ghoniem G, GhoniStanford E, Kenton K, et al. Evaluation and outcome measures in the treatment of female urinary stress incontinence: International Urogynecological Association (IUGA) guidelines for research and clinical practice. *Int Urogynecol J Pelvic Floor Dysfunct.* 2008;19(1):5–33.

COWPER DUCT CYST

DESCRIPTION The Cowper glands are paired periurethral structures located in the urogenital diaphragm and are drained by 2–3-cm long ducts that empty into the bulbous urethra through small, flush openings. These glands secrete a clear fluid that functions as a

lubricant and a coagulation factor for semen during ejaculation and to neutralize traces of acidic urine in the urethra. Abnormalities of these glands and their ducts may result from obstruction and, less frequently, trauma and infection. This diagnosis should be considered in any male presenting with irritative or obstructive urinary symptoms, particularly when there is a complaint of persistent postvoid dribbling or incontinence. Urethrography and cystourethroscopy are the diagnostic studies of choice.

SYNONYMS
- Cowper syringocele
- Bulbourethral gland duct ectasia

TREATMENT
Endoscopic unroofing of the syringocele (marsupialization) into the bulbar urethra

REFERENCE
Bevers F, Abbekerk EM, Boon TA. Cowper's syringocele: Symptoms, classification and treatment of an unappreciated problem. *J Urol.* 2000;163:782–784.

COWPER GLAND CARCINOMA

DESCRIPTION Rare tumor that can present with obstructive symptoms, pain with defecation, or constipation. Most have a palpable perineal mass. Microscopically, these appear as adenocarcinoma. However, local necrosis and tissue destruction may prevent exact localization of the site of origin. Combined surgical and radiation therapy has been employed.

REFERENCE
Mitsumori K, Elwell MR. Tumours of the male accessory sex glands. *IARC Scientific Pub.* 1994;111:431–449.

COWPERITIS (INFLAMMATION OF BULBOURETHRAL GLAND)

DESCRIPTION Normally, the bulbourethral glands are not palpable. 1 gland lies on each side of the membranous urethra, between the inferior edge of the prostate and the inner border of the anal canal. When they are inflamed, they are exquisitely tender and palpable. In chronic inflammation, they enlarge from the size of a pea to that of a hazelnut. With a finger in the rectum, the thumb is held outside on the median raphe of the scrotum just anterior to the anus and the tissue is compressed to detect tenderness or a mass.

REFERENCE
Chughtai B, Sawas A, O'Malley RL, et al. A neglected gland: A review of Cowper's gland. *Int J Androl.* 2005;28(2):74–77.

CREATININE, SERUM, INCREASED/DECREASED

DESCRIPTION Serum creatinine represents the breakdown product of muscle creatine and is an ideal marker of glomerular filtration rate (GFR). 5–10% of excreted creatinine is secreted in the proximal tubule, rather than filtered through the glomerulus. Serum creatinine can estimate the GFR (eGFR) by 2 methods: The modification diet of renal disease (MDRD) or the

Cockcroft–Gault formula. Increased levels can signify renal failure, renal infection, rhabdomyolysis, urinary tract obstruction, acute tubular necrosis, dehydration, eclampsia, drug toxicity, etc. Decreased levels may reflect female gender, advanced age, late stages of muscular dystrophy, or myasthenia gravis. (See also Section IV: "Urine Studies III Creatinine Clearance and Glomerular Filtration Rate.")

REFERENCE

CREDé MANEUVER

DESCRIPTION Used to facilitate voiding in those patients with decreased bladder tonicity and low outlet resistance. The maneuver involves placing the thumb of each hand over the left and right anterior superior iliac spine, and the fingers over the suprapubic area and pressing into the abdomen. Both hands are then pressed downward into the pelvis. It may not always be an effective technique to empty the bladder, since the external urethral sphincter may contract during the maneuver.

SYNONYM

Manual compression of bladder

CREMASTERIC REFLEX

DESCRIPTION The cremasteric reflex is a useful sign in the evaluation of the acute scrotum. The classic presentation of testicular torsion is sudden onset of severe unilateral pain, often associated with nausea or vomiting. The normal reflex consists of cremasteric contraction with elevation of the testis, elicited by stroking the ipsilateral upper medial thigh. The innervation is carried via the genital branch of the genitofemoral nerve. The reflex was previously reported to be absent in 100% of cases of testicular torsion; however, there have been reported cases of preserved cremasteric reflex in the setting of testicular torsion. As such, the presence or absence of this reflex should not influence the decision to perform a scrotal exploration when there is a clinical suspicion of torsion.

REFERENCE

Nelson CP, Williams JF, Bloom DA. The cremasteric reflex: A useful but imperfect sign in testicular torsion. *J Pediatr Surg.* 2003;38(8):1248–1249.

CRIBRIFORM CLEAR CELL HYPERPLASIA OF THE PROSTATE

DESCRIPTION This condition may be misdiagnosed as cribriform prostate carcinoma, but anticytokeratin staining of the basal cell layer distinguishes the 2 lesions. Also, hyperplasic

cells lack cytologic atypia, which is in contrast to carcinoma. The natural history is unknown; the lesion is usually found in the central area of the gland.

REFERENCE

Epstein J. Precursor lesions to prostatic adenocarcinoma. *Virchows Arch*. 2009;454(1):1–16.

CRYPTOCOCCUS, GENITOURINARY

DESCRIPTION An opportunistic fungal infection, *Cryptococcus neoformans* thrives in areas inhabited by birds. A pulmonary site is most common primary infection site, but immunocompromised patients can develop disseminated disease (AIDS, transplant). Adrenal insufficiency has been reported, but the most common sites of GU involvement are the prostate and kidney. The prostate may be a reservoir in patients with AIDS. Epididymis and penis involvement have also been reported. GU involvement is considered a manifestation of systemic disease. (See also Section I: "Fungal Infections, Genitourinary.")

TREATMENT

- Systemic antifungal therapy with IV amphotericin B, flucytosine, fluconazole, or combination of drugs
- Surgical drainage of large abscesses may be considered

CRYSTAL-INDUCED ACUTE KIDNEY INJURY (ACUTE RENAL FAILURE)

DESCRIPTION Intratubular precipitation of crystals poorly soluble in human urine can lead to AKI. This form of AKI most commonly occurs as a result of acute uric acid nephropathy (tumor lysis syndrome) or following the administration of other drugs/toxins, such as acyclovir, sulfonamides, methotrexate, indinavir, triamterene, ethylene glycol, and high doses of Vitamin C. The presentation is usually asymptomatic and detected by worsening serum creatinine, although renal colic symptoms may be present. Severe volume depletion (prerenal state) is the most important predisposing factor to crystal-induced AKI when patients are receiving the above medications. Likewise, the 1st step in treatment is correction of volume status, usually with isotonic saline and loop diuretics in order to wash out crystals. (See also Section I: "Acute Kidney Injury, Adult [Renal Failure, Acute].")

REFERENCE

Lochy S, Jacobs R, Honoré PM, et al. Phosphate induced crystal acute kidney injury – an under-recognized cause of acute kidney injury potentially leading to chronic kidney disease: case report and review of the literature. *Int J Nephrol Renovasc Dis*. 2013;6:61–64.

CT SCAN, UROLOGIC CONSIDERATIONS

DESCRIPTION A computed tomography (CT) of the abdomen and pelvis can be performed with and without IV or PO contrast. Noncontrast studies are most useful in the evaluation of

nephrolithiasis. IV contrast is useful to delineate vascular, renal, and collecting system anatomy. Delayed images (excretory phase) provide information on urinary tract drainage and ureteral anatomy. Protocols have been developed to delineate renal tumors, stones, urothelial tumors, and arterial supply by adjusting the presence of contrast and the timing of the study. Modern CT machines can provide detailed images quickly and efficiently, but the clinician must be aware of contrast complications and contrast-induced nephropathy (see also Section I: "Contrast Allergy and Reactions"; Section II: "Contrast Induced Nephropathy [CIN].") and the increased risk of malignancy with repeat scans, especially in children. Approximate CT radiation exposure varies with type. Some radiation exposure comparisons average, in MilliSieverts (mSv):

- CT electron beam (EBT): 11 mSv Chest, 26 mSv Abdomen
- CT Sequential: 4 mSv Chest, 20 mSv Abdomen
- CT Spiral: 2 mSv Chest, 7 mSv Abdomen
- CT Pelvis: 7 mSv
- Intravenous pyelogram: 8 mSv
- Standard chest x-ray (2 view): 0.06–0.25 mSv
- Natural sources: Annual (Germany): 2.4 mSv/yr
- Survivors of Hiroshima and Nagasaki Atomic bombings: 50–150 mSv
- Mean lethal dose radiation (kills 50% within 60 days): 3,500–4,000 mSv

CULP-DEWEERD PYELOPLASTY

DESCRIPTION A pyeloplasty technique best suited for management of UPJ obstruction in the setting of a long segment of strictured proximal ureter. A spiral incision is carried out over the anterior and medial aspect of the renal pelvis and continued down across a point beyond the UPJ obstruction. The apex of the flap is brought down to the apex of the ureterotomy, where a 5-0 chromic stay suture is placed. The posterior and anterior anastomoses are completed with interrupted 5-0 chromic sutures.

CUNNINGHAM CLAMP

DESCRIPTION A clamp device designed to compress the penile urethra and prevent urinary incontinence in males only. The clamp is usually placed on the midshaft of the penis and requires the user to have manual dexterity, intact penile skin, good cognition, and a sensate

penis and bladder. The clamp has a ratchet-type closure with foam padding and comes in small, medium, and large sizes. It is inexpensive and the most commonly used clamp device. Other types are commercially available based on this urethral compression concept.

CYCLOPHOSPHAMIDE (CYTOXAN) TOXICITY

DESCRIPTION Cyclophosphamide (sometimes referred to through the historic brand name Cytoxan) is an alkylating chemotherapeutic agent used to treat many blood cell cancers and as an effective immunosuppressant for other diseases such as rheumatoid arthritis. Common side effects include bone marrow suppression, diarrhea, alopecia, and lethargy. However, Cytoxan has unique toxicities, including the development of hemorrhagic cystitis and secondary cancers such as urothelial carcinoma of the bladder and leukemia. Acrolein, a metabolite of Cytoxan, is the main cause of acute hemorrhagic cystitis (and thought to be the cause of long-term increased risk of urothelial carcinoma in patients treated with Cytoxan). Hemorrhagic cystitis can be prevented by administering Mesna at the time of Cytoxan readministration; Mesna binds the toxic metabolite acrolein. (See also Section I: “Cystitis, Hemorrhagic [Infectious, Noninfectious, Radiation]”; Section II: “Chemotherapy Toxicity, Urologic Considerations.”)

TREATMENT

- Mesna can be given either PO or IV, and its routine concurrent use is recommended in the treatment of patients receiving cyclophosphamide and ifosfamide. It should be discontinued when hemorrhagic cystitis is present as it can prevent the development of the cystitis but is ineffective in treating active bleeding.
- Hydration: Forced saline diuresis and the medication Mesna were similar in preventing the incidence of cyclophosphamide-induced hemorrhagic cystitis in some studies.
  – ASCO recommends that patients receiving high-dose cyclophosphamide in the setting of hematopoietic cell transplantation receive Mesna in conjunction with saline diuresis.

CYSTADENOCARCINOMA, GENITOURINARY

DESCRIPTION Commonly seen in other organ systems, such as the ovary, pancreas, appendix, and thyroid. In the GU system, cystadenocarcinoma has been reported in testes, prostate, paratesticular structures, and kidney. Grossly, multilocular cystic masses are noted.

Microscopically, cuboidal to columnar epithelium is seen lining the cysts. These cells can secrete serous or mucinous substances. Malignant cells will demonstrate multilayering of epithelium, nuclear atypia, and invasion of surrounding stroma. It is treated by primary surgical resection.

REFERENCE

Yu CC, Huang JK, Chiang H, et al. Papillary cystadenocarcinoma of the epididymis: A case report and review of the literature. *J Urol*. 1992;147(1):1622–1625.

CYSTADENOMA, GENITOURINARY

DESCRIPTION A benign cystic epithelial-lined mass that has been described in the kidney, seminal vesicle, prostate, and epididymis (most common GU tract site). It is often described as a papillary cystadenoma and represents benign epithelial hyperplasia. It usually causes very few symptoms. Lesions can be bilateral, and 2/3 may be associated with Von Hippel–Lindau syndrome. Grossly, the lesion appears cystic. Microscopically, it demonstrates cells with clear, vacuolated cytoplasm arranged in glandular or papillary structures. It appears as a cystic to solid mass at the head of the epididymis on ultrasound. Treatment is observation or radical orchiectomy, if the diagnosis is in doubt.

REFERENCE

Choyke PL, Glenn GM, Wagner JP, et al. Epididymal cystadenomas in von Hippel-Lindau disease. *Urology*. 1997;49(6):926–931.

CYSTADENOMA/CYSTADENOCARCINOMA, RETROPERITONEAL

DESCRIPTION Primary retroperitoneal tumors of mucinous type are extremely rare. They can be sub-divided into cystadenoma (a benign cystic epithelial-lined mass), borderline, and cystadenocarcinoma (multilocular cystic masses with multilayer epithelium, nuclear atypia, and invasion of surrounding stroma). Prompt diagnosis is important, as the majority of cystadenocarcinomas are malignant. Presenting symptoms can be vague. Given their malignant nature, they should be considered in the differential diagnosis of chronic abdominal pain. Cross-sectional abdominal imaging is the primary diagnostic modality. Radical resection remains the treatment of choice. (See also Section I: “Retroperitoneal Masses, Fluid and Cysts.”)

CYSTATIN C

DESCRIPTION A 13 kDa nonglycosylated endogenous protein found in all nucleated cells that has a constant rate of production unaffected by diet. Its clearance is not affected by renal tubular functions. It is not currently widely available, but it will likely replace serum creatinine as the standard test in GFR measurement.

REFERENCE
Stevens LA, Coresh J, Schmid CH, et al. Estimating GFR using serum cystatin C alone and in combination with serum creatinine: a pooled analysis of 3,418 individuals with CKD. *Am J Kidney Dis*. 2008;51(3):395.

CYSTIC FIBROSIS, UROLOGIC CONSIDERATIONS

DESCRIPTION In this genetic disease affecting 1 in 2,000 Caucasian births, defective chloride transport across the epithelium occurs. This leads to complications involving the pancreas, liver, salivary glands, and lungs. Urogenital findings include bilateral absence of the vas deferens, leading to infertility. Abnormal development of the mesonephric system, inguinal hernias, hydroceles, and undescended testes are also seen. Risk of testicular cancer may be increased. (See also Section I: “Vas Deferens, Congenital Absence.”)

REFERENCE
Oates RD. Clinical evaluation of the infertile male with respect to genetic etiologies. *Syst Biol Reprod Med*. 2011;57:72–77.

CYSTINOSIS

DESCRIPTION Rare autosomal recessive metabolic disorder involving lysosomal storage of the amino acid cysteine due to a defective membrane transport protein: Cystinosin. There are 3 types described, based on the age at diagnosis. Nephropatic or infantile–the most severe, inevitably leading to terminal renal failure in the 1st decade of life, and major identifiable cause of Fanconi syndrome in children. Intermediate–resembles the nephropathic form but onset is during adolescence. Nonnephropathic or ocular cystinosis—usually occurs in adulthood is characterized by corneal crystals and photophobia. The condition is characterized by the intracellular accumulation of excessive quantities of cystine. Daily excretion of cystine is only 5–10% of that found in cystinuria. Stone formation is rare. This condition has a varied range of severity, with severe forms progressing to end stage renal disease (ESRD). Medical management includes hydration, potassium, bicarbonate, vitamin D, and calcium supplementation. Cysteamine bitartrate (Cystagon) is a cysteine depleting medication. ESRD may require real transplantation.

REFERENCE
Nestorave G, Gahl WA. Cystinosis: The evolution of a treatable disease.*Pediatr Nephrol*. 2013;28(1):51–59.

CYSTITIS CYSTICA

DESCRIPTION Similar to von Brunn nests, which are areas of benign urothelium in the submucosa, except that in cystitis cystica the centers of the nests have undergone eosinophilic liquefaction (degeneration) to form small cystic mucin cavities; when intestinal metaplasia with gland formation is found it is described as *cystitis glandularis*. Both conditions are thought to be benign. Found in 60% of normal bladders at autopsy, cystoscopically they appear as small pearly white or yellowish lesions, usually <5 mm, but occasionally larger.

No clear relation to malignant transformation is noted. There is no specific treatment; diagnosis is usually established by biopsy to rule out cancer.

REFERENCE

Alijani M, Ng KJ, Dickinson IK, et al. An unusual case of cystitis cystica. *BJU International.* 2002;89:634.

CYSTITIS, EMPHYSEMATOUS

DESCRIPTION A rare UTI with gas formation in the bladder wall or bladder lumen. Predominant in older women with diabetes. Presents with abdominal pain, dysuria, and possibly pneumaturia; gas can be seen on imaging studies. *Escherichia coli* and *Klebsiella pneumoniae* are most common pathogens and medical management is similar to acute complicated pyelonephritis. (See also Section I: "Pneumaturia [Gas in Urine].")

REFERENCE

Thomas AA, Lane BR, Thomas AZ, et al. Emphysematous cystitis: A review of 135 cases. *BJU Int.* 2007;100(1):17–20.

CYSTITIS, EOSINOPHILIC

DESCRIPTION A rare and severe form of allergic cystitis. Symptoms include hematuria, urgency, dysuria, and suprapubic discomfort. Urine analysis may show eosinophiluria. Cystoscopic findings may reveal raised plaques or ulcers that mimic CIS or invasive bladder cancer. Bladder biopsy revealing eosinophilic infiltrate is pathognomonic. Potential causes include food or drug allergies (including methicillin, anthranilic acid, intravesical mitomycin, and thiotepa). Parasitic infections should also be considered as etiologies. Some confusion in the literature exists between this entity and granulomatous cystitis. Conservative medical management with oral antibiotics, antihistamines, and steroids with an allergy evaluation are required. (See also Section II: "Cystitis Granulomatous.")

TREATMENT

- Conservative medical management with oral antibiotics, antihistamines, and steroids
- A full allergy evaluation is required

REFERENCE

Zaman SR, Vermeulen TL, Parry J. Eosinophilic cystitis: Treatment with intravesical steroids and oral antihistamines. *BMJ Case Rep.* 2013; pii: bcr2013009327. doi: 10.1136/bcr-2013-009327.

CYSTITIS FOLLICULARIS

DESCRIPTION Cystitis follicularis (also called "bacteriuric bumps" or "follicular cystitis") is characterized by the formation of lymphoid follicles in the lamina propria of the trigonal region of the bladder. It is caused by repeated or chronic UTIs. It may appear grossly as punctate, yellow submucosal nodules. It is not associated with malignancy, and treatment of the underlying infection is curative.

REFERENCE

McIntire M, Scudiere JR, Gattuso P. Cystitis follicularis in bladder washings: Report of 2 cases and review of the literature. *Diagn Cytopathol*. 2007;35(8):537–538.

CYSTITIS GLANDULARIS AND CYSTITIS GLANDULARIS OF INTESTINAL TYPE

DESCRIPTION Similar to von Brunn nests, which are areas of benign urothelium in the submucosa, except these urothelial cells have undergone glandular metaplasia. It is usually only detected microscopically, but occasionally can appear as a grossly visible lesion and may appear papillary. *Typical cystitis glandularis* is the most common form. Diffuse *cystitis glandularis of the intestinal type* is seen in chronically irritated bladders, and is associated with an increased risk of bladder cancer (adenocarcinoma) and may be associated with pelvic lipomatosis. No specific treatment except follow-up due to cancer risk. (Image ☼)

REFERENCE

Rau AR, Kini H, Pai RR. Morphological evaluation of cystitis glandularis. *Indian J Pathol Microbiol*. 2009;52(2):203–205.

CYSTITIS, GRANULOMATOUS

DESCRIPTION Granulomatous cystitis (sometimes called *eosinophilic cystitis* or *eosinophilic granulomatous cystitis* in the literature, thus leading to some confusion of this entity) is a rare allergic cystitis in patients who often have a significant allergic history. It mimics other forms of intractable cystitis, such as interstitial cystitis, TB, and bladder neoplasms. The cause is unknown, but believed to be various antigens that form immune complexes and stimulate eosinophilic infiltration. It can be seen in some patients after the use of intravesical BCG for bladder cancer as a thickened, edematous bladder with erythematous plaques, ulcerations, and submucosal hemorrhage. Microscopy reveals fibrosis and inflammatory cells with extensive eosinophil infiltration of bladder wall. Patients present with frequency, dysuria, and hematuria.

TREATMENT

- Condition is usually benign with self-limited course
- Optimal management is unclear; usually NSAIDs, steroids, and antihistamines

REFERENCES

Littleton R, Farah RN, Cerny JC. Eosinophilic cystitis: An uncommon form of cystitis. *J Urol*. 1982;127(1):132–133.

CYSTITIS, POLYPOID AND PAPILLARY

DESCRIPTION These benign lesions may appear cystoscopically as papillary urothelial neoplasms and are a reaction to urothelial injury. Polypoid cystitis becomes papillary cystitis when the condition becomes chronic. Similar lesions occur throughout the urothelial tract

and are referred to as *polypoid urethritis, polypoid ureteritis,* and *polypoid pyelitis* when present in the urethra, ureter, and renal pelvis, respectively; these are clinically and diagnostically similar lesions. Clinical settings for this diagnosis include evaluation of gross hematuria, bladder and/or urethral stones, prostate cancer with radiation therapy, history of urothelial carcinoma treatment, long-term urinary stents, and colovesical fistulas. Proper diagnosis relies on low-power microscopic identification of the reactive process with an inflamed background that is edematous or densely fibrous with predominantly simple, nonbranching, broad-based fronds of relatively normal-thickness urothelium. If the tissue is examined at higher power, some fronds may appear to resemble a urothelial neoplasm. Treatment is directed at the inciting cause.

REFERENCE

Lane Z, Epstein JI. Polypoid/papillary cystitis: A series of 41 cases misdiagnosed as papillary urothelial neoplasia. *Am J Surg Pathol.* 2008;32(5):758–764.

CYSTITIS, RADIATION

DESCRIPTION Radiation cystitis can be caused during the treatment of pelvic malignancies (prostate, cervical, colorectal) when the bladder is in the radiation treatment field. Patients may experience urgency, frequency, dysuria, and urination of small volumes. Bladder spasms may also be present. This can progress to hemorrhagic cystitis with diffuse bladder mucosal inflammation and hemorrhage. The initial response of the bladder to radiation exposure results in an edematous and friable bladder. There can be extensive endarteritis with friable mucosa. Long-term radiation cystitis may present with delayed bleeding remote from the exposure to radiation (6 mo–20 yr after). The hallmark is neovascularity that bleeds easily, however when bladder bleeding occurs long term, bladder cancer should be ruled out. Life-threatening hemorrhage is a possible consequence of radiation-induced hemorrhagic cystitis. Amifostine has shown potential in prevention of GI and acute bladder toxicity from radiation. (See Section I: “Cystitis, Hemorrhagic Infectious, Noninfectious, Radiation.”)

TREATMENT

- Local irrigation with evacuation of clots is the initial intervention along with the correction of any coagulopathy if present should be the initial conservative management based on the clinical presentation
- Endoscopic electrocoagulation or laser ablation of bleeding sites
- Intravesical alum
- Hyperbaric oxygen (100% oxygen at higher than atmospheric pressure) 60–93% effective
- Pentosan polysulfate 100 mg 3 times a day; conjugated estrogens
- Intravesical instillation of formalin (37% solution of formaldehyde) in the absence of reflux
- Refractory life-threatening hemorrhage may require more aggressive intervention: Using selective embolization of the vesical or internal iliac arteries, diversion of the urinary stream (nephrostomy tubes, ileal conduit) with or without cystectomy (Image ☼)

CYSTITIS, VIRAL

DESCRIPTION Viruses are increasingly recognized as the cause of lower UTIs—especially hemorrhagic cystitis among immunocompromised patients. Viral cystitis is caused most commonly by adenovirus, papovavirus, or influenza A. BK virus, adenovirus, and CMV are predominant pathogens involved in hemorrhagic cystitis after stem cell and solid-organ transplantation, and their early diagnosis and treatment may prevent significant morbidity. These can produce clinically significant symptoms, such as dysuria, hematuria, and frequency. Standard urine culture is negative. Urine analysis may show WBCs and RBCs. Cytology may be suspicious for malignancy, with abnormally large cells having prominent nuclei. The diagnosis of viral lower UTI is based on molecular techniques, and real-time polymerase chain reaction is often the method of choice because it allows for quantification of viral load. (See also Section I: "Cystitis, Hemorrhagic"; "Polyoma virus (BK, JC), urologic considerations"; Section II: "BK Virus, Urologic Considerations.")

TREATMENT

- Viral cystitis is usually self-limited
- In immunosuppressed patients, the use of antiviral agents (cidofovir, vidarabine, ribavirin) administered by PO, IV, or intravesical routes is recommended

REFERENCE

Paduch DA. Viral lower urinary tract infections. *Curr Urol Rep*. 2007;8(4):324–335.

CYSTOCELE GRADING: BADEN–WALKER, PELVIC ORGAN PROLAPSE QUANTIFICATION (POP-Q)

DESCRIPTION The grading and evaluation of cystoceles have evolved from the Baden–Walker grading scale to the current Pelvic Organ Prolapse Quantification (POP-Q) system. Although the 2-staging systems are widely used in clinical practice, POP-Q is more commonly used in the literature. The classic Baden–Walker grading system was 1st described in 1968. POP-Q was later developed in 1996. Both staging systems base the degree of prolapse on the leading edge during a Valsalva maneuver. (See also Section I: "Pelvic Prolapse [Cystocele and Enterocele]"; Section II: "Pelvic Organ Prolapse Quantification System [POPQ]."") (Image☼ Cystocele/Pelvic Organ Prolapse Classification)

Baden–Walker Grading	
Grade 0:	No prolapse
Grade 1:	Leading edge descends halfway to the hymen
Grade 2:	Leading edge descends to the hymen
Grade 3:	Leading edge descends halfway past the hymen
Grade 4:	Procidentia or vault eversion

POP-Q Staging	
Stage 0:	No prolapse
Stage I:	Leading edge is >1 cm above the hymen
Stage II:	Leading edge is between 1 cm above and 1 cm below the hymen
Stage III:	Leading edge is >1 cm below the hymen but less than total vaginal length – 2 cm (TVL (total vaginal length) – 2 cm)
Stage IV:	Leading edge is below hymen by more than TVL – 2 cm

CYSTOGRAM, INDICATIONS AND TECHNIQUE

DESCRIPTION A cystogram is a radiologic exam of the urinary bladder that can show the bladder's position, shape, presence of vesicoureteral reflux, bladder perforation and/or filling defects. A catheter is inserted into the bladder and used to fill the bladder with a contrast agent under gravity drainage. Typically, 300–350 mL of contrast is utilized depending on the patient's anatomy. Fluoroscopic images are then taken of the opacified bladder in the AP and oblique views. A postdrainage view is important to evaluate residual volume and to ensure no missed contrast extravasation behind the bladder. Common indications include abdominal/pelvic trauma, infection, fistula, reflux disease, and incontinence. Cystography has been largely replaced by the use of the CT cystogram.

REFERENCE

Chan DP, Abujudeh HH, Cushing GL Jr, et al. CT cystography with multiplanar reformation for suspected bladder rupture: Experience in 234 cases. *AJR Am J Roentgenol.* 2006;187(5):1296–1302.

CYSTOMETROGRAM

DESCRIPTION A cystometrogram evaluates the filling and/or storage phases of detrusor function. Catheters to measure intravesical pressure, abdominal pressure and to fill the bladder with saline, water, or CO_2 are utilized. The bladder filling rate is 1–50 mL/min.

Simultaneous measurements of pressure and volume are recorded and a curve is created. Variables observed are compliance, contractility, sensation, and capacity. During filling, the bladder volumes are recorded at (1) the 1st sensation of filling, (2) sensation of urgency to void, and (3) sensation of maximum capacity. Abnormalities that may be detected include altered sensation, changes in detrusor compliance, disorders of detrusor contractility, and/or presence of detrusor overactivity (DO).

REFERENCE

Pressure/flow cystometry. In: Chapple CR, MacDiarmid SA, Patel A, eds. *Urodynamics Made Easy.* 3rd ed. London: Elsevier; 2009.

CYSTOSARCOMA PHYLLODES, PROSTATE

DESCRIPTION Histopathologically resembles its counterpart in the breast: Distinctive biphasic pattern with hyperplastic epithelium-lined cysts, leaf-like intraluminal epithelium-lined stromal projections, and variable spindle cell stroma. Grossly, the tumor is unusually soft, cystic, and spongy. It can present with LUTS. Case reports indicate normal PSA levels or only slightly elevated. It can range from benign to malignant and its treatment is surgical resection.

REFERENCE

Fujii T, Shimada K, Tanaka N, et al. Phylloides tumor of the prostate. *Pathol Int.* 2012;62(3):204–208.

CYSTOSCOPE PROCESSING

DESCRIPTION Flexible fiberoptic cystoscopes are a major component of urology practice used for both diagnostic and therapeutic procedures. The American Urologic Association (AUA) and Society of Urologic Nurses and Associates (SUNA) have issued joint recommendations for reprocessing flexible cystoscopes. The key findings are summarized here:

- Cystoscopes as "semi-critical" devices requiring high-level disinfection or sterilization between patients. High-level disinfection differs from sterilization: High-level disinfection does not kill large numbers of bacterial spores; sterilization is the complete destruction of all microbial life.
- In the office setting, high-level disinfection (using glutaraldehyde or another chemical disinfectant) should include precleaning, leak testing, cleaning, disinfection, rinsing, and drying.
- Glutaraldehyde "soak times" are 20–45 min. With no precleaning a 45-min glutaraldehyde soak is required. A 20-min soak is adequate if recommended reprocessing steps are followed prior to immersion in glutaraldehyde.
- One chemical disinfectant (ortho-phthalaldehyde [OPA]) has been associated with anaphylaxis in bladder cancer patients, and should be avoided in these patients.

CYTOKERATIN STAINING

DESCRIPTION Commonly used in prostate cancer diagnosis (ie, to differentiate PIN from basal cell hyperplasia or distinguish various forms of acinar proliferations that are not cancer on needle biopsy) 34β3E12, which detects basal cell–specific CK, is commonly used. If basal cell staining is present, this helps to rule out carcinoma; it is also used to examine lymph nodes or periprostatic tissues for prostate cancer and may increase the accuracy of lymph node staging. It has shown promise in breast cancer staging, where up to 1/3 of patients have unsuspected micrometastasis to lymph nodes. Its utility in prostate cancer metastasis is being

investigated. (See also Section II: “Immunohistochemical Staining, Urologic Considerations.”)

REFERENCE

Moul JW, Lewis DJ, Ross AA, et al. Immunohistologic detection of prostate cancer pelvic lymph node micrometastases: Correlation to preoperative serum prostate-specific antigen. *Urology*. 1994;43(1):68–73.

CYTOLOGY, PROSTATE

DESCRIPTION Exam of cells, usually obtained by fine-needle aspiration (FNA), for the detection of malignancy. Characteristics that can be determined include DNA ploidy status, cell cycle distribution, and cytologic grade. Its advantages over standard pathologic techniques include ease and rapidity of technique; when used in combination with flow cytometry, it seems to increase accuracy. The findings must be read by an experienced cytopathologist to ensure reliability. The use of this technique has declined greatly in favor of needle biopsy. (See also Section II: “Fine-Needle Aspiration, Prostate.”)

REFERENCE

CYTOLOGY, URINARY

DESCRIPTION Microscopic exam of the urine, usually performed for the detection of malignant cells during follow-up of urothelial carcinoma. Criteria for malignancy include increased cytoplasmic-to-nuclear ratio, eccentric nucleus, nuclear pleomorphism and irregularity, hyperchromasia, chromatin clumping, nuclear crowding and overlapping, prominent nucleoli, mitotic figures, lack of cytoplasmic vacuolization, and loss of cell cohesion. Highly accurate (95%) in high-grade carcinoma and CIS but less (10–50%) accurate in low-grade bladder cancer, it is also useful in detecting unresected residual tumor, and may predict future tumor recurrence after transurethral resection (Image ☼).

REFERENCE

Jones JS, Larchian WA. Non-Muscle Invasive Bladder Cancer (Ta, T1, and CIS). In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2012:2351.

CYTOMEGALOVIRUS (CMV), UROLOGIC CONSIDERATIONS

DESCRIPTION CMV is the most important infectious threat to renal transplant recipients. Risk factors include the serologic status of donor and recipient, as well as the immunosuppressive regimen utilized. Other effects include voiding dysfunction by invading peripheral nerves. CMV cystitis has been reported to occur in AIDS, and it is 1 of the TORCH infections that can cause fet al malformations. CMV has been associated with perinatal renal vein thrombosis, and it can be a cause of virally induced hemorrhagic cystitis. Ganciclovir has been effective in transplant patients. (See also Section I: “Immunocompromised Patients, Urologic Considerations.”)

DAVIS INTUBATED URETEROTOMY

DESCRIPTION Rarely used today, it was developed for surgical repair of lengthy or multiple ureteral strictures. An incision is carried out over the strictured area. A flap is then created attempting to maximally preserve its blood supply. Nephrostomy tube drainage is placed to avoid urinoma formation. A stenting catheter is passed through the cortex of the kidney, down the stenotic segment, and into the distal ureter/bladder. Apex of the flap is brought over the stent as far down as possible over the ureterotomy and closed with interrupted or running absorbable suture. The stenting catheter can be removed at 6 wk, after which an antegrade nephrostogram is done to ensure patency of the ureter. Nephrostomy catheter is removed afterward.

DAYTIME FREQUENCY SYNDROME (POLLAKIURIA)

DESCRIPTION The complaint of frequent daytime voiding or *pollakiuria* (from the Greek pollakis, meaning often) is a fairly common pediatric complaint. Other terms to describe the condition include extraordinary *daytime urinary frequency*, and in early literature, *sham urinary tract infection*. It is seen somewhat more often in boys usually between 4 and 10 yr. In children the differential includes UTI, diabetes mellitus, detrusor instability (DI), constipation, and bladder detrusor instability. If no cause can be determined simple behavioral regimen has demonstrated effectiveness including reassuring the parents and child and waiting for the condition to self-resolve. Reducing dietary intake of oxalate-rich beverages such as, tea and acidic juices such as apple in children who consume large amounts of them, along with liberal intake of water, have been proposed as ancillary approaches. The child needs to learn to ignore the urges and postpone voiding with some type of reward system.

REFERENCE

Farber JM. A strategy to treat pollakiuria. Contemporary Pediatrics. March 1, 2013.

DEEP VENOUS THROMBOEMBOLISM (DVT) PROPHYLAXIS: AUA GUIDELINES

DESCRIPTION Venous thromboembolism (DVT or PE) can occur in 1–5% of patients after major urologic surgery. Risk factors include advanced age, prior venous thromboembolism, cancer, hypercoagulable states, immobilization, obesity, smoking, pelvic dissection, lithotomy position, and many others. Bleeding risk must be weighed against the benefits of prophylaxis. Risk stratification:

- Low risk: Minor surgery, <40 yo, no additional risk factors
- Moderate risk: Minor surgery with additional risk factors or patients 40–60 yo with no additional risk factors

- High risk: Patients >60 yo OR patients 40–60 yo with additional risk factors
- Very high risk: Patients with multiple risk factors

RECOMMENDATIONS
- Transurethral or low-risk procedures: Early and frequent ambulation only
- Moderate Risk: Heparin 5,000 U SQ q12h start post op OR Enoxaparin 40 mg SQ/daily (if CrCL <30 mL/min 30 mg)
- High risk: Heparin 5,000 U SQ q8h start post op OR Enoxaparin 40 mg SQ/daily (if CrCL <30 mL/min 30 mg)
- Very high risk: Heparin 5,000 U SQ q8h start post op OR Enoxaparin 40 mg SQ/daily (if CrCL <30 mL/min 30 mg) AND adjuvant pneumatic compression device
- Active bleeding: Compression stockings and/or intermittent pneumatic compression
- Selected very high-risk patients: Consider postdischarge enoxaparin or warfarin

DEHYDROEPIANDROSTERONE (DHEA) AND DHEA SULFATE (DHEA-S) BLOOD TEST

DESCRIPTION Because they are produced in the adrenal cortex, serum levels of DHEA and the sulfated form (DHEA-S) reflect adrenal gland function. Normal value ranges differ by age and sex. Common clinical reasons to measure these levels include female virilism, hirsutism, precocious puberty, CAH, and adrenal cancer. DHEA-S is the major form in serum. Generally, blood levels of both forms decrease in the aging male, and replacement has been linked with improved outcomes in Alzheimer disease and systemic lupus.

	DHEA (ng/mL)	DHEA-S (μg/mL)
Child	1–3	N/A
Male	1.7–9.5	80–560
Female	2–10	35–430

REFERENCE

Baulieu E, Thomas G, Legrain S, et al. Dehydroepiandrosterone (DHEA), DHEA sulfate, and aging: Contribution of the DHEAge Study to a sociobiomedical issue. *Proc Natl Acad Sci U S A.* 2000;97(8):4279–4284.

DELAYED NEPHROGRAM

DESCRIPTION In most imaging studies, contrast is typically appreciated within a few minutes of injection. In a delayed nephrogram, contrast appearance in the kidney is delayed. The most common cause is obstruction of the collecting system or ureter by calculus, tumor, or clot. Other causes are:
- Extraluminal obstruction of the collecting system by extrinsic mass
- Intrarenal obstruction, usually by precipitated substances in the tubules, such as Tamm–

Horsfall protein
- Azotemia
- Hypotension
- Renal vein thrombosis
- Rarely, acute kidney injury (AKI)

REFERENCE

Friedenberg RM. Excretory urography in the adult. In: Pollack HM, et al., eds. *Clinical Urography*. 1st ed. Philadelphia, PA: Saunders; 1990.

DEMENTIA AND VOIDING DYSFUNCTION

DESCRIPTION Dementia represents a debilitating neurologic cognitive disability, which can be associated with Alzheimer disease, Parkinson disease, and Lewy body disease. These patients typically develop lowerurinary tract symptoms (LUTS) of urgency, frequency, and urge incontinence. The incontinence may be a result of urgency and/or functional status. The more advanced the dementia and lack of mobility, the greater the role of functional incontinence. These patients are very difficult to manage successfully and require significant ancillary care. Incontinence in patients with a neurologic diagnosis is typically caused by DO. (See also Section I: "Neurogenic Bladder, General Considerations.").

TREATMENT
- Anticholinergic medication
- α-Blocker medication
- Behavioral modifications
- Address underlying cause of dementia

REFERENCE

Ransmayr GN, Holliger S, Schletterer K, et al. Lower urinary tract symptoms in dementia with Lewy bodies, Parkinson disease, and Alzheimer disease. *Neurology*. 2008;70(4):299–303.

DENT DISEASE

DESCRIPTION Characterized by hypercalciuria, nephrocalcinosis, kidney stones, renal failure, and rickets. It is a disorder of the proximal tubules with X-linked recessive inheritance. Symptomatic disease is almost exclusively confined to males. Typical childhood presentation is polyuria, microscopic hematuria, asymptomatic proteinuria, or urolithiasis. Treatment is focused on reducing the hypercalciuria. (See Section II: "Hypercalciuria [Absorptive, Renal, and Resorptive].")

REFERENCE

Stechman MJ, Loh NY, Thakker RV, et al. Genetic causes of hypercalciuric nephrolithiasis. *Pediatr Nephrol*. 2009;24(12):2321–2332.

DENYS-DRASH SYNDROME (DDS), UROLOGIC CONSIDERATIONS

DESCRIPTION Also called Drash syndrome, a rare disorder consisting of congenital

nephropathy, Wilms tumor, and DSD (male pseudohermaphroditism) resulting from WT-1 gene mutations on chromosome 11p13. Patients develop hypertension, end stage renal disease (ESRD), and gonadoblastomas in their dysgenetic gonads.

TREATMENT
- Early prophylactic bilateral nephrectomy
- Gonadectomy
- Chemotherapy based on National Wilms Tumor protocol
- Renal transplantation after 2 yr of disease free on dialysis

REFERENCE
Shapiro O, Welch TR, Sheridan M, et al. Mixed gonadal dysgenesis and Denys-Drash syndrome: Urologists should screen for nephrotic syndrome. *Can J Urol.* 2007;14(6):3767–3769.

DERMATITIS HERPETIFORMIS

DESCRIPTION Dermatitis herpetiformis (also called Duhring disease) is an autoimmune blistering disorder associated with gluten sensitivity, and autoimmune and lymphoproliferative disorders. It is characterized by grouped excoriations, urticarial plaques, and papules with vesicles, and has been described on the external genitalia. It is extremely pruritic, and the vesicles are often excoriated to erosions by the time of physical exam. Diagnosis is made by the presence of IgA deposits in the upper papillary dermis seen on direct immunofluorescence of a skin biopsy specimen. The mainstays of treatment are dapsone and a gluten-free diet.

REFERENCE
Alonso-Llamazares J, Gibson LE, Rogers RS 3rd. Clinical, pathologic, and immunopathologic features of dermatitis herpetiformis: Review of the Mayo Clinic experience. *Int J Dermatol.* 2007;46(9):910–919.

DERMATOPHYTE, EXTERNAL GENITALIA

DESCRIPTION Dermatophytes are the most common type of fungi that cause skin and nail infections, and they can involve the external genitalia. The irritation is often caused by the dermatophyte, *Trichophyton rubrum.* They typically present in obese adults with excessive perspiration as a major risk factor. Skin manifestations include red, raised, sharply defined, itchy lesions in the groin that may extend to the buttocks, inner thighs, and external genitalia. Warm weather and tight clothing encourage fungus growth. Also consider treating tinea pedis ("athlete's foot"), as this is often the original site of the offending organism.

SYNONYMS
- Tinea cruris
- Ringworm
- Jock itch

TREATMENT
- Weight loss; improved personal hygiene; talcum, cornstarch, or other desiccant powders to

keep the area dry
- Topical antifungals (powders, creams, lotions, solutions) such as terbinafine (Lamisil), clotrimazole (Lotrimin), econazole (Spectazole), ciclopirox (Loprox)

REFERENCE

Nadalo D, Montoya C, Hunter-Smith D. What is the best way to treat tinea cruris? *J Fam Pract.* 2006;55(3):256–258.

DERMOID CYST, TESTICULAR

DESCRIPTION Dermoid cysts (*epidermoid cyst*) are benign intratesticular neoplasms and a variant of cystic teratomas that contain ectodermic derivatives. Patients present with a palpable, firm, nontender testicular mass. Case reports indicate occurrence over a wide range of ages, from 5–85 yr. Dermoid cysts are typically well-encapsulated and unilocular. They occur more often in the right testicle (upper/lower pole) and are usually treated with focal excision or enucleation.

REFERENCE

Viganò P, Picozzi SC, Manganini V, et al. 7-year history of an intratesticular mass: Patient description and review of the literature about dermoid cysts of the testis. *Urol Int.* 2006;77(3):281–283.

DESMOPLASTIC SMALL ROUND CELL TUMOR

DESCRIPTION Rare, usually very aggressive mesenchymal tumor that typically presents in the abdominal cavity but might involve the GU system. Those patients with GU involvement tend to be younger men. Histologically, irregular nests of small round cells surrounded by fibrous connective tissue are seen. Immunohistochemical studies reveal both epithelial and nonepithelial origins. Associated with a unique translocation between chromosomes 11 and 22, that involves EWSR1 and WT1 genes. Prognosis is particularly poor, largely due to majority of patients presenting with metastatic disease. Surgical resection and multidrug chemotherapy have been employed with poor success.

REFERENCE

Dufresne A, Cassier P, Couraud L, et al. Desmoplastic small round cell tumor: current management and recent findings. *Sarcoma.* 2012;2012:714986.

DE TONI-FANCONI-DEBRE SYNDROME

DESCRIPTION Syndrome of multiple defects of tubular function, characterized by aminoaciduria, phosphaturia, glycosuria, osteomalacia, and renal tubular acidosis. The proximal renal tubule is shortened and replaced by a thin tubular structure, constituting the swan-neck deformity.

TREATMENT
- Replacement of cation deficits (especially potassium)
- Correction of acidosis with bicarbonate or citrate

- Replacement of phosphate loss with isoionic neutral phosphate solution
- Encouragement of liberal calcium intake with added vitamin D

REFERENCE

Ogier H, Lombes A, Scholte HR, et al. De Toni-Fanconi-Debre syndrome with Leigh syndrome revealing severe muscle cytochrome C oxidase deficiency. *J Pediatr*. 1988;112(5):734–739.

DETRUSOR OVERACTIVITY

DESCRIPTION Involuntary or uninhibited contraction of the detrusor muscle (as seen with multichannel urodynamics) in the absence of a neurologic cause. According to the Incontinence Society definition: DO is a urodynamic observation characterized by involuntary detrusor contractions during the filling phase which may be spontaneous or provoked. Clinically, DO usually presents as urinary urgency, with or without urinary frequency urgency incontinence. (See also Section I: "Overactive Bladder.") The etiology of DO can be either neurogenic or idiopathic.

SYNONYM

Overactive bladder

TREATMENT

- Behavior modification: Fluid restriction, avoidance of bladder irritant
- Pelvic floor exercises
- Anticholinergic/antimuscarinic therapy
- β3-Adrenergic receptor agonist therapy
- Botulinum toxin type A
- Sacral neuromodulation
- Posterior tibial nerve stimulation
- Surgical treatments: Ileovesicostomy, augmentation cystoplasty

REFERENCES

DEXAMETHASONE SUPPRESSION TEST

DESCRIPTION The dexamethasone suppression test is designed to diagnose and differentiate among the various types of Cushing syndrome and other hypercortisolism states. Results indicative of Cushing disease involve no change in cortisol on low-dose dexamethasone but inhibition of cortisol on high-dose dexamethasone. If the cortisol levels are unchanged by both low- and high-dose dexamethasone, then a cortisol-secreting adrenocortical tumor is suspected or an ectopic ACTH source. Occasionally, other conditions (such as major depression, alcoholism, stress, obesity, kidney failure, pregnancy, or

uncontrolled diabetes) may interfere with cortisol levels.

The low-dose test depends on the fact that only the correct dose of dexamethasone will suppress ACTH – and thus cortisol release in normal subjects – whereas patients with corticotrophic adenomas will not suppress below a specified cutoff. Traditionally, high-dose dexamethasone has been used to suppress pituitary sources of ACTH and thus serum cortisol levels to help distinguish Cushing disease from the ectopic ACTH syndrome. 2 mg of dexamethasone is given q6h for 48 hr, after which urinary cortisol is measured. Suppression of basal urinary cortisol levels (measured in the initial screening) by 90% is the commonly quoted cutoff for this test. It is advised that high-dose dexamethasone suppression be used more as a confirmatory test, if at all, for the diagnosis of Cushing disease.

REFERENCE

Gross BA, Mindea SA, Pick AJ, et al. Diagnostic approach to Cushing disease. *Neurosurg Focus*. 2007;23(3):E1.

DIABETES INSIPIDUS (DI), UROLOGIC CONSIDERATIONS

DESCRIPTION DI may cause polyuria. DI is further distinguished as neurogenic or nephrogenic in origin. Of urologic interest, the IVP can show marked hydronephrosis, dilated ureters, and megacystis secondary to the great increase in urine flow. Signs include hypernatremia and hyperosmolarity. The condition is diagnosed by the inability to concentrate urine despite water deprivation and administration of ADH. Neurogenic DI is caused by the loss of ADH secretion from trauma, tumor, or for iatrogenic reasons. Nephrogenic DI can be idiopathic, due to medications, or a result of obstructive uropathy.

TREATMENT

- Neurogenic: Replace ADH
- Nephrogenic:
  - Remove the underlying cause
  - Chlorothiazide with low sodium diet

REFERENCE

Garofeanu CG, Weir M, Rosas-Arellano MP, et al. Causes of reversible nephrogenic diabetes insipidus: A systematic review. *Am J Kidney Dis*. 2005;45(4):626–637.

DIETL CRISIS

DESCRIPTION The most severe manifestation of nephroptosis, originally described by Jozef Dietl in 1864. Classically described as colicky flank pain, nausea, chills, tachycardia, oliguria, and transient hematuria or proteinuria. Hydronephrosis secondary to vascular obstruction of the ureter is the postulated cause. Physical exam reveals an enlarged, tender kidney.

TREATMENT

- Manual reduction of the ptotic kidney was initially used
- Nephropexy has been used for nephroptosis and was 1 of the most commonly performed operations of the early 20th century; uncommon procedure today

REFERENCE

Moss S. Floating kidneys: A century of nephroptosis and nephropexy. *J Urol*. 1997;158:699–702.

DIMERCAPTOSUCCINIC ACID (DMSA) RENAL SCAN

DESCRIPTION DMSA allows the visualization of detailed renal cortical anatomy because it accumulates in the kidney at the proximal renal tubules and is slowly excreted in the urine. DMSA renal imaging is the most sensitive radiologic study used to detect pyelonephritic changes and scarring in the kidneys.

REFERENCE

Hardy R, Austin J. DMSA renal scans and the top-down approach to urinary tract infection. *Pediatr Infect Dis J*. 2008;27(5):476–477.

DIURETIC RENOGRAM

DESCRIPTION A noninvasive nuclear medicine study that provides functional information regarding upper urinary tract obstruction (sometimes referred to as “Lasix renogram”). This test is most commonly utilized to determine obstruction in the setting of hydronephrosis. A tubular agent is preferred, therefore MAG3 is widely used for its high extraction fraction, rapid parenchymal transit, low radiation absorbed dose, and excellent imaging properties. The recommended dose of furosemide (Lasix) in adults is 40 mg IV. In the standard protocol, Lasix is injected when the collecting system appears to be full (usually 15–20 min after tracer injection, called F + 20). In patients with equivocal results, a 2nd study with administration of Lasix 15 min before tracer injection (called F – 15) is performed to maximize the diuretic stress, which improves the sensitivity and specificity and reduces the chances of equivocal outcome. Quantitative parameters, such as time to peak (TTP), 20 min to peak activity ratio (20/MAX), pelvic T1/2 clearance time, and parenchymal transit time (PTT) are calculated (Image ☼).

REFERENCE

Foda MM, Gatfield CT, Matzinger M, et al. A prospective randomized trial comparing 2 diuresis renography techniques for evaluation of suspected upper urinary tract obstruction in children. *J Urol*. 1998;159(5):1691–1693.

DOPPLER, PENILE

DESCRIPTION Currently, the most widely utilized method to measure arterial flow and prove arterial insufficiency as an etiology of impotence. It allows visualization of individual arteries and measurement of flow. Performed in the flaccid and erect states (after the intracavernosal injection of vasoactive agents). An increase in mean arterial diameter of >75% of the flaccid value and a mean peak flow velocity of >25 cm/s after vasoactive agent injection is used to determine adequate arterial capacity. A wide variability in some patients has been shown.

REFERENCE

Burnett AL. Evaluation and management of erectile dysfunction. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2012:721–748.

DOWN SYNDROME, UROLOGIC CONSIDERATIONS

DESCRIPTION Also known as trisomy 21, the findings of this commonly seen trisomy include brachycephalic skull; congenital nasal hypoplasia; broad, short hands; and GU anomalies in the form of undescended testicles and a small penis. Males affected are hypogonadal with a smaller than average phallus. Approximately 25% will have cryptorchidism. Microscopic renal cysts, usually of the glomerular space, can also occur.

REFERENCE

Rabinowitz R. General consideration of congenital anomalies. In: Gillenwater JY, Grayhack JT, Howards SS, Duckett JW, eds. *Adult and Pediatric Urology*. 3rd ed. St. Louis, MO: Mosby; 1996.

DRIBBLING, POSTVOID

DESCRIPTION A complaint of loss of urine that occurs after completion of voiding, thought to be caused by retained urine in the urethra distal to the sphincter in men and retained urine in the vagina or urethral diverticulum in women. In men, it is a complaint associated clinically with BPH, following radical prostatectomy and stricture disease. Recent data suggests it may be a surrogate for median lobe hypertrophy in BPH.

REFERENCE

Ablove T. Post void dribbling: Incidence and risk factors. *Neurourol Urodyn*. 2010;29(3):432–436.

DROMEDARY HUMP

DESCRIPTION A normal anatomic variant of the left kidney consisting of a bulge of normal tissue that mimics a tumor. Dromedary humps arise from the superolateral aspect of the left kidney secondary to molding by the spleen. It is usually mistaken for tumors on IVP or kidney tomograms. Other imaging, such as CT, MRI, or renal US can be used to rule out a tumor. Appropriately named after the dromedary camel. (See also Section II: “Renal Pseudotumor.”)

REFERENCE

Dyer R, Chen MY, Zagoria RJ. Classic signs in uroradiology. *Radiographics*. 2004;24:S247–S280.

DROOPING LILY SIGN

DESCRIPTION Excretory urographic description for the lower pole moiety in a duplicated collecting system. The nonfunctioning upper pole produces a mass effect that pushes the lower pole downward. The lower pole ureter tends to be orthotopic, whereas the upper pole is typically ectopic.

REFERENCE

Amis ES, Newhouse JH. *Essentials of Uroradiology*. 1st ed. Boston, MA: Little Brown; 1991:263.

DROP METASTASES

DESCRIPTION Upper tract urothelial tumors can spread to urothelial structures that are either distal or proximal to the primary tumor called "drop metastases." Upper urinary tract tumors frequently are multiple or can occur synchronously with bladder tumors. This may reflect the propensity of neoplastic cells to flow down from the renal pelvis or reflux from the bladder to the ureter, forming an invasive implant. However drop metastases may be difficult to differentiate from separate primary lesions. Recurrent bladder tumors tend to cluster around the ureteral orifice of an affected ureter. This suggests their origin as metastases from the original primary tumor.

REFERENCE

Ritchei, JP, Kantoff PW. Malignancies of the renal pelvis and ureter. UpToDate.com, Accessed March 8, 2014.

DRUG ERUPTION, FIXED

DESCRIPTION This sharply localized dermatitis characteristically recurs at the same site each time the offending drug is administered (penis is most common site), with an acute phase followed by desquamation and hyperpigmentation. Symptoms usually appear after 6 hr, although lesions can occur 24–48 hr later. A macrophage migration inhibition factor (MIF) assay is essential for diagnosis.

Common medications responsible include phenolphthalein, trimethoprim-sulfamethoxazole, antipyrine, quinine, tetracycline, salicylates/NSAIDS, and hydroxyzine hydrochloride. Discontinuation of the drug causing the reaction results in complete resolution of the fixed drug eruption. Supportive topical therapy (steroids) is used, as needed.

REFERENCE

Cohen HA, Barzilai A, Matalon A, et al. Fixed drug eruption of the penis due to hydroxyzine hydrochloride. *Ann Pharmacother*. 1997;31(3):327–329.

DYSFUNCTIONAL VOIDING

DESCRIPTION Dysfunctional voiding is characterized by an intermittent and/or fluctuating flow rate due to involuntary intermittent contractions of the periurethral striated muscle during voiding in neurologically normal individuals. Although dysfunctional voiding is not a very specific term, it is preferred to terms such as "nonneurogenic neurogenic bladder". Other terms such as " idiopathic detrusor sphincter dyssynergia," or "sphincter overactivity voiding dysfunction," may be preferable. However, the term dysfunctional voiding is very well established. The condition occurs most frequently in children. While it is felt that pelvic floor contractions are responsible, it is possible that the intraurethral striated muscle may be important. It was originally described by Hinman and Bauman in 1973 after a review of similar reported cases. Upper tract damage can occur. Diagnosis is through

videourodynamics. (See also Section II: “Hinman Syndrome [Hinman–Allen Syndrome].”)

REFERENCE

Abrams P, Cardozo L, Fall M, et al. The standardisation of terminology in lower urinary tract function: report from the standardisation sub-committee of the International Continence Society. *Urology.* 2003;61(1):37–49.

DYSGERMINOMA

DESCRIPTION Malignant tumor of the ovary, which is roughly the counterpart of seminoma of the testes, occurring in children and young women. It is occasionally seen in gonadal dysgenesis or testicular feminization syndrome. Patients may present with pelvic mass or abdominal pain. Pure dysgerminomas do not secrete tumor markers such as AFP or hCG.

TREATMENT

- Surgical resection for local disease
- Radiation therapy or chemotherapy for advanced disease

REFERENCE

Berek JS. Ovarian cancer. In: Hacker NF, et al., eds. *Essentials of Obstetrics and Gynecology*. 2nd ed. Philadelphia, PA: Saunders; 1992.

DYSORGASMIA

DESCRIPTION Pain with orgasm can affect both men and women and is not well described in the literature. In men, largely self-limited if experienced after radical prostatectomy (RP). Some reports that seminal vesiculectomy following RP can be therapeutic. In women often manifests as lower abdominal cramping pain.

REFERENCE

Matsushita K, Tal R, Mulhall JP. The evolution of orgasmic pain (dysorgasmia) following radical prostatectomy. *J Sex Med.* 2012;9(5):1454–1458.

DYSPAREUNIA, MALE (PARTNER DYSPAREUNIA, HISPAREUNIA)

DESCRIPTION The term dyspareunia means “bad or difficult mating.” Pain with intercourse is traditionally ascribed to female complaints. Recently cases of male dyspareunia and penile trauma have been reported due to the use of alloplastic materials in female pelvic floor surgery. This is often related to prominence or frank exposure of the sling material. Changes of male sexual function and particularly pain after sling insertion in their female partners may be due to sling exposure. Sexual interest and drive may be negatively influenced and can be treated effectively by correcting the sling exposure.

REFERENCE

Mohr S, Kuhn P, Mueller MD, et al. Painful love-”hispareunia” after sling erosion of the female partner. *J Sex Med.* 2011;8(6):1740–1746.

DYSRAPHISM, SPINAL

DESCRIPTION Most common cause of neurogenic bladder dysfunction in childhood, dysraphism is defined as failure of closure of the vertebral canal during embryonic development, leading to spinal cord dysfunction. The most common dysraphism, myelodysplasia, includes meningoceles, myelomeningoceles, and lipomeningoceles. Reflux, continence, sexuality, and bowel function are often important issues with these patients. Many rarer forms also exist, including tight filum terminale, dermoid cysts, and aberrant nerve roots with varying levels of resulting dysfunction. (See also Section II: "Myelodysplasia [Myelomeningocele], Urologic Considerations"; Section III: "Tethered Cord Syndrome.")

REFERENCE

Bauer SB, MacLellan DL. Neuropathic dysfunction of the lower urinary tract In: Wein AJ, et al., *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2012:3431–3456.

DYSTHYROIDISM (HYPO/HYPERTHYROIDISM) UROLOGIC CONSIDERATIONS

DESCRIPTION Thyroid disease (hyper/hypo) may occasionally be associated with male factor infertility and erectile dysfunction (ED). Hyperthyroidism is commonly associated with diminished libido (may be caused by increased circulating estrogen levels). In hypothyroidism, low testosterone secretion and elevated prolactin levels contribute to ED. Subclinical hypothyroidism does not impact semen parameters. In patients undergoing urologic surgery, they should be euthyroid prior to their intervention. Thyrotoxicosis or thyroid storm can present with fevers, tachycardia, confusion, and cardiovascular collapse. Hypothyroidism is generally associated with an increased sensitivity to medications such as anesthetic agents and narcotics; its severe form can be associated with myocardial dysfunction, coagulopathy, electrolyte imbalance, and decreased gastrointestinal motility.

REFERENCE

Vira MA, Steckel J. Core principles of perioperative care. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2012:159–176.

ECCHYMOSIS, FLANK

DESCRIPTION The presence of ecchymosis in the flank region (*Grey–Turner sign*) is a physical sign of retroperitoneal bleeding. Common associations may include renal trauma, ruptured abdominal aortic aneurysm, and acute pancreatitis.

REFERENCE

Bonani M, Franzen D, Anabitarte P, et al. Images in emergency medicine. Cullen's sign and Grey–Turner's sign. *Ann Emerg Med*. 2008;51(4):448–458.

ECHINOCOCCUS, RENAL

DESCRIPTION Renal hydatid disease is a parasitic tapeworm infestation that results in renal cysts that occupy space and cause local mass symptoms. This infection is caused by the larval stage of the cestode *Echinococcus granulosus*, whose definitive host is the dog and principal intermediate is the sheep. Common symptoms include flank pain, hematuria, and local pressure. The diagnosis of renal echinococcus requires a high index of suspicion and despite a complete clinical history, serologic, radiologic, and urine data, the yield is only 50%. Radiographic findings include a calcified, curvilinear cystic mass in the kidney. During cyst excision, great care must be taken to not spill or rupture the cyst, because the liberated parasites could be spread and cause anaphylaxis. (See also Section II: "Hydatid Cysts.")

SYNONYMS

- Cystic hydatid disease
- Hydatid cysts

TREATMENT

- Surgical excision of intact cyst, with care not to spill or rupture cyst (praziquantel and albendazole may be given preoperatively 7–10 days before surgery)
- Medical treatment is reserved for nonsurgical candidates (albendazole 400 mg twice daily for 1–6 mo)

REFERENCE

Angulo J, Sanchez-Chapado M, Diego A, et al. Renal echinococcosis: Clinical study of 34 cases. *J Urol*. 1997;157(3):787–794.

EDEMA, LOWER EXTREMITY, UROLOGIC CONSIDERATIONS

DESCRIPTION Edema of the lower extremity can present bilaterally or unilaterally and can have multiple urologic implications, depending on the clinical presentation. Unilateral edema in the peri- or postoperative period may be a manifestation of deep venous thrombosis or an expected result after lymphadenectomy. Bilateral edema may be a result of underlying congestive heart failure or generalized anasarca. Postoperative fluid management should be closely monitored with this finding. In endemic regions, filariasis may present with significant bilateral lower extremity edema.

CAUSES

- Anasarca
- Congestive heart failure
- Deep venous thrombosis
- Filariasis
- IVC thrombosis/obstruction
- Lymphadenectomy (retroperitoneal, pelvic, inguinal)
- Superficial thrombophlebitis
- Urinary obstruction/retention

REFERENCE

EDWARD SYNDROME

DESCRIPTION Also known as *trisomy* 18, it is the 2nd most common autosomal trisomy after Down syndrome. Characterized by structural heart defects, kidney malformations, esophageal atresia, omphalocele, facial clefts, diaphragmatic hernias, and genital hypoplasia among other signs. High incidence of urologic abnormalities noted with Horseshoe kidney in about 20% of cases; hydronephrosis, hypospadias, and cryptorchidism are also common. Up to 90% of patients die within the 1st yr of life, usually secondary to cardiopulmonary problems. Uterine and vaginal abnormalities are common in females.

REFERENCE

Surányi A, Bitó T, Vajda G, et al. Unusual clinical history of a male infant with Edwards syndrome. *Pathol Oncol Res*. 2009;15(1):147–152.

EJACULATION, FEMALE

DESCRIPTION So called “female ejaculation" is the expulsion of fluid by females during or before sexual orgasm. The prevalence varies between 10–54%, whereas the amount of fluid ranges from 1–900 mL. These are natural sexual responses but may also represent symptoms of urinary incontinence. The term encompasses various phenomena with different underlying pathophysiologic mechanisms noted below:

- Vaginal lubrication: Vaginal fluid is forced out by the contractions of perivaginal muscles.
- Ejaculation orgasm: Either orgasmic expulsion of whitish secretion produced by the “female prostate” (known as Skene glands), or orgasmic expulsion of diluted urine (squirting/gushing), or the combination of both.
- Coital incontinence: Leakage of urine that occurs during penetrations or orgasm. Usually associated with stress or urge urinary incontinence.

Penetration incontinence occurs more frequently and is usually caused by SUI. Urodynamic diagnoses of detrusor overactivity (DO) and SUI are observed in orgasmic incontinence. (See also Section I: “Incontinence, Urinary, Adult Female”; Section II; “Coital Incontinence [Coital Leakage/Intercourse Incontinence].”)

REFERENCE

Pastor Z. Female Ejaculation Orgasm vs. Coital Incontinence: A Systematic Review. *J Sex Med.* 2013;10(7):1682–1691.

EJACULATION, PAINFUL

DESCRIPTION The incidence of pain associated with or immediately after ejaculation is 1–9.7%. Can be iatrogenic, physiologic, or psychogenic in nature. Ejaculatory or postorgasmic pain is believed to arise from interference with the coordination of the muscles of the pelvic floor and male genitalia that are responsible for semen transport during ejaculation. (See also Section II: "Dysorgasmia.")

CAUSES
- Prostatitis
- BPH
- Ejaculatory duct obstruction (EDO) by calculi
- Postoperative (prostatectomy)
- Antidepressants
- Pudendal neuropathy

TREATMENT
- α-Adrenoreceptor inhibitors
- Rule out and treat EDO
- Pudendal nerve injection with bupivacaine/triamcinolone
- Pudendal nerve release

REFERENCE

Ilie CP, Mischianu DL, Pemberton RJ. Painful ejaculation. *BJU Intern.* 2007;99(6):1335–1339.

EJACULATORY ANHEDONIA

DESCRIPTION A rare condition, affecting males predominantly, in which ejaculation occurs without an accompanying sense of orgasmic pleasure. Most common causes are psychogenic in origin or related to SSRI antidepressants usage.

REFERENCE

Lue TF, Giuliano F, Montorsi F, et al. Summary of the recommendations on sexual dysfunctions in men. *J Sex Med.* 2004;1(1),6–23.

EJACULATORY DUCT OBSTRUCTION (EDO)

DESCRIPTION EDO is found in 1–5% of infertile men, producing azoospermia with low-volume, acidic ejaculate that has no fructose. Obstruction of the ejaculatory ducts prevents the emission of sperm and seminal fluid into the posterior urethra during ejaculation. Congenital causes include utricular, müllerian and wolffian duct cysts; ejaculatory duct stenosis; or atresia. Acquired causes include infection, calculus, trauma, or prior instrumentation. Physical exam is usually normal, with the occasional palpable midline mass or dilated seminal vesicles. Semen analysis shows low-volume, acidic pH, absent fructose, and failure to coagulate. Transrectal ultrasonography (TRUS) demonstrates a cystic midline

structure within the prostate, with dilated seminal vesicles. When TRUS is equivocal, additional tests include TRUS-guided seminal vesicle aspirate (demonstrates abundant spermatozoa) or vasography. (See also Section II: "Vasography, Technique and Indications.")

TREATMENT
Through transurethral resection of ejaculatory duct, in which the ejaculatory duct cyst is unroofed by transurethral resection at the level of the verumontanum, until efflux from the ducts is seen.

REFERENCE
Fisch H, Lambert SM, Goluboff ET. Management of ejaculatory duct obstruction: Etiology, diagnosis, and treatment [review]. *World J Urol.* 2006;24(6):604–610.

ELECTROEJACULATION

DESCRIPTION Procedure for obtaining sperm for ARTs in patients who cannot ejaculate on their own, such as SCI patients, typically used after failure of vibratory penile stimulation. General anesthesia is used, except in cases of complete spinal cord compromise. A transrectal probe is positioned with electrodes against the anterior rectal wall. Electrical stimulation causes erection and ejaculation in >80% of patients. Rectosigmoidoscopy is performed before and after the procedure to rule out rectal injury. Blood pressure monitoring is essential during the procedure for patients who may have autonomic dysreflexia.

REFERENCE
Sønksen J, Ohl DA. Penile vibratory stimulation and electroejaculation in the treatment of ejaculatory dysfunction. *Int J Androl.* 2002;25(6):324–332.

ELECTROMYOGRAPHY, EXTERNAL SPHINCTER

DESCRIPTION Generally, electromyography is the measurement of bioelectric potentials generated by the depolarization of muscle. During urodynamics, the activity of the external sphincter can be monitored by transperineal needle electrodes or surface electrodes. During filling, there should be increase in activity, which will reach maximum near capacity. During voiding, there should be a persistent cessation of sphincter activity. At the end of the voiding phase, sphincter activity returns to baseline. To assess external sphincter activity, the patient may be asked to interrupt voiding in the middle of the stream, at which point there should be an abrupt increase in sphincter activity sufficient to stop the flow. Abnormal EMG patterns may be detected in detrusor sphincter dyssynergia and dysfunctional voiding. EMG monitoring may also be used during biofeedback therapy for dysfunctional voiding.

REFERENCE
Voiding disorders and bladder outlet obstruction. In: Chapple CR, MacDiarmid SA, Patel A, eds. *Urodynamics Made Easy.* 3rd ed. London, Elsevier, 2009:127–148.

ELEJALDE SYNDROME

DESCRIPTION Also known as *acrocephalopolydactylous dysplasia,* this exceedingly rare

autosomal recessive syndrome is characterized by craniosynostosis and fibroblast hyperproliferation in organs such as skin, liver, kidney, and pancreas. High birth weight, craniofacial dysmorphism, polydactyly, hepatomegaly, splenic abnormalities, hypertrophic kidneys, and renal cysts are also common features.

REFERENCE

Silhánová E, Plevová P, Curík R, et al. 2006. Elejalde syndrome: A case report. *Am J Med Genet Part A*. 140A:2223–2226.

ELEPHANTIASIS, SCROTUM (ELEPHANTIASIS SCROTI)

DESCRIPTION Also called *elephantiasis scroti*, this is the end result of a progressive lymphatic obstruction in which the scrotum and penis can become massively enlarged. Usually associated with filariasis, which is uncommon in the United States. Differential includes filariasis and other infectious causes; malignancy obstructing lymphatics; surgical therapy that has altered lymphatic drainage; and idiopathic, such as Milroy disease. (See also Section I: "Edema, External Genitalia (Lymphedema, Peno-Scrotal Edema)"; Section II: "Filariasis, Urologic Considerations." and (Image ☼))

TREATMENT

- Drug therapy for any infectious etiology
- Surgery for resection of redundant scrotum with flap coverage of testes

REFERENCE

Zacharakis E, Dudderidge T, Zacharakis E, et al. Surgical repair of idiopathic scrotal elephantiasis. *South Med J*. 2008;101(2):208–210.

ENCOPRESIS, UROLOGIC CONSIDERATIONS

DESCRIPTION Children who are incontinent of stool, even with minor fecal soiling, usually have significant constipation. Occult pathology of the bowel or nervous system must be ruled out as a possible cause. Encopresis usually is helpful in identifying bowel problems when the parents of a child are not aware of the child's stool habits. Children with encopresis and constipation have a higher risk of UTI and urinary incontinence. Successful treatment of functional constipation will usually resolve encopresis and associated urinary tract problems. The term "fecal incontinence" is sometime used as the preferred term over encopresis or soiling. (See also Section I: "Dysfunctional Elimination Syndrome.")

TREATMENT

- Diet changes
- Laxatives, stool softeners
- Toilet schedules

REFERENCE

Combs AJ, Van Batavia JP, Chan J, et al. Dysfunctional elimination syndromes: how closely linked are constipation and encopresis with specific lower urinary tract conditions? *J Urol*. 2013;190(3):1015–1020.

ENCRUSTED CYSTITIS AND PYELITIS

DESCRIPTION Inflammatory ulcerating condition of the bladder and pelvicalyceal system characterized by encrustation with calcium deposits (struvite and apatite calculi). Commonly, the presence of alkaline urine, infection by urea-splitting Corynebacterium urealyticum (formerly called Corynebacterium group D2), a multiple antibiotic-resistant urea-splitting bacterium, is the most frequently incriminated agent, and recent history of a urologic procedure in a immunocompromised host (eg, renal transplant) is found. Clinical manifestations of encrusted cystitis are often fever, dysuria, and gross hematuria. Encrusted pyelitis may have lumbar pain in addition to symptoms of encrusted cystitis. Imaging on US and CT may reveal calcific encrustations with thick-walled edema of the bladder and/or pyelocaliceal system. Calcifications seldom appear on plain abdominal radiographs unless in association with staghorn calculi. The endoscopic appearance is of calcified white plaques adherent to a severely inflamed and ulcerated mucosa. Bacteriologic diagnosis of *Corynebacterium* group D2 requires culture for 48–72 hr at 37°C on media enriched with 5% carbon dioxide (CO_2) or sheep blood agar.

TREATMENT

- Treat *Corynebacterium* infection according to sensitivity; most are susceptible to vancomycin and teicoplanin (not available in the United States)
- Acidify urine through irrigation (eg, Suby's solution G, Thomas C24) or PO acetohydroxamic acid
- Remove calcified plaques where bacteria harbor: TUR, endoscopic

REFERENCE

López-Medrano F, García-Bravo M, Morales JM, et al. Urinary tract Infection due to Corynebacterium urealyticum in kidney transplant recipients: An underdiagnosed etiology for obstructive uropathy and graft dysfunction—Results of a prospective cohort study. *Clin Infect Dis*. 2008;46(6):825–830.

ENCRUSTED URETERAL STENT

DESCRIPTION Indwelling ureteral stents are routinely employed for the prevention and treatment of ureteral obstruction secondary to intrinsic, extrinsic, and iatrogenic causes such as urolithiasis, strictures, and/or malignancy. Indwelling time seems to affect rate of encrustation: Consensus is that stents should not remain in place longer than 3–6 mo (high degree of variation according to different series). Reported risk factors include urinary tract infections (urease-producing microorganisms) and pregnancy. Site and degree of encrustation will guide the appropriate approach (single or multimodal). For this purpose several grading systems and management algorithms have been proposed. Good communication between physician and patient is imperative in preventing this challenging complication.

REFERENCE

Acosta-Miranda AM, Milner J, Turk TM. The FECal Double J: A simplified approach in the management of encrusted and retained ureteral stents. *J Endourol*. 2009;23(3):409–415.

ENDOCARDITIS (SBE) PROPHYLAXIS, UROLOGIC CONSIDERATIONS

DESCRIPTION Antimicrobial prophylaxis for genitourinary procedures solely to prevent infectious endocarditis is no longer recommended by the American Heart Association; the risk of adverse events exceeds the benefit. The AHA guidelines concluded that bacteremia resulting from random daily activities are much more likely to cause infectious endocarditis than bacteremia associated with GU procedures.

REFERENCE

Wilson W, Taubert KA, Gewitz M, et al. Prevention of infective endocarditis: Guidelines from the American Heart Association: a guideline from the American Heart Association Rheumatic Fever, Endocarditis, and Kawasaki Disease Committee, Council on Cardiovascular Disease in the Young, and the Council on Clinical Cardiology, Council. *Circulation*. 2007;116(15):1736–1754.

ENDOCERVICOSIS, BLADDER

DESCRIPTION This rare mucinous analog of endometriosis histologically demonstrates glandular lesions characterized by a prominent endocervical-type epithelium that may involve the urinary bladder in women of reproductive age. Typically are observed in the posterior wall of the bladder or the dome. Lack of awareness may lead to confusion with an adenocarcinoma, particularly of urachal origin given its location. Because of this, patients are presumed to have an underlying malignancy and are treated surgically. Patients usually present with irritative voiding symptoms and pelvic pain. Transurethral resection or partial cystectomy is curative, and close follow-up is recommended.

REFERENCE

Young RH. Tumor-like lesions of the urinary bladder. *Modern Pathology*. 2009;22:s37–s52.

ENDOMETRIOSIS, GENITOURINARY

DESCRIPTION Endometriosis is a condition in which endometrial tissue is found outside the uterus. Most common sites in the GU system are the bladder and distal 3rd of ureter. Symptoms are variable and may include dysmenorrhea and pelvic pain with or without urinary symptoms of gross hematuria, flank pain, frequency, or urgency. Urinary symptoms may or may not be exacerbated with menstruation, and the classic symptom of “cyclical hematuria” is uncommon. Diagnosis is through IVP/CT urography and urine analysis, laparoscopy to inspect the pelvis and obtain tissue biopsy, or cystoscopy or ureteroscopy to evaluate hematuria and obtain biopsy.

TREATMENT

- Hormonal therapy with oral contraceptives, danocrine, or GNRH agonists
- Surgery when medical treatment fails
- Partial cystectomy, ureterolysis, ureteric reimplantation, or ureteral stenting may be performed

REFERENCE

Umar SA, MacLennan GT, Cheng L. Endometriosis of the ureter. *J Urol.* 2008;179(6):2412.

EPCA-2 (EARLY PROSTATE CANCER ANTIGEN)

DESCRIPTION A nuclear matrix protein (NMP) that showed promise as a new serum-based biomarker of prostate cancer, which was postulated to have better sensitivity and specificity than PSA. However, at the request of the authors (Leman et al., *Urology*. 2012;79(2):490), the original article was retracted as there were inconsistencies in validating their data collection.

REFERENCE

Leman ES, Cannon GW, Trock BJ, et al. EPCA-2: A highly specific serum marker for prostate cancer. *Urology*. 2007;69:714–720.

EPIDIDYMAL CYST

DESCRIPTION Epididymal cysts tend to occur in the head of the epididymis and may be mistaken for a testicular mass. They are increased in male offspring of mothers who used DES during pregnancy. They are often asymptomatic. The distinction between a spermatocele and an epididymal cyst is based on size; epididymal cystic masses > 2 cm are called spermatoceles. Spermatoceles are always located superior to the testis and are palpated as distinct from the testis, which differentiates them from hydroceles. Transscrotal ultrasound is diagnostic and no treatment is necessary. (See also Section I: "Scrotum and Testicle, Mass" and "Spermatocele"; Section II: "Epididymal Cystadenoma/Papillary Cystadenoma.")

REFERENCE

Eyre RC. Evaluation of nonacute scrotal pathology in adult men. www.UpToDate.com. Wolters Kluwer, Accessed April 1, 2014.

EPIDERMOID CYST, TESTICLE

DESCRIPTION Epidermoid cysts account for ~1% of testicular tumors. Producing keratinizing, stratified, squamous cell–lined cysts supported by fibrous tissue, these cysts are considered special cases of teratoma, but are not truly considered a teratoma since only a single germinal layer and not the required 2 layers is represented. Benign in behavior; scrotal US is suggestive of the diagnosis but not usually definitive. (See also Section I: "Scrotum and Testicle, Mass.")

TREATMENT

- Inguinal orchiectomy
- Some advocate organ-sparing surgery if the diagnosis is definitively proven by frozen section

REFERENCE

Heidenreich A, Engelmann UH, Vietsch HV, et al. Organ preserving surgery in testicular epidermoid cysts. *J Urol.* 1995;153(4):1147–1150.

EPIDIDYMAL CYSTADENOMA/PAPILLARY CYSTADENOMA

DESCRIPTION This is a benign tumor that accounts for 1/3 of all primary epididymal

tumors. Epididymal cystadenomas are seen in up to 2/3 of patients with von Hippel–Lindau disease and are often bilateral with this syndrome. They have a cystic appearance on ultrasound and can be up to 6 cm. Cut surface is gray-brown and contain fluid. The histologic appearance is that of dilated tubules with a single or double layer of cuboidal or low columnar epithelium. Rarely can be mistaken for metastatic RCC. Papillary cystadenomas are benign and generally asymptomatic and no treatment is required. (See also Section I: "Scrotum and Testicle, Mass," "Spermatocele," and "Von Hippel–Lindau Disease/Syndrome" and Section II: "Epididymal Cysts.")

EPIDIDYMIS, METASTASIS TO

DESCRIPTION Extremely rare, with primary sites reported to include colon, stomach, kidney, prostate, carcinoid, and pancreatic tumors. Prognosis is related to that of the primary disease. Patients can present with pain and swelling or as an incidental finding on orchiectomy for prostate cancer. 4 mechanisms for spread have been proposed, including direct extension, retrograde venous extension, retrograde lymphatic extension, and arterial embolism.

REFERENCE

Powell BL, Craig JB, Muss HB. Secondary malignancies of the penis and epididymis: A case report and review of the literature. *J Clin Oncol*. 1985;3:110–116.

EPIDIDYMIS, OBSTRUCTION

DESCRIPTION A cause of obstructive azoospermia. Most common cause is vasectomy, which results in a fixed obstruction and elevated vessel pressures resulting, in the blowout of the epididymal tubules. Other causes include trauma, congenital malunion of the vas and epididymis, infection, inflammatory damage to the epididymis, and idiopathic. Epididymovasostomy is the treatment of choice. (See also Section I: "Infertility, Urologic Considerations" and "Vas Deferens, Congenital Absence"; Section II: "Azoospermia.")

REFERENCE

Kim ED, Winkel E, Orejuela F, et al. Pathological epididymal obstruction unrelated to vasectomy: Results with microsurgical reconstruction. *J Urol*. 1998;160(6, Part 1):2078–2080.

EPITHELOID HEMANGIOMA, PENIS AND SCROTUM

DESCRIPTION Rare vascular lesion, typically arising on the head and distal extremities, whose pathogenesis is not fully understood. Genital involvement has rarely been reported. These lesions do not recur following excision and no metastasis has been reported.

Macroscopically, the lesions are described as an inflammatory red to brown nodule. Microscopically, the lesions are characterized by endothelial cells arranged in nests surrounded by immature vessels and eosinophilic cell infiltrate. Differential diagnosis includes epithelioid hemangio-endothelioma, epithelioid hemangiosarcoma, Kimura's disease, and bacillary angiomatosis. Treatment is local excision.

REFERENCE

Ismail M, Damato S, Freeman A, et al. Epithelioid hemangioma of the penis: case report and review of literature. *J Med Case Rep*. 2011;5:260.

ERECTILE DYSFUNCTION INVENTORY OF TREATMENT SURVEY (EDITS)

DESCRIPTION A validated satisfaction questionnaire for both patient (11 items) and partner (5 items) based on their subjective evaluation of the treatment for ED. Few of the disease-specific instruments used to assess ED address sexual dysfunction related quality of life, psychosocial impact, and satisfaction. EDITS attempts to address both patient and partner satisfaction with ED treatment, in addition to sexual functioning.

REFERENCE

Althof SE, Corty EW, Levine SB, et al. EDITS: Development of questionnaires for evaluating satisfaction with treatments for erectile dysfunction. *Urology*. 1999;53(4):793–799.

ERECTION HARDNESS SCORE (EHS) FOR ED

DESCRIPTION The EHS was developed as a single-item, patient-reported outcome to quantify erection hardness data. It is easy to use and highly responsive to treatment. Psychometric analysis supports its use as a simple, valid, reliable, and responsive tool for the assessment of erection hardness in clinical research.

REFERENCE

Mulhall JP, Goldstein I, Bushmakin AG, et al. Validation of the erection hardness score. *J Sex Med*. 2007;4(6):1626–1634.

ERYSIPELAS, EXTERNAL GENITALIA

DESCRIPTION Superficial bacterial infection of the dermis with marked dermal lymphatic involvement. The irritation afflicts extremes of ages, and the most common site of involvement is the face. Typically heralded by pain, superficial erythema, and plaque-like edema with a sharply defined margin to normal skin, it may often be described as a *peau d'orange* appearance. The clinician must differentiate erysipelas from cellulitis and Fournier gangrene (exclusion of this diagnosis is a priority in all cutaneous infections of the external genitalia). It is usually caused by Group A hemolytic streptococcus (eg, *S. pyogenes*), or rarely *S. aureus*.

TREATMENT

- Mild infection: PO penicillin, macrolides, or clindamycin
- Severe infection: Parenteral penicillin or vancomycin

REFERENCE

Link RE. Cutaneous disease of the external genitalia. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2012:416–467.

ERYTHEMA MULTIFORME (EM), EXTERNAL GENITALIA

DESCRIPTION EM is a common acquired blistering skin condition that affects all age groups, ethnicities, and sex. EM minor is a mild subtype that usually is confined to skin and oral involvement. EM major (Stevens–Johnson syndrome) affects skin and often other mucoepithelial-lined surfaces including the eyes, oral cavity, and external genitalia. The hallmark of EM is a target lesion, a circular erythematous macular lesion resembling a bulls-eye, commonly occurring on the hands. Painful rash is characteristic, and macules, papules, urticaria, vesicles, bullae, purpura, or petechiae are pleomorphic. In EM major, large tracts of skin and oral mucosa may be denuded, along with conjunctivitis, and GU and upper GI involvement. HSV is the most common cause but virtually any infectious agent or drug can cause EM. Main differential is toxic epidermal necrolysis.

TREATMENT

- EM minor: Wet compress with topical astringent, topical acyclovir (for HSV-related EM)
- EM major (Stevens–Johnson syndrome): Hospitalization required, nutrition, hydration, aggressive topical nursing care equivalent to burn protocols

REFERENCE

Fine JD. Blistering diseases. In: Kerdel FA, FJimenez-Acosta, eds. *Dermatology: Just the Facts.* New York, NY: McGraw-Hill; 2003:143–145.

ERYTHRASMA

DESCRIPTION Superficial, asymptomatic cutaneous infection by the diphtheroid Corynebacterium minutissimum. Physical exam reveals sharply delineated, round to oval patches with scales in the intertriginous or interdigital regions. Wood's lamp exam reveals coral-red fluorescence. Histologically, only the stratum corneum is affected, with all other layers normal. More common in tropical climates. Despite there being no consensus on the ideal treatment for the condition, usually it consists of topical or oral antibiotic therapy for 14 days (erythromycin or tetracycline). Recent evidence suggests single-dose clarithromycin may be an alternative regimen.

REFERENCE

Blaise G, Nikkels AF, Hermanns-Lê T, et al. Corynebacterium-associated skin infections. *Int J Dermatol.* 2008;47(9):884–890.

EXCRETORY UROGRAM, INTRAOPERATIVE ("ON TABLE IVP"/"SINGLE-SHOT IVP")

DESCRIPTION The preferred imaging study for renal trauma is contrast-enhanced CT, and the indications for intraoperative excretory urography is uncommon. However, a "single-shot" IVP may be performed in a setting in which renal trauma is suspected during abdominal

exploration for a trauma patient too unstable for CT. A single film is shot on the operative table at 10 min after administration of 2 mL/kg of IV contrast. An abnormal or inconclusive study should prompt renal exploration to complete staging of the renal injury and perform appropriate repairs; a properly performed study can potentially reduce the need for renal exploration by 32%. The study is also valuable in confirming the presence of a normal contralateral renal unit before renal exploration.

EXPRESSED PROSTATIC SECRETIONS (EPS)

DESCRIPTION EPS represents prostatic fluid expressed after vigorous prostatic massage. Evaluation of this fluid is part of the Stamey test used in the evaluation of prostatitis. Note that prostate massage is contraindicated in the setting of acute bacterial prostatitis. The WBC count in an EPS for a diagnosis of chronic bacterial prostatitis (NIH category II) is >10 WBCs/hpf (40× objective) or clumping of WBCs with the presence of oval fat bodies and a positive EPS bacterial culture. NIH category III prostatitis is divided into IIIa and IIIb, based on whether greater or fewer than 10 WBCs are seen on microscopic exam of the EPS, respectively. The pH of prostatic fluid increases with infection (6.5–>8.0).

REFERENCE

Nickel JC, Shoskes D, Wang Y, et al. How does the premassage and postmassage 2-glass test compare to the Meares-Stamey 4-glass test in men with chronic prostatitis/chronic pelvic pain syndrome? *J Urol.* 2006;176(1):119–124.

EXSTROPHY–EPISPADIAS COMPLEX (EEC)

DESCRIPTION EEC is a rare congenital urogenital anomaly with a spectrum of complexity ranging from epispadias and bladder exstrophy to cloacal exstrophy. Incidence of bladder exstrophy is between 1 in 10,000 and 1 in 50,000 live births, with a male preponderance. The risk of recurrence in a family is 1 in 100. The condition is believed to be due to failure of the cloacal membrane to be reinforced by in growth of mesoderm, therefore preventing the medial migration of mesenchymal tissues and lower abdominal wall development. The defective cloacal membrane ruptures prematurely and, depending on the stage of development during which the rupture occurs, a variant of the complex will result. Most anomalies relate to defects of the abdominal wall, bladder, genitalia, pelvic bones, rectum, and anus. (See also Section I: “Epispadias” and “Exstrophy, Bladder [Classic Exstrophy].”)

TREATMENT

- Immediate at birth: Prevent irritation/trauma to exposed mucosal surfaces (eg, Saran wrap)
- Surgical reconstruction must consider appearance of lower abdomen and genitalia, pelvic bone reconstruction, continence, and subsequent sexual function

- Staged reconstruction: Early bladder, abdominal wall, and posterior urethral closure, with osteotomy. Epispadias repair between 6 and 12 mo. Reconstruction of continent bladder neck and ureteric reimplantation, usually at age 4–5 yr.
- Single-stage reconstruction

REFERENCE

Eeg K, Khoury A. The exstrophy-epispadias complex. *Curr Urol Rep*. 2008 9;9(2):158–164.

EXTRAGONADAL GERM CELL TUMORS (EGCT)

DESCRIPTION Rare entity representing 3–5% of all GCT. There is a clinical association with Klinefelter syndrome, and testicular ultrasound is necessary to exclude primary tumor. Extragonadal GCT must show no evidence of a primary tumor in the testes (or ovaries in females). Primary EGCT are usually midline in decreasing frequency: Mediastinum, retroperitoneum, pineal/suprasellar region, and the sacrococcygeal region. All tumor types are reported, with nonseminomatous being most common. They can present with wide local invasion and advanced metastasis with few symptoms. Transformation to sarcoma or carcinomas has been reported with chemotherapy resistance common in these cases. 1 or both testicular tumor markers (β-HCG or AFP) are elevated in 85% of cases of EGCT. Management of EGCT parallels that of metastatic testicular GCT, however EGCT have a worse prognosis.

TREATMENT

- Surgical excision, if feasible
- Chemotherapy, irradiation, or combination based on histology and in general follows testicular cancer regimens.

REFERENCE

Bokemeyer C, Nichols CR, Droz JP, et al. Extragonadal germ cell tumors of the mediastinum and retroperitoneum: Results from an international analysis. *J Clin Oncol*. 2002;20(7):1864–1873.

EXTRAMAMMARY PAGET DISEASE, UROLOGIC CONSIDERATIONS

DESCRIPTION A rare cutaneous malignancy arising from ducts of apocrine-gland bearing skin, most often involving the anogenital region, more commonly seen in the elderly and women. The condition presents with a well-circumscribed erythematous scaly patch, similar in appearance to mammary Paget disease. There is a 10% association with underlying metachronous GU (most commonly bladder) or GI (most commonly colon) malignancy. Differential diagnoses include SCC in situ or malignant melanoma.

TREATMENT

- Surgical excision with wide margin, Moh's microsurgical excision, or radiation
- Screen for occult GU and GI malignancy

REFERENCE

Smoller BR. Paget's disease. In: Morgan MB, et al. eds. *Deadly Dermatologic Diseases:*

Clinicopathologic Atlas and Text. New York, NY: Springer; 2007:43–50.

EXTRAMEDULLARY HEMATOPOESIS, RENAL

DESCRIPTION This is a reactive process in response to the failure of hematopoiesis in the bone marrow. It commonly occurs in organs such as the liver, spleen, and kidney. It commonly occurs in the presence of myelofibrosis (most common), chronic myeloproliferative disorder, polycythemia vera, and essential thrombocytosis. Considered a cause of renal pseudotumor, a renal mass in association with any of these disorders should raise the possibility of an extramedullary hematopoiesis. Biopsy confirmation is usually required.

REFERENCE

Bhatt S, MacLennan G, Dogra V. Renal pseudotumors. *AJR Am J Roentgenol.* 2007;188:1380–1387.

EXTRAVASATION DURING UROLOGIC SURGERY

DESCRIPTION Perforation of the urinary tract can lead to extravasation of irrigation fluid, contrast, urine, and/or blood. This can lead to flank pain, fever, and ileus, depending on the site of perforation. Potential complications include formation of an infected urinoma or hematoma. The extent of fluid collection can be documented by imaging studies in the form of CT scan or ultrasound. Fluid collections due to extravasation can be managed with either observation, when appropriate, or drainage.

REFERENCE

Lytton B, Weiss RM, Green DF, et al. Complications of ureteral endoscopy. *J Urol.* 1987;137:649–653.

FABRY DISEASE/SYNDROME

DESCRIPTION Fabry disease is a rare X-linked disorder caused by deficient activity of the lysosomal enzyme α-galactosidase A. Progressive accumulation of the substrate Globotriasylceramide (Gb3) leads to progressive organ failure and premature death. Findings consist of multiple cutaneous lesions (*angiokeratoma corporis diffusum*), corneal opacification, and progressive renal insufficiency. Symptoms of severe burning pain in the extremities usually begin in the 1st decade, and can cause febrile episodes. Cardiovascular effects include coronary artery disease and congestive heart failure. Renal failure leads to uremia and hypertension in the 3rd–5th decades.

TREATMENT

- Enzyme replacement therapy with agalsidase-β
- Renal replacement therapy

Mehta A, Ricci R, Widmer U, et al. Fabry disease defined: Baseline clinical manifestations of 366 patients in the Fabry Outcome Survey. *Eur J Clin Invest.* 2004;34(3):236–242.

FAMILIAL TESTOTOXICOSIS

DESCRIPTION Cause of isosexual precocity inherited as an autosomal dominant pattern. Markedly elevated levels of testosterone with normal LH secretion are noted, but sleep-associated LH pulses are absent. Patients typically present with family history and testicular enlargement around ages 3–4. Diagnosis is a lack of testosterone response to hCG administration, despite a measurable increase in LH. Hyperplasia of Leydig cells is noted on biopsy. Ketoconazole, antiandrogens, aromatase inhibitors, and/or medroxyprogesterone acetate have been used in different combinations with success.

REFERENCE

Lenz AM, Shulman D, Eugster EA, et al. Bicalutamide and third-generation aromatase inhibitors in testotoxicosis. *Pediatrics*. 2010;126(3):728–733.

FANCONI SYNDROME

DESCRIPTION An acquired or inherited disorder characterized by abnormalities of renal proximal tubular function, including glucosuria, phosphaturia, aminoaciduria, and bicarbonate wasting. The aminoaciduria is generalized, and defects in uric acid, water, potassium, and sodium absorption can also occur. The basic abnormality is unknown. Acquired disease is caused by 6-mercaptopurine or outdated tetracycline, renal transplantation, multiple myeloma, amyloidosis, intoxication with heavy met als or other chemical agents, and vitamin D deficiency. Inherited form (usually seen with other disorders) presents in infancy with proximal tubular acidosis, hypophosphatemic rickets, hypokalemia, polyuria, and polydipsia. In the nephropathic form, failure to thrive and growth retardation are common, with progressive renal failure. Diagnosed by demonstrating the abnormalities of renal function.

TREATMENT

- Sodium bicarbonate for acidosis
- Renal transplantation has been successful

FATTY CASTS

DESCRIPTION Fatty casts contain fat globules embedded within tubular epithelial casts. Polarized light microscopy may reveal a "Maltese cross" appearance if cholesterol is present. These are most commonly associated with nephrotic syndrome, but occasionally seen also after long-bone fractures, and classically seen in fat embolism syndrome.

FECAL INCONTINENCE, UROLOGIC CONSIDERATIONS

DESCRIPTION Numerous studies have identified a relationship between urinary symptoms and fecal incontinence. In the Nurses' Health Study of over 64,000 women ages 62–87 yr, the prevalence of dual urinary and fecal incontinence was 7% (fecal incontinence alone was 4% and urinary incontinence alone was 38%). Risk factors for dual incontinence in women included: age >80 yr; depression; neurologic disease; functional limitations, multiparity; and childbirth of a heavy newborn (>9.5 lb). As compared with white race, black race was associated with a decreased risk of dual incontinence. Men and women with overactive bladder (OAB) are significantly more likely to report having chronic constipation or fecal incontinence compared with those without OAB. Causes of fecal incontinence include vaginal delivery with anal sphincter damage, surgical trauma, diabetes mellitus, decreased rectal compliance (ulcerative proctitis and radiation proctitis), impaired rectal sensation (diabetes, MS, demential, meningo-myelocele, SCI), fecal impaction, medications, food intolerance, and idiopathic. Stool impaction with the rectum in close proximity to the bladder can elicit local, spontaneous neurogenic activity, prompting urinary frequency, and/or incontinence.

In children with fecal incontinence urinary tract issues are often present. Up to 29% children have daytime wetting and 34% have nighttime wetting. Urinary tract infections have been associated with fecal incontinence in 33% of girls and 3% of boys. (See also Section I: "Dysfunctional elimination Syndrome.")

FECALURIA

DESCRIPTION The presence of fecal matter passed per urethra, suggestive of a fistulous communication between the urinary and intestinal tract. Etiologies include a pathologic process such as Crohn's disease, diverticulitis, and cancer, or iatrogenic causes such as perineal surgery, radiation, or trauma. Initial evaluation should include cross-sectional imaging in the form of CT (modality of choice) or MRI to help delineate the location of the fistulous tract.

REFERENCE

Rovner ES. Urinary tract fistulae. In: Wein AJ, Kavoussi LR, Novick AC, et al. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2012:2223–2261.

FEMALE HYPOACTIVE SEXUAL DESIRE DISORDER

DESCRIPTION Female sexual dysfunction has been defined in the DSM-IV manual as persistently or recurrently deficient (or absent) sexual fantasies and desire for sexual activity that causes marked distress or interpersonal difficulty. Prevalence ranges from 39–43% in recent studies. The operational definition of desire/arousal is currently being reviewed. The DSM-V is scheduled for release in May 2013.

CAUSES

- Hormonal: Hypothalamic/pituitary dysfunction, menopause, chronic oral contraceptive pills
- Musculogenic: Hyper- or hypotonicity of pelvic floor
- Neurogenic: Spinal cord injury (SCI), other nervous system disorders (DM, CVA)
- Psychogenic: Relationship problems, poor body image/self-esteem, mood disorders
- Vasculogenic: Poor blood flow, pelvic atherosclerosis, trauma
- Iatrogenic: Medication use (antidepressants, esp. SSRIs)

TREATMENT

- Education: Desire-arousal-orgasm axis, emotional intimacy, anatomic explanation
- Lifestyle modification: Stress management, adequate rest, regular exercise
- Pharmacology: Topical/vaginal estrogens improve vaginal lubrication and atrophy, but have shown no effect on sexual desire. Testosterone (300 μg/d transdermally) has shown benefit in postmenopausal women, but remains unapproved by the FDA. Phosphodiesterase inhibitors have not shown improvement for women with diminished desire.

FEMALE SEX FUNCTION INDEX (FSFI)

DESCRIPTION The FSFI is a validated questionnaire to assess female sexual function. It was developed for the specific purpose of assessing domains of sexual functioning (eg, desire,

sexual arousal, lubrication, orgasm, satisfaction, pain) in clinical trials. It was not designed for use as a diagnostic instrument and should not be used as a substitute for a complete sex history in clinical evaluation. The FSFI was validated in 2 groups of women, including subjects with sexual arousal disorder (determined by history) and age-matched controls. The instrument reliably differentiated these 2 groups in all domains of sexual functioning.

REFERENCE

FEMINIZING GENITOPLASTY

DESCRIPTION Surgical treatment of ambiguous genitalia may be indicated in the genetic female with virilization of external genitalia for psychosocial development. The most common cause of virilization in the female newborn is CAH. Feminizing genitoplasty may be performed early in infancy to facilitate gender-appropriate upbringing, or delayed until adolescence when the patient can participate in consent. Extensive counseling of parents of any infant with a disorder of sexual development is critical before considering genitoplasty. Goals of surgery are to create external genitalia with an esthetic female appearance, and permit sexual function and, if possible, fertility. (See also Section I: “Disorders of Sexual Development [DSD]”; Section II: “Congenital Adrenal Hyperplasia.”)

REFERENCE

Schober JM. Feminization (surgical aspects). In: Stringer MD, Oldham KT, Mouriquand PDE, eds. *Pediatric Surgery and Urology: Long-term Outcomes*. New York, NY: Cambridge; 2006:595–611.

FERTILE EUNUCH DISEASE/SYNDROME

DESCRIPTION Syndrome characterized by prepubertal androgen deficiency or eunuchoidism caused by LH deficiency but pubertal or almost adult-sized testes in which advanced-stage spermatogenesis is present due to relatively preserved FSH secretion. However, spermatogenesis usually is not completely normal in these men, and they are not fertile. Because there is only relative gonadotropin deficiency and some spermatogenesis is present, treatment with LH-like activity (hCG) stimulates Leydig cell testosterone production and ameliorates androgen deficiency, stimulating spermatogenesis sufficient for induction of fertility.

FIBROEPITHELIAL POLYP, GENITOURINARY

DESCRIPTION The most common benign ureteral tumor, arising from the upper 3rd of the ureter, these polyps resemble a smooth nodule or may be pedunculated. Histologically, a

central fibrous core surrounded by normal or hyperplastic urothelium is seen. Patients present with flank pain and hematuria, usually as a young adult. Radiographically, smooth filling defects are seen. Hydroureteronephrosis can be seen, as well as ureteral intussusception. They can recur locally.

TREATMENT
Ureteroscopic resection, open ureterotomy with polypectomy, or partial ureterectomy if the diagnosis cannot be confirmed preoperatively.

REFERENCE
Sun Y, Xu C, Wen X, et al. Is endoscopic management suitable for long ureteral fibroepithelial polyps? *J Endourol.* 2008;22(7):1459–1462.

FIBROEPITHELIAL POLYP, PENIS

DESCRIPTION Fibroepithelial polyp of the penis is a rare benign finding with only a few reported cases in the literature. Most of these patients have a long-term history of usage of condom catheter. The possible pathogenesis is a chronic irritation. Histologically, it contains loosely arranged spindle to stellate cells in a collagenous and edematous stroma with variable-sized thin-walled vascular channels, with perivascular hyalinization. Fibroepithelial polyp of prepuce differ from conventional cutaneous fibroepithelial polyp (also known as a skin tag, acrochordon) by being larger, having notable stromal edema and vascular dilatation and by having greater stromal cellularity. Skin tags are usually <5 mm in size and they have a predilection for the axilla, neck, and eyelid.

REFERENCE
Banerji JS, Shah S, Kekre NS. Fibroepithelial polyp of the prepuce: A rare complication of long-term condom catheter usage. *Indian J Urol.* 2008;24(2):263–264.

FIBROUS HAMARTOMA OF INFANCY

DESCRIPTION Uncommon subcutaneous and lower dermis proliferative lesion, with the most common anatomic distributions being the axillary region, upper arm, upper trunk, inguinal region, and external genital area. Vast majority of cases occur within the 1st year of life and present as a painless nodule with rapid growth. There is a predilection for boys with a male/female ratio of 2.4. Local excision is curative with very low recurrence rates even in the setting of incomplete excision. Should be in the differential diagnosis of genital masses. Histologically, it demonstrates mature adipose tissue, scattered mesenchymal cells, and bundles of fibrous tissue.

REFERENCE
Dickey GE, Sotelo-Avila C. Fibrous hamartoma of infancy: Current review. *Pediatr Dev Pathol.* 1999;2(3):236–243.

FIBROUS PSEUDOTUMOR OF TESTICULAR TUNIC

DESCRIPTION Reactive, benign process of the tunica vaginalis in which multiple firm

nodules occur in the tunica or within it. Presents as testicular mass, sometimes associated with trauma or hydrocele. It may be difficult to distinguish from malignant processes. Histologically, the lesion can demonstrate granulation tissue, fibroblastic proliferation, and nodules of hyalinized tissue.

SYNONYMS
- Fibrous pseudotumors
- Multiple fibromas of the tunica vaginalis testes
- Reactive periorchitis

TREATMENT
Orchiectomy usually necessary to confirm diagnosis but local excision can be considered.

REFERENCE
Parker PM. Benign fibrous pseudotumor of tunica vaginalis testis. *Urology*. 2006;68(2):427:e17–e19.

FIDUCIAL MARKERS

DESCRIPTION External beam radiotherapy is a valuable tool in the treatment of localized prostate cancer; however, this form of treatment is limited by the difficulty in accurately localizing the prostate gland. The implantation of intraprostatic gold fiducial markers under transrectal ultrasound guidance is a safe outpatient procedure that aids in identifying anatomic structures of interest during radiation treatment (most importantly the prostate-rectal interface). Markers are usually cylindrical allowing ease of placement with a hollow bore needle. Surface features prevent migration. The preprocedure regimen is similar to transrectal ultrasound-guided prostate biopsy. Prophylactic antibiotics are administered, anticoagulant medications withheld 7 days before procedure, and cleansing enemas given to empty the rectal vault. Patients are routinely placed in the left lateral decubitus position. A transrectal ultrasound probe is utilized to calculate prostate volume in the standard fashion. Local anesthesia should be placed bilaterally at the level of the neurovascular bundles. An 18-gauge implant needle is utilized to place markers into the right base, left base, and apex of the prostate. Standard prostate biopsy discharge instructions are given. Patients then follow up with a radiation oncologist for pretreatment planning imaging and subsequent radiotherapy (Image ☼).

REFERENCE

FILARIASIS, UROLOGIC CONSIDERATIONS

DESCRIPTION Filariasis is transmitted by mosquitoes, most commonly *Wuchereria bancrofti,* endemic to areas of the Caribbean, Venezuela, Colombia, the Guianas, Brazil, Central America, sub-Saharan Africa, North Africa, Turkey, and Asia. Filariasis (Bancroftian, Malayan, and Timorian) is often asymptomatic. The parasite causes symptoms due to inflammation and dysfunction of the lymphatics, where the adult worms develop (fever, headache, myalgia, and

lymphadenitis). In lymphatic disease, manifestations usually occur 3 mo–1 yr after acquisition. Occasionally, moderate lymphadenopathy, particularly involving the inguinal lymph nodes, occurs. Inflammation of the lymphatics of the extremities and genitalia leads to retrograde adenolymphangitis. Epididymitis, orchitis, and funiculitis can also occur, along with fever, chills, and other nonspecific systemic symptoms. Lymphatic dysfunction, with resulting chronically progressive edema of the limbs and genitalia, is relatively infrequent in children. Elephantiasis can result from fibrosis caused by chronic dysfunction of the lymphatic channels. Chyluria can occur as a manifestation of bancroftian filariasis. Lymphatic filariasis must be diagnosed clinically because serologic assays are not available, and in elephantiasis the microfilariae may no longer be present. Eosinophilia of 25% frequently occurs in early disease. (See also Section I: “Edema, External Genitalia [Peno-Scrotal Edema].”)

TREATMENT

- Diethylcarbamazine citrate is the drug of choice. The late obstructive phase of the disease is not affected by chemotherapy.
- Ivermectin, an investigational drug in the United States, is effective against the microfilariae of *W. bancrofti*, but is unlikely to become the drug of choice for lymphatic filariasis.
- Complex, decongestive physiotherapy may be effective in treating elephantiasis.
- Plastic surgical repair of the genitalia gives variable results.
- Chyluria originating in the bladder responds to fulguration; chyluria originating in the kidney is much more difficult to correct.

FINE-NEEDLE ASPIRATION (FNA) OF PROSTATE

DESCRIPTION In the detection of prostatic carcinoma, FNA cytology of the prostate has largely been replaced by core needle biopsy of the prostate, as cytology does not allow Gleason grading. However, the detection rates of prostatic carcinoma by either core needle biopsy or FNA appear to be comparable. Largely replaced by core biopsy techniques. (See also Section II: “Cytology, Prostate.”)

FISH: URINARY FLUORESCENT IN SITU HYBRIDIZATION (UROVYSION TEST)

DESCRIPTION Cytogenetic studies describe frequent alterations in chromosomes 1, 3, 4, 7, 8, 9, 11, 17, etc., in urothelial cancers. FISH allows the study of genetic abnormalities within formalin-fixed cancer cells. UroVysion test is a multitargeted multicolor FISH assay that stains exfoliated cells from urine specimens with probes for chromosome 3, 7, 17, and 9p21, and

allows observation of the cells under a fluorescence microscope. Reported sensitivity of UroVysion test is higher for higher-grade tumors (83–97%) and CIS (almost 100%), than with low-grade low-stage tumors (36–57%). Specificity is high (89–96%). A false-positive UroVysion test may predict for future recurrence or simply reflect urothelium that is at risk of malignant transformation. A study to detect bladder cancer in a high-risk population showed FISH to be comparable to urine cytology with a higher false-positive rate (Image ☼).

REFERENCE

FISTULA, ENTEROVESICAL

DESCRIPTION An abnormal fistulous communication between the bowel (such as *colovesical fistula*) and urinary bladder due to various inflammatory and neoplastic causes. Usually presents with fecaluria, pneumaturia, and/or recurrent UTI. Gouverneur syndrome is the "classic" presentation of vesicoenteric fistula: Suprapubic pain, urinary frequency, dysuria, and tenesmus. Causes include inflammatory processes (diverticulitis, Crohn disease), neoplasia (bladder or colonic malignancy), and radiation. Diagnosis may require the use of ≥1 diagnostic modality, such as endoscopy (colonoscopy, cystoscopy), contrast imaging (cystography, contrast enema), and CT. Oral-activated charcoal and urinary straining on a stone filter may be useful, as well as the Bourne test. (See Section II: "Bourne Test" and (Image ☼).)

TREATMENT

- Surgical resection of fistulous tract with or without fecal and urinary diversion
- Fecal and urinary diversion
- Conservative management

REFERENCES

Kavanagh D, Neary P, Dodd JD, et al. Diagnosis and treatment of enterovesical fistulae. *Colorectal Dis.* 2005;7(3):286–291.

Randall D, Tittle V, Wright G, et al. Crohn's disease and enterovesical fistulae: Common things are common. *Br J Hosp Med.* 2010;71(9):530–531.

FISTULA, RECTOURETHRAL

DESCRIPTION An abnormal communication between the urethra and rectum, almost exclusively in males due to anatomic reasons. May present with passage of urine in the stools. Causes include iatrogenic (transurethral instrumentation and surgery, RP, cryosurgery or radiotherapy of prostate), trauma, inflammatory bowel disease, pelvic infection, or congenital malformations. Diagnosis may require the use of ≥1 diagnostic modality, such as endoscopy (proctosigmoidoscopy, cystoscopy), contrast imaging (urethrocystography, contrast enema), CT or MRI with endorectal coil.

TREATMENT

- Surgical excision of fistulous tract, urethral repair, tissue interposition, and rectal closure with possible use of advancement flaps or vascularized flaps
- Posterior trans-ano-sphincteric, transperineal, transanal, transabdominal approaches described
- Possible vascularized flaps include dartos flap, scrotal myocutaneous flap, island groin flap, gracilis flap, and omental flap
- Proximal bowel diversion usually recommended
- Fecal and urinary diversion
- Conservative management

REFERENCE

Gupta G, Kumar S, Kekre NS, et al. Surgical management of rectourethral fistula. *Urology.* 2008;71(2):267–271.

FISTULA, URETEROARTERIAL

DESCRIPTION May present with microscopic hematuria, intermittent gross hematuria, or torrential hemorrhage in extremis. Risk factors include prior pelvic surgery, chronic indwelling ureteric stents, pelvic irradiation, and arterial disease. Rarely, this is the etiology for hematuria, but should be considered for persistent gross hematuria or torrential bleeding in a patient with associated risk factors. General guideline to reduce the risk of fistula development is the use of the smallest caliber, softest flexible ureteric stent for the shortest possible period. In a stable patient, CT, retrograde uretero-pyelography, and angiography may be nonspecific but aid in planning reconstructive options. Removal of stents and ureteral manipulation should be performed with caution and in a facility where immediate angiographic or surgical intervention is available.

TREATMENT

- If stable, early reconstruction of vascular and urinary structures:
  - Vascular occlusion with angiographic stent or embolization; *OR*
  - Vascular ligation, with or without bypass procedure
  - Ureteric reconstruction by uretero-ureterostomy, cutaneous ureterostomy, transverse ureteroureterostomy, or ureteric ligation with nephrostomy
  - Endovascular stenting is increasingly used in lieu of open techniques due to the high operative risk and comorbidities in patients with ureteroarterial fistulas
- In the actively bleeding patient, immediate surgical intervention or angiographic occlusion

REFERENCE

Fox JA, Krambeck A, McPhail EF, et al. Ureteroarterial fistula treatment with open surgery versus endovascular management: Long-term outcomes. *J Urol.* 2011;185(3):945–950.

FISTULA, VESICOCUTANEOUS

DESCRIPTION An abnormal communication between the urinary bladder and skin of the anterior abdominal wall or groin. The fistulous tract that exists after placement of suprapubic catheter is the most commonly seen. Causes include urinary diversion (suprapubic

catheterization); infected urachal remnant; radiation; dehiscence of urinary bladder repair, usually in association with complex pelvic and bowel surgery; and others (bladder calculus, inguinoscrotal hernia). Diagnosis is made by cystoscopy and CT contrast imaging.

TREATMENT

- Surgical excision of fistulous tract and repair
- Conservative management

REFERENCE

Kobori Y, Shigehara K, Amano T, et al. Vesicocutaneous fistula caused by giant bladder calculus. *Urol Res.* 2007;35(3):161–163.

FISTULA, VESICOUTERINE

DESCRIPTION Rare, usually caused by simultaneous injury to uterus and bladder. Urinary incontinence is present if the cervical os is incompetent. The lesion occasionally presents with Youseff syndrome, which describes menouria (urine in menses), cyclic hematuria with apparent amenorrhea, infertility, and urinary incontinence in patients with prior low-segment cesarean section, which is the most common cause. Other causes include uterine rupture during obstructed labor tearing the posterior bladder wall, placenta percreta, and others (IUD, brachytherapy, traumatic bladder catheterization). Differential diagnosis includes vesicovaginal fistula (VVF), ureterovaginal fistula (UVF), and endometriosis of bladder. Diagnosis is made by cystography, cystography, and contrast CT or MRI of the pelvis, which helps exclude concomitant ureteric injury and (Image ☼).

TREATMENT

- Prolonged bladder drainage with or without fulguration of fistula tract, and await spontaneous resolution. Option of hormonal induction of menopause to help induce involution of uterus
- Surgical management:
  - Hysterectomy and bladder repair, if fertility not desired
  - Uterine-sparing surgery if fertility preferred

REFERENCE

Rao MP, Dwivedi US, Datta B, et al. Post caesarean vesicouterine fistulae-Youssef syndrome: Our experience and review of published work. *ANZ J Surg.* 2006;76(4):243–245.

FISTULA, VESICOVAGINAL AND URETEROVAGINAL

DESCRIPTION Vesicovaginal fistula (VVF) is an abnormal communication between the urinary bladder and vagina that may be associated with urethrovaginal fistula (UVF) in 12%. Patients present with continuous urinary incontinence, with prior history of recent pelvic or gynecologic surgery or other causes.

CAUSES

- Iatrogenic following obstetric and gynecologic surgery
- Pelvic malignancy
- Pelvic radiation

- Inflammatory: Pelvic and abdominal infections
- Penetrating trauma
- Foreign body

DIAGNOSIS
- Pelvic exam
- Cystoscopy with cystography and/or retrograde pyelography
- Contrast imaging (eg, CT urography with delayed imaging, CT cystogram)

TREATMENT
UVF should be managed by reimplantation of ureter. Before undergoing a ureteral reimplantation, a patient can be temporarily managed with ipsilateral percutaneous nephrostomy drainage. Small VVFs may close spontaneously with prolonged bladder drainage. If a VVF requires primary repair, a multilayer closure can be achieved through a transvaginal or transabdominal approach. If diagnosis has been delayed by several weeks, then it is prudent to delay repair for approximately 3 mo. Principles of VVF repair include:
- Demarcation of fistula
- Approaches: Transvaginal, transabdominal
- Excise diseased tissue if present
- Multilayered closure with interrupted absorbable sutures and nonoverlapping suture lines
- Consider vascularized tissue interposition (eg, Martius flap, pedicled muscle flap, peritoneal flap, omental flap), especially when quality of tissue healing is expected to be compromised (eg, previous failed repair, postirradiation)
- Adequate postoperative bladder drainage (Image ☼)

REFERENCE
Wong MJ, Wong K, Rezvan A, et al. Urogenital fistula. *Female Pelvic Med Reconstr Surg.* 2012;18(2):71–78.

FITZ–HUGH–CURTIS SYNDROME

DESCRIPTION Perihepatic inflammation and right upper quadrant pain found in a small segment of patients with pelvic inflammatory disease (PID). PID is a polymicrobial, ascending, postcoital infection of the upper genital tract usually associated with gonorrhea, *Chlamydia*, *Haemophilus,* or *Streptococcus*. Fitz–Hugh–Curtis is believed to occur from transperitoneal or vascular dissemination of PID organisms, often suggesting a profound pathologic inoculation. The diagnosis is confirmed by laparoscopic visualization of filmy perihepatic adhesions.

REFERENCE
Torrealday S, Torrealday S. Benign gynecologic conditions. *Surg Clin North Am.* 2008;88:245–264.

FLANK HERNIA FOLLOWING NEPHRECTOMY

DESCRIPTION True flank hernias are rare, and careful palpation may reveal the fascial edges. Obesity, immunocompromised states, and poor nutrition status are risk factors. Flank

"bulge" is not a true hernia and is believed to be due to laxity of the transversus and oblique abdominal wall muscles, caused by injury to the intercostal nerves, in particular the 11th intercostal, and accentuated in part by unopposed contraction of contralateral musculature. About 15% of patients develop flank bulge after a retroperitoneal flank incision. Care should be taken to avoid injury to the intercostal nerves during incision and closure.

TREATMENT

- Flank hernia: Generally should be repaired with or without mesh, based on surgeon preference, patient comorbidities, and clinical factors specific to each case. If the patient is asymptomatic or debilitated, a corset can be offered
- Flank bulge: Repair seldom needed except for cosmesis (Image ☼)

REFERENCE

Baumann DP, Butler CE. Lateral abdominal wall reconstruction. *Semin Plast Surg.* 2012;26(1):40–48.

FLUORESCENT (BLUE LIGHT) CYSTOSCOPY

DESCRIPTION Drugs for fluorescence diagnosis, such as 5-ALA and hexaminolevulinate (Hexvix [EU]; Cysview [US]), are placed intravesically where they preferentially stain malignant or premalignant tissue and emit a red fluorescence when excited by visible blue light. Requires specific endoscopic equipment fitted with the blue light, camera, and lens with filters. In a meta-analysis, fluorescent cystoscopy (92.4%) sensitivity was superior to white-light cystoscopy (60.5%). Reports have shown fluorescent cystoscopy to be limited by specificity, which is equivalent to or poorer than white-light cystoscopy. Fluorescent cystoscopy can enhance the diagnosis of patients with positive cytology and no visible lesion on white-light cystoscopy, and for surveillance of high-risk bladder cancers and/or CIS (Image ☼).

REFERENCE

FOLEY Y-V PYELOPLASTY

DESCRIPTION The triangular portion of the Y is incised in the dependent portion of the pelvis, with the apex pointing to the stricture, and a single 2- to 3-cm longitudinal incision is continued from the apex anteriorly down across the stricture to complete the Y configuration. The apex of the triangle flap is then brought down to the lower apex of the ureterotomy and a 5-0 chromic stay suture is placed. Interrupted 5-0 chromic sutures are used to complete the anastomosis. Used for UPJ repair.

FORDYCE SPOTS (ECTOPIC SEBACEOUS GLANDS), PENIS

DESCRIPTION Fordyce spots are ectopic sebaceous glands on the lips and buccal and genital mucosa (glans penis and labia minor). Lesions are multicentric and whitish to yellowish in color with slightly elevated papules and plaques with sizes ranging from 1–3 mm. Most patients are asymptomatic but some consider receiving treatment for cosmetic reasons since the lesions do not resolve spontaneously. CO_2 laser can be used for ablation.

REFERENCE

Lee JH, Lee JH, Kwon NH, et al. Clinicopathologic manifestations of patients with Fordyce's Spots. *Ann Dermatol.* 2012;24(1):103–106.

FOREIGN BODY, BLADDER AND URETHRA

DESCRIPTION Almost every conceivable foreign body has been inserted into the urinary bladder and urethra, usually for erotic exploration and curiosity, or because of psychiatric disorder or mental retardation. Amazonian parasitic catfish (*Candiru*) and leeches have also been reported to enter the urethra while bathing in a river. Symptoms include urethral pain, dysuria, urinary retention, hematuria, frequency, painful voiding, weak stream, and sepsis. (See also Section II: "Bladder Filling Defect.")

TREATMENT

- Urethral foreign body: Endoscopic retrieval may be easier by 1st pushing back into bladder; alternatively, urethrotomy, especially when periurethral abscess is present
- Bladder foreign body: Endoscopic retrieval; open vesicostomy (Image ☼)

REFERENCE

Van Ophoven A, DeKernion JB. Clinical management of foreign bodies of the genitourinary tract. *J Urol.* 2000;164(2):274–287.

FORMALIN INSTILLATION, INDICATIONS AND TECHNIQUE

DESCRIPTION Formalin (37% formaldehyde) instillation is an option in the management of hemorrhagic cystitis which is refractory to more conservative measures. A solution of 50 mL of 1% formalin is typically utilized. Instillation must be done in the operating room and usually with general anesthesia, as the procedure may cause pain. Prior to instillation, a cystogram must be performed to rule out vesicoureteral reflux. If reflux is present, then formalin may cause damage to the ureters and intrarenal collecting system. Use of Fogarty catheters to occlude the ureters in the case of reflux has been reported. Bladder fibrosis with reduced capacity and increased urinary frequency is a common outcome after formalin instillation. (See also Section II: Cystitis, Hemorrhagic.")

REFERENCE

Joseph CM, Bowley DM. Formalin treatment of refractory hemorrhagic cystitis. *J Pediatr Urol.* 2005;1(5):365–367.

FOSSA NAVICULARIS DIVERTICULUM

DESCRIPTION 1st described by Guérin (1864), this diverticulum is partially separated from the urethra by a septum. On voiding cystorethrogram (VCUG), it can often be seen as a small spherical collection of contrast at the tip of the penis. It is thought to result embryologically from an incomplete breakdown of the wall between the ectoderm and the urethra being formed by the urethral folds. It is a common anatomic finding with rare symptoms, including dysuria, gross hematuria, spotting of blood, or hematospermia.

SYNONYMS

- Valve of Guérin
- Dorsal urethral diverticulum
- Lacuna magna

TREATMENT

If symptomatic, the wall can be divided with tenotomy scissors or under direct vision with a resectoscope.

REFERENCE

Seskin FE, Glassberg KI. Lacuna magna in 6 boys with postvoid bleeding and dysuria: Alternative approach to treatment. *J Urol.* 1994;152(3):980–982.

FOWLER SYNDROME (PRIMARY DISORDER OF URETHRAL SPHINCTER RELAXATION)

DESCRIPTION This syndrome describes young women (usually under the age of 30) with idiopathic urinary retention and no evidence of neurologic disease. The classic patient will present with the inability to void for an entire day and will have a large volume of urine in her bladder. For diagnosis, a retained urine volume of 1 L or more and lack of sensation or urgency is necessary. EMG activity of the urethral sphincter indicates abnormally increased sphincter activity making appropriate relaxation difficult. There is an association with polycystic ovarian syndrome.

TREATMENT

Use of botulinum toxin, pharmacotherapy, and hormonal modulation have not proven to be successful. Sacral neuromodulation has proven to be successful. 1 study reported efficacy approaching 70%.

FOWLER–STEPHENS ORCHIOPEXY

DESCRIPTION This procedure is used in the treatment of high intra-abdominal testes. It

entails ligating the spermatic vessels and hinges on the premise that the testicle will survive from the vasal and cremasteric collaterals. The operation was originally described as a 2-stage procedure in which the vessels are divided, and then 6 mo later the testicle is brought down to the scrotum, after collaterals have become well developed. However, the procedure is now performed also a 1-stage procedure. Both techniques have a fairly high success rate, but 2-stage is reported to have a slightly better success rate (85% for 2-stage vs. 80% for 1-stage). It is now commonly performed using laparoscopy.

FRACTURE RISK ASSOCIATED WITH PROSTATE CANCER AND ANDROGEN DEPRIVATION THERAPY

DESCRIPTION Androgen deprivation therapy (ADT) for treatment of prostate cancer leads to a hypogonadal state. This state predisposes men to osteopenia or osteoporosis with subsequent increased risk of fracture. There is a direct correlation between length of time on ADT and risk of fracture. 1 study reported that after 5 yr on ADT, the risk of fracture rises nearly 7% compared to controls.

TREATMENT

Men being treated with ADT should be considered for a baseline DEXA scan to assess bone mineral density (BMD). Increased weight-bearing exercise and cessation of smoking should be encouraged. Also, calcium and vitamin D supplementation can help improve BMD. Daily supplementation of calcium (1,200 mg/d with most taken through dietary means) and vitamin D (1,000–1,200 IU daily) is recommended. Systemic therapy (bisphosphonate or denosumab) therapy has also been shown to play a role in the prevention of osteoporosis and reduce fracture risk. Densoumab is approved for men on ADT or with osteoporosis 60 mg SC Q 6 mo (Prolia). Bisphosphonates such as zoledronic acid (Reclast) can be given IV 5 mg/yr, alendronate (Fosamax, Fosamax Plus D) and risedronate (Actonel) are given orally weekly. Alternative dosing forms are given with the presence of bone metastasis to decrease skelet al related events (SRE). Densosumab (Xgeva) is given 4 mg SC monthly and zoledronic acid (Zometa) is administered IV 4 mg monthly.

FRAGILE X SYNDROME

DESCRIPTION The most common cause of inherited mental retardation. The affected gene encodes a protein known as FMR1, which is required for normal cognitive development. Facial dysmorphism and bilateral macro-orchidism (MO) are also seen. Measurement of testis size in mentally retarded males has been suggested as a simple screening test for this condition.

REFERENCE

Healy A, Rush R, Ocain T. Fragile X syndrome: an update on developing treatment modalities. *ACS Chem Neurosci.* 2011;2(8):402–410.

FRALEY SYNDROME

DESCRIPTION A condition in which vascular obstruction of the superior infundibulum might lead to hydrocalyx, bleeding, and intermittent flank pain or infection. Vessels causing obstruction may be arteries, veins, or both. Impaired drainage on delayed films or isotope renography must be confirmed before surgery. On ultrasound, diuretics will accentuate the caliectasis.

TREATMENT

Surgery can provide relief in severely symptomatic patients. Various techniques including infundibulo-infundibulostomy, infundibulopyelostomy, infundibulorrhaphy, and vasopexy have been reported to be successful in treating symptoms.

FRENCH CATHETER SCALE

DESCRIPTION Used to measure the outer diameter of catheters, cystoscopes, and other endoscopes. The diameter in millimeters of the instrument is determined by dividing the French size by 3 (eg, an 18 Fr catheter has a diameter of 6 mm). The system was introduced by a 19th century French medical instrument manufacturer. (See Section VII: "Catheter Guide.")

REFERENCE

FREQUENCY, URINARY

DESCRIPTION Urinary frequency is defined as the patient's perception that he/she voids too often by day. Although often associated with an overactive bladder and/or bladder outlet obstruction, urinary frequency is 1 of many complaints included in the nonspecific,

nondiagnostic symptom complex known as lower urinary tract symptoms or LUTS. Frequency is further categorized as 1 of the storage symptoms (experienced during the bladder filling phase or storage phase of micturition), as opposed to a voiding or postmicturition symptom.

REFERENCE
Haylen BT, de Ridder D, Freeman RM, et al. An International Urogynecological Association (IUGA)/International Continence Society (ICS) joint report of the terminology for female pelvic floor dysfunction. *Neurourol Urodyn.* 2010;29(1):4–20.

FREQUENCY–DYSURIA SYNDROME

DESCRIPTION Occurring in children and women, this is also referred to as the "urethral syndrome." Patients present with complaints of frequency and dysuria, but evaluation finds no infectious, anatomic, functional, or physiologic abnormalities. Because this term is so nonspecific, it is not a currently accepted meaningful term for diagnosis or treatment planning. In childhood, hypercalciuria was theorized and in adults, fastidial organisms were once thought to be the cause. (See also Section II: "Urethral Syndrome.")

REFERENCE
Brock JW III. The frequency and frequency dysuria syndromes of childhood: Hypercalciuria as a possible etiology. *Urology.* 1994;44(3):411–412.

FUHRMAN NUCLEAR GRADING CLASSIFICATION, RENAL CELL CARCINOMA (RCC)

DESCRIPTION A classification used to grade renal cell carcinoma, based on the concept that nuclear features correlate with survival, this scale consists of 4 grades based on size, contour, and conspicuousness of nucleoli. Large series have confirmed the correlation with survival. Grade 1 is round, uniform nuclei with minute or absent nucleoli. Grade 2 is slightly irregular nuclei about 15 μm, with nucleoli visible at 400×. Grade 3 is more irregular nuclei, 20 μm, with nucleoli visible at ×. Grade 4 is similar to grade 3, with bizarre features noted. There is a noted correlation between tumor size and Fuhrman grade (Image ☼).

REFERENCE
Zhang, C, Li X, Hao H, et al. The correlation between size of renal cell carcinoma and its histopathological characteristics: a single center study of 1867 renal cell carcinoma cases. *BJU Int.* 2012;110(11 Pt b):E481–E485.

FUNGURIA

DESCRIPTION Funguria (sometimes called candiduria due to the frequent finding of *Candida* species) refers to fungus in the urine (fungal UTI of the bladder or kidney). It is a common nosocomial infection. Organisms are typically *C. albicans* and *C. glabrata*. Other organisms can involve the kidney through disseminated infection (eg, *Aspergillus* sp., *Fusarium*, others). Associated predisposing factors include catheters, antibiotics, diabetes mellitus, hospitalization, and immunocompromised states. Urinary colonization is usually

asymptomatic, whereas invasive fungal infection of bladder may have irritative voiding symptoms. Fungal infection of the kidney is often hematogenous in origin from other sources or the GI tract; fungal renal or perirenal abscesses present similar to pyelonephritis. Infection should be suspected when urine microscopy shows budding fungal hyphae. Positive fungal urine culture demands investigation. (See Section I: "Fungal Infections, Genitourinary"; Section II: "Bezoars, Genitourinary.")

TREATMENT

- Remove predisposing factors
- Asymptomatic candiduria rarely requires antifungal therapy (unless in the setting of neutropenia, neonates, or urinary tract instrumentation):
  - Fluconazole, 200–400 mg (3–6 mg/kg) daily for several days if urinary tract instrumentation is planned
- Symptomatic cystitis: Fluconazole 200 mg (3 mg/kg) daily for 2 wk or amphotericin B 0.3–0.6 mg/kg for 1–7 days; or flucytosine 25 mg/kg QID for 7–10 days. Amphotericin B bladder irrigation is recommended only for fluconazole-resistant organisms (eg, *C. krusei* and *C. glabrata*).
- Symptomatic infections should be treated
- Bezoars should be removed

FUNICULITIS

DESCRIPTION Inflammation of the spermatic cord; the entire spermatic cord is subject to inflammatory diseases, usually as a result of trauma or pyogenic bacteria, and this condition is occasionally seen with scrotal inflammation or epididymitis. Parasitic infections (filariasis, schistosomiasis) can also induce inflammatory changes in the cord (see also Section I: "Spermatic Cord Mass and Tumors.")

REFERENCE

GAMETE INTRAFALLOPIAN TRANSFER (GIFT)

DESCRIPTION GIFT is similar to IVF but is rarely performed currently with the improved pregnancy rates in IVF. Current indications for GIFT include patients who have ethical or religious objections to IVF and prefer fertilization in vivo rather than in vitro. Technique involves inducing superovulation, aspirating the ovarian follicles vaginally under US guidance, and identifying eggs. Sperm is collected and capacitated. During laparoscopy, sperm and eggs are mixed and transferred into 1 of the fallopian tubes, allowing in vivo fertilization. A 20–30% pregnancy rate per cycle is reported. Limitations of GIFT are that patients must have normal fallopian tubal function and the procedure requires general anesthesia and laparoscopy.

GANGLIONEUROBLASTOMA, ADRENAL

DESCRIPTION Extremely rare tumor originating from neural crest cells, this ganglioneuroblastoma exists on a spectrum of diseases between neuroblastoma and ganglioneuroma. It is varied in appearance and malignant potential, with prognosis and behavior depending on histology. The cause is unknown, but it has been reported to have a genetic predisposition. Treated by surgical resection.

REFERENCE

Koike K, Iihara M, Kanbe M, et al. Adult-type ganglioneuroblastoma in the adrenal gland treated by a laparoscopic resection: Report of a case. *Surg Today*. 2003;33(10):785–790.

GANGLIONEUROMA, ADRENAL

DESCRIPTION A tumor originating from neural crest cells, this is the benign counterpart of neuroblastoma. It does not metastasize, but can locally recur after resection and be locally aggressive. It most commonly presents as an abdominal mass. Histologically, the lesion is composed of ganglion cells with abundant cytoplasm and large nuclei. Treatment is by surgical resection.

REFERENCE

Gupta R, Dinda AK. Ganglioneuroma of the adrenal gland: A rare case. *Indian J Pathol Microbiol.* 2007;50(4):782–784.

GARTNER DUCT CYST

DESCRIPTION Gartner duct cyst is a rare congenital anomaly associated with urogenital maldevelopment, usually located posterior to the urinary bladder. It is caused by a failure of separation of the ureteric bud from the mesonephric duct that leads to persistence of the

Gartner duct, often with cystic dilation. The Gartner duct is associated with müllerian duct developmental anomalies and with abnormal ureteric development, such as ureteric ectopia. Abnormal development of the ureter also results in the maldevelopment, ectopic kidney, or absence of the ipsilateral kidney. The usual presentation is an anterior vaginal wall mass with ipsilateral renal dysgenesis with or without urinary incontinence. Differential diagnoses include ectopic ureterocele, urethral diverticulum, urethral tumor, Skene gland cyst or abscess, and vaginal wall cysts or tumors. Diagnosis is by voiding cystourethrography, cystourethroscopy, and retrograde pyelography (maldevelopment of the bladder neck and hemitrigone; ureteric ectopia or ureteric dysgenesis) and renal and bladder US (a cystic lesion behind bladder is suggestive of Gartner duct cyst and ipsilateral renal agenesis or ectopic kidney). Treated surgically, depending on anatomic anomalies, including transvaginal or transabdominal excision of the Gartner duct and closure of any associated urinary fistula; reconstruction of bladder neck and urethra; reimplantation of ipsilateral and/or contralateral ureter; or removal of nonfunctioning renal unit and ectopic ureter.

Dwyer PL, Rosamilia A. Congenital urogenital anomalies that are associated with the persistence of Gartner's duct: A review. *Am J Obstet Gynecol.* 2006;195:354–359.

GENITAL AROUSAL DISORDER (PERSISTENT)

DESCRIPTION A condition of spontaneous, intrusive, and frequently unwanted genital arousal including throbbing, pulsating, and tingling. These feelings are usually unrelated to any sexual arousal. Physical arousal caused by this syndrome can persist for extended periods of time. Orgasm can sometimes provide temporary relief, but within hours the symptoms return suddenly. Can be debilitating and negatively impact quality of life.

TREATMENT

While not well-studied, treatment options include antidepressants, antiandrogens, psychotherapy, and local nerve blocks (pudendal nerve is most frequent)

GENITAL PIERCING, UROLOGIC CONSIDERATIONS

DESCRIPTION Urologists must be familiar with complications from genital piercing. In males, piercings include the penile glans, shaft, urethra, scrotum, and combinations of these. Clitoral and labial piercings in females are also performed. Complications include:

- Transmission of infectious agent: HIV, Hepatitis B and C, or an STD
- Bleeding
- Cellulitis
- "Cutting-out" or erosion
- Priapism
- Paraphimosis

- Recurrence of condyloma acuminatum
- Urethral fistula
- Hypertrophic scarring, keloid
- Trauma during intercourse: To partner or self

REFERENCE

Anderson W, Summerton DJ, Sharma DM, et al. The urologist's guide to genital piercing. *BJU Int.* 2003;91(3):245–251.

GENITAL SKIN LOSS

DESCRIPTION Genital skin loss is most commonly iatrogenic, as the result of skin debridement for necrotizing infection by polymicrobial infection—Fournier gangrene. Skin loss can less commonly occur as a result of trauma, usually blunt; however, penetrating trauma can also result in skin loss. Burns can also lead to genital skin loss.

TREATMENT

Reconstruction is the mainstay of treatment. In the case of skin loss to due to debridement for infection, the infection should be stable prior to reconstruction being performed. In the case of penile skin loss in an uncircumcised male, a flap using redundant foreskin may be harvested to address a proximal defect. Flaps may also be created using scrotal, abdominal, or thigh tissue. Split-thickness skin grafts can be used to address both penile and scrotal skin defects. Vacuum-assisted closure therapy has been effective in early management with skin grafts (see also Section I: "Scrotum and Testicle, Trauma.")

GENITAL ULCERS

DESCRIPTION Genital ulcers may be due to multiple causes: Infection, Behçet syndrome, erythema multiforme, Crohn disease, lichen planus, amebiasis, drug reaction, trauma, and carcinoma in situ are all possible causes. They are most commonly a manifestation of sexually transmitted infections, including chancroid, genital herpes, lymphogranuloma, and primary syphilis. Characteristics of the ulcers associated with sexually transmitted infections are as follows:

- Chancroid: Tender papule that turns painful which has a purulent ulcer underneath; may be single or multiple
- Genital herpes: Multiple painful vesicles
- Lymphogranuloma: A small painless papule or vesicle that ulcerates
- Primary syphilis: Painless, indurated ulcer; usually single

TREATMENT

If a sexually transmitted infection is suspected, empiric antibiotic therapy should be initiated

even before confirmatory testing. Chancroid is treated with a single oral dose of azithromycin, or a single intramuscular dose of ceftriaxone, or oral erythromycin for 7 days. Genital herpes is treated with antiviral drugs such as Acyclovir. Lymphogranuloma is usually treated with tetracycline or erythromycin. Primary syphilis is treated with a single dose of intramuscular penicillin G or a single dose of oral azithromycin in a penicillin allergic patient. (See also Section I: “Sexually Transmitted Infections [STIs]; Sexually Transmitted Diseases [STDs], General.”)

GENITOURINARY PAIN INDEX (GUPI)

DESCRIPTION GUPI is a validated 9 question instrument to assess severity of symptoms, in men and women with urologic pain conditions. The GUPI can differentiate men with chronic prostatitis or interstitial cystitis, those with other symptomatic conditions (dysuria, frequency, chronic cystitis), and those with none of these diagnoses. It can discriminate between women with interstitial cystitis, those with incontinence, and those with none of these diagnoses.

GENOMIC TESTING, PROSTATE CANCER

DESCRIPTION A variety of genomic tests have been recently approved. The more common tests are shown in the table. All rely on either needle biopsy or radical prostatectomy tissue analysis. Their role in the definitive management of patients with prostate cancer is currently evolving.

Common Prostate Cancer Genomic Tests Comparisons		
	ConfirmMDx (MDxHealth)	**Decipher (GenomeDx)**
Indications	To reduce unnecessary repeat biopsies. Performed on previous negative biopsy tissue.	Treatment decisions after radical prostatectomy
Outcome predicted	Presence or absence of occult cancer detection; direct follow up biopsy based on "halo" effect	Risk of clinical metastasis following radical prostatectomy
Assay	3 epigenetic methylation markers	22 genetic markers on RP specimen
	Prolaris (Myriad)	**Oncotype DX (Genomic Health)**
Indications	Biopsy and post RP risk of disease progression; active surveillance decision	Risk assessment on biopsy; active surveillance decision
Outcome predicted	PCa-specific mortality, metastasis, recurrence, progression	Adverse pathology: Primary Gleason 4, any 5, pT3
Assay	46 gene Cell Cycle Progression (CCP) panel	17 gene Genomic Prostate Score (GPS)

REFERENCE

http://www.cancernetwork.com/oncology-journal/new-biomarkers-prostate-cancer/page/0/2, Accessed April 1, 2014.

GERM CELL APLASIA (SERTOLI CELL ONLY SYNDROME)

DESCRIPTION Total absence of germ cells within a normal interstitium. Patients present with infertility, and usually with small to normal testes and azoospermic semen specimens. Phenotypically, these patients are normally virilized males. Histologically, Sertoli cells line the seminiferous tubules with a complete absence of germ cells and normal interstitium. Plasma FSH is usually elevated due to the absence of germ cells. Plasma testosterone and LH are normal. Diagnosis is based on an elevated FSH and FNA of the testis. Aplasia may represent the endpoint of various etiologies, resulting in this histologic appearance. Adoption or use of donor sperm is necessary if children are desired.

REFERENCE

Odabas O, Ugras S, Aydin S, et al. Assessment of the testicular cytology by fine-needle aspiration and the imprint technique: Are they reliable diagnostic modalities? *Br J Urol.* 1997;79(3):445–448.

GESTATIONAL AGE ASSESSMENT, UROLOGIC CONSIDERATIONS

DESCRIPTION Gestational age assessment can be derived from 3 clinical methods: (1)

physical exam, (2) ultrasound, and (3) history, using the date of the last menstrual period (LMP) to calculate the estimated date of delivery ("due date" or EDD). The clinical assessment of gestational age or duration of pregnancy reflects the "menstrual age." Studies have shown ultrasound to be superior to physical exam or history. Rapid determination of gestational age in the delivery room includes assessment of soles of the feet, breast nodules, earlobe, hair, and the external genitalia of males. Babies born 36 wk and earlier the testes are usually partially descended, the scrotum is small with very few rugae. Term infants (39 wk and beyond) should have the testes fully descended, the scrotum should appear normal sized with prominent rugae.

REFERENCE

Gomella, TL ed. *Assessment of Gestational Age in Neonatology*. 7th ed. New York, NY: McGraw Hill, 2013.

GIBBON CLASSIFICATION OF VOIDING DYSFUNCTION

DESCRIPTION Historic classification based in large part on the system proposed by Bors-Comarr. 5 categories are proposed to be important: (1) Full general and neurologic diagnosis, (2) state of the bulbocavernosus and anal reflexes in cord injuries, (3) presence or absence of reflex detrusor contractions, (4) urodynamic findings, and (5) failure of storage, emptying, or control when dealing with incontinence.

REFERENCE

Gibbon NOK. Nomenclature of neurogenic bladder. *Urology*. 1976;8:423–431.

GIBSON INCISION

DESCRIPTION A curvilinear incision is made starting 2–3 cm medial to the anterior superior iliac spine, running parallel to the inguinal ligament down to 2–3 cm superior and just lateral to the pubic tubercle. The external and internal obliques and the transversalis muscle are bluntly opened along their fibers. After transecting the transversalis fascia, the peritoneum is swept medially to expose the ureter at its midsection. Useful for distal ureteral stones, distal ureterectomy and renal transplant.

REFERENCE

Yang WH, Ou CH. A muscle sparing modified Gibson incision for hand-assisted retroperitoneoscopic nephroureterectomy and bladder cuff excision–an approach through a window behind the rectus abdominus muscle. *Urology*. 2012;79(2):470–474.

GIGGLE INCONTINENCE (ENURESIS RISORIA)

DESCRIPTION Giggle incontinence, also referred to as enuresis risoria, is urinary leakage that occurs only with laughter in children with rare exception exclusively occurs in girls. It is characterized by large-volume voids. These children have normal bladder function when the child is not laughing. The disorder is thought to be mediated by the central nervous system and has similarities to detrusor instability.

TREATMENT

- Treatment of this condition is not well studied
- Anticholinergics (eg, oxybutynin)
- Methylphenidate
- Biofeedback was effective in 1 series in patients refractory to medical management

GIL-VERNET EXTENDED PYELOLITHOTOMY

DESCRIPTION An open approach to remove a large renal calculi, such as a staghorn calculi. Using a flank incision, the kidney is exposed and freed at the upper pole, lower pole and posteriorly. The ureter is identified and traced to the renal pelvis. The renal pelvis is incised and the incision can be continued to include the calices to allow for removal of more significant calculi.

REFERENCE

Gil-Vernet J. New surgical concepts in removing renal calculi. *Urol Int.* 1965;20:255–288.

GIL-VERNET ORTHOTOPIC URINARY DIVERSION

DESCRIPTION A continuous segment of terminal ileum, cecum, and ascending colon are isolated. The unit is rotated 180° to allow anastomosis of the reduced end of the ascending colon to the urethra and the ureters to the terminal ileum.

REFERENCE

Benson MC, Olsson CA. Continent urinary diversion. In: Walsh PC, Retik AB, Vaughan ED, et al., eds. *Campbell's Urology*, 7th ed. Philadelphia, PA: Saunders; 1998:3190–3245.

GIL-VERNET URETERAL REIMPLANTATION

DESCRIPTION Through a transvesical approach, the ureters are dissected free from their hiatus. The principle involves advancing the ureters across the trigone to the midline such that both ureteral orifices are juxtaposed. A single incision is made in the trigone mucosa, which will serve to join traction sutures from each ureter that are anchored in the midline.

REFERENCE

Khoury AE, Bagli DJ. Vesicoureteral reflux. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2012:3267–3309.

GITELMAN SYNDROME

DESCRIPTION Gitelman syndrome is an autosomal recessive disorder characterized by

hypokalemia, hypocalciuria, and hypomagnesemia with metabolic alkalosis. It is caused by loss of function mutations of a thiazide sensitive sodium-chloride symporter found in the distal convoluted tubule of the kidney.

TREATMENT
Replacement of respective electrolytes.

GITTES NEEDLE URETHROPEXY

DESCRIPTION Historically used to treat female stress incontinence. A Stamey needle is delivered through a stab incision at the upper border of the pubis, then transferred under digital guidance through the anterior vaginal wall at the level of the bladder neck. A No. 2 proline suture is used to suspend the bladder neck on both sides, and the vaginal sutures eventually cut through the wall and become buried in the scar.

REFERENCE

GLEASON GRADE, TERTIARY PATTERN

DESCRIPTION The standard Gleason grading system reports the primary and secondary Gleason pattern. The tertiary pattern (3rd most prevalent) is noted if it is high grade. Retrospective data suggest that a high-grade tertiary component after RP, even when present in a small percentage of total tumor volume, has prognostic significance. Its presence is associated with biochemical recurrence and adverse pathologic features such as seminal vesicle invasion, extraprostatic extension, and positive surgical margins.

REFERENCES

GLEASON GRADING/SCORING SYSTEM

DESCRIPTION A widely accepted system to describe the aggressiveness of prostatic adenocarcinoma was developed by Dr. Donald Gleason between 1969 and 1974, in which prostate cancer mortality data were correlated to low-magnification architectural patterns of prostate carcinoma. 5 grades are described, ranging from well differentiated to undifferentiated. To account for variations within tumors, 2 grades are recorded: The predominant, or primary, grade and the less extensive, or secondary, grade. These are

summated to give the Gleason score (or Gleason sum). Gleason system, the most prevalent and the 2nd most prevalent pattern (if at least 5% of the tumor) are added together to obtain a Gleason score (eg, Gleason grade 3 + 4 = 7). The Gleason score is a strong independent predictor of cancer behavior and treatment outcome for prostate cancer patients. Pattern 3 is separated from pattern 4 because this separation usually distinguishes Gleason score 6 from Gleason score 7 tumors, with the latter having a significantly worse prognosis.

- **Gleason pattern 1:** Very well-circumscribed nodule of single, separate, closely packed, back-to-back glands. There is no infiltration into adjacent benign prostatic tissue. The glands are fairly large, round or oval, and are approximately equal in size and shape. Gleason pattern 1 is usually found in transition zone cancers and is rare. When present, it is usually associated with a pattern 2 tumor. Distinction from pattern 2 is not critical, as they have a similar prognosis.
- **Gleason pattern 2:** Usually, but not always, seen in transition zone carcinomas. Well-circumscribed nodule of single, separate glands with the glands more loosely arranged and not as uniform as in pattern 1. Minimal invasion by neoplastic glands into the surrounding benign prostatic tissue. The cells are smoothly rounded or oval with open lumens and are not angular, as seen in pattern 3. The cytoplasm is more abundant and pale staining than intermediate-grade tumors.
- **Gleason pattern 3:** Infiltrative with extension into adjacent benign prostatic tissue. The glands vary in size and shape and are often elongated or angular. These small glands are often called microglands and are usually smaller than Gleason pattern 1 or 2 glands. However, some of the glands of pattern 3 may be moderate to large sized. The small glands of pattern 3, in contrast to small poorly defined glands of pattern 4, are distinct glandular units and 1 should be able to draw an imaginary circle around each of them. Cribriform glands may also be Gleason pattern 3, with these glands being slightly larger than benign glands and having regular outer contours. They resemble intraductal cribriform carcinoma of the breast. Cribriform pattern 3 must be separated from cribriform pattern 4, intraductal cribriform proliferations, and prostatic duct adenocarcinoma.
- **Gleason pattern 4:** The glands are no longer single and separate as seen in pattern 1–3. They are fused, poorly defined with only occasional lumen formation, or cribriform. Fused glands are chains, nests, or masses of glands that are no longer completely separated by intervening stroma. Fused glands contain rare strands of residual stroma that may give the appearance of partial separation of the glands. Consequently, fused glands may have a scalloped appearance peripherally. The “hypernephromatoid” pattern described by Gleason is an uncommon variant of fused glands and resembles RCC. Cribriform glands of pattern 4 are either large cribriform glands (cribriform sheets) or small cribriform glands with irregular infiltrating borders. The small cribriform glands with irregular infiltrating borders of pattern 4 must be distinguished from cribriform pattern 3, in which the small cribriform glands have regular borders. Fragments of cribriform carcinoma in needle biopsies of the prostate imply a cribriform cancer and are designated pattern 4.
- **Gleason pattern 5:** The tumor has virtually no glandular differentiation. It is composed of solid sheets, solid cords, or single cells. Nests of tumor with central comedonecrosis are also classified as pattern 5. It is controversial whether cribriform glands of cancer that otherwise would be considered Gleason pattern 4 should be considered Gleason pattern 5 if

comedonecrosis is present. Separating poorly defined pattern 4 glands from cords and nests of tumor with virtually no glandular differentiation or with only vacuoles is a problem, but usually not critical because any combination of the 2 patterns will lead to a Gleason score of 8–10, all of which are poorly differentiated (Image ☼).

Egevad L, et al. Gleason Grading of prostate carcinoma. Available at http://web.archive.org/web/20051016170005/pathology2.jhu.edu/gleason/patterns.cfm (archive accessed March 2, 2014).

GLEASON GRADING SYSTEM, MODIFIED

DESCRIPTION The International Society of Urologic Pathology held a consensus conference in 2005 at which the "old Gleason grading system" for prostatic carcinoma from 1966 underwent its 1st major revision. With this modified grading system, a shift of the most frequent Gleason scores from 6–7a (3 + 4) in biopsy specimens and an increased degree of agreement between specimens of biopsies and radical prostatectomies with carcinoma of the prostate could be demonstrated. After modified grading of GS 3 + 4 = 7a tumors, 95% were stage pT2, whereas 79% of GS 4 + 3 = 7b tumors were stage pT3–4. In cases with PSA <10 ng/mL and tumor extent <20%, the most frequent Gleason scores were 6 and 7a. Cases with serum PSA >10 ng/mL or tumor extent of >20% had higher scores (7b or higher). Cancers with tumor infiltration of <1 mm in 1 of 12 cores and PSA <10 ng/mL were mainly low grade (Gleason scores 6 and 7a) and may correspond to so-called insignificant carcinoma of the prostate. Using the modified Gleason system, grade, stage, tumor extent, and serum PSA show good correlations and characterize the difference between low- and high-grade malignancy of the prostate.

GLENN-ANDERSON URETERONEOCYSTOSTOMY

DESCRIPTION Through a transvesical approach, the ureter is mobilized from its hiatus and advanced toward the bladder neck through a submucosal tunnel, where it is reimplanted. Used to treat vesicoureteral reflux or resection of a ureteral orifice.

REFERENCE

Kay R. Reimplantation of the ureter. In: Novick AC, Streem SB, Pontes JE, eds. *Stewart's Operative Urology*. Baltimore, MD: Williams & Wilkins; 1989: 526–538.

GLOMERULOCYSTIC KIDNEY DISEASE (CORTICAL MICROCYSTIC DISEASE)

DESCRIPTION Rare, bilateral cystic kidney disease that can be inherited (autosomal dominant) or sporadic. Presents most commonly in childhood with bilateral flank masses,

which are large kidneys with many cysts. Seen rarely in adults with hypertension, hematuria, and end stage renal disease (ESRD). Cysts are confined to the cortex and arise from the Bowman space. Renal biopsy may be necessary to confirm diagnosis. Radiologically, the lesions are similar to autosomal-dominant polycystic kidney disease (ADPKD). Treatment is supportive, with renal replacement therapy if renal failure occurs.

REFERENCE

Gusmano R, Caridi G, Marini M, et al. Glomerulocystic kidney disease. *Nephrol Dial Transplant.* 2002;17:813–818.

GLOMERULOSCLEROSIS

DESCRIPTION An accumulation of homogeneous eosinophilic material in the glomerulus, made up of plasma proteins that have exuded from the plasma into glomerular structure; this is a light microscopic feature known as hyalinization. This change contributes to obliteration of capillary lumina of the glomerular tuft, a feature of glomerulosclerosis. Hyalinization and glomerulosclerosis are a consequence of endothelial or capillary wall injury and the end result of various forms of glomerular damage.

REFERENCE

Alpers CE. The kidney. In: Kumar V, Abbas AK, Fausto N, eds. *Robbins and Cotran: Pathologic Basis of Disease.* 7th ed. Philadelphia, PA: Elsevier Saunders; 2005.

GLUCAGON STIMULATION TEST

DESCRIPTION Indicated when the diagnosis of pheochromocytoma is highly suspected by history and clinical findings but blood pressure is normal and diagnostic biochemical tests are equivocal (catecholamines only modestly elevated). The mode of action is the stimulation of glucagon-sensitive adenylate cyclase receptors expressed on the tumor, which can lead to dangerous rises in blood pressure; thus, this test is rarely used. A physician must be present throughout the test, and it should only be performed in patients whose blood pressure is well controlled. A rise in plasma norepinephrine to $>$3-fold or $>$2,000 pg/mL is diagnostic of pheochromocytoma.

REFERENCE

GLYCOSURIA, RENAL

DESCRIPTION Normal urine contains small amounts of glucose. Increased amounts represent either inefficient handling by the tubule or hyperglycemia. Diabetes is the most common cause of glycosuria. Causes of primary glycosuria are either intestinal glucose–galactose malabsorption or benign familial renal glycosuria. Some substances are known to cause false-positive glucose readings on dipstick, such as ascorbic acid and salicylates. Medications such as ACE inhibitors may also have a direct effect on the kidney and cause

glycosuria. Pregnancy can be causative. Glycosuria may also be part of Fanconi syndrome or RTA.

SYNONYM
Glucosuria

REFERENCE
Bakris GL, Fonseca VA, Sharma K, et al. Renal sodium-glucose transport: Role in diabetes mellitus and potential clinical implications. *Kidney Int.* 2009;75(12):1272–1277.

GOLDSTEIN TEST

DESCRIPTION Intraoperative diagnostic pneumoperitoneum, also known as Goldstein test, is done in the a setting of pediatric open inguinal hernia repair. To prevent unnecessary contralateral inguinal exploration, the test is performed by introducing a soft rubber catheter through the ipsilateral hernia sac. Air is insufflated into the peritoneal cavity, distending it, and the contralateral groin is palpated for crepitus. The presence of crepitus constitutes a positive test and necessitates repair of a metachronous hernia. Currently, this practice has been largely supplanted by the use of laparoscopy.

REFERENCE
Haynes JH. Inguinal and scrotal disorders. *Surg Clin North Am.* 2006;86(2):371–381.

GOLDSTON SYNDROME

DESCRIPTION Rare syndrome with principal features of kidney, liver, and brain abnormalities. The kidneys are cystic and large bilaterally. Histologic lesions of the liver are triads with a double band of fibrous tissue without bile ducts. The brain shows the Dandy–Walker malformation, which is the cystic dilation of the 4th ventricle, secondary to obstruction of the foramina of Luschka and Magendie. Renal replacement therapy, as indicated, and hydrocephalus requiring a shunt are standard treatments.

REFERENCE
Gloeb DJ, Valdes-Dapena M, Salman F, et al. The Goldston syndrome: Report of a case. *Pediatr Pathol* 1989;9(3):337–343.

GONADAL DYSGENESIS, MIXED

DESCRIPTION Gonadal dysgenesis syndromes include Turner syndrome (45, XO), 46, XX "pure" gonadal dysgenesis, mixed gonadal dysgenesis (45, XO/46, XY), partial gonadal dysgenesis (aka, dysgenetic male pseudohermaphroditism), and bilateral vanishing testis syndrome. It is the 2nd most common cause of ambiguous genitalia in the newborn after CAH. Mixed gonadal dysgenesis is characterized by unilateral testis, often intra-abdominal; contralateral streaked gonads; and persistent müllerian structures with varying degrees of inadequate masculinization ("testis plus streak gonad"). A *streak gonad* is dysgenetic and resembles ovarian stromal tissue, but no germ cells are present. Usual karyotype is 45, XO/46, XY mosaicism. Phenotype is variable, ranging from a female with Turner syndrome,

to ambiguous genitalia, to (rarely) normal-appearing males. Almost all have a uterus, vagina, and fallopian tubes, but with varying degrees of phallic development, labioscrotal fusion, and undescended testis. Increased risk exists of gonadoblastoma (incidence 20%) in either dysgenetic testis or streak gonad (more frequently testis), as well as an increased risk of Wilms tumor. Clinical diagnosis is at birth and with confirmatory karyotyping. (See also Section I: "Disorders of Sexual Development [DSD]"; Section II: "Gonadal Dysgenesis, Pure.")

TREATMENT

- Determine gender assignment, based upon potential for normal function of external genitalia and gonads
- Perform appropriate gonadectomy (if male, consider prophylactic gonadectomy versus bringing testis down to scrotum for purpose of screening of gonadoblastoma)
- Screen for Wilms tumor
- Initiate appropriate sex and growth hormone replacement

REFERENCE

Kolon TF. Disorders of sexual development. *Curr Urol Rep.* 2008;9(2):172–177.

GONADAL DYSGENESIS, PURE

DESCRIPTION 46, XX "pure" gonadal dysgenesis ("bilateral streak gonads") is closely related to Turner syndrome, except that it lacks the somatic stigmata associated with Turner syndrome. Patients present with amenorrhea and lack of pubertal development. Evaluation reveals normal female external genitalia and müllerian ducts, absent wolffian ducts, normal height, sexual infantilism, bilateral streaked gonads, and 46, XX karyotype. A streak gonad is dysgenetic and resembles ovarian stromal tissue, but no germ cells are present. This is an autosomal recessive trait with no increased risk of gonadoblastoma (unlike in mixed gonadal dysgenesis). It is treated with cyclic estrogen and progesterone replacement. (See also Section I: "Disorders of Sexual Development [DSD]"; Section II: "Gonadal Dysgenesis, Mixed.")

REFERENCE

Kolon TF. Disorders of sexual development. *Curr Urol Rep.* 2008;9(2):172–177.

GONADOBLASTOMA

DESCRIPTION Rare tumor comprising 0.5% of all testes tumors that occurs almost always in gonadal dysgenesis (intersex disorders). This is a benign tumor that has the potential for malignant transformation. Patients present either with a palpable mass or virilization secondary to androgen production. It has 2 distinct cell types: Large germ cells (similar to dysgerminoma and seminoma) and small cells resembling immature Sertoli or granulosa cells. Tubules microscopically contain PAS-positive staining Call–Exner bodies. Upregulation of the TSPY gene is implicated in this tumor. (See also Section I: "Testis Cancer, Adult General Considerations" and "Testis Cancer, Pediatric, General Considerations"; Section II: "Turner Syndrome.")

SYNONYMS

- Tumors of dysgenetic gonads

- Mixed germ-cell tumor
- Gonadocytoma

TREATMENT
- With an intersex disorder or Turner syndrome: Prophylactic removal of the dysgenic gonad before developing gonadoblastoma
- Radical orchiectomy with possible contralateral orchiectomy secondary to high incidence of bilaterality

REFERENCE
Brant WO, Rajimwale A, Lovell MA, et al. Gonadoblastoma and Turner syndrome. *J Urol.* 2006;175(5):1858–1860.

GOODPASTURE SYNDROME

DESCRIPTION Characterized by a triad of pulmonary hemorrhage, iron deficiency anemia, and glomerulonephritis (GN), representing <1% of all cases of GN. Anti-GBM antibody deposition in the lungs and kidneys is the cause. Antibody production appears to be self-limited. Histologically, it shows focal proliferative and necrotizing glomerular lesions that progress rapidly to diffuse proliferation with crescents. Immunohistochemical studies show diffuse linear deposition of IgG along the GBM. Primarily a disease of young white males (Male > Female, 6:1) with a mean age of 21. About 1/3 of patients die of pulmonary involvement. Renal involvement is usually severe and progressive, with rapid development of oliguria and renal failure.

TREATMENT
- Steroid pulse therapy with prednisone
- Plasma exchange therapy to remove circulating anti-GBM antibody
- Cyclophosphamide to inhibit further antibody production
- Renal replacement therapy for ESRD

REFERENCE
Shah MK, Hugghins SY. Characteristics and outcomes of patients with Goodpasture's syndrome. *South Med J.* 2002;95(12):1411–1418.

GOODWIN URETERAL ANASTOMOSIS

DESCRIPTION Through a transcolonic approach, a nonrefluxing anastomosis is performed by raising a tunnel of mucosa with a mosquito hemostat for a 3–4-cm distance, then exiting the bowel wall. The ureter is grasped and pulled through the tunnel. The spatulated ureter is anastomosed to the colonic mucosa while incorporating some muscularis for security.

REFERENCE

GORLIN SYNDROME

DESCRIPTION Autosomal dominant cancer condition characterized by an increased risk of multiple basal cell carcinomas. Features include disorders of the skin, skelet al, eye, nervous system, and endocrine glands. The lesions are sensitive to ionizing radiation.

SYNONYMS
- Nevoid basal cell carcinoma syndrome
- Basal cell nevus syndrome

REFERENCE
Mitchell G, Farndon PA, Brayden P, et al. Genetic predisposition to cancer: The consequences of a delayed diagnosis of Gorlin syndrome. *Clin Oncol (R Coll Radiol).* 2005;17(8):650–654.

GOUT, UROLOGIC CONSIDERATIONS

DESCRIPTION An inherited disorder of purine metabolism characterized by elevated serum urate levels and severe recurrent arthritis, gout leads to an increased risk of urate urolithiasis and uric acid nephropathy. Most patients with uric acid stones, however, do not have gout. About 20% of patients with gout will develop a stone. Gout may also produce a type IV RTA, resulting in hyperkalemia and a mild metabolic acidosis. (See Section I: "Renal Tubular Acidosis"; Section I: "Urolithiasis, Uric Acid.")

TREATMENT
- Alkalinization of urine and increasing urine output help prevent stones.
- Allopurinol or following a low-purine diet will decrease serum urate levels.

REFERENCE
Liebman SE, Taylor JG, Bushinsky DA. Uric acid nephrolithiasis [review]. *Curr Rheumatol Rep.* 2007;9(3):251–257.

GOUVERNEUR SYNDROME

DESCRIPTION Classic presentation of vesicoenteric fistula, with suprapubic pain, urinary frequency, dysuria, and tenesmus.

REFERENCE
Vidal Sans J, Pradell Teigell J, Palou Redorta J, et al. Review of 31 vesicointestinal fistulas: Diagnosis and management. *Eur Urol.* 1986;12(1):21–27.

GRANULOMA INGUINALE (DONOVANOSIS)

DESCRIPTION Ulcerative disease of the genitals with significant locoregional lymphadenopathy, caused by *Klebsiella granulomatis* (*formerly known as Calymmatobacterium granulomatis).* The disease occurs rarely in the United States and is endemic in some tropical and developing areas (India; Papua, New Guinea; the Caribbean; central Australia; and southern Africa). Clinically, the disease is commonly characterized as painless, slowly progressive ulcerative lesions on the genitals or perineum without regional lymphadenopathy; subcutaneous granulomas (pseudoboboes) might also occur. The lesions are highly vascular (ie, beefy red appearance) and bleed easily on contact. Ulceration at site inoculation may be

on the genitals or extragenital sites, and prominent lymphadenopathy often results in further skin ulceration over the nodes. Untreated, it results in lymphedema and genital mutilation. (See also Section I: "Sexually Transmitted Infections [STIs]; Sexually Transmitted Diseases [STDs], General.")

Diagnosis is based on rapid Giemsa stained-smear of ulcer (RapiDiff), to look for Donovan bodies. For smear-negative cases, biopsy of the ulcer is necessary. Culture and PCR are available only in specialized centers.

TREATMENT

- Doxycycline 100 mg orally twice a day for at least 3 wk and until all lesions have completely healed
- Alternative regimens (treat until all lesions healed): Azithromycin 1 g orally once per week for at least 3 wk OR ciprofloxacin 750 mg orally twice a day for at least 3 wk OR erythromycin base 500 mg orally 4 times a day for at least 3 wk OR trimethoprim-sulfamethoxazole 1 double-strength (160 mg/800 mg) tablet orally twice a day for at least 3 wk

REFERENCES

O'Farrell N. Donovanosis. *Sex Transm Infect.* 2002;78:452–457.

GRANULOSA CELL TUMORS

DESCRIPTION The most common ovarian neoplasm. Usually small, cystic, unilateral, and secretes estrogens. Often presents in childhood as precocious puberty or as postmenopausal bleeding in older women. During the reproductive years, prolonged and irregular bleeding and a pelvic mass are most common. These tumors can also present with urinary symptoms, and they can rarely be present in the testes.

TREATMENT

- Surgical excision is usually curative.
- Close follow-up of the contralateral ovary is necessary.

REFERENCE

Chan YF, Restall P, Kimble R. Juvenile granulosa cell tumor of the testis: Report of 2 cases in newborns. *J Pediatr Surg.* 1997;32(5):752–753.

GRAPEFRUIT AND GRAPEFRUIT JUICE, INTERACTION WITH UROLOGIC MEDICATIONS

DESCRIPTION Grapefruit or grapefruit juice can affect the metabolism of many medications, increasing the risk of toxicity and adverse events. These oral medications tend to be metabolized through the intestinal cytochrome P450 3A4 (CYP3A4) system and can also inhibit the drug concentration for up to 72 hr. The following mediations are used in urologic practice and do not represent an exhaustive listing. Typically there is increased drug levels by grapefruit interaction.

- Immunosuppressive agents:
  – Cyclosporine everolimus, sirolimus, tacrolimus, temsirolimus
- Phosphodiesterase Type 5 inhibitors (PDE-5I)
  – Tadalafil, vardenafil
- Tyrosine kinase inhibitors (TKI)
  – Axitinib, everolimus, pazopanib, sunitinib, temsirolimus

REFERENCE

Stump AL, Mayo T, Blum A. Management of grapefruit-drug interactions. *Am Fam Physician*. 2006;74(4):605–608.

GRATIFICATION DISORDER

DESCRIPTION Also known as *infantile masturbation*, usually peaks at 4 yo but can be seen as early as 3 mo of age. The disorder may occur in the absence of genital manipulation and can consist of vocalizations with quiet grunting, diaphoresis, and pressure on the perineum with characteristic posturing of the lower extremities. The patient is commonly referred for seizures or a movement disorder because of the recurrent paroxysmal movements.

Yang ML, Fullwood E, Goldstein J, et al. Masturbation in infancy and early childhood presenting as a movement disorder: 12 cases and review of the literature. *Pediatrics*. 2005;116:1427–1432.

GRIESS TEST

DESCRIPTION Detects the presence of nitrite in urine, which is formed when bacteria reduce the normally present nitrate. With a lower sensitivity and specificity than microscopy and culture, this test in combination with leukocyte esterase has been used to screen asymptomatic patients. Microscopy is indicated for the higher-risk population for UTI.

REFERENCE

GRISS SEX FUNCTION INDEX (GOLOMBOK–RUST INVENTORY OF SEXUAL SATISFACTION)

DESCRIPTION Golombok–Rust Inventory of Sexual Satisfcation (GRISS) is a validated psychometric instrument intended for heterosexual couples or individuals. The questionnaire is based on a 28-item scale, with separate forms for men and women. It contains subscales of ED, orgasmic disorders, vaginismus, and male and female nonsensuality. It may be used in individuals undergoing marital or sex therapy.

REFERENCE

Wiegel M, Wincze JP, Barlow DH. Sexual dysfunction. In: Barlow D, ed. *Assessment and Treatment Planning for Psychological Disorders.* New York, NY: Guilford Press; 2002.

GROIN HERNIA, PEDIATRIC

DESCRIPTION The most common surgery in the pediatric age group. Most hernias in this population are indirect and congenital. The incidence is higher in preterm births, with a male to female ratio of 6:1. The hernia is formed from the persistence of the processus vaginalis and can present as a communicating hydrocele, hydrocele of the cord, simple hydrocele, or incarceration and strangulation of intraperitoneal contents. Surgical repair is usually indicated.

REFERENCE

Warner BW. Pediatric surgery. In: Townsend CM, Sabiston DC, eds. *Sabiston Textbook of Surgery*. 18th ed. Philadelphia, PA: Saunders; 2008.

GROWING TERATOMA SYNDROME

DESCRIPTION Refers to an enlarging mature teratoma arising during or after chemotherapy for a nonseminomatous germ-cell tumor. The AFP and β-HCG serum levels are normal. The preferred treatment is complete surgical resection as teratomas are chemotherapy and radiation therapy resistant.

REFERENCE

Vaughn DJ, Flaherty K, Lal P, et al. Treatment of growing teratoma syndrome. *N Engl J Med.* 2009;360:423–424.

GUILLAIN–BARRé (TRANSVERSE MYELITIS) SYNDROME: UROLOGIC CONSIDERATIONS

DESCRIPTION Also known as *acute inflammatory demyelinating polyneuropathy*, an inflammatory demyelinating disorder of the autonomic and peripheral nervous system. It is thought to be triggered by a bacterial or viral antigen, causing the immune system to cross-react and attack neural tissue. Symptoms may include muscle weakness, respiratory difficulties, autonomic neuropathy, and cardiac, bowel, bladder, and sexual dysfunction. Lower urinary tract dysfunction can range from urgency and stress incontinence to urinary retention.

TREATMENT

- Manage lower urinary tract dysfunction (Clean intermittent catherization (CIC), anticholinergics, etc.)
- Plasmapheresis
- IV immunoglobulin

REFERENCE

Ganesan V, Borzyskowski M. Characteristics and course of urinary tract dysfunction after acute transverse myelitis. *Dev Med Child Neurol.* 2001;43(7):473–475.

GUN SHOT WOUND, EXTERNAL GENITALIA

DESCRIPTION The genitalia have several characteristics that are somewhat protective against sustained injury. Characteristics such as the laxity of skin, flaccidity, and multiple sources of blood supply assist with dampening the blow of trauma and help with reconstruction efforts. Nevertheless, the location of major vasculature and visceral organs make these injuries potentially life-threatening. Greater than 50% of injuries to the penis have urethral injuries and 75% have other significant associated injuries. A majority of these injuries require exploration with copious irrigation, excision of foreign material, antibiotics, and primary closure. In injuries to the urethra, imaging such as retrograde urethrogram should be implemented and, if warranted, abdominal/pelvic imaging should be obtained. (See also Section I: "Penis, Trauma"; Section I: "Scrotum and Testicle, Trauma.")

REFERENCE

Phonsombat S, Master VA, McAninch JW. Penetrating external genital trauma: A 30-year single institution experience. *J Urol.* 2008;180(1):192–195.

GUN SHOT WOUND, KIDNEY

DESCRIPTION The kidney is subject to the majority of external injuries in the GU system. Hematuria is a good indicator of injury but its amount or absence does not eliminate renal injury nor does it dictate the degree of injury. Any degree of hematuria in penetrating trauma should prompt imaging. Kidney injury is graded from I–V in accordance with the American Association for Surgery of Trauma Organ Injury Severity Scale for the Kidney. In carefully selected patients, management can be nonoperative, with careful observation or segmental embolization used. Absolute indications for surgical exploration include expanding perirenal hematoma, evidence of persistent renal bleeding, and pulsatile perirenal hematoma. Relative indications include urinary extravasation, nonviable tissue, delayed diagnosis of arterial injury, segmental arterial injury, and incomplete staging. (See also Section I: "Renal Trauma, Adult"; Section I: "Renal Trauma, Pediatric"; Section II: "American Association for Surgery of Trauma Organ Injury Severity Scale.")

REFERENCE

Voelzke BB, McAninch JW. Renal gunshot wounds: Clinical management and outcome. *J Trauma.* 2009;66(3):593–600.

HAILEY–HAILEY DISEASE (BENIGN FAMILIAL PEMPHIGOID)

DESCRIPTION Autosomal dominant skin disease arising from mutations of the *ATP2C1* gene. The appearance begins as a flaccid vesicle or bulla with associated itching, irritation, and a possible odor. The lesions may erupt and leave crusted erosions, and some may have a dry center and inflammatory periphery. The onset usually occurs within the 2nd–3rd decades of life, and lesions are seen in intertriginous areas (ie, axillary fold, groin, and perianal areas). Lesions heal without scarring. Treatment involves antibiotics for superinfection, steroids, and dermabrasion.

REFERENCE

McKibben J, Smalling C. Hailey-Hailey. *Skinmed.* 2006;5(5):250–252.

HALD–BRADLEY CLASSIFICATION OF VOIDING DYSFUNCTION

DESCRIPTION Based on the anatomic location of the neurologic lesion, voiding dysfunction is broken down into 5 classes: (1) Suprasacral, (2) suprasacral spinal, (3) infrasacral, (4) peripheral autonomic neuropathy, and (5) muscular lesions. Examples include coordinated voiding with hyperreflexia in suprasacral lesions, whereas muscular lesions may be a decompensated bladder from long-standing bladder outlet obstruction.

REFERENCE

Hald T, Bradley WE. The neurogenic bladder. In *The Urinary Bladder, Neurology and Urodynamics*. Baltimore, MD: Williams and Wilkins; 1982.

HAND FOOT SYNDROME

DESCRIPTION Many oncologic medications have been implicated (such as capecitabine, fluorouracil, others), but this condition appears to be a relatively common problem with multikinase inhibitors such as sunitinib and sorafenib, which are used to treat tumors such as metastatic renal cell carcinoma (RCC). Symptoms include tingling or burning, redness, flaking, swelling, and small blisters and sores on the palms of the hands or soles of the feet. Some patients experience eventual skin hardening (Image ☼).

SYNONYMS

- Palmar–plantar erythrodysesthesia (PPE)
- Plantar–palmar toxicity
- Palmoplantar keratoderma

TREATMENT

- Reduce exposure of hands and feet to friction and heat (ie, hot water, avoid pressure on feet, avoid using tools, cool hands and feet with an ice pack, moisturizing creams).
- Stopping the medication temporarily reduces the symptoms. The drug can often be restarted at a lower dose.

REFERENCE

An overview of toxicity and dosing strategies. *Oncologist.* 2008;13(10):1084–1096.

HAUTMANN POUCH

DESCRIPTION This ileal neobladder is created from 70 cm of ileum, starting 15 cm from the ileocecal junction. The bowel is opened up along the antimesenteric border, and is arranged into an M or W shape. The limbs are sutured to each other with absorbable suture material to form a broad ileal plate. A preselected segment is anastomosed to the urethra, and the ureters are implanted in a LeDuc fashion. The plate is then closed into a pouch and anastomosed to the urethra.

REFERENCE

Hautmann RE, Egghart G, Frohneberg D, et al. The ileal neobladder. *J Urol.* 1988;139(1):39–42.

HEIKEL–PARKKULAINEN REFLUX CLASSIFICATION SYSTEM

DESCRIPTION Described by Heikel and Parkkulainen in 1966, this system is used to grade vesicoureteral reflux based on ureteral diameter and pelvicalyceal dilatation. It gained much popularity in Europe. Later, features of this system were used to create the International Classification System, which is now the standard.

REFERENCE

Heikel RE, Parkkulainen KV. Vesico-ureteric reflux in children: A classification and results of conservative treatment. *Ann Radiol.* 1966;9:37–40.

HEMATOCELE

DESCRIPTION Collection of blood within the layers of the tunica vaginalis. Hematocele can present as scrotal swelling and may be asymptomatic. It may be difficult to distinguish from tumor, in which case transcrotal ultrasound (US) is helpful. Causes include trauma, infection, bleeding disorders, tumor, and rarely uremia. (See also Section I: “Scrotum and Testicle, Mass”; Section I: “Scrotum and Testicle, Trauma.”)

TREATMENT

Conservative management if patient asymptomatic and diagnosis confirmed. Often, diagnosis by surgical exploration

REFERENCE

Chaudhary S, Bhullar JS, Subhas G, et al. Hematocele after laparoscopic appendectomy. *JSLS.* 2012;16(4):660–662.

HEMATURIA, ATHLETIC (RUNNERS’ HEMATURIA)

DESCRIPTION Described mostly in adults after strenuous exercise. The phenomenon of gross or microscopic hematuria can occur in contact or noncontact sports. The RBCs seen in the urine may be glomerular or nonglomerular in shape. The cause of the hematuria can be from trauma of the posterior bladder wall hitting against the bladder base. Nontraumatic

causes are hypothesized to be from hypoxic changes secondary to the vasoconstriction of the splanchnic and renal vessels or to constriction of the efferent glomerular arteriola resulting in increased filtration pressures in the kidney. The hematuria should be distinguished from myoglobinuria and hemoglobinuria.

SYNONYMS
- Sports hematuria
- Athletically induced hematuria

TREATMENT
- Should be self-limited and provoked by strenuous exercise.
- Co-existing urologic pathology should be ruled out if history or physical exam is suspicious.

REFERENCE
Abarbanel J, Benet AE, Lask D, et al. Sports hematuria. *J Urol.* 1990;7143:65887–65890.

HEMATURIA–DYSURIA SYNDROME

DESCRIPTION Hematuria–dysuria syndrome is the most common reported complication of gastrocystoplasty. The syndrome of dysuria and hematuria is defined as 1 or a combination of the following symptoms: Bladder spasm or suprapubic, penile or periurethral pain, coffee brown or bright red hematuria without infections, skin irritation or excoriation, and dysuria without infections.

REFERENCE
Chadwick PJ, Snodgrass WT, Grady RW, et al. Long-term follow-up of the hematuria-dysuria syndrome. *J Urol.* 2000;164(3 Pt 2):921–923.

HEMATURIA–LOIN PAIN SYNDROME

DESCRIPTION A cause of recurrent gross hematuria that may be confused with IgA nephropathy, loin pain-hematuria syndrome generally affects young women and is characterized by recurrent episodes of gross hematuria associated with dull unilateral or bilateral loin pain and sometimes low-grade fever. BP and renal function are usually normal. The syndrome has been associated most often with the use of oral contraceptive agents and generally resolves when these agents are discontinued. Renal autotransplantation has been described as a treatment modality.

HEMIZONA ASSAY

DESCRIPTION This assay assesses the ability of sperm to bind to the zona pellucida of the egg. It is performed by dividing intact zona pellucida and incubating it separately with donor sperm and the patient's sperm. A hemizona index is derived by dividing the number of bound donor sperm by the number of bound patient sperm. An index <0.60 is seen in males who

failed IVF. Its use is limited by the availability of human ova. Since this technique potentially bypasses the step of zona binding, men whose sperm cannot bind may be good candidates for these procedures.

REFERENCE

Yao YQ, Yeung WS, Ho PC. The factors affecting sperm binding to the zona pellucida in the hemizona binding assay. *Hum Reprod.* 1996;11(7):1516–1519.

HEMORRHAGE, POSTOPERATIVE, UROLOGIC CONSIDERATIONS

DESCRIPTION Postoperative hemorrhages can occur after any urologic procedure, but are most common and significant with percutaneous procedures of the kidney. The risk of hemorrhage increases in patients with underlying coagulopathy, aberrant anatomy, multiple needle passages, tract dilation, or nephrostomy tube placement. Parenchymal bleeding can be persistent, and a large high-pressure balloon can be placed through the nephrostomy tube tract to promote tamponade and hemostasis. Not uncommonly, venous lacerations may occur and can be managed by placing a large nephrostomy tube and clamping the tube to allow for tamponade. If arterial bleeding is persistent, selective arterial embolization may be employed. Delayed bleeding can occur soon after surgery, or weeks to months later in the setting of renal pseudoaneurysms or arteriovenous fistulas. If these diagnoses are suspected, evaluation with angiography and treatment with selective embolization can be performed.

REFERENCE

Srivastava A, Singh KJ, Suri A, et al. Vascular complications after percutaneous nephrolithotomy: Are there predictive factors. *Urology.* 2005;66:38–40.

HEMORRHAGE, RETROPERITONEAL AND PERINEPHRIC

DESCRIPTION Retroperitoneal and perinephric hemorrhage are uncommon in the absence of trauma. Spontaneous retroperitoneal and perinephric hemorrhage is most commonly from the kidney. The most common renal causes are angiomyolipoma (AML) and renal cell carcinoma (RCC). Vascular diseases such as polyarteritis nodosa (PAN), renal artery aneurysm, infections of kidney such as cortical abscess, pyelonephritis, and renal cysts are occasional etiologic factors. Adrenal hemorrhage (AH) is seen with severe stress conditions (sepsis, burns, trauma), pheochromocytoma, adrenal carcinomas, myelolipoma, and cortical adenomas. Clinical presentation depends on the amount of bleeding ranging from mild flank pain to shock and oliguria. CT scan is considered the gold standard for diagnosis. (See also Section I: “Retroperitoneal Masses, Fluid and Cysts” and Section II: “Retroperitoneal Hematoma.”)

REFERENCE

Goyal A, et al. Spontaneous retroperitoneal haemorrhage: Diagnostic and therapeutic approach. *Indian J Urol.* 2001;18:70–73.

HEMOSIDERIN, URINARY

DESCRIPTION Hemosiderin occurs when hemoglobin is reabsorbed by the proximal tubular

cells and then catabolized into ferritin and hemosiderin. Urinary hemosiderin can occur up to 2 days after an acute hemolytic episode, and is also demonstrated in chronic hemolytic states and hemochromatosis.

HENOCH–SCHöNLEIN PURPURA (HSP)

DESCRIPTION HSP is a form of purpura with an underlying pathologic feature of vasculitis, affecting mainly small blood vessels. The disease is predominately seen in children. Clinically, the purpuric skin lesions are typically located on the lower extremities. However, the hands, arms, and trunk can be affected. Joint pain, abdominal pain, and GI bleeding may be present. Hematuria denotes a renal lesion, which is usually reversible. HSP is similar to IgA nephropathy, but somewhat more severe, particularly in adults. Progressive renal failure occurs in at least 25%. Kidney biopsy reveals segmental glomerulonephritis with crescents and mesangial deposition of IgA and sometimes IgG. Lab tests reveal high ESR and normal to high platelet counts. If renal involvement is not severe, the disease will subside without sequelae within 6 wk.

TREATMENT

- Currently no effective treatment is available.
- Immunosuppressive (steroids, cytotoxics) drugs have shown some success in nephropathies caused by that disorder.

REFERENCE

Assadi F. Childhood Henoch-Schönlein nephritis: A multivariate analysis of clinical features and renal morphology at disease onset. *Iran J Kidney Dis.* 2009;3(1):17–21.

HEPATITIS A & B (HAV/HBV), UROLOGIC CONSIDERATIONS

DESCRIPTION HAV and HBV both belong to a family of 5 hepatropic viruses. HAV is a picornavirus and is mostly enterically transmitted by fecal–oral routes. Transmission has been noted in men who have sex with men and with oral–anal contact regardless of sexual preference. No significant transmission occurs through semen or vaginal secretions, but transmission through blood products is rare but possible. Extrahepatic manifestations include vasculitis, cardiac abnormalities, Guillain–Barré (transverse myelitis), and renal failure. HBV is a double-shelled hepadnavirus and is mostly transmitted parenterally, which can take place from mother to fetus, through blood products, and through cutaneous and mucosal exposure to infectious blood or bodily fluid. Unlike HAV, HBV has a chronic phase that may lead to hepatocellular carcinoma.

REFERENCE

Curry M, Chopra S. Acute viral hepatitis. In: Mandell GL, Bennett JE, Dolin R, eds. *Principles and Practice of Infectious Diseases*, 6th ed. Philadelphia, PA: Churchill Livingstone; 2005.

HEPATORENAL SYNDROME

DESCRIPTION Known as progressive oliguric renal failure complicating the course of end-stage liver disease, the cause is thought to be functional, due perhaps to discharge of the sympathetic nervous system and/or metabolic imbalances, including endothelin and nitric oxide. The prognosis usually involves recovery of renal function and for survival overall. Urine is characteristically hyperosmolar, with a high creatine-to-plasma ratio and a very low sodium concentration.

TREATMENT

- A transjugular intrahepatic portosystemic shunt has been attempted in the past
- Orthotopic liver transplantation

REFERENCE

Lata J. Hepatorenal syndrome. *World J Gastroenterol.* 2012;18(36):4978–4984.

HEREDITARY LEIOMYOMA RENAL CELL CARCINOMA (HLRCC) SYNDROME

DESCRIPTION HLRCC syndrome is manifested by uterine leiomyomas, multiple cutaneous leiomyomas, and RCC (papillary cell carcinoma). The disorder results from an autosomal dominant germline mutation encoding for fumarate hydratase. The renal tumors have been found to be aggressive, leading to early metastases and death. (See also Section I: “Renal Cell Carcinoma, General.”)

TREATMENT

- Early diagnosis and close follow-up
- Nephrectomy (partial or radical) when indicated

REFERENCE

Hayedeh G, Fatemeh M, Ahmadreza R, et al. Hereditary leiomyomatosis and renal cell carcinoma syndrome: A case report. *Dermatol Online J.* 2008;14(1):16.

HEREDITARY PAPILLARY RENAL CELL CARCINOMA (HPRCC)

DESCRIPTION HRPCC is an autosomal dominant disorder associated with type 1 papillary RCC. Activation of a proto-oncogene, rather than inactivation of a tumor suppressor gene, is the inciting event. Missense mutations of the c-MET proto-oncogene on chromosome 7 at 7q31 have been described as the relevant genetic locus causing the disorder. A majority of the mutations were isolated on the tyrosine kinase domain of the c-MET gene. Tumors linked to these mutations are thought to be less aggressive than the sporadic type. (See also Section I: “Renal Cell Carcinoma, General.”)

HERNIA UTERINE INGUINALE

DESCRIPTION A cause of male pseudohermaphroditism, thought to be due to an isolated defect in the production of müllerian inhibition substance or the response to müllerian inhibiting factor (MIF). This is a rare syndrome of müllerian ducts persistence. Affected males are not ambiguous at birth and generally present later, most commonly with an inguinal hernia on 1 side and an impalpable contralateral testes. Hernia sac may contain the uterus. Karyotype is 46, XY. The gonadal tissue is exclusively testicular. Both wolffian and müllerian duct derivatives are present, with a vas and epididymis alongside an ipsilateral uterus, fallopian tube, and upper vagina. Testes have malignant potential. No uterine or vaginal malignancies have been reported.

TREATMENT

- Sex assignment as male
- Primary or staged orchidopexy
- Müllerian structures do not require removal, as the vas deferens may be damaged.

REFERENCE

Snyder HM. Intersex. *Practical Cases in Urology.* Series XIX, Course 4, 1996.

HERPES ZOSTER, GENITOURINARY

DESCRIPTION If the herpes zoster virus invades the sacral dorsal root ganglia and posterior nerve roots, then detrusor areflexia and urinary retention can result. These symptoms are usually noted days to weeks after the onset of primary viral symptoms, such as painful cutaneous lesions. The urologic symptoms usually spontaneously resolve in 4–8 wk. Cystoscopy may reveal bladder lesions similar to the cutaneous lesions.

HIDRADENITIS SUPPURATIVA (ACNE INVERSA), UROLOGIC CONSIDERATIONS

DESCRIPTION A chronic suppurative disease of the apocrine gland–bearing areas of the body, such as the axilla, buttocks, and groin. Not primarily infectious; caused by plugging of the follicles. Secondary infection can occur after the follicle plugs, with resultant inflammatory response. Lesions resemble boils and can resolve without scarring but more typically result in fibrosis, keloids, and sinus tract formation. Mild cases resemble simple boils (furunculosis). Diagnosed primarily by location and clinical course. Pain, fluctuation, discharge, and sinus tract formation are characteristic. In chronic cases, coalescence of inflamed nodules may cause palpable cordlike bands. The condition may become extensive and disabling; if the pubic and genital areas are severely involved, walking may be difficult.

TREATMENT

- Avoid irritants such as antiperspirants

- Conservative treatment with rest, moist heat, and prolonged antibiotics (tetracycline or erythromycin)
- Oral isotretinoin and intralesional corticosteroids may be effective
- Surgical excision and plastic repair of the affected areas may be necessary

REFERENCE

HINMAN SYNDROME (HINMAN–ALLEN SYNDROME) (NONNEUROGENIC NEUROGENIC BLADDER) (OCCULT NEUROPATHIC BLADDER)

DESCRIPTION 1st described in 1937 by Hinman and Bauman, this is a syndrome of vesicourethral dysfunction (dysfunctional voiding) that is associated with recurrent UTIs, vesical trabeculation, poor emptying, and hydronephrosis with possible progression to renal failure. Hinman syndrome is thought to occur from bladder sphincteric dysfunction with no signs of neurologic cause and may begin in the neonate or in the child around the time of toilet training.

SYNONYM

Nonneurogenic neurogenic bladder

TREATMENT

- Clean intermittent catheterization (CIC)
- Cutaneous vesicostomy

REFERENCE

Mosawi AJ. Identification of nonneurogenic neurogenic bladder in infants. *Urology.* 2007;70:356–357.

HISPAREUNIA (MALE DYSPAREUNIA)

DESCRIPTION Sling erosion/extrusion is a recognized complication after suburethral sling insertion to treat female stress urinary incontinence (SUI). Erosion occurs in up to 6% of patients. Female symptoms may include discharge, infections, postcoital bleeding, and alterations of the sexual function. Changes of male sexual function and particularly pain after sling insertion in their female partners may be due to sling exposure and has been termed “hispareunia.” Sexual interest and drive may be negatively influenced. Male dyspareunia is a complaint that appears to be effectively treated by correcting the sling exposure in the female partner.

HISTOPLASMOSIS, GENITOURINARY

DESCRIPTION *Histoplasma capsulatum* grows in soil enriched by bird guano, with outbreaks reported in caves, construction sites, and on bird farms. Disseminated virulent disease is seen in AIDS, children, and immunosuppressed individuals. GU involvement is a manifestation of systemic disease and can result in sloughed papilla, prostatic obstruction, or prostatic abscess. Epididymitis can resemble sperm granulomas. Up to 7% can experience adrenal insufficiency from adrenal destruction. (See also Section I: "Fungal infections, Genitourinary.")

TREATMENT

2 g of amphotericin B with maintenance therapy with itraconazole to prevent relapse

REFERENCE

Wise GJ, Freyle J. Changing patterns in genitourinary fungal infections. *AUA Update.* Vol. XVI, Lesson 1, 1997.

HIV NEPHROPATHY

DESCRIPTION HIV nephropathy (HIVAN) is the most common cause of chronic renal failure among HIV seropositive patients. It can occur in both the chronic and acute phase of the illness. Presentation may include nephrotic syndrome, hypertension, hematuria, and renal insufficiency. Pathologically, there is a focal segmental glomerulosclerosis, collapsing nephropathy with podocyte hypertrophy, and hyperplasia. (See also Section I: "HIV/AIDS, Urologic Considerations.")

TREATMENT

- Highly active antiretroviral therapy
- Steroids
- ACE inhibitor

REFERENCE

Audard B, Avouac J, Wirden M, et al. HIV-related nephropathies associated with changes in blood and kidney tissue virus load. *Kidney Int.* 2008;73:651–655.

HODGKIN DISEASE, UROLOGIC CONSIDERATIONS

DESCRIPTION Hodgkin disease is a type of lymphoma differentiated from other lymphomas partially on the basis of the presence of Reed–Sternberg cells. It has become 1 of the most curable forms of malignancy. It has many urologic associations, and an association with a higher incidence in RCC patients has been proposed. Treatment with radiation for Hodgkin may predispose to bladder cancer. The kidney and bladder have been reported to be primary sites of Hodgkin disease. Extensive retroperitoneal lymphadenopathy may cause ureteral obstruction. Renal radiation-induced arterial stenosis can be a treatment effect. (See also Section II: "Lymphoma, Urologic Considerations.")

REFERENCE

Jones MW. Primary Hodgkin's disease of the urinary bladder. *Br J Urol.* 1989;63(4):438.

HODGSON TYPES I, II, III HYPOSPADIAS REPAIR

DESCRIPTION Type I: Chordee is repaired. A longitudinal tube along the urethral axis is formed on the inner surface of the prepuce, which is then transferred to the ventrum through a buttonhole incision at the base of the tube. The proximal neourethra is anastomosed to the proximal native urethra, and the distal neourethral tube is used to create the meatus.

Type II: Hodgson modified type I for the very distal hypospadias where no chordee exists, and the native urethral plate remains intact. The inner surface of the prepuce is again transferred to the ventrum via a buttonhole at the base. In this repair, the prepuce flap is sutured onto the urethral plate.

Type III: This is modified for the more proximal hypospadias repair. Here, the buttonhole is created at the base of the penis, and a longer tubular neourethral is created, based on preputial and shaft skin.

REFERENCE

Devine CJ, Horton CE. Repair of hypospadias and epispadias. In: Novick AC, Streem SB, Pontes JE, et al., eds. *Stewart's Operative Urology*. Baltimore, MD: Williams & Wilkins; 1989:689–714.

HONEYMOON CYSTITIS

DESCRIPTION Urinary tract infection which affects young sexually active women. It accounts for 4% of UTIs and for 75–90% of episodes in young sexually active women. The pathogenesis of this disorder involves transmission of bowel flora from the perineum into the female's introitus during sexual intercourse. The proximity of the bladder to the perineum enables the development of an ascending infection through the female's short urethra. Spermicide use, independent of sexual frequency, increases the risk of UTIs. (See also Section I: "Urinary Tract Infection [UTI], Adult Female"; Section II: "Postcoital Prophylactic Antibiotics.")

TREATMENT

- High fluid intake
- Postcoital voiding (controversial if useful)
- Identify any triggers (Spermacide, positioning during sexual activity, etc.)
- Consider single dose of antibiotic before or after intercourse if >3 symptomatic UTIs/yr (eg, Trimethoprim/sulfamethoxazole, trimethoprim, nitrofurantoin, cephalexin, ciprofloxacin, others)

REFERENCE

Nicolle LE. Uncomplicated urinary tract infection in adults including uncomplicated pyelonephritis. *Urol Clin North Am.* 2008;35(1):1–12.

HORSESHOE KIDNEY

DESCRIPTION The most common fusion anomaly, present in 1 in 400 births, with a male predominance. Usually, this represents a true fusion of the lower poles, which may be composed of thick functioning parenchyma or merely a fibrous band. Associated anomalies are seen in 1/3 of patients and include multisystem disturbances of the skelet al and

cardiovascular systems and GI tract, as well as GU abnormalities, such as an increased frequency of ureteral duplication, reflux, and dysplasia. Usually asymptomatic, a horseshoe kidney may be associated with urolithiasis and UPJ obstruction. Radiographic diagnosis can be made with IVP or CT, which reveals deviation of the axis of the kidneys. Renal scan may be helpful in surgical decision making, if necessary. The condition is caused by fusion of poles during ascent of the kidneys. (See also Section I: "Renal Fusion Anomalies.")

TREATMENT

- Pyeloplasty and ureteral implantation may be required for proven UPJ obstruction or severe reflux, respectively
- Can affect management of many other disease conditions, such as neoplasm, aortic aneurysm, and transplantation

REFERENCE

O'Brien J, Buckley O, Doody O, et al. Imaging of horseshoe kidneys and their complications. *J Med Imaging Radiat Oncol.* 2008;52(3):216–226.

HORTON-DEVINE "FLIP-FLAP" HYPOSPADIAS REPAIR

DESCRIPTION The distal ventral skin over the urethra is mobilized, and the distal urethra is also mobilized. Parallel incisions are made in the glans to create a urethral plate, and the proximal flap is flipped over and sutured onto the urethral plate. The wings of the glans are then approximated over this distal repair.

REFERENCE

HOUNSFIELD UNITS

DESCRIPTION Named after Sir Godfrey Newbold Hounsfield, the inventor of the CT scanner, this is an arbitrary scale created to compare density of different substances seen on CT. Water is represented by 0 HU. Air is –1,000 HU. Bone is 1,000 HU. Fat is in the range of –100 to 0 HU, whereas water with electrolytes is slightly above 0 HU. Soft tissue is in the range of 35 HU.

REFERENCE

Miraldi F. Imaging principles in computed tomography. In: Haaga JR, Alfidi RJ, eds. *Computed Tomography of the Whole Body*. 1st ed. St. Louis, MO: Mosby; 1983.

HPC-1 (HEREDITARY PROSTATE CANCER 1 LOCUS)

DESCRIPTION A locus found on chromosome 1q24–25, which has been potentially linked to inherited prostate cancer. Families in which this altered gene is found were determined to have a lower age at diagnosis, a higher grade of cancer, and more cases of advanced disease than normal.

REFERENCE

Gronberg H, Isaacs SD, Smith JR, et al. Characteristics of prostate cancer in families potentially linked to the hereditary prostate cancer 1 (HPC1) locus. *JAMA*. 1997;278(15):1251–1255.

HPV (HUMAN PAPILLOMA VIRUS), UROLOGIC CONSIDERATIONS

DESCRIPTION This family of viruses, with double-stranded DNA, causes various warts, papillomas, and cervical cancer. Types 6, 11, 42, and 44 are associated with condyloma acuminatum. Types 16, 18, 31, 33, 35, and 39 have an association with cancer. Types 6 and 11 have been associated with Buschke–Lowenstein tumor. Subclinical condyloma can be detected with application of 5% acetic acid and inspection with a magnifying glass. HPV is associated also with Bowenoid papulosis and squamous cell carcinoma of the penis and urethra. Bladder cancer association is controversial. (See also Section I: “Condylomata Acuminata [Venereal Warts]”; “Penis, Lesion, General”; and Section II: “Buschke-Lowenstein Tumor.”)

TREATMENT

- Podophyllin or trichloroacetic acid for condyloma
- Laser therapy is also effective

HUMAN GROWTH HORMONE (hGH), UROLOGIC CONSIDERATIONS

DESCRIPTION Use of hGH has been approved for children with short stature. There are multiple off-label uses; hGH has also been used in the aging patient to increase energy and possibly libido, and to add muscle mass in athletes. These therapeutic applications are not supported by evidence-based studies. There have been some concerns expressed that the use of hGH may increase the risk of germ cell tumors (GCT’s) anywhere in the body; vigilant monitoring is mandatory in treated GCTs who are hGH replaced.

REFERENCES

Allen DB, Fost N. hGH for short stature: Ethical issues raised by expanded access. *J Pediatrics*. 2004;144(5):648–652.

HUNNER ULCER

DESCRIPTION Cystoscopic finding of ulceration of the bladder mucosa in patients with interstitial cystitis/painful bladder syndrome (IC/PBS). This fulfills 1 of the NIH criteria for

IC/PBS. Found in a variable number of patients with IC/PBS, it was 1st described by Hunner in 1918, when he noted the ulcer in association with the constellation of clinical findings of IC/PBS. (See also Section I: "Interstitial Cystitis.")

REFERENCE

Hillelsohn JH, Rais-Bahrami S, Friedlander JI, et al. Fulguration for Hunner ulcers: Long-term clinical outcomes. *J Urol.* 2012;188(6):2238–2241.

HUTCH DIVERTICULUM

DESCRIPTION Herniation of the bladder mucosa through the weakest point of the hiatus, in the detrusor above the intramural ureter, producing a Hutch diverticulum and reflux. The condition is usually due to a chronic increase in intravesical pressure as a result of bladder outlet obstruction. (See also Section I: "Vesicoureteral Reflux, Adult" and "Vesicoureteral Reflux, Pediatric.")

REFERENCE

Hutch JA, Ayres RD, Loquvam GS. The bladder musculature with special reference to the uretero vesical junction. *J Urol.* 1961;85:531.

HYDATID CYST (HYDATID DISEASE)

DESCRIPTION Infection occurs after ingestion of the dog parasite, *Echinococcus granulosus* (tapeworm). Sheep are the intermediate hosts. Cases occur in the Middle East, Australia, and Argentina. The hydatid is the larval form of *E. granulosus*, and the cysts represent a thick parasitic membrane that is enveloped in fibrous tissue. The cysts are fluid filled and contain the parasites. They grow slowly over many years and typically involve the kidney (2% incidence with echinococcus), with cases of seminal vesical involvement also reported. 3% affect the kidneys. Large cysts form that can be asymptomatic or present with flank pain. Renal cysts may cause pressure and chronic pain but do not affect renal function. They may rupture, causing new metastatic cysts. A peripheral eosinophilia is seen with a positive hydatid complement-fixation test. X-rays and CT show a thick-walled, fluid-filled spherical cyst with a calcified wall. (See also Section II: "Echinococcus, Renal.")

TREATMENT

- Medical therapy is with albendazole.
- Where surgical excision is indicated, cysts can be 1st sterilized with formalin or alcohol. Praziquantel is also recommended preoperatively or if cyst contents are spilt (which can cause systemic anaphylaxis).

REFERENCE

Kaya K, Gokce G, Kaya S, et al. Isolated renal and retroperitoneal hydatid cysts: A report of 23 cases. *Trop Doct.* 2006;36(4):243–246.

HYDROCALYCOSIS

DESCRIPTION A relatively rare cystic dilation of a major calyx. A calyceal diverticulum is

distal to a minor calyx, whereas the hydrocalyx is a dilation of a major calyx. Caused by a congenital anomaly secondary to acquired intrinsic obstruction from a parapelvic cyst or crossing vessel causing infundibular stenosis. Differential diagnoses includes megacalycosis, ureteral obstruction and hydronephrosis, calyceal clubbing due to pyelonephritis or medullary necrosis, renal TB, or calyceal diverticulum. Patients may complain of flank pain, hematuria, or infection. Dismembered pyeloplasty or percutaneous treatment of the narrowed infundibulum is curative.

REFERENCE

Craver R, Boyd R, Ward K, et al. Renal hypertrophic infundibular stenosis. *Fet al Pediatr Pathol.* 2004;23(4):285–292.

HYDROCELE OF THE SPERMATIC CORD

DESCRIPTION A loculated fluid collection along the spermatic cord, the process is caused by a failure of the process vaginalis to close during development. The hydrocele can be in communication with the peritoneum at the internal inguinal ring (funicular) or may be encysted, where the fluid collection does not communicate with the peritoneum or the tunica vaginalis. Patients usually present with groin swelling and should be evaluated with US, which will exhibit an oval anechoic mass in the groin along the spermatic cord and above and separated from the testis and the epididymis. (See also Section I: "Hydrocele, Adult and Pediatric"; Section I: "Spermatic Cord Mass.")

REFERENCE

Rathaus V, Konen O, Shapiro M, et al. US features of spermatic cord hydrocele in children. *Br J Radiol.* 2005;74:818–820.

HYMENAL SKIN TAGS

DESCRIPTION A polypoid lesion of the hymenal ring. A normal variant and rarely symptomatic (ie, bleeding, irritation), treatment involves observation or excision when symptomatic or to exclude malignancy.

REFERENCE

Rink RC, Kaefer M. Surgical management of disorders of sexual differentiation, cloacal malformation and other abnormalities of the genitalia in girls. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders, 2012:3629–3666.

HYPERBARIC OXYGEN, UROLOGIC CONSIDERATIONS

DESCRIPTION This therapy involves use of oxygen at higher than atmospheric level. A variety of uses have been reported. Mainly, hyperbaric oxygen has been used to aid in wound healing. Reports of its efficacy in healing after radiation-induced wounds and iatrogenic debridement following necrotizing fasciitis of the genitourinary tract (Fournier gangrene) have been described. Hyperbaric oxygen has also been reported in the treatment of hematuria from radiation cystitis. (See also Section I: "Fournier gangrene"; "Cystitis, Hemorrhagic [Infectious, Noninfectious, Radiation"] and Section II: "Cystitis: Radiation.")

REFERENCES

HYPERCALCEMIA, UROLOGIC CONSIDERATIONS

DESCRIPTION In urology, hyperuricemia is generally the result of metastatic lesions to bone, hydrochlorothiazide therapy, hyperparathyroidism, or chronic renal failure. Symptoms include anorexia, weakness, somnolence, polyuria, and coma. This condition may also occur as a paraneoplastic syndrome from RCC and can lead to hypercalciuria, which can increase chances of urolithiasis.

TREATMENT
- Initial therapy involves diuresis by nonthiazide diuretics and IV saline.
- Inorganic phosphate and EDTA may be used for an emergency.
- Mithramycin, steroids, and etidronate disodium have also been used.

REFERENCE
Assadi F. Hypercalcemia: An evidence-based approach to clinical cases. *Iran J Kidney Dis.* 2009;3(2):71–79.

HYPERCALCIURIA (ABSORPTIVE, RENAL, AND RESORPTIVE)

DESCRIPTION Hypercalciuria is the most commonly encountered metabolic abnormality in patients with calcium nephrolithiasis. Defined as urinary excretion of >275–300 mg of calcium per day in men or >250 mg of calcium per day in women on a regular unrestricted diet. An alternative definition in patients on a calcium-restricted diet (400 mg calcium, 100 mEq sodium) is a urinary calcium level of >4 mg/kg/d or with a urinary level >200 mg calcium/L of urine. Hypercalciuria consists of several types:
- **Absorptive hypercalciuria.** Caused by the intestinal hyperabsorption of calcium. Hypercalciuria results from the increased filtered load and reduced renal tubular reabsorption of calcium, caused by parathyroid suppression. Absorptive hypercalciuria type I is a severe, uncommon form; type II is mild–moderate and the most common form of this condition. Type III, sometimes called *renal phosphate leak*, is uncommon.
- **Renal hypercalciuria.** Also called *renal calcium leak*, this is caused by impairment in the renal tubular reabsorption of calcium. There may be excessive mobilization of calcium from bone and an enhanced intestinal absorption of calcium because of the parathyroid hormone excess and the stimulation of the renal synthesis of 1,25–$(OH)_2D$. Unlike primary hyperparathyroidism, serum calcium is normal and the hyperparathyroidism is secondary.
- **Resorptive hypercalciuria.** The hypercalciuria is due to primary hyperparathyroidism with excessive resorption of bone resulting from hypersecretion of PTH. Intestinal absorption of calcium is frequently elevated because of the PTH-dependent stimulation of the renal synthesis of 1,25–$(OH)_2D$.

As a guide to testing for hypercalciuria, calcium load usually consists of 1 g of oral calcium gluconate.

Hypercalciuria Type	Urinary Calcium on 400-mg Calcium Diet (Normal = <200 mg/24 h)	Fasting Calcium/ Creatinine Ratio (Normal = <0.11)	Postcalcium Load Calcium/Creatinine Ratio (Normal = <0.20)
Normal	Normal	Normal	Normal
Absorptive type I	High	Normal	High
Absorptive type II	Normal	Normal	High
Absorptive type III (renal phosphate leak)	High	High	High
Renal calcium leak	High	High	High
Resorptive (hyperparathyroidism)	High	High	High

Based on data from Leslie SW. Hypercalciuria. http://www.emedicine.com/med/TOPIC1069.HTM, Accessed May 18, 2013.

TREATMENT

- General recommendations include increased urine volume to >2 L/d, do not use calcium-restricted diet, but avoid excessive intake of dairy products, salty foods, and red meat protein. (Note: A low calcium intake increases intestinal oxalate absorption, with a subsequent increase in urinary oxalate stone formation.) Patients may be at risk for osteoporosis and osteopenia.
- Absorptive hypercalciuria:
  - Thiazide is not a selective therapy for absorptive hypercalciuria, since it does not decrease intestinal calcium absorption. However, this drug is used because of its hypocalciuric action and the high cost and inconvenience of alternative therapy (sodium cellulose phosphate).
- Absorptive hypercalciuria type I:
  - Thiazide does not correct the basic, underlying physiologic defect in absorptive hypercalciuria.
  - Potassium supplementation (as potassium citrate), should be employed when using thiazide therapy to prevent hypokalemia and hypocitraturia (eg, potassium citrate 15–20 mEq BID)
  - Amiloride in combination with thiazide may be more effective than thiazide alone in reducing calcium excretion.
  - Potassium supplementation should be used with caution in patients taking amiloride.
  - Thiazides may lose their hypocalciuric effect over time and cause hypokalemia, hypocitraturia, and increased uric acid.
  - Recent data suggest bisphosphonates (eg, alendronate [Fosamax], risedronate [Actonel], and ibandronate [Boniva] increase bone deposition of calcium and reduce urinary calcium levels.
- Absorptive hypercalciuria type II:
  - No specific drug treatment may be necessary since the physiologic defect is not as severe as in absorptive hypercalciuria type I. Low calcium intake (400–600 mg/d) and high fluid intake (sufficient for a minimum urine output >2 L/d) is helpful. Normo-calciuria can be restored by dietary calcium restriction alone, and increased urine volume has been shown to reduce urinary saturation of calcium oxalate.
- Absorptive hypercalciuria type III (renal phosphate leak) is treated with slow-release neutral

potassium phosphate (Neutra-Phos K) that corrects the hyperphosphatemia.

- Renal hypercalciuria:
  - Thiazide diuretic augments calcium reabsorption in the distal tubule, causes extracellular volume depletion, and stimulates proximal tubule reabsorption of calcium. Agents include hydrochlorothiazide 50 mg BID, chlorthalidone 50 mg/d, or indapamide 1.25–2.5 mg/d. Potassium supplementation (~40 mEq/d) is required to prevent hypokalemia and attendant hypocitraturia. Potassium citrate has been shown to be effective in averting hypokalemia and in increasing urinary citrate when administered to patients with calcium nephrolithiasis taking thiazide.
  - Triamterene is contraindicated because of the risk of triamterene renal stone formation.
- Resorptive hypercalciuria: Parathyroidectomy is the optimum treatment.

HYPERCARBIA DURING LAPAROSCOPY

DESCRIPTION CO_2 is the most abundantly used insufflant in the United States for laparoscopic surgery. CO_2 has the ability to diffuse easily into body tissues and out of the peritoneum during surgery. This can lead to increases in blood levels or hypercarbia that can stimulate the sympathetic nervous system, leading to increases in vascular resistance, tachycardia, and impaired cardiac contractility. Patients who have pulmonary compromise (ie, COPD, fibrosis) may have difficulty compensating for the increased CO_2 levels. Rarely a CO_2 gas embolism may occur.

REFERENCE

Bandi G, Gomella LG. Basic principles of laparoscopy: Transperitoneal, extraperitoneal and hand-assisted techniques. In: Graham S, Keane T, eds. *Glenn's Operative Urology*. 7th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2009.

HYPERCONTINENCE

DESCRIPTION A condition described in the literature referring to the increased likelihood that females are more likely to require intermittent catheterization than men following continent urinary diversion such as orthotopic neobladder. Hypercontinence is reported in up to 31% of females and is much less common in men.

REFERENCE

Rouanne M, Legrand G, Neuzillet Y, et al. Long-term women-reported quality of life after radical cystectomy and orthotopic ileal neobladder reconstruction. *Ann Surg Oncol*. 2014;21(4):1398–1404.

HYPERKALEMIA, UROLOGIC CONSIDERATIONS

DESCRIPTION Hyperkalemia usually occurs in urologic patients as a result of renal insufficiency, addisonian crisis, trauma, shock, and diabetic acidosis. It can also be a

consequence of small bowel substitution used in urinary diversion. ECG changes are characteristic, including peaked T waves, long PR interval, long QRS complex, and absent P wave.

TREATMENT

- Monitor patient on ECG if symptomatic or if K^+ is >6.5 mEq/L; discontinue all K^+ intake, including IV fluids; order a repeat stat K^+ to confirm.
- Pseudohyperkalemia should be ruled out. If doubt exists, obtain a plasma K^+ in a heparinized tube; the plasma K will be normal if pseudo-hyperkalemia is present.
- Rapid correction: These steps only protect the heart from K^+ shifts, and total body K^+ must be reduced by 1 of the treatments shown under slow correction:
  - Calcium chloride, 500 mg, slow IV push
  - Alkalinize with 50 mEq (1 amp) Na^+ bicarbonate (causes intracellular K^+ shift)
  - 50 mL D50W, IV push, with 10–15 units regular insulin, IV push (causes intracellular K^+ shift)
- Slow correction:
  - Sodium polystyrene sulfonate (Kayexalate) 20–60 g PO with 100–200 mL of sorbitol or 40 g Kayexalate with 40 g sorbitol in 100-mL water given as an enema. Repeat doses QID as needed.
- Dialysis (hemodialysis or peritoneal):
  - Correct underlying cause, such as stopping K-sparing diuretics, ACE inhibitors, mineralocorticoid replacement for hypokalemia

REFERENCE

Fluids and electrolytes. In: Gomella LG, Haist SA, eds. *Clinician's Pocket Reference.* 11th ed. New York, NY: McGraw-Hill; 2007.

HYPERMAGNESEMIA, UROLOGIC CONSIDERATIONS

DESCRIPTION Hypermagnesemia (Mg >2.5 mEq/L [mmol/L]) usually results from excessive intake (including laxatives, enemas, antacids), renal failure, hypothyroidism, or adrenal insufficiency. Symptoms include nausea and vomiting, weakness, and hyporeflexia. At higher serum levels, cardiac arrhythmias and severe cardiovascular abnormalities can result.

TREATMENT

- Stop administration of any magnesium containing medications.
- Maximize excretion of magnesium—for patients with normal renal function diuretics are used and for patients in renal failure dialysis should be initiated.
- Calcium gluconate can be administered as a cardioprotective agent.

REFERENCE

Fluids and electrolytes. In: Gomella LG, Haist SA, eds. *Clinician's Pocket Reference.* 10th ed. New York, NY: McGraw-Hill; 2007.

HYPERNATREMIA, UROLOGIC CONSIDERATIONS

DESCRIPTION Hypernatremia in the urologic patient can result from iatrogenic causes and various disease states. Classified according to the mechanisms described below, the symptoms depend on the absolute level and also how rapidly the Na^+ level has changed. Symptoms may include confusion, irritability, lethargy, stupor, coma, muscle twitching, and seizures. Signs can include hyperreflexia and mental status changes:

- Combined sodium and water losses (hypovolemic hypernatremia): Water loss in excess of Na^+ loss results in low total body Na^+. Due to renal (diuretics, osmotic diuresis due to glycosuria, mannitol, post-obstructive diuresis, etc.) or extrarenal (sweating, GI [vomiting, NG suction], respiratory) losses.
- Excess water loss (isovolemic hypernatremia): Total body Na^+ remains normal, but total body water is decreased. Caused by diabetis insipudus (DI) (central and nephrogenic), excess skin losses, respiratory loss, others.
- Excess sodium (hypervolemic hypernatremia): Total body Na^+ increased. Caused by iatrogenic Na^+ administration (ie, hypertonic dialysis, hypertonic saline enemas, Na-containing medications) or other exogenous sources (seawater ingestion, salt tablets) or adrenal hyperfunction (Cushing syndrome, hyperaldosteronism).

TREATMENT

- Check the serum Na^+ levels frequently while attempting to correct hypernatremia:
  - Hypovolemic hypernatremia. Determine if the patient's volume is depleted by determining if orthostatic hypotension is present; if volume is depleted, rehydrate with NS until patient is hemodynamically stable, then administer hypotonic saline (1/2 NS).
  - Euvolemic/isovolemic (no orthostatic hypotension): Calculate the volume of free water needed to correct the Na^+ to normal as follows:

    Body water deficit = Normal total body water - Current TBW
    Normal TBW = 0.6 - Body weight in kg
  - Give free water as D5W, 1/2 the volume in the 1st 24 hr and the full volume in 48 hr. (Caution: The rapid correction of the Na^+ level using free water (D5W) can cause cerebral edema and seizures.)
  - Hypervolemic hypernatremia: Avoid medications that contain excessive Na^+ (carbenicillin, etc.). Use furosemide along with D5W.

REFERENCE

HYPEROXALURIA, UROLOGIC CONSIDERATIONS

DESCRIPTION The greatest significance of hyperoxaluria is the increased risk of urolithiasis, which is more significant than calcium in the formation of most kidney stones. Oxalate and calcium form an insoluble compound that can result in urolithiasis. The normal upper level of urinary oxalate excretion is 40 mg (440 μmol)/24 hr. Hyperoxaluria is caused

by dietary excess, bowel disorders such as extensive ileal resection, and primary hyperoxaluria. Primary hyperoxalurias are disorders associated with a congenital defect in the oxalate pathway. (See also Section I: "Urolithiasis, Calcium Oxalate/Phosphate."):

- Enteric hyperoxaluria: Accounts for a relatively small number of cases of hyperoxaluria (5%). Caused by chronic diarrhea and malabsorption (colitis or jejunoileal bypass), through the reduced GI calcium availability to bind oxalate and keep it from being absorbed systemically.
- Dietary hyperoxaluria: Caused by increased intake of foods high in oxalates (eg, nuts, chocolate, tea, spinach, rhubarb, beets, wheat bran, strawberries, and other plant products). Reduced dietary calcium intake can also result in hyperoxaluria due to reduced intestinal binding of oxalate and increased oxalate absorption.
- Idiopathic: The most common cause; may be due to increased dietary absorption or due to increased intrinsic production of oxalate, with some suggestions of a genetic predisposition.
- Primary hyperoxaluria type I (also called *glycolic aciduria*): A form of primary hyperoxaluria caused by an enzymatic deficiency of glyoxylate carboligase transmitted as an autosomal recessive trait. Caused by a deficiency of the peroxisomal liver-specific alanine-glyoxylate aminotransferase (AGT) gene. Pyridoxine (vitamin B6) is a cofactor in this pathway that normally converts glyoxylic acid to glycine. With a block in this conversion, because of deficiency or absence of this enzyme, high levels of glycolic and oxalic acids result that are converted to oxalate that is then excreted in the urine. This causes extensive nephrocalcinosis with kidney failure common in childhood. Most patients die at <30 yr. The condition often presents with stone disease in childhood. Type I can be associated with ESRD secondary to stones and interstitial deposits of calcium oxalate.
- Primary hyperoxaluria type II: Less common than type I hyperoxaluria, this entity is caused by deficiency of D-glyceric dehydrogenase that causes the conversion of glyoxylate to oxalate. Type I and II primary hyperoxaluria result in about the same degree of hyperoxaluria, with renal failure slightly less common in patients with type II disease. Pyridoxine is generally not effective in type II primary hyperoxaluria.
- Other: Increased hepatic conversion, due to pyridoxine deficiency, type I glycol ingestion, and methoxyflurane anesthesia

TREATMENT

- Primary hyperoxaluria: Oral phosphates and dietary oxalate restriction are usually unsuccessful. Increase urine flow. Prescribe high-dose pyridoxine (vitamin B6) 150–500 mg/d. Liver–kidney transplantation is often required at end stage.
- Enteric hyperoxaluria: Calcium citrate without vitamin D, potassium citrate 40–60 mEq/d in divided doses (increases urinary pH and citrate). Dietary restriction of oxalate with low fat and reduced meat protein diet.
- Idiopathic hyperoxaluria: Increase urine flow. Avoid excess Vitamin C (can be converted to oxalate). Prescribe high-dose pyridoxine (vitamin B6) 150–500 mg/d.

HYPERPARATHYROIDISM, UROLOGIC CONSIDERATIONS

DESCRIPTION Hyperparathyroidism can cause a variety of urologically related conditions and problems, including nephrolithiasis, hypercalciuria, nephrocalcinosis, chronic renal insufficiency, and abnormalities in renal tubular function (decreased concentrating ability). Also associated in the MEN1 syndrome. About 5% of new stone formers have hyperparathyroidism, whereas up to 20% of patients with hyperparathyroidism will have stones (most common calcium oxalate). These patients usually exhibit elevated serum and urine calcium with an inappropriately normal or elevated serum PTH level and elevated calcitriol level. Treatment is through parathyroidectomy and workup for MEN when appropriate. (See also Section II: "Hypercalciuria and Multiple Endocrine Neoplasia.")

REFERENCE

Reinmark L, Vestergaard P, Mosekilde L. Nephrolithiasis and renal calcifications in primary hyperparathyroidism. *J Clin Endocrinol Metab*. 2011;96(8):2377–2385.

HYPERPHOSPHATEMIA, UROLOGIC CONSIDERATIONS

DESCRIPTION Hyperphosphatemia (>1.6 mmol/L) can result from hypoparathyroidism, osteomalacia, medications, and chronic renal failure. Signs include muscle cramps, tetany, perioral numbness, renal osteodystrophy, and secondary hyperparathyroidism.

TREATMENT

Dietary restriction, stopping medications that include phosphate, and binding agents are the mainstays of therapy.

REFERENCE

Prie D, Beck L, Urena P, et al. Recent findings in phosphate homeostasis. *Curr Opin Nephrol Hypertens*. 2005;14:318–324.

HYPERSPERMIA AND HYPOSPERMIA

DESCRIPTION Hyperspermia is a poorly studied condition characterized by an excessive volume of ejaculate defined in studies as >5.5–6.5 mL/semen analysis. Hypospermia is generally defined as a total ejaculate of <1.5 mL. (See also Section II: "Semen Analysis, Abnormal Findings and Terminology"; Section II: "Semen Analysis, Technique and Normal Values.")

REFERENCE

Cooke S, Tyler JP, Driscoll GL. Hyperspermia: The forgotten condition? *Human Reprod.* 1995;10(2):367–368.

HYPERTENSION, UROLOGIC CONSIDERATIONS

DESCRIPTION Primary hypertension is the most common form of this disease, but when significant findings on evaluation are present or if the hypertension is refractory to intensive multiple-drug therapy or requires hospitalization, a secondary cause should be sought. Common urologic considerations are primary aldosteronism, congenital adrenal hyperplasia

(CAH), Cushing syndrome, pheochromocy-toma, and renovascular disease. Workup entails physical exam, endocrinologic workup, and imaging.

REFERENCE

Victor G. Arterial hypertension. In: Goldman L, ed. *Cecil Medicine*. 23rd ed. Philadelphia, PA: Saunders; 2007.

HYPERURICOSURIA

DESCRIPTION Hyperuricosuria refers to the uric acid excretion in the urine of >800 mg/d in men and >750 mg/d in women. Uric acid, the end product of purine metabolism, is relatively insoluble in water and can lead to the formation of uric acid calculi. Overproduction and over-excretion of uric acid can be due to excess dietary intake of purine-rich foods and in patients with malignancies (such as lymphoma, leukemia, myeloproliferative disease) especially after chemo or radiation induces rapid cell lysis (tumor lysis syndrome). Inherited enzyme defects can also lead to hyperuricosuria and hyperuricemia such as hypoxanthine-guanine phosphoribosyltransferase deficiency (Lesch–Nyhan syndrome) and glucose-6-phosphatase deficiency (glycogen storage disease, type I). Hyperuricosuria can be associated with hyperuricemia. The term "gouty diathesis" refers to the formation of urinary stones in persons with gout. These patients may present with other manifestations of gout such as "gouty arthritis." These high levels of uric acid can predispose to urolithiasis that can be uric acid, calcium or a combination of both. Uric acid stones are more likely with a low urine pH (ie, <6) where the solubility of uric acid is low. Allopurinol and febuxostat reduce urinary levels of uric acid. Urate crystals in the urine tend to be needle-shaped or appear as flat, square plates. (See also Section I: "Urolithiasis, Uric Acid.")

HYPOCITRATURIA

DESCRIPTION Citrate is a urinary inhibitor of crystal formation. Hypocitraturia is defined as urinary citrate excretion of <320 mg/d, but the absolute value can vary. It is a common cause of calcium urolithiasis, because citrate combines with calcium to form a nondissociable soluble complex with less calcium to combine with oxalate. Citrate also inhibits crystal agglomeration, in which individual calcium oxalate crystals combine to form a stone. Hypocitruria may develop from distal renal tubular acidosis (type I), chronic diarrhea,

thiazide use, very high animal protein diet, and gastrocystoplasty, or it may be idiopathic.

TREATMENT

- Correction of acidosis in RTA
- Replacement therapy with potassium citrate (powder: 1 packet in water after meals and at bedtime; adjust dose to urinary pH; solution: 15–30 mL after meals and at bedtime; adjust dose based on urinary pH)

REFERENCE

Pak CY. Pharmacotherapy of kidney stones. *Expert Opin Pharmacother.* 2008;9(9):1509–1518.

HYPOGONADISM, SOCIETY DEFINITIONS

DESCRIPTION The lab diagnosis of testosterone/androgen deficiency is a challenge. The Endocrine Society defines male hypogonadism as a clinical syndrome that results from failure of the testis to produce physiologic levels of testosterone (androgen deficiency) and the normal number of spermatozoa caused by disruption of 1 or more levels of the hypothalamic–pituitary–gonadal (HPG) axis. Unfortunately there is no consensus among specialists (endocrinologists, urologists, pathologists) as to what lab values defines a "low" testosterone level. Serum testosterone levels are subject to many variables including diurnal, seasonal, and age-related variations. Illness and medications (opiates, glucocorticoids), may impact testosterone levels. In addition testosterone levels are impacted by alterations in sex-hormone binding globulin (SHBG). Further there are a variety of assays that differ in their measurement of testosterone levels leading to a wide variety of normal ranges reported by different labs. The Food and Drug Administration (FDA) uses a cut-off value of 300 ng/dL to define hypogonadism for clinical trial development and enrollment. Society definitions of testosterone levels and hypogonadism are summarized in the table. (See also Section I: "Andropause [Late Onset Male Hypogonadism]," "Testosterone, Decreased [Hypogonadism]," "Sex-Hormone Binding Globulin," and "Testosterone [Free and Total] Lab Testing.")

HYPOKALEMIA, UROLOGIC CONSIDERATIONS

DESCRIPTION Hypokalemia (K^+ of <3.6 mEq/L [mmol/L]) can result from excessive upper GI losses, diarrhea, diuretic therapy, steroid administration, and hyperaldosteronism. Metabolic alkalosis is often associated and causes an intracellular redistribution of potassium. Other high-renin states, such as renin-secreting tumors, have been reported as a cause. A serum K^+ level of 2 mEq/L (mmol/L) probably represents a deficit of at least 200 mEq (mmol) in a 70-kg adult; to change K^+ from 3–4 mEq/L (mmol/L) takes about 100 mEq (mmol) of K^+ in a 70-kg adult.

TREATMENT

- Treat underlying cause.

- Hypokalemia potentiates the cardiac toxicity of digitalis. In the setting of digoxin use, hypokalemia should be aggressively treated.
- Treat hypomagnesemia if present. It will be difficult to correct hypokalemia in the presence of hypomagnesemia.
- Rapid correction: Give KCl IV. Monitor heart with replacement at >20 mEq/h; IV KCI can be painful and damaging to veins:
  - Patient <40 kg: 0.25 mEq/kg/h × 2 hr
  - Patient >40 kg: 10–20 mEq/h × 2 hr
  - Severe [<2 mEq/L (mmol/L)]: Maximum 40 mEq/h IV in adults. In all cases, check a stat K^+ following each 2–4 hr of replacement.
- Slow correction: Give KCl PO:
  - Adult: 20–40 mEq BID or TID
  - Pediatric patients: 1–2 mEq/kg/d in divided doses. Potassium supplementation either with PO or IV forms

REFERENCE

Fluids and electrolytes. In: Gomella LG, Haist SA, eds. *Clinician's Pocket Reference.* 10th ed. New York, NY: McGraw-Hill; 2007.

HYPOMAGNESEMIA, UROLOGIC CONSIDERATIONS

DESCRIPTION Hypomagnesemia (Mg of <0.7 mEq/L [mmol/L]) can result from inadequate magnesium intake, malabsorption, chronic diarrhea, stress, alcoholism, and medications such as diuretics. Symptoms of hypomagnesemia include weakness, muscle cramps, muscle tetany, confusion, hallucinations, hypertension, and arrhythmias. Often accompanied by hypokalemia.

TREATMENT

Replacement can be either oral for patients with mild symptoms or parenterally for more severe symptoms.

- Tablet (Mag-Ox): 1–2 tablets PO daily or capsule (Uro-Mag): 4–5 capsules PO daily
- Parenteral replacement: Mild 1 g IM q6h × 4 doses; More severe: 5 g IV over 3 hr
- Changing diuretics to agents such as amiloride (a potassium-sparing diuretic with mild hypocalciuric activity) reduces the magnesium loss caused by thiazides.

REFERENCE

Fluids and electrolytes. In: Gomella LG, Haist SA, eds. *Clinician's Pocket Reference.* 10th ed. New York, NY: McGraw-Hill; 2007.

HYPONATREMIA, UROLOGIC CONSIDERATIONS

DESCRIPTION Hyponatremia is a sodium/Na^+ level of <136 mEq/L (mmol/L). Many causes exist, but an acute cause in urology is a result of excessive nonelectrolyte irrigant absorption during endourologic procedures. As the fluid is absorbed, volume expansion and dilutional hyponatremia occur. Known as transurethral resection (TUR) syndrome, nausea, mental confusion, and sensory disturbances are seen, and, if allowed to progress, blindness,

convulsions, hypotension, coma, oliguria, and death can occur. Other causes include nephrotic syndrome, renal failure, SIADH, adrenal insufficiency, diuretics, renal tubular acidosis (RTA), GI losses, and mineralocorticoid insufficiency. (See also Section I: "Transurethral Resection [TUR] Syndrome.")

TREATMENT

- Treat the underlying cause.
- Therapy is based on determination of volume status. Evaluate volume status by physical exam: HR and BP lying and standing after 1 min, skin turgor, and edema, and by determination of the plasma osmolality. It is not necessary to treat hyponatremia from pseudo-hyponatremia (increased protein or lipids) or hypertonic hyponatremia (hyperglycemia); treat underlying disorder (see above):
  - Life-threatening (seizures, coma): 3–5% NS can be given in the ICU setting. Attempt to raise the Na to at least 125 mEq/L with 3–5% NS.
  - Isovolemic hyponatremia (SIADH): Restrict fluids (1,000–1,500 mL/d). Demeclocycline can be used in chronic SIADH.
  - Hypervolemic hyponatremia: Restrict Na and fluids (1,000–1,500 mL/d). Treat with furosemide.
  - Hypovolemic hyponatremia: Give D_5NS or NS.
    - Arginine vasopressin antagonists are indicated to raise serum sodium in hospitalized patients with euvolemic and hypervolemic hyponatremia
      - Conivaptan (Vaprisol) Load: 20 mg IV infusion over 30 min the 20 mg IV continuous infusion over 24-hr period for 2–4 days
      - Tolvaptan (Samsca) Initial: 15 mg PO daily followed by maintenance. Increase dose PRN after >24 hr to 30 mg qDay; may increase further 60 mg/d maximum dose. Not to exceed 30 days.

REFERENCE

Fluids and electrolytes. In: Gomella LG, Haist SA, eds. *Clinician's Pocket Reference.* 11th ed. New York, NY: McGraw-Hill; 2007.

HYPOPHOSPHATEMIA, UROLOGIC CONSIDERATIONS

DESCRIPTION Hypophosphatemia (<1.0 mmol/L) can result from inadequate intake, malabsorption, alcohol abuse, and hyperparathyroidism. It may manifest as muscle weakness, or mental status changes. More severe states can produce problems at the cellular level leading to white blood cell dysfunction or anemia.

TREATMENT

Replacement can be either oral for patients with mild symptoms or parenterally for more severe symptoms.

- Potassium phosphate/sodium acid phosphate (K-Phos Neutral, Neutra-Phos) 1–2 tablets PO QID; also lowers urinary calcium level in idiopathic hypercalciuria
- Parenteral: KPO_4 Phos or Na PO_4 (mixed 15 mmol/250 mL) 0.25 mmol/kg IBW infused over 4–6 hr

REFERENCE

Felsenfeld AJ, Levine BS. Approach to treatment of hypophosphatemia. *Am J Kidney Dis*. 2012;60(4):655–661.

HYPOSPADIAS, FREE GRAFT REPAIR

DESCRIPTION When local skin is not available or the quality of the preputial flap is poor during planned hypospadias repair, the use of free grafts from the bladder (1st introduced in 1947 by Memmelaar) or buccal mucosa tissue is generally employed. From a historical perspective, genital skin or bladder mucosa was commonly utilized during free graft repair. However, buccal mucosa has now become the graft of choice in the modern era. The preferred harvesting area is the inner cheek, taking care to avoid Stensen's duct. Multiple small incisions are then made in the harvested graft to prevent hematoma formation after placement. Excellent results have been reported in both the single and 2 step stages utilizing free buccal mucosa graft for repair.

HYPOSPADIAS, TUBULARIZED INCISED PLATE (TIP) REPAIR

DESCRIPTION For distal hypospadias repairs, the most commonly performed operation is the tubularized incised plate or TIP repair. The penis is degloved and a midline incision of the urethral plate is made from within the meatus to the end of the plate without entering the glans. This incision allows for easier tubularization of the tissue and creates less tension on the ventral reconstruction. Urethral plate tubularization is then performed from the end of the plate to create a rounded meatus. Subepithelial running is used to complete a 2-layer closure. A dartos flap is then created and rotated ventrally to cover the neo-urethra. Glansplasty and shaft skin closure and reconstruction complete the procedure. Sponge bathing and antibiotic therapy are advised until the urethral catheter is removed. Oxybutynin is also provided to older patients to reduce bladder spasms. As with other hypospadias techniques, the most common complications from TIP urethroplasty is fistula formation, which can be low as 2% in the hands of an experienced surgeon. It has proven to be a versatile procedure used in both distal and midshaft hypospadias repairs.

REFERENCE

Snodgrass WT. Snodgrass technique for hypospadias repair. *BJU Int.* 2005;95(4):683–693.

HYPOSPADIAS, 2-STAGE REPAIR

DESCRIPTION The basic tenet of the 2-stage hypospadias repair is to create a new urethral plate with a graft of alternative tissue in the 1st stage and then tubularize this tissue to create a neo-urethra in the 2nd stage. The main grafts for the 1st-stage repair can be categorized

into the following:
- Byars' flap—pedicled flaps of the dorsal hood foreskin rotated ventrally
- Mesh free skin graft in an onlay fashion
- Buccal mucosa free graft in an onlay fashion
- Bracka graft—a free partial-thickness skin graft

The choice of graft depends on a multitude of factors including surgeon experience or preference, availability of preputial skin, and history of previous surgeries.

During the 1st stage, an orthoplasty is performed and a chosen graft is placed on the ventral penis. The next stage is generally performed 6 mo or more after completion of the 1st stage where the main goal is to create a neo-urethra that corrects the hypospadias. Tubularization of local skin proceeds in a Thiersch–Duplay fashion. This step is followed by reapproximation of the glans over the newly formed urethra and 2nd layer coverage with local subcutaneous tissue or a tunica vaginalis flap. Finally, urinary diversion with either a urethral or suprapubic catheter should be done for 1–2 wk postoperatively. Daily meatal dilation for 6 mo is recommended to prevent meatal stenosis. Complications include urethrocutaneous fistula, bleeding, infection, meatal stenosis, urethral stricture, and partial or complete breakdown of the repair.

HYPOSPADIAS, URETHRAL ADVANCEMENT FOR SUBGLANULAR AND MIDSHAFT DEFECTS

DESCRIPTION The meatal advancement and glanuloplasty incorporated (MAGPI) procedure was 1st described by Duckett in 1981 as an option for patients with a glanular or subcoronal hypospadias. A dorsal meatotomy with glanulopasty is performed to advance the neo-urethra distally. This was later modified by Zaontz in 1989 for patients with a coronal or glanular hypospadias with a deep glanular groove and a fish mouth meatus as the glans approximation or "GAP procedure". For midshaft defects, rolled mid-line tube techniques based on the initial reports of Thiersch–Duplay in the 1800s have gained renewed popularity. The Snodgrass incised plate procedure (TIP), a variant of the Thiersch-Duplay technique, is now among the most popular methods of hypospadias repair. Other techniques include meatal based flap procedures (eg, Mathieu) and on-lay flap repairs with native tissue or free grafts.

HYSTERECTOMY, UROLOGIC CONSIDERATIONS

DESCRIPTION Hysterectomy is among the most frequent surgeries performed on female patients and has been reported to contribute to up to 54% of all ureteral injuries. The reported rates of ureteral injury vary between 0.5 and 14% during laparoscopic hysterectomy.

Whereas at least 1/3 of ureteral injuries are recognized intraoperatively during open operations, fewer are identified during laparoscopy. Therefore, a high index of suspicion with intimate knowledge of anatomy is critical during gynecologic surgery. Repair of the ureter is determined by location and extent of injury and can include ureteroureterostomy, ureteroneocystostomy with or without a Boari flap or psoas hitch, or even more extreme examples such as kidney autotransplantation or bowel interposition.

Nearly half of all bladder injuries result from iatrogenic causes, mainly obstetric or gynecologic complications during surgery. Again, a high index of suspicion along with knowledge of the anatomy is crucial in recognizing these injuries. Tests with indigo carmine can be utilized to assist in identification of either ureteral or bladder injuries. In addition, blood or gas (during laparoscopic surgery) in the foley bag can be a sign of a potential injury. When identified, intraperitoneal bladder injuries during hysterectomy should repaired in the same operative setting.

IC (INTERSTITIAL CYSTITIS) SYMPTOM INDEX

DESCRIPTION Also called the *Oleary–Sant Symptom Index*, this is a validated questionnaire for patients with IC/PBS (interstitial cystitis/painful bladder syndrome) to measure urinary and pain symptoms. It is based on 4 questions that are graded from 0–5, with 5 being the most severe. It is frequently used with the IC problem index.

REFERENCE

O'Leary MP, Sant GR, Fowler FJ Jr, et al. The interstitial cystitis symptom index and problem index. *Urology*. 1997;49(5A Suppl):58–63.

ICE WATER TEST

DESCRIPTION Historically performed after standard cystometrogram, this test may aid in differentiation of upper and lower motor neuron lesions. Ice water is rapidly instilled into the bladder and left for 1 min. If the water is ejected or the bladder pressure rapidly rises, the test is positive. Most patients with upper motor neuron/suprasacral lesions (eg, Parkinson, MS, CVA) have a positive test. Patients with lower motor neuron lesions almost never have a positive test.

ICIQ-MLUTS (INTERNATIONAL CONSULTATION ON INCONTINENCE QUESTIONNAIRE-MALE LOWER URINARY TRACT SYMPTOMS)

DESCRIPTION The ICIQ-MLUTS is a patient questionnaire used to evaluate men with LUTS and impact on quality of life. The original questionnaire compromised of 22 items and was shortened to 11 items in 2 distinct factors of voiding and incontinence. Unlike other questionnaires, such as the American Urological Association symptom score, the ICIQ-MLUTS contains separate subscores for the domains of incontinence and voiding with separate consideration of frequency, nocturia, and impact on quality of life. It has been shown to be a validated and reliable instrument for evaluating men with LUTS.

REFERENCE

IIEF (INTERNATIONAL INDEX OF ERECTILE FUNCTION)

DESCRIPTION The IIEF is a validated self-administered patient questionnaire useful in the assessment of male sexual dysfunction. A score of 0–5 is given to each of 15 questions in 4 main male sexual function domains: Erectile function, orgasmic function, sexual desire, and intercourse satisfaction. The IIEF questionnaire is limited by a superficial assessment of psychosexual issues and also partner relationship factors which can both impact male sexual

dysfunction. The abridged 5-item questionnaire was subsequently developed to specifically diagnose the presence and severity of erectile dysfunction.

IMMUNOHISTOCHEMICAL STAINING, UROLOGIC CONSIDERATIONS

DESCRIPTION The following are common markers and patterns of immunohistochemical (IHC) and other staining patterns commonly used in urologic pathology. Individual labs and pathologists may use individual panel testing with selective staining (Image ☼).

Tumor Type	IHC Stains Positive	IHC Stains Negative
Prostate adenocarcinoma	AMACR (P504S), PSA, pPSA, PSAP, PSMA, ERG, NK3.1	Basal cell markers: HMWK and P63 or CK14, CK5/6; CK7, CK20
Prostate small-cell carcinoma	Chromogranin, synaptophysin, CD56, NSE, TTF1, AMACR, CK7, AE1/AE3	CD45, CD99
RCC, clear cell	RCC, CD10, vimentin, EMA, AE1/AE3, CAM5.2, CAIX, PAX2, PAX8	CK7, CK20, CEA, C-Kit, Ksp-cadherin, HMWK
RCC, papillary and papillary adenoma	CK7, vimentin, AMACR, EMA, AE1/AE3	RCC, Ksp-cadherin, HMWK, WT1
RCC, chromophobe	CK7, C-Kit, Ksp-cadherin, EMA, CAM5.2, AE1/AE3, EpCAM, Hale's Colloidal Iron[a]	Vimentin, RCC, CD10
Renal oncocytoma	C-Kit, Ksp-cadherin, EMA, CAM5.2, AE1/AE3	CK7, EpCAM, vimentin, RCC, CAIX, Hale's Colloidal Iron[a]
Renal metanephric adenoma	WT1, AE1/AE3, vimentin	EMA, CK7
Renal MITF/TFE family translocation-associated carcinoma	TFE3, TFEB, CD10, RCC, AMACR (TFEB tumors show + Melan-A and HMB45)	AE1/AE3, CK7, EMA, vimentin. (TFEB tumors: CD10, RCC)
Renal angiomyolipoma	HMB45, Melan-a	AE1/AE3, EMA
Urothelial carcinoma	CK7, CK20, HMWK, p63, p53, uroplakin, thrombomodulin, GATA-3	Vimentin, CDX2, PSA, PSAP, PSMA, NK3.1
Testis, seminoma	PLAP, C-kit, OCT4	AE1/AE3, EMA, CD30, AFP, inhibin
Testis, embryonal carcinoma	PLAP, CD30, AE1/AE3, CAM5.2, OCT4	EMA, AFP
Testis, yolk sac	PLAP, AFP, AE1/AE3, CAM5.2, α1-antitrypsin	EMA, CD30
Testis, choriocarcinoma	PLAP, β-HCG, EMA, AE1/AE3, CAM5.2, inhibin, CEA	
Testis, Leydig cell tumor	Inhibin, CD99, vimentin, S100, CAM5.2	PLAP, EMA
Testis, Sertoli cell tumor	Inhibin α, CD99, vimentin, S100, CAM5.2, NSE, synaptophysin	PLAP

AE1/AE3, pan-cytokeratin; AFP, α-fetoprotein; AMACR, alpha-methylacyl CoA racemase; CAIX, carbonic anhydrase IX; C-Kit, CD117; EMA, epithelial membrane antigen; ERG, erythroblast transformation-specific (ETS) transcription factor; GATA, endothelial transcription factor 3; HMWK, high–molecular-weight keratin (34βE12); Ksp-cadherin, kidney-specific cadherin; MITF, microphthalmia-associated transcription factor; NSE, neuron-specific enolase; OCT4 (OCT3/4); PAX, paired box gene; PLAP, placental like alkaline phosphatase; pPSA, pro prostate-specific antigen; PSA, prostate-specific antigen; PSAP (PAP), prostatic acid phosphatase; PSMA, prostate surface membrane antigen; RCC, renal cell carcinoma and RCC antibody; TFE, transcription factor binding; TFE3, transcription factor binding to IGHM enhancer 3; TFEB, transcription factor EB; TTF1, transcription termination Factor 1; WT1, Will's tumor 1; β-HCG, human chorionic gonadotropin β-subunit;
[a] histochemical stain.

IMPERFORATE HYMEN

DESCRIPTION The hymen is composed of endoderm from the urogenital sinus epithelium and is located between the vaginal canal and vestibule. Normally, it opens during embryonic development. If it does not open, the hymen is called imperforate. Patients may present with hydrocolpos or mucocolpos that may obstruct the urinary tract. At puberty, females may present with primary amenorrhea and cyclic abdominal pain. Treatment is surgical if it causes symptoms.

REFERENCE

Katz V, Lentz G. Congenital abnormalities of the female reproductive system. In: Katz VL, ed. *Comprehensive Gynecology*. St. Louis, MO: Mosby; 2007.

IN VITRO FERTILIZATION (IVF) AND EMBRYO TRANSFER

DESCRIPTION Currently IVF is used for women with nonfunctioning oviducts, severe endometriosis, and in couples with male factor infertility or unexplained infertility. In most clinics, the female patient undergoes ovarian hyperstimulation with hormonal agents to increase the number of oocytes for follicle aspiration. The oocyte retrieval is performed by aspiration through the vagina with US guidance of needle placement. After aspiration of the oocyte, the eggs are incubated and placed in culture media. Sperm from the male is then integrated into the culture media after being separated from the semen. After about 48–96 hr, 1–4 splitting embryos are placed in the uterus via transcervical injection. (See also Section II: "Assisted Reproductive Techniques [ARTs].")

REFERENCE

INCONTINENCE CLAMPS

DESCRIPTION The underlying pathophysiology of male incontinence is related to either detrusor over activity or external sphincter weakness, or a combination of the 2. Incontinence clamps are external devices that are used to treat male incontinence by increasing outflow resistance. They are applied externally to the penis to exert nonsurgical compression of the urethra, thereby preventing leakage of urine. The safety, efficacy, comfort, and patient satisfaction with 3 types of commercially available penile incontinence clamps (C3, U-Tex Male Adjustable Tension Band, and Cunningham clamp) has been studied in a small 12 patient trial. Results indicated that the Cunningham clamp was the most efficacious and most accepted by users. There was a concern over reduced distal blood flow velocity. None of the devices completely eliminated urine leakage when applied at a comfortable pressure. Complications of penile clamps can include edema, pain, urethral erosion, and obstruction.

Penile clamps should not be used for >4 hr at a time. (See also Section I: "Incontinence, Urinary, Adult Male" and Section II: "Cunningham Clamp.")

INCONTINENCE IMPACT QUESTIONNAIRE (IIQ-7)

DESCRIPTION Short version of the IIQ (Incontinence Impact Questionnaire). A 7-question validated questionnaire to assess the impact of female urinary incontinence on activities of daily living. Commonly used in a perioperative setting for patients undergoing anti-incontinence procedures and for research purposes.

REFERENCE

Ubersax JS, Wyman JF, Shumaker SA, et al. Short forms to assess life quality and symptom distress for urinary incontinence in women: The Incontinence Impact Questionnaire and the Urogenital Distress Inventory. *Neurourol Urodyn*. 1995;14(2):131–139.

INCONTINENCE (URINARY) WITH ORGASM (CLIMACTURIA)

DESCRIPTION Coital urinary incontinence can be divided into 2 forms: Incontinence at penetration and incontinence during orgasm. Incontinence during orgasm has been associated with detrusor overactivity (DO), whereas female incontinence during penetration has been associated with stress incontinence. The term *climacturia* is used mostly when referring to males who have incontinence associated with orgasm; this condition is seen mostly after radical prostatectomy. (See also Section II: "Coital Incontinence [Coital Leakage/Intercourse Incontinence].")

INDEVUS URGENCY SEVERITY SCALE (IUSS)

DESCRIPTION A validated patient-reported questionnaire for the report of urgency severity associated with overactive bladder. This scale has been validated to capture the urgency severity per toilet void. This scale, when combined with a 24-hr diary of frequency and urge incontinence episodes, creates the Overactive Bladder Symptom Composite Score (OAB-SCS).

REFERENCE

INDIANA POUCH

DESCRIPTION A urinary reservoir is created from the right colon, and the ileal cecal apparatus is used as a continent catheterizable limb. Originally described by Gilchrist et al. in 1950, the pouch was modified by Rowland and co-workers at the University of Indiana. Modifications included detubularizing the colon with subsequent closure in a Heineke–Mikulicz configuration, strengthening of the ileocecal valve with imbricating sutures (which are performed on the ileal limb), and then performing a tunneled ureterocolonic anastomosis (Image ☼).

REFERENCE

Bihrle R. The Indiana pouch continent urinary reservoir. *Urol Clin North Am*. 1997;24(4):773–779.

INFERTILE MALE SYNDROME

DESCRIPTION Syndrome caused by mutations in the androgen receptor gene, leading to partial androgen insensitivity and infertility. This is the mildest form of partial androgen insensitivity syndrome (PAIS) and has been termed the infertile male syndrome. Described as phenotypically normal males with azoospermia or oligospermia, and high/normal serum gonadotropins and testosterone. Testicular histology varies from complete absence of germinal elements to maturation arrest of spermatogenesis.

REFERENCE

INFLAMMATORY BOWEL DISEASE, UROLOGIC CONSIDERATIONS

DESCRIPTION Crohn disease and ulcerative colitis are inflammatory diseases of the GI tract. The inflammatory response in ulcerative colitis is mostly confined to the mucosa and submucosa, as opposed to Crohn disease, which can be transmural. These diseases can give rise to a number of urologic manifestations including fistula to the urinary tract, malabsorption syndromes leading to nephrolithiasis, and pyoderma gangrenosum of the genitalia (Image ☼).

REFERENCE

Stenson P. Inflammatory bowel disease In: Goldman L, ed. *Cecil Medicine*. 23rd ed. Philadelphia, PA: Saunders; 2007.

INFLAMMATORY PSEUDOTUMOR (PSEUDOSARCOMATOUS FIBROMYXOID TUMOR)

DESCRIPTION A benign mesenchymal tumor of the bladder also referred to by many other names: Postoperative pseudosarcomatous response or lesion, spindle cell nodule, pseudosarcomatous or atypical fibromyxoid tumor, atypical myofibroblastic tumor, plasma cell granuloma, nodular fasciitis, and pseudosarcomatous myofibroblastic proliferation. The

differential diagnosis of benign inflammatory pseudotumors primarily includes the spindle variant of carcinoma and sarcomas. Immunohistochemical stains are used to distinguish spindle variants of carcinoma from benign inflammatory pseudotumors. These can be seen endoscopically as pedunculated nonpapillary intraluminal lesions or as difficult to identify submucosal lesions. These are more common in females. Management is by compete transurethral resection as inflammatory pseudotumors are benign lesions that grow slowly and do not metastasize or undergo malignant transformation.

INFUNDIBULAR STENOSIS

DESCRIPTION Infundibular stenosis can be characterized by a narrow infundibulum leading to a nondilated calyx which may or may not contain stones. Etiologies include extrinsic compression by either malignancy or retroperitoneal fibrosis or from intrinsic narrowing from TB, nephrolithiasis, or infection chronic scarring from renal surgery (eg, PCNL) and local neoplasm. The condition can be rarely caused by a crossing segmental artery. Patients can present with flank pain, hematuria, or deterioration of global kidney function. Indications for surgery include obstruction or to allow access to treat stones in an obstructed calyx. The use of a holmium:YAG laser or balloon is generally employed to incise or dilate the stenosis.

INFUNDIBULOPELVIC DYSGENESIS

DESCRIPTION This is an obstructive process secondary to narrowing of the infundibulopelvic system that produces various congenital anomalies such as hydrocalycosis, calyceal diverticula, ureteropelvic junction stenosis, and multicystic kidney.

REFERENCE

Uhlenhuth E, Amin M, Harty JI, et al. Infundibulopelvic dysgenesis: A spectrum of obstructive renal disease. *Urology*. 2007;35:334–337.

INGUINAL HERNIA, ADULT, UROLOGIC CONSIDERATIONS

DESCRIPTION A direct hernia is the most common inguinal hernia in adult males. It occurs when there is a protrusion of intra-abdominal contents in an area called the Hesselbach triangle (formed by the rectus abdominis muscle, inferior epigastric artery, and inguinal ligament). Untreated bladder outlet obstruction can lead to recurrent hernia. In addition, urinary retention can occur after hernia repair. In cases of a large inguinal hernia, a portion of a distended bladder can herniate into the groin. Indirect inguinal hernias are more

common in infants and children and are caused by a patent processus vaginalis.

INGUINAL HERNIA, PEDIATRIC, UROLOGIC CONSIDERATIONS

DESCRIPTION Typically, an indirect hernia is the most common type of inguinal hernia in the pediatric population. During embryologic development, the spermatic cord and testis descend through the anterior abdominal wall to the inguinal canal through the projection of the process vaginalis. If the process vaginalis persists, an indirect inguinal hernia may form and is always associated with a hydrocele.

REFERENCE

Jeyarajah R, Harford WV Jr. Abdominal hernias and gastric volvulus In: *Sleisenger & Fordtran's Gastrointestinal and Liver Disease*. 8th ed. Philadelphia, PA: Saunders; 2006.

INJECTION THERAPY FOR VESICOURETERAL REFLUX

DESCRIPTION Endoscopic treatment of vesicoureteral reflux disease was 1st described in 1981 by Matouschek using polytetrafluoroethylene (PTFE) paste at the ureteral orifice. The primary principle behind injection therapy is to endoscopically inject a bulking agent beneath the ureteral orifice, which then helps to coapt the distal ureter. The technique involves placement of the needle approximately 2 mm distal to the 6 o'clock position of the ureteral orifice. The objective is to create a "volcano" like mound appearance of the ureteral orifice. Agents used for endoscopic correction of ureteral reflux should be nontoxic, cause minimal local inflammation, not migrate to other organs, and should be easy to inject. Broadly they can be categorized into 2 main categories: Nonautologous and autologous. PTFE (Teflon), bovine collagen, dextranmoer hyaluronic copolymer (Deflux), and coaptite are all examples of nonautologous materials. Chondrocytes, fat, collage, and muscles are some of the autologous materials that have been used (Image ☼).

INSECT BITE, PENIS AND SCROTUM

DESCRIPTION Insect bites and stings are typically acute processes with rapid onset of various symptomatologies, including pain, pruritus, signs of ecchymosis, and edema preceding exfoliating dermatitis. While this is a benign process requiring only analgesics and antihistamines for its treatment, it is imperative to rule out pathologic events such as testicular torsion or cancer.

REFERENCE

of acute scrotum. *J Urol.* 1992;147(4):1085–1086.

INTERMITTENT HORMONAL THERAPY (IHT)/INTERMITTENT ANDROGEN DEPRIVATION (IAD)

DESCRIPTION The role of testosterone and prostate cancer has been well established. The role of androgen deprivation therapy (ADT) is to achieve serum testosterone levels similar to that induced by surgical castration. The impact of ADT in patient overall survival is not well known and the ideal serum testosterone level is debated. Intermittent ADT is an alternative to continuous ADT. ADT is continued until PSA reaches a nadir level. ADT is then stopped and restarted when PSA rises to pretreatment levels. In general, intermittent ADT is better tolerated and improves overall quality of life when compared to standard ADT. A recent review stated: "There is fair evidence to recommend use of IAD instead of continuous androgen deprivation (CAD) for the treatment of men with relapsing, locally advanced, or metastatic prostate cancer who achieve a good initial response to androgen deprivation. This recommendation is based on evidence against superiority of either strategy for time-to-event outcomes and substantial decrease with IAD in exposure to androgen deprivation, resulting in less cost, inconvenience, and potential toxicity."

INTERNATIONAL CHILDREN'S CONTINENCE SOCIETY (ICCS), TERMINOLOGY

DESCRIPTION The ICCS has developed standardized definitions for bladder dysfunction symptoms. These generally apply to children who are 5 or more years of age (unless noted otherwise). (See also Section I: "Incontinence, Urinary, Pediatric.")

- Daytime frequency: Voiding 8 or more times during waking hours. Decreased daytime frequency is defined as 3 or fewer voids. (Note: Pollakiuria is also used to define abnormally frequent small voids in a previously toilet-trained child without evidence of polyuria or UTI).
- Hesitancy: Difficulty in the initiation of voiding or if a child must wait a considerable amount of time before voiding begins. Hesitancy can be applied to children who have achieved bladder control regardless of age.
- Holding maneuvers: Observed behavior used to either postpone voiding or suppress urgency. These maneuvers include: Standing on tiptoe, forcefully crossing the legs, or squatting with a hand or heel pressed into the perineum (also referred to as "Vincent's curtsy"). These may be observed in children who have achieved bladder control regardless of age.
- Incontinence: Uncontrolled leakage of urine. Incontinence can be continuous or intermittent.

- Intermittent stream (Intermittency): A voiding stream of urine that occurs in several discrete bursts rather than in the normal continuous stream. Considered a normal physiologic pattern in children 3 yr of age or younger.
- Nocturia: Awakening to void at night.
- Postmicturition dribbling: Involuntary urine leakage immediately after completion of voiding in children who have achieved bladder control regardless of age.
- Straining: The application of abdominal pressure (a.k.a. Valsalva maneuver) to initiate and maintain voiding. Considered a pertinent finding in all age groups.
- Urgency: The sudden and unexpected experience of the immediate need to void.
- Weak stream: The observed ejection of urine with a weak force. Considered a pertinent finding in all age groups.

REFERENCE

INTERNATIONAL GERM CELL CANCER COLLABORATIVE GROUP (IGCCCG)

DESCRIPTION Effective chemotherapy regimens for germ cell tumors (GCT) resulted in the development of prognostic groups for patients with metastatic disease. With good-risk disease, the goal is to minimize the toxicity of current regimens, while preserving the high cure rates. In patients with high-risk disease, investigational studies have been designed to improve long-term response rates. In the IGCCCG staging system, patients are divided into good-, intermediate-, and poor-risk groups, based upon primary site of the GCT, sites of metastasis, and serum tumor markers. Within each risk group, criteria differ for seminomas and nonseminomatous GCT. Survival in >5,200 patients is correlated with risk status: Good-risk disease, 91% 5-yr survival; intermediate-risk disease, 79% 5-yr survival; poor-risk disease, 48% 5-yr survival. (See also Section I: "Testis, Cancer, General"; Section I: "Testis, Nonseminomatous Germ Cell Tumors, General"; Section I: "Testis, Seminoma.")

SEMINOMA: GOOD RISK

All of the following:
- Any primary site
- No nonpulmonary visceral metastases
- Normal serum AFP

SEMINOMA: INTERMEDIATE RISK

All of the following:
- Any primary site
- Nonpulmonary visceral or brain metastases present
- Normal serum AFP

NONSEMINOMATOUS GERM CELL TUMORS: GOOD RISK

All of the following;

- Testicular or retroperitoneal primary tumors
- No nonpulmonary visceral metastases
- Serum AFP <1,000 ng/mL and β-hCG <5,000 mlU/mL and LDH <1.5 × upper limit of normal

NONSEMINOMATOUS GERM CELL TUMORS: INTERMEDIATE RISK

All of the following:

- Testicular or retroperitoneal primary tumors
- No nonpulmonary visceral metastases
- Intermediate level of any of the following: AFP 1,000–10,000 ng/mL or β-hCG 5,000–50,000 mlU/mL or LDH 1.5–10 × upper limit of normal

NONSEMINOMATOUS GERM CELL TUMORS: POOR RISK

Any of the following:

- Mediastinal primary germ cell tumor
- Nonpulmonary visceral metastases,
- Serum AFP >10,000 ng/mL
- Serum β-hCG >50,000 mlU/mL
- LDH >10 × upper limit of normal

INTERNATIONAL PROSTATE SYMPTOM SCORE (I-PSS)

DESCRIPTION A patient self-scoring instrument used for assessment of symptom severity in men with LUTS. The symptoms are scored from mild (0–7), moderate (8–19), to severe (20–35); the score can also be used to measure treatment response. The I-PSS uses the same 7 questions as the AUA Symptom Index for BPH with the addition of the disease-specific QoL question (known as the *bother score*), scored on a scale from 0–6 points (delighted to terrible). (See Section VII: “AUA Symptom Index for BPH” and “the I-PSS Appendix VII.”)

INTERSTITIAL NEPHRITIS

DESCRIPTION Acute interstitial nephritis is most commonly caused by drugs, but

autoimmune diseases (eg, lupus) and a variety of infections (eg, streptococcal or legionella) can also be the cause. Many drug-related causes have been described, but the most common are penicillins, cephalosporins, NSAIDs, ciprofloxacin, rifampin, sulfonamides, allopurinol, cimetidine, and indinavir. Nonspecific symptoms and signs, along with acute renal dysfunction include nausea, vomiting, and malaise. Urine analysis reveals WBCs, RBCs, WBC casts. Proteinuria is usually absent or mild (<1 g/d). With drug-related interstitial nephritis, allergic-type reactions may be present, such as rash, fever, and eosinophilia. Diagnosis can only be confirmed on renal biopsy. Chronic interstitial nephritis is typically caused by long-term exposure to medications such as analgesics, anticonvulsants, and Chinese herbal medications; heavy met al exposure; chronic obstruction; and other causes. Presentation is insidious with hypertension, inability to concentrate urine, acidosis, and anemia being the more common symptoms. Treatment involves stopping the offending medication or treating the underlying infection or condition (eg, lupus or sarcoidosis). Steroids are controversial in treating acute interstitial nephritis but they may benefit chronic interstitial nephritis; most cases resolve spontaneously, although persistent renal dysfunction may remain.

INTRACYTOPLASMIC SPERM INJECTION (ICSI)

DESCRIPTION An assisted repoduction technique (ARRT) in which a single spermatozoon is injected into the cytoplasm of an ovum. This technique is typically utilized in males with severe oligospermia or azoospermia, as the cost is high. (See also Section II: “Assisted Reproductive Techniques [ARTs].”)

REFERENCE

INTRAOPERATIVE FLOPPY IRIS SYNDROME (IFIS)

DESCRIPTION The triad of intraoperative observations of flaccid iris stroma that undulates and billows in response to ordinary intraocular fluid currents, a propensity for the floppy iris to prolapse toward the phacoemulsification tip and incision, and progressive intraoperative pupil constriction. This syndrome has been associated with α-blocker therapy in men with BPH, especially tamsulosin and is due to relaxation of the dilator muscle. Discontinuation of tamsulosin appears to be unpredictable and may not reliably reduce the severity. To mitigate the intraoperative problems, pharmacologic and mechanical strategies are used.

REFERENCE

Friedman AH. Tamsulosin and the intraoperative floppy iris syndrome. *JAMA*. 2009;301(19):2044–2045.

INTRAUTERINE INSEMINATION (IUI)

DESCRIPTION An ART in which the placement of spermatozoa that have been separated from the seminal fluid are placed into the endometrial cavity through a small catheter. Typically used to treat male factor infertility caused by oligospermia and abnormalities of semen volume or viscosity. Also used with cervical stenosis or "hostile cervical mucous" in females (See also Section II: "Assisted Reproductive Techniques [ARTs].")

REFERENCE

INTRINSIC SPHINCTER DEFICIENCY (ISD)

DESCRIPTION ISD is one of many components that contribute to stress urinary incontinence (SUI) and is defined as the loss of coaptation and compression of the urethra along its length. Its etiology is usually multifactorial. ISD in women may occur simultaneously with urethral hypermobility, but should be differentiated, as the latter is an anatomic cause of SUI and not synonymous with ISD. After radical prostatectomy, SUI caused by ISD in most cases. The clinical parameters for ISD are loosely defined as a Valsalva leak-point pressure <60 cm H_2O or a maximal urethral closure pressure <20 cm H_2O, consensus is lacking.

CAUSES

- Complete loss of urethral tone (catheter trauma, surgical trauma)
- Pudendal nerve dysfunction and denervation of the mid-urethral complex (external sphincter)
- Estrogen deficiency (resulting in mucosal changes effecting coaptation)
- Diabetes (autonomic dysfunction of smooth and nonstriated skelet al muscle)
- Parity (pudendal neuropathy and pelvic floor destruction)
  - Sphincteric injury during RP or other transurethral procedure
  - Traumatic injury (ie, pelvic fracture)

TREATMENT

- Conservative management including Kegel exercises and biofeedback
- Females: Retropubic and needle suspension; periurethral bulking agents; synthetic (mesh) urethral sling; fascial urethral sling; artificial urinary sphincter
- Males: Male sling; artificial urinary sphincter (Image ☼)

INVERTED PAPILLOMA, BLADDER

DESCRIPTION An uncommon tumor of the urinary tract characterized by proliferating urothelium arranged as inverting cords and nests with an intact overlying urothelium. Inverted papilloma is thought to be a benign lesion but because of reports of multiplicity, recurrence, and associated TCC have been seen in the literature. Its management has been controversial (Image ☼).

REFERENCE
Picozzi S, Casellato S, Bozzini G, et al. Inverted papilloma of the bladder: A review and an analysis of the recent literature of 365 patients. *Urol Oncol.* 2013;31(8):1584–1590.

INVERTED PAPILLOMA, URETER AND RENAL PELVIS

DESCRIPTION Considered by most researchers to be benign, this lesion can coexist with malignant tumors. These rare, benign lesions have a presentation similar to that of other upper tract tumors. Papillary fronds project opposite into the mucosa, appearing as smooth-surfaced, pedunculated, or sessile lesions of the urothelium. There is a strong male predominance (91%). The lesions are typically small (<3 cm), pedunculated, and polypoid. Muscularis invasion is not seen microscopically. Inverting cords and nests of urothelial cells continuous with the urothelium is a typical finding. The etiology is unknown, but probably generated by reaction to inflammation. Although benign, the lesions have a high association with urothelial carcinoma (TCC). Diagnosis is by ureteroscopy for direct visualization and biopsy. Treatment has been nephroureterectomy; however, local excision is possible, but careful follow-up for other sites of cancer along the urinary tract is essential.

IRS (INTERGROUP RHABDOMYOSARCOMA STUDY) CLINICAL CLASSIFICATION

DESCRIPTION A generally accepted classification and staging system used in the IRS. (See Section I: "Rhabdomyosarcoma, Pediatric [Sarcoma Botryoides].")

- Group I: Localized disease, completely removed, regional nodes not involved
  - A: Confined to muscle or organ of origin
  - B: Contiguous involvement, with infiltration outside the muscle or organ of origin; this group includes both gross impression of complete removal and microscopic confirmation of complete removal
- Group II:
  - A: Grossly removed tumor with microscopic residual disease; no evidence of gross residual tumor; no evidence of regional node involvement
  - B: Regional disease, completely removed (regional nodes involved and/or extension of tumor into an adjacent organ; no microscopic residual disease)
  - C: Regional disease with involved nodes, grossly removed, but with evidence of microscopic residual disease
- Group III: Incomplete removal or biopsy with gross residual disease
- Group IV: Distant metastatic disease present at onset

JABOULAY/WINKELMAN PROCEDURE (HYDROCELECTOMY)

DESCRIPTION Hydrocelectomy is performed by incision of the hydrocele sac after complete mobilization of the hydrocele. Partial resection of the sac is then performed and the edges are sewn together behind the spermatic cord in the Jaboulay/Winkelman technique. Care is taken not to injure any spermatic cord contents.

REFERENCE

Ku JH, Kim ME, Lee NK, et al. The excisional, placation, and internal drainage techniques: A comparison of the results for idiopathic hydrocele. *BJU Int.* 2001;87(1):82–84.

JACK STONES

DESCRIPTION A term that refers to irregular, spiculated calcium oxalate stones, resembling children's jacks, which are sometimes seen in the bladder.

REFERENCE

Dyer RB, Chen MY, Zagoria RJ. Classic Signs in Uroradiology. *Radiographics*. 2004;24:S247–S280.

JARISCH–HERXHEIMER REACTION

DESCRIPTION Originally observed by Jarisch in 1895 and later by Herxheimer and Kraus, this reaction occurs after patients are given mercury for the treatment of syphilis. The reaction is now associated with the antimicrobial treatment of spirochete infections such as leptospirosis, Lyme disease, tick-borne relapsing fever, and also syphilis. The reaction mostly occurs within 12–24 hr after treatment, and presents with symptoms such as rigors, malaise, headache, hypotension, and sweating. The reaction may be caused by a release of endotoxins or a transient elevation of cytokines, and it may be prevented with TNF-α antibodies or steroids.

REFERENCE

Pound MW, May DB. Proposed mechanisms and preventative options of Jarisch-Herxheimer reactions. *J Clin Pharm Ther*. 2005;30:291–295.

JEJUNAL–ILEAL BYPASS, UROLOGIC CONSIDERATIONS

DESCRIPTION Jejunal–ileal bypass is a form of bariatric surgery for treatment of morbid obesity. The complications following jejunal-ileal bypass center on a malabsorptive state and include mineral and electrolyte imbalances, protein malnutrition, enteric complications, and a list of other extra-intestinal manifestations (eg, arthritis, peripheral neuropathy, liver disease, etc.). Bariatric surgery has more recently developed newer techniques (eg, gastric sleeve, Roux-en-y bypass) which limit these complications and the jejunal-ileal bypass procedure has fallen out of favor. From a urologic perspective, bariatric bypass surgery can lead to a state of enteric hyperoxaluria and result in an increased risk of kidney stone formation. For patients with a prior history of nephrolithiasis, a 31.4% recurrence rate has been reported after bypass

surgery. It is important for the urologist to establish appropriate prevention techniques and institute treatment when necessary for this high-risk group. (See also Section II: “Bariatric Surgery, Urologic Considerations.”)

REFERENCE

Whitson JM, Stackhouse GB, Stoller ML. Hyperoxaluria after modern bariatric surgery: case series and literature review. *Int Urol Nephrol.* 2010;42(2):369–374.

JEUNE SYNDROME (ASPHYXIATING THORACIC DYSPLASIA)

DESCRIPTION Jeune syndrome is a form of lethal, short-limbed dwarfism with features that include constriction of the upper thorax and polydactyly. It has autosomal recessive inheritance. Of urologic interest, renal dysplasia, sometimes leading to end stage renal disease (ESRD), is associated with the condition.

REFERENCE

Ring E, Zobel G, Ratschek M, et al. Retrospective diagnosis of Jeune’s syndrome in 2 patients with chronic renal failure. *Child Nephrol Urol.* 1990;10(2):88–91.

JOINT REPLACEMENT, UROLOGIC CONSIDERATIONS

DESCRIPTION Prophylaxis is no longer routinely indicated for patients receiving orthopedic pins, plates, and screws or even total joints. Antimicrobial prophylaxis is intended to reduce the risk of hematogenous joint infection in patients who fit the criteria for increased risk of total joint infection and who have an increased risk of bacteremia and who meet *BOTH* sets of criteria in the table here. For patients *NOT* meeting both these criteria, antimicrobial prophylaxis still may be indicated to reduce the risk of other infections. (Based on AUA Guidelines Best Practice Policy Statement on Urologic Surgery Antimicrobial Prophylaxis.)

Increased Risk of Hematogenous Total Joint Infection	Increased Risk of Bacteremia Associated with Urologic Procedures
Patients during the 1st 2 yr after prosthetic joint replacement Immunocompromised patients with prosthetic joint replacements: • Inflammatory arthropathies (eg, rheumatoid arthritis, systemic lupus erythematosus) • Drug-induced immunosuppression • Radiation-induced immunosuppression Patients with prosthetic joint replacements and comorbidities: • Previous prosthetic joint infections • Malnourishment • Hemophilia • HIV infection • Diabetes • Malignancy	Any stone manipulation (includes shock-wave lithotripsy) Any procedure with transmural incision into urinary tract (does not include simple ligation with excision or percutaneous drainage procedure) Any endoscopic procedures of upper tract (ureter and kidney) Any procedure that includes bowel segments Transrectal prostate biopsy Any procedure with entry into the urinary tract (except for urethral catheterization) in individuals with higher risk of bacterial colonization: • Indwelling catheter or intermittent catheterization • Indwelling ureteral stent • Urinary retention • History of recent recurrent urinary tract infection or prostatitis • Urinary diversion

TREATMENT

Recommended antimicrobial regimens:

- A single systemic level dose of a quinolone (eg, ciprofloxacin, 500 mg; levofloxacin, 500 mg; ofloxacin, 400 mg) PO 1–2 hr preoperatively.
- Ampicillin 2 g IV (or vancomycin 1 g IV over 1–2 hr in patients allergic to ampicillin) plus gentamicin 1.5 mg/kg IV 30–60 min preoperatively.
- For some procedures, additional or alternative agents may be considered for prophylaxis against specific organisms and/or other infections.

JUVENILE GANGRENOUS VASCULITIS, SCROTAL (PYODERMA GANGRENOSUM)

DESCRIPTION A variant of scrotal gangrene of unknown etiology, which is thought to be a variant of pyoderma gangrenosum. The lesions usually occur in healthy individuals <30 yo, following an upper respiratory infection. The lesions can present with scrotal itching or stinging, with ≥ 1 skin lesions. Lab findings can show an increased erythrocyte sedimentation

rate (ESR) with normal microbiologic tests. Biopsy of the lesions reveals mostly neutrophilic dermal infiltrate and fibrinoid necrosis of small blood vessels without vasculitis. Treatment is systemic corticosteroids. The condition is often self-limited.

REFERENCE

JUXTAGLOMERULAR CELL TUMOR, KIDNEY

DESCRIPTION Rare but important benign renal mass caused by the secretion of renin and generally affects adolescents and young adults. The ultimate cause is surgically curable hypertension. Patients (typically young females) present with severe diastolic hypertension, hypokalemia, and elevated plasma renin levels. CT, renal angiography, and renal vein sampling may be helpful in localization. The tumor is well circumscribed with fibrous capsule and the cut surface shows yellow or gray-tan color with frequent hemorrhage. The tumor is composed of monotonous polygonal cells with entrapped normal tubules. Immunohistochemically, tumor cells exhibit a positive reactivity for renin, vimentin, and CD34. Infrequent aggressive forms have been reported. Partial nephrectomy or enucleation is the treatment of choice.

KALLMANN SYNDROME

DESCRIPTION Also known as *hypogonadotropic hypogonadism with anosmia,* caused by failure of GnRH secretion by the hypothalamus, leading to testicular failure. KAL1, encoding the extracellular glycoprotein anosmin-1, is responsible for the X-linked recessive form of the disease. It is a cause of male infertility due to the defect in the short arm of the X chromosome, and has variable inheritance and penetrance. Anosmia, cleft palate, renal anomalies, microphallus, cryptorchidism, blindness, and deafness are also associated conditions. Testes are typically small. Delayed puberty is often an initial presenting sign.

TREATMENT

- Androgens can virilize but will not promote spermatogenesis.
- hCG with FSH and LH may help fertility.

REFERENCE

Dodé C, Hardelin JP. Kallmann syndrome. *Eur J Hum Genet.* 2009;17(2):139–146.

KAPOSI SARCOMA, UROLOGIC CONSIDERATIONS

DESCRIPTION A tumor of reticuloendothelial system that presents as a raised, painful papule or ulcer with a bluish hue. In the United States, it is seen most commonly in association with AIDS. Most common site in the GU system is the penis, with a much higher incidence in homosexual males. It may cause urethral obstruction. (See also Section I: "HIV/AIDS, Urologic Considerations.")

TREATMENT

- Radiation or penectomy (partial or total) aimed at palliation
- Proximal urethrostomy for obstruction not responsive to other treatment

KARTAGENER SYNDROME (IMMOTILE CILIA SYNDROME)

DESCRIPTION Also called *primary ciliary dyskinesia syndrome,* this syndrome is characterized by situs inversus, chronic sinusitis, otitis media, airway disease, and immotile sperm leading to infertility. The absence of the inner and outer dynein arm of cilia is the primary pathology. Most men have live but immotile spermatozoa and are infertile, whereas some have motile spermatozoa but immotile cilia. Women have decreased fertility, with $<50\%$ completing pregnancy. This is the most common of a group of inherited ciliary defects that lead to respiratory disorders called primary ciliary dyskinesias. ICSI may be used for reproduction, but genetic counseling should be offered.

KEGEL EXERCISES

DESCRIPTION 1st described by Arnold Kegel in 1948, these exercises can be used as treatment for both stress and urgency urinary incontinence. Modern cure/improvement rates range from 50–80%. The usual regimen consists of multiple contractions of the pelvic floor muscles ≥3 times a day. Patients can practice by starting and stopping their urinary stream. Biofeedback, electrical stimulation, and cystometry are adjuncts to Kegel exercises.

SYNONYM

Pelvic floor exercises

KELAMI CLASSIFICATION SYSTEM (MODIFIED)

DESCRIPTION A classification system developed by Kelami to define the severity of penile curvature. The system consists of a grading system from 1–3: Grade 1, curvature of ≤30°; grade 2, curvature of 30–60°; and grade 3, ≥60° curvature. (See also Section I: "Penis, Curvature and/or Pain.")

REFERENCE

KELLY PLICATION

DESCRIPTION A transvaginal surgical technique to treat female SUI. The fibromuscularis tissue underlying the bladder neck is plicated in the midline through an anterior vaginal wall incision. No longer a commonly used treatment modality for SUI due to the availability of superior treatment modalities and the risk of postoperative voiding dysfunction.

REFERENCE

Thaweekul Y, Bunyavejchevin S, Wisawasukmongchol W, et al. Long term results of anterior colporrhaphy with Kelly plication for the treatment of stress urinary incontinence. *J Med assoc Thai*. 2004;87(4):357–360.

KERR KINKS

DESCRIPTION Kinking of the renal pelvis due to a deformity of the pyelocalyceal system, caused by traction of a strictured infundibulum and parenchymal fibrosis of a tuberculous kidney. The deformity leads to obstruction and dilatation of areas not directly affected by

tuberculous ulcerations and eventual pressure atrophy of renal tissue.

REFERENCE

Barrie HJ, Kerr WK, Gale GL. The incidence and pathogenesis of tuberculous strictures of the renal pelvis. *J Urol.* 1967;98:584–589.

KETAMINE ABUSE, UROLOGIC CONSIDERATIONS

DESCRIPTION Ketamine is generally used as a dissociative anesthetic compound by licensed anesthesiologists. When used recreationally, it can cause hallucinations, derealization, and thought disorders. It has seen an increase in use in young adults. Ketamine abuse can cause urinary tract changes. These include findings of bilateral upper tract narrowing, hydronephrosis, and contracted bladder states on urodynamic studies.

REFERENCE

Lai Y, Wu S, Ni L, et al. Ketamine-associated urinary tract dysfunction: an under-recognized clinical entity. *Urol Int.* 2012;89(1):93–96.

KIBRICK TEST

DESCRIPTION A test designed to evaluate circulating immune factors, as an aid to diagnosing causes of infertility. Dilutions of serum from both partners are combined with semen samples in a medium with an agglutinating gelatin. Agglutination will occur if antibodies in the serum are reactive against the sperm. Controls are usually also run with the samples to prevent errors.

KIDNEY, METASTASIS TO

DESCRIPTION Kidney metastases may present as a renal mass and grossly appear as a renal primary neoplasm. Discovered most often at autopsy, with an incidence of about 7%. They are frequently asymptomatic, but flank pain, hematuria, or hemorrhage may occur. Common primary tumors are lung (bronchogenic carcinoma most common), ovary, bowel, breast, and lymphoma. Virtually any origin is possible.
