SPANISH PROVERB

PREFACE

I am very pleased to present the third edition of *The 5-Minute Urology Consult*. The first edition was released almost 15 years ago, with the second edition published in 2010. The continuing advances in urology lead to this much-needed 2015 update. The goal of this book is to provide the reader with useful information in a quick reference format to help with the everyday care of patients with urologic problems. This third edition has undergone extensive editing and updating to reflect the most current data possible at the time of publication.

Urologic diseases and conditions are common problems seen by all health care providers. Almost one-third of all congenital disorders involve the genitourinary system, and the urinary tract accounts for almost 25% of all solid tumors in adults. While this book is written primarily for urologists, any health care practitioner who deals with urologic complaints and conditions should find the book a useful resource. Students of urology, residents and fellows preparing for oral and written in-service examination, and practicing urologists preparing for certification examinations will find the book a useful study aid. While primarily written for practitioners in the United States, the table of contents has been reviewed by our international editorial board, which represent more than three dozen countries, in an attempt to capture as many diseases and conditions as possible for international readers.

The broad array of topics addressed in this book is based on reviews of published literature, major textbooks, grand rounds case presentations, validated Internet resources, and actual patient consultations. Topics are meant to represent "real-world" clinical questions from very broad to very specific topics. Some of the topics may appear redundant, such as Section I topics "Scrotum and testicle, mass" and "Testis, tumor and mass, adult, general considerations." There is a deliberate reason for this, namely, to frame the thought process to differentiate scrotal masses from testicular masses when the presenting problem is not clear. If it is clearly a testicular mass, then the one topic deals effectively with that setting. If it is not a clear mass in the testicle, the reader can approach the problem more broadly in terms of a mass within the scrotum that may or may not involve the testicle. Coverage includes adult and pediatric urology, as well as subspecialty areas of urology such as urologic oncology, endourology, female urology, neurourology, andrology, infectious diseases, and renal transplantation. It represents a core of essential "must-know" and practical information specifically written for the field of urology. While some surgical techniques are discussed, this is not meant to be a comprehensive urologic surgical text. Numerous high-quality publications address the finer points of urologic surgery. This book addresses pre and post operative care as well as some intra-operative techniques; however the focus is on more global patient management issues.

I am often surprised when asked why medical books such as this are even necessary as a reference in the modern world because there is so much information readily available on devices such as smartphones via the Internet. While the reality is that virtually any topic can be searched for on the Internet, the ability to sort through the information presented, confirm the validity, and rapidly find the specific information needed is often very time-consuming and can be prone to error. Multiple studies have shown that many websites can contain erroneous, misleading, or out-of-date information. Readers of this book can be assured that

the information presented is held to the highest standards possible, as it is written, reviewed, and further edited primarily by academic urologists and other academic specialists. Every effort is made to present the most up-to-date standards of care at the time of publication.

This book, a member of the popular "5-Minute Consult" series published by Wolters Kluwer Health, generally follows the organizational formatting of the other books in the series. However, there are notable exceptions, as this book is focused on a primarily surgical subspecialty. **Section I: Urologic Diseases and Conditions** provides information on more than 300 major topics in the field of urology. The style of this section, while similar to the other books in the series, focuses more attention on the surgical management, where appropriate. Furthermore, evidence-based medicine references, standard fare in the "*5-Minute Consult*" series, are included in this urology edition. This is representative of the trend in the field of medicine to assign "levels of evidence" to treatment recommendations (see page ix for a further discussion). A challenge with any surgical discipline is that, when reviewing published literature, this type of information is not as well represented as in other medical disciplines. The reader will note that in this edition, the use of evidence-based medicine is identified in chapters as appropriate. Many topics are further supported by algorithms and the enhnaced image library available in the ebook version provided along with the print version. Both *ICD-9* and preliminary high level *ICD-10* codes have been incorporated in preparation for the rollout of *ICD-10* in late 2015.

Section II: Short Topics: A to Z consists of more than 1,300 diseases, conditions, presenting complaints, or key concepts in the field that the practitioner must be aware of but may not be worthy of a complete 2-page chapter. **Section III** has been greatly expanded and now features nearly 90 visual algorithms to enhance many more clinically relevant topics. **Section IV** is dedicated exclusively to a core discipline in our field, **Urinalysis and Urine Studies. Section V: Alternative and Complementary Urologic Therapies** is a focused review that is of interest to both patients and caregivers alike. **Section VI: Urologic Drug Reference** is a very unique collection of information on hundreds of drugs used in urologic practice in the United States as well as some traditionally nonurologic medications that are clinically significant to the urologic practitioner. Additional urologic applications not often found on the package insert for "off-label" use in daily care are included for many medications. These "off-label" applications are noted on the basis of published literature with additional input and the personal observations of the authors and editors. Finally, **Section VII: Reference Tables** is a collection of useful reference information and forms. A media and image collection is available in the ebook version of this book. Please see information inside front cover on how to access this content.

In any project of this magnitude, there are numerous individuals responsible for its success. I would like to thank the following individuals who provided the initial guidance in 1996 to develop the first urology version of the 5-Minute Consult: Lippincott Williams & Wilkins editors Carroll Cann and Craig Percy, and an early pioneer of the 5-Minute Consult concept, Dr. Mark Dambro. Thanks to my administrative assistants Denise Tropea and Barbara Devine, who provided key support to keep the contributors and this edition organized. A special thanks to the more than 370 authors and editors who took the time to contribute to this edition and the numerous contributors to the previous editions that laid a strong foundation for this third update. To my colleagues who served as Associate, Consulting, Specialty and

International Editors, my most sincere gratitude and appreciation for the time you took to recruit authors, create and review content. It is also with great sadness that one of our international editors and an icon in the field of Urology, Professor John Fitzpatrick passed away during the completion of this book. He will be missed by all but his numerous contributions to our field will live on.

Residents from the Department of Urology of Thomas Jefferson University and from the University of West Virginia deserve special acknowledgement. They supported the content of both Section II “Short Topics" and Section III “Algorithms." Their names appear in the contributor listing as having been authors but are not specifically recognized for their work in these sections. Now however, they are.

The editorial and production staff at Wolters Kluwer Health have distinguished themselves as the best publishing team I have had the opportunity to work with. My personal interactions with the company and their willingness to discuss any and all issues relating to the book are testimony to their corporate philosophy in respecting the authors’ opinions to develop the best educational products possible in the field of medicine. Brian Brown, Keith Donnellan, and Brendan Huffman are the best partners a medical author could hope to work with. In the final production stages, David Saltzberg and Harish Kumar kept everything moving to stay on schedule. Special thanks to Philadelphia-based friend and professional photographer Robert Neroni, who captured the spirit of urology in our cover photo.

Our children, Leonard, Patrick, Andrew, and Michael, deserve credit for their encouragement and patience over the many years of my time spent working on this project. In this edition, i am very proud that a few of the boys were actually able to make tangible professional contributions.

Most importantly, I would like to thank my wife, Tricia, with the usual and customary accolades that authors share about their spouses in acknowledging the love and support provided. However, her attention to detail as a behind-the-scenes editorial partner and skilled reviewer for final content of this book added a degree of accuracy that I could never have accomplished alone.

Please contact me if you have corrections or suggestions on ways to improve future editions of the book. I hope that *The 5-Minute Urology Consult* will provide useful information to allow all of us to care for our urology patients in the best way possible.

Leonard G. Gomella, MD

EVIDENCE-BASED MEDICINE

Evidence-based medicine (EBM) is generally defined as the use of current best medical evidence to aid in making decisions about the care of an individual patient. While the ultimate decision-making process for or against a given treatment must be made between the patient and the health care provider, EBM seeks to assess the quality of evidence that a specific course of action is based on. The underlying principle is the evaluation of medical interventions and the literature that supports these interventions in a systematic and organized fashion. Since its introduction as a concept in the modern medicine over 30 years ago, there has been increased emphasis on this concept in daily patient care. While there are currently many different systems of EBM, we have adopted the *5-Minute Clinical Consult* standard of the "SORT Taxonomy" from the American Academy of Family Physicians. The key components are summarized later. A full review of this article can be viewed at http://www.aafp.org/afp/20040201/548.html. Throughout this edition of *The 5-Minute Urology Consult*, these evidence-based recommendations can be found. However, we recognize that in a primarily surgical-based specialty such as urology, this area is not yet as well defined as in more general areas of medical practice. As an illustrative example in a chapter on hypertension, the EBM recommendation might read:

> "Use thiazide diuretics as a first-line agent for the treatment of essential hypertension, as it has the greatest efficacy in preventing the vascular complications of hypertension (5)[A]."

The A designation, as noted in the algorithm later, implies this recommendation is based on the highest-quality, patient-oriented evidence, and should be followed. The number 5 refers to the source, which would be listed under the "References" heading as reference #5. Recommendations that are level A evidence are shaded blue in the text.

Strength of recommendation	Definition
A	**Recommendation based on consistent and good-quality patient-oriented evidence.** • Highest-quality resource, such as a systematic review. This is a summary of the medical literature on a given topic that uses strict, explicit methods to perform a thorough search of the literature and then provides a critical appraisal of the individual studies concluding in a recommendation. The Cochrane reviews are considered by many to be the most prestigious collection of systematic reviews (www.cochrane.org).
B	**Recommendation based on inconsistent or limited-quality patient-oriented evidence.** • This implies that the data referenced are derived from high-quality randomized controlled trials that were performed to minimize bias in their outcome. Bias is anything that may interfere with the truth; in the medical literature, it is often unintentional but is more common than we appreciate. In short, always assume that some degree of bias exists in any research endeavor.
C	**Recommendation based on consensus, usual practice, opinion, disease-oriented evidence, or case series for studies of diagnosis, treatment, prevention, or screening.** • This implies that the reference used does not meet het "A" or "B" requirements; these are often treatments recommended by consensus groups (such as the American Cancer Society). In some cases, they may be the standard of care. But implicit in a group's recommendations is the bias of the group or author that supports the reference.

Modified from Domino FJ, ed. *The 5-Minute Clinical Consult 2010*. Philadelphia: Lippincott Williams & Wilkins; 2009.

Professor of Urology in Surgery
University of Pennsylvania
Director, Pediatric Urology
The Children's Hospital of Philadelphia
Philadelphia, Pennsylvania

Daniel J. Canter, MD
Associate Member
Fox Chase Cancer Center
Vice Chairman
Urologic Institute of Southeastern Pennsylvania
Philadelphia, Pennsylvania

Christina Carpenter, MD
Resident
Department of Surgery
Division of Urology
Rutgers University--New Jersey Medical School
Newark, New Jersey

Brett S. Carver, MD
Assistant Attending
Department of Surgery
Division of Urology
Memorial Sloan-Kettering Cancer Center
New York, New York

Pasquale Casale, MD, FACS
Joan and Irene Given Professor of Urology
Columbia University
Chief
Pediatric Urology Morgan Stanley
Children's Hospital of New York Presbyterian

Division of Pediatric Urology
Columbia University Medical Center
New York, New York

Jed-Sian Cheng, MD, MPH
Chief Resident
Department of Urology
SUNY Upstate Medical University
Syracuse, New York

Kai-Wen Chuang, MD
Chief Resident
Arthur Smith Institute for Urology
North Shore-Long Island Jewish Health System
Manhasset, New York

Ryan Christopher Cleary, MD
Resident
Department of Urology
Thomas Jefferson University
Philadelphia, Pennsylvania

Jonathan Cloutier, MD
Fellow in Endourology
Department of Urology
Tenon Hospital
University of Pierre et Marie Curie
Paris, France

Michael S. Cookson, MD
Chairman and Professor
Donald D. Albers Endowed Chair
Department of Urology
University of Oklahoma Health Sciences Center
Oklahoma City, Oklahoma

Christopher S. Cooper, MD, FAAP, FACS
Professor of Pediatric Urology
Associate Dean
Student Affairs & Curriculum
University of Iowa Carver College of Medicine
Iowa City, Iowa

Anthony T. Corcoran, MD
Urologic Oncology Fellow
Fox Chase Cancer Center

Philadelphia, Pennsylvania

Nicholas G. Cost, MD
Assistant Professor
Department of Surgery
Division of Urology
University of Colorado School of Medicine
Aurora, Colorado

Nicholas Cowan, MD
Resident
Department of Urology
Oregon Health & Science University
Portland, Oregon

Nick Cowan, MD
Department of Urology
Oregon Health & Science University
Portland, Oregon

Brian Cox, MD
Chief Resident
Department of Urology
Oregon Health & Science University
Portland, Oregon

Bic N. Cung, MD
Resident
Department of Urology
Temple University School of Medicine
Philadelphia, Pennsylvania

Akhil Das, MD, FACS
Assistant Professor of Urology
Department of Urology
Sidney Kimmel Medical College
Thomas Jefferson University
Philadelphia, Pennsylvania

Michel Daudon, PhD
Service des Explorations Founctionnelles
Tenon Hospital
University of Pierre et Marie Curie
Paris, France

Ross M. Decter, MD, FRCS

Professor and Chief
Division of Urology
Surgery
MS Hershey Medical Center
The Pennsylvania State University College of Medicine
Hershey, Pennsylvania

Jessica M. DeLong, MD
Fellow, Adult & Pediatric Reconstructive Urology
Urology
Eastern Virginia Medical School
Virginia Beach, Virginia

Joan C. Delto, MD
Urology Resident
Mount Sinai Medical Center
Miami Beach, Florida

Robert B. Den, MD
Assistant Professor of Radiation Oncology and Cancer Biology
Radiation Oncology
Kimmel Cancer Center
Sidney Kimmel Medical College
Thomas Jefferson University
Philadelphia, Pennsylvania

Adam P. Dicker, MD, PhD
Professor and Chair
Radiation Oncology
Sidney Kimmel Medical College
Sidney Kimmel Cancer Center
Thomas Jefferson University
Philadelphia, Pennsylvania

Roger R. Dmochowski, MD, MMHC, FACS
Professor of Urology
Vice Chair Section of Surgical Sciences
Department of Urology
Vanderbilt University Medical Center
Nashville, Tennessee

Mary Ellen T. Dolat, MD
Resident
Division of Urology in the Department of Surgery
Virginia Commonwealth University

Richmond, Virginia

Steve Dong, MD
Clinical Instructor
Department of Urology
University of Southern California
West Hollywood, California

Philip J. Dorsey, Jr., MD, MPH
Resident
Department of Urology
Tulane University School of Medicine
New Orleans, Louisiana

Elizabeth V. Dray, MD
Resident
Department of Urology
Loyola University Medical Center
Maywood, Illinois

Daniel Dugi, III, MD
Assistant Professor
Department of Urology
Oregon Health & Science University
Portland, Oregon

John B. Eifler, MD
Clinical Instructor
Department of Urologic Surgery
Vanderbilt University Medical Center
Nashville, Tennessee

Justin D. Ellett, MD, PhD
Resident
Medical University of South Carolina
Charleston, South Carolina

Chandy Ellimoottil, MD
Resident
Department of Urology
Loyola University Medical Center
Maywood, Illinois

Leigh Mark Ettinger, MD, MS
Clinical Assistant at the Hackensack University Medical Center
Assistant Professor of Pediatrics at the University of Medicine & Dentistry of New Jersey

Department of Pediatrics
Hackensack University Medical Center
Hackensack, New Jersey

Thomas M. Facelle, MD
Resident
Division of Urology
Rutgers New Jersey Medical School
Newark, New Jersey

Ahmer V. Farooq, DO
Assistant Professor
Department of Urology
Loyola University Medical Center and
Stritch School of Medicine
Maywood, Illinois

Brad Figler, MD
Assistant Professor of Urology
Sidney Kimmel Medical College
Thomas Jefferson University
Philadelphia, Pennsylvania

T. Ernesto Figueroa, MD, FAAP, FACS
Clinical Associate Professor
Sidney Kimmel Medical College
Chief, Division of Pediatric Urology
Nemours/Alfred I. DuPont Hospital for Children
Wilmington, Delaware

Jason C. Fisher, MD
Assistant Professor of Surgery
Division of Pediatric Surgery
Joseph M. Sanzari Children's Hospital
Hackensack, New Jersey

Sallyanne M. Fisher, MSN, FNP-BC, CUNP
Urology Nurse Practitioner
Department of Veteran's Affairs Medical Center
Wilmington, Delaware

Carrie L. Fitzgerald, DO, MPH
Fellow
Department of Urology
University of Iowa Hospitals and Clinics
Iowa City, Iowa

Robert C. Flanigan, MD, FACS
Albert J. Jr. and Claire R. Speh Professor and Chair
Department of Urology
Loyola University Stritch School of Medicine
Chicago (Maywood), Illinois

Drew A. Freilich, MD
Resident
Department of Urology
New York Medical College
White Plains, New York

Debra L. Fromer, MD
Chief
Female Pelvic Medicine & Reconstructive Medicine
Department of Urology
Hackensack University Medical Center
Hackensack, New Jersey

Nilay M. Gandhi, MD
Resident
James Buchanan Brady Urologic Institute
Johns Hopkins Medical Institutions
Baltimore, Maryland

Francisco Gelpi-Hammerschmidt, MD
Chief Resident
Department of Urology
Thomas Jefferson University
Philadelphia, Pennsylvania

Kristin A. Greco, MD
Resident
Department of Urology
Loyola University Medical Center
Maywood, Illinois

Bradley C. Gill, MD, MS
Resident in Urology
Department of Urology
Cleveland Clinic
Cleveland, Ohio

Leonard G. Gomella, MD, FACS
The Bernard W. Godwin Professor of Prostate Cancer
Chairman

Department of Urology
Sidney Kimmel Medical College
Associate Director, Jefferson Sidney Kimmel Cancer Center
Clinical Director, Jefferson Sidney Kimmel Cancer Network
Thomas Jefferson University
Philadelphia, Pennsylvania

Tricia Lacy Gomella, MD
Part Time Assistant Professor
Department of Pediatrics
The Johns Hopkins University School of Medicine
Baltimore, Maryland

Patrick T. Gomella, MD, MPH
Resident
Department of Urology
George Washington University
Washington, DC

Michael A. Gorin, MD
Resident
James Buchanan Brady Urologic Institute
Johns Hopkins Medical Institutions
Towson, Maryland

Shaun G.S. Grewal, MD
Chief Resident
Division of Urologic Surgery
Washington University
Tulsa, Oklahoma

Tomas L. Griebling, MD, MPH, FACS
John P. Wolf 33-Degree Masonic Distinguished Professor and
Vice Chair of Urology and Faculty Associate
The Landon Center on Aging
Department of Urology
The University of Kansas
Kansas City, Kansas

Jennifer A. Hagerty, DO
Assistant Professor
Departments of Urology and Pediatrics
Sidney Kimmel Medical College
Division of Urology
Nemours/Alfred I. DuPont Hospital for Children

Wilmington, Delaware

Sang Won Han, MD
Professor of Urology
Department of Urology
Yonsei University College of Medicine
Seoul, Korea

Won K. Han, MD
Associate Professor
Department of Medicine
Division of Nephrology
Sidney Kimmel Medical College
Thomas Jefferson University
Philadelphia, Pennsylvania

Misop Han, MD
Associate Professor of Urology and Oncology
Department of Urology
Brady Institute of Urology
Johns Hopkins Medical Institutions
Baltimore, Maryland

Jessica H. Hannick, MD
Resident
Loyola University Medical Center and
Stritch School of Medicine
Maywood, Illinois

Samuel Haywood, MD
Resident
Glickman Urologic and Kidney Institute
Cleveland Clinic Foundation
Cleveland, Ohio

Kelly A. Healy, MD
Assistant Professor
Department of Urology
Sidney Kimmel Medical College
Thomas Jefferson University
Philadelphia, Pennsylvania

Jennifer E. Heckman, MD, MPH
Resident in Urology
Department of Urology
University of Wisconsin

Madison, Wisconsin

Jason C. Hedges, MD, PhD
Assistant Professor
Department of Urology
Oregon Health & Science University
Portland, Oregon

Lauren N. Hendrix, MD
Resident
Division of Urology
Department of Surgery
University of Kentucky
Lexington, Kentucky

Amin S. Herati, MD
Resident
Department of Urology
Smith Institute for Urology Hofstra North Schore -- LIJ School of Medicine
Briarwood, New York

Duane R. Hickling, MD
Female Pelvic Medicine and Reconstructive Surgery Fellow
NYU School of Medicine
New York, New York

Irvin H. Hirsch, MD
Clinical Professor
Department of Urology
Thomas Jefferson University
Philadelphia, Pennsylvania

Steve J. Hodges, MD
Associate Professor
Department of Urology
Wake Forest School of Medicine
Winston-Salem, North Carolina

Jean Hoffman-Censits, MD
Assistant Professor
Department of Medical Oncology
Sidney Kimmel Medical College
Thomas Jefferson University
Philadelphia, Pennsylvania

James M. Hotaling, MD, MS

Andrology Fellow
Department of Urology
University of Illinois at Chicago
Chicago, Illinois

Wayland Hsiao, MD
Assistant Professor
Department of Urology
Emory University School of Medicine
Atlanta, Georgia

Jonathan H. Huang, MD
Resident
Department of Urology
Emory University School of Medicine
Atlanta, Georgia

Scott G. Hubosky, MD
Assistant Professor
Vice Chair for Quality and Safety
Department of Urology
Sidney Kimmel Medical College
Jefferson Medical College
Philadelphia, Pennsylvania

Chad P. Hubsher, MD
Resident in Urology
Division of Urology
West Virginia University
Morgantown, West Virginia

Mark Hurwitz, MD
Professor and Director of Thermal Oncology
Department of Radiation Oncology
Sidney Kimmel Medical College
Sidney Kimmel Cancer Center
Thomas Jefferson University
Philadelphia, Pennsylvania

Youngjae Im, MD
Assistant Professor in Urology
Department of Urology
Yonsei University College of Medicine
Seoul, Korea

Mohamed T. Ismail, MD

Assistant Professor
Department of Urology
Sidney Kimmel Medical College
Thomas Jefferson University
Philadelphia, Pennsylvania
Chief of Urology
Wilmington VA Medical Center
Wilmington, Delaware

Mohamed S. Ismail, MBChB, MRCS, PhD
Specialist Registrar in Urology
Department of Urology
Southmead Hospital
South Gloucestershire, England

Emma F.P. Jacobs, MD
Resident
Department of Urology
Indiana University
Indianapolis, Indiana

Robert Janssen, MD
Resident
Division of Urology
West Virginia University
Morgantown, West Virginia

Mark L. Jordan, MD, FACS
Chief of Urology
VA Long Beach Health Care System
Clinical Professor
Department of Urology
University of California
Irvine, California

Adam O. Kadlec, MD
Resident
Department of Urology
Loyola University Medical Center
Maywood, Illinois

Jonathan S. Karpelowsky, MD, PhD
Senior Lecturer/Staff Specialist
Pediatric Surgery
Children's Hospital at Westmead & University of Sydney

Westmead, New South Wales, Australia

SECTION I

Urologic Diseases and Conditions

Section Editor: Leonard G. Gomella, MD, FACS

ABDOMINAL MASS, ADULT, UROLOGIC CONSIDERATIONS

Brian M. Benway, MD
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION

- Urologic masses are usually retroperitoneal in adults
  - May arise from several sites
    - Renal (malignant and benign)
    - Adrenal
    - Germ cell (retroperitoneal lymphadenopathy)
    - Metastatic
    - Other (retroperitoneal fibrosis [RPF], hematoma, abscess, lymphocele, lymphoma, urinary retention)

EPIDEMIOLOGY

Incidence

- Renal cell carcinoma: 55,000 new cases per year. Incidence is rising (1)
- Testis cancer: 8,000 new cases per year

Prevalence

Varies with disease type

RISK FACTORS

- Cancer (renal, adrenal, testis)
- Prior surgery (lymphocele)
- Infection (abscess, RPF)
- Trauma (hematoma, urinoma)
- Urinary retention

Genetics

- Renal lesions have some known genetic alterations:
  - von Hipple Lindau (VHL)
  - Hereditary papillary renal cell
  - Birt–Hogg–Dubé
  - Hereditary leiomyomatosis
  - Tuberous sclerosis

PATHOPHYSIOLOGY

- Various urologic pathologic conditions may present with a mass:
- Primary renal neoplasms:
  - Malignant: Renal cell carcinoma (RCC), renal sarcoma, adult Wilms tumor, urothelial carcinoma, lymphoma
  - Benign: Renal cortical adenoma, renal oncocytoma, renal hamartoma (angiomyolipoma) fibroma

- Primary adrenal neoplasms: Adrenal cortical carcinoma, pheochromocytoma, adrenal adenoma, paraganglioma
- Hydronephrosis
- Primary and metastatic germ cell tumor (GCT): Are composed of seminoma, embryonal cell carcinoma, yolk sac tumor, teratoma, and choriocarcinoma
- Primary extragonadal GCTs can occur intraperitoneally
  – Metastatic GCTs are associated with retroperitoneal lymphadenopathy
- Renal abscesses: Usually follow insufficient treatment of lobar nephronia; needle aspiration may be needed to make a diagnosis
- TB can cause cold abscess formation. Pus developing from a renal source may track alongside psoas muscle and appears in the groin, where it must be distinguished from hernia.
- Perinephric abscess: Usually arises as a result of pre-existing renal factors such as renal calculi, ureteral calculi, hydronephrotic changes, renal cystic disease, or infected carcinoma
- Hematomas: May be caused by a ruptured kidney or ureteral avulsion. Blood in the retroperitoneal space may track to the corresponding iliac fossa
- Renal cysts
- Bladder-related: Retention, tumors and urachal abnormality, or cancer
- Metastatic tumors to the adrenal glands and kidney

ASSOCIATED CONDITIONS
- Hydronephrosis, renal insufficiency (malignant obstruction)
- Aortitis, aortic aneurysm (RPF)
- Stauffer syndrome (RCC)

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Weight loss, cachexia, night sweats (malignancy or chronic septic disease)
- Spiking fevers, flank pain (infectious)
- Recent trauma with or without hematuria
- History of testis mass
- Classic triad for renal cell carcinoma (hematuria, flank pain, palpable mass) is relatively uncommon in modern era

PHYSICAL EXAM
- Abdominal wall masses such as lipomas, hematomas, lymph nodes, and hernias can be readily determined by physical exam
- Palpable abdominal mass
  – Location, tenderness
- Any mucoid drainage from the umbilicus
- Hypertension
- Lymphadenopathy
- Lower extremity edema

- Lower extremity pulses
- Varicocele (more common on right)
  – Left side consider renal mass with occlusion of renal vein
- Scrotal exam

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC, complete metabolic panel
- Urinalysis and culture
- Adrenal metabolic workup if adrenal mass is suspected – see Section I "Adrenal Adenoma"
- Tumor markers
  – Testis – AFP, β-HCG, LDH
    ◦ AFP – may be elevated in embryonal, teratocarcinoma, yolk sac, but never in pure choriocarcinoma or pure seminoma
    ◦ LDH may indicate retroperitoneal involvement, but not specific to testis
- Pregnancy testing where appropriate

Imaging

- Ultrasound
  – Good for detecting cystic lesions, but not optimum for calcified masses or smaller stones. Quality is operator-dependent.
- Computed tomography (CT)
  – Good for detecting solid abdominal masses, metastatic lesions, and stone.
  – CT angiography can evaluate renal vasculature.
  – PET-CT approved for diagnosis of RCC metastases.
- Magnetic resonance imaging (MRI)
  – Good for evaluating adrenal masses and indeterminate renal lesions.
  – Can be used in patients with iodine allergies and renal insufficiency, though caution should be exercised in the latter.
- ^{131}I-metaiodobenzylguanidine (MIBG)
  – Only role for evaluating pheochromocytoma.
- Intravenous pyelogram/excretory urogram
  – Largely historical, replaced by CT or MR urography.

Diagnostic Procedures/Surgery

- Fine-needle aspiration or core biopsy of mass
  – Renal biopsy sensitivity enhanced by use of coaxial core biopsy techniques (2)

Pathologic Findings

Varies depending upon type and location of mass

DIFFERENTIAL DIAGNOSIS

- Adrenal mass: See Section I "Adrenal Mass"
- Distended bladder
- GI tract:
  – Hepatomegaly, splenomegaly, pancreatitis, pancreatic mass, tumors, volvulus, constipation

- Gynecologic:
  - Pregnancy, uterine fibroids, ovarian cysts, malignancy
  - Hydronephrosis
- Other: Intra-abdominal abscess, ascites
- Renal mass: See Section I "Renal Mass"
- Retroperitoneal mass: See Section I "Retroperitoneal Masses, Fluid, and Cysts"
- Ruptured abdominal aortic aneurysm
- Urachal abnormality

TREATMENT

GENERAL MEASURES

- Varies by underlying ailment
  - Renal malignancy – radical or partial nephrectomy, ablation, observation (3)
  - Adrenal malignancy – adrenalectomy
  - Adrenal adenoma – excision or observation
  - Testis cancer – retroperitoneal lymph node dissection, chemotherapy, radiation
  - Renal abscess, xanthogranulomatous pyelonephritis – antibiotics, drainage, nephrectomy
  - Cysts – observation, decortication, drainage and sclerosis
  - Retention – placement of Foley catheter
  - Hydronephrosis – double-J stent placement or percutaneous nephrostomy tube placement

MEDICATION

First Line

- Antibiotics for abscess or obstruction
- Corticosteroids, tamoxifen for RPF

Second Line

Mycophenolate mofetil, azathioprine for RPF

SURGERY/OTHER PROCEDURES

Depends upon clinical diagnosis

ADDITIONAL TREATMENT

Radiation Therapy

- Limited utility for renal cell carcinoma
- Used for seminomatous germ cell tumors

Additional Therapies

Depends upon clinical diagnosis

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Prognosis depends upon clinical diagnosis and staging

COMPLICATIONS

See associated chapters regarding disease-specific interventions

FOLLOW-UP

Patient Monitoring

Depends upon clinical diagnosis and management. See associated chapters regarding specific disease processes.

Patient Resources

N/A

CODES

ICD9

- 189.0 Malignant neoplasm of kidney, except pelvis
- 194.0 Malignant neoplasm of adrenal gland
- 789.30 Abdominal or pelvic swelling, mass, or lump, unspecified site

ICD10

- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- C74.90 Malignant neoplasm of unsp part of unspecified adrenal gland
- R19.00 Intra-abd and pelvic swelling, mass and lump, unsp site

CLINICAL/SURGICAL PEARLS

- Abdominal masses in the adult can arise from several different processes.
- Radiographic information is often essential to diagnosis.
- Management varies upon disease type.

ABDOMINAL MASS, NEWBORN/CHILD, UROLOGIC CONSIDERATIONS

Yong Seung Lee, MD
Sang Won Han, MD

BASICS

DESCRIPTION

- Traditional presentation was palpable mass in the newborn/child abdomen
- Current presentation is usually by prenatal ultrasound
- Most masses are nonsurgical; 87% of surgical lesions are benign
- Almost 2/3 of infantile abdominal masses arise from kidneys, followed by GI tract (12%), female genital system (10%), retroperitoneum (9%)

EPIDEMIOLOGY

Incidence

Abdominal mass in 1 per 1,000 live births

Prevalence

Varies with disease type

RISK FACTORS

Genetics

- Disease specific
- Neuroblastoma
  - Chromosome 1p deletion
  - Allelic loss of 11q
  - Gain of copies of 17q correlate with more aggressive tumor
  - N-*MYC* oncogene amplification
- Polycystic kidney disease, autosomal recessive (ARPKD)
  - Gene locus at chromosome 6p21
- Rhabdomyosarcoma (RMS)
  - Mutation of TP53 gene found in tumors of patients with Li–Fraumeni syndrome
  - Alveolar RMS is associated with translocation between chromosomes 1 or 2 and 13
  - Embryonal RMS demonstrates LOH on chromosome 11p15.5
- Wilms tumor
  - WT1 (11p13): Denys–Drash and WAGR (Wilms tumor, aniridia, genitourinary problems, retardation)
  - WT2 (11p15): Beckwith–Wiedemann
  - *WTX* (Xq11.1): Inactivated in up to 1/3 of Wilms tumors
  - FWT1 (17q), FWT2 (19q): Familial
  - LOH at 1p and 16q is associated with an increased risk of tumor relapse and death

PATHOPHYSIOLOGY

Disease specific, related to organ of origin

ASSOCIATED CONDITIONS
Disease specific

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Prenatal ultrasound (1)
  - Oligohydramnios: Associated with PUV, bilateral UPJ, urethral atresia, polycystic or multicystic dysplastic kidneys, renal agenesis
  - Polyhydramnios: Associated with high GI obstructions
- Postnatal history
  - Initial discovery
  - Duration from detection of mass
  - Rapidity of growth
  - Constitutional symptoms: Fever, pain, weight loss, UTI, dysuria, hematuria, melena, anorexia, bilious vomiting

PHYSICAL EXAM
- Perform thorough abdominal exam (2):
  - Size and location
  - Solid or cystic
  - Tender or nontender
  - Smooth, irregular, indurated, or soft
  - Fixed or mobile
  - Auscultation, percussion, and transillumination
- Additional exam:
  - Nasogastric tube for intestinal decompression
  - Foley catheter for urinary decompression
  - Rectal/introital exam

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Labs should be tailored to clinical suspicion
- CBC:
  - Anemia, neutropenia, thrombocytopenia may suggest bone marrow involvement
  - Leukocytosis suggests possible infection/ obstruction
- BUN/creatinine/electrolytes
  - Elevated BUN/creatinine suggests renal compromise, dehydration
- Urinalysis:
  - Hematuria seen in Wilms tumor, renal vein thrombosis, UPJ obstruction after trauma
- 24-hr urine
  - Elevated homovanillic acid and vanillylmandelic acid seen in neuroblastoma or pheochromocytoma
- Serum β-hCG and α-fetoprotein:

– Used in tumors such as teratoma, liver, and germ-cell tumors

Imaging

- Plain abdominal x-rays:
  – Check for obstruction/ileus; air–fluid levels on upright and lateral; absence of air in rectum
  – Calcifications can suggest neuroblastoma, teratoma, hepatoblastoma, meconium peritonitis, urinary, or biliary stones
- Abdominal US:
  – Primarily evaluation modality
  – Used to establish location, size, organ of origin, internal architecture, and vascular supply
  – Can determine cystic vs. solid
  – Inexpensive and noninvasive; rarely requires sedation
- CT:
  – Used to enhance findings on US or solid mass on US
  – Good anatomic detail
  – Useful in older children and suspected malignancies
  – Limitation: High sensitivity of pediatric patients to radiation exposure, may require sedation
- MRI:
  – Good for vascular involvement, adrenal origin
  – Good anatomic detail
  – May gather functional and quantitative information
  – Limitation: May require sedation/anesthesia
- Radionuclide scans:
  – Renal scans: Used to determine renal function, scarring, infection, and obstruction
  – Biliary scans: Evaluate for choledochal cysts
  – Liver–spleen scans: Used for diagnosis of liver tumors or splenic enlargement
- VCUG:
  – Used to rule out lower urinary tract pathology

Diagnostic Procedures/Surgery

N/A

Pathologic Findings

Disease specific

DIFFERENTIAL DIAGNOSIS

- Hydronephrosis: Most common cause of neonatal abdominal mass (1):
  – UPJ obstruction: Most common cause of hydronephrotic abdominal mass
  – Other causes: UVJ obstruction, PUV, VUR, megaureter, and ureteroceles
  – $<$15% of neonates present with mass
  – Later presentation: UTI, flank pain, hematuria after trauma
- Multicystic dysplastic kidney:
  – 2nd most common cause; together with UPJ constitute 40% of all neonatal abdominal masses
  – Unilateral flank mass; more common on left, and in boys

  - US shows multiple noncommunicating cysts of various sizes; nuclear scan shows nonfunction on affected side
- Multilocular cystic nephroma:
  - Spectrum from benign cyst to cystic Wilms tumor
  - Present in males <5 yr and females >30 yr
  - Diagnosis by surgical excision
- Renal vein thrombosis:
  - Most common cause of neonatal hematuria; 65% occur in neonatal period, 30% after age 1; male predominance
  - Classic features: Flank mass, hematuria, thrombocytopenia
  - Occurs in conditions associated with dehydration, maternal diabetes, sepsis, diarrhea, or sickle cell disease
- Polycystic kidney disease:
  - Autosomal recessive; diagnosed in neonatal period; 50% die in 1st few hours or days usually from respiratory failure; of survivors, 86% alive at 1 yr and 67% at 15 yr
- Congenital mesoblastic nephroma:
  - Most common renal tumor diagnosed on antenatal US
  - Most common renal neoplasm of infancy
  - Mean age 3.5 mo
  - Surgery is usually curative
- Wilms tumor:
  - Most common childhood abdominal malignancy; most common malignant renal neoplasm in children
  - Usually presents as smooth, nontender, unilateral abdominal mass
  - Rare >10 yr and <6 mo; median age 3.5 yr
  - 80% of cases occur in age <5 yr
  - Increased frequency in WAGR, Beckwith–Wiedemann, and Denys–Drash syndromes
  - Combination surgery, chemotherapy, and radiation yields success rates >90% in favorable histology; lower in unfavorable histology
- Neuroblastoma:
  - Most common solid neonatal abdominal mass
  - Most common malignancy of newborn
  - 50% of all malignant tumors in children; 50% before age 2
  - Fixed, painful, irregular mass that often crosses midline
  - Fever, malaise, weight loss; ill-appearing compared to Wilms tumor
  - 90% have catecholamine excess
- Adrenal hemorrhage:
  - 1–2% of healthy infants
  - Predisposing factors: Birth trauma, large birth weight, perinatal asphyxia, sepsis, and coagulopathy
  - Supportive care, rare intervention
- Genital mass – Hydrocolpos and hydrometrocolpos (3):
  - Hydrocolpos: Gross distension of the vagina
  - Hydrometrocolpos: Gross distension of the vaginal and uterus

  - Due to obstruction from vaginal atresia or stenosis, imperforate hymen, or cloacal anomaly
  - Pelvic midline mass; US shows fluid-filled mass between bladder and rectum
- Genital mass – Ovarian cyst:
  - 1:3,000 girls
  - Most common cause of abdominal cystic tumor in female fetus
  - Presents as large mobile midabdominal mass
  - Cysts and tumors: 17% neonatal to age 4; 28% from 5–9 yr; 55% 9–18 yr
  - Prepuberty 50% are malignant, teratoma most common
- Genital mass – RMS:
  - 15–20% arise from genitourinary system: Prostate, bladder, paratesticular, vulvar/vaginal, uterine
  - 2 major subtypes: Embryonal (most common), alveolar (worse prognosis)
- GI masses:
  - 12% of neonatal abdominal masses
  - Intestinal duplication:
    - Common; congenital cystic abnormalities, with ileum most common, followed by esophagus, duodenum
  - Hypertrophic pyloric stenosis
  - Intestinal cysts: Meconium, omental, duplication, mesenteric
- Hepatobiliary masses:
  - Primary liver tumors are 3rd most common solid abdominal mass in childhood (15% total)
  - Benign lesions: 1/3 (hemangioendothelioma, mesenchymal hamartoma, adenoma, focal nodular hyperplasia, congenital cysts)
  - Malignant: 2/3 (hepatoblastoma most common <5 yr; hepatocellular carcinoma present ages 12–15)
- Splenic masses:
  - Congenital splenic cysts
  - Congenital hemolytic anemias: Hemoglobinopathies, thalassemias, hereditary spherocytosis
- Lymphoma: Common in boys >5 yr
  - 60% non-Hodgkin; 1/3 involve abdomen; can present as intussusception

TREATMENT

GENERAL MEASURES

Stabilize patient as necessary. Treatment is based on diagnosis.

MEDICATION

First Line

- Neuroblastoma
  - Chemotherapy is a part of a multidisciplinary approach including surgery, and bone or stem cell transplantation
  - Treatment schema based on INSS stage, age, N-*MYC* amplification, DNA ploidy, and

Shimada histopathology
- RMS
  – Chemotherapy is 1st line prior to radiation or surgical resection in all cases except those amenable to immediate partial cystectomy
- Wilms tumor
  – Adjuvant chemotherapy is based on NWTSG recommendations
  – SIOP studies favor preop chemotherapy

Second Line
N/A

SURGERY/OTHER PROCEDURES
Surgery is specific to disease process. In general, tumors, obstructive/infection problems will need surgery.

ADDITIONAL TREATMENT
Radiation Therapy
- RMS: Part of a multidisciplinary approach to curative therapy including surgical excision and chemotherapy
- Wilms tumor: For higher stage favorable histology, or for patients with focal or diffuse anaplasia

Additional Therapies
Neuroblastoma: Multidisciplinary approach may include bone or stem cell transplantation

Complementary & Alternative Therapies

- 789.3 Abdominal or pelvic swelling, mass, or lump
- 789.30 Abdominal or pelvic swelling, mass, or lump, unspecified site

ICD10

- C64.9 Malignant neoplasm of unsp kidney, except renal pelvis
- C74.90 Malignant neoplasm of unsp part of unspecified adrenal gland
- Q61.19 Other polycystic kidney, infantile type

CLINICAL/SURGICAL PEARLS

- Determining the age (neonates vs. children) can differentiate between likely etiologies. In general, older children are more at risk of developing malignant masses compared with neonates and young children.
- Two most common entities causing neonatal abdominal mass (UPJ obstruction and MCDK), can be differentiated by renal scan. The renal scan usually shows some function in the hydronephrotic kidney and nonfunction MCDK.
- Concerning malignant masses, neuroblastoma, and hepatoblastoma are more likely in children <2; older children are more susceptible to Wilms, hepatocellular carcinoma, genitourinary tract tumors, and germ-line tumor.

ACUTE KIDNEY INJURY, ADULT (RENAL FAILURE, ACUTE)

Joan C. Delto, MD
Fernando J. Bianco, Jr., MD

BASICS

DESCRIPTION

- The term acute kidney injury (AKI) has replaced the older descriptor of acute renal failure (ARF)
  - Rapid decline in renal function characterized by progressive azotemia, with or without oliguria (< 500 mL/d)
  - Decreased glomerular filtration rate
- Attempts to standardize the definition of AKI have been proposed by different groups as noted below. However, their utility in daily clinical care has not been confirmed (1)
  - Acute dialysis quality initiative (ADQI) group RIFLE criteria
  - Acute kidney injury network (AKIN)
  - Kidney Disease/Improving Global Outcomes (KDIGO) Clinical Practice Guidelines

EPIDEMIOLOGY

Incidence

- 5% of hospital admissions
- 30% of ICU admissions
- 25% of hospital patients develop AKI
  - 50% are iatrogenic

RISK FACTORS

- Preoperative risk factors for development of AKI:
  - Age > 56
  - Male
  - Emergency surgery
  - Intraperitoneal surgery
  - Diabetes mellitus
  - Active CHF
  - Ascites
  - Hypertension
  - Preoperative renal insufficiency

Genetics

No genetic association

PATHOPHYSIOLOGY

- Pre-renal
  - Transient renal hypoperfusion (reversible)
  - Stimulation of sympathetic nervous system and RAS causing renal vasoconstriction and sodium reabsorption; stimulation of antidiuretic hormone

  - Water reabsorption, low urine output, concentrated urine
- Intrarenal
  - Acute tubular necrosis (ATN)
    - Renal ischemia
    - Depletion of ATP
    - Dysfunction of plasma membrane
    - Reperfusion injury
    - Oxidative stress leading to tubular cell damage
    - Rhabdomyolysis and hemolysis
- Postrenal (obstruction)
  - Intrinsic obstruction
  - Extrinsic compression
- Iatrogenic (urinary extravasation, fistula)
  - Reabsorption of BUN, Cr

ASSOCIATED CONDITIONS
- Dehydration
- Trauma
- Burns
- Sepsis
- Urinary tract infection
- Chronic renal insufficiency
- Hypertension
- Congestive heart failure
- Liver disease, cirrhosis
- Nephrolithiasis
- BPH
- Advanced prostate or bladder cancer, malignancy
- Malignant hypertension

GENERAL PREVENTION
- Hydration
- Proper renal dosing of medication; daily dosing of aminoglycosides
- Avoidance of nephrotoxic agents
- Adequate voiding (timed, double voiding)
- Risk of contrast-induced AKI may be reduced by N-acetylcysteine 600 mg PO BID on day prior to and day of contrast and isotonic $NaHCO_3$ 3 mL/kg/h × 1 hr before and 1 mL/kg/h × 6 hr after contrast administration

ALERT
Determine if the patient is on any nephrotoxic medication? Has there been recent contrast injection? Is the foley draining?

DIAGNOSIS

- **HISTORY**

  - Urination history—frequency, urgency, strength of stream, hematuria
  - Fever, chills
  - Nausea, vomiting, diarrhea
  - Flank or abdominal pain
  - Recent strenuous activity
  - Review medications—nephrotoxic agents, diuretics
  - Comorbidities
    - Renal disease
    - Diabetes
    - Hypertension
    - Liver disease
  - Infections
  - Nephrolithiasis
  - BPH
  - Malignancies, metastatic disease
  - Previous abdominal or pelvic surgeries
  - Radiation
  - Chemotherapy
  - Prior ureteroscopy or endoscopy
- ***Social History***
  - Smoking
  - Alcohol
  - Drug use

PHYSICAL EXAM

- Vital signs: Blood pressure, heart rate, orthostatic changes
- Volume status, body weight
- Urinary output, drain output
- Neck vein distention, lung rales
- Abdominal exam
  - Bruits
  - Palpable mass
  - Distention, palpable bladder
  - Costovertebral angle tenderness
- Digital rectal exam—prostate size/nodularity
- Patency of urinary catheters, stents
- Peripheral edema, rash

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC, BUN, creatinine, electrolytes (including Ca/Mg/Phos), consider arterial blood gases (ABGs)
- AKI
  - Rise in serum creatinine (SCr) of at least 0.3 mg/dL over a 48-hr period
  - Over 1.5 times the baseline SCr value within the 7 previous days
- Common lab abnormalities in AKI:

  - Increased: K+, phosphate, Mg, uric acid
  - Decreased: Hematocrit (Hct), Na, Ca
- NephroCheck™ detects the presence of insulin-like growth-factor binding protein 7 (IGFBP7) and tissue inhibitor of met alloproteinases (TIMP-2) in the urine (both AKI associated); the test provides a risk score of developing AKI within 12 hrs
- Creatinine kinase (rhabdomyolysis)
- Immune antibodies (vasculitis)
- Urine
  - Urinalysis: Blood, protein, cells, casts, crystals
    - Transparent hyaline casts—prerenal etiology; pigmented granular/muddy brown casts—ATN; WBC casts—acute interstitial nephritis; RBC casts—glomerulonephritis
  - Urine eosinophils: ≥1% eosinophils by Hansel's stain suggestive of acute interstitial nephritis (sensitivity, 67%; specificity, 83%)
  - Urine electrolytes (Urine Na; U_{Na})
  - Urine osmolality (U_{osm})
  - Fractional excretion of sodium (FENA)
- Prerenal
  - FENA <1%; BUN/Cr >20
  - U_{Na} <10; U_{osm} >500
- Intrarenal
  - FENA >2%; BUN/Cr <15
  - U_{Na} >20; U_{osm} <350
- Postrenal
  - FENA >4%; BUN/Cr >15
  - U_{Na} >40; U_{osm} <350

Imaging

- Renal/bladder ultrasound
  - Hydronephrosis
  - Stones
  - Bladder volume, post void residual
  - Prostatic size
  - Bladder masses causing obstruction
  - Ureteral jets, resistive indices
- Abdominal x-ray (KUB)
  - Calcifications
  - Stent location
- CT abdomen/pelvis
  - Obstructing stones
  - Obstructing masses
- Renal scan
  - Obstruction
  - Kidney function

Diagnostic Procedures/Surgery
- Cystoscopy with retrograde pyelography
- Renal biopsy (acute glomerular nephritis)

Pathologic Findings
- Acute interstitial nephritis
  - Interstitial edema, marked interstitial infiltrate of T cells and monocytes
  - Eosinophilic plasma cells
  - PMN cells
  - Granulomata

DIFFERENTIAL DIAGNOSIS (4)
- Prerenal (~55%): Hypotension; volume depletion (GI losses, excessive sweating, dehydration, hemorrhage); renal artery stenosis/embolism; burns; heart failure; liver failure
- Intrarenal (~40%): ATN (from prolonged prerenal insufficiency, radiographic contrast material, aminoglycosides, NSAIDs, or other nephrotoxic substances); glomerulonephritis; acute interstitial nephritis (drug-induced); arteriolar insults; vasculitis; accelerated hypertension; cholesterol embolization (common after arterial procedures); intrarenal deposition/sludging (uric acid nephropathy and multiple myeloma [Bence Jones proteins])
- Postrenal (~5%): Extrinsic compression (eg, BPH, carcinoma, pregnancy); intrinsic obstruction (eg, calculus, tumor, clot, stricture, sloughed papillae); decreased function (eg, neurogenic bladder)
- Pseudo-AKI: Endogenous chromogens (eg, bilirubin, ascorbic acid, uric acid) and exogenous chromogens (eg, cephalosporins, trimethoprim, cimetidine) may interfere with the creatinine assay and cause falsely elevated results

TREATMENT

GENERAL MEASURES
- AKI requires close management of fluid, acid–base, and electrolyte balance and the removal of uremic toxins
- Fenoldopam, a dopamine agonist, may decrease dialysis and mortality in AKI (4)
- Furosemide is ineffective in preventing and treating AKI
- Prerenal
  - Restoration of renal perfusion; isotonic fluid
- Intrarenal
  - Cessation of nephrotoxic drugs
  - Renal dosing of medications
- Postrenal
  - Foley or suprapubic tube drainage
  - Ensure patency of drains
    - Ensure proper placement within bladder
    - Rule out catheter obstruction (mucus, clot)
  - Percutaneous nephrostomy tube
- Treatment of hyperkalemia (3)
  - Monitor EKG when K^+ >6 mmol/L

    - IV calcium
    - Sodium bicarbonate (if acidotic)
    - Insulin and glucose
    - Kayexalate
    - Hemodialysis for severe hyperkalemia or refractory to treatment
- Control of urinary extravasation
- Dietary considerations
  – Maintain carbohydrate and protein intake
  – Restrict: Phosphorus, potassium, sodium

MEDICATION

First Line

See above

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Postrenal
  – If cannot drain bladder per urethra, consider suprapubic tube
  – Ureteral stent
  – Percutaneous nephrostomy
  – If clot retention, removal of clots. May require cystoscopy, clot evacuation
  – If BPH, consideration for outpatient TURP
- Indications for dialysis (called renal replacement therapy can be hemo or peritoneal dialysis: For these urgent and potentially life-threatening indications:
  – Metabolic disturbances refractory to medical management such as hyperkalemia, metabolic acidosis, hypo/hypercalcemia, hyperphosphatemia
  – Pericarditis or pleuritis
  – Uremic encephalopathy
  – Uremia-related bleeding diathesis
  – Volume overload refractory to diuretics
  – Severe refractory hypertension

ONGOING CARE

PROGNOSIS

- Prerenal
  – Good if renal function improvement within 24–72 hr after fluid repletion
- ATN
  – Mortality rate of ATN generally 50%
  – Mortality rate of ATN in ICU 75%
  – Of those who survive ATN, 50% have complete resolution of renal function
  – 5% of AKI patients will require chronic renal replacement therapy
- Postrenal
  – Great recovery once obstruction and insult are resolved

COMPLICATIONS

- Postobstructive diuresis
- Sepsis post relief of obstruction with instrumentation
- Stent inflammation, crusting, and pain
- Chronic renal failure

FOLLOW-UP

Patient Monitoring

- Blood pressure control
- Monitoring of creatinine, potassium, calcium, and phosphorus
- Repeat imaging (US) to re-evaluate hydronephrosis
- If question of stent migration, obtain KUB or US
- Ureteral stents will need to eventually be exchanged or removed
- Consideration of internalization of percutaneous nephrostomy tubes

Patient Resources

- 584.9 Acute kidney failure, unspecified
- 593.81 Vascular disorders of kidney

ICD10

- N17.0 Acute kidney failure with tubular necrosis
- N17.9 Acute kidney failure, unspecified
- N28.0 Ischemia and infarction of kidney

CLINICAL/SURGICAL PEARLS

- Maximize urinary drainage.
- Avoid nephrotoxic agents.
- Upper tract obstructive uropathy should be acutely managed by stent vs. percutaneous nephrostomy.

ACUTE KIDNEY INJURY, PEDIATRIC (RENAL FAILURE, ACUTE)

Leigh Mark Ettinger, MD, MS
Kenneth Lieberman, MD

BASICS

DESCRIPTION

- A sudden or recently acquired functional impairment of the kidney relative to physiologic demands with or without actual kidney injury (1)
- Causes mild to potentially life-threatening alterations in fluid, electrolyte, acid–base and hormonal homeostasis
- Terminology evolving from acute tubular necrosis (ATN) to acute renal failure (ARF) to acute kidney injury (AKI) of varying grades to standardize reporting, clinical care, and research
- Diagnosed by the Pediatric Modified Risk Injury Failure Loss End Stage Renal Disease (pRIFLE) criteria based on the estimated creatinine clearance (eCCl, based on Schwartz formula) and urine output (UOP) (2)
  - Risk: eCCl decrease by 25% and/or UOP <0.5 mL/kg/h for 8 hr
  - Injury: eCCl decrease by 50% and/or UOP <0.5 mL/kg/h for 16 hr
  - Failure: eCCl decrease by 75% or eCCl <35 mL/min/1.73 m^2 and/or UOP <0.3 mL/kg/h for 24 hr or anuric for 12 hr
  - Loss: Persistent failure >4 wk
  - End stage renal disease (ESRD): Persistent failure >3 mo
- No standardized definition for neonatal AKI

EPIDEMIOLOGY

Incidence

- A difficult assessment since, until recently, there was no unifying criteria to make the diagnosis
  - Recent meta-analysis showed reported incidences in hospitalized pediatric population from 1–82% (3)

Prevalence

Unknown

RISK FACTORS

- Chronic kidney disease (CKD) increases the risk for AKI
- Hospitalization, especially in the ICU
- Exposure to potentially nephrotoxic agents, such as nonsteroidal anti-inflammatories (NSAIDs), contrast, aminoglycosides
- Recent surgery, solid organ or marrow transplant, cardiopulmonary bypass

Genetics

- If recurrent rhabdomyolysis, consider an underlying defect in muscle metabolism

- If recurrent hemolytic uremic syndrome (HUS) consider a defect in the complement cascade
- If AKI in the presence of CKD then consider inherited forms of ESRD, such as autosomal recessive polycystic kidney disease

PATHOPHYSIOLOGY

- Prerenal and intrinsic renal injury disrupt the regional perfusion of, and subsequent oxygen delivery to, the kidney (3)
  - The natural arterial gradient of oxygen tension from cortex to medulla makes the kidney highly susceptible to hypoxic and oxidative injury during ischemia and reperfusion
  - Poorly perfused glomerular endothelial cells release vasoactive substances, proteases, reactive oxygen species, and nitric oxide and activate the coagulation cascade and complement pathways
  - Even well-perfused kidneys can develop AKI during sepsis from circulating cytokines, lymphocytes, T cells, and other factors
  - When found in the presence of cardiac, pulmonary, or hepatic failure it is likely due to endothelial activation and circulatory aberrations
  - Nephrotoxic agents each have their own mechanism of damage, eg, by forming crystals in the microstructures of the kidney
  - Rhabdomyolysis causes intrarenal vasoconstriction, direct ischemic tubule injury, and tubular obstruction in acidic urine
- Postrenal injury is due to antegrade urine flow disruption from the kidney
  - Must be bilateral to cause pRIFLE findings but can be unilateral if only one kidney is present due to congenital absence, prior nephrectomy, or kidney transplant
- Etiology may be multifactorial, especially in the ICU setting

ASSOCIATED CONDITIONS

CKD increases the risk for AKI

GENERAL PREVENTION

- Prerenal
  - Prevent volume depletion (1)[B]
  - Maintain cardiac output and oxygenation with vasopressors and blood transfusions as needed (1)[C]
- Intrinsic renal
  - Careful dosing and therapeutic drug level monitoring of aminoglycosides or avoidance altogether
  - Use lipid formulation of amphotericin B or another antifungal alternative
  - Contrast-induced AKI
    - Avoid the use of contrast
    - Use either iso- or low-osmolar iodinated contrast media
    - Intravenous fluid expansion for those patients at risk
  - Avoid NSAIDs
  - Animal models have shown the potential benefit of vasodilators, growth factors, antioxidants, and anti-inflammatory drugs in preventing AKI
- A single dose of theophylline given to neonates with severe perinatal asphyxia has been shown to significantly reduce the risk of AKI

DIAGNOSIS

HISTORY

- Evaluate for shock, sepsis, bleeding, dehydration, gastrointestinal losses
- Assess recent medication exposure, including natural products
- History of urologic surgery, anatomic problems, or kidney transplantation
- Family history of ESRD, HUS
- Recent trauma, crush injury
- Seek signs of CKD, such as growth delay
- Review recent blood tests to determine baseline serum creatinine (SCr) and onset of AKI

PHYSICAL EXAM

- Assess hydration status, blood pressure, heart rate, and temperature
- Lungs for rales
- Abdomen for masses

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- SCr and blood urea nitrogen will be elevated
- May have hyperkalemia, acidosis
- Hemoglobin will be low if bleeding
- HUS causes thrombocytopenia, increased lactate dehydrogenase
- When muscular damage is the cause creatinine kinase will be elevated and urinary myoglobin will be positive
- Urinalysis to detect red blood cells, proteinuria
- Urine eosinophils indicate interstitial nephritis
- Strict UOP monitoring to assess AKI stage and progression
- Atypical-AKI
  - Clinical AKI fails to meet the definition
    - SCr falsely lowered by dilution due to large volume fluid resuscitation or transfusions, thereby reflecting the blood donors' kidney function
    - SCr falsely lowered by muscle wasting or reduced muscle mass due to quadriplegia, cerebral palsy, or other neuromuscular disorders
    - SCr falsely lowered during sepsis by decreased muscle perfusion
- Real-time markers of AKI are being sought
  - Candidates include serum cystatin C, kidney injury molecule-1, interleukin-18, liver fatty acid–binding protein, neutrophil gelatinase-associated lipocalin

Imaging

- Renal ultrasound with Doppler analysis of the renal artery and veins
  - Hydronephrosis indicates obstruction
  - Increased echogenicity consistent with medical renal disease
  - Thrombosis of renal artery or vein
  - Small echogenic kidneys, cystic kidneys indicate CKD
- Bladder ultrasound
  - Trabeculated, thick-walled bladder may indicate lower urinary tract abnormality such as a neurogenic bladder or obstruction

- Technetium-99m MAG3 renal scan can be used in prolonged AKI to differentiate prolonged ATN from permanent cortical necrosis

Diagnostic Procedures/Surgery

Kidney biopsy rarely necessary but may be indicated to diagnosis prolonged AKI without a clear etiology

Pathologic Findings

Kidney biopsy may reveal ATN, interstitial disease, thrombotic microangiopathy, medication-induced crystal formation, glomerulonephritis

DIFFERENTIAL DIAGNOSIS

- Prerenal
  - Intravascular volume depletion
    - Dehydration, hemorrhage, gastrointestinal losses, burns, pancreatitis, peritonitis
    - Congestive heart failure, sequestration in interstitial spaces, shock, anaphylaxis
- Intrinsic renal
  - ATN, hypoxic/ischemic insults, sepsis/toxin mediated, multiple organ dysfunction syndrome, interstitial nephritis, tumor lysis syndrome, glomerulonephritis, vascular thrombosis, cortical necrosis, HUS, cortical dysplasia or hypoplasia, rhabdomyolysis
  - Potentially nephrotoxic agents such as aminoglycoside antibiotics, NSAIDs, radio-opaque contrast, antivirals, antifungals, chemotherapeutic agents
  - Chinese herb nephropathy is an acute to chronic interstitial fibrosis caused by Aristolochia fangchi, an herb still available in natural products ordered online
- Postrenal
  - Obstruction in the ureter(s) or urethra
  - Bilateral nephrolithiasis due to cystinuria has been reported as a cause of pediatric AKI
- Pseudo-AKI
  - Always interpret lab data in clinical context to avoid overdiagnosis of AKI
    - Endogenous chromogens (eg, bilirubin, ascorbic acid, uric acid) and exogenous chromogens (eg, cephalosporins, trimethoprim, cimetidine) may interfere with the creatinine assay and cause falsely elevated results
    - Weight-based determination of UOP may falsely cause the obese patient to fulfill the criteria without actual AKI

TREATMENT

GENERAL MEASURES

- Reduce risk of dehydration or fluid overload by only replacing calculated insensible fluid losses and measured UOP
  - Intravenous fluid should have no potassium
- Maintain renal perfusion and oxygenation (1)[C]
  - Renal dilators (dopamine, fenoldopam) have not been shown to improve pediatric AKI
  - No studies relating fluid type used in pediatric resuscitation on AKI incidence or outcome
- Continuous renal replacement therapy (CRRT) has not been shown to improve kidney function or mortality, although there is controversy about the timing of initiation, dose,

route, and duration (1)[C]
- Hemodialysis or peritoneal dialysis may play a role in supportive care of the patient with AKI
- Discontinue potentially nephrotoxic drugs
- Medications with renal clearance require dosing/timing adjustments/drug level monitoring, when available, to reduce the risk of toxicity
- Nutritional research is limited to observational studies
  – Critically ill children should receive 100–130% of their basal energy needs

MEDICATION

First Line

- Diuretics to convert oliguric AKI to nonoliguric AKI have not been shown to affect outcomes (1)[C]
- IV sodium bicarbonate has been administered to correct the acidosis of AKI but has not been studied with randomized controlled trials
- Emerging treatments include apoptosis inhibitors, iron chelators, anti-inflammatory agents, repair agents (eg, stem cells)

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Central venous access may be needed for renal replacement therapy (CRRT or hemodialysis)
- Postrenal AKI may require decompression surgery, nephrostomy tube, or ureteral stent
- Nephrolithiasis may respond to extracorporeal shock wave lithotripsy, endoscopic surgery, or surgery (open, laparoscopic, robotically assisted)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- With multisystem organ failure the addition of AKI increases mortality from 10–57%
- A 3–5-yr follow-up study after resolution of AKI showed that 40–50% of pediatric patients showed signs of CKD (3)

COMPLICATIONS

- Hyperkalemia, fluid overload, pulmonary edema, hypertension, acidosis, reduced drug excretion, and uremic symptoms
  – Overcorrection of any of the above
- Nephrogenic systemic fibrosis (NSF) is a rare but potentially lethal fibrosing disorder of the

skin, liver, heart, lungs, diaphragm, and skelet al muscle observed in patients with AKI or CKD who were exposed to gadolinium used in MRI (4)
  – 335 cases in the NSF International Registry at the time of writing; some were children
  – Gadolinium should be avoided in AKI
- Patients exposed to the Aristolochia fangchi herb are at increased risk for urothelial malignancies

FOLLOW-UP

Patient Monitoring

Monitor SCr, blood pressure, somatic growth, urinalysis for signs of CKD after resolution of AKI

- N17.9 Acute kidney failure, unspecified

CLINICAL/SURGICAL PEARLS

- AKI is often multifactorial.
- Seek prerenal, intrinsic renal, and postrenal causes of the AKI.
- Stage AKI with pRIFLE criteria.
- Avoid potentially nephrotoxic drugs and gadolinium during AKI.

ACUTE SCROTUM

Patrick T. Gomella, MD, MPH
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION

- Acute pain and swelling in the scrotum is typically related to testicular pathology and is usually referred to as "acute scrotum" in the absence of obvious trauma.
- Occasionally pain from ureteral colic can be referred to the testicle but swelling is usually absent.
- Chronic testicular pain is referred to orchalgia.
- Testicular torsion is a major cause of the acute scrotum particularly in children and requires timely diagnosis and treatment to avoid testicular loss.
- In adults acute epididymo-orchitis is the most common cause of an acute scrotum.
- In children torsion of a testicular appendix or testicle are most common causes.

EPIDEMIOLOGY

Incidence

- Testicular torsion occurs most commonly in neonates and postpubertal boys and is more common on the left
  - However in 1 series 39% of patients were reported to be in men >21 yr of age (1)
- Torsion of an appendix more common in prepubertal boys
- Approximately 600,000 cases of epididymitis/yr in US

Prevalence

Testicular torsion: 1:4,000 males <25 yr old

RISK FACTORS

- Testicular torsion
  - Cryptorchidism
  - Bell clapper deformity
- Epididymitis
  - Unprotected sex in younger men
  - Prostate disorders in older men
  - Urinary tract instrumentation
  - Anal insertive intercourse

Genetics

Testicular torsion reported in 10% of family members; may be autosomal or X-linked recessive; no specific genetic defects identified

PATHOPHYSIOLOGY

- Testicular torsion can be either intravaginal or extravaginal
  - Intravaginal testicular torsion is twisting of the spermatic cord *within* the tunica vaginalis
    - Usually due to a so-called "bell clapper deformity": A failure of normal posterior

anchoring of the gubernaculum, epididymis and testis. Leaves the testis free to rotate within the tunica vaginalis of the scrotum much like the clapper inside of a bell (present in 12% of males)
  - Extravaginal testicular torsion is twisting of both the spermatic cord *and* tunica vaginalis
- Perinatal: Extravaginal testicular torsion is usually the cause
- Appendix torsion is a result of vascular compromise may be related to pedunculated anatomy of the appendage
  - Appendix testis 95% of appendix torsions
  - Appendix epididymis torsion is less common
- Epididymitis
  - Can present as acute or chronic epididymitis
    - Acute: Severe swelling, tenderness, rigors, high fevers
  - Infectious causes
    - In men >35 yr of age, *Chlamydia trachomatis* and *Neisseria gonorrhoeae* (sexually transmitted infections) are the most common pathogens
    - In men >35 yr of age coliforms most common
    - Less common pathogens: Ureaplasma, TB, Brucella species; with HIV infection, Cytomegalovirus and Cryptococcus
  - Less frequent causes include autoimmune diseases, vasculitis, trauma
  - In a prepubertal boy epididymitis is almost always associated with a urinary tract anomaly

ASSOCIATED CONDITIONS

- Torsion
  - Bell clapper deformity: 10–15% of males
  - Cryptorchidism
- Epididymitis
  - Other sexually transmitted infections
  - Prostatic hypertrophy

GENERAL PREVENTION

- Torsion: Reduce testicular loss risk by
  - Early diagnosis and treatment
  - Community awareness about testis pain
  - Elective bilateral orchidopexy for intermittent pain or contralateral orchidopexy at surgery for an episode of acute torsion
- Epididymitis
  - Safe sex practices

DIAGNOSIS

HISTORY

- Rule out any traumatic insult to the groin area
  - Some patients report minor trauma before presentation of torsion
- Sexual practice history
- Recent urinary tract instrumentation
- Testicular torsion

- The classic presentation is sudden hemiscrotal pain often awakening the patient from sleep
- Pain can radiate to the groin
- Nausea and/or vomiting can be present
- Movement tends to worsen the pain
- A history of intermittent testicular discomfort may be present suggesting past torsion and detorsion

• Appendix torsion
- Symptoms are similar to testicular torsion but not as severe

• Epididymitis
- Can present with acute: Fever, chills, rigors, or as chronic testicular/scrotal discomfort
- More likely to be associated with voiding complaints than torsion

PHYSICAL EXAM

• General
- Vital signs; low-grade fever with torsion, fever with UTI
- Presence of inguinal hernia
- Abdominal and flank tenderness

• GU exam
- Assess cremasteric reflex (2):
  - Stroke or pinch the skin of the upper thigh
  - Normal reflex is contraction of the cremaster muscle with elevation of the testis.
  - Absent reflex may aid in distinguishing testicular torsion from epididymitis/other causes of an acute scrotum where reflex is present
  - Phren sign (pain relief with elevation of testicle) is no longer considered accurate for diagnosis of torsion

• Testicular torsion
- Testicle may be high riding
- Very tender and may assume a transverse lie due to twisting of the cord
- The spermatic cord will not usually be palpable
- May be scrotal wall erythema and swelling
- Cremasteric reflex often absent

• Torsion appendix
- Pain may be localized to upper pole of testicle
- Cremasteric reflex usually present
- Blue dot sign: Rare, more likely in prepubertal boys;
  - Tender nodule with blue discoloration on the upper pole of the testis and more easily seen in light-skinned individuals
- In late findings scrotal swelling and reactive hydrocele may be present

• Epididymitis
- Cremasteric reflex usually present
- Acute epididymitis may have significant swelling and tenderness; with chronic epididymitis there is tenderness but usually no scrotal swelling

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis
  - White cells and positive leukocyte esterase
    - Suspect epididymitis or UTI
  - Red blood cells suggest renal or ureteral source of pain (eg, stone)
  - In cases of torsion UA usually negative
- Urine culture if epididymitis or UTI suspected
- Consider urethral swab if urethral discharge present: Culture and nucleic acid amplification testing for chlamydia and gonorrhea

Imaging

- Scrotal US with Doppler
  - Intravaginal testicular torsion findings
  - Usually shows decreased or absent arterial flow but may be normal
- Appendix torsion findings
  - Normal exam most common
  - Supratesticular complex mass without vascular flow may be present
- Epididymitis
  - Enlarged epididymis reported as “epididymitis” often present
  - Doppler flow normal or increased

Diagnostic Procedures/Surgery

In cases of testicular torsion, surgical exploration is usually diagnostic and therapeutic

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Abscess or other infection such as Fournier gangrene
- Appendix torsion (appendix testis or epididymis testis)
  - Most commonly seen in prepubertal boys
  - Most common cause of acute scrotum in this age group
- Epididymitis due to UTI or STD: Rare or uncommon in pediatric age group; more likely in adult
- Fat necrosis of scrotal wall
- Henoch–Schönlein purpura
  - Rash usually present
- Incarcerated inguinal hernia
- Orchitis: With the exception of mumps orchitis, isolated orchitis without epididymitis in adults is rare
- Referred pain: Urolithiasis or intra-abdominal process such as appendicitis
- Testicular infarction due to spermatic cord injury or thrombosis
- Testicular torsion: Most common in peripubertal boys but can occur at any age; less common than appendix torsion
- Testicular tumor: Usually painless but may have tenderness with trauma
- Trauma and possible testicular rupture: History suggestive; hematocele usually present
- Orchalgia; consider voiding dysfunction

TREATMENT

ALERT
Testicular torsion is a surgical emergency because the likelihood of testicular salvage diminishes with the duration of torsion.

GENERAL MEASURES

- Clinical history, exam, and diagnostic studies (urinalysis, Color Doppler Ultrasound) have a high degree of accuracy in making the diagnosis
- Emergent exploration indicated if evaluation suggests intravaginal testicular torsion or diagnosis is equivocal
- If torsion is present and surgery cannot be performed in a reasonable amount of time, manual detorsion should be considered
- Most cases of epididymitis can be treated on an outpatient basis

MEDICATION

First Line

- Epididymitis: Acute
  - Ice, scrotal elevation, and NSAIDs with antipyretic for high temperature
  - Younger male: Ceftriaxone (250 mg IM) with doxycycline (100 mg PO BID × 10 days).
  - Older males: Ceftriaxone (250 mg IM) along with a 10-day course of fluoroquinolone for enteric organisms (ofloxacin 300 mg PO BID or levofloxacin (500 mg PO BID)
- Epididymitis: Chronic
  - Scrotal elevation, avoid sexual and athletic activity, warm baths, and NSAIDs
- Appendix torsion: Ibuprofen to reduce inflammation and discomfort
- Testis torsion: Pain control may require opioids

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Urgent scrotal exploration, bilateral fixation for extravaginal testicular torsion to avoid asynchronous contralateral torsion
- Manual detorsion: Use only if surgery is delayed >2 hr
  - Testicle most often rotates medially during torsion
  - Manual detorsion is accomplished by attempting to rotate the testicle laterally toward the thigh
  - The twisting can range from 180–720 degrees such that multiple detorsion twists may be required
  - However in up to 1/3 of cases, the torsion rotation can be lateral
  - Successful detorsion still requires operative intervention and orchidopexy
  - Hallmarks of successful manual detorsion include pain relief, testicle assuming a lower position in the scrotum, reorientation of the testicle from transverse lie to vertical positioning, restoration of Doppler blood flow

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- In cases of testicular torsion 12 hr is considered the point at which the testis suffers irreversible damage
- Torsion surgery outcomes appear better in children than in adults
  - Salvage rates in males <21 yr was 70% vs. those >21 yr who had a salvage rate of 41% (3)
    - Potential explanations: Time to presentation impacted salvage and patients over 21 yr of age had a greater degree of cord twisting than the younger patients

COMPLICATIONS
- Testicular torsion
  - Testicular loss and or atrophy
  - Infertility
- Appendix testis/epididymis torsion
  - Usually none long term
- Epididymitis
  - Scrotal abscess
  - Urosepsis
  - Chronic orchalgia

FOLLOW-UP
Patient Monitoring
Epididymitis due to culture-proven *C. trachomatis* or *N. gonorrhoeae*: refer sex partners for evaluation and treatment disease

Patient Resources

CODES

ICD9

- 604.90 Orchitis and epididymitis, unspecified
- 608.9 Unspecified disorder of male genital organs
- 608.20 Torsion of testis, unspecified

ICD10

- N44.00 Torsion of testis, unspecified
- N45.3 Epididymo-orchitis
- N50.9 Disorder of male genital organs, unspecified

CLINICAL/SURGICAL PEARLS

- Color Doppler ultrasonography is the preferred imaging technique for evaluating the acute scrotum.
- Cremasteric reflex is usually absent in testicular torsion.

ACUTE TUBULAR NECROSIS

Costas D. Lallas, MD, FACS

BASICS

DESCRIPTION

- Acute tubular necrosis is the most common type of intrarenal acute renal injury (AKI)
  - Usually due to prolonged ischemia or administration of nephrotoxins
- A syndrome of intrinsic renal failure secondary to ischemic or toxic insults
- Histopathologic findings of ATN variable
- Decreased urine output:
  - Can be nonoliguric, oliguric >500 mL/d, or anuric. Mortality increases from 20–60% to 80% if the patient is oliguric or anuric.
- Signs of underlying disorder:
  - Signs of sepsis or of hypotensive events secondary to trauma, cardiac disease, surgery with excessive blood loss, or interruption of blood supply to kidneys

EPIDEMIOLOGY

Incidence

- ARF is present in 209 per million population.
- ARF may affect 2–5% of patients in a tertiary care hospital, and the incidence of ARF in the surgical or medical ICU may exceed 20–30%
- Breakdown of ARF: ATN, 45%; prerenal causes, 21%; acute or chronic renal failure, 13%; urinary tract obstruction, 10%; glomerulonephritis or vasculitis, 4%; acute interstitial nephritis, 2%; atheroembolism, 1%

RISK FACTORS

- Decreased renal perfusion from:
  - Prolonged hypotension, surgical interruption of blood flow, NSAIDs, ACE inhibitors, cyclosporine
- Nephrotoxic agents:
  - Radiocontrast media (low osmolality is possibly safer), aminoglycosides, cisplatin, amphotericin, drug intoxications with acetaminophen or ethylene glycol
  - The most commonly seen nephrotoxins in the hospitalized patient include radiographic contrast material, antibiotics (especially aminoglycosides and amphotericin B), chemotherapeutic agents, NSAIDs, and ACE inhibitors

Genetics

N/A

PATHOPHYSIOLOGY (1)

- Acute tubular injury
- Renal hypoperfusion and renal ischemia are the most common causes of ATN
- The ischemic form is due to the reductions in glomerular filtration rate (GFR) are secondary to vascular and tubular factors

  - Ischemia from reductions in GFR from decreased renal plasma flow or dilatation of the efferent arteriole. After return of normal blood flow, ATN persists secondary to tubular changes
  - In addition, both exogenous and endogenous nephrotoxic compounds exist.
- Tubular factors: Backleak and tubular obstruction. Tubular obstruction secondary to a sloughed brush border, cellular debris, Tamm–Horsfall protein, and decreased filtration pressure contribute to obstruction and maintenance of ATN

ASSOCIATED CONDITIONS
- Sepsis
- Hemorrhage (operative, obstetric, trauma)
- Pre-existing renal insufficiency (diabetes, hypertension)
- Edematous states such as CHF

GENERAL PREVENTION
- Avoid prolonged renal ischemia by timely management of hemorrhage, dehydration and other causes of renal hypoperfusion
- Avoidance of contrast agents in the setting of renal insufficiency (contrast-induced nephropathy)
- Appropriate management of potentially nephrotoxic medications

DIAGNOSIS
HISTORY
- Specific attention to:
  - Hypotensive episodes, blood transfusions, intravenous contrast exposure
- Meticulous listing of medications to include dosage to assure appropriate dosing for level of renal function
- Make sure other medications which depend on renal metabolism are also given at appropriate doses to avoid side effects

PHYSICAL EXAM
- Vital signs and hemodynamic parameters should be critically assessed.
- A patient's weight is helpful information, and its daily measurement is important in the diagnosis and management of ARF.
- Evaluate the volume status of the patient.
- Evaluate neck veins and auscultation of heart and lungs; assess extremities and the presacral area for edema.
- General exam
- Evaluate for bladder distention and assess for signs of vasculitis or cutaneous rashes.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum tests (2)
  - BUN/plasma creatinine ratio: The ratio is normal at 10 to 15:1 in ATN, but >20:1 in prerenal disease due to the increase in passive reabsorption of urea, the ratio may also be increased with GI bleed, muscle breakdown, and administration of corticosteroids or

tetracycline
  - Rate of rise of plasma creatinine: Rise of >0.3–0.5 mg/dL in ATN vs. slower rise with fluctuations with prerenal disease
- Urine tests
  - Urinalysis: Muddy brown granular and epithelial cell casts and free epithelial cells secondary to sloughing of the tubular epithelium vs. near-normal in prerenal disease
  - The classic sediment of ATN includes pigmented (muddy brown) granular casts and renal tubular epithelial cells, which may be seen in nearly 80% of cases of oliguric ARF
  - Urine sodium concentration: High >40 mEq/L due to tubular injury vs. <20 mEq/L in prerenal disease in an attempt to conserve sodium
  - Fractional excretion of sodium (FENa): Above 2% in ATN while <1% in prerenal disease, measured as urine Na divided by plasma Na times plasma CR divided by urine CR, although causes of ATN associated with a low FENa are that due to intravenous contrast material, rhabdomyolysis, sepsis, and multisystem organ failure
  - Urine osmolality: Urine osmolality <450 mOsm/kg in ATN secondary to loss of concentrating ability; >500 mOsm/kg in prerenal disease
- Urine creatinine concentration divided by plasma creatinine concentration: Ratio is <20 in ATN while >40 in prerenal disease, reflecting loss of tubular water reabsorption

Imaging
- Renal ultrasonography
  - Sensitive test to determine obstruction. Doppler can detect gross blood flow in renal vein and artery
- Plain abdominal film
  - Identifies the presence or location of renal calculi and is particularly helpful to discern the proper position of stents and drains
- Functional studies
  - Nuclear scans can determine perfusion or tubular secretion; MRI can give some functional information while providing anatomic information

Diagnostic Procedures/Surgery
N/A

Pathologic Findings
- Tubule cell injury (2):
  - Tubular epithelial cells are particularly sensitive to ischemia and are also vulnerable to toxins. The structural changes include those of reversible injury (such as cellular swelling, loss of brush border and polarity, blebbing, and cell detachment) and those associated with lethal injury (necrosis and apoptosis)
- Disturbances in blood flow:
  - Intrarenal vasoconstriction results in both reduced glomerular blood flow and reduced oxygen delivery to the functionally important tubules in the outer medulla (thick ascending limb and straight segment of the proximal tubule)

DIFFERENTIAL DIAGNOSIS
- Prerenal azotemia
- Postrenal azotemia

- Other forms of renal azotemia
- Glomerulonephritis, disseminated intravascular coagulopathy, arterial or venous obstruction, intrarenal precipitation

TREATMENT

GENERAL MEASURES

- Define and treat the underlying cause.
- Discontinue any nephrotoxic agents.
- Prophylaxis and treatment of complications of ARF.
- Early nephrology consultation.
- Management of fluid disturbances.
- Maintain a euvolemic state by restricting total fluids to no more than urine output plus insensible losses.

MEDICATION

First Line

- High-dose loop diuretics (1–3 g/d) may convert oliguric to nonoliguric ATN in some patients; it has not been determined that this conversion decreases the duration of ATN or mortality. Dopamine may increase urine output, but its benefit is in question.
  - Studies suggest that patients who respond to mannitol, furosemide, or dopamine with an increased urine output have better outcomes than nonresponders.
- Management of electrolyte disturbances
  - Electrolyte disturbances can be minimized by prophylactic institution of a low-potassium, low-protein diet accompanied by fluid restriction and oral phosphate binders.
- Hyperkalemia is the most common and most dangerous abnormality and should be treated aggressively with calcium supplementation until potassium levels can be reduced with combinations of insulin and glucose or potassium-binding resins.

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Hemodialysis (HD), peritoneal dialysis (PD), and continuous arteriovenous hemofiltration (CAVH)
  - CAVH: Need ICU, limited mobility, need anticoagulation, removes fluid well but slow correction of electrolyte abnormalities
  - PD: No anticoagulation needed but slower correction of electrolyte abnormalities
  - HD: Expensive, anticoagulation necessary, vascular access necessary but allow rapid correction of fluid and electrolyte abnormalities

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Slight improvements in survival in those patients with ATN requiring dialysis in an ICU setting
  - The Mayo Clinic compared 1977–1979 with 1991–1992 showed high survival both in hospital (52% vs. 32%) and at 1 yr (30% vs. 21%)
  - Higher mortality rates are seen in elderly patients and in patients with respiratory failure, multiple organ failure, pre-existing chronic diseases, and systemic hypotension
- Major causes of death are infection and underlying disease, not renal failure
  - Patients at risk are generally very ill, with evidence of multiple organ dysfunction
- Of patients who survive ATN, nearly half will have a complete recovery of renal function and a majority of the remainder have an incomplete recovery. Only about 5% of all ARF patients require chronic maintenance dialysis

COMPLICATIONS
- Fluid overload, electrolyte disturbances, metabolic acidosis
  - Hypertension, edema, acute pulmonary edema, hyponatremia, hyperkalemia, hypermagnesemia, hypercalcemia, hyperphosphatemia, hyperuricemia
  - Uremic signs and symptoms
- GI: Nausea, vomiting, GI bleed; neurologic: Encephalopathy, coma, seizures, peripheral neuropathy; cardiac: Pericarditis uremic pneumonitis; hematologic: Bleeding, anemia; immunologic: Impaired granulocyte/lymphocyte function

FOLLOW-UP
Patient Monitoring
- Duration
  - Renal failure phase usually lasts 7–21 days if the primary insult (ischemia, nephrotoxin) can be corrected. Recovery is usually heralded by a progressive increase in urine output and a return of BUN and CR to the previous baseline.
- Recovery of renal function
  - Irreversible loss of renal function can occur if the combination of pre-existing renal disease and prolonged ARF secondary to repeat ischemic insults and/or nephrotoxin administration
  - If the patient survives, baseline CR is usually only 1–2 mg/dL above baseline.
- Those patients that need dialysis and have bioincompatibility with the dialysis membrane or have repeat episodes of hypotension have a worse prognosis.

ADDISON DISEASE

Shaun G.S. Grewal, MD
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION

- Primary adrenal insufficiency
- Inadequate production of glucocorticoid and mineralocorticoid
  - Differentiated from secondary (pituitary) and tertiary (hypothalamic) causes of adrenal causes of adrenocorticoid insufficiency in which mineralocorticoids are normally spared

ALERT

Acute adrenal insufficiency (Addisonian crisis):

- Life-threatening hypotensive shock.
- Most common cause is acute withdrawal of chronic steroid.
- Acute stress (ie, surgery) without an adequate stress dose of steroids.

EPIDEMIOLOGY

Incidence

- 4.7–6.2 per million in Western populations (1)
- Females more frequently affected than males
  - TB most common cause in underdeveloped nations
  - Autoimmune disorders most common cause in developed nations (90%)

Prevalence

- 93–140 per million (1)
  - Mortality 0.3 per 100,000

RISK FACTORS

- Tuberculosis
- Autoimmune disease
- AIDS
- Immunosuppression
- Bilateral adrenal hemorrhage
- Bilateral adrenalectomy
- Drug induced
  - Mitotane, aminoglutethimide, etomidate, ketoconazole, suramin, mifepristone

Genetics

- 40% of patients with a 1st-/2nd-degree relative with an associated disorder
- Isolated autoimmune adrenalitis
  - HLA-DR3, CTLA 4
- APS type 1
  - Adrenal insufficiency, hypoparathyroidism, chronic mucocutaneous candidiasis
  - AIRE gene (21q22)

- APS type 2
  - Adrenal insufficiency, Thyroid disease, Type I DM
  - HLA-DR3, CTLA-4
- APS type 4
  - Other autoimmune diseases
- Congenital adrenal hyperplasia
  - 21β-hydroxylase (CYP21 mutation)
  - 11β-hydroxylase (CYP 11B1 mutation)
  - 17∂-hydroxylase (CYP17 mutation)
- Adrenoleukodystrophy (ALD)
  - Demyelination of CNS
- Triple A syndrome (Allgrove)
  - Alacrima, achalasia, neurologic impairment

PATHOPHYSIOLOGY

- Autoimmune disorders are the most common cause in developed nations (80–90%)
- Partial or complete T-cell mediated destruction of adrenal cells
  - 90% of adrenal gland must be destroyed to cause insufficiency
  - Decreased production of cortisol, aldosterone, and adrenal androgens
  - Hypovolemia and prerenal azotemia cause orthostatic hypotension, dizziness, and lethargy
  - Adrenal crisis mostly attributable to mineralocorticoid deficiency
  - Pituitary compensation with increased ACTH
  - ACTH and proopiomelanocortin-related peptides stimulate melanocytes causing hyperpigmentation
- Adrenal dysgenesis or hypoplasia
  - AHC or Triple A syndrome
- Adrenal destruction
  - APS1, APS2, APS4, ALD
  - Infectious
    - TB, HIV, CMV, histoplasmosis, cryptococcus, coccidioidomycosis
  - Adrenal hemorrhage
    - Sepsis
    - Disseminated intravascular coagulation
    - Anticoagulant therapy
  - Bilateral adrenalectomy
- Adrenal infiltration
  - Adrenal metastasis, primary adrenallymphoma, sarcoidosis, amyloidosis, hemochromatosis
- CAH (see Genetics)

ASSOCIATED CONDITIONS

- Autoimmune endocrine disorders
- Thyroid disorder (17%)
- Diabetes mellitus (12%)
- Gonadal dysfunction (12%)

GENERAL PREVENTION

No general prevention guidelines exist for prevention of primary hypoaldosteronism.

DIAGNOSIS

HISTORY

- Vague symptoms; requires high index of suspicion
  - Fatigue, weight loss, anorexia, vomiting, GI complaints, abdominal pain, diarrhea, muscle aches, salt craving, hypotension, behavioral changes, headaches, sweating, depression, decreased libido, lethargy
  - Acute adrenal insufficiency: Life-threatening hypotension, acute abdominal pain, vomiting, fevers

PHYSICAL EXAM

- Vitals: Orthostatic hypotension
- Weight loss
- Hyperpigmentation
- Pigmented buccal mucosa and nail beds
- Loss of axillary and pubic hair
- Vitiligo
- Goiter

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Electrolyte disturbances
  - Classic triad: Hyponatremia, hyperkalemia, azotemia
  - Hypercalcemia
  - Lymphocytosis
  - Hypoglycemia
  - Metabolic acidosis
- Screening test
  - Measure cortisol, ACTH
    - Low cortisol (< 165 nmol/L)
    - Elevated ACTH (> 45 pmol/L)
- Confirmation of abnormal screening test
  - Short corticotropin test
    - 250 μg ACTH
    - Serum cortisol at 0, 30, and 60 min
    - Peak cortisol < 550 nmol/L diagnostic (2)

Imaging

- Routine imaging not recommended in cases of definite autoimmune adrenalitis
- CT or MRI in cases of suspected infection, malignancy, infiltration, hemorrhage
- Calcifications present in up to 50% with TB

Diagnostic Procedures/Surgery

No specific diagnostic procedures

Pathologic Findings

Atrophic adrenals in autoimmune adrenalitis

DIFFERENTIAL DIAGNOSIS
- Primary adrenal insufficiency (Addison disease)
- Secondary adrenal insufficiency (pituitary failure)
  - No hyperpigmentation (lack of ACTH elevation)
  - Etiologies include chronic steroids, panhypopituitarism, Sheehan syndrome (postpartum necrosis), brain trauma, pituitary apoplexy, pituitary surgery
- Tertiary adrenocortical insufficiency

TREATMENT

GENERAL MEASURES
- Acute adrenal insufficiency (addisonian crisis)
  - 5 S's:
    - Salt
    - Sugar
    - Steroids
    - Support
    - Search for precipitating cause

MEDICATION
First Line
- Corticosteroid replacement:
  - Hydrocortisone 15–25 mg/d
    - BID dosing: 20 mg, 10 mg
    - TID dosing: 10 mg, 5 mg, 5 mg
    - Monitor body weight and signs/symptoms of over/under replacement
- Mineralocorticoid replacement:
  - Fludrocortisone 0.05–0.20 mg/d
  - Monitor blood pressure, peripheral edema, serum sodium, and potassium
- Major stress: Surgery, trauma, sepsis:
  - IV hydrocortisone 100–300 mg/d (TID dosing) then taper
- Minor stress
  - Increase steroid dose 2–3-fold then taper over several days

Second Line
- Dehydroepiandrosterone (DHEA) replacement
  - 25–50 mg/d
  - Impacts mood/feeling of well-being (3)

SURGERY/OTHER PROCEDURES
Stress dose steroids: 25–150 mg hydrocortisone or 5–30 mg methylprednisolone IV day of the procedure in addition to maintenance therapy; taper to the usual dose over 1–2 days.

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies

- Salt loading prior to major stress recommended by some
- Future advances using long-acting hydrocortisone preparations to better mimic physiologic state

Complementary & Alternative Therapies

No established alternative therapies

ONGOING CARE

PROGNOSIS

- Adrenal crisis may be lethal.
- Recommended dosages for glucocorticoid and mineralocorticoid replacement rarely cause significant side effects; close monitoring is essential to prevent excess treatment.

COMPLICATIONS

- Side effects of excess steroid replacement:
  - Weight gain, high BP, hyperglycemia, growth retardation, bruising, cardiovascular risks, gastric ulcers, poor wound healing, skin striae, osteoporosis
- Side effects of excess mineralocorticoid:
  - Hypertension, bradycardia, hypernatremia, congestive heart failure, suppressed renin levels, growth retardation
- Acute withdrawal of chronic steroid replacement may precipitate acute adrenal crisis
- Must rule out or treat glucocorticoid deficiency prior to initiation of thyroxine for hypothyroidism, as this may precipitate adrenal crisis.

FOLLOW-UP

Patient Monitoring

- Medic-alert bracelet to be worn at all times
- Instruct patients on proper use of emergency hydrocortisone injections
- Monitor for signs of appropriate glucocorticoid and mineralocorticoid replacement

Patient Resources

- Addison Disease (Adrenocortical Insufficiency) Algorithm

• Waterhouse–Friderichsen Syndrome

CODES

ICD9

255.41 Glucocorticoid deficiency

ICD10

E27.1 Primary adrenocortical insufficiency

CLINICAL/SURGICAL PEARLS

• Addisonian crisis: Is acute, life-threatening shock.
• 5 S's for treatment of addisonian crisis
  – Salt; Sugar; Steroids; Support; Search for precipitating cause.
• Classic triad: Hyponatremia, Hyperkalemia, Azotemia.
• Use "stress dose" steroids for patients with Addison disease undergoing surgical procedures.

ADENOMATOID TUMORS, TESTICULAR AND PARATESTICULAR

Ramiro J. Madden-Fuentes, MD
Judd W. Moul, MD, FACS

BASICS

DESCRIPTION
- Adenomatoid tumors are benign lesions of the male testicular adnexa.
- Usually ~1 cm in size (range 0.5–7.5 cm) (1)[C]
- Most often asymptomatic
- Mesenchymal origin (2)[C]

EPIDEMIOLOGY
Incidence
- The majority of patients present within the 3rd–5th decades of life (3)[C].
- Adenomatoid tumors are the most common neoplastic processes involving the testicular adnexal and spermatic cord structures (3)[C].
- Adenomatoid tumors in females occur in uterus > fallopian tubes > ovary (1)[C].

Prevalence
Not well defined

RISK FACTORS
None described

Genetics
N/A

PATHOPHYSIOLOGY
- Mesothelial origin is most accepted theory (3)[C]
- Benign with no reported cases of metastasis
- Capable of local invasion
- Epididymis, tunica vaginalis, spermatic cord are most common sites

ASSOCIATED CONDITIONS
N/A

GENERAL PREVENTION
- Routine self-exam for identification of scrotal content masses
- Routine genital exam by physician

DIAGNOSIS

HISTORY
- Duration of lesion and size
- Interval growth

- Associated pain, dysuria, tenderness – epididymitis
- Prior malignancy or scrotal pathology
- Exposure to tuberculosis (TB)
- History of sarcoidosis, histoplasmosis
- History of urinary tract infection or sexually transmitted infection
- Recent GU manipulation – bacillus Calmette–Guérin (BCG) instillation

PHYSICAL EXAM

- Scrotal exam
  - Identify location of mass – single or multiple
  - Evaluate for varicocele or hydrocele
  - Compare with contralateral scrotal contents
  - Evaluate if fixed, mobile, indurated, or encroaching on other structures
  - Evaluate for spermatic cord involvement
  - Transillumination – to identify if fluid filled (spermatocele, hydrocele)
- Inguinal exam
  - Evaluate for lymphadenopathy
  - Hernia

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Tumor markers if concern for testicular mass – α-fetoprotein (AFP),
- β-human chorionic gonadotropin (β-HCG)
- Lactate dehydrogenase (LDH)
  - Purified protein derivative (PPD) if TB suspected
  - No specific labs to diagnose adenomatoid tumors

Imaging

- Scrotal ultrasound
  - Solid vs. cystic
  - Location – testicular or paratesticular
    - If located in the tunica albuginea can grow into the testicular parenchyma and resemble a testicular malignancy
  - Vascular or avascular

Diagnostic Procedures/Surgery

- Excision via inguinal approach
- Frozen section for pathology – proceed to orchiectomy with high cord ligation if malignant

Pathologic Findings

- Gross
  - Small (1 cm), well circumscribed without fibrous capsule
  - Tan-white, homogeneous
- Microscopic
  - Adenomatoid cells within fibrous stroma
  - Occasional cystic dilation
  - Irregular, somewhat branched-appearing tubular structures appear within the tumor, a

coalescence of the cellular vacuoles, which form a false lumen (4)[C]

DIFFERENTIAL DIAGNOSIS

- Benign tumors of epididymis:
  - Leiomyoma
  - Papillary cystadenoma (associated with von Hippel–Lindau syndrome)
  - Lipomas
  - Hamartomas
  - Adrenal cortical adenomas
- Malignant tumors of the epididymis:
  - Sarcoma (rhabdomyosarcoma, leiomyosarcoma, fibrosarcoma, liposarcoma)
  - Melanotic neuroectodermal tumor of the epididymis
- Extension of primary testicular tumor
- Metastatic tumor to epididymis:
  - Urologic (prostate, kidney)
  - GI (stomach, colon, carcinoid, pancreas)
- Other lesions of the epididymis
  - Granuloma (sperm, TB, sarcoidosis)
  - Spermatocele
  - Epididymitis
  - Epidermoid inclusion cyst
  - Epididymal abscess

TREATMENT

GENERAL MEASURES

- Excision via inguinal approach – for benign lesions
- Epididymitis – consider sexually transmitted infection as source in young men and treat accordingly (see Sexually Transmitted Infections section)

MEDICATION

First Line

N/A

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Excision of suspicious lesion via inguinal approach with proximal vascular control
- Frozen section
- If positive for malignancy, radical orchiectomy
- Further surgical therapy guided by pathology but may include retroperitoneal lymph node dissection if rhabdomyosarcoma

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
Adenomatoid tumors are uniformly benign with no well-documented cases of true invasion, metastasis, or recurrence after excision (3)[C]

COMPLICATIONS
Scrotal hematoma, pain, infection

FOLLOW-UP
Patient Monitoring
- Oncologic follow-up if malignant disease
- Patient testicular self-exam

Patient Resources
http://www.aafp.org/afp/1998/0215/p685.html

CODES

ICD9

- 222.0 Benign neoplasm of testis
- 222.3 Benign neoplasm of epididymis
- 222.8 Benign neoplasm of other specified sites of male genital organs

ICD10

- D29.8 Benign neoplasm of other specified male genital organs
- D29.20 Benign neoplasm of unspecified testis
- D29.30 Benign neoplasm of unspecified epididymis

CLINICAL/SURGICAL PEARLS

- Adenomatoid tumors are benign with no reported metastasis.
- Excision via inguinal approach with proximal vascular control preferred.
- Treatment for epididymitis is guided by risk of sexually transmitted infections as a source.
- Ultrasound is important to delineate a testicular vs. paratesticular origin of the mass.

ADRENAL ADENOMA

Aaron G. Boonjindasup, MD, MPH
Raju Thomas, MD, MHA, FACS

BASICS

DESCRIPTION

- Adrenal adenoma is a benign cortical neoplasm that may or may not have endocrine activity (functioning)
- Up to 80% are nonfunctioning and benign; the other 20% need further evaluation
  - Generally <4 cm and discovered incidentally

EPIDEMIOLOGY

Incidence

$\sim$1% if <30 yr old and 7% if >70 yr old

Prevalence

- Found in 1.8–8.7% of autopsies
- Incidental adrenal masses found on 0.5–5% of abdominal CTs (82% nonfunctional, 5% Cushing, 5% pheochromocytoma, 1% Conn)
  - Usually between 20 and 60 yr old

RISK FACTORS

Slightly more common in females

Genetics

More common in multiple endocrine neoplasia (MEN) type I, Beckwith–Wiedemann syndrome, and the Carney complex

PATHOPHYSIOLOGY

- Primary hyperaldosteronism (Conn syndrome)
  - Excess production of aldosterone (Zona Glomerulosa): Hypokalemia, Alkalosis, HTN
- Cushing syndrome
  - Excess production of cortisol (Zona Fasciculata): Suppresses ACTH from pituitary

ASSOCIATED CONDITIONS

- Hypertension
- Glucose intolerance
- MEN1 syndrome
- Subclinical Cushing syndrome (SCS) (obesity, hypertension, type 2 diabetes, hypercholesterolemia)

DIAGNOSIS

HISTORY

- Determine history of hypertension, obesity, and glucose intolerance
  - Suggestive of Cushing syndrome or adrenocortical carcinoma

- Hypertension and history of hypokalemia
  - Aldosterone-producing adenoma
- History of malignancy
- Patient medications ("polypharmacy" for hypertension)
- Family history

PHYSICAL EXAM

- Blood pressure and heart rate
- Look for stigmata of Cushing syndrome
  - Hirsutism, oligomenorrhea, easy bruising, excessive acne, muscle weakness, truncal obesity, buffalo hump, purple striae

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Extent of endocrine evaluation in patients with adrenal adenoma is controversial. Basic screening evaluation consists of:
  - Basic metabolic panel (BMP)
    - If elevated K^+ and patient also hypertensive may be aldosterone-secreting lesion
  - Plasma metanephrines: Most sensitive test for pheochromocytoma
  - 24-hr urine cortisol
  - Low-dose dexamethasone suppression test to R/O SCS if suspected clinically
- Complete endocrine evaluation should be performed if findings on examination and history suggest excess of specific hormone or if positive findings found on screening examination
- Primary hyperaldosteronism (Conn syndrome)
  - Basic metabolic profile
    - Hypokalemia, alkalosis, HTN
  - Aldosterone: Renin ratio
    - Values that define a positive screen subject to lab variability but >30 suggested by NIH as cutoff for positive aldosterone to renin ratio and indicates need for confirmatory testing
  - Confirmatory testing for hyperaldosteronism
    - 3-day oral sodium-loading test—high sodium diet for 3 days followed by 24-hr urine measurements of aldosterone, sodium, and creatinine
    - + test = 24-hr aldosterone > 12 mg/d
    - Captopril suppression test may be used for patients with cardiac and renal disease which prohibit sodium loading
- Cushing syndrome
  - 24-hr urine cortisol >100 mg
  - If equivocal, perform low-dose dexamethasone suppression test
    - 1 mg dexamethasone at 11 PM
    - Plasma cortisol between 8 AM and 9 AM
    - Normal: Cortisol <5 ng/mL
    - Cushing syndrome: Inability to suppress cortisol production
  - Rule out ACTH-dependent cause (ectopic or pituitary hypersecretion of ACTH)
  - Measure late-afternoon ACTH

- – >15 pg/mL – ACTH dependent
- – <15 pg/mL – ACTH independent (adrenal)
- – Adrenal venous sampling may be indicated if bilateral adrenal lesions present to establish lateralization of aldosterone secretion in surgical candidates

ALERT

Subclinical Cushing syndrome (SCS can occur where abnormalities of the hypothalamic–pituitary–adrenal axis exists in the absence of overt signs and symptoms of Cushing syndrome.

- May occur in 5–24% of patients with incidentally discovered adrenal tumors.
- May not be clinically evident following standard screening for cortisol hypersecretion.
- 1 mg overnight dexamethasone suppression test most sensitive for SCS.
- Should be performed in ALL patients with adrenal mass and metabolic syndrome.
- SCS is an indication for adrenalectomy.
- Patients are at risk for postoperative adrenal insufficiency (AI).
- Pheochromocytoma:
  - – If screening: Stop tricyclic antidepressants, phenoxybenzamine before testing
  - – Screening tests
  - – Plasma-free metanephrines
    - Stop acetaminophen 5 days prior
    - Draw sample in supine position
  - – 24-hr fractionated urinary metanephrines
    - Verify normal renal function before testing
- See pheochromocytoma section for details.

Imaging

- Adrenal adenoma: Small, well defined, homogeneous
- Size criteria important
  - – ≤5 cm usually benign
  - – ≥6 cm – 25% malignant
- May see atrophy of contralateral adrenal
- CT (triphasic adrenal scan)
  - – CT Adenoma characteristics: Sharp margin, smooth and homogeneous, lipid rich, <10 HU density on noncontrasted images, density reduces by 60% on initial contrast density at scan delayed 15 min
  - – <10 HU on noncontrast CT
    - 71% sensitive, 98% specific for adenoma
  - – >60% washout at 15 min
    - 100% sensitive/100%specific for adenoma
  - – Adrenal myelolipoma – low HU, but never below 20 HU
- MRI
  - – Both carcinoma and pheochromocytomas are hyperintense on T2 images (ie, they “light up” as they go from T1 to T2)
  - – Signal from cortical adenomas drops out in opposed phase
    - Loss of signal between in- and out-of-phase images (microscopic fat-sensitive sequence)

suggest adenoma
  - MRI T2 intensity < 0.8 compared to liver
  - 80% sensitive/80% specific for adenoma

Diagnostic Procedures/Surgery
- Adrenal biopsy or fine needle aspiration may be performed in select cases
  – Reserved for differentiation of metastatic disease and benign lesion
  – May not be able to differentiate between benign from malignant adrenocortical tumor
- Rule out pheochromocytoma with plasma metanephrine screening before performing biopsy on an adrenal mass

Pathologic Findings
- Aldosterone-producing adenoma
  – Spironolactone bodies – eosinophilic laminated cytoplasmic inclusions
    - Found after treatment with spironolactone
  – Cortisol-producing adenoma
  – Vacuolated neoplastic cells
  – Intracytoplasmic lipid
- Bilateral adrenal adenomas
  – Fungal, TB, histoplasmosis

DIFFERENTIAL DIAGNOSIS
- Adrenal cortical carcinoma (up to 80% functional)
- Adrenal hemorrhage
  – Bilateral lesions
- Adrenal hyperplasia (pituitary hypersecretion of ACTH)
- Adrenal myelolipoma
- Lymphoma
- Metastatic lesion
  – Melanoma, lung, breast, kidney
- Neuroblastoma
- Nonfunctioning adenoma
- Pheochromocytoma
- TB, or other infectious cause

TREATMENT

GENERAL MEASURES
- Based on functional status and size of lesion
- Correct hypertension and electrolyte abnormalities.

MEDICATION

First Line
- For hormonally active adenomas in patients who refuse surgery or have contraindications to surgery
- Conn syndrome
  – Spironolactone, eplerenone

- Aldosterone receptor antagonists in the distal convoluted tubule (DCT).
- 2nd line – Amiloride, triamterene
  - Inhibitors of DCT aldosterone sensitive sodium channels
- Cushing syndrome
- Aminoglutethimide
  - Blocks the 1st step in cortisol synthesis (cholesterol to pregnenolone)
- Metapyrone
  - Blocks the final step in cortisol synthesis (11-deoxycortisol to cortisol)
- Ketoconazole
  - Inhibits 1st step and to a lesser extent the last step in cortisol synthesis

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Surgical indications
  - Hormonally active masses
  - Any masses ≥5 cm (25% of masses >6 cm are assumed to be adrenal cortical carcinomas)
  - Masses with suspicious imaging characteristics of carcinoma
    - Homogeneous, irregular borders, HU >20
- Laparoscopic and robotic approaches described, but may have limitations with larger lesions
- Retroperitoneal approach possible for both open and laparoscopic surgery; may reduce ileus
- Perioperative stress dose steroids indicated during unilateral adrenalectomy for cortisol-producing adenomas and may be indicated for patients with SCS
- Preoperatively: 50 mg hydrocortisone IV q8h postop day 1
- Steroid supplementation will be needed after adrenalectomy for cortisol-producing tumors until suppressed HPA recovers (median of 15 mo)
  - Postoperatively (POD 2): Hydrocortisone 20 mg PO qAM, 10 mg qPM
  - Hydrocortisone slowly tapered over 3 mo to 10 mg daily
  - AM cortisol should be measured and repeated until >10 ng/dL
  - Confirm recovery of HPA with cosyntropin test
- Monitor for electrolyte disturbances with BMP and postoperative AI in patients with hormonally active tumors and/or SCS
- Acute AI (addisonian state)

ALERT

This is a life-threating condition often preceded by hypotension unresponsive to fluid resuscitation.

- May occur in the postoperative state in the setting of cortisol-secreting lesion with downregulated contralateral adrenal function, and in patients with previous contralateral adrenal resection or due to concurrent illness or infection.
- Other nonspecific symptoms may include abdominal pain, salt craving, nausea, vomiting, fatigue, and fever.
- Electrolyte abnormalities such as hypernatremia or hyperkalemia and other laboratory anomalies such as anemia, lymphocytosis, or eosinophilia may also be found.

- Prolonged use of etomidate may increase risk of postoperative adrenal insufficiency.
- May begin steroid replacement if high clinical index of suspicion.
- Diagnosis Obtain AM serum cortisol and ACTH level:
  - Normal >10 ng/dL, low–normal (3.4–10 ng/dL), AI <3.4 ng/dL
  - Confirmatory testing with evaluation of response to ACTH stimulation (cosyntropin test)
    - Measure serum cortisol at baseline
    - Give cosyntropin 0.25 mg IV × 1
    - Measure serum cortisol 60 min after dose
    - Adequate response: Cortisol >18 μg/dL
- If acute AI is highly suspected, don't wait for result before treating:
  - Give 2–3 L D5 NS quickly and 4 mg dexamethasone IV
  - Use dexamethasone because IV cortisol will interfere with the diagnosis later during hospitalization
- Maintenance therapy:
  - Hydrocortisone 30 mg/d
  - Fluorohydrocortisone 0.05–0.1 μg/d

ONGOING CARE

PROGNOSIS

- Untreated Cushing syndrome can be fatal due to cardiovascular, thromboembolic, or hypertensive complications or infection
- Surgical removal of hormonally active adenomas is usually *curative*

COMPLICATIONS

- Hypertension
- Diabetes mellitus
- Atherosclerosis
- Poor wound healing
- Nephrolithiasis
  - 15% of patients with Cushing syndrome – due to hypercalciuria
- Adrenal insufficiency (Addison disease)

FOLLOW-UP

Patient Monitoring

- Nonfunctioning benign adrenal mass can be followed with physical and radiologic examinations
  - 5–20% show enlargement >1 cm
  - No guideline on growth velocity on surgical treatment

CODES

ICD9

- 227.0 Benign neoplasm of adrenal gland
- 255.0 Cushing's syndrome
- 255.12 Conn's syndrome

ICD10

- D35.00 Benign neoplasm of unspecified adrenal gland
- E24.0 Pituitary-dependent Cushing's disease
- E26.01 Conn's syndrome

CLINICAL/SURGICAL PEARLS

- Adrenal lesions should be surgically treated if ≥5 cm or if functional/active.
- No guideline on normal growth velocity for adrenal lesions.
- Melanoma, lung, breast, colon, and renal cell cancers have metastatic predilection to adrenal gland.

ADRENAL CORTICAL CARCINOMA

John M. Lacy, MD, FACS
Stephen E. Strup, MD, FACS

BASICS

DESCRIPTION

Adrenal cortical carcinoma is a primary malignancy arising in the adrenal cortex

EPIDEMIOLOGY

Incidence

- Rare: 0.5–2 cases per million people per year
- Bimodal occurrence:
  - Initial peak in children <5 yr old;
  - 2nd peak in adults in 4th and 5th decades of life
- Female:male ratio ~1.5:1
- ~80–130 cases in USA annually
- <5% of all adrenal incidentalomas, with correlation between size of tumor and likelihood of ACC
  - 2% of lesions <4 cm
  - 6% of lesions 4–6 cm
  - 25% of lesions >6 cm

Prevalence

Mirrors incidence, as prognosis is poor

RISK FACTORS

Genetic associations (see below)

Genetics

- Sporadic cases
  - Inactivation of p53 on 17q13
  - Alterations at 11p15 locus, site of IGF-2
  - Activation of β-catenin gene
- Familial syndromes
  - Li–Fraumeni syndrome
  - Beckwith–Wiedemann syndrome
  - Multiple endocrine neoplasia (MEN) 1
  - Congenital adrenal hyperplasia
  - Adenomatous polyposis coli

PATHOPHYSIOLOGY

- Difficult to distinguish benign from malignant adrenal tumors in absence of metastatic disease.
- Pathologic features such as mitotic activity, grade, vascular invasion, various architectural features, and tumor size have not consistently correlated with prognosis.

• Most (60–70%) ACCs are functioning, although this is related to the extent of workup.

ASSOCIATED CONDITIONS
• Cushing's syndrome secondary to functional tumors
• Familial syndromes (see above)

GENERAL PREVENTION
No recommendations

DIAGNOSIS
HISTORY
• Most common symptoms are related to excess cortisol production (Cushing's syndrome) in 50–60%, then virilization (20%), or mixed syndromes (20–30%)
• History of onset of symptoms < 12 mo is suspicious for ACC
• Constitutional symptoms:
  – Weight loss, malaise, weakness, nausea, or vomiting usually associated with poor prognosis
• In children, suggested by generalized weight gain and delayed linear growth
• Nonfunctional tumors may be larger and present with mass effect
  – Painful or palpable mass
  – Lower extremity edema
  – Urinary obstruction
  – Budd–Chiari syndrome
  – GI symptoms
• Hyperaldosteronism (rare):
  – Hypertension
  – Hypokalemic alkalosis
• Feminization (rare)
• Incidental finding during imaging workup for other morbidities

PHYSICAL EXAM
• Palpable abdominal mass
• Signs of Cushing's syndrome (functional ACCs): Violaceous striae, moon facies, truncal obesity, buffalo hump, glucose intolerance, hyperpigmentation
• Signs of virilization (oligomenorrhea, hirsutism, cystic acne, excessive muscle mass, voice deepening, temporal balding, clitoromegaly)
• Gynecomastia

DIAGNOSTIC TESTS & INTERPRETATION
Lab
• Tests for glucocorticoid excess (minimum 3 out of 4 tests)
  – Dexamethasone suppression test
  – 24-hr urinary free cortisol
  – Basal cortisol (serum)
  – Basal ACTH (plasma)
• Sexual steroids and steroid precursors

- DHEA-S (serum)
- 17-OH-progesterone (serum)
- Testosterone (serum)
- 17-β-estradiol
- 24-hr urine steroid metabolite exam

• Mineralocorticoid excess
- Potassium (serum)
- Aldosterone/renin ratio
  - Only used in patients with arterial hypertension and/or hypokalemia

• Catecholamine excess to exclude pheochromocytoma
- Meta- and normetanephrines (plasma)
- Catecholamines or metanephrine excretion (24-hr urine)

Imaging

• CT of abdomen is preferred initial study in patients adrenal lesion:
- Benign tumors
  - Homogeneous appearance with well-delineated margins
  - Generally <4–6 cm, smooth and round or oval contour
  - <10 HFU or rapid washout of contrast <15 min
- Primary ACCs:
  - Nonhomogeneous internal architecture
  - Irregular contour, invasion of surrounding structures
  - >10 HFU or delayed washout of contrast >15 min

• MRI not proven to be more sensitive in differentiating malignant from benign tumors:
- Preferred imaging modality for evaluation of vena caval involvement
- ACCs generally isodense to the liver on T1-weighted images; intermediate to high signal intensity (brighter white) on T2-weighted images (less bright than pheochromocytoma).

• FDG-PET potentially useful in radiologically indeterminate lesions.

• Bone scan if suspicious of skelet al metastases.

Diagnostic Procedures/Surgery

• Role of percutaneous biopsy limited
- Difficult to distinguish between benign and malignant tissue
- Concern for seeding biopsy tract

Pathologic Findings

• Macroscopic:
- Lobulated, orange tumor with necrotic areas, calcifications, intratumoral hemorrhages

• Microscopic:
- Weiss criteria for malignancy includes ≥ 3 of the following:
  - High nuclear grade
  - Mitotic rate $>$ 5/50/hpf
  - Atypical mitotic fevers
  - Eosinophilic tumor cell cytoplasm
  - Diffuse architecture in $>33\%$ of tumor
  - Necrosis

    - Vascular invasion
    - Sinusoidal invasion
    - Capsular invasion
- Antigen Ki-67 is a promising new immunohistochemical marker
  – Marker of proliferative activity
  – Low-risk ACC – expressed in $<10\%$ of cells
  – High-risk ACC – expressed in $>10\%$ of cells

DIFFERENTIAL DIAGNOSIS
- Functioning adrenal masses:
  – Adenoma, aldosteronoma, pheochromocytoma
- Nonfunctioning adrenal masses:
  – Hemorrhage, cyst, metastatic tumor, neuroblastoma
- Other: Renal cell carcinoma

TREATMENT

GENERAL MEASURES
Complete surgical excision is treatment of choice in resectable stage I or II tumors and children

MEDICATION
First Line
- Mitotane is the treatment of choice for metastatic ACC
  – Objective regression in tumor size in 35%
  – Dosage escalated to tolerance, which is limited
  – Significant toxicity – GI, CNS, endocrine
  – Must monitor serum levels closely
  – Strong inhibitor of steroidogenesis
    - Both glucocorticoid and mineralocorticoid replacement necessary
- Mitotane monotherapy may be used in patients with low tumor burden or indolent disease
- Polychemotherapy indicated with high tumor burden or rapidly progressive disease
  – Cytotoxic chemotherapy under investigation
    - Etoposide, doxorubicin, cisplatin, and mitotane
    - Streptozotocin and mitotane

Second Line
- If failed mitotane monotherapy, add cytotoxic chemotherapy
- If failed initial polychemotherapy regimen, may try whichever regimen was not used
- Clinical trials underway for targeted therapies
  – IGF-1 receptor inhibitors
  – Multi-tyrosine-kinase inhibitors

SURGERY/OTHER PROCEDURES
- Indications for surgery (1)
  – Hormonally active mass
  – Size >5–6 cm

- Open approaches
  - Anterior approach (chevron or subcostal incision) for the rare low-stage ACC
  - For more advanced ACCs, a thoracoabdominal incision provides optimal exposure
  - Avoid risk of port side seeding associated with laparoscopy
- Laparoscopy
  - Feasible in stage I and stage II tumors <10 cm in size
  - Many studies report equivalent oncologic outcomes (1)
  - Postoperative advantages
    - Less analgesic requirement
    - Lower blood loss
    - Shorter postop fasting period
    - Reduced length of hospital stay
- Advanced local disease may require resection of adjacent visceral organs, portions of vena cava and/or tumor thrombus
- Surgery may also play a role in the setting of metastatic disease
  - Primary tumor represents the bulk of disease
  - Complete resection is feasible
  - Tumor objectively responds to medical treatment or stabilizes over period of 6 mo
- Lymphadenectomy provides improved staging and may lead to favorable oncologic outcomes (2)

ADDITIONAL TREATMENT

Radiation Therapy

- ACCs formerly considered radioresistant
- Now radiation used in 2 scenarios:
  - Adjuvant therapy in patients with high risk for recurrence
  - Palliative control of local symptomatic metastases to bone, brain, or vena cava obstruction (3)

Additional Therapies

- Inhibitors of steroid synthesis may be useful in controlling symptoms of glucocorticoid excess
  - Metyrapone
  - Aminoglutethimide
  - Ketoconazole
  - Etomidate

ALERT
Hydrocortisone must be administered during surgery and postoperatively if patients with glucocorticoid excess.

Complementary & Alternative Therapies

- Locoregional therapy may be indicated in cases of progression despite mitotane
  - Arterial chemoembolization
  - Radiofrequency ablation

ONGOING CARE

PROGNOSIS

- Overall prognosis is poor, with overall 5-yr survival ranging from 15–60% based on stage
- Overall recurrence rate 17–85%
  - 23% in R0 patients
  - 51% for R1 and R2 patients
- Stage at diagnosis is the most important prognostic variable
- ~70% of patients present with advanced disease (stage III or IV)

COMPLICATIONS

- Fever due to tumor necrosis
- Anemia from hemorrhage into the tumor
- Adrenal crisis in patients who undergo surgery for functioning tumors without adequate steroid prep

FOLLOW-UP

Patient Monitoring

- Close follow-up is critical
- Abdominal CT or MRI and chest CT recommended every 3 mo for a minimum of 2 yr
- Serum and urinary steroid levels should also be monitored, though they are less sensitive for detection of recurrence than imaging
- Follow-up should be long-term, since late recurrence of ACC (after ≥10 yr) is not uncommon

CODES

ICD9

- 194.0 Malignant neoplasm of adrenal gland
- V84.09 Genetic susceptibility to other malignant neoplasm

ICD10

- C74.00 Malignant neoplasm of cortex of unspecified adrenal gland
- C74.02 Malignant neoplasm of cortex of left adrenal gland
- Z15.09 Genetic susceptibility to other malignant neoplasm

CLINICAL/SURGICAL PEARLS

- Rapid development of symptoms is key to distinguishing ACC from Cushing's syndrome.
- Lymphadenectomy provides improved staging and may lead to favorable oncologic outcomes.
- Radiation therapy useful as adjuvant therapy in high-risk patients and for local palliation.
- Laparoscopic adrenalectomy feasible in experienced surgeon's hands if mass $<$8–10 cm.
- Close follow-up is critical, as late recurrence is reported.

ADRENAL INSUFFICIENCY, ACUTE (ADRENAL CRISIS)

Debasish Sundi, MD
Misop Han, MD

BASICS

DESCRIPTION

- Acute adrenal insufficiency (Sometimes called Addisonian crisis) symptoms are attributable to mineralocorticoid deficiency—there are many etiologies (1)[A].
- Adrenal crisis is a subtype of acute adrenal insufficiency; it is a rapid and intensive process triggered by a stressor such as surgery or sepsis.
- Symptoms of the Addison disease (chronic adrenal insufficiency) are difficult to recognize; often the diagnosis of Addison disease is made when patients present with an acute crisis.
- Patient may present in hemodynamic compromise secondary to sodium and plasma volume depletion.
- Addisonian crisis should be treated immediately; treatment should not be delayed pending diagnostic test results.
- The disease usually results from bilateral adrenal cortex destruction: Destruction of the adrenal cortex causes a combined deficiency of glucocorticoids, mineralocorticoids, and adrenal androgens.

ALERT
Hypotension and shock refractory to resuscitation with fluids and vasopressors should be considered Addisonian crisis and treated with intravenous steroids.

EPIDEMIOLOGY

Incidence

- Addison disease incidence: 0.6/100,000 per year
- Up to 0.7% of patients undergoing major surgery may experience adrenal insufficiency

Prevalence

- Addison disease prevalence: 4–11/100,000
- >75% of patients with septic shock manifest adrenal insufficiency

RISK FACTORS

- Neonates: Bilateral adrenal hemorrhage from birth trauma
- Children: Pseudomonal or meningococcal septicemia leading to acute hemorrhagic destruction of both adrenal glands (Waterhouse–Friderichsen syndrome)
- Adults: Adrenal crisis after surgical or septic stress; bilateral adrenal hemorrhage from systemic anticoagulation or coagulation disorder
- Special at-risk populations: Pregnant women, patients with idiopathic adrenal vein thrombosis, patients who have undergone venography or vascular embolization of adrenal adenoma
- Most common cause: Rapid withdrawal of steroids from patients with adrenal atrophy secondary to chronic steroid use

- Medications: Ketoconazole, aminoglutethimide, dronabinol, mitotane, phenytoin, rifampin

Genetics

- Hereditary factors may influence development of autoimmune adrenal insufficiency.
- Familial glucocorticoid insufficiency may be associated with a recessive gene pattern.
- Addison disease has been associated with a variety of autoimmune diseases.

PATHOPHYSIOLOGY

- The adrenal cortex produces 3 classes of steroid hormones: Mineralocorticoids (aldosterone), glucocorticoids (cortisol), and androgens.
- Cortisol deficiency is primarily responsible for the manifestations of the crisis.
- Primary adrenal insufficiency is due to failure of the adrenal cortex.
- Secondary adrenal insufficiency is caused by failure of ACTH stimulation of the adrenal cortex.
- Chronic steroid administrations result in suppression of ACTH production via feedback inhibition

ASSOCIATED CONDITIONS

Nearly 50% of patients with adrenalitis have some form of autoimmune disease: Hypoparathyroidism, gonadal collapse, diabetes mellitus type I, hypothyroidism (Hashimoto thyroiditis), or hyperthyroidism (Grave disease).

GENERAL PREVENTION

- Perioperative stress dose steroid replacement when indicated (3)[B].
- Low threshold to intervene with IV glucocorticoid replacement at early signs of fluid refractory hypotension

DIAGNOSIS

HISTORY

- Prior steroid use:
  - Risk increases with minimum 20 mg/d prednisone or equivalent for at least 5 days within the past 12 mo
  - Patients receiving normal physiologic levels require about 1 mo to recover normal adrenal function.
  - Extensive topical use of high-potency steroids or high-dose inhaled steroids over prolonged periods can also be a factor
- Lapse in steroid therapy in a patient on chronic therapy
- Severe physiologic stress such as burn, surgery, or severe bacterial infection
- Bleeding diathesis or anticoagulant use
- Worsening or possibly intractable nausea, vomiting, and abdominal pain
- Fever may be severe or completely absent
- Primary or secondary adrenal insufficiency usually present insidiously with nonspecific symptoms of chronic fatigue, weakness and lethargy, anorexia, weight loss, postural hypotension, and somnolence
- Acute adrenal crisis usually presents acutely with hypotension or hypotensive shock:
  - Clinical picture is more complex as a result of a mixture of preceding slow-onset

symptoms and signs including abdominal pain, sepsis, pituitary or adrenal hemorrhage, surgery, or trauma
  - Acute adrenal insufficiency should be considered in patients presenting in the emergency room with abdominal pain, nausea, diarrhea, hypotension, and fever
  - The etiology of hypotension is profound hypovolemia
  - Hypotension may be one of the last signs (preterminal) because mineralocorticoid secretion is usually somewhat preserved in patients on chronic glucocorticoid replacement.

PHYSICAL EXAM

- Check blood pressure: Extreme hypotension and/or shock refractory to fluids and vasopressors suggests acute adrenal crisis.
- Vitiligo often coexists with Addison disease: Hyperpigmentation along palmar creases, buccal mucosa, pressure points, perianal mucosa, and nipple areolas.
- Check for signs of generalized weakness and specifically muscle weakness.
- Check for loss of axillary hair in females.
- In adrenal crisis, patients may be hyper- or hypothermic.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Plasma cortisol: Early AM levels < 3 μg/dL (80 nmol/L) suggests diagnosis
- Serum ACTH:
  - If low in the setting of low cortisol, patient has pituitary/hypothalamic disease
  - If high in the setting of low cortisol, primary adrenal insufficiency exists
- Electrolyte abnormalities: Decreased sodium and chloride levels, increased potassium levels and an increased BUN/Cr ratio (reflecting hypovolemia)
- Hypercalcemia may be seen during adrenal crisis
- Hypocalcemia may be seen with associated polyglandular failure and hypoparathyroidism
- Excess proopiomelanocortin and melanocyte-stimulating hormone levels may be found

ALERT

Labs are used only in the setting of nonemergent adrenal insufficiency and have no role in the acute management of adrenal crisis.

Imaging

- Abdominal x-rays may show adrenal calcifications if adrenocortical insufficiency is secondary to fungal or TB infection.
- Abdominal CT may show enlarged adrenal glands with TB infection or malignant mass.
- Adrenals may be small secondary to idiopathic atrophy, autoimmune adrenalitis, or advanced TB.
- Adrenal gland hemorrhage or thrombosis may be seen.

Diagnostic Procedures/Surgery

- Rapid ACTH stimulation (cosyntropin, a synthetic derivative of ACTH) test:
  - Following collection of baseline serum cortisol, 250 μg of synthetic ACTH is administered IM or IV.
  - Plasma cortisol response is reassessed at 60 min.

– Those with no response have primary adrenal failure; if the cortisol levels increase following synthetic ACTH injection, the adrenal insufficiency is secondary to pituitary dysfunction.

Pathologic Findings

- Autoimmune adrenal cortical infiltrate
- Adrenal cortical infarction/necrosis, with or without hemorrhage
- Metastatic carcinoma in adrenal gland
- Tuberculous granuloma of adrenal
- Radiation effect

DIFFERENTIAL DIAGNOSIS

- Acute insufficiency (addisonian crisis) (1)[A]
  – Shock (septic, cardiogenic, or hemorrhagic)
  – Acute abdomen
- Chronic insufficiency (Addison disease)
  – Secondary adrenocortical insufficiency
  – Celiac disease
  – Syndrome of inappropriate ADH secretion
  – Lead exposure
  – Severe nutritional deficiencies
  – Neurofibromatosis
  – Peutz–Jeghers syndrome
  – Porphyria cutanea tarda
  – Salt-depletion nephritis
  – Bronchogenic carcinoma
  – Anorexia nervosa, depression

TREATMENT

GENERAL MEASURES

- In critically ill and decompensating patients, maintain airway, and ensure adequate ventilation.
- Treatment instituted with IV fluid and dexamethasone or hydrocortisone should not be delayed in suspected adrenal crisis. Start treatment and perform more extensive tests once patient is stabilized.

MEDICATION

First Line

- IV fluids: 0.9% NS or 5% dextrose in NS
- Hydrocortisone: 100 mg IV bolus immediately; followed by either 100 mg q6h or 10 mg/h continuous infusion for 2–3 days (2)[A].
- Dexamethasone: 2–8 mg as a single dose; this may be repeated as necessary

Second Line

- Pediatric considerations
  – Hydrocortisone: 1–2 mg/kg/dose bolus immediately; followed by 25–150 mg/d given in

divided doses q6–8h (infants and young children)
- Geriatric considerations
  - Start dosage on the low end of the dosing range due to greater frequency of impaired cardiac and renal function
  - Increased susceptibility to adverse effects such as glaucoma, diabetes, and osteoporosis with long-term therapy
- Pregnancy considerations
  - During labor and delivery, IV normal saline 0.9% and 25 mg of IV hydrocortisone should be given q8h with quick tapering after delivery
  - Considered compatible with lactation: Infant must be monitored for adverse effects including hypoadrenalism

SURGERY/OTHER PROCEDURES
- Perioperative management during routine urologic surgery
  - Consultation with the preoperative physician for medical clearance and the procedural anesthesiologist is advised.
  - Many patients taking low-dose prednisone (such as for autoimmune inflammatory disorder) are able to undergo major surgery without any endocrine morbidity even without administration of intraoperative stress-dose steroids (3)[B]. Incident fluid-refractory hypotension in this group should be promptly treated with IV hydrocortisone.
  - Patients with chronic adrenal failure and complete physiologic steroid replacement do generally require procedural stress-dose steroids.
  - Individualization of stress-doses and postoperative taper regimens is recommended.

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
- Maintenance doses of steroids:
  - Hydrocortisone (oral): 15–20 mg qAM and 5–10 mg qPM
  - Prednisone (oral): 5 mg AM and 2.5 mg PM
  - Fludrocortisone (oral): 0.05–0.2 mg/d

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- There is a high risk of morbidity and mortality associated with unrecognized acute crisis. May result in cardiovascular collapse if not recognized.
- Excellent long-term prognosis following immediate management of acute crisis and long-term maintenance therapy.

COMPLICATIONS
- Abdominal distention, peptic ulcer

- Edema, glaucoma, increased intraocular pressure
- Hyperglycemia, hypertension
- Immunosuppression
- Mood changes, weight gain, hirsutism

FOLLOW-UP

Patient Monitoring

- Consider increase in steroid dosing when the patient has an episode of minor fever, infection, trauma, or physical stress.
- Monitor blood pressure, weight, serum electrolytes, and blood glucose levels.
- Monitor growth in pediatric patients.
- Bone density, ophthalmologic exams.

Preoperative anesthesia consultation for perioperative stress dose steroid replacement is

recommended for any patient on steroid therapy.

ADRENAL MASS

Kyle A. Richards, MD

BASICS

DESCRIPTION

- An adrenal mass is generally considered to be an adrenal lesion >1 cm
- Often found after abdominal imaging and often termed "adrenal incidentaloma"
- Rarely presents with acute or chronic symptoms

EPIDEMIOLOGY

Incidence

- Incidental adrenal mass (1,2)[A]
  - Peak incidence at age 50–70
  - 50–60% right side, 30–40% left side, 10–15% bilateral
- Female:Male 1.2–1.5:1
- Nonsecretory adenoma 75%
- Cortisol-producing 8%
- Pheochromocytoma 5%
- Adrenocortical carcinoma 5% (3)[A]
  - Bimodal age distribution: Age <5 and 40–50
  - 1–2 per million persons per year
  - 2–6% bilateral
  - Slightly higher incidence on left side
- Metastases 2%
- Aldosteronoma 1%

Prevalence

- 4% in patients undergoing CT scan
- 6% in autopsy series
- Increases with age (2)[A]
  - 0.2% age 20–29; 7% age ≥70

RISK FACTORS

- Sex (1)[A]
  - Malignant adrenal mass: Male > female (2:1)
  - Benign adrenal mass: Female > male (1.7:1)
- Aging
- Prior history of cancer especially melanoma, lung, breast, or kidney
  - 50% of these adrenal masses are metastases

Genetics

- Rare genetic syndromes may predispose to adrenal masses (1,4)[B]
  - Beckwith–Wiedemann

- Overexpression of insulin-like growth factor II gene
- Adrenocortical carcinoma

– Li–Fraumeni
- Mutations in p53 tumor suppressor gene
- 10–20% have adrenocortical carcinoma

– Multiple endocrine neoplasia 1
- 40% have adrenal masses
- Adenoma and adrenocortical carcinoma

– Multiple endocrine neoplasia 2
- RET-2 proto-oncogene abnormalities associated with pheochromocytoma
- 40–50% have adrenal masses

– Carney complex
- 30% have adrenal hypercortisolism

– McCune–Albright syndromes
- Associated with adrenal hypercortisolism

– Von Hippel–Lindau disease
- 10–20% have pheochromocytoma

– Neurofibromatosis type 1
- Up to 5% have pheochromocytoma

PATHOPHYSIOLOGY

- Adrenal glands consist of an outer cortex and inner medulla and are part of endocrine system
- Aberrant secretion of hormones = symptoms
- Adrenal cortex
  – Zona glomerulosa
    - Produces mineralocorticoid aldosterone
    - Regulates sodium and fluid homeostasis
    - Promotes exchange of potassium for sodium in distal tubule of nephron
    - Excess aldosterone = Conn's syndrome
  – Zona fasciculata
    - Produces glucocorticoid cortisol
    - Regulates cellular and glucose metabolism, immune processes, and other regulatory functions
    - Excess cortisol = Cushing's syndrome
  – Zona reticularis
    - Produces adrenal androgens
    - Excess androgens = virilization
- Adrenal medulla
  – Produces catecholamines
  – Excess catecholamines = pheochromocytoma
- Addison's disease = adrenal insufficiency
  – Usually not caused by adrenal masses

ASSOCIATED CONDITIONS

- See "Genetics"

- Hypertension (paroxysmal or sustained)
- Osteoporosis/osteopenia (cortisol excess)
- Diabetes mellitus (cortisol excess)
- Hypokalemia (aldosterone excess)
- Hyperlipidemia (cortisol excess)
- Pheochromocytomas
  - Multiple endocrine neoplasia IIa or IIb
  - Neurofibromatosis type 1
  - Von Hippel–Lindau syndrome
  - Tuberous sclerosis
  - Sturge–Weber syndrome
  - Carney triad
- Adrenocortical carcinoma
  - Multiple endocrine neoplasia 1
  - Li–Fraumeni syndrome
  - Carney complex
  - Beckwith–Wiedemann

GENERAL PREVENTION

None

DIAGNOSIS

HISTORY

- Focus on symptoms suggestive of adrenal hyperfunction or malignant disease
  - Cushing's syndrome
    - Weight gain
    - Easy bruising
    - Poor wound healing
    - Proximal muscle weakness
    - Emotional and cognitive changes
    - Opportunistic and fungal infections
    - Altered reproductive function
  - Pheochromocytoma
    - Episodic symptoms
    - Forceful heartbeat, pallor, tremor, headache, and diaphoresis
    - Spontaneous or precipitated by postural change, anxiety, meds, and Valsalva
  - Primary hyperaldosteronism
    - Nocturia/polyuria (due to hypokalemia)
    - Muscle cramps and palpitations
  - Adrenocortical carcinoma
    - Abdominal/back pain
    - Cushing's syndrome (see above)
    - Altered reproductive or sexual function
    - Hyperaldosteronism (see above)
  - Sex steroid-secreting tumor

- Altered reproductive or sexual function
  - Metastatic cancer
    - History of extra-adrenal cancer
- Medical history
  - Malignancy or syndromes
- Medications such as exogenous steroids
- Family history: See “Genetics”

PHYSICAL EXAM

- Blood pressure and heart rate
- Focus on signs suggestive of adrenal hyperfunction or malignant disease
  - Cushing’s syndrome
    - Hypertension
    - Central adiposity
    - Facial rounding and plethora
    - Supraclavicular and upper back fat pads
    - Thin skin, purple striae, and acne
    - Hirsutism
  - Pheochromocytoma
    - Hypertension, orthostasis, tachycardia
    - Fever, pallor, tremor
    - Retinopathy
  - Primary hyperaldosteronism
    - Edema, paresthesias, weakness, tremors
  - Adrenocortical carcinoma
    - Abdominal mass
    - Cushing’s syndrome signs (see above)
    - Gynecomastia
  - Sex steroid-secreting tumor
    - Gynecomastia or testicular atrophy

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Assess all for biochemical function (2)[A]
- Cushing’s syndrome
  - Hyperkalemic, hyperglycemic
  - 24-hr urinary free cortisol (5)[A]
    - <80 μg/24 h excludes diagnosis
  - Cortisol suppression testing
    - 1 mg dexamethasone at 11 PM and measure serum cortisol at 8 AM next day
    - Serum cortisol $>$ 5 μg/dL is diagnostic
    - 97% specificity
- Pheochromocytoma
  - Plasma metanephrines
    - 96–100% sensitivity, 85–89% specificity

- 24-hr urine fractionated metanephrines
  - 91–98% sensitivity and specificity
- Primary hyperaldosteronism
  - Hypokalemia, mild hypernatremia, alkalosis
  - 40% normokalemic
  - Aldosterone-to-renin ratio (morning)
    - Patients must stop spironolactone, eplerenone, or amiloride
    - Cutoff for + result is lab dependent
  - Confirmatory testing
    - Saline infusion test
    - 24-hr urinary aldosterone excretion test while patient maintains high sodium diet
- Adrenocortical carcinoma (3)[A]
  - Most commonly cortisol secreting
  - Serum dehydroepiandrosterone (DHEA)
- Sex steroid-secreting tumor
  - Serum testosterone and 17β-estradiol in women with virilization or men with feminization

Imaging

- CT scan (2)[A]
  - Benign adrenal adenoma
    - Usually <3 cm and homogeneous
    - Density <10 HU with >50% washout of contrast at 10 min
  - Adrenocortical carcinoma or adrenal mets
    - Usually >4 cm, heterogeneous, calcifications, necrosis
    - Density >25 HU and <50% washout of contrast at 10 min
- MRI
  - Benign adrenal adenoma
    - Rapid contrast washout and high lipid content; isointense with liver on T2
  - Adrenocortical carcinoma or adrenal mets
    - Hyperintense with liver on T2 imaging
  - Pheochromocytoma
    - "Light bulb" sign: see very high signal intensity on T2-weighted imaging
- Metaiodobenzylguanidine (MIBG) scan
  - Useful for extra-adrenal pheochromocytoma

Diagnostic Procedures/Surgery

- Primary hyperaldosteronism
  - Adrenal vein sampling for lateralization of aldosterone production, if unclear by imaging
- Biopsy
  - Rule out pheochromocytoma prior to biopsy
  - Helpful if concern for metastases or infection

Pathologic Findings

See "Differential Diagnosis"

DIFFERENTIAL DIAGNOSIS

- Adrenal cortical tumors (4)[A]
  - Adenoma
  - Carcinoma
  - Nodular hyperplasia
- Adrenal medullary tumors
  - Pheochromocytoma
  - Ganglioneuroma/neuroblastoma
- Other adrenal tumors
  - Myelolipoma, lipoma, hemangioma
  - Metastases
  - Hamartoma, teratoma
- Infectious or inflammatory
  - Abscess or fungal infection
  - Amyloidosis, sarcoidosis
  - Cytomegalovirus
  - Cysts (pseudocysts, parasitic, epithelial- and endothelial-lined cysts)
- Congenital adrenal hyperplasia
- Hemorrhage
- Pseudoadrenal masses
  - Splenic, pancreatic, renal lesions
  - Vascular lesions or technical artifacts

TREATMENT

GENERAL MEASURES

- Observation, resection, or medical therapy
- Depends on size of lesion, functionality, malignant potential, and overall health of patient

MEDICATION

First Line

- Cushing's syndrome (5)[C]
  - Aminoglutethimide, metyrapone, ketoconazole
- Pheochromocytoma
  - Phenoxybenzamine, propranolol
- Primary hyperaldosteronism: Spironolactone
- Adrenocortical carcinoma: Mitotane

Second Line

- Adrenocortical carcinoma
  - Cisplatin, etoposide, 5-flurouracil, doxorubicin, vincristine

SURGERY/OTHER PROCEDURES

- Should remove all functional adrenal masses
- Open surgery if large or locally advanced; evaluate for vein thrombus or adjacent organ invasion
- Minimally invasive surgery is now accepted

- Remove masses >5 cm; high malignancy risk
- Consider partial adrenalectomy for solitary adrenals, bilateral disease, familial syndromes

ADDITIONAL TREATMENT

Radiation Therapy

Only for palliation of bone metastases from adrenal cortical carcinoma

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Adrenalectomy cures hypertension in 33–72% of patients with primary hyperaldosteronism (5)[B]
- 10–15% recurrence rate after resection of pheochromocytoma
- Adrenocortical carcinoma has poor prognosis
  - Mean survival 18 mo (4)[B]
  - 5-yr survival 15–47%

COMPLICATIONS

- Adrenal insufficiency post adrenalectomy
- Unrecognized malignancy/pheochromocytoma

FOLLOW-UP

Patient Monitoring

- Conservative management principles (2)[B]
  - Repeat imaging at 6, 12, and 24 mo
  - Repeat hormonal testing annually for 4 yr
  - If growth ≥1 cm or autonomous hormonal secretion, consider surgery

Patient Resources

- Remove all adrenal masses >5 cm.
- Do not biopsy pheochromocytoma.

AMYLOIDOSIS, GENITOURINARY

Christopher Wright, MD
Mark L. Jordan, MD, FACS

BASICS

DESCRIPTION

- Heterogeneous group of disorders with extracellular deposition of protein in abnormal fibrillar form:
  - Can involve any organ system
  - Kidney, ureters, seminal vesicles, prostate, penis, and testis can be involved
  - >50% of genitourinary (GU) tract cases involve the bladder
  - Commonly forms "pseudotumors" in bladder, ureter, or renal pelvis
- 25 structurally unrelated proteins known to cause amyloidosis
- May be primary, secondary, or hereditary
- May be organ limited or systemic

EPIDEMIOLOGY

Incidence

- Uncommon disorder and exact worldwide incidence is unknown
  - In the United States appears to be stable at 6–10 cases per million person-years
- Age-specific incidence rates increase in each decade over age 40
  - Median age at diagnosis is 64 yr and <5% of patients are under age 40 (1)

RISK FACTORS

- Chronic and recurrent mucosal and submucosal inflammation
- Hemodialysis patients develop deposits in kidneys
- Chronic inflammatory disorders

Genetics

- Familial or hereditary amyloidosis exists
- Dozens of specific variations described
- Familial forms often do not present until adulthood
- Patients with immunoglobulin light chain (AL) amyloidosis frequently have chromosomal abnormalities but there is no single chromosome change that is diagnostic

PATHOPHYSIOLOGY

- More than 20 distinct low–molecular-weight proteins are recognized to form amyloid fibrils, the 2 most common being (2):
  - AL, formerly referred to as primary amyloidosis
    - Fibrils composed of fragments of monoclonal light chains
    - Affected patients may have amyloidosis alone or in association with other plasma cell dyscrasias (eg, multiple myeloma)
  - AA amyloidosis
    - Fibrils composed of fragments of the acute phase reactant serum amyloid A

    - Typically reactive (secondary) to chronic inflammation
- Thought to be a misfolding event; misfolded variants are prone to self-aggregation
  – These become insoluble complexes that accumulate in tissues
- Renal amyloid is often a glomerular deposition leading to proteinuria

ASSOCIATED CONDITIONS
- End-stage renal disease (ESRD) requiring dialysis
- Nephrotic syndrome
- Diabetes
- Multiple myeloma
- Familial Mediterranean fever (FMF)
  – Hereditary inflammatory disorder characterized by severe attacks of abdominal pain in 95% of patients
  – AA amyloidosis with renal failure is common complication

GENERAL PREVENTION
N/A

DIAGNOSIS
- Clinical presentation depends on the number and nature of the organs affected
- Even in patients with multiple-organ involvement, it is usually possible to identify 1 organ as the “dominant” site of involvement

HISTORY
- Nonspecific symptoms such as fatigue and weight loss are common
- Patient on dialysis
- Family history of amyloidosis
- Chronic disease or inflammation
- Cardiac:
  – 60% of patients
  – Signs/symptoms of heart failure
- Neurologic:
  – 20% with mixed sensory and peripheral neuropathy
  – Carpal tunnel syndrome
- Liver:
  – 70% will have hepatomegaly
- Bladder:
  – Painless hematuria in 75%
  – Irritative symptoms (urgency, frequency)
  – Clinically similar to bladder cancer
- Ureter:
  – Flank pain if obstruction
  – Anuria if bilateral amyloidosis
  – Hematuria
- Prostate:
  – Hematuria

- Bladder outlet obstruction may be present

PHYSICAL EXAM

- Peripheral edema (nephritic syndrome)
- Hepatosplenomegaly
- Generally no specific physical exam findings

DIAGNOSTIC TESTS & INTERPRETATION

- Proteinuria in 50–80%
- Renal failure in 50%
- Elevated liver function tests (cholestatic pattern)
- Diagnosis of AL amyloidosis requires evidence of a monoclonal proliferative disorder
  - Serum or urine monoclonal (M) protein can be detected

Imaging

- CT or ultrasound (US) may demonstrate hydronephrosis secondary to obstruction (ureteral amyloid)
- Magnetic resonance imaging (MRI):
  - T2-weighted images are suggestive of amyloid deposition. Can be confused with prostate cancer invading into seminal vesicles on MRI for prostate

Diagnostic Procedures/Surgery

- Cystoscopy for hematuria
  - Lesions are difficult to distinguish from transitional cell carcinoma (TCC) without biopsy or resection
- Ureteroscopy or retrograde pyelogram for ureteral involvement
- Biopsy
  - Abdominal fat pad aspirate or bone marrow biopsy have high success rates and are preferred sites of biopsy
  - Renal biopsy performed if former is negative with high suspicion
    - Will be positive in >90% of cases

Pathologic Findings

- Diagnosis requires histologic demonstration of amyloid deposits:
  - Congo red stain
    - Orange under light microscope
    - Green birefringence under polarized light
  - Electron microscopy can be used to identify microfibrils
  - Immunohistochemical analysis assists in typing:
    - Diagnosis of transthyretin-type amyloidosis limits need for further evaluation as it identifies the amyloidosis as inherited
- Seminal vesicle amyloidosis can be seen in radical prostatectomy specimens but the significance is unknown

DIFFERENTIAL DIAGNOSIS

- Bladder
  - Difficult to distinguish from TCC without biopsy
- Ureter

– May be confused with stones or other causes of obstruction (eg, strictures)
• Nephrotic syndrome and glomerulonephritis

TREATMENT

GENERAL MEASURES

• In AL amyloidosis treatment is aimed at reducing the production of monoclonal light chain precursor with chemotherapy or, occasional, radiotherapy or surgery of a localized amyloidogenic plasmacytoma
• In AA amyloidosis treatment is generally supportive with therapy directed at primary cause if identified

MEDICATION

First Line

• High-dose melphalan chemotherapy followed by autologous blood stem cell transplantation (2)
– 25–67% complete hematologic response seen in single and multicenter trials
– Response far exceeds cyclic oral melphalan and prednisone (see 2nd line)
• Colchicine can be used in FMF to prevent proteinuria

Second Line

• Low-dose oral melphalan with prednisone in a cyclical fashion
– Rarely results in complete hematologic response or reversal of amyloid-related organ dysfunction

SURGERY/OTHER PROCEDURES

• Renal transplant
– Graft survival similar to matched controls without amyloidosis
– Recurs in graft in 20–33% due to continued activity of underlying disease
• TUR of bladder lesion with fulguration
– Adjuvant intravesical DMSO has shown success in preventing recurrence (3)

ADDITIONAL TREATMENT

Radiation Therapy

Only rarely used for localized amyloidogenic plasmacytoma

Additional Therapies

• Supportive care
– Management of heart failure
– Salt restriction, diuretics, and treatment of secondary hyperlipidemia for nephrotic syndrome
– Analgesics for neuropathic pain

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Single institution experience of 421 patients who received high-dose melphalan with stem cell transplant shows event-free survival and overall survival of 2.6 and 6.3 yr, respectively (4)
- Long-term survival in those who develop renal failure remains poor
  – Ranges from 12–24 mo
- AA amyloidosis has better prognosis

COMPLICATIONS

See above

FOLLOW-UP

Patient Monitoring

- Bladder or urethra
  – Repeat periodic surveillance cystoscopies
  – Recurrence rates >50%
- Ureters
  – US or CT to monitor hydronephrosis

Patient Resources

Amyloidosis foundation (www.amyloidosis.org)

CODES

ICD9

- 277.30 Amyloidosis, unspecified
- 277.39 Other amyloidosis
- 583.81 Nephritis and nephropathy, not specified as acute or chronic, in diseases classified elsewhere

ICD10

- E85.3 Secondary systemic amyloidosis
- E85.8 Other amyloidosis
- N08 Glomerular disorders in diseases classified elsewhere

CLINICAL/SURGICAL PEARLS

- Both surgically and radiologically, genitourinary amyloidosis may mimic TCC in GU tract, therefore biopsy is needed.
- Abdominal fat pad aspirate is preferred location to obtain biopsy, followed by bone marrow and finally kidney.

ANDROPAUSE (LATE-ONSET HYPOGONADISM)

Katie S. Murray, DO
Tomas L. Griebling, MD, MPH, FACS

BASICS

DESCRIPTION

- Hypogonadism is a reduction in serum testosterone and other circulating androgens
  - Primary hypogonadism: Arises directly from testicular causes
  - Secondary hypogonadism is where changes occur in hypothalamic–pituitary–testicular axis
  - Late-onset hypogonadism is a gradual reduction in serum testosterone levels in elderly men; often referred to as "andropause."

EPIDEMIOLOGY

- Estimates suggest more than 4.5 million elderly American men may be affected
- 80% of men report moderate or severe scores consistent with hypogonadism on surveys (1) [B]
- Thought to be underreported and underdiagnosed in elderly males

RISK FACTORS

Decreases in serum testosterone occur naturally as part of the aging process

Genetics

- Attenuated action of androgen receptor (AR) may contribute
- Those with longer AR CAG repeat polymorphism are at higher risk of andropausal symptoms (2)[B]

PATHOPHYSIOLOGY

- Testosterone age-related declines vary by reported study:
  - Testosterone declined approximately 100 ng/dL (3.5 nmol/L) from age 20–80 yr
  - European Male Aging Study (EMAS) total testosterone (TT) fell 0.4% a year and the free testosterone fell 1.3% from age 40–79 yr
- As age increases, there is:
  - Decreased number of Leydig cells within the testicle (site of testosterone production)
  - Decreased testicular responsiveness to LH
  - Dampening in the amplitude of circadian release of T
  - Increased serum sex hormone binding globulin (SHBG)
    - binds T, therefore less bioavailable (functionally active) T
- Relationship with cardiovascular (CV) disease is thought to be multifactorial
  - Nitric oxide (NO) is an important mediator in both CV health and erectile function

ASSOCIATED CONDITIONS

- Metabolic syndrome
- Diabetes mellitus

- Hypertension
- Tobacco abuse
- Sleep apnea
- Psychological disorders
- Social stress

GENERAL PREVENTION
None

DIAGNOSIS
HISTORY
- Patients often complain of:
  - Frailty-decreased grip strength, diminished gait speed, easy fatigue and exhaustion, unintentional weight loss, and low levels for physical activity
  - Decreased energy
  - Decreased mentation
  - Diminution in muscle mass and strength
  - Decreased libido
  - Erectile dysfunction
  - Loss of morning erections
  - Increased visceral fat
  - Decrease in bone mineral density (osteoporosis and osteopenia)
  - Sleep disturbances
  - Depression
  - Metabolic syndrome
  - Poor glycemic control and diabetes mellitus
  - Coronary/CV disease

PHYSICAL EXAM
- Overall energy, muscle mass, and disposition
- Psychological evaluation
  - Screen for clinical depression
- Include complete GU exam
  - Testis (size, consistency), digital rectal exam

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- TT: Diurnal variations so most accurate specimens are obtained in the morning (prior to 10:00 AM)
  - General accepted values although there is no clear lab definition of hypogonadism
  - < 300 ng/dL with symptoms
  - < 200 ng/dL without symptoms
  - FDA research trial definition: < 300 ng/dL
- Free testosterone
  - < 50 pg/mL
- SHBG (sex hormone binding globulin)

  – Increases with aging, which leaves a greater percentage of protein-bound testosterone and lower levels of circulating free testosterone
- Estradiol: Increased aromatization of testosterone to estradiol in adipose tissue
- If abnormal TT levels, then check LH and prolactin
- Blood glucose to screen for diabetes mellitus
- PSA for prostate cancer screening
- Monitoring while on testosterone replacement therapy (TRT)
  – CBC to monitor hematocrit (risk of polycythemia)
  – PSA
  – Liver function tests

Imaging

Bone density scan to evaluate for osteopenia or osteoporosis

Diagnostic Procedures/Surgery

Prostate biopsy if PSA and DRE are suspicious for prostate cancer

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Acute critical illness (surgery, head trauma)
- Age-related decline ("Andropause")
- Alcoholism
- Chronic illness (liver failure, chronic renal failure, hypertension, hypothyroidism, diabetes, sleep apnea, obesity, anorexia nervosa, depression, HIV)
- Hematologic (sickle cell disease, thalassemia)
- Hemochromatosis of the pituitary, Leydig cells
- Hypopituitarism (hypothalamic/pituitary)
- Kallmann syndrome (congenital absence of GnRH)
- Klinefelter syndrome
- Medications: LHRH analogs/antagonists, glucocorticoids, androgens, estrogens, progestins (eg, megestrol), chronic opioids, marijuana (controversial)
- Noonan syndrome
- Pituitary infections, infiltration, trauma, radiation (decreased LH/FSH production)
- Pituitary tumors, macroadenomas, hyperprolactinemia
- Prader–Willi syndrome
- Sertoli-cell-only syndrome
- Testicular failure (primary): Congenital or acquired anorchia, cryptorchidism, mumps orchitis, radiation therapy, chemotherapy
- Testicular tumors

TREATMENT

GENERAL MEASURES

- Can treat ED with phosphodiesterase-5 inhibitors if no contraindications
  – Avanafil

- Sildenafil
- Tadalafil
- Vardenafil
- Start at lowest dose and titrate up for efficacy

MEDICATION

First Line

- TRT (3)[B]
  - Intramuscular, transdermal (patches and gels), and buccal preparations. See Section I "Testosterone Replacement Therapy, General Principles" for specifics on TRT agents
  - Selection is dependent on patient/physician preference and feasibility
  - Considerations in the older male: The American Geriatrics Society (AGS) lists testosterone in the Beers Criteria as a medication to generally avoid in older adults because of potential for cardiac problems and men with personal history of prostate cancer (4)[A]
  - The choice of TRT should be individualized on specific clinical needs
  - Absolute contraindications: Personal history of breast cancer or untreated prostate cancer
  - Relative contraindications: Polycythemia, BPH causing urinary retention, treated prostate cancer

Second Line

N/A

SURGERY/OTHER PROCEDURES

Men with primary erectile dysfunction complaints can discuss surgical placement of penile prostheses, use of vacuum erection devices, or vasoactive intracavernosal injection therapy

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

- Increased weight-bearing exercise
- Diet and exercise
- Weight loss
- Phytotherapies: Limited research on safety and efficacy of herbal medications
  - Limited data on ability of any OTC supplement to influence T levels

ONGOING CARE

PROGNOSIS

- TRT is associated with improved responses in many areas
  - Quality of life
  - Mood and affect
  - Sexual function and libido
  - Cognitive function

– Glycemic control

COMPLICATIONS

- Prostate cancer diagnosis or progression of disease
- Polycythemia
  – Potential for cardiac and cerebral vascular events

FOLLOW-UP

Patient Monitoring

- Hemoglobin and hematocrit
- Bone mineral density
- DRE and PSA for prostate cancer screening
- Continued monitoring of testosterone levels
- Overall men's health issues
  – Blood glucose
  – Serum lipids
  – Overall cardiovascular health

CLINICAL/SURGICAL PEARLS

Treatment is based upon symptomatology more than lab values.

ANORECTAL MALFORMATIONS: IMPERFORATE ANUS, CLOACA, AND UROGENITAL SINUS ANOMALIES

Youngjae Im, MD
Sang Won Han, MD

BASICS

DESCRIPTION

- Anorectal malformations (ARMs) are a spectrum of congenital anomalies involving the anorectal and urogenital systems, such that the anus and distal rectum are often absent
  - Imperforate anus: Absence of an anus, typically with a fistula between rectum and lower urinary tract
  - Persistent urogenital sinus (UGS) is seen in 4 entities (1):
    - Genital ambiguity state: Most common being congenital adrenal hyperplasia (CAH)
    - Pure UGS: With normal external genitalia
    - Cloaca: In females, a common channel between lower urinary tract, vagina, and rectum
    - Female exstrophy

EPIDEMIOLOGY

Incidence

- ARM: 1 in 4,000–5,000 live births:
- Cloaca: 1 in 40,000–50,000 live births
- UGS: 1 in 500 live births
- Incidence of ARM in the setting of genetic disease is about 5–10%

Prevalence

N/A

RISK FACTORS

- Proposed association with in utero vascular accidents, maternal diabetes and obesity, maternal ingestion of thalidomide, phenytoin, and trimethadione and maternal exposure to smoking and caffeine
- Some degree of heritability, as incidence of subsequent children having ARM is 1%

Genetics

- ARM found in certain congenital syndromes with associated genetic abnormalities (2)
  - Trisomy 21: Imperforate anus without fistula
  - Microdeletion of chromosome 22q11.2
  - Familial inheritance pattern: ARM with a rectovestibular or rectoperineal fistula, almost 15% had a positive family history for an ARM
  - Currarino triad: ARM, sacral agenesis, presacral mass (or meningocele); autosomal dominant
  - Townes–Brocks syndrome: ARM, external ear abnormalities, hearing loss, polydactyly, renal anomalies; autosomal dominant
  - Cat eye syndrome: ARM, coloboma, preauricular tag, heart defect, urinary tract

abnormalities, mental retardation

PATHOPHYSIOLOGY

- Classic theory: The urorectal septum (mesoderm), fails to grow caudally to meet the lateral Rathke folds to divide the cloacal membrane (endoderm and ectoderm) into the anterior urogenital membrane and the posterior anal membrane.
- Alternative theory: A mesenchymal mass displaces the dorsal cloacal membrane anteriorly, preventing its joining with the hind gut.

ASSOCIATED CONDITIONS

- About 50–67% of all ARM are associated with other anomalies
  - In general, the higher the ARM, the more likely there are associated abnormalities
- Can occur as an isolated abnormality or as part of a syndrome:
  - VACTERL: Vertebral, anorectal, cardiac, tracheoesophageal fistula, renal, limb abnormalities
- Spinal and bony abnormalities are present in 33–50% of ARM:
  - Tethered cord in 20–30%
  - Sacral agenesis, the most common vertebral anomaly
- Genitourinary abnormalities ranges from 33% to almost 50% of ARM:
  - VUR present in 14–56% of ARM
  - Renal agenesis: 12–30%
  - Neurogenic bladder: 4–25%
  - Renal anomalies: Horseshoe kidney, ectopic kidney, multicystic dysplastic kidney 4–12%
  - Cryptorchidism/hypospadias: 4–6%
- Gynecologic problems are common in ARM, but most may not be diagnosed until puberty or adulthood
  - Duplicated vaginas with septum
  - Absent vagina; vaginal atresia
  - Bicornuate uterus
  - Clitoromegaly in UGS associated with CAH
- Cardiovascular abnormalities are present in 10–30% of ARM:
  - Atrial septal defects and ventricular septal defects are most common
- Tracheoesophageal fistula (TEF) and esophageal atresia (EA) occur in 5–10% with ARM

GENERAL PREVENTION

International Consortium on Anorectal Malformations aims to identify genetic and environmental risk factors in ARM. No prevention reduction strategies are currently available.

DIAGNOSIS

HISTORY

- Prenatal diagnosis: Low sensitivity/specificity
  - Dilated colon, oligohydramnios, and distended vagina on prenatal US may be signs of ARM
  - Antenatal findings suggestive of cloacal anomaly:
    - Transient fet al ascites with bilobed or trilobed pelvic cystic structures
    - Bilateral hydronephrosis or oligohydramnios

- Lower-level ARM and UGS may go undiagnosed in newborn until later symptoms develop:
  - Constipation, abdominal distension in rectal atresia, anorectal stenosis
  - Urinary incontinence and/or retention in UGS
  - Amenorrhea and abdominal distension due to hydrometrocolpos or hematocolpos at puberty in UGS

PHYSICAL EXAM

- Thoroughly examine the perineum to determine number and position of orifices:
  - Perineum flattened in higher-level ARM
- Inspect the genitalia: Rule out hypospadias, cryptorchidism, clitoromegaly
- Assess vertebrae: Look for sacral abnormalities
- Palpate for an abdominal mass that may represent a distended bladder or hydrometrocolpos
- Rule out associated pathologies:
  - Cardiac auscultation for murmur
  - Insert nasogastric tube for tracheoesophageal fistula
  - Skelet al/limb assessment
- Once the diagnosis of an imperforate anus is made, assess for the presence of a fistula
  - It may take up to 24 hr for signs of fistula to be evident

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Renal profile
- Urinalysis: Abnormal if fistula to urinary tract
- 17-hydroxy-progesterone in UGS with virilization to rule out CAH
- Karyotype if ambiguous genitalia

Imaging

- Studies to determine level of ARM:
  - Prone, cross-table lateral plain film
    - Should be performed at 24 hr after birth to allow enteric gas to reach the most distal area of the colon
    - Distance between rectal gas shadow and perineal opening measured
- Abdominal US: Evaluate bilateral kidneys, bladder, ± müllerian structures
- Voiding cystourethrogram (VCUG)/cloaca gram/genitogram: Evaluate presence of VUR as well as relation of urinary tract to rectum (and to müllerian structures)
- Colostogram: Distal to mucous fistula and proximal to colostomy to evaluate colon and its relation to other pelvic structures prior to definitive surgery
- Spinal imaging:
  - Spinal US prior to 6 mo of age
  - Spinal MRI after 6 mo of age

Diagnostic Procedures/Surgery

- Echocardiogram and ECG: Rule out cardiac anomalies
- Urodynamic study : Especially in cases of UTI, VUR, urinary incontinence, spinal anomalies
  - The most common finding on UDS is an upper motor neuron lesion with an overactive detrusor and/or detrusor sphincter dyssynergia (DSD)
- Exam under anesthesia/endoscopy: Helps delineate relationships between structures and

measure length of common channel and proximity of fistula/confluence to bladder neck

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Classification systems for ARM (3)
  - Wingspread classification: Traditional "low," "intermediate," or "high" ARM
  - Pena classification: Based on the presence and position of the fistula
  - Krickenbeck anatomic classification: An anatomic description of ARM, type of surgical procedure performed, and postop assessment of bowel movements, constipation, and soiling
- Lesions in the male: Classifying patients (ie, into low-lying or higher lesions) have important clinical implications with regard to their treatment and prognosis
  - Imperforate anus without fistula, rectal atresia, rectoperineal fistula
  - Recto bulbar urethral fistula
  - Recto posterior urethral fistula
  - Rectovesical fistula
- Lesions in the female:
  - Imperforate anus without fistula, rectal atresia, rectoperineal fistua
  - Rectovestibular fistula: Most common defect
  - Cloaca: Further subdivided into length of common channels:
    - Short (<3 cm): Good prognosis
    - Long (>3 cm): More complicated and worse prognosis
  - UGS:
    - Some associated with virilization, as in CAH
    - Some not associated with virilization
    - Can be result of congenital cloaca following isolated repair of the rectum

TREATMENT

GENERAL MEASURES

- Newborn should not be given any enteric intake and should have nasogastric suction
- Hydrometrocolpos (present in 50% of cloaca) and urinary retention in newborn period managed with catheter drainage until operative intervention

MEDICATION

First Line

- IV antibiotics neonatally and perioperatively
- Prophylactic antibiotics continued at least until VUR is ruled out
- Eventual fecal incontinence may be treated with combination of enemas and antimotility agents
- Eventual constipation may be treated with combination of enemas and laxatives
- Anticholinergics may be necessary for neurogenic bladder

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Newborn:
  - Diverting colostomy with mucous fistula needed in all but the lowest of ARM:
    - Level of colostomy should be distal on descending colon; distance between stomas should be wide to minimize the length of bowel that could potentially be in contact with urine in cases of fistula
  - Neonatal posterior sagittal anorectoplasty (PSARP) in low ARM
  - In cases of hydrometrocolpos, vaginotomy may be necessary as newborn
  - In cases of urinary retention, cutaneous vesicostomy may be necessary as newborn
- Definitive surgery at age 2–24 mo:
  - Lower lesions: Approached through a PSARP
  - Higher lesions: Laparotomy as well as PSARP
  - In cloaca with a long common channel, when vagina will not reach perineum, can interpose a section of bowel between vagina and perineum
  - Genitoplasty in cases of virilized genitalia
- Colostomy take-down a few months after definitive reconstruction, once anal dilations satisfactory
- Further urologic surgery later as indicated (ureteral reimplantation for VUR, bladder neck reconstruction for incontinence, augmentation for small capacity, poorly compliant bladder)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Clean intermittent catheterization may be necessary in cases of neurogenic bladder

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Bowel function (4):
  - Voluntary bowel movements in 75% of ARM after definitive repair
  - Fecal soiling occurs in about half of patients with voluntary bowel movements
  - Total fecal continence (voluntary bowel movements, no soiling) in 37% of ARM; the lower the ARM, the chance of fecal continence
  - Constipation in 48% of ARM; the lower the ARM, the more likely to have constipation
- Positive prognostic factors for fecal continence: Good perineal raphe, well-defined anal dimple, normal spine, brisk muscle reflex
- Urinary incontinence (4):
  - Present overall in 9% of ARM
  - Highest probability in cloaca (19% if common channel <3 cm, 69% if >3 cm)
- Renal failure (CKD): 1–6% (5)

COMPLICATIONS

- Ongoing problems usually due to underlying congenital abnormality, not iatrogenic causes
- NGB in many ARM, but rarely due to surgery

FOLLOW-UP

Patient Monitoring

- Close follow-up needed to manage long-term problems like fecal and urinary incontinence and associated urologic abnormalities
- Should follow through puberty and child-bearing age due to potential for hydrometrocolpos/ hematocolpos, infertility, ectopic pregnancy, delivery issues

Patient Resources

CLINICAL/SURGICAL PEARLS

ARM usually requires neonatal surgical interventions and follow-up to obtain and maintain fecal and urinary continence.

ANORGASMIA, MALE

Robert L. Segal, MD, FRCS(C)
Arthur L. Burnett, II, MD, MBA, FACS

BASICS

DESCRIPTION

- Anorgasmia is defined as the complete inability to achieve an orgasm (the physical and emotional sensation experienced at the peak of sexual excitation) (1)
  - In males, orgasm is typically associated with ejaculation (antegrade semen passage through the urethra)
  - There is more robust literature in the female population with anorgasmia
  - Also described in some references as orgasmic disorder, orgasmic dysfunction, or orgasmic inhibition
- Anorgasmia is often associated with delayed/inhibited ejaculation or anejaculation, although orgasm and ejaculation are separate phenomena
  - Orgasm is a cerebrally mediated event, whereas ejaculation is localized to the genitourinary tract
- Must result in personal distress or interpersonal difficulty according to definitions by the DSM-IV-TR and the World Health Organization Second Consultation on Sexual Dysfunction (2)
- May be lifelong or acquired; may be global (every sexual encounter), intermittent or situational (in a certain environment, with a particular partner)

EPIDEMIOLOGY

Incidence

N/A

Prevalence

- Difficult to clearly report, as there is no clear definition of normal ejaculatory latency time
- In general, DE is reported at low rates in the literature, rarely exceeding 3% (3,4), but has been reported in up to 25% of clinical cohorts (2)

RISK FACTORS

- Advancing age
- Endocrinopathies (hypothyroidism, hypogonadism)
- Pelvic trauma/surgery (radical prostatectomy, proctocolectomy, bilateral sympathectomy)
- Pelvic radiation therapy
- Neuropathy (multiple sclerosis, diabetes mellitus, spinal cord injury)
- Secondary to medication (thiazide diuretics, tricyclic and selective serotonin reuptake inhibitor [SSRI] antidepressants, alcohol, gabapentin)

Genetics

N/A

PATHOPHYSIOLOGY

- Unless a specific organic cause is noted (see Risk Factors), anorgasmia is associated with underlying psychological factors
  - Fear, anxiety, hostility, and relationship difficulties
  - It has been suggested to relate to orthodoxy of religious belief (ie, it is sinful to experience orgasm/sexual pleasure)
  - "Performance anxiety" may be a common cause
- May relate to men deriving greater arousal/enjoyment from masturbation than intercourse (2)
  - Masturbatory frequency/style may be predisposing factors, as men with coital anorgasmia may report high levels of masturbation (2)
- Alcohol may transiently cause anorgasmia

ASSOCIATED CONDITIONS
- Anejaculation
- Delayed/inhibited ejaculation
- Depression
- Infertility

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Is the problem lifelong or acquired?
- Sexual history
  - Establish the conditions (if any) where the patient is able to experience orgasm
- Assess the presence of life stressors or other psychological factors, the quality of the patient's nonsexual relationship with the partner
- Medication use
  - SSRIs and gabapentin have been implicated

PHYSICAL EXAM
- Genital exam to verify the presence and normalcy of testicles and epididymides bilaterally
- Secondary sexual characteristics and hair distribution
- Neurologic exam to assess genital sensation
- May not be contributory

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum morning testosterone level
- As indicated
  - Semen analysis
  - Semen culture
  - Urine culture
  - Urine cytology
  - Thyroid screen

Imaging
Scrotal/transrectal ultrasound if indicated

Diagnostic Procedures/Surgery
None

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Psychiatric distress (anxiety, depression)
- Retrograde ejaculation
- Anejaculation
- Delayed ejaculation
- Reduced ejaculation
- Penile hypnoanesthesia

TREATMENT

GENERAL MEASURES
- Treatment should be etiology specific
- May include patient/couple psychoeducation and/or psychosexual therapy [C]
- Pharmacologic treatment has met limited success (2)

MEDICATION
First Line
None currently FDA approved

Second Line
- No drugs are specifically approved for treatment of anorgasmia, so any treatment is off-label (2)
  - Cyproheptadine (increases cerebral serotonin levels)
  - Amantadine (stimulant of dopaminergic nerves)
  - Bupropion, buspirone, and yohimbine have been anecdotally employed to reverse SSRI-induced anorgasmia

SURGERY/OTHER PROCEDURES
None

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
- Psychotherapy
- Masturbation retraining
- Education on revised sexual techniques which maximize arousal

Complementary & Alternative Therapies
Yohimbine has utility in anecdotal reports

ONGOING CARE

PROGNOSIS

- Continued support/psychotherapy may be required
- Anorgasmia related to trauma/surgery, radiation therapy, and neuropathies may not be reversible

COMPLICATIONS

None

FOLLOW-UP

Patient Monitoring

N/A

- Erectile Dysfunction, Following Pelvic Surgery or Radiation

CODES

ICD9

- 302.74 Male orgasmic disorder
- 608.89 Other specified disorders of male genital organs

ICD10

- F52.32 Male orgasmic disorder
- N53.11 Retarded ejaculation

CLINICAL/SURGICAL PEARLS

- Anorgasmia is often associated with ejaculatory disorders.
- Unless a specific organic cause is noted, anorgasmia is associated with underlying psychological factors.
- Anorgasmia related to trauma/surgery, radiation therapy, and neuropathies may not be reversible.
- There are no approved pharmacologic treatments for anorgasmia.

ANURIA AND OLIGURIA, ADULT

Won K. Han, MD

BASICS

DESCRIPTION

- Anuria: No urine output or <50 mL/d
- Oliguria: Urine output of 500 mL/d or <0.5 mL/kg/h
- Often the earliest sign of impaired renal function
- Associated with a severe decrease in the glomerular filtration rate (GFR) compromising kidney's main functions
  - Maintenance of body composition (such as fluid, acid–base, electrolyte content, and concentration)
  - Excretion of metabolic end products and foreign substances (urea, toxins, and drugs)

EPIDEMIOLOGY

Incidence

- Frequency depends on various clinical settings:
  - 1% at admission
  - 2–5% during hospitalization
  - 4–15% after cardiopulmonary bypass

Prevalence

N/A

RISK FACTORS

- Chronic kidney disease
- Congestive heart failure
- Diabetes mellitus
- Hypertension
- Myeloma
- Nephrotoxic medications

Genetics

N/A

PATHOPHYSIOLOGY

- Oligoanuria may result from 3 broad pathophysiologic processes: Prerenal, intrarenal, and postrenal causes
- Prerenal:
  - Physiologic responses that lead to decreased GFR
  - Maintain GFR by afferent arterial dilatation and efferent arteriolar constriction (mediated by angiotensin II)
  - Enhanced tubular reabsorption of salt and water
  - Prolonged renal hypoperfusion can lead to acute tubular injury
    - True volume depletion: Hemorrhage, gastrointestinal loss (vomiting, diarrhea, bleeding),

renal loss (diuretics, osmotic diuresis), skin or respiratory loss (insensible loses, burns), 3rd spacing (pancreatitis, crush injury, or skelet al fracture)
    - Decrease in effective circulating blood volume: Sepsis, heart failure, hepatic failure, nephrotic syndrome, anaphylaxis
    - Drugs affecting glomerular hemodynamics: Afferent arteriolar dilatation (nonsteroidal anti-inflammatory drugs [NSAIDs] or calcineurin inhibitors [CNIs]), efferent arteriolar constriction (angiotensin-converting enzyme inhibitors [ACEIs] or angiotensin II receptor blockers [ARBs])
- Intrarenal:
  - Associated with structural renal damage
    - Vascular (renal infarction, renal artery stenosis, renal vein thrombosis, etc.)
    - Tubular (ischemia, nephrotoxin)
    - Glomerular (acute glomerulonephritis, vasculitis, thrombotic microangiopathy)
    - Interstitium (interstitial nephritis, tumor infiltration)
- Postrenal (obstructive uropathy):
  - Mechanical or functional obstruction of the flow of urine
    - Intraureteral obstruction (stones, crystals, clots, tumor)
    - Extraureteral obstruction (tumor, retroperitoneal fibrosis)
    - Prostatic hypertrophy
    - Neurogenic bladder

ASSOCIATED CONDITIONS
- Chronic kidney disease
- Nephrolithiasis
- Diabetes mellitus
- Peripheral vascular disease
- Bladder outlet obstruction
- Pelvic and abdominal tumors

GENERAL PREVENTION
- Avoid nephrotoxic medications (NSAIDs, ARBs (angiotensin receptor blockers), ACEIs (angiotensin-converting-enzyme inhibitors), radiographic contrast) especially in the setting of impaired renal function
- Avoid hypotension (keep mean arterial pressure [MAP] >60 mmHg)
- Adequate hydration

DIAGNOSIS
HISTORY
- Age, gender
- Duration of symptoms
- Chronic kidney disease
- Diabetes mellitus
- Hypertension
- Cardiac disease
- Liver disease

- Organ transplantation
- Episode of hypotension (MAP <60 mmHg)
- Fluid losses
  - Vomiting, diarrhea
  - Diuretics
  - Burns, trauma, surgery
- Exposure to nephrotoxic medications
  - ACEIs, ARBs, NSAIDs
  - CNIs (cyclosporine, tacrolimus)
  - Aminoglycosides, cephalosporins amphotericin B, radiographic contrast
  - Acyclovir, sulfonamides, indinavir (can precipitate within the tubular lumen)
  - Anticholinergics
  - Chemo agents (cisplatin, methotrexate, 5-fluorouracil, interleukin-2, etc.)
- Symptoms of urinary tract obstruction
  - Anuria or oliguria
  - Urinary urgency, hesitancy
  - Intermittent polyuria
  - History of kidney stones
  - Gross hematuria

PHYSICAL EXAM

- Signs of intravascular depletion
  - Orthostatic hypotension
  - Tachycardia
  - Decreased skin turgor
  - Dry mucous membrane
- Signs of heart failure
  - Jugular venous distension
  - Rales or crackles in lung exam
  - Dyspnea, orthopnea
  - Gallop rhythm
- Signs of volume overload
  - Generalized edema
  - Ascites
  - Dyspnea
  - Paroxysmal nocturnal dyspnea
- Signs of abdominal compartment syndrome
  - Abdominal distension
  - Abdominal tenderness
- Signs of postrenal obstruction
  - Bladder distention
  - Enlarged prostate on rectal exam
  - Signs of urethral trauma
  - Pelvic mass
  - Patients with indwelling catheters should be irrigated to rule out blockage

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum electrolytes
  - Acute kidney injury (AKI)
    - Rise in serum creatinine (SCr) of at least 0.3 mg/dL over a 48-hr period
    - Over 1.5 times the baseline SCr value within the 7 previous days
  - Electrolyte and acid–base disorders
    - Metabolic acidosis
    - Hyponatremia
    - Hyperkalemia
    - Hyperphosphatemia
- Urinalysis with microscopic exam
  - Prerenal: High specific gravity, normal, or hyaline casts
  - Intrarenal:
    - Acute tubular necrosis (ATN): Low specific gravity, granular casts, muddy brown cast, tubular epithelial cells
    - Glomerulonephritis: Proteinuria, hematuria, red blood cell casts
    - Interstitial nephritis: White blood cells (WBCs), WBC casts, eosinophils, hematuria
    - Vascular disorders: Normal or hematuria
  - Postrenal: Normal or hematuria. WBCs, occasional granular casts
- Urine indices
  - Prerenal: Fractional excretion of sodium (FeNa) $<1\%$, serum Bun/Cr ratio $>20:1$
  - Intrarenal: FeNa $>1\%$, serum Bun/Cr ratio $<20:1$
  - Postrenal: FeNa variable, serum Bun/Cr ratio $>20:1$

Imaging

- Renal/bladder ultrasonography: 1st line in imaging, noninvasive, no radiation exposure
  - Hydronephrosis and hydroureter
  - Kidney stones
  - Pelvic/retroperitoneal masses
- Duplex Doppler ultrasound: To evaluate the patency of renal artery and vein
- Voiding cystourethrogram: To evaluate vesicoureteral reflux
- Nuclear renal scans (such as technetium 99 m mercaptoacetyltriglycine [MAC3]): To assess the adequacy of renal perfusion and obstructive uropathy
- Intravenous urography or intravascular contrast dye generally does not indicate as it may exacerbate renal injury

Diagnostic Procedures/Surgery

- Foley catheter placement: To rule out lower urinary tract obstruction
- Retrograde pyelography with cystoscopy: To define the site and cause of obstruction
- Urodynamic study: To evaluate functional abnormality of the bladder (neurogenic bladder)
- Renal biopsy: To determine intrarenal etiology

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Prerenal causes of AKI
  - Gastrointestinal loss
  - Renal loss
  - Heart failure
  - Hepatic failure
  - Nephrotic syndrome
  - Medications affecting renal hemodynamics
- Intrarenal causes of AKI
  - Renal ischemia
  - Nephrotoxins
  - Acute glomerulonephritis
  - Interstitial nephritis
  - Vascular complication
- Postrenal causes of AKI
  - Intraureteral obstruction
  - Extraureteral obstruction
  - Bladder outlet obstruction

TREATMENT

GENERAL MEASURES

- Prompt diagnosis of cause for oliguria/anuria to guide treatment
- All patients with oliguria/anuria should have a Foley catheter placed to monitor accurate urine output and eliminate lower urinary tract obstruction causes
- Appropriate medical managements for acid–base disorder, fluid imbalance, electrolyte imbalance (such as hyperkalemia, hyperphosphatemia, hypocalcemia)
- Renal replacement therapy: If supportive medical managements are not successful
  - Refractory hyperkalemia
  - Refractory volume overload
  - Refractory acidosis
  - Uremic pericarditis

MEDICATION

First Line

- Prerenal causes: Usually rapidly reversed following restoring renal perfusion
  - Replace fluid with intravenous hydration or blood product transfusion
  - Discontinue the nephrotoxic medications (NSAIDs, ARBs, ACEIs)
  - Optimize cardiac output and volume status
- Intrarenal causes: ATN is the most common cause
  - There is no single or sequence of interventions that will significantly improve renal function after onset of ATN (1)[A]
  - Use of diuretics and low-dose dopamine
    - Increasing urine output does not shorten the duration of renal failure, decrease the requirement for dialysis or improve survival in patients with established oliguric AKI (2,3)[A]

- Diuretics may be given for a short length of time for volume control
- Low-dose dopamine (1–3 μg/kg/min, intravenously) does not reduce mortality or promote the recovery of renal function (4)[A]

SURGERY/OTHER PROCEDURES

- Obstructive uropathy: Usually responds to release of the obstruction and type of procedure is depending on level of obstruction
  - Nephrostomy tube
  - Ureteral stent
  - Foley catheter
- Thrombotic microangiopathies and dysproteinemias (intrarenal causes)
  - Plasmapheresis/or plasma exchange

ONGOING CARE

PROGNOSIS

- Mortality rate depends on the underlying cause and associated medical condition
- In most clinical situations, acute oliguria is reversible and does not result in permanent renal impairment
- Identification and timely treatment of reversible causes are crucial because the therapeutic window may be small

COMPLICATIONS

- Inability to manage electrolytes and fluid balance resulting in various complications
  - Cardiovascular
    - Arrhythmias
    - Congestive heart failure
  - Gastrointestinal
    - Nausea and vomiting
    - Ileus
    - Bleeding
  - Neurologic
    - Confusion
    - Asterixis
    - Seizures
  - Infection
- Requirement of renal replacement therapy

FOLLOW-UP

Patient Monitoring

- Serial renal function testing for resolution
- Subsequent renal imaging study to confirm the resolution of postrenal obstruction

CODES

ICD9

• 593.9 Unspecified disorder of kidney and ureter
• 599.60 Urinary obstruction, unspecified
• 788.5 Oliguria and anuria

ICD10

• N13.9 Obstructive and reflux uropathy, unspecified
• N28.9 Disorder of kidney and ureter, unspecified
• R34 Anuria and oliguria

CLINICAL/SURGICAL PEARLS

• Oliguria is often the earliest sign of impaired renal function.
• Prompt diagnosis and timely treatment of reversible causes are crucial because the therapeutic window may be small.
• Diuretics and low-dose dopamine do not reduce mortality or promote the recovery of renal function.

ANURIA AND OLIGURIA, PEDIATRIC

Jennifer A. Hagerty, DO

BASICS

DESCRIPTION

- Typically 1st sign of impaired renal function
- Anuria: No urine output
- Oliguria: Significantly reduced urine volume
  - < 1 mL/kg/h in infants
  - < 0.5 mL/kg/h in children

EPIDEMIOLOGY

Incidence

- 10% of newborns in the NICU (1)[C]
- 2–5% of children in the ICU (1)[C]
- 10–30% of children undergoing cardiac surgery (1)[C]

Prevalence

N/A

RISK FACTORS

- Hypovolemia
- Intrinsic renal disease
- Urinary tract obstruction
- Glomerulonephritis
- Nephrotoxic medications

Genetics

Dependent on diagnosis

PATHOPHYSIOLOGY

- Prerenal failure
  - Most common cause of oliguria
  - Hypoperfusion in otherwise normal kidneys
  - Administration of nephrotoxic agents can precipitate oliguria when reduced renal perfusion is present
- Intrinsic renal failure
  - Associated with structural kidney damage including acute tubular necrosis (ischemia, drugs, or toxins), primary glomerular diseases, or vascular lesions
  - Altered tubule cell metabolism leads to ischemia, then altered metabolism and subsequently cell death
- Postrenal failure
  - Obstructive uropathy
  - Usually reversible with relief of the obstruction

ASSOCIATED CONDITIONS
- Pre-existing renal disease
- Obstructive uropathy

GENERAL PREVENTION
- Maintain adequate hydration
- Avoid nephrotoxic agents in children with underlying renal disease

DIAGNOSIS
HISTORY
- Age, sex
- Duration of symptoms
- Pre-existing renal disease
- Medications
- Symptoms of urinary tract obstruction
- Antenatal history
- Family history

PHYSICAL EXAM
- Signs of hypovolemia
  - Tachycardia
  - Hypotension
  - Decreased skin turgor
  - Dry mucous membranes
- Signs of hypervolemia
  - Edema
- Signs of obstructive uropathy
  - Palpable bladder or kidney
  - Meatal stenosis

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis
  - Protein, red cells, casts: Possible glomerulonephritis
  - Low specific gravity: Possible acute interstitial nephritis or intrinsic renal disease
  - High specific gravity: Possible prerenal cause
  - Nitrate: Suggests infection
- Basic metabolic panel
  - BUN/Cr ratio: >20 suggests prerenal cause
  - Evaluate renal function and electrolyte balance

Imaging
- Renal and bladder ultrasound for hydronephrosis and bladder distention and thickening of the wall
- VCUG for suspected bladder outlet obstruction
- Nuclear renal scan for function, dysplasia, and drainage

Diagnostic Procedures/Surgery
Placement of a urethral catheter

Pathologic Findings
Dependent on diagnosis

DIFFERENTIAL DIAGNOSIS
- Prerenal
  - Burns
  - Dehydration
  - Drugs
  - GI losses
  - Heart disease
  - Hemorrhage
  - Respiratory distress syndrome
  - Shock/sepsis
- Intrinsic renal disease
  - Acute tubular necrosis
  - Exposure to nephrotoxins (drugs, myoglobin, uric acid)
  - Congenital kidney disease
  - Renal vascular abnormalities
  - Glomerulonephritis
- Urinary tract obstruction
  - Neurogenic bladder
  - Posterior urethral valves
  - Meatal stenosis
  - Bilateral UPJ or ureteral obstruction or unilateral in a solitary kidney
  - Bilateral obstructing calculi

TREATMENT

GENERAL MEASURES
- Treatment of the underlying cause
- Appropriate medical managements for acid–base disorder, fluid imbalance, electrolyte imbalance (such as hyperkalemia, hyperphosphatemia, hypocalcemia)
- Strict volume monitoring of input and output
- Avoidance of nephrotoxic agents (NSAIDs, ARBs (angiotensin receptor blockers), ACEIs (angiotensin-converting-enzyme inhibitors))

MEDICATION
First Line
Hydration to optimize cardiac output and volume status

Second Line
- Diuretics considered if adequate intravascular volume status and patient remains oliguric
- Hemodialysis or peritoneal dialysis to be considered if severe electrolyte abnormalities or volume overload

SURGERY/OTHER PROCEDURES
Relief of obstruction with urethral catheter, ureteral stenting, or nephrostomy tube

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
None

ONGOING CARE
PROGNOSIS
- Acute oliguria is often completely reversible if recognized and treated promptly
- Small increases in serum creatinine can be indicative of worsening outcome (2)[C]

COMPLICATIONS
- Progression to permanent renal injury
- Infections secondary to uremia leading to impaired defenses
- Cardiovascular complications secondary to fluid overload and electrolyte abnormalities
- Neurologic changes: Confusion, lethargy, and seizures
- Gastrointestinal effects: Anorexia, nausea, and vomiting

FOLLOW-UP
Patient Monitoring
- Serial renal function testing until resolution of anuria/oliguria
- Imaging based on diagnosis
  – Monitor renal/bladder ultrasound for obstructive uropathy

Patient Resources
- American Society of Pediatric Nephrology: www.aspneph.com
- National Kidney Foundation: www.kidney.org

CODES

ICD9
- 276.52 Hypovolemia
- 599.60 Urinary obstruction, unspecified
- 788.5 Oliguria and anuria

ICD10
- E86.1 Hypovolemia
- N13.9 Obstructive and reflux uropathy, unspecified
- R34 Anuria and oliguria

CLINICAL/SURGICAL PEARLS
- Prerenal oliguria is typically reversible with complete return of renal function within 24–72 hr.
- Avoid nephrotoxic agents in patients with underlying intrinsic renal failure.

AUTONOMIC DYSREFLEXIA

Michael J. Amirian, MD
Patrick J. Shenot, MD, FACS

BASICS

DESCRIPTION

- Autonomic dysreflexia (AD) occurs in patients with spinal cord lesions at and above the 6th thoracic level (T6)
- Potentially life-threatening condition in response to noxious stimuli
  - Genitourinary cause is the most common trigger for AD
  - Bladder distention, instrumentation of the urinary tract, and UTI are the most common causes to trigger AD
- Rapid, extreme BP elevation, bradycardia, headache, diaphoresis, sweating, nausea, and piloerection

EPIDEMIOLOGY

Incidence

Unknown

Prevalence

- ~85% of quadriplegic and high paraplegic individuals prone to AD in response to noxious stimuli
- More common in men than women
  - Due to increased bladder outlet resistance

RISK FACTORS

- Male
- High spinal cord injury (SCI)

Genetics

None

PATHOPHYSIOLOGY

- Activation of sympathetic neurons in lateral horn of spinal cord causing unopposed reflex sympathetic activity
  - Stimuli (bladder or bowel distention and pain) cause activation
- Vasoconstriction and subsequent hypertension (HTN)
  - In response, vagal nerve triggers bradycardia
- Vagal nerve is able to vasodilate above injury (flushing in face), but vessels below injury remain vasoconstricted
- Other symptoms of sympathetic activation
  - Diaphoresis and piloerection

ASSOCIATED CONDITIONS

SCI

GENERAL PREVENTION
- Avoid rapid or prolonged bladder distention
- Maintain regular schedule of bowel emptying
- Monitor for pressure sores

DIAGNOSIS
HISTORY
- SCI or transverse myelitis at T6 or above
- Screen for urologic causes
  - Bladder distention
  - Recent instrumentation
  - Indwelling urethral or suprapubic tube
  - Urinary tract infection
  - Renal, ureteral, or bladder calculi
  - Epididymitis or orchitis
  - Ejaculation
  - Urodynamic testing
- Nonurologic causes
  - Bowel distention
  - Pressure sores
  - Tight clothing
  - Ingrown toenails
  - Sexual intercourse
  - Pregnancy and labor
- Symptoms may include blurred vision, nasal congestion, anxiety

PHYSICAL EXAM
- BP often severely elevated and often accompanied by bradycardia
  - Consider that the resting BP is decreased after SCI (ie, 90/60)
  - A normal BP of 120/80 may actually represent HTN in this patient population
  - A BP 20–40 mmHg above the patients baseline may be a sign of AD
- Flushing and profuse sweating above level of injury
- Piloerection (“goose bumps” with cold or clammy skin below the level of the SCI)
- Evaluate for noxious stimuli below level of SCI
  - Skin
    - Infection, pressure sores
    - Ingrown nails
    - Burns
    - Tight-fitting clothing

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis and urine culture
  - Evaluate for infection
  - UTI can be a trigger for AD

Imaging
- CT of abdomen and pelvis
  - Evaluate for urolithiasis if cause not apparent

Diagnostic Procedures/Surgery
- Urodynamic tests to:
  - Evaluate bladder compliance
  - Rule out persistently elevated bladder pressures

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Brain stem tumors
- Paroxysmal HTN
- Pheochromocytoma
- Preeclampsia

TREATMENT

GENERAL MEASURES
- Removal of triggering stimulus is the 1st step
  - Minimize noxious stimuli below level of injury
  - Bladder drainage or bowel decompression
  - If present, consider gentle Foley catheter irrigation with no more than 10–20 mL saline to make sure that the catheter is patent
- Monitor BP closely during acute episodes
  - BP >150 mmHg requires urgent management to avoid severe complications
- Sitting the patient upright might reduce BP

ALERT
Left untreated consequences of autonomic dysreflexia can cause seizures, intracranial bleeds, hypertensive encephalopathy, and death.

MEDICATION
First Line
- Acute episodes managed with nitrates or arterial dilators under closely monitored conditions
  - Nitrates: Sub lingual nitroglycerine, apply 1”, 2% nitro paste
    - Nitrates should be avoided in patients who may be using PDE-5 inhibitors (sildenafil vardenafil, tadalafil) for erectile dysfunction
  - Nifedipine 10 mg PO immediate release form
    - “Bite and swallow” technique
  - Captopril 25 mg SL
  - Hydralazine or labet alol 10 mg IV
- Chronic treatment with α-blockers may improve some symptoms of AD (1)[B]
  - Doxazosin 2–8 mg PO QD
  - Terazosin 2–5 mg PO QD-BID

– Tamsulosin 0.4 mg PO QD
– Alfuzosin 10 mg PO QD

- Appropriate antibiotics if UTI suspected

Second Line

- Phenoxybenzamine 10 mg PO BID
- Botulinum toxin injection into the detrusor
  – For patients on intermittent catheterization to decrease bladder pressure
- Botulinum toxin injection into external sphincter
  – For patients who void reflexively to decrease voiding pressures

SURGERY/OTHER PROCEDURES

- Sphincterotomy or sphincter stent prosthesis
  – Allows reflex voiding with low-pressure bladder emptying into a condom catheter (2)[A].
- Bladder augmentation
  – Only in patients with ability to catheterize
- Sacral rhizotomy
  – For severe cases (3)[B]

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Managed effectively will have little impact on patient

COMPLICATIONS

Intracerebral and subarachnoid hemorrhage

FOLLOW-UP

Patient Monitoring

- Clean intermittent catheterization
  – Frequent (at least 4 times daily)
- Regular bowel program
- Assess AD symptoms and BP at every appointment
- Teach SCI patients significance of AD
  – Symptoms should prompt patients to empty bladder and bowel

- Autonomic Dysreflexia Image
- Detrusor-Sphincter Dyssynergia
- Spinal Cord Injury

CODES

ICD9

- 337.3 Autonomic dysreflexia
- 596.89 Other specified disorders of bladder
- 599.0 Urinary tract infection, site not specified

ICD10

- G90.4 Autonomic dysreflexia
- N32.89 Other specified disorders of bladder
- N39.0 Urinary tract infection, site not specified

CLINICAL/SURGICAL PEARLS

- Most common triggers are from the genitourinary system such as bladder distention or instrumentation.
- AD occurs at and above level of T6.
- Chronic treatment with α-blockers may improve some symptoms of AD.
- Sphincterotomy or sphincter stent prosthesis allows reflex voiding with low-pressure bladder emptying into a condom catheter.

BACTERIURIA AND PYURIA

Mary K. Powers, MD
Raju Thomas, MD, MHA, FACS

BASICS

DESCRIPTION

- Urinary tract infection (UTI) is an inflammatory response of urothelium to bacterial invasion that is usually associated with bacteria and pyuria.
- Bacteriuria: Presence of bacteria in the urine, which is normally bacteria free
- Bacteriuria = valid indicator of bacterial infection or colonization
  - Can be either symptomatic or asymptomatic
  - Significant bacteriuria: Quantitative count $>1 \times 10^5$ colony forming units (CFL/mL) in 2 consecutive specimens
  - Majority of individuals with significant bacteria have significant pyuria
  - Usually 1 organism
  - >1 organism: Either contamination or polymicrobial infection
- Pyuria: Presence of WBC in the urine:
  - Generally implies an inflammatory response or infection
  - Significant pyuria: >10 WBCs/HPF centrifuged
  - Close association between pyuria and bacteriuria; 96% of patients who are symptomatic and bacteriuric have >10 WBCs/HPF
- Sterile pyuria: Presence of WBCs in the urine in the absence of bacteriuria:
  - Contamination: Vaginal or prepuce secretions
  - Infections: Treated UTI, mycobacterial, TB, chlamydial, gonococcal, fungal (GU or systemic), viral, haemophilus, bilharzia
  - Other infections: Appendicitis, diverticulitis, prostatitis
  - Noninfectious: Nephritis, stones, foreign bodies, transplant rejection, trauma, malignancy, chemotherapy, nephrotoxic substances, drug-induced interstitial nephritis
- Cystitis: Clinical syndrome of dysuria, frequency, urgency occasionally with suprapubic pain
  - Usually indicative of bacterial cystitis but can be associated with infections of the urethra or vagina or noninfections process such as interstitial cystitis, bladder carcinoma, or calculi

EPIDEMIOLOGY

Incidence (1)

- 0.3–0.5 episodes of bacteriuria per person per year among asymptomatic females aged 18–40
- Newborns:
  - Males: 1.5–3.6%; females: 0.4–1.0%
- 1–5 yr:
  - Males: 0.0–0.4%; females: 0.7–2.7%
- School-age:

  – Males: 0.04–0.2%; females 0.7–2.3%
- Adult (middle-age):
  – Males <1%; females 4–6%
- Older adults:
  – Males 11–13%; females 6–33%
- Almost 100% prevalence of bacteriuria in individuals with long-term, indwelling catheters

Prevalence

- Pregnancy: 2–7% of all pregnant females (2)
- Elderly: 20% of females, 10% of males
  – 24% of nursing home residents vs. 12% of healthy domiciliary elderly (3)

RISK FACTORS

Age, diabetes mellitus, sexual intercourse, use of diaphragm or spermatocide, delayed postcoital micturition, history of recent infection, immunosuppression, long-term indwelling catheters, pregnancy, neurologic disorders, foreign bodies, stones, obstructive uropathy, vesicoureteral reflux.

Genetics

Certain populations may be more susceptible to bacteriuria and recurrent UTIs due to distinct molecular defects causing impaired host responses. Certain receptor sites on epithelial cells may predispose some women to UTIs.

PATHOPHYSIOLOGY

- Urinary tract is normally sterile.
- Bacteriuria usually ascends up the urinary tract from colonizing flora of the gut, vagina, or distal urethra.
- Bacteriuria can also invade the urinary tract hematogenously or through direct transfer after instrumentation.
- Bacteria colonize the urinary tract and then multiply, causing inflammation with pyuria.
- Bacterial factors:
  – Certain bacteria are more efficient at adhering to mucosal cells than others due to fimbria.
  – Virulence factors: Hemolysis, adhesions, colicin, metabolic properties, etc.
- Host factors:
  – Cystitis prone: Certain patients are more prone to bacteriuria (transitional cell bacterial receptor sites).
  – Menstrual cycle: Bacteriuria may be influenced by hormones.
  – Postmenopausal: Increasing incidence of bacteriuria
  – Vaginal pH: Normally acidic pH; colonization with uropathogens may occur as vaginal pH rises
  – Competitive organisms: Normal vaginal flora discourages uropathogenic colonization
  – Buccal and vaginal cells: More receptive to uropathogens' adherence in cystitis-prone patients
  – Local production of IgA, IgG may play defense role.
  – Production of mucous protective layer as a local bladder defense
  – Blood group antigen (secretors) saturate or block bacterial adherence.

ASSOCIATED CONDITIONS
Diabetes mellitus, pregnancy, immunosuppression, structural urinary tract abnormalities, indwelling catheters

GENERAL PREVENTION
- Screening and treatment of asymptomatic bacteriuria in at-risk populations such as pregnant patients or prior to urologic intervention can prevent subsequent morbidity of UTIs.
- Screening of asymptomatic spinal cord injury patients or those with indwelling Foley catheter is not recommended.
- Bacteriuria and pyuria from an incompletely treated UTI may be avoided with the appropriate use of antibiotic class with sufficient duration; patient compliance should be encouraged.

DIAGNOSIS
HISTORY
- Dysuria, frequency, urgency, malaise, rarely low-grade fever, malodorous urine
- Occasionally hematuria (gross): Especially in the female patient; uncommon in children and men
- Fever and flank pain with upper tract origin: Pyelonephritis
- Asymptomatic or atypical symptoms: Young and old patients
- Young patients: Abdominal discomfort, failure to thrive, fever, vomiting, jaundice
- Older patients: May be asymptomatic or have incontinence, fevers, frequency, and urgency
- Varied symptoms with sterile pyuria associated with differeing conditions
- History of childhood fevers: May imply UTIs and associated congenital abnormalities
- Problems with toilet training, urgency, incontinence
- UTI family history: Mothers, daughters, sisters
- History of a risk factor for bacteriuria

PHYSICAL EXAM
- Suprapubic tenderness: Cystitis
- Flank tenderness: Pyelonephritis
- Fever: Usually with upper tract infection
- Children may have abdominal discomfort, tenderness, or distention.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Indications for screening:
  - Symptomatic patients
  - Pregnant women
  - Prior to genitourinary procedures
- Urine dipstick: Best for screening:
  - Leukocyte esterase test:
    - Detects enzyme release by WBCs
    - Sensitivity 90%, specificity 95% for UTI
  - Conversion of nitrate to nitrite (Griess test): 70–80% sensitivity for UTI
  - Catalase test: Cannot differentiate infection from inflammation

- Microscopy:
  - Rapid in-office test: 80% accurate; usually fresh unspun
  - Centrifugation: Increases finding 10-fold
  - Difficult to see bacteria if $<1 \times 10^5$ CFU/mL
  - Vaginal organisms may be misread as uropathogens: Lactobacilli and Corynebacterium
- Gram stain: Increases identification of bacteria with sensitivity and specificity of 96.2% and 93.0%, respectively
- Urine culture:
  - Clean-catch midstream urine: Commonly used
  - Catheterized urine: May be necessary to assure diagnosis or in special situations (ie, children, patients unable to void, the debilitated, the obese)
  - Segmented urine specimen, initial 10 mL, midstream, post exam: For localization of bacteria or WBCs
  - Quantitative counts in UTI are usually $>1 \times 10^5$ CFU/mL with a uropathogen
    - Range 1×10^2 to 1×10^6
    - $<10^5$ per milliliter in 47% of patients
    - $<10^4$ per milliliter in 30% of patients
    - $>10^2$ per milliliter: Uropathogen; suspect UTI
- Conditions causing variation: Hydration, bacterial growth rate, urinary pH, pyelonephritis, catheterized specimen:
  - Multiple organisms usually indicate contamination or polymicrobial infection
- Uncomplicated infections: *Escherichia coli*, other Enterobacteriaceae, *Staphylococcus saprophyticus*, enterococci
- Complicated infections: *E. coli*, other Enterobacteriaceae, *Pseudomonas*, *S. aureus*, coagulase negative staph, enterococci
- Contaminants: Lactobacilli, streptococci, diphtheroids, *Gardnerella, Mycoplasma*, coagulation-negative staph

Imaging

- Bacteriuria:
  - Childhood: US, VCUG, radionuclide cystogram, IV pyelogram
  - Adult: Only indicated if suspicious of pathology or childhood history, obstruction, stone disease, hematuria, febrile infections, failure to respond to therapy, recurrent UTIs
  - Imaging in routine UTIs involving normal adult females: Very low yield of pathology
- Pyuria:
  - Associated with infection and bacteriuria: Same indications
  - Sterile pyuria evaluation for other causes
  - Isotopic function studies and cystogram
  - CT: Localization of nidus or abnormality responsible for bacteriuria/pyuria (ie, abscess)

Diagnostic Procedures/Surgery

Localization of bacteria: Segmented urine, ureteral catheterization, immunologic antibody studies

DIFFERENTIAL DIAGNOSIS

- Cystitis: Pyuria, positive culture, abrupt onset
- Urethritis: Pyuria, negative urine culture, gradual onset
- Vaginitis: No pyuria, vaginal discharge, pruritus
- Pyelonephritis
- Noninfectious causes
  - Interstitial cystitis
  - Nonuropathogenic cause, as in sterile pyuria
- Contamination with vaginal/skin flora

TREATMENT

GENERAL MEASURES

- Obtain urine culture:
  - Indwelling catheters should be used as infrequently as possible
  - In patients with indwelling catheter, urine specimen for culture should be obtained at the time catheter is changed under sterile conditions from newly placed catheter

MEDICATION

- Asymptomatic bacteriuria is treated as a UTI in childhood, prior to urologic surgery, and in pregnancy.
  - Persistent or recurrent bacteriuria may need treatment for more prolonged periods followed by chronic low-dose medication.
    - TMP-SMX (Trimethoprim-sulfamethoxazole) 40/200 mg daily
    - Nitrofurantoin 50–100 mg daily
    - Cephalexin 250 mg daily
  - Postmenopausal: Treated only if symptomatic or associated with complicating factors:
  - Diabetes, obstruction, immunosuppression (14–21 days of therapy)
    - Norfloxacin 400 mg PO BID
    - Ciprofloxacin 500 mg PO BID
    - Gentamicin 1–1.7 mg/kg IV Q8h
    - Ceftriaxone 1–2 mg IV/Q 24 h
  - Catheter-associated bacteriuria, if asymptomatic, should not be treated (may be due to colonization).
- Bacteriuria in pregnancy should be treated, as untreated bacteriuria is linked with prematurity, IUGR, low birth weight, and neonatal death.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

Cranberry juice may decrease frequency of bacteriuria and pyuria in selected populations.

ONGOING CARE

PROGNOSIS

Variable severity ranging from asymptomatic bacteriuria to severe UTI with urosepsis and secondary organ failure

COMPLICATIONS

20–40% of untreated bacteriuria in pregnancy leads to pyelonephritis

FOLLOW-UP

Patient Monitoring

- Repeat exam: 2 wk posttreatment, not necessary in young women who are asymptomatic after therapy
  - Microscopic urinalysis and culture
- Periodic office visits to verify sterile urine
- 2008 USPSTF guidelines:
  - In pregnant women, high certainty exists that net benefit of screening for asymptomatic bacteriuria is substantial (1)[A].
  - In men and nonpregnant women, there is moderate certainty that the harms of screening for asymptomatic bacteriuria outweigh the benefits. (1)[D]
  - Adults with diabetes were included in this recommendation, for the general adult population, the USPSTF did not consider evidence for screening specific patient groups at high risk for severe UTIs, including transplant recipients, patients with sickle cell disease, and those with recurrent UTIs.

CLINICAL/SURGICAL PEARLS

Screening of asymptomatic spinal cord injury patients or those with indwelling Foley catheter is not recommended.

BALANITIS AND BALANOPOSTHITIS

H. Henry Lai, MD, FACS
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION

- Balanitis: Inflammation of the glans penis.
- Balanoposthitis: Inflammation of the foreskin and glans penis (affects uncircumcised men).

EPIDEMIOLOGY

Incidence

- Can occur at any age.
- No incidence studies of balanoposthitis have been reported in US.
  - 1.5% of uncircumcised boys ages 0–15 were affected in a Japanese cohort.

Prevalence

- Common, the exact prevalence is unknown.
  - Balanitis affects 11% of adult men and 3% of boys seen in urology clinics.

RISK FACTORS (1)

- Presence of a foreskin (uncircumcised)
- Tight foreskin (phimosis)
- Poor genital hygiene
- Intertrigo (see below)
- Sexual contact (with or without infection)
- Poorly controlled diabetes mellitus
- Immunocompromised host
- Coexisting penile cancer

Genetics

N/A

PATHOPHYSIOLOGY (2)

- The pathophysiology is usually different in young boys compared to adult men:
  - Boys: From bacterial invasion of tissue
  - Men: Combination of poor genital hygiene, intertrigo, irritant dermatitis, maceration injury, and bacterial, or candidal overgrowth
  - Candida is the most common infectious cause
- Intertrigo refers to a condition in which damp, moist body areas are predisposed to inflammation:
  - Involves genitals, inner thighs, underbelly
  - Risk factors: Grossly overweight, diabetes, bed rest, diaper use, poor personal hygiene
  - Skin dampness predisposes to secondary opportunistic bacterial or fungal overgrowth
- Balanitis xerotica obliterans (BXO) is a specific form of balanitis:
  - Chronic, progressive, fibrotic disease (a form of lichen sclerosis isolated to the penis)

  - Elastin is replaced by collagen
  - The skin around the meatus becomes white, featureless, contracted, causing meatal stricture
  - BXO may spread to the foreskin and coronal sulcus. In extreme cases, the entire end of the penis is replaced by fibrotic tissue, becomes thickened and nonretractile, causing sexual and voiding issues (eg, weak stream, obstruction)

ASSOCIATED CONDITIONS
Diabetes mellitus

GENERAL PREVENTION
- Maintain good genital hygiene
- Retraction of foreskin to clean the glans
- Keep the glans and foreskin dry
- Circumcision
- Safe sexual contact
- Manage risk factors (eg, glycemic control)

DIAGNOSIS

HISTORY
- Symptoms may include: Pain, discharge, irritation, voiding symptom (dysuria, weak stream)
- Prior episodes and treatment
- Uncircumcised
- Foreskin retractability
- Genital hygiene habits
- Sexual contacts, sexually transmitted diseases
- Other systemic risk factors (eg, diabetes)

PHYSICAL EXAM
- Inspection (ulcers, mass, genital pus, edema)
- Palpation (tenderness, induration, mass)
- Inguinal lymph nodes should be nonpalpable

DIAGNOSTIC TESTS & INTERPRETATION
Lab
Swab of glans/foreskin for viral, bacterial, and fungal culture

Imaging
N/A

Diagnostic Procedures/Surgery
- Potassium hydroxide and Tzanck preparation for men
  - Potassium hydroxide smear evaluates for fungus
  - Tzanck preparation for herpes virus

Pathologic Findings
- Biopsy is indicated for:
  - Balanitis that persists and in which the cause remains unclear warrants biopsy to rule out

coexisting neoplasm or premalignant lesions
– For definitive diagnosis of BXO

DIFFERENTIAL DIAGNOSIS
- Fixed drug eruption (allergy)
- Contact dermatitis
- Squamous cell carcinoma of the penis
- Carcinoma in situ of the penis
- Zoon (plasma cell) balanitis
- Psoriasis
- Reiter syndrome (Reactive arthritis/reactive arthritis triad) (with circinate balanitis)
- Human papilloma virus

TREATMENT

GENERAL MEASURES
- Meticulous genital hygiene
- Keep the glans and foreskin clean and dry
- Expose the glans to air as often as possible
- Avoid excessive dampness in the genitals
- Avoid soaps while inflammation is present
- Cleaning with soap and water routinely
- Manage risk factors (eg, glycemic control)

MEDICATION
Treatment depends on the underlying cause (infectious vs. inflammatory) and organisms

First Line
- Candidal infection: The most common cause of infectious balanitis
  – Clotrimazole cream 1%
  – Miconazole cream 2%
  – Apply BID until symptoms resolve
  – Oral fluconazole if symptoms are severe
  – Nystatin cream if allergic to imidazole
  – Imidazole with hydrocortisone if inflammation
- Anaerobic infection:
  – Metronidazole 400 BID for 1 wk
  – Optimal dosage schedule is unknown
  – Alternatively, amoxicillin/clavulanic acid PO or clindamycin topically
- Aerobic infection:
  – Group A streptococci, *Staphylococcus aureus*, *Gardnerella vaginalis* are all reported cases of balanitis.
  – Treatment based on sensitivity of the culture (topical antibiotics, occasionally oral antibiotics)
- BXO:
  – Topical steroids (clobetasol propionate or betamethasone valerate) offers limited efficacy

- Zoon (plasma cell) balanitis:
  – Topical steroids with or without antibacterial cream
- Circinate balanitis (Reiter syndrome):
  – Hydrocortisone cream 1% apply BID
  – Treatment of associated infection
- Irritant, allergic balanitis:
  – Avoid exposure to irritants especially soaps
  – Emollients aqueous cream: Apply PRN and used as a soap substitute while inflammation is present
  – Hydrocortisone 1% apply QD or BID until symptoms resolve

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Circumcision is reserved for recurrent balanitis, balanoposthitis, or phimosis that have failed conservative treatments.
- Occasionally dorsal slit may be performed.
- For BXO that does not respond to steroid:
  – Periodical self-dilation with tapered dilators
  – Dilation by urologists
  – Formal surgical reconstructive repair

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Can be recurrent or persistent
- 10% recurrence rate
- Some patients may require circumcision to prevent recurrence and ensure resolution.

COMPLICATIONS

- Abscess formation
- Penile cellulitis
- Progression to Fournier gangrene
- Scarring and subsequent phimosis

FOLLOW-UP

Patient Monitoring

- After an acute episode and treatment is implemented, patients should be seen again to

ensure resolution of symptoms and infection.
– Progression to cellulitis or gangrene may occur in diabetic patients with genital infection.
• Follow closely with genital dysplasia among those men with condyloma with a history of balanoposthitis than those with no such history.

• 607.1 Balanoposthitis
• 607.81 Balanitis xerotica obliterans

ICD10
• N47.1 Phimosis
• N47.6 Balanoposthitis
• N48.1 Balanitis

CLINICAL/SURGICAL PEARLS
• Maintaining good genital hygiene is a key preventive strategy (keep the foreskin and glans clean and dry).
• Underlying risk factors should also be managed (eg, glycemic control in diabetes).
• Treatment depends on the underlying cause (infectious vs. inflammatory) and organisms.
• Circumcision is reserved for recurrent balanitis, balanoposthitis, or phimosis that have failed conservative treatments.
• Balanitis that persists and if the cause remains unclear warrants biopsy to rule out coexisting neoplasm or premalignant lesions.

BCG SEPSIS/BCG-OSIS

John B. Eifler, MD
Michael S. Cookson, MD

BASICS

DESCRIPTION

- BCG sepsis: Potentially life-threatening event secondary to intravasation of intravesical BCG resulting in cardiovascular collapse and acute respiratory distress
  - Possible etiologies include hypersensitivity reaction and bacterial sepsis
- "BCG-osis" is a term used to refer to disseminated disease in patients treated with BCG
  - The lungs and liver are typically involved
  - Patients are usually hemodynamically stable

EPIDEMIOLOGY

Incidence

- >95% of patients treated with BCG have no significant morbidity (1).
- 1 in 15,000 patients treated with intravesical BCG will develop BCG sepsis (2).
- 10 reported deaths due to BCG sepsis (3).

Prevalence

N/A

RISK FACTORS

- Inadequate delay after transurethral instrumentation (TURBT or bladder biopsy)
- Traumatic catheterization or gross hematuria at time of intravesical instillation

Genetics

N/A

PATHOPHYSIOLOGY

- BCG is live attenuated *Mycobacterium bovis*
- Intravasation of BCG through damaged urothelium with subsequent systemic response
- Symptoms may be related to mycobacterial infection and/or hypersensitivity reaction

ASSOCIATED CONDITIONS

- Recent transurethral instrumentation
- Traumatic catheterization
- Concomitant UTI
- Age >70

GENERAL PREVENTION

- The following will minimize the risk of BCG sepsis; however, no strategy has been shown to be effective at eliminating the risk (2,4)
  - Defer installation of BCG at least 2 wk after instrumentation
  - Abort instillation if hematuria or traumatic Foley catheter placement
  - Do not treat with active UTI

– Avoid BCG in immunocompromised host
– BCG cystitis (see below): Delay future instillations until complete resolution of symptoms
– BCG sepsis: Avoid any future BCG instillation

DIAGNOSIS

HISTORY

- BCG cystitis: Dysuria, frequency 2–4 hr after installation +/– low-grade fever, malaise, hematuria
  – Typically resolves within 48 hr
- Regional infection is common though often asymptomatic (eg, 75% develop granulomatous prostatitis) and distant infection (hepatitis, osteomyelitis, pneumonitis) may occur
- Symptoms often occur within 2 hr of instillation but may occur years after therapy
- Symptoms of systemic infection: Intermittent fever >39°C (102.2°F) with drenching night sweats lasting >48 hr
- BCG sepsis: Fever, rigors, progressing to vascular collapse and respiratory distress
  – Often occurs within hours of instillation

PHYSICAL EXAM

- BCG sepsis
  – High fevers (>38.5°C/101.3°F) within 2 hr of treatment, resembling gram-negative sepsis
  – Hypotension/shock physiology
- BCG cystitis
  – Suprapubic tenderness to palpation
  – Hematuria
  – Low-grade fevers

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Mild/moderate symptoms
  – Urine culture
- Severe symptoms (Sepsis, severe cystitis symptoms >48 hr)
  – Urine, blood cultures
  – Liver function tests to assess for hepatitis
  – CXR to assess for pneumonitis
  – Acid-fast testing of urine
  – Consider PCR testing for mycobacterial DNA if disseminated BCG suspected
- Coagulation studies: PT/PTT/fibrinogen if DIC suspected

Imaging

See “Lab”

Diagnostic Procedures/Surgery

See “Lab”

Pathologic Findings

- Noncaseating granulomas
  – May be found in lung, liver, bone, prostate, kidney, epididymis

DIFFERENTIAL DIAGNOSIS

- Post-BCG bacterial cystitis
- BCG cystitis (cytokine release without intravasation of BCG)
- Gram-negative sepsis

TREATMENT

GENERAL MEASURES

- Consultation with infectious disease specialist is recommended for septic patients (2,4)
- If antitubercular therapy required, intravesical BCG should be discontinued (2)

MEDICATION

First Line

- Mild/moderate symptoms including low-grade fevers < 48 hr (BCG cystitis) (2,4,5)
  - Analgesics
  - NSAIDs
  - +/– Fluoroquinolone
    - Such as levofloxacin 500 mg/d
    - Helpful for bacterial cystitis and has mild antitubercular activity
- Antitubercular medications should be initiated for signs of sepsis or severe cystitis symptoms > 48 hr (2 – 5)
  - Typically isoniazid 300 mg/d and rifampin 600 mg/d for 3–6 mo
  - For solid organ involvement, ethambutol 15 mg/kg/d added
  - BCG resistant to cycloserine and pyrazinamide
  - Prednisone 40 mg/d recommended for septic shock or if hypersensitivity reaction suspected

Second Line

N/A

SURGERY/OTHER PROCEDURES

Not indicated; supportive care only

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Good if treatment initiated in timely manner

COMPLICATIONS

Solid organ involvement

FOLLOW-UP

Patient Monitoring

ICU admission with invasive monitoring for BCG sepsis

Patient Resources

N/A

- 999.39 Infection following other infusion, injection, transfusion, or vaccination

ICD10

- A41.89 Other specified sepsis
- T80.29XA Infct fol oth infusion, transfuse and theraputc inject, init

CLINICAL/SURGICAL PEARLS

- Patients undergoing intravesical BCG therapy who have traumatic catheterization or gross hematuria should delay therapy until symptoms resolve.
- Patients with high fever (>38.5°C/101.3°F) or severe cystitis symptoms lasting >48 hr should be hospitalized and undergo additional testing.

BLADDER AREFLEXIA (DETRUSOR AREFLEXIA)

H. Henry Lai, MD, FACS
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION

- Bladder areflexia (detrusor areflexia) is the inability of the bladder to contract to empty.
- Requires urodynamics study for diagnosis.
- Presentation may include urinary retention, incomplete emptying, and overflow incontinence.

EPIDEMIOLOGY

Incidence

No incidence study has been reported. The risk of urinary retention may increase with aging.

Prevalence

- No prevalence study has been reported in US.
  - 40% of men and 13% of women over the age of 65 have detrusor underactivity during urodynamics in a Korean cohort (1,179 patients).
  - 48% of men and 12% of women over the age of 70 have underactivity in a study from Israel.

RISK FACTORS

- Diabetes mellitus
- Longstanding bladder outlet obstruction
- Neurologic diseases
- Recent radical pelvic surgery

Genetics

- Genetic diseases predisposing to bladder dysfunction include:
  - Muscular dystrophy
  - Neurofibromatosis

PATHOPHYSIOLOGY

- May result from primary detrusor muscle failure (myogenic causes) and/or neurologic causes (eg, from lower motor neuron lesions, injury to sacral spinal cord, multiple sclerosis).
- Patients often attempt to void by valsalva.
- Success of emptying depends on resistance of smooth and striated sphincter mechanisms.
- Continence depends on sphincter competence.

ASSOCIATED CONDITIONS

- Cauda equina syndrome
- Diabetes mellitus
- Fowler syndrome (“nonneurogenic, neurogenic bladder”)
- Intervertebral disc diseases

- Longstanding bladder outlet obstruction with detrusor decompensation (myogenic failure)
- Lumbosacral spinal surgery
- Lyme disease
- Multiple sclerosis
- Myelodysplasia, spina bifida
- Radical pelvic surgery
- Recent spinal or brain trauma ("spinal shock")
- Sacral spinal cord injury

GENERAL PREVENTION

N/A

DIAGNOSIS

HISTORY

- Symptoms may include: Incomplete bladder emptying, frequency, urgency, incontinence (urge or stress), weak urine stream, straining to empty.
- History of any risk factors listed in the section entitled "Associated Conditions."
- Medication: Recent use of anticholinergic medications or over-the-counter cold medicine.
- Recurrent bladder infections.

PHYSICAL EXAM

- Palpable suprapubic mass (distended bladder)
- Stress incontinence on pelvic exam (overflow)
- High post-void residual volumes
- Abnormal neurologic exam:
  - Perianal and perineal sensation
  - Anal sphincter tone
  - Bulbocavernous reflex
- Enlarged prostate on rectal exam
- Sacral abnormalities:
  - Sacral dimple
  - Tuft of hair
  - Sacral agenesis
  - Spinal surgical scar

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Blood: Creatinine to assess renal function.
- Urine: Urinalysis to assess urinary infection.

Imaging

Renal and bladder ultrasound (to assess renal stones, bladder stones, hydronephrosis).

Diagnostic Procedures/Surgery

- Bladder scanner
  - High post-void residuals may be identified to support the diagnosis
- Multi-channel urodynamics study:

- No or minimal detrusor contraction (P_{det} line)
- Urodynamics criteria:
  - Bladder contractility index (BCI) <100
  - Maximal flow rate (Q_{max}) <12 mL/s
  - Detrusor pressure P_{det} at Q_{max} <10 cm water
- To distinguish detrusor areflexia from bladder outlet obstruction (benign prostatic hyperplasia).
- To assess detrusor compliance and storage pressure. Detrusor leak point pressure >40 cm of water poses risk to the upper urinary tract.
- To identify the etiology of incontinence.
- To guide rational, safe management strategy.

Pathologic Findings

Bladder wall thickening and fibrosis may be found in decompensated bladder from obstruction.

DIFFERENTIAL DIAGNOSIS

- Bladder outlet obstruction causing retention:
  - Benign prostatic hyperplasia
  - Urethral stricture disease
- Functional outlet obstruction (eg, detrusor external sphincter dyssynergia)
- Potential reversible causes of areflexia:
  - Recent spinal shock or stroke
  - Recent radical pelvic surgery
  - Medication use (eg, anticholinergics)
  - Fowler syndrome

TREATMENT

GENERAL MEASURES

- Intermittent catheterization is preferred over chronic indwelling catheters (Foley or suprapubic catheter) to reduce the risks of infection and stones.
- Sacral neuromodulation (InterStim) may be considered for nonobstructive urinary retention (eg, good results in Fowler syndrome).

MEDICATION

First Line

- Bethanechol was ineffective in reducing residual volumes in a randomized, placebo trial (1) [C].
  - Bethanechol may decrease the duration of transient urinary retention in patients who underwent radical hysterectomy or anorectal surgery in randomized, controlled trials (1) [C].
  - Typical dosage: 10–50 mg PO BID–TID.

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Sacral neuromodulation (InterStim) in selected patients who do not have contraindications.
  - Effective in restoring voiding in patients with Fowler syndrome (1)[C].
  - May be selectively considered in patients with nonobstructive urinary retention (2)[C].
- Bladder augmentation may be considered in patients with poor detrusor compliance, and high detrusor leak point pressure and storage pressure.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Most cases are irreversible, except the few circumstances described in "Differential Diagnosis"
- However with proper urologic management, secondary complications may be minimized.

COMPLICATIONS

- Bladder neoplasm from indwelling catheter
- Hydronephrosis and hydroureters
- Recurrent urinary tract infections
- Renal and bladder stones
- Renal insufficiency, failure, and dialysis
- Urethral erosion from chronic Foley catheter
- Urinary incontinence
- Urosepsis and death

FOLLOW-UP

Patient Monitoring

- Patients with poor detrusor compliance need periodic urodynamics studies, upper tract imaging, and creatinine lab work to minimize complications.
- Patients who refuse to catheterize should be monitored closely.
- Patients with chronic indwelling catheter should undergo cystoscopy periodically due to the increased risk of bladder neoplasm.

- 788.29 Other specified retention of urine
- 788.38 Overflow incontinence

ICD10

- R33.8 Other retention of urine
- N36.44 Muscular disorders of urethra
- N39.490 Overflow incontinence

CLINICAL/SURGICAL PEARLS

- Detrusor areflexia requires urodynamics for diagnosis.
- Urodynamics can distinguish detrusor areflexia from bladder outlet obstruction.
- Intermittent catheterization is preferred over chronic indwelling catheters.
- Sacral neuromodulation (InterStim) may be selectively considered in patients with nonobstructive urinary retention or Fowler syndrome.
- Patients with chronic indwelling catheter should undergo cystoscopy and urine cytology periodically due to the increased risk of bladder neoplasm.

BLADDER CALCULI (VESICAL CALCULI)

Mohamed S. Ismail, MBChB, MRCS, PhD
Francis Xavier Keeley, Jr., MD, FRCS

BASICS

DESCRIPTION

- Bladder calculi (also called bladder stones) are calcified material that are present in the bladder.
- It can originate primarily in the bladder.
- It can be a secondary renal stone that formed in the kidney and passed into the bladder.
- Often associated with bladder outlet obstruction in the US.
- Historically the removal of bladder calculus was performed via an incision in the perineum with the patient in a supine position and the legs elevated (the origin of the term "lithotomy position").

EPIDEMIOLOGY

Incidence

- The incidence of bladder calculi in the Western world has significantly dropped as a result of improved diet, nutrition, and infection control
- Bladder calculi are endemic in Thailand, Burma, Indonesia, Middle east, and north Africa
- Mostly in middle age men
- In catheterized patients the incidence of developing bladder calculi is 25% in 5 yr
- The incidence in children has declined significantly however in the developing countries they are common in boys younger than 11 yr
- Vaginal prolapse and urethral surgery are common causes in women

Prevalence

- Bladder calculi constitute 10–15% of the stone burden in adult and 15–30% in children
- Data on the world wide incidence are not available

RISK FACTORS

- Urinary stasis
  - Bladder outlet obstruction
    - Benign prostatic hyperplasia
    - Urethral stricture
    - Bladder neck contracture
  - Neurogenic bladder
- Foreign body such as urethral catheter and ureteric stent that act as nidus for stone formation
- Urinary tract infection
- Urinary diversion and bladder substitution
  - Secondary to foreign body, infection, and systemic acidosis
  - Rarely patients may place foreign bodies in bladder that become calcified

Genetics
N/A

PATHOPHYSIOLOGY
- Bladder calculi are primarily formed in the bladder, rarely can be a secondary renal stone that has formed in the kidney and passed into the bladder
  - Foreign bodies, retained catheter balloon fragments
  - Patients on chronic intermittent catheterization may force pubic hair into the bladder that can become calcified over time
- Stone analysis frequently reveals uric acid stone in 50% of the cases
- Other constituents are ammonium urate, calcium oxalate, and calcium phosphate
- In infected urine, struvite stones are the most common
- In patients with spinal cord injuries (SCIs), bladder stones are often composed of struvite or calcium phosphate
- In endemic areas, low phosphate diet results in increased ammonium excretion in the urine
- Low intake of animal protein contributes to high urinary oxalate and low urinary citrate levels with increased risk of stone formation
- Solitary stone are present in 75% of cases

ASSOCIATED CONDITIONS
- Foreign bodies in the bladder
- Intermittent catheterization
- Low phosphate diet
- Low protein diet
- Urinary stasis (prostatic hypertrophy, stricture, congenital abnormalities [ureterocele], diverticulum, cystocele)
- Urinary tract infection

GENERAL PREVENTION
- Adequate hydration
- Treatment of bladder outlet obstruction
- Prevention of urinary tract infection
- Prevention of urololithiasis as appropriate
  - Allopurinol for uric acid stones
  - Reduce oxalate intake
  - Increase urinary citrate
  - Low sodium low diet

DIAGNOSIS
HISTORY
- Patients with SCI, neurogenic bladder may be at increased risk
- Bladder calculi may be asymptomatic and may be incidental finding on imaging (plain x-ray, renal ultrasound, CT, or flexible cystoscopy)
- Patients commonly presents with
  - Suprapubic or perineal pain
  - Irritative urinary symptoms

  - Intermittent urinary stream
  - Hematuria, gross, and microscopic
  - Recurrent urinary tract infection

PHYSICAL EXAM

- Examine the abdomen for palpable bladder or suprapubic tenderness
- Examine the external genitalia for any abnormalities (meatal stenosis) that may contribute to outlet obstruction
- Digital rectal exam to assess for BPH and prostate cancer

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine analysis: Hematuria, leukocytes, and crystalluria may be present
- Urine culture and sensitivity in case of suspected infection
- Urine cytology in the presence of calculi is nonspecific
- Serum creatinine
- Stone analysis should be considered when removed

Imaging

- Calcified stones can be visible on plain x-ray (KUB)
  - Stones may be densely radiopaque.
  - Occasionally laminations may be visible on plain x-ray
- Uric acid and ammonium acid urate stones are radiolucent but will be seen on ultrasounds or CT scan.
- Bladder calculi may not be visible on MRI
- CT without contrast is highly sensitive and specific to detect calculi, however it is rarely used to diagnose bladder stones

Diagnostic Procedures/Surgery

- Cystoscopy to visualize the stone and guide subsequent removal of the stone
  - Allows evaluation of bladder outlet obstruction or other abnormality such as bladder diverticulum

Pathologic Findings

- Acute and chronic inflammation
- Squamous metaplasia and squamous cell carcinoma can result from chronic vesical calculus irritation

DIFFERENTIAL DIAGNOSIS

- Bladder diverticulum
- Bladder malignancy with or without calcification
  - Urothelial carcinoma
  - Other bladder malignancies
- Chronic pelvic pain syndrome
- Fungal bezoar or blood clot
- Interstitial cystitis
- Lower urinary tract symptoms due to bladder outlet obstruction
- Overactive bladder

- Urinary tract infection
- Ureteral urolithiasis
  – Distal ureteral stone can cause significant vesical irritation

TREATMENT

GENERAL MEASURES

- Surgical removal is the mainstay treatment
- Determining and correcting the cause (ie, bladder outlet obstruction) should be a priority

MEDICATION

First Line

- Medical therapy is used to treat associated urinary tract infection
- Bladder outlet obstruction is treated with alpha blockers such as tamsulosin 0.4 mg QD and 5 alpha reductase inhibitors such as dutasteride 0.5 mg QD

Second Line

- Alkalinization of urine to a PH of 6.5 in case of uric acid stones
  – Use potassium citrate 60 mEq/d PO

SURGERY/OTHER PROCEDURES

- Endoscopic cystolitholapaxy using stone fragmenting forceps
- Electrohydraulic, ultrasonic, laser, and pneumatic lithotrites are used for larger or harder stones
- Large stones can be removed through small abdominal incision (open cystolitholapaxy)
- Cystolitholapaxy can be safely combined with procedures such as TURP or TUIP for bladder outlet obstruction

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- ESWL has a limited role in treating bladder calculi
- Bladder outlet procedure may be necessary if urinary stasis is causing vesical calculus to improve bladder emptying
- Consideration to repair of bladder diverticulum or other anatomic abnormality if contributory

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Excellent with complete stone removal and associated bladder outlet obstruction are treated
- Metabolic stone evaluation may be considered if appropriate (ie, multiple upper tract calculi, recurrent bladder calculi, etc.)

COMPLICATIONS

- Recurrent urinary tract infection
- Squamous metaplasia
- Chronic irritation may result in secondary malignancy (ie, squamous cell carcinoma)

FOLLOW-UP

Patient Monitoring

- Urine analysis
- Flowmetry and postvoid residual
- Renal ultrasound scan to screen for upper tract urolithiasis

Patient Resources

- N32.0 Bladder-neck obstruction

CLINICAL/SURGICAL PEARLS

If an otherwise healthy person is found to have a bladder calculus, a complete evaluation is warranted to evaluate for causes such as urinary stasis.

BLADDER CANCER, ADENOCARCINOMA

Matthew A. Young, MD
Sandip M. Prasad, MD, MPhil

BASICS

DESCRIPTION

- Adenocarcinoma of the bladder is an uncommon and frequently aggressive nonurothelial cancer.
- It is frequently muscle-invasive or metastatic at the time of diagnosis and therefore carries a poor prognosis.
- A common site is the urachus.

EPIDEMIOLOGY

- 0.5–2.0% of all primary bladder malignancies, making it the 3rd most common epithelial tumor of the bladder
- Can arise from the urachus or nonurachal epithelium, or in association with exstrophy of the bladder
- Most common tumor arising in the bladder of exstrophy patients, who have a 4% lifetime risk
- A majority of nonurachal, nonexstrophy-associated adenocarcinomas occur in men and are frequently associated with long-term inflammation or infection
- Occurs more frequently in areas where Schistosoma is endemic
- Urachal cancer: $<1\%$ of primary bladder cancer; 1/3 of bladder adenocarcinomas

RISK FACTORS

In tissue recombinant studies, adenocarcinoma can be produced from bladder urothelium under the appropriate hormonal and mesenchymal stimuli.

Genetics

Associated with gain of function in regions 20q and 8q, or loss of function at regions 5q and 8p (1)

PATHOPHYSIOLOGY

- Classification: Three groups related to site of tumor origin (2,3)
  - Primary adenocarcinoma of bladder
  - Urachal adenocarcinoma
  - Extravesical adenocarcinoma (metastatic)
- Primary vesical adenocarcinoma: Can occur anywhere in the bladder, but the dome and the trigone of the bladder are common
  - Most common type of cancer in bladder exstrophy
  - All histologic variants of enteric carcinoma may occur in the bladder
  - Papillary or solid; most are mucin-producing
  - Most are poorly differentiated and invasive at the time of diagnosis
  - Poor response to radiotherapy and chemotherapy

- Urachal carcinoma
  - For classification as a urachal carcinoma, there must be:
    - Presence of a urachal remnant
    - Clear demarcation between the tumor and adjacent bladder mucosa
    - Predominant invasion of the muscularis propria or deeper structures of the bladder or extension to the space of Retzius, anterior abdominal wall, or umbilicus
    - Possible production of mucoid drainage from the umbilicus
- M.D. Anderson Cancer Center Diagnostic Criteria for Urachal Carcinoma
  - Location in bladder dome or elsewhere in the midline of the bladder
  - Sharp demarcation between tumor and normal surface epithelium
  - Supportive criteria
    - Enteric-type histology
    - Absence of urothelial dysplasia
    - Absence of cystitis cystica or cystitis glandularis transitioning to the tumor
    - Absence of primary adenocarcinoma of another organ
- May produce stippled calcifications on plain films
- Prognosis is worse for urachal carcinoma than for primary adenocarcinoma of the bladder
- Urachal carcinoma demonstrates more extensive infiltration of the bladder wall, and for this reason, radical cystectomy is preferred over partial cystectomy, although the latter is still an option
- Urachal carcinomas are not always adenocarcinomas (most common type); others include transitional cell carcinoma, squamous cell carcinoma, and rarely sarcoma
- Metastatic lesions are very rare
  - Adenocarcinomas from the colon, stomach, breast, ovary, endometrium, and prostate can metastasize to the bladder
  - Local invasion of a colonic primary tumor is more common than metastasis
  - Bladder adenocarcinoma is histologically indistinguishable from adenocarcinoma of the colon
- Sheldon Staging System for Urachal Carcinoma
  - Stage I: No invasion beyond the urachal mucosa
  - Stage II: Invasion confined to the urachus
  - Stage III: Local extension into the
    - bladder (IIIA)
    - abdominal wall (IIIB)
    - peritoneum (IIIC)
    - viscera other than bladder (IIID)
  - Stage IV: Metastases to the
    - regional lymph nodes (IVA)
    - distant site (IVB)

ASSOCIATED CONDITIONS
- Bladder exstrophy
- Schistosomiasis

GENERAL PREVENTION
Elimination of factors leading to chronic bladder inflammation

DIAGNOSIS

HISTORY

- Hematuria, mucosuria (uncommon)
  - Usually painless
- Irritative voiding symptoms (frequency, urgency, dysuria)
- Foreign travel: Schistosomiasis
- Weight loss, flank pain, umbilical discharge (rare)
- Chronic infection
- History of exstrophy or other bladder pathology
- History of colon cancer or other malignancy; risk of metastatic lesion

PHYSICAL EXAM

- Pelvic mass by bimanual/rectal exam
- Bloody or mucoid umbilical discharge or umbilical mass
- Digital rectal exam; presence of blood in stool

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine studies: Urinalysis, culture and sensitivity, urine cytology
- Serum electrolytes: BUN/Creatinine, liver function tests
- Carcinoembryonic antigen (CEA), CA125, and CA 19-9 may be elevated in 40–60% of patients presenting with peritoneal carcinomatosis

Imaging

- Urachal cancers may show stippled calcifications on plain x-ray films
- 60% of bladder tumors are detected with IVP, which has been largely replaced with the CT scan
- CT scan: Imaging method of choice for staging of bladder tumors; useful for detecting presence of pelvic lymphadenopathy and extravesical tumor extension
  - Sensitivity: 64–94%, specificity: 62–100%
- Other investigations: CXR (staging), bone scan (staging, if bone pain is present), GI endoscopy, and breast exam (to exclude primary tumor) if clinically indicated

Diagnostic Procedures/Surgery

- Diagnostic cystoscopy and biopsy
  - Essential for definitive diagnosis
  - Bloody efflux from ureteral orifices suspicious for upper tract pathology

Pathologic Findings

- All histologic variants of enteric carcinoma may occur in the bladder
- Adenocarcinoma can have glandular, mucinous, or signet ring patterns
- Most produce mucin
- Primary adenocarcinoma of the bladder is associated with cystitis glandularis and is thought to arise from glandular metaplasia of the urothelium. These tumors can be papillary or solid
- Signet ring tumors produce linitis plastica of the bladder. They are aggressive and radical surgical excision should be considered

DIFFERENTIAL DIAGNOSIS

- Metastasis from colon, prostate, or other adenocarcinoma
- Benign or malignant urothelial tumors

TREATMENT

GENERAL MEASURES

- Site of origin and tumor behavior are factors important in determining treatment
- Adenocarcinoma of the bladder is generally unresponsive to radiation and chemotherapy.
  - Radical cystectomy is treatment of choice.
  - Excision of the urachus and umbilicus is usually required if a urachal primary is suspected
- Adjuvant chemotherapy or radiotherapy may be used, but surgery remains the most consistently effective treatment (4,5,6)

MEDICATION

First Line

- Generally unresponsive to radiation and cytotoxic chemotherapy (7)
- Some response to standard regimens such as combination methotrexate, vinblastine, adriamycin, cisplatin (MVAC)
- Recently, 5-FU and cisplatin-based chemotherapy have demonstrated a modest response rate
- A clinical trial at M.D. Anderson using gemcitabine, 5-FU, leucovorin, and cisplatin (Gem-FLP) reported a clinical response rate in 30–40% of patients
- Currently there is no role for neoadjuvant chemotherapy for clinically node-negative resectable disease

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Radical cystectomy with pelvic lymph node dissection remains the gold standard
- Adjuvant chemotherapy or radiotherapy has not improved survival significantly
- Partial cystectomy (with bladder mucosal sampling) with en bloc removal of the urachus and umbilicus is an option for low-volume, low-stage urachal carcinoma

ADDITIONAL TREATMENT

Radiation Therapy

Urachal adenocarcinoma is radio resistant

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Signet cell variant has a 50% mortality at 1 yr
- Urachal adenocarcinoma: Overall 11–55% 5-yr survival, but early-stage disease may have up to 93% 5-yr survival

- Nonurachal adenocarcinoma: 27–61% 5-yr survival
- Recurrence risk for urachal carcinoma
  - Positive margin
  - Umbilicus sparing resections are associated with a higher risk of relapse
  - Tumor involving the peritoneal surfaces or the abdominal wall
  - Occult lymph node metastases

COMPLICATIONS
- Ureteral obstruction from local spread of tumor
- Metastasis to pelvic lymph nodes, liver, lung, mediastinum, and bone
- Surgical complications: Bleeding, infection, rectal injury

FOLLOW-UP

Patient Monitoring
- Abdominal imaging (CT)
- Metastatic workup if suspected

Patient Resources
- American Cancer Society:
  - www.cancer.org
- National Cancer Institute
  - www.nci.nih.gov
- United Ostomy Association:

CODES

ICD9

- 188.1 Malignant neoplasm of dome of urinary bladder
- 188.7 Malignant neoplasm of urachus
- 188.9 Malignant neoplasm of bladder, part unspecified

ICD10

- C67.1 Malignant neoplasm of dome of bladder
- C67.7 Malignant neoplasm of urachus
- C67.9 Malignant neoplasm of bladder, unspecified

CLINICAL/SURGICAL PEARLS

- Umbilicus may be involved in up to 7% of patients with adenocarcinoma of the bladder.
- Most common tumor arising in the bladder of exstrophy patients, who have a 4% lifetime risk.
- Adenocarcinoma of the bladder is generally unresponsive to radiation and chemotherapy.

BLADDER CANCER, GENERAL

Matthew A. Young, MD
Sandip M. Prasad, MD, MPhil

BASICS

DESCRIPTION

- Bladder cancer is the most common site of malignancy in the urinary system
- Includes multiple histologic types:
  - Urothelial cell carcinoma (formerly transitional cell carcinoma) is most common
  - Other: Adenocarcinoma, squamous cell carcinoma, and small-cell carcinoma
  - TNM staging: Initially based on clinical findings (bladder biopsy) (See Section VII: "Reference tables: TNM Classification: Urinary Bladder cancer.")
  - T staging: Primary tumor
    - Ta/Tis/T1: Superficial/nonmuscle invasive bladder cancer (NMIBC)
    - T2a/T2b: Muscle invasive bladder cancer (MIBC)
    - T3a/T3b/4a: Locally advanced
  - Regional lymph node (N) staging: Regional lymph nodes (the true pelvis); all others are considered distant metastasis
  - Distant metastasis (M) staging
  - Stage grouping:
    - Stage 0: Tis, N0, M0
    - Stage 1: Ta-T1, N0, M0
    - Stage II: T2, N0, M0
    - Stage III: T3a-T4a, N0, M0
    - Stage IV: T4b, N0, M0 or any T, N1,2,3, M0 or any T, any N, M1

EPIDEMIOLOGY

Incidence

- American Cancer Society 2014 new case estimates: 74,690 (male: 56,390 female: 18,300)
  - Estimated 155,800 deaths in 2014
- 3:1 male–female ratio
- 4th most common cancer in males, 7th most common cancer in females
- Median age of diagnosis is 70 yr

Prevalence

3rd most prevalent cancer in men (high recurrence)

RISK FACTORS

- Tobacco smoking confers a 2–4 times risk over those that have never smoked
  - Risk reduction after quitting takes up to 20 yr
- Occupational exposures:
  - Painters, leather, petroleum, chemical and met al workers, dry cleaners, truck drivers, hairdressers
  - Aromatic amines such as aniline dyes, benzidine, naphthylamine, 4-aminobiphenyl, and

coal soot
- Cyclophosphamide treatment
  – Caused by toxic metabolite, acrolein
- Pelvic radiation
- Risk for squamous cell carcinoma
  – Indwelling catheters, bladder calculi
  – Schistosomiasis (*Schistosoma hematobium*)

Genetics
- No clear hereditary causes identified
- Tumor suppressor p53 is the most commonly altered gene in bladder cancer

PATHOPHYSIOLOGY
- 70% of tumors present as nonmuscle-invasive lesions
  – 70% of these are Ta, 20% T1, 10% CIS
- Risk of recurrence
  – CIS: 50–90%
  – Ta low grade: 50–70%
  – Ta high grade: 60%
  – T1 high grade: 70–80%
  – Risk of recurrence in upper tracts 2–4%
- Risk of progression
  – CIS >50%
  – Ta low grade: 5–10%
  – Ta high grade: 15–40%
  – T1 high grade: 30–50%
    - Most important prognostic factor is grade
    - Concurrent upper-tract UCC in patients with bladder cancer is 2–4%

ASSOCIATED CONDITIONS
Other smoking related illnesses (COPD)

GENERAL PREVENTION
- Avoid occupational exposure and smoking
- Urinalysis for hematuria screening
- High-fat diet has been associated with increased risk of bladder cancer
- Vitamins A and B compounds have not shown conclusive benefit for primary prevention
- Long-term hydration may be beneficial

DIAGNOSIS

HISTORY
- Gross painless hematuria is the most common presenting symptom
- Irritative voiding symptoms (present in 20%)
  – Often associated with CIS
- Smoking history (quantify in pack years and if/when patient quit)
- Occupational exposures (see “Risk Factors”)

PHYSICAL EXAM

- Rarely abnormal in NMIBC
- General
  - Weight loss, abdominal/pelvic masses, lymphadenopathy, flank tenderness
- DRE with bimanual exam in men and women may reveal palpable mass in bladder

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis with microscopy: RBCs
- Urine cytology
  - High specificity (96%), more sensitive for high-grade tumors (50%)
- Other urinary markers
  - FISH (evaluate aneuploidy for chromosomes 3,7,17 and 9p21)
    - Sensitivity 77%, specificity 98%
  - NMP-22 (marker of urothelial cell death)
    - Sensitivity 56%, specificity 85%
- Renal function tests (BUN, Creatinine)
  - May indicate renal impairment secondary to ureteral obstruction
- Liver function tests
  - May be abnormal due to metastasis

Imaging

- CT abdomen/pelvis
  - Can detect lymphadenopathy and other intra-abdominal disease
  - Presence of hydronephrosis is suggestive of muscle-invasive disease
  - CT urography has replaced IVP as standard for evaluating upper tracts
- MRI may be useful for local staging
- Chest x-ray (CXR): Metastasis with muscle invasion
- Bone scan is recommended only in patients with bone pain, elevated calcium, or elevated alkaline phosphatase

Diagnostic Procedures/Surgery

- Cystoscopy is the most accurate initial diagnostic procedure
  - Can be done in office with local anesthesia
- Bladder biopsy
  - Establishes pathologic diagnosis
  - May be definitive treatment if tumor can be completely removed
- Prostatic urethra biopsies are not routinely performed unless there is:
  - Multifocal disease of the bladder
  - CIS of the bladder
  - Visible abnormality in the prostatic urethra
- Retrograde pyelography
  - May be used in setting of renal impairment or contrast allergy
  - Further evaluate equivocal findings on CT

Pathologic Findings

- Carcinoma in situ (CIS) is a urothelial cancer that is flat, high grade, and noninvasive but

has metastatic potential. Patients with bladder CIS have a 20% risk of upper-tract disease
- Histologic types
  - Transitional cell carcinoma (urothelial carcinoma), 90%
  - Squamous cell carcinoma, 3–7%
  - Adenocarcinoma, < 2%
  - Small cell, sarcomas (leiomyosarcoma, rhabdomyosarcoma) uncommon

DIFFERENTIAL DIAGNOSIS
- Hematuria
  - Trauma: Iatrogenic, other
  - Neoplasms: Malignancies: (30% of adults with painless, gross hematuria and ~10% with painless microscopic hematuria have a malignancy), benign tumors, endometriosis
  - Inflammatory causes: UTI (most common cause of hematuria in adults), other infections (Schistosomiasis, TB, syphilis) radiation cystitis
  - Renal/glomerular diseases: Nephritis, Goodpasture syndrome, IGA nephropathy, lupus nephritis, glomerular diseases (membranoproliferative, poststreptococcal, or rapidly progressive glomerulonephritis)
  - Urolithiasis: 85% have hematuria
  - Congenital/Familial causes: Cystic disease, benign familial hematuria, etc.
  - Hematologic causes: Bleeding dyscrasias (eg, hemophilia), Sickle cell anemia/trait (renal papillary necrosis)
  - Vascular causes: Hemangioma, AVM (rare), Nutcracker syndrome, renal artery/vein thrombosis, arterial emboli to kidney
  - Chemical causes: Nephrotoxins (Aminoglycosides, cyclosporine), analgesics, oral contraceptives, Chinese herbs
  - Obstruction: Strictures or posterior urethral valves, hydronephrosis (any cause) benign prostatic hyperplasia: Rule out other causes of hematuria.
  - Other causes: Loin pain hematuria, menses
- Bladder filling defect:
  - Air: Artifactual, postinstrumentation, vesicoenteric fistula
  - Benign tumors: Prostatic enlargement, etc.
  - Blood clot, calculus, fungus ball (bezoar)
  - Congenital: Ureterocele
  - Extrinsic compression
  - Infective, inflammatory: Inflammatory edema
  - Instruments (catheters), foreign body
  - Malignant tumor: Bladder and prostate malignancy, tumors invading urinary bladder
  - Radiologic artifact: Fold in bladder

TREATMENT

GENERAL MEASURES
- Transurethral resection of bladder tumor (TURBT) determines diagnosis (grade/stage/type)
- Primary treatment is surgery
  - Bladder biopsy can be both diagnostic and therapeutic (for nonmuscle-invasive tumors)

  - For T1, repeat TURBT should be performed 2–6 wk after initial resection as upstaging occurs in up to 30% of cases.
- Radical cystectomy with pelvic lymphadenectomy
  - Initial therapy for muscle-invasive tumors
  - May be needed for recurrent high-grade T1 tumors or CIS that has failed to respond to intravesical therapy

MEDICATION

First Line

- Intravesical therapy for higher-risk NMIBC
- BCG (Bacillus Calmette-Guerin) (1)
  - Only after bladder healed (usually 4 wk); 40% reduction in recurrence, 23–27% reduction in progression
  - Maintenance BCG increases recurrence-free time; BCG: Superior to intravesical chemotherapy for CIS
  - Side effects: Cystitis, dysuria, hematuria, malaise, fatigue, low-grade fever
  - Complications: Fever >101.5°F (38.6°C) for >12–24 hr may require broad-spectrum antibiotics and isoniazid
    - Sepsis (0.4%) – fever >102°F (38.8°C) or signs of sepsis. Treat with prednisone, broad-spectrum antibiotics, and anti-tuberculosis drugs
- Mitomycin C
  - Alternative when BCG cannot be used
  - Reduces tumor recurrence up to 40%
  - Given as a single dose within 24 hr of TURBT (40 mg in 20-mL saline or sterile water)
  - Contraindicated with bladder perforation
  - Side effects: Dermatitis, irritative voiding, absorption may cause myelosuppression
- Platinum-based drug regimens are the most effective systemic chemotherapeutic agents (2)
  - Neoadjuvant or adjuvant therapy for invasive disease (Stage II/III)
  - Metastatic disease (Stage IV)
    - MVAC (mitomycin, vinblastine, adriamycin, cisplatin)
    - Overall response rate 40–50%
    - Common toxicities: Mucositis, renal toxicity, myelosuppression, sepsis, cardiac toxicity
  - Gemcitabine and cisplatin
    - Common toxicity: Myelosuppression
    - Overall response rate 40–50%, similar to MVAC with better toxicity profile
- Neoadjuvant platinum-based chemotherapy: 5-yr overall survival benefit of 5%

Second Line

- Valrubicin: Intravesical therapy of BCG-refractory CIS in patients for whom immediate cystectomy would be associated with unacceptable morbidity or mortality
- Other intravesical agents after BCG failure: Mitomycin C, gemcitabine, interferon α 2b

SURGERY/OTHER PROCEDURES

- "Blue light" (Cysview) cystoscopy FDA approved may improve lesion detection
- Narrow band imaging evolving for diagnosis

ADDITIONAL TREATMENT

Radiation Therapy

- Bladder preservation approaches (trimodality therapy) (3)
  - 1. TURBT: Must be completely resected
  - 2. Chemotherapy: Platinum-based regimens
  - 3. Radiation therapy
  - Optimal patients have solitary T2 tumors that can be completely resected, no hydronephrosis, no associated CIS, normal renal function
  - Usually biopsy mid-treatment: Recommend cystectomy if no response
  - 5-yr survival is similar to radical cystectomy

Additional Therapies

Oncovite (high-dose vitamin A, B6, C, E, and zinc) after TUR and induction BCG had a reduction in recurrence vs. RDA vitamins (secondary prevention)

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- 5-yr survival by stage: I, 85–96%; II, 55–65%; III, 38–59%; IV, 15–27%
- Recurrence: CIS, 80%; Ta, 50%; T1, 50–70%
  - Progression: CIS, 20% after a complete response to BCG; Ta, 5%; T1, 30–40%

COMPLICATIONS

- Urinary retention from gross hematuria or tumor infiltrating or blocking bladder outlet
- Ureteral obstruction

FOLLOW-UP

Patient Monitoring

- NMIBC: Cystoscopy and cytology every 3 mo for 2 yr, then every 6 mo for 2 yr, then annually
  - Upper-tract surveillance every 1–2 yr
- Muscle-invasive disease
  - Liver function tests, creatinine, electrolytes, CXR every 6–12 mo
  - Upper-tract imaging, baseline and every 2 yr
  - Cytology every 6–12 mo ± male urethral wash (cutaneous diversion)

- C67.9 Malignant neoplasm of bladder, unspecified

CLINICAL/SURGICAL PEARLS

70% of bladder cancers present as nonmuscle-invasive lesions.

BLADDER CANCER, NON-MUSCLE-INVASIVE BLADDER CANCER (TA, T1) (NMIBC)

John B. Eifler, MD
Michael S. Cookson, MD

BASICS

DESCRIPTION

- Bladder cancer is a malignant neoplasm usually arising from originating from the lining of the bladder (urothelium)
  - A papillary tumor confined to the mucosa is classified as stage Ta according to the Tumor, Node, Metastasis (TNM) classification system.
  - Tumors that have invaded the lamina propria are classified as stage T1.
  - Ta and T1 tumors can be removed by transurethral resection (TUR), and are called NMIBC (nonmuscle-invasive bladder cancer)
- Most common histology: Urothelial carcinoma (previously called transitional cell carcinoma/TCC)
- ~70% of bladder cancers are nonmuscle-invasive at presentation
- Challenging management: Due to recurrence and potential to progress to lethal disease
- Due to need for lifelong monitoring, highest cost per patient of any cancer

EPIDEMIOLOGY

Incidence

- In US, all cases estimated 74,690 in 2014
  - 15,580 estimated cancer deaths in 2014
- Highest incidence: Men >60, women >70
- Caucasian > African American > Latino
- 4th most common cancer in men

Prevalence

- 2nd most prevalent cancer in middle-aged and elderly men
- Male:female ~3:1

RISK FACTORS

- Tobacco smoking history (most common risk factor)
  - Overall 2.8× higher incidence in smokers
  - Risk increases with number of pack-years
    - 6× risk for 60 pack year history
  - Latency often >20 yr from time of exposure
  - Quitting decreases risk
    - 15 yr after quitting, relative risk 1.1
- Occupational exposure
  - Organic chemicals, especially aromatic (aryl)-amines
    - Naphthalenes, benzidine, aniline dyes, 4-aminobiphenyl

  - High-risk occupations: Petroleum/rubber/leather/paint/textile workers, hairdressers, truck drivers, aluminum electroplaters
  - Arsenic contamination of drinking water
  - Latency may be 40 yr
- Chemotherapy with cyclophosphamide (Cytoxan)
- Pelvic radiation
  - 4× increased risk after RT for cervical cancer
  - ~1.5× risk after RT for prostate cancer
- Chronic cystitis → SCC
  - Indwelling catheters, chronic bladder calculi, cystitis due to *Schistosoma hematobium*

Genetics

- 2× increased risk for 1st-degree relatives of bladder cancer patients
- Genetics affect susceptibility to carcinogens (eg, slow acetylators NAT2, null GSTM1)
- Lynch syndrome – typically increased upper-tract UC, though some subtypes increase risk of bladder cancer

PATHOPHYSIOLOGY

- Inciting genetic event
  - Low grade (LG): Deletion of part of chr 9 (RB gene) and/or mutation in FGFR-3
  - High grade (HG): Numerous mutations (particularly TP53), aneuploidy of chr 7, 9, 17
- NMIBC comprises ~70% of bladder cancer
  - Recurrence rate: ~60% for LG, >80% for HG
    - Most recurrences within 1st 6 mo after TURBT, but may occur after many years
    - May also recur in upper tracts or prostatic urethra
  - Progression influenced by stage and grade
    - Stage Ta, LG: 5–10%; HG: 15–40% at 5 yr
    - Stage T1, HG 30–50% at 5 yr
  - Eventual death rate 10–25% for HG Ta, 33% for HG T1 (1)
- Other risk factors for progression
  - Architecture: Nodular/sessile/broad based > papillary
  - Multifocality > solitary
  - Size >5 cm
  - Lymphovascular invasion
  - Mutations in *TP53*, *RB*, and *PTEN* predict poor prognosis

ASSOCIATED CONDITIONS

See “Risk Factors”

GENERAL PREVENTION

- Smoking cessation
- Avoidance of occupational exposure
- Hydration long term beneficial

DIAGNOSIS

HISTORY

- Most common in men >50; Males > Females due to smoking prevalence
- 1st occurrence: 85% present with either gross or microscopic hematuria. Painless gross hematuria is hallmark of bladder CA
- Irritative symptoms (eg, dysuria, urgency, frequency) occasionally due to bladder CA, especially CIS
  – Microscopic hematuria typically present if due to cancer
- Smoking history:
  – Record total pack-years, current packs/day, and years since quitting if applicable
- Occupational risk factors

PHYSICAL EXAM

Usually unremarkable for NMIBC

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- U/A, including dipstick and micro evaluation for RBCs
- Urine cytology: High specificity but low sensitivity. Best at detecting HG NMIBC and CIS
- Other urinary tests: Urine cytology, BTA-Stat, NMP22, UroVysion FISH: Low sensitivity and specificity for LG disease. Not generally recommended for routine workup of microscopic hematuria but may be considered for high-risk patients (see "Additional Reading")

Imaging

- Goal: Evaluate renal parenchyma, renal collecting system and ureters
- CT urogram (3-phase CT abd/pelvis with IV contrast): Study of choice for evaluation of gross/microscopic hematuria
- If patient cannot receive IV contrast, consider MRI + RPG (retrograde pyelogram)
  – U/S + RPG if patient cannot receive gadolinium

Diagnostic Procedures/Surgery

- Bladder CA typically detected on cystoscopy
  – Cystoscopy indicated for gross hematuria and most cases of microscopic hematuria (see chapter "Hematuria, gross and microscopic, adult")
    - In office, under local anesthesia, at time of initial presentation. It may be combined with biopsy
    - TURBT under general or spinal anesthesia is definitive
- Retrograde pyelography may be used for equivocal CT urogram or when CT urogram/MRI contraindicated to exclude concomitant upper-tract lesions in patients with hematuria or positive cytology

Pathologic Findings

- Urothelial Dysplasia
  – Precursors to CIS/Urothelial cancer
- Papilloma
  – Papillary lesion with low recurrence risk (0–8%) or progression risk (2%)
- Papillary Urothelial Neoplasm of Low Malignant Potential (PUNLMP)
  – Papillary growth, minimal cytologic atypia
  – Recurrence 35%, progression 4%

- CIS: See chapter "Bladder cancer, urothelial, superficial, carcinoma in situ (CIS)"
- Papillary cancer: Confined to either urothelium (stage Ta) or invasion of lamina propria (stage T1) and may be LG or HG

DIFFERENTIAL DIAGNOSIS

See Section I "Bladder cancer, general" for complete differential diagnosis of hematuria and bladder filing defect

TREATMENT

GENERAL MEASURES

- Resection with selective use of intravesical therapy is the mainstay
- TURBT of all visible tumor: 1st-line treatment; both diagnostic and therapeutic
  - For sessile lesions, HG disease, or CIS, random biopsies of the bladder and prostatic urethra in men should be considered

MEDICATION

First Line

- Intravesical therapy: Adjuvant to surgery to reduce tumor recurrence/progression
  - Intravesical chemotherapy
    - Drugs: Thiotepa, doxorubicin (Adriamycin), mitomycin, valrubicin
    - Single-dose perioperative intravesical chemotherapy within 6 hr of TURBT reduces tumor recurrence for LG disease
    - Marginal (7–14%) reduction in long-term recurrence rate
    - No decrease in tumor progression
  - Intravesical BCG
    - Live suspension of attenuated *Mycobacterium bovis* vaccine strain instilled in bladder via Foley and retained for 2 hr
    - Give 2–4 wk after TURBT; Weekly administration × 6 wk for induction course.
    - Maintenance courses improve efficacy
    - Most effective intravesical agent, with initial response rates up to 84%
    - Most ultimately recur (30% disease-free survival at 10 yr)
    - Decreases risk of progression by ~35%, but benefit mostly seen in maintenance therapy
    - Toxicity: Generally well tolerated though urinary frequency, dysuria, and low-grade fever common
    - Risk of systemic BCG infection (see Section I "BCG sepsis/BCGosis.")
- BCG: Greater efficacy than intravesical chemotherapy though higher morbidity (4)

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Repeat TURBT indicated for T1 and HG Ta as 25–50% may harbor worse prognostic findings on 2nd TURBT
- Bladder biopsies (random): Helpful if positive cytology with no obvious lesion
- Laser/electrofulguration: Useful for recurrent, small, LG papillary tumors; may be performed under local anesthesia

- Fluorescence "Blue Light"/Cysview cystoscopy
  - Intravesical agent binds porphyrins in neoplastic tissue and fluoresces under blue light
  - Improves detection of papillary tumors and CIS; Decreases recurrence but not progression
  - Recommended by EAU guidelines
- Narrow band imaging (NBI) is an evolving endoscopic technology
- Radical cystectomy: Indicated in HG NMIBC refractory to BCG, particularly if 2nd induction course fails

ADDITIONAL TREATMENT

Radiation Therapy

No role in superficial disease

Additional Therapies

Adjuvant intravesical chemotherapy/immunotherapy (as above)

Complementary & Alternative Therapies

Mediterranean diet (high intake of fruit, vegetables, legumes) thought to lower risk of urothelial cancer (5)

ONGOING CARE

PROGNOSIS

See "Pathophysiology"

COMPLICATIONS

TURBT: Bleeding, irritative symptoms, bladder perforations (mainly extraperitoneal); usually can be managed conservatively with catheter drainage and anticholinergics

FOLLOW-UP

Patient Monitoring

- Surveillance after TURBT: Cystoscopic and urine cytology every 3–6 mo for 2 yr, then increasing interval as appropriate
  - Schedule resets with each recurrence
- TURBT as necessary, depending on cytology results and cystoscopic appearance
- Upper-tract surveillance studies (CT urogram) every 2–3 yr for HG bladder tumors and CIS

CODES

ICD9

188.9 Malignant neoplasm of bladder, part unspecified

ICD10

C67.9 Malignant neoplasm of bladder, unspecified

CLINICAL/SURGICAL PEARLS

- Greatest risk factor for progression to MIBC is high-grade disease.
- Administration of mitomycin C at the time of TURBT for low-grade NMIBC decreases risk of recurrence but not progression.
- Though the majority of men with high-grade NMIBC respond to BCG, most will ultimately recur.

BLADDER CANCER, SQUAMOUS CELL CARCINOMA

Daniel J. Canter, MD

BASICS

DESCRIPTION

- Squamous cell carcinoma (SCC) of the bladder is a histologic variant of bladder cancer
  - Most frequent histologic form of bladder cancer in countries with endemic schistosomiasis
  - SCC comprises 2–5% of all bladder cancers—most common histologic variant in Western countries

EPIDEMIOLOGY

Incidence

- 2–5% of bladder cancers in Western countries
- Originally reported that patients with spinal cord injuries (SCIs) had an incidence of SCC of the bladder of 2.3%—more recent data only suggests 0.39% incidence
- Approximately 75–80% of all bladder cancers are SCCs in regions with endemic schistosomiasis

Prevalence

Difficult to assess since so many of these patients will ultimately die of bladder cancer

RISK FACTORS

- Schistosomiasis infection
- Transitional cell carcinoma (TCC) can differentiate into any histology
- Smoking
- Chronic bladder infection/irritation
  - Patients with SCIs
  - Chronic indwelling Foley catheter/CIC
  - Chronic infection
  - Bladder stones
  - Leukoplakia
  - Squamous metaplasia
- HPV infection
- Industrial exposures for workers involved in the production of rubber, leather, textiles, and paint (traditionally more associated with the development of pure urothelial carcinoma)

Genetics

- Association with variations in inflammatory genes
- Epidermal growth factor receptor and p53 overexpression implicated as well as p16 abnormalities
- Keratin 10 and caveolin-1 identified as potential markers of differentiation from TCC to SCC

PATHOPHYSIOLOGY (1)

- Schistosomiasis infection
- Transitional cell dedifferentiation

  – Transitional cells possess unique ability to dedifferentiate into any cell type
- Chronic irritation of bladder mucosa due to a variety of etiologies, especially SCIs
- Most common bladder sites are the lateral wall and trigone

ASSOCIATED CONDITIONS
- Neurogenic bladder/SCIs
- Need for chronic indwelling Foley/CIC
- Smoking history
- Living and travel to areas endemic with schistosomiasis

GENERAL PREVENTION
- No good screening test for bladder cancer in general
- Smoking cessation
- Patients with indwelling catheters (Foley, suprapubic tube, etc.) should be screened with yearly cystoscopy +/– biopsy
  – When to start is open to debate
- Treatment of patients infected with schistosomiasis (praziquantel)

DIAGNOSIS

HISTORY
- History of living/travel to countries with endemic schistosomiasis
- In general, in Western countries, patients who have SCC of the bladder present in the same manner as urothelial carcinoma of the bladder
  – Hematuria
  – Constitutional symptoms
  – Flank/back pain due to ureteral obstruction
  – History of chronic irritation to bladder mucosa

PHYSICAL EXAM
- Palpable mass on rectal/vaginal exam
- Gross hematuria

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis/urine culture
- Urinary cytology usually not reliable
- CBC
- Comprehensive metabolic panel, including (liver function testing) LFTs, alkaline phosphatase, and albumin

Imaging
- Cross-sectional imaging of the chest, abdomen, and pelvis based on patient's renal function (CT scan vs. MRI)
- Bone scan if elevated calcium, alkaline phosphatase, or unexplained pain

Diagnostic Procedures/Surgery
- Exam under anesthesia (EUA) and transurethral resection of bladder tumor (TURBT) of primary tumor for histologic diagnosis and clinical staging

- Radical cystectomy with lymph node dissection and urinary diversion is considered 1st-line treatment

Pathologic Findings
- Mixed urothelial and squamous carcinomas are more common than pure SCCs
  - The term SCC of the bladder is used only if tumor is solely composed of squamous cell component, with no urothelial carcinoma component
- Grading unreliable. Mostly considered a high-grade neoplasm
- Histologic findings
  - Squamous metaplasia
  - Keratinized islands
  - Squamous pearls
  - Intercellular bridges
  - Mitotic figures common

DIFFERENTIAL DIAGNOSIS
- Urothelial carcinoma of the bladder
- Squamous metaplasia
- Other histologic variant of bladder (adenocarcinoma, sarcomatoid, etc.)
- Invasive cervical cancer: Often squamous cell

TREATMENT

GENERAL MEASURES
- Treatment is related to stage
- In general, SCC of the bladder presents with locally advanced disease, and radical cystectomy with urinary diversion is an integral part of the treatment paradigm
- Although uncommon, noninvasive lesions can be treated with local resection and diligent surveillance

MEDICATION

First Line
- Systemic chemotherapies have been used with limited experience in treating SCC of the bladder
- Small series have reported positive responses to cisplatin-based therapies, similar to pure urothelial carcinoma
- At present, role for neoadjuvant/adjuvant chemotherapy is poorly defined

Second Line

N/A

SURGERY/OTHER PROCEDURES (2)
- After diagnosis is confirmed, radical cystectomy is 1st-line treatment
- Bladder-preserving therapies can be considered if tumor is nonmuscle invasive and completely resected, and patient is willing to commit to intensive surveillance protocol
- Limited experience with chemoradiotherapy as primary treatment modality

ADDITIONAL TREATMENT

Radiation Therapy
Can be used in adjuvant setting for patients with positive surgical margins at time of surgery

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Related to pathologic stage (3)
  - Evidence suggests that patients with SCC of the bladder tend to present with higher-stage (pT3/T4) disease at the time of radical cystectomy
- Overall survival has ranged from 4.8 to 50%
- 5-yr cancer-specific survival in contemporary series has ranged from 57 to 64%

COMPLICATIONS
- Related to radical cystectomy and urinary diversion
  - Perioperative mortality approaches 2%
  - 40–50% of patients will experience a postoperative complication
  - Gastrointestinal complication is most common, eg, ileus, small bowel obstruction

FOLLOW-UP
Patient Monitoring
- Related to tumor stage at the time of radical cystectomy
  - In general, patients are followed with history, physical exam, laboratory studies (CBC and comprehensive metabolic profile, including liver function tests) and cross-sectional imaging of chest, abdomen, and pelvis every 3–6 mo after surgery for the first 2 yr then semiannually for 2 yr then annually
  - Renal function needs to be followed annually as well

Patient Resources

See Also (Topic, Algorithm, Media)

- Bladder Cancer, General
- Bladder Cancer, Squamous Cell Carcinoma Image ☼
- Bladder Cancer, Urothelial, Muscle Invasive (Clinical and Pathologic T2/T3/T4) (MIBC)

CODES

ICD9

188.9 Malignant neoplasm of bladder, part unspecified

ICD10

C67.9 Malignant neoplasm of bladder, unspecified

CLINICAL/SURGICAL PEARLS

- With the control of schistosomiasis in endemic regions, the rate of SCC is dropping relative to the diagnosis of urothelial carcinoma.
- Radical cystectomy is the gold standard for muscle-invasive SCC of the bladder.

BLADDER CANCER, UROTHELIAL, METASTATIC (CLINICAL AND PATHOLOGIC N+, M+)

Jean Hoffman-Censits, MD
Wm. Kevin Kelly, DO

BASICS

DESCRIPTION

- Inoperable and metastatic bladder cancers are less common presentations than noninvasive-bladder cancer.
- Though radical cystectomy for muscle-invasive bladder cancer is potentially curative, up to 50% of patients will develop recurrent disease within 2 yr.
- Most deaths from bladder cancer are from metastatic disease.
- Lymph nodes, bones, lung, liver, and peritoneum are the most common sites of metastasis from bladder cancer. The brain can also be a site, especially after systemic chemotherapy. Other unusual sites: Heart, kidney, spleen, pancreas, and reproductive system.
- The 5-yr survival for distant metastasis is 5.4%. This is in comparison to the 5-yr survival for localized bladder cancer of 70.2%.

EPIDEMIOLOGY

Incidence

- 74,690 new cases of bladder cancer will be diagnosed in 2014 with 15,580 deaths
- Bladder cancer is the 4th most common cancer diagnosed in men. Bladder cancer is much more common in men than women, whites, and those over 55 yr of age

Prevalence

An estimated 563,640 people are living with all stages of bladder cancer in US.

RISK FACTORS

- Cigarette smoking
- Chemical and occupational exposure association (aromatic amine exposure, workers in rubber, textile, leather, painting, printing, machinist, hairdressing, dry-cleaning, and trucking industries)
- Pelvic radiation and chemotherapy (Cytoxan)

Genetics

- A family history of bladder cancer increases risk, either from genetic or environmental factors
- Patients with hereditary nonpolyposis colorectal cancer (HNPCC, Lynch syndrome) are at increased risk of developing urothelial cancers
- Genetic alterations in FGFR3/RAS, p53, EGFR, PIK3CA, Her-2, and others

PATHOPHYSIOLOGY

- Alterations in genes which contribute to toxin breakdown within the bladder (such as *GST* and *NAT*), may make bladder cancer more likely

- Tumor multifocality and high recurrence rate within the bladder, ureters, and renal pelvis with a bladder cancer history support a field effect, in part from toxin exposure

ASSOCIATED CONDITIONS
- The majority of bladder cancer diagnosed in US has no other associations.
- In Egypt and other endemic regions, chronic bladder inflammation from schistosomiasis infection can lead to squamous cell carcinoma, as can chronic bladder irritation or inflammation, such as from chronic indwelling catheter use.

GENERAL PREVENTION
- Smoking cessation
- Limit or modify chemical exposure
- Hydration may limit toxin exposure

DIAGNOSIS
HISTORY
- Many tumor recurrences are noted during routine radiographic surveillance, which is standard following radical cystectomy.
- Pain from bone metastasis, lymphatic progression in the retroperitoneum, bowel obstruction with carcinomatosis, and symptoms of visceral progression such as in the lungs and liver can be symptoms of metastatic bladder cancer.

PHYSICAL EXAM
- Most with early advanced or metastatic disease have no significant external exam findings.
  - Palpable lymphadenopathy, hepatomegaly from liver involvement, as well as cachexia of malignancy can be noted.
- Leg edema with venous thromboembolism is present (incidence 1–8%); higher incidence with platinum combination therapy.
- Poor nutrition and increased abdominal girth in setting of ascites and soft tissue intra-abdominal recurrence can contribute to edema.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Lab abnormalities can include anemia of chronic disease, iron deficiency anemia in patients with longstanding hematuria, renal insufficiency in patients with ureteral obstruction, transaminitis (elevation of liver transaminases), and elevation in bilirubin in patients with liver involvement.
- Hypercalcemia is rare and associated with poor prognosis (typically associated with squamous differentiation)
- No serum tumor marker for bladder cancer.

Imaging
- Staging guidelines recommend abdomen and pelvis imaging with CT or MRI
- Imaging of the upper tract collecting system
- Chest imaging
- Bone scan if clinical suspicion of bone metastasis by pain or alkaline phosphatase elevation
- PET may be useful but not standard of care

- Documentation of normal cardiac ejection fraction required for Adriamycin

Diagnostic Procedures/Surgery

- Needle biopsy of suspected metastatic lesions
- Confirmatory needle biopsy at the time of radiographic recurrence, particularly for a patient with residual invasive or node-positive disease at cystectomy following preoperative chemotherapy, is at physician discretion

Pathologic Findings

- Urothelial (formerly transitional cell) carcinoma is the most common subtype, and for which the most data exists.
  - Many patients may have urothelial cancer with squamous or other foci of dedifferentiation.
- Less common histologic subtypes are squamous cell carcinoma, adenocarcinoma, and small cell carcinoma.

DIFFERENTIAL DIAGNOSIS

- Pelvic and retroperitoneal adenopathy
  - Malignancy: Lymphoma (non-Hodgkin, Hodgkin, others); metastatic (adrenal, renal, urothelial, prostate, urethral, penile, germ cell, cervical, ovarian, uterine), GI (carcinoid, lymphomas), colorectal, melanoma
  - Infectious/inflammatory:
    - Granulomatous: TB, sarcoidosis, histoplasmosis, lymphogranuloma venereum, Castleman disease, etc.
    - Nongranulomatous: Viral, bacterial (if abscess in local areas), sinus histiocytosis, retroperitoneal fibrosis
  - Other: Cystic retroperitoneal masses (lymphocele, urinoma, hemorrhage) aneurysms
- Bone lesions
  - Congenital (bone islands, others)
  - Endocrine/metabolic (hyperparathyroidism, Paget disease)
  - Neoplasm primary (osteosarcoma) or secondary (prostate, breast, kidney, lung, thyroid)
  - Trauma fracture (stress or healing)
  - Others: Autoimmune diseases, drugs (Vitamin D, fluoride), infection (osteomyelitis), inflammatory/Idiopathic, vascular (hemangiomas, infarct)
- Pulmonary nodules
  - Benign: Abscesses, septic emboli, fungal (histoplasmosis, etc.), parasites, mycobacterial, inflammatory conditions (Wegner granulomatosis), pulmonary AVM, pneumoconiosis, silicosis
  - Malignant: Primary lung cancer, bladder cancer, choriocarcinoma, renal and thyroid cancer, melanoma, Kaposi's sarcoma

TREATMENT

GENERAL MEASURES

- Treatment of urothelial (transitional cell) carcinoma with cisplatin-based chemotherapy has increased survival but cures are limited. With good performance status and renal function

cisplatin-based combination chemotherapy is the initial approach (Grade 1A) (1)
- "Fitness" for cisplatin-based therapy is not well defined: Generally assessment of renal function(>60 mL/min), hearing (>25 dB at 2 contiguous frequencies), performance status (WHO/ECOG performance status 2 or less), baseline peripheral neuropathy and cardiac function (New York Heart Association [NYHA] Class II or better)
- In the setting of impaired renal function correct reversible causes (obstruction, etc.)

MEDICATION

First Line

- Cisplatin-based chemotherapy combinations are the most active and superior to carboplatin regimens. Survival outcome is similar in patients treated with standard multiday MVAC (methotrexate, vinblastine, adriamycin, cisplatin) compared to cisplatin with gemcitabine (GC), with less toxicity in the GC group (1,2)
- High-dose intensity chemotherapy with MVAC plus GMCSF (HD-M-VAC) compared to classic M-VAC led to a better overall response rate (64 vs. 50%) and improved survival (21.8% in the HD-M-VAC vs. 13.5%) at 7 yr. The toxicity profile of HD-M-VAC was superior with better dose intensity, and thus established HD-M-VAC as an alternative to standard M-VAC (3)
  - MV chemotherapy is usually given every 14 days with the AC given along each 28 days
  - HD-M-VAC is also referred to as "dose dense" MVAC (DDMVAC) regimen gives the same drugs at the same doses closer together, all drugs every 14 days with hematopoietic growth factor support and is recommended by the NCCN guidelines
- Adding paclitaxel to cisplatin and gemcitabine, compared to GC led to a modest but not significant improvement in survival and is not endorsed for most patients (4)
- Some typical regimens reported in the literature include
  - MVAC: Methotrexate (30 mg/m^2 on days 1, 15, 22), vinblastine (3 mg/m^2 on days 2, 15, 22), doxorubicin (30 mg/m^2 on day 2), and cisplatin (70 mg/m^2), repeated every 28 days for 6 cycles
  - GC: Gemcitabine (1,000 mg/m^2 days 1, 8, 15) plus cisplatin (70 mg/m^2 day 2), repeated every 28 days for a maximum of 6 cycles

Second Line

- There is no standard therapy for patients who have disease recurrence or progression following 1st-line cisplatin/gemcitabine or MVAC chemotherapy, and clinical trial participation is encouraged.
- Small nonrandomized studies support the use of taxanes, gemcitabine, 5-fluorouracil, methotrexate, pemetrexed, and others in the 2nd line with modest benefit of single-agent therapy.
- The substitution of carboplatin for gemcitabine in the palliative setting in the GC regimen is reasonable for those felt unfit for cisplatin.

SURGERY/OTHER PROCEDURES

- Retrospective series support consideration of salvage surgery for patients who initially present with unresectable or metastatic disease with robust chemotherapy response (5). Survival rates were consistently better in those with pathologic complete response to induction chemotherapy and in those with node only metastasis. (See Section I "Bladder

cancer, urothelial, muscle invasive (clinical and pathologic T2/T3/T4)(MIBC) neoadjuvant therapy.")

ADDITIONAL TREATMENT

Radiation Therapy

Palliative radiotherapy is an option for patients with painful bony metastasis

Additional Therapies

- Studies suggest benefit of zolendronic acid or denosumab in patients with metastatic bladder cancer to bone (6)
- Granulocyte colony-stimulating factor can help limit myelosuppression with cisplatin and others

Complementary & Alternative Therapies

Supportive care includes adequate nutrition and hydration, particularly for patients undergoing multimodality therapy

ONGOING CARE

PROGNOSIS

For patients with metastatic disease, ECOG status ≥ 1, hemoglobin ≤ 10, and visceral involvement are prognostic for overall survival (survival 14.2 mo for those with none of these features vs. 1.7 mo with all 3 features)

COMPLICATIONS

- Cisplatin: Nephrotoxicity, ototoxicity, peripheral neuropathy, fatigue
- Adriamycin (in MVAC regimen): Cardiac toxicity
- MVAC toxicity is a major concern: Myelosuppression, neutropenic fever, sepsis, mucositis, nausea, and vomiting are common (up to 54% may require readmission for toxicity)
- Neutropenia (including life-threating febrile neutropenia) associated with multimodality chemotherapy for bladder cancer. Granulocyte growth factor is standard in the high-dose intensity MVAC regimen, and is used to support patients on gemcitabine and platinum combinations
- Gemcitabine: Rash and cytopenias
- Taxanes (ie, paclitaxel): Fluid retention, neuropathy, myelosuppression
- Ureteral obstruction (tumor or lymphadenopathy) is common and can be alleviated with ureteral stenting or percutaneous nephrostomy drainage

FOLLOW-UP

Patient Monitoring

In patients with metastatic disease on chemotherapy, imaging should be performed every 2–3 mo to assess response. In patients with durable responses of chemotherapy, imaging should be done every 3 mo for the 1st 2 yr of response.

CODES

ICD9

- 188.9 Malignant neoplasm of bladder, part unspecified
- 196.9 Secondary and unspecified malignant neoplasm of lymph nodes, site unspecified
- 198.89 Secondary malignant neoplasm of other specified sites

ICD10

- C67.9 Malignant neoplasm of bladder, unspecified
- C77.9 Secondary and unsp malignant neoplasm of lymph node, unsp
- C79.89 Secondary malignant neoplasm of other specified sites

CLINICAL/SURGICAL PEARLS

- Single-agent chemotherapy provides low response rates of usually short duration.
- For 1st-line chemotherapy, performance status and the presence or absence of visceral metastases are independent prognostic factors for overall survival.
- Brisk diuresis helps limit cisplatin renal toxicity.

BLADDER CANCER, UROTHELIAL, MUSCLE INVASIVE (CLINICAL AND PATHOLOGIC T2/T3/T4) (MIBC)

Zachary L. Smith, MD
S. Bruce Malkowicz, MD, FACS

BASICS

DESCRIPTION

- Muscle-invasive bladder cancer (MIBC) refers to invasion into or through the muscularis propria of the bladder wall (≥T2)
- Depth of invasion important for staging and treatment decisions
- Urothelial carcinoma accounts for >90% of bladder cancers (BCa)
- Less common etiologies include:
  - Squamous cell carcinoma (SCC) (5%)
  - Adenocarcinoma (2%)
  - Urachal carcinoma (<1%)

EPIDEMIOLOGY

Incidence

- 74,690 new cases of BCa in 2014 in US (1)
- Male > Female (4:1)
- 73 yr old: Average age at diagnosis
  - ~90% of patients are >55 yr at diagnosis

Prevalence

>500,000 in US (all stages)

RISK FACTORS

- Cigarette smoking (>50% of cases)
- Occupational exposure (dye, textile, rubber, and leather factory workers)
- Chronic indwelling catheters are risk factor for SCC.
  - Also, schistosomiasis in some parts of Middle East and Africa

Genetics

- Hereditary patterns:
  - Autosomal dominant
  - Multifactorial polygenic
- Cytogenetic abnormalities:
  - Loss of heterozygosity in chromosome 9 (>50% all grades and stages BCa)
  - Loss of chromosomes 17q, 5q, 3p (MIBC)
  - Inactivating mutation in p53, p21, or Rb (MIBC)
  - TP53 and/or P16 abnormalities (high-grade BCa)

PATHOPHYSIOLOGY

- Growth patterns: Papillary (70%), nodular (10%), and sessile or mixed (20%)

- Invasive tumors (T2–T4) are present in 30% at initial presentation
- 50–70% of noninvasive BCa will recur, despite conservative measures
  - Recurrent superficial BCa will progress to MIBC in 10–15%
- High-grade T1 lesions, especially if associated with lymphovascular invasion and/or carcinoma in situ (CIS), have high progression rate, requiring aggressive management
- Metastases occurs via hematogenous and/or lymphatic spread:
  - Location (most to least common): Lymph nodes (obturator, external iliac, common iliac), liver, lung, bone, adrenal
  - Most patients with metastatic disease die within 2 yr

ASSOCIATED CONDITIONS
Those secondary to smoking (lung disease, other malignancies)

GENERAL PREVENTION
- Avoidance of exposure to cigarette smoke and industrial risk factors.
- Appropriate and timely workup of both microscopic and/or gross hematuria (early diagnosis, not prevention)

DIAGNOSIS
HISTORY
- History of smoking or other risk factors
- Prior bladder tumors or hematuria
- Family history of BCa
- Signs and symptoms:
  - Painless hematuria (80%)
  - Irritative voiding symptoms (frequency, urgency, dysuria) (35%)
  - Stigmata of locally invasive or metastatic disease (pelvic pain/fullness, fixed bladder or palpable mass, inguinal lymphadenopathy, flank pain, weight loss, bone pain)

PHYSICAL EXAM
- General: Nutritional status, abdominal/pelvic masses, lymphadenopathy
- Digital rectal exam (male), bimanual pelvic exam (female), which can be performed under anesthesia

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Blood: CBC, electrolytes, LFT (elevated alkaline phosphatase suggests liver or bone involvement)
- Urine:
  - Urinalysis with microscopy
  - Cytology: Specificity ~95%; sensitivity good for high-grade, poor for low-grade
  - Other markers, less widely used: UroVysion (fluorescence in situ hybridization), BTA stat, BTA TRAK, NMP22, ImmunoCyt/uCyt+

Imaging
- Abdominal imaging:
  - CT urogram (triple phase: Noncontrast, nephrographic, excretory) is the current standard

of care
  - MR urogram acceptable, where available
  - If renal insufficiency, retrograde pyelograms combined with noncontrast CT or US
- Chest imaging: Chest x-ray (CXR) or CT
- Bone scan

Diagnostic Procedures/Surgery
- Cystoscopy to evaluate bladder for lesions
- Bladder biopsy or transurethral resection of bladder tumor (TURBT) establishes diagnosis

Pathologic Findings
- BCa will be analyzed by pathologist for grade and depth of invasion
- Grading (WHO/ISUP, 2004):
  - Papillary urothelial neoplasm of low malignant potential (well-differentiated)
  - Low-grade (moderately differentiated)
  - High-grade (poorly differentiated)
- Depth of invasion:
  - Into detrusor muscle (T2)
  - Into perivesical fat (T3)
  - Into adjacent structures (prostate, uterus, vagina, pelvic/abdominal wall) (T4)

DIFFERENTIAL DIAGNOSIS
- Gynecologic and other pelvic tumors directly invading bladder
- Adenocarcinomas more likely to be metastatic in origin
- Mass seen at bladder base on imaging is sometimes actually prostate median lobe

TREATMENT

GENERAL MEASURES
- Preoperative evaluation, as most patients also have significant cardiopulmonary disease
- Discuss treatment options and urinary diversion options
  - If ileal conduit, meet with stoma therapy nurse preop and postop for care/teaching
  - For continent diversion, preop teaching imperative
- If bladder preservation chosen, coordinate with radiation oncology and medical oncology

MEDICATION
First Line
- Intravesical treatments not used for MIBC
- Chemotherapy used as:
  - Neoadjuvant/adjuvant therapy with radical cystectomy (RC) urothelial carcinoma primarily
  - Primary treatment of metastatic disease
  - In combination with radiation therapy (RT) or TURBT for bladder preservation protocols
- Chemotherapy regimens differ based on patient factors:
  - MVAC is the historical gold standard and still commonly used
  - Gemcitabine/cisplatin has equivalent efficacy with much less toxicity and has become more commonly used

Second Line

- Carboplatin substituted for cisplatin in renal insufficiency
- Mitomycin/5-fluorouracil is a newer regimen which has emerging data to support its use
- Taxanes also promising as both single and combination agent

SURGERY/OTHER PROCEDURES

- RC with pelvic lymphadenectomy and urinary diversion considered gold standard therapy for MIBC (2)
  - Complete extirpation and pelvic lymphadenectomy provide best chances for local control and long-term survival
  - Ureteral frozen sections to ensure negative margins before urinary tract reconstruction is standard practice
  - Patients with ≥T3 disease on clinical staging may be offered neoadjuvant chemotherapy
  - RC gives no survival benefit in metastatic disease, but may be palliative in patients with intractable hematuria or pelvic pain
  - Lymphadenectomy may be prognostic and therapeutic:
    - Positive nodes in ~25%
    - Patients with limited nodal burden have higher survival rates
    - Extended lymphadenectomy (to include presacral, paraaortic, and paracaval nodes) may improve survival
    - May identify patients most suited for adjuvant therapies
- Urinary diversion (3):
  - Options include continent catheterizable stoma, continent orthotopic neobladder, or ileal conduit; each with advantages and disadvantages
    - Ileal conduit used most commonly, least complications
    - Neobladders typically reserved for younger, motivated patients who are able to perform self-catheterization if needed
- Partial cystectomy:
  - Strict patient selection criteria: Stage T2 only, solitary lesion allowing for 2-cm margins, lack of CIS, not involving trigone or ureteral orifices
  - Recurrence common within 2 yr
  - Still allows for lymphadenectomy
- Radical TURBT:
  - As a sole therapy, outcomes poor for MIBC
  - Usually palliative in patients who will not tolerate RC or systemic therapy (such as elderly with significant comorbidities)
- Urethrectomy:
  - Simultaneous (during RC) or delayed urethrectomy if CIS or tumor involves prostatic urethra, ducts, or stroma
  - Orthotopic reconstruction should not be made until negative frozen-section distal urethral margin is examined

ADDITIONAL TREATMENT

Radiation Therapy

- RT as a monotherapy is considered inferior to RC
- RT in combination with chemotherapy has a role in selected patients undergoing organ

preservation (see below)

Additional Therapies

- Combination RT and chemotherapy after TURBT is the most efficacious bladder preservation technique
  - Developed for patients who are either not candidates for or refuse RC. Ideal candidates for bladder preservation:
    - Complete visual resection on TURBT
    - Solitary tumor
    - No hydronephrosis
  - 5-yr overall survival 30–50%; better in T2 disease than T3–T4

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Prognostic factors:
  - Tumor cell type (SCC and adenocarcinoma less favorable)
  - Tumor grade and stage
  - Disease-free survival correlates with stage
  - Node burden (>8 positive) and node density (>20%) has worse prognosis
- Survival rates after RC:
  - Disease-free survival (5-yr) without positive nodes: 72% (62–84%) for pT2; 40% (19–57%) for pT3; 24% (0–36%) for pT4
  - Disease-free survival with positive nodes: 30% (15–48%)

COMPLICATIONS

- General:
  - Commonly due to local invasion and advancement of disease
    - Urinary obstruction, hydronephrosis
    - Hematuria, clot retention
  - Malnutrition, infection, etc.
- Associated with RC:
  - 90-day hospital readmission: 32%
  - 90-day mortality: ~6%
  - Bowel obstruction (4–10%), ureteral anastomotic stricture (5–10%), PE (2%)

FOLLOW-UP

Patient Monitoring

- Follow-up remains controversial and dependent on disease severity. Example:
  - T1/T2 disease: Semiannual physical exam, serum chemistries, and CXR with CT scan every 2 yr (T1) or yearly (T2)
  - T3/T4 disease: Exam, labs, and CXR every 3 mo with semiannual CT scan
  - If disease free at 5 yr, surveillance can be lessened per patient/practitioner comfort level
  - Patients with intact urethra should be monitored for urethral recurrence

- Consider urethral washing or cystoscopy

CODES

ICD9

188.9 Malignant neoplasm of bladder, part unspecified

ICD10

C67.9 Malignant neoplasm of bladder, unspecified

CLINICAL/SURGICAL PEARLS

- MIBC represents an aggressive disease with lethal potential.
- Surgical resection in the form of RC is the gold standard therapy.
- Role for multimodal treatment of MIBC with chemoradiotherapy and aggressive TUR is not as well established as RC, however, has shown promising results.

BLADDER CANCER, UROTHELIAL, MUSCLE INVASIVE (CLINICAL AND PATHOLOGIC T2/T3/T4) (MIBC) NEOADJUVANT THERAPY

Jean Hoffman-Censits, MD
William Kevin Kelly, DO

BASICS

DESCRIPTION

- Detrusor muscle-invasive bladder cancer (T2, 3, 4 MIBC) is much less common than noninvasive bladder cancer.
- May present with de novo invasive cancer, a minority progress from superficial bladder cancer
- Radical cystectomy for muscle-invasive bladder cancer is potentially curative; up to 50% of patients will develop recurrence within 2 yr.
  - This high recurrence has led to the increasing use of neoadjuvant chemo before cystectomy.
  - Neoadjuvant cisplatin-based chemo has improved survival vs. radical cystectomy alone.

EPIDEMIOLOGY

Incidence (1)

- 74,690 new cases of bladder cancer will be diagnosed in 2014 with 15,580 deaths
  - Most deaths due to metastatic disease
- Bladder cancer is the 4th most common cancer diagnosed in men
- Bladder cancer is much more common in men than women, whites, and those over 55 yr old

Prevalence

>500,000 in US (all stages)

RISK FACTORS

- Cigarette smoking
- Chemical and occupational exposure association (aromatic amine exposure, workers in rubber, textile, leather, painting, printing, machinist, hairdressing, dry-cleaning, and trucking industries)

Genetics

- A family history of bladder cancer increases risk, either from genetic or environmental factors
- Patients with hereditary nonpolyposis colorectal cancer (HNPCC) are at increased risk of developing urothelial cancers
- Hereditary patterns:
  - Autosomal dominant
  - Multifactorial polygenic
- Cytogenetic abnormalities:

– Loss of heterozygosity in chromosome 9 (>50% all grades and stages BCa)
– Loss of chromosomes 17q, 5q, 3p (MIBC)
– Inactivating mutation in p53, p21, or Rb (MIBC)
– TP53 and/or P16 abnormalities (high-grade BCa)

PATHOPHYSIOLOGY
- Alterations in genes which contribute to toxin breakdown within the bladder (such as *GST* and *NAT*), may make some more likely to develop bladder cancer
- Tumor multifocality and the high rate of recurrence of urothelial cancers within the bladder, ureters, and renal pelvis in patients with a bladder cancer history can be due to the field effect in part from toxin exposure
- T2: Muscularis propria invasion
- T3:Perivesical tissue invasion
- T4: Invasion of pelvic structures (eg, prostate stroma, seminal vesicles, uterus, vagina, pelvic side wall, or abdominal wall)

ASSOCIATED CONDITIONS
- The majority of bladder cancer diagnosed in US has no other associations.
- In Egypt and regions in SE Asia, chronic bladder irritation from Schistosomiasis infection can lead to squamous cell carcinoma, as can chronic bladder irritation or inflammation, such as from chronic indwelling catheter use.

GENERAL PREVENTION
- Smoking cessation
- Limit or modify chemical exposure

DIAGNOSIS
HISTORY
- Gross or microscopic hematuria is the most common presenting sign
- Dysuria, frequency, and urgency are common
- Symptoms of locally advanced disease such as pelvic pain and constipation
- Flank pain or renal insufficiency due to ureteral obstruction by tumor

PHYSICAL EXAM
- Most with muscle-invasive bladder cancer have no significant external exam findings
- Palpable lymphadenopathy, hepatomegaly from liver involvement, or other signs from obstructive processes in later-stage disease.
- Leg edema with DVT
  – Incidence 1–8%; higher in patients treated with platinum combination therapy

DIAGNOSTIC TESTS & INTERPRETATION
Lab
Lab abnormalities can include anemia of chronic disease, iron deficiency anemia in patients with longstanding hematuria, gross or microscopic hematuria, and renal insufficiency in patients with ureteral obstruction.

Imaging
- Staging guidelines recommend abdomen and pelvis imaging with CT or MRI

- Imaging of the upper tract collecting system
- Chest imaging
- Bone scan if clinical suspicion of metastasis or alkaline phosphatase elevation
- PET may be useful in determining metastatic or node-positive disease but not yet standard
- Understaging, despite adequate radiographic and pathologic data from transurethral resection of bladder tumor (TURBT), is common

Diagnostic Procedures/Surgery
- Cystoscopy with TURBT for staging and debulking of invasive disease
  – Detrusor muscle must be present in specimen for accurate pathologic staging
- Examination under anesthesia (EUA) is part of bladder cancer staging; fixation suggests locally advanced disease

Pathologic Findings
- Urothelial (formerly transitional cell) carcinoma is most common. Many patients have urothelial cancer with squamous or other differentiation.
- Less common histologic subtypes: Squamous cell carcinoma (associated with chronic inflammation), adenocarcinoma, and small cell carcinoma with or without sarcomatous changes.

DIFFERENTIAL DIAGNOSIS
- See Section I “Bladder cancer, urothelial, muscle invasive (clinical and pathologic T2/T3/T4)(MIBC)”

TREATMENT

GENERAL MEASURES
- Neoadjuvant cisplatin-based chemo should be considered for patients with muscle invasion (cT2–T4) undergoing radical cystectomy
- Overall survival benefit of 5% with lower recurrence based on meta-analysis (2)
- MVAC (methotrexate, vinblastine, adriamycin, cisplatin) preferred in healthy patients <70 yr. CMV or gemcitabine (GC) are alternatives if older or with comorbidities

MEDICATION

First Line
- Cisplatin-based chemo combinations are superior to carboplatin-based regimens. Carboplatin should not be substituted for cisplatin in patients being treated with curative intent.
- Neoadjuvant chemo has shown benefit in overall survival and in pathologic downstaging
  – Neoadjuvant MVAC trial (methotrexate, vinblastine, adriamycin, cisplatin) vs. cystectomy alone (77 vs. 46 mo 5-yr survival) (3)
- In the advanced and metastatic setting, survival outcome is similar in patients treated with MVAC compared to cisplatin with GC, with less toxicity with GC
- Several studies of neoadjuvant HD-MVAC have yielded similar rates of complete pathologic response at cystectomy compared to MVAC with manageable toxicity. HD-MVAC also referred to as “dose dense" MVAC (DDMVAC) gives the same drugs at the same doses closer together (all drugs every 14 days with hematopoietic factor support) (4)

- HD-MVAC is the neoadjuvant regimen choice at some centers, but GC is also commonly used
- CMV neoadjuvant chemo (cisplatin, methotrexate, vinblastine): Survival benefit at 10 yr (36% survival vs. 30% without chemo) (5)
- Common neoadjuvant regimens (6)
  - MVAC: Methotrexate (30 mg/m^2 days 1, 15, 22), vinblastine (3 mg/m^2 days 2, 15, 22), doxorubicin (30 mg/m^2 day 2), cisplatin (70 mg/m^2 on day 2) every 28 days × 3 cycles
  - CMV: Methotrexate (30 mg/m^2) and vinblastine (4 mg/m^2) days 1 and 8 plus cisplatin (100 mg/m^2 on day 2), with folinic acid (15 mg every 6 hr × 4 doses) days 2, 9, repeated every 28 days × 3 cycles
  - GC: GC (1,000 mg/m^2 days 1, 8, 15) plus cisplatin (70 mg/m^2 day 2) every 28 days × 6 cycles maximum
- "Fitness" for cisplatin is not well defined, but includes: Renal function, hearing, performance status, baseline neuropathy, and cardiac function

Second Line

- For patients treated with perioperative cisplatin-based chemo with disease recurrence, particularly for those with recurrence >12 mo following chemo, cisplatin rechallenge can be considered.
  - With disease progression while on or closely following cisplatin-based chemo, there is no standard second line therapy.
  - Many small studies have shown modest benefit of single agent or combination regimens.

SURGERY/OTHER PROCEDURES

- Radical cystectomy is the treatment of choice for patients with invasive (T2–T4) disease, patients with multifocal tumors, large tumors, hydronephrosis, node-positive disease (N1).
  - Consider consolidative cystectomy in patients with extensive nodes or locally advanced disease with durable responses to chemo.
- Bilateral pelvic lymphadenectomy: Include common iliac, internal iliac, external iliac, hypogastric, presacral, and obturator nodes.
  - Increased number of lymph nodes removed and lymph node density (# positive LN / # total LN removed) in patients with positive lymph nodes can improve recurrence rates (7).
  - A randomized trial of standard vs. extended pelvic lymph node dissection is ongoing.

ADDITIONAL TREATMENT

Radiation Therapy

- Multimodality treatment with chemo-radiotherapy can be considered for patients who are medically inoperable or selected patients who wish for bladder preservation (8).
  - Tumors <5 cm, no carcinoma in situ, no hydronephrosis, complete TURBT resection, T2–T3, functional bladder at baseline.
- Neoadjuvant chemo followed by cystectomy and chemo-radiotherapy have not been compared head to head in a prospective trial

Additional Therapies

- Multidisciplinary evaluation should be considered to asses best plan of care
- For patients who have received standard cisplatin-based neoadjuvant chemo, there is currently no recommendation for adjuvant chemo following cystectomy

- For patients with invasive or node-positive disease following cystectomy who did not receive neoadjuvant chemo, adjuvant platinum-based therapy should be considered
- Positive surgical margins can increase risk of local failure; consider adjuvant radiotherapy

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Patients with pathologic complete response (pT0) at radical cystectomy have superior relapse free and overall survival outcomes compared to those with residual invasive disease – 10.6% complete pathologic downstaging
- Treatment with neoadjuvant cisplatin-based chemo increases the rate of pT0 over patients treated with TURBT alone (38 vs. 15%) in the Phase III study of preoperative MVAC compared to cystectomy alone

COMPLICATIONS

- Cisplatin: Nephrotoxicity, ototoxicity, peripheral neuropathy, and fatigue
- Adriamycin (in MVAC): Cardiac toxicity
- Neutropenia, including life threating febrile neutropenia is associated with multimodality chemo for bladder cancer. Granulocyte growth factor is standard in the high-dose intensity MVAC regimen, and can be used to support patients on GC/platinum combinations
- GC: Rash and cytopenias
- Ureteral obstruction (tumor or nodes): Alleviate with ureteral stenting or percutaneous nephrostomy to improve renal function
- 30-day perioperative mortality following cystectomy approximately 1%; average 30-day readmission rate 21–32%
- Perioperative morbidity following cystectomy: Ileus, blood loss, infection, thromboembolism, wound dehiscence, ostomy complications.

FOLLOW-UP

Patient Monitoring

- Following radical cystectomy, imaging of the chest, abdomen and pelvis including upper tract evaluation and CBC and electrolyte assessment should occur every 3–6 mo. Based on recurrence risk for the first 2 yr, then as clinically indicated.
- Urine cytology and electrolytes should be monitored every 3–6 mo. Based on recurrence risk for the first 2 yr., then as clinically indicated.
- Continent diversion: Monitor B12 deficiency

CODES

ICD9

188.9 Malignant neoplasm of bladder, part unspecified

ICD10

C67.9 Malignant neoplasm of bladder, unspecified

CLINICAL/SURGICAL PEARLS

- Outcomes after radical cystectomy indicate increased survival in patients who had more, rather than fewer, lymph nodes resected.
- Patients with pathologic complete response following neoadjuvant chemotherapy appear to have the best long-term survival.

BLADDER CANCER, UROTHELIAL, SUPERFICIAL CARCINOMA IN SITU (CIS) (NMIBC)

Megan M. Merrill, DO
Surena F. Matin, MD, FACS

BASICS

DESCRIPTION

- Carcinoma in situ (CIS) of the bladder is a flat, multifocal, "velvety" lesion of the urothelium
  - CIS is a flat, high-grade tumor that are confined to the mucosa
  - Can be occult and diagnosed by random biopsies of normal appearing mucosa
  - Although can occur alone, most often seen with concomitant high-grade papillary lesions
- Classified as nonmuscle-invasive bladder cancer (NMIBC) similar to stage Ta and T1, however CIS is considered high grade and aggressive with a propensity to invade the bladder wall and metastasize

EPIDEMIOLOGY

Incidence

True incidence not known given the flat superficial nature of this lesion, which can be destroyed by cautery effect during transurethral resection of bladder tumor (TURBT)

Prevalence

- Occurs as isolated CIS in 3–5% cases
- Estimated 5–10% of patients with noninvasive urothelial carcinoma have CIS (1)
- 45–65% patients with invasive urothelial carcinoma have CIS (2)

RISK FACTORS

- No risk factors specific for CIS beyond that of urothelial carcinoma
- Tobacco smoking-cigarettes
- Occupational exposure
  - Organic chemicals: Aromatic amines, benzenes, aniline dyes
  - High-risk occupations: Petroleum, chemical, rubber, textile workers, hairdressers
- Medications
  - Phenacetin-containing analgesics
  - Cyclophosphamide
- Pelvic radiation

Genetics

- p53 mutation most important deletion/mutation found with CIS (2)
- Chromosome 9q deletions common
- Loss of CDKN2/p16 (tumor suppressor gene)

PATHOPHYSIOLOGY

- CIS usually multifocal and can occur in the upper tracts, prostatic ducts, and urethra as well as the bladder

- Natural history—highly aggressive
  - Progression to MIBC in 54–83% of untreated cases (3,4)
  - Increase risk of recurrence if found with NMIBC papillary lesions
- Bacillus Calmette-Guerin (BCG) reduces risk of progression by 35% compared with other intravesical therapies (1,3)
- BCG confers disease-free rate approximately 51% at 3.75 yr (1)
- If concomitant muscle-invasive lesion, prognosis and treatment depends on invasive lesion

ASSOCIATED CONDITIONS
- NMIBC (Ta,T1)
- Invasive bladder cancer (T2,T3,T4)

GENERAL PREVENTION
- Smoking cessation
- Increased fluid intake
- Avoid occupational exposures

DIAGNOSIS
HISTORY
- Age and sex
- Presence of gross hematuria
- Irritative voiding symptoms—dysuria commonly occurs with CIS
- History of bladder cancer
- Family history of bladder cancer
- Smoking history
- Occupational risk factors

PHYSICAL EXAM
- Usually unremarkable
- Bimanual exam should be performed at time of cystoscopy/TURBT—If CIS is found in presence of advanced stage/invasive bladder cancer may appreciate palpable mass

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis, including microscopic evaluation
- Urine cytology—highly specific and sensitive (>90%) for detecting CIS and high-grade urothelial carcinoma (5)
- UroVysion, HA-HAase, and BLCA-4 have a high sensitivity to detect CIS however should not replace classic urine cytology (1) (Grade B)

Imaging
- No imaging specific for diagnosing CIS
- Renal/bladder ultrasound (US): Detects hydronephrosis that may be caused by ureteral obstruction from bladder tumor; bladder US can visualize larger bladder tumors
- Computed tomography (CT) urogram: Triple phase CT abdomen/pelvis is the gold standard for evaluation of painless gross hematuria; can detect more advanced bladder tumors, hydronephrosis, and upper tract filling defects that may represent upper tract urothelial

carcinoma

Diagnostic Procedures/Surgery

- Cystoscopy with bladder biopsy
  - Appearance can be flat, grossly erythematous, granular or cobblestone mucosa or visually normal
  - May be performed in office at initial visit
  - TURBT under general or spinal anesthesia may be required if papillary bladder tumor present
  - Retrograde pyelography also should be performed to assess the upper tracts if not already evaluated with a CT urogram
  - Positive cytology with no visible tumor and negative random bladder biopsies suggests disease outside of bladder
    - Biopsy of prostatic urethra indicated
    - Selective cytology from upper tracts; evaluate for urothelial carcinoma/CIS of renal pelvis or ureters. CIS of upper tracts suspected in absence of solid tumor and with positive cytology, rarely able to obtain adequate biopsy to confirm CIS histologically
- Fluorescent "Blue light" cystoscopy
  - More sensitive than conventional white light cystoscopy for detecting CIS
    - In a prospective study additional detection rate of 20% for all tumors and 23% for CIS (6)
  - False-positives can result in the presence of inflammation, recent TUR, or BCG instillation

Pathologic Findings

- Arises from surface uroepithelium
- Severe cytologic atypia and nuclear aplasia (2)
  - Large, irregular hyperchromatic nuclei
  - Mitotic activity common
- Thought to be a precursor of invasive disease
- Some pathologists use the term "severe dysplasia" to describe CIS

DIFFERENTIAL DIAGNOSIS

- Nonurothelial cancers (squamous cell carcinoma, adenocarcinoma)
- Inflammatory lesion from prior radiation, interstitial cystitis, infection

TREATMENT

GENERAL MEASURES

- Resection of all visible tumor followed by intravesical therapy
- For BCG-refractory CIS: Radical cystectomy

MEDICATION

First Line

- BCG—live suspension of the attenuated *Mycobacterium bovis* vaccine strain
  - Standard of care for CIS
  - Therapy initiated no earlier than 2–4 wk after TURBT/biopsy to give uroepithelium time to heal and prevent systemic complications of BCG

- Administered as induction therapy—6 consecutive weekly bladder instillations; then maintenance treatment recommended for at least 1 yr (1) (Grade A)
- BCG has the highest complete response rate and durable disease-free rate among all intravesical treatments (1) (Grade A)
- Initial response rates approximately 70–90%, however up to 1/2 of patients will recur
- Response to BCG instillation should be assessed at 3 mo
  - If no response can give another 6-wk course of BCG vs. proceed to radical cystectomy
  - Approximately 50% will respond to second course of BCG (1) (Grade B)

Second Line

- Intravesical chemotherapy
  - Mitomycin C—an alternative for patients who cannot tolerate BCG
  - Valrubicin—an option for poor surgical candidates with BCG-refractory disease
  - Gemcitabine

SURGERY/OTHER PROCEDURES

- TURBT—Resection of all visible papillary bladder tumors is essential prior to BCG therapy
- For CIS refractory to intravesical therapy—radical cystectomy
  - Disease-specific survival rates excellent if cystectomy performed early (instead of BCG instillation), however 40–50% could be overtreated (4) (Grade A)

ADDITIONAL TREATMENT

Radiation Therapy

No role in treatment of CIS

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Depends on stage of concomitant invasive papillary urothelial lesion
- CIS alone or with NMIBC—high rate of progression to muscle-invasive disease if untreated
  - See “Pathophysiology”
  - BCG reduces risk of recurrence and progression to muscle-invasive disease
- CIS of prostatic urethra unfavorable (1)
  - Prostatic tissue stromal invasion worst prognosis—cystoprostatectomy advised
- Disease-specific survival rates excellent if cystectomy performed early (instead of BCG instillation), however 40–50% could be overtreated (4) (Grade A)

COMPLICATIONS

- BCG toxicity
  - Low, but serious risk of systemic BCG infection (BCGosis)—avoid treatment in presence of recent TURBT, hematuria, foley trauma, or urinary tract infection
  - Has side effect of dysuria and can be intolerable in some patients

- Usually experienced within the first 6 mo of treatment

FOLLOW-UP

Patient Monitoring

At 3 mo patients should have cystoscopy and urine cytology. If negative, this should be repeated every 3 mo × 2 yr, every 6 mo thereafter until year 5 and then yearly (3)

CODES

ICD9

233.7 Carcinoma in situ of bladder

ICD10

D09.0 Carcinoma in situ of bladder

CLINICAL/SURGICAL PEARLS

- Urine cytology is the best marker (>90% sensitivity/specificity) for diagnosis of CIS.
- Positive cytology in absence of visible bladder lesions—differential includes CIS bladder, prostatic urethra, or upper tract urothelial carcinoma.
- BCG is the treatment of choice for CIS of the bladder; highest response rate and most durable disease-free rates of all intravesical therapies.
- To prevent systemic complications of BCG do not administer after TURBT until urothelium healed (approximately 2 wk).
- For BCG refractory CIS: A second induction course BCG can be administered vs. proceeding immediately to radical cystectomy.

BLADDER INJURY, INTRAOPERATIVE

Costas D. Lallas, MD, FACS
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION

- Bladder injury during surgery can be either intraperitoneal or extraperitoneal.
- The bladder is the urologic organ most subjected to iatrogenic injury.
- Described during open, endoscopic, laparoscopic, or robotic procedures.
- May be blunt/sharp dissection, trocar, or electrocautery injury.
- Needle or trocar passage during transvaginal tape or pubovaginal sling procedures are particularly high-risk procedures.
- Cystoscopy with overdistension and transurethral bladder tumor resections are also high risk for bladder perforation injury.

EPIDEMIOLOGY

Incidence (1,2)

- Intraoperative bladder injuries account for:
  - Laparoscopic injuries (0.2–8.3%)
  - Laparoscopic injuries intraoperative diagnosis: 53.2%
- Location:
  - Intraperitoneal (38–40%)
  - Extraperitoneal (54–56%) of injuries

Prevalence

N/A

RISK FACTORS

- General factors
  - Inexperienced surgeon
  - Over aggressive TURBT or bladder biopsy
  - Complex surgical anatomy (prior surgery or radiation therapy)
  - Poor laparoscopic visualization
  - Full/overdistended bladder
  - Thin bladder wall (transurethral injury) more common in older females due to thin bladder wall
- Risk factors associated with specific conditions and procedures based on EAU review
  - Cesarean delivery
    - Previous caesarean delivery
    - Previous pelvic surgery
    - Presence of labor
    - Station of presenting fet al part $> +1$
    - Fet al weight > 4 kg
  - Hysterectomy

- Malignancy
- Endometriosis
- Prior pelvic surgery
- Concomitant anti-incontinence or pelvic organ prolapse surgery

– General surgery
- Malignancy
- Diverticulitis
- Inflammatory bowel disease

– Midurethral sling operations
- Retropubic route
- Previous caesarean delivery
- Previous colposuspension
- BMI < 30 kg/m^2
- Rectocele
- Procedures under local anesthesia
- Inexperienced surgeon

– TURBT
- Tumor size
- Elderly patients
- Pretreated bladder (previous TURB, intravesical instillation, radiotherapy)
- Tumor location at the dome or in diverticulum

Genetics

N/A

PATHOPHYSIOLOGY

- Bladder injury with urinary leakage is consistent with complete tear through mucosa, submucosa, and muscularis
- Leakage of urine can be into the extra- or intraperitoneal space
- Perforation of the bladder dome during Veress needle or trocar insertion
- Large bladder perforations during TURBT requiring intervention are rare (0.16–0.57%)
  – Extraperitoneal TURBT perforations are more frequent than intraperitoneal ones

ASSOCIATED CONDITIONS

- Bladder cancer
- Prostate benign and malignant tumors
- Pelvic anatomic anomalies
- Prior pelvic surgery or radiation
- Pelvic trauma
- Tissue fibrosis or inflammation (eg, radiation, chronic catheter)

GENERAL PREVENTION

- Decompress bladder with a catheter placed before initial incision or trocar placement for laparoscopic cases
- Initial use of Veress needle for insufflation
  – Small bladder perforation not as significant as with trocar injury
  – Open “Hasson” trocar technique

- Familiarity with bladder anatomy can minimize risk:
  - Pediatric bladder is primarily intraperitoneal.
  - Adult bladder is retropubic and extraperitoneal.
  - Peritoneum is cephalad to bladder.
  - Bladder is attached laterally and at bladder neck
  - Bladder wall consists of 3 layers: Mucosa, submucosa, muscularis
  - Ureters attached posterolateral in trigone
- Perform bladder biopsy or TURBT with bladder at mid filling
  - Avoid over or underdistention that can increase risk of perforation of bladder

DIAGNOSIS

HISTORY

- Determine any prior surgical or other interventions that can increase the risk of intraoperative bladder injury
  - Past surgical history such as bladder neck suspension, cesarean section, radical prostatectomy, partial cystectomy, ureteral reimplantation, any lower abdominal surgery that may result in the bladder adhering to the posterior fascia
  - Prior pelvic radiation
  - History of neurogenic bladder

PHYSICAL EXAM

- Intraoperative:
  - Findings may be subtle. Need high degree of suspicion
  - Blood or gas in Foley, especially during transperitoneal laparoscopic procedure
    - Anesthesia may be first to recognize if monitoring catheter collection bag
  - Urine in wound
  - For transurethral surgery: Intraoperative abdominal distension/rigidity may be noted or if hypotonic irrigation is being used, patient may develop signs/symptoms of TUR syndrome
- Postoperative:
  - Distended abdomen
  - Peritonitis and abdominal rebound pain
  - Decreased urine production; oliguria or anuria
  - Abdominopelvic ascites
  - Urinoma
  - Urine leakage from wound
  - Bloody urine
  - Fever

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- With urinary ascites elevation in serum BUN and creatinine as well as hyperkalemia and hyponatremia can be seen
  - Elevated creatinine over serum level observed with urine leak due to systemic absorption
- Drain fluid sent for creatinine
  - Urine vs. serum

Imaging

- Postoperative diagnosis (3):
  - Extraperitoneal injury: Contrast contained in the extraperitoneal space
  - Intraperitoneal injury: Contrast extravasates between loops of small bowel and the anterior pararenal fascia
- Cystogram can be done using standard technique or CT imaging with postcontrast evacuation (3)
  - 300 cc gravity filling
  - 3-view cystogram or CT cystogram
  - All cystograms must include a postcontrast evacuation study to evaluate for residual contrast outside of the bladder
- US can identify urinoma
- CT for pelvic "urinary" ascites or urinoma
- Intraoperative diagnosis during transurethral surgery: Intraoperative cystogram can be obtained

Diagnostic Procedures/Surgery (1,4)

- Intraoperative diagnosis:
  - Normal saline with indigo carmine into Foley and observe for extravasation (blue staining)
  - Avoid use of methylene blue due to extensive tissue staining risk
- Intraoperative cystoscopy can be useful in selected situations and may be the most reliable method of immediately assessing bladder wall integrity
- Cystoscopy
  - Recommended after suburethral sling operations via the retropubic route
  - May be considered after sling insertion via the obturator route (controversial as bladder injuries are rare with this technique).
- Cystoscopy after transvaginal mesh procedures is preferable.
- Some authors have recommended routine cystoscopy due to the higher risk of bladder injuries during hysterectomy or after any major gynecologic procedure.

Pathologic Findings

Rupture through mucosa, submucosa, and muscularis of detrusor usually causes urine leak

DIFFERENTIAL DIAGNOSIS

- Prostatourethral injury
- Small or large bowel injury
- Ureteral injury
- Vascular injury

TREATMENT

GENERAL MEASURES

- Prompt recognition improves opportunity for improved outcome.
- Bladder injury can be found intraoperatively or postoperatively, and will be intraperitoneal or extraperitoneal.

- For most bladder injures Foley catheter for 10–14 days with follow-up cystogram is recommended

MEDICATION

First Line

- Consider antibiotics: Gentamicin or fluoroquinolone for 24 hr
- Anticholinergic for postoperative bladder spasm: Oral or suppository

Second Line

N/A

SURGERY/OTHER PROCEDURES (5)

- Laparoscopic or robotic injury:
  - 1-layer laparoscopic or robotic repair
- Intraoperative intraperitoneal injury:
  - Open bladder/2-layer repair
- Intraoperative extraperitoneal injury:
  - Foley or 2-layer repair
- Postoperative intraperitoneal injury:
  - Exploratory laparotomy with repair
- Postoperative extraperitoneal injury:
  - Initial catheter drainage with antibiotics
- Transurethral procedure:
  - Extraperitoneal perforation
    - Exploratory laparotomy with repair for large perforation. Carefully inspect bowel for potential injury
    - Small leak can be initially managed with catheter drainage and close monitoring
  - Extraperitoneal perforation
  - Usually managed with catheter drainage
  - Large perforations complicated by symptomatic collections require drainage, with or without formal closure of the perforation
- Bladder perforation during midurethral sling or transvaginal mesh placement
  - Sling reinsertion and urethral catheterization (1–2 days) should be performed (4,6).

ADDITIONAL TREATMENT

In the setting of any bladder perforation during TURBT intravesical postoperative chemotherapy should not be administered

ONGOING CARE

PROGNOSIS

- Extraperitoneal: Usually heals with Foley catheter drainage and without further intervention
- Intraperitoneal: Good prognosis if identified intraoperatively and repaired. Prognosis worse if delayed diagnosis

COMPLICATIONS

- Peritonitis or abscess
- Ileus

- Fistula
- Reoperation

FOLLOW-UP

Patient Monitoring

- Foley catheter or suprapubic tube to monitor urine output
- Usually no need for outpatient antibiotics

CODES

ICD9

- 867.0 Injury to bladder and urethra, without mention of open wound into cavity
- 867.1 Injury to bladder and urethra, with open wound into cavity
- 998.2 Accidental puncture or laceration during a procedure, not elsewhere classified

ICD10

- N99.71 Acc pnctr & lac of a GU sys org during a GU sys procedure
- N99.72 Accidental pnctr & lac of a GU sys org during oth procedure
- S37.23×A Laceration of bladder, initial encounter

CLINICAL/SURGICAL PEARLS

- Intraoperatively, visual inspection is a reliable method of assessing bladder injury.

- Extraperitoneal: Usually heals with Foley catheter drainage and without further intervention.
- Intraperitoneal: Good prognosis if identified intraoperatively and repaired. Prognosis worse if delayed diagnosis.
- All cystograms must include a postcontrast evacuation study to evaluate for residual contrast outside of the bladder.

BLADDER OUTLET OBSTRUCTION (BOO)

Garjae D. Lavien, MD
Michael J. Naslund, MD

BASICS

DESCRIPTION

- Bladder outlet obstruction (BOO) refers to a pathologic obstruction to urinary flow
- Definitions include the following:
  - A reduction in urinary flow to <12 cc/s during a sustained detrusor contraction of over 40–50 cm H_2O
  - BOO index >40 on the International Continence Society nomogram based on urodynamic testing

EPIDEMIOLOGY

Incidence

2.2–6.8 events of acute urinary retention per 1,000 person years (1)[A]

Prevalence

None

RISK FACTORS

- Increasing age
  - Microscopic BPH starts as early as the 30s but clinical BPH usually presents after the age of 50
- Infection
- Urethral trauma
- Pelvic radiation
- Prior urologic procedures

Genetics

N/A

PATHOPHYSIOLOGY

- BOO can be due to both static and dynamic factors:
- Dynamic factors
  - Stimulation or lack of relaxation of the smooth muscle along the proximal urethra or bladder neck
  - Results in increased resistance along the prostatic urethra
- Static factors
  - Constricted outlet by enlarged prostatic tissue, bladder neck contracture, or urethral stricture
- Outlet obstruction leads to detrusor hypertrophy and the symptoms of BOO

ASSOCIATED CONDITIONS

- BPH

- Urethral stricture disease
- Detrusor sphincter dyssynergia

GENERAL PREVENTION
None

DIAGNOSIS
HISTORY
- Detailed description of obstructive voiding symptoms consistent with BOO
  - Slow urinary stream
  - Urinary hesitancy
  - Intermittent urinary stream
  - Straining to void
  - Sense of incomplete bladder emptying
  - Urinary retention
- History of irritative symptoms
- Medical history of gynecologic, neurologic, and GI illness
- Past surgical history for pelvic and spinal procedures
- Medication review for anticholinergics, α-agonists, psychotropic agents
- Voiding diary
- International Prostate Symptom Score

PHYSICAL EXAM
- Abdominal exam:
  - Palpate for bladder distention (>150 cc retained urine needed to be palpable in an adult)
  - Inguinal hernia can be associated with severe BPH and retention
- Digital rectal exam:
  - Examine for an enlarged prostate
  - Note any findings suspicious for cancer: Nodules, firmness, and asymmetry
  - Assess anal sphincter tone
- Pelvic exam (women) for pelvic organ prolapse and urethral diverticula
- Neurologic exam for gross defects

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- PSA:
  - If elevated, consider prostate cancer, prostatic inflammation, benign prostatic hyperplasia
- Urinalysis:
  - If hematuria or urinary infection is present, further evaluation is necessary (see Chapter on “Hematuria, Gross and Microscopic, Adult”)
- Creatinine
  - Not necessary unless patient is in urinary retention

Imaging
- Renal and bladder US
  - Evaluate for hydronephrosis if there is renal insufficiency

  – Allows noninvasive determination of PVR
- Upper tract imaging with CT urogram to evaluate causes of hematuria
- Uroflowmetry:
  – Measures peak flow, demonstrate voiding pattern, and voided volume
  – Peak flow <10–12 cc/s (for voided volume >150 cc) is suggestive of obstruction, although an acontractile bladder cannot be ruled out
- Cystoscopy: Endoscopic evaluation of urethra and bladder
  – Used to evaluate prostatic length, median lobe component of prostatic obstruction, and bladder mucosa
  – Can reveal other etiology for the BOO, such as strictures, stones, diverticula, urethral masses, and bladder tumors
- Urodynamics: Pressure-flow study to determine if a low flow rate is due to obstruction or reduced bladder contractility:
  – Videourodynamics: Fluoroscopy combined with urodynamics. Recommended in patient suspected to have primary bladder neck obstruction
  – ICS nomogram is the most widely used measurement of BOO; plots maximal flow against detrusor pressure at the time of flow
  – EMG: Evaluates for neurogenic etiology of BOO

Diagnostic Procedures/Surgery

See "Imaging" and "Surgery/other procedures"

Pathologic Findings

Depends on etiology of BOO

DIFFERENTIAL DIAGNOSIS

- Inadequate bladder contractility
- BOO after incontinence surgery
  – The most common etiology of BOO/urinary retention in women
- Prostatic obstruction (BPH)
  – Most common etiology of BOO in men
- Primary bladder neck obstruction
- Infection:
  – Prostatitis, intraurethral condyloma (men and woman), periurethral abscess
- Neurologic:
  – Detrusor sphincter dyssynergia, diabetes mellitus with atonic bladder
- Medications that affect bladder contractility
  – Anesthetics, narcotic, psychotropics
- Urethral caruncle, urethral diverticulum (primarily women)
- Urethral cancer
- Penile cancer (usually advanced)

TREATMENT

GENERAL MEASURES

- Management of BOO depends on etiology and severity.

- A urethral catheter is used for temporary management of severe obstruction or retention.
- A suprapubic tube is used if a urethral catheter cannot be placed (severe stricture or BPH) or urethral catheter is contraindicated (acute prostatitis).
- Long-term treatment of BOO is medical and surgical.

MEDICATION

First Line

- α-Blockers: Rapidly relax the smooth muscle of the bladder neck and prostate without impairing bladder contractility:
  - Alfuzosin (10 mg/d)
  - Doxazosin (start 1 mg/d to max 8 mg; XL form 2–8 mg daily)
  - Silodosin (8 mg/d)
  - Tamsulosin (start 0.4 mg to max 0.8 mg)
  - Terazosin (start 1 mg/d to max 20 mg)
- 5-α-reductase inhibitors in males: Effective in larger glands (>40 cc) to reduce prostate size, improve symptoms, and reduce progression risk:
  - Finasteride (5 mg/d)
  - Dutasteride (0.5 mg/d)

Second Line

- Phosphodiesterase-5 inhibitors (PDE5i) in males
  - Tadalafil only PDE5i currently approved by the FDA for treatment of LUTS in the setting of BPH with or without coexisting erectile dysfunction (2)[A]

SURGERY/OTHER PROCEDURES

- Urethral strictures
  - Urethral dilation
  - Endoscopic incision
  - Open excision (with primary anastomosis, grafts, or flaps)
- Urethrolysis
  - Primary surgical approach to urethral obstruction following anti-incontinence surgery in women
- Sphincterotomy
  - Utilized for patients with detrusor sphincter dyssynergia
- BPH
  - Transurethral needle ablation
  - Transurethral microwave therapy
  - Transurethral incision of prostate
  - Transurethral resection of prostate (TURP)
  - Laser-assisted techniques such as holmium laser enucleation of the prostate (HoLEP), others
  - Photovaporization of prostate
  - Simple open prostatectomy

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies
- Long-term catheter drainage for patients with severe comorbidities
- Clean intermittent catheterization
- Prostatic stents
- Urinary diversion

Complementary & Alternative Therapies
- Saw Palmetto (Serenoa Repens)
  - No difference in reduction of lower urinary tract symptoms compared to placebo (3)[A]

ONGOING CARE

PROGNOSIS
Excellent with definitive management

COMPLICATIONS
- Urinary retention
- Gross hematuria
- Renal insufficiency/failure
- Bladder stones
- UTIs
- Bladder diverticula and flaccid bladder
- Postobstructive diuresis:
  - Occurs with severe BOO and bilateral ureteral obstruction due to urinary retention
  - Self-limited and corrected by the fluid hydration
  - If the patient cannot keep up with the urine output, then IV replacement with 1/2 normal saline at a rate of 1/2 of the urine output
  - Serum electrolytes must be monitored closely

FOLLOW-UP
Patient Monitoring
- Periodic follow-up visits to assess symptom progression (IPSS)
- Yearly urinalysis and PSA measurement
- Serial measurement of uroflow and PVR urine
- Counsel on the possibility of progression of symptoms and complications
- Management of BPH does not eliminate the risk of developing prostate cancer

Patient Resources
- Urology Care Foundation
  - www.urologyhealth.org

- Prostate, Benign Obstruction (Benign Prostatic Obstruction, [BPO])

CODES

ICD9

- 596.0 Bladder neck obstruction
- 600.01 Hypertrophy (benign) of prostate with urinary obstruction and other lower urinary tract symptoms (LUTS)
- 788.29 Other specified retention of urine

ICD10

- N32.0 Bladder-neck obstruction
- N40.1 Enlarged prostate with lower urinary tract symptoms
- R33.8 Other retention of urine

CLINICAL/SURGICAL PEARLS

- If a male patient has lower urinary tract symptoms check to ensure a low post-void residual which generally confirms that treatment is not necessary.
- Strong consideration should be given for evaluation for multiple sclerosis in young female patients with new onset urinary retention.

BLADDER TRAUMA

Brad Figler, MD
Hunter Wessells, MD, FACS

BASICS

DESCRIPTION

- Bladder trauma generally comprises blunt and penetrating types of injury.
- When not distended, bladder is protected from injury by bony pelvis.
- Pelvic fracture and bladder distention increase risk of traumatic injury.
- Important to distinguish between extraperitoneal (EBR), intraperitoneal (IBR), and combined EBR/IBR.
- Iatrogenic bladder injury is discussed in the section "Bladder Injury, Intraoperative."

EPIDEMIOLOGY

Incidence

1.6% of blunt abdominal trauma

Prevalence

- Unknown

RISK FACTORS

- Motor vehicle crashes (MVCs)
- Falls
- Industrial trauma (pelvic crush injury)
- Penetrating injuries to lower abdomen
- Bladder outlet obstruction
- Alcohol intoxication (bladder distention and decreased sensorium)
- Pelvic fracture
  - ~80% of bladder injures associated with pelvic fracture
  - ~6% of patients with pelvic fracture sustain a bladder injury
- Urethral injury (present in 15% of cases)

Genetics

N/A

PATHOPHYSIOLOGY

- The bladder is generally well protected from blunt trauma unless significantly distended
- In an adult, the bladder lies in the true pelvis, but can rise to umbilicus when full
- In a child, bladder lies in abdomen and more prone to injury
- EBR or combined EBR/IBR
  - Pelvic fracture leads to shearing injury from bone fragment or compression with rupture
  - Direct injury from penetrating trauma
- IBR
  - Blow to lower abdomen in the presence of a full bladder

ASSOCIATED CONDITIONS
- Bladder neck injury
- Pelvic fracture
- Solid abdominal organ injury
- Urethral injury

GENERAL PREVENTION
- Avoid high-risk activity
- Seatbelt proper positioning and use

DIAGNOSIS
HISTORY
- Type of blunt trauma to pelvis
  - Associated injuries
- For gunshot, number, and trajectory
- Stab wounds type of knife if known
- Gross hematuria
- Alcohol use
- Past urologic history
- Complaints
  - Location of lower abdominal pain
  - Urinary retention
  - Dysuria or voiding complaints

PHYSICAL EXAM
- Abdominal distention
- Lower abdominal/suprapubic tenderness
- Peritonitis
- Seatbelt sign
- Site/extent of abdominal/pelvic bruising
- Site/extent/trajectory of penetrating objects
- Blood at meatus
- Rectal and vaginal exam (assess integrity)
- Open pelvic fractures

ALERT
Gross hematuria is the hallmark sign of injury to the bladder.

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis (UA): Blood usually present
- Serum creatinine can be elevated with IBR due to intraperitoneal resorption of urine
- Hyperkalemia, hypernatremia, uremia, acidosis can also be seen with urinary extravasation into the peritoneum
- CBC (assess for leukocytosis and anemia)

Imaging

- Indications for performing cystography:
  - Blunt trauma
    - Pelvic ring fracture with gross or microscopic (3+ or >30 RBC/HPF) hematuria
    - Gross hematuria in presence of otherwise unexplained free intraperitoneal fluid
    - High clinical suspicion (pelvic fluid collection, inability to void, elevated serum creatinine, abdominal distention, suprapubic tenderness, intoxicated or unresponsive, poorly functioning Foley catheter, displaced obturator ring fracture, or large pubic symphysis diastasis
  - Penetrating injury
    - Trajectory suggests bladder injury
    - Involvement of buttock, pelvis, or lower abdomen with any degree of hematuria
    - High clinical suspicion
- If ureteral injury is suspected, this should be assessed preoperatively (CT with delayed images) or intraoperatively (retrograde pyelogram/direct inspection)
- When combined upper and lower tract urologic injuries are suspected, upper tract contrast study should be performed prior to cystogram (retained bladder contrast in abdomen or retroperitoneum can obscure upper tract pathology)

Diagnostic Procedures/Surgery

- Cystogram is easy to do and highly sensitive
  - CT cystogram
    - At least as sensitive as conventional cystography for diagnosing bladder rupture (1)
    - Dilute contrast to limit artifact (1:6)
    - Postdrainage films not necessary
    - Excellent visualization of bladder neck
    - Readily identify foreign bodies
  - Conventional cystogram
    - Dilute contrast 1:2
    - Scout, AP, oblique, and postdrainage films
  - For both CT and conventional cystography, fill bladder to capacity (at least 350 mL in an adult, or determine by formula: (Age in years + 2) × 30.

ALERT
CT with delayed images is inadequate for the diagnosis of bladder injuries: when bladder injury is suspected, a cystogram is mandatory (2).

Pathologic Findings

Injured tissue typically remains healthy, though there is potential for local ischemia (particularly if angio-embolization was performed for pelvic bleeding)

DIFFERENTIAL DIAGNOSIS

- Bladder contusion
- Urethral injury
- Renal or ureteral injury

TREATMENT

GENERAL MEASURES

Stabilize patient if major trauma present

MEDICATION

First Line

For nonoperative management of EBR, antibiotics with gram-positive and gram-negative coverage are recommended while catheter is indwelling

Second Line

N/A

SURGERY/OTHER PROCEDURES

- When associated with significant pelvic bleeding, open pelvic fractures, and abdominal solid organ injury, supportive care is indicated while more urgent injuries are temporized
- IBR
  - Laceration is typically large (6–8 cm), at dome
  - Nonoperative management generally contraindicated secondary to size of defect and morbidity of chemical peritonitis
  - Should be closed in 2 layers with absorbable suture via midline incision
  - Laparoscopic repair has been reported in stable patients with no other injuries (3)
  - Drain is not necessary
  - Foley catheter 7–10 days, with cystogram to confirm absence of extravasation
- EBR
  - Nonoperative management
  - Acceptable in the appropriate patient, but higher complication risk (4)
  - 20-French or larger catheter
  - Cystogram after 10–14 days
  - Antibiotics with gram-positive and gram-negative coverage while catheter is indwelling
  - Contraindications to nonoperative management:
    - Inadequate catheter drainage
    - Vaginal or rectal injury
    - Bladder neck injury
    - Concomitant urethral injury
    - Internal fixation of pelvic fracture
    - Stable and undergoing laparotomy
- Operative repair
  - Midline abdominal incision or Pfannenstiel
  - Avoid unnecessary pelvic dissection, as there can be significant bleeding from original trauma
  - Minimal debridement to ensure healthy wound edges
  - Removal of foreign bodies and bony fragments
  - Assess ureteral orifices if not imaged
  - 2-layer watertight closure with absorbable suture
  - Drain is not necessary, but may be helpful
  - Foley catheter 10–14 days, with cystogram to confirm absence of extravasation
  - Suprapubic tube not necessary

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Injuries to urethra, bladder neck, or ureters may necessitate endoscopic realignment, repair of bladder neck, or ureteral reimplant

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Prompt diagnosis and appropriate management allow excellent results and minimal morbidity.
- Complications usually are associated with delay in diagnosis and management.

COMPLICATIONS

Unrecognized injury can result in fistula, sepsis, ileus, incontinence, and stricture.

FOLLOW-UP

Patient Monitoring

- Monitor for signs/symptoms of:
  - Pelvic bleeding
  - Unrecognized abdominal injury
  - UTI
  - Urinary leak

- Bladder Injury, Intraoperative
- Bladder Trauma Algorithm
- Bladder Trauma Image
- Ureter, Trauma
- Urethra, Trauma (Anterior and Posterior)

CODES

ICD9

- 867.0 Injury to bladder and urethra, without mention of open wound into cavity
- 867.1 Injury to bladder and urethra, with open wound into cavity

ICD10

- S37.20XA Unspecified injury of bladder, initial encounter
- S37.22XA Contusion of bladder, initial encounter
- S37.23XA Laceration of bladder, initial encounter

CLINICAL/SURGICAL PEARLS

- Gross hematuria is hallmark of bladder injury.
- In addition to diagnosing bladder rupture, CT cystogram is useful in identifying foreign bodies and bladder neck injuries.
- CT with delayed images is inadequate for the diagnosis of bladder injuries: When bladder injury is suspected, a cystogram is mandatory.

BLADDER TUMORS, BENIGN AND MALIGNANT, GENERAL CONSIDERATIONS

Gurdarshan S. Sandhu, MD
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION

- Most bladder masses represent a malignant tumor
- Bladder tumors can be benign, low-grade, or aggressive high-grade malignancies
- There are a number of nonneoplastic and inflammatory disorders that can manifest as a focal bladder mass and mimic malignancy

EPIDEMIOLOGY

Incidence

- Bladder cancer: 9th most common cancer
  - 73,510 cases diagnosed in US in 2012 (55,600 males and 17,910 females) (1)
  - 14,880 total deaths in US in 2012 (10,510 males and 4,370 females)
  - Male:female > 3:1
  - Incidence increases with age and peaks in 8th decade of life
  - Median age at diagnosis is 73
  - 3× more common in White than Black men
  - 1.5× more common in White than Black women

Prevalence

Estimated 437,180 male and 148,210 female bladder cancer survivors in US as of 2012 (2)

RISK FACTORS

- Malignant bladder tumors
  - Smoking—main risk factor for bladder cancer
    - 2–6× increased risk urothelial cancer
    - Risk is linearly dose and duration related, with 15–20 yr latency
    - 2nd-hand smoke does not increase risk of bladder cancer formation
  - Chemical exposure:
    - Especially aniline dyes and aromatic amines
    - High-risk industries include textiles, aluminum, dye, leather, launderers, and rubber workers
  - Pelvic irradiation
    - Latency is 15–30 yr
    - Increased risk in prostate and cervical cancer treated with radiation
  - Chemotherapy
    - Cyclophosphamide has a 4–9× increased risk for bladder cancer
  - Inflammation is a risk factor for squamous cell carcinoma (SCC)
    - Indwelling catheters

- Chronic urinary tract infection (UTI)
- Chronic bladder stones
- *Schistosoma hematobium* infection

Genetics

- Heredity plays a minor role
  - History in a 1st-degree increases risk 2×
    - No clear inheritance patterns
- p53 gene on chromosome 17
  - Overexpression leads to higher rates of progression and lower rates of response to chemotherapy
- Loss of Retinoblastoma (Rb) gene on chromosome 9
  - Development of superficial tumors
- Slow metabolizers and slow acetylators more susceptible to environmental carcinogens

PATHOPHYSIOLOGY

- Patterns of spread of bladder cancer
  - Lymphatic
  - Hematogenous—to liver, lung, bone, etc.
  - Implantation
  - Direct extension

ASSOCIATED CONDITIONS

None

GENERAL PREVENTION

- Smoking cessation
  - Decreases risk after approximately 15 yr
- Avoid occupational exposures
- Mediterranean diet: Lowest bladder cancer risk
- Antioxidants including vitamins A, C and E, and micronutrients selenium and zinc may be protective
- Increased fluid intake may be protective

DIAGNOSIS

HISTORY

- Painless, gross hematuria
- Irritative voiding symptoms—frequency, urgency, dysuria
- Mucosuria: Adenocarcinoma, colovesical fistula
- Weight loss, cachexia, bone pain, flank pain
- Inquire about risk factors reviewed earlier
- Egyptian or Middle Eastern heritage are risk factors for SCC

PHYSICAL EXAM

- Rarely abnormal
  - Bimanual exam done under anesthesia before and after transurethral resection of bladder tumor (TURBT)

– Digital rectal exam

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis (for red blood cells) and culture
- Urine cytology
  – More sensitive in high-grade disease and carcinoma in situ (>90%)
- Flow cytometry
  – Measures DNA content of cells to quantitate aneuploid cell populations
- Other urine markers are commercially available (eg, BTA Stat, NMP 22, BladderChek), and have better sensitivities but worse specificities than cytology

Imaging

- Upper tract evaluation can be done with intravenous urogram, retrograde pyelography, computerized tomography (CT), or magnetic resonance imaging
- Metastatic evaluation includes chest imaging and bone scan

Diagnostic Procedures/Surgery

- Cystoscopy with bladder tumor resection or biopsy
  – Fluorescence cystoscopy may increase detection of carcinoma in situ or additional lesions

Pathologic Findings

- **Benign lesions**
  – Nephrogenic adenoma: Metaplastic response to chronic inflammation
  – Von Brunn nests: Benign urothelial cells within the lamina propria
  – Squamous metaplasia: Common in women (40%)
  – Cystitis cystica: Central cystic degeneration of Von Brunn nests
  – Eosinophilic cystitis
  – Malacoplakia: Chronic reaction, Michaelis–Gutmann bodies (bulls-eyed histiocytes) are needed for diagnosis
  – Papilloma: Benign growth, can recur but does not progress or invade
  – Inverted papilloma: Benign lesion with inverted growth pattern
  – Leiomyoma: Benign smooth muscle tumor covered by urothelium
  – Inflammatory pseudotumor (pseudosarcomatous fibromyxoid tumor)
  – Endometriosis
  – TB
  – Schistosomiasis
  – Crohn disease: Fistulas from inflamed small and large bowel
  – Diverticulitis: Colovesical fistulas
- Extrinsic compression resembling masses: Prostate, uterine, and ovarian organs; ureteroceles, extramedullary hematopoiesis; urachal cysts; paraganglionic tissue; hamartomas; amyloidosis; and vascular malformations
- Premalignant lesions
  – Leukoplakia: Squamous metaplasia with 20% risk for SCC
  – Cystitis glandularis: Glandular metaplasia with risk for adenocarcinoma
- Urothelial carcinomas (90% of tumors)
  – Papillary urothelial neoplasia of low malignant potential (PUNLMP)

  - Carcinoma in situ: High-grade tumor confined to urothelium, looks erythematous and velvety
    - Precursor lesion for invasive disease
    - 40–83% progress to muscle invasive disease
  - Urothelial carcinoma
    - 80% are nonmuscle invasive
    - Correlation between grade and stage
- SCC (5%): Seen with chronic inflammation
- Adenocarcinoma (2%): Seen in bladder exstrophy and urachal tumors
  - Important to rule out gastrointestinal primary
- Small cell carcinoma: Aggressive neuroendocrine tumor (rare)

DIFFERENTIAL DIAGNOSIS
- Bladder wall mass: See "Pathologic findings"
- Irritative voiding symptoms: UTI, urinary calculi, interstitial cystitis, bladder cancer, chronic prostatitis

TREATMENT
GENERAL MEASURES
- Bladder cancer: Increase fluid intake; avoid or quit smoking: Best preventive measure; avoid exposure to aromatic amines or aniline dyes other occupational exposure
- Form management of benign bladder lesions see individual topic in index

MEDICATION
First Line
- Bacillus Calmette Guérin (BCG) [A]
  - Attenuated strain of *Mycobacterium bovis*
  - Typical induction course consists of 6 weekly bladder instillations
  - Maintenance schedule improves response
  - Absolute contraindications include immunosuppression, prior history of BCG sepsis, gross hematuria, and immediately following TURBT

Second Line
- Mitomycin C [A]
  - Alkylating antibiotic that inhibits DNA synthesis, decreases recurrence
  - Given as 40 mg in 40 mL of NS or water, given weekly × 8 weeks then monthly × 1 yr
  - Also given perioperatively after TURBT
- Interferon α-2B
  - Given as monotherapy or in combination with low-dose BCG
  - Dose not standardized
- Thiotepa: Alkylating agent
  - Dose ranges from 30 mg in 30 mL of water/saline to 60 mg in 60 mL of water/saline
  - Given weekly × 8 weeks then monthly × 1 yr
  - Myelosuppression when absorbed systemically
- Doxorubicin: Anthracycline antibiotic, prevents recurrence, not progression

- Valrubicin for BCG refractory CIS
  - 800 mg in 75 mL of saline, administered weekly for 6 wk
- Gemcitabine: Activity in nonmuscle-invasive bladder cancer
  - 2 gm in 50–100 mL NS, weekly for 6 wk

SURGERY/OTHER PROCEDURES
- TURBT
  - Diagnostic: Consider repeat resection for T1 disease
  - Therapeutic: For nonmuscle-invasive disease
- Partial cystectomy
  - For selected patients with unifocal disease, urachal tumors, and tumors in diverticula
- Radical cystectomy
  - For muscle-invasive disease
  - Consider for recurrent high-grade superficial disease

ADDITIONAL TREATMENT

Radiation Therapy
- Can be used in bladder sparing protocols
  - External beam radiotherapy combined with chemotherapy to improve outcomes
    - 5-yr overall survival ~50%

Additional Therapies
- Cisplatin-based therapy is 1st line for small cell carcinoma
- Neoadjuvant chemotherapy for locally advanced disease prior to cystectomy
- Chemotherapy for metastatic disease with either methotrexate, vinblastine, doxorubicin and cisplatin, or gemcitabine and cisplatin

Complementary & Alternative Therapies
- Phototherapy: No long-term date
- Laser therapy
- Vitamins (6)
  - Regular vitamin E use for ≥10 yr may be associated with a decreased risk of bladder cancer mortality
  - Megadose multivitamins A, B6, C, and E plus zinc may decrease bladder tumor recurrence in patients receiving BCG immunotherapy
  - Increased carotene intake, including beta-carotene, alpha-carotene and lycopene, is associated with decreased bladder cancer risk

ONGOING CARE

PROGNOSIS
- Progression and recurrence depend upon grade, stage, size, the presence of CIS, multifocality, and frequency of prior recurrences.

COMPLICATIONS
- Bladder perforation from TURBT
- Disease progression and metastases
- Hematuria

- Ureteral obstruction
- UTI or sepsis

FOLLOW-UP

Patient Monitoring

- History and physical, urinalysis, cystoscopy, and urine cytology every 3 mo for 2 yr, then every 6 mo for 2–3 yr, then once a year.
- Periodic upper tract imaging for high-risk patients

Patient Resources

- BCAN http://www.bcan.org/facing-bladder-cancer/support-groups/

- 223.3 Benign neoplasm of bladder
- 236.7 Neoplasm of uncertain behavior of bladder

ICD10

- C67.9 Malignant neoplasm of bladder, unspecified
- D30.3 Benign neoplasm of bladder
- D41.4 Neoplasm of uncertain behavior of bladder

CLINICAL/SURGICAL PEARLS

- Painless gross hematuria must be investigated to rule out bladder cancer.
- Smoking is the most common risk factor for bladder cancer.
- TURBT with biopsy is mandatory for diagnosis and staging of all bladder tumors.

BOWEN DISEASE AND ERYTHROPLASIA OF QUEYRAT

Justin D. Ellett, MD, PhD
S. Walker Nickles, MD

BASICS

DESCRIPTION

- Bowen Disease is squamous cell carcinoma in situ (CIS) of the follicle-bearing epithelium of the shaft and scrotum.
- Erythroplasia of Queyrat (EQ) is squamous cell carcinoma in situ (CIS) arising within the penile mucocutaneous (mucosal) epithelium of the glans penis or inner side of the foreskin. 80–90% of cases are seen in uncircumcised men.
  - Sometimes EQ is referred to as "Bowen disease (BD) of the glans penis."
  - EQ more likely to develop into invasive squamous cell carcinoma of the penis than Bowen disease.

EPIDEMIOLOGY

Incidence

- Penile cancer occurs in $<1\%$ of all malignancies in men, and EQ and BE are a fraction of these
- Most often occurs in Caucasian males
- Mostly in uncircumcised men
- Majority in men ages 50–70, but described in adult males of all ages

Prevalence

N/A

RISK FACTORS

- Uncircumcised men
  - Phimosis present in 75% of cases
  - Smegma thought to be carcinogenic
- Coinfection of HPV type 8 and carcinogenic genital HPV types (16, 18, 39, 51) have been reported (1)

  Relative risk factors:
  - Therapeutic immunosuppression for organ transplants
  - Immunosuppression from HIV/AIDS
  - Arsenic exposure from well-water and other sources
  - Ionizing radiation
  - Thermal injury
  - Chronic dermatoses
  - Lichen sclerosis of the glans penis
  - Smoking
  - Multiple sexual partners
  - Poor genital hygiene
  - Penile trauma

Genetics
N/A

PATHOPHYSIOLOGY
- Carcinogenic insults from:
  - Chronic injury and inflammation from poor hygiene, urine, smegma
  - Radiation
  - Exposure to chemical carcinogens, such as arsenic or smoking
  - HPV infection
- Decreased immune surveillance due to HIV/AIDS or medical immunosuppression

ASSOCIATED CONDITIONS
- Progression to invasive SCC in 5–30% of cases; more likely with EQ
- Lichen sclerosis, balanitis xerotica obliterans (BXO)

GENERAL PREVENTION
- Circumcision
- Daily genital hygiene by retraction of foreskin and cleansing
- Elimination of risk for HPV infection
- Early detection of lesions
- Treatment of phimosis

DIAGNOSIS
HISTORY
- Age: Median age >50
- Sexual promiscuity (increases risk for HPV infection)
- History of phimosis or difficulty retracting foreskin
- History of exposure to ionizing radiation or arsenic
- History of nonhealing wounds, pruritus, bleeding, discharge

PHYSICAL EXAM
- Solitary or multiple nontender erythematous plaques
  - EQ: Velvety, smooth, shiny on glans
  - BD: Scaly, verrucoid plaque on shaft
- Individual lesion may be 10–15 mm in diameter
- Bleeding from lesion
- Presence of ulceration increases likelihood of invasive SCC
- Examination of inguinal nodes
- Important factors to assess:
  - Diameter of lesion
  - Location
  - Number of lesions
  - Morphology (papillary, nodular, ulcerous, or flat)
  - Relationship to other structures (submucosal, corpora spongiosa and/or cavernosa, urethra)

DIAGNOSTIC TESTS & INTERPRETATION

Lab
Lab testing for carcinogenic HPV types

Imaging
Imaging only indicated in instances of clinical suspicion of invasion, and would include MRI or ultrasound

Diagnostic Procedures/Surgery
- Definitive diagnosis may only be made by biopsy
  - Early invasion should be excluded via the use of multiple biopsies

Pathologic Findings
- Pathology will show full-thickness epidermis with:
  - Discordant architecture
  - Abnormal mitoses
  - Dyskeratosis
  - Involvement of associated pilosebaceous apparatus with intact epidermal junction
  - Chronic inflammatory infiltrate into dermis
  - Epithelial rete extension into submucosa that is elongated and bulbous; submucosa shows capillary proliferation and ectasia with plasma-cell rich infiltrate (these distinguish from localized balanitis)

DIFFERENTIAL DIAGNOSIS (2)
- Invasive SCC
  - Ruled out by biopsy
- Bowenoid papulosis
  - Benign course, but histologically similar except abnormal keratinocytes are spread discontinuously throughout epidermis
  - Tendency for multiple lesions that may coalesce
  - Typically in younger patients (ages 25–30)
  - Usually spontaneously regresses
- Invasive SCC
  - Ruled out by biopsy
- Nummular eczema
  - Pruritic, coin-shaped plaques of small grouped papules on erythematous base
- Psoriasis
  - Well-demarcated red or whitish, scaly lesion
  - Usually associated with lesions at other sites
- Superficial basal cell carcinoma
  - Pearly, skin-toned papule or plaque, often with overlying telangiectasias
  - Treated with local excision; low malignant potential
- Balanitis circinata
  - Dry and scaling lesions of the glans in circumcised or uncircumcised males
  - Associated with Reiter's syndrome
  - Can be moist and erythematous in uncircumcised males
- Candidal balanitis
  - Usually found in uncircumcised diabetics

  – Reddened and edematous lesions
  – Usually treated with antifungal therapy
- Zoon balanitis
  – Usually in elderly, uncircumcised males
  – Cayenne pepper-appearing red, raised lesion
  – Usually distinguished from CIS on biopsy by band-like infiltrate of plasma cells

TREATMENT

GENERAL MEASURES (3)

Treatment based on multiple biopsy samples of adequate depth to rule out invasion

MEDICATION

First Line

- Topical therapy
  – 5-fluorouracil cream BID for 4–5 wk or
  – 5% imiquimod cream daily for 16 wk
  – Proven effective for large lesions not amenable to surgery or for recurrent lesions
  – Utilized with rubber condom to increase contact time

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Circumcision can decrease likelihood of recurrence
- With lesions on the foreskin, circumcision, or excision with 5-mm margin is adequate for local control
  – Lesions on the glans are difficult to excise with this strategy when trying to preserve penile anatomy
  – Ensure adequate depth of resection to rule out invasion
- Mohs micrographic surgery has been utilized to accomplish adequate excision without disfigurement
- Nd:YAG, KTP, or carbon dioxide laser ablation has been shown to be effective
  – Nd:YAG preferred due to depth of penetration

ADDITIONAL TREATMENT

Radiation Therapy

Radiation therapy can be used for patients resistant to topical treatment or who are not surgical candidates.

Additional Therapies

Additional therapies include cryotherapy, curettage, and photodynamic therapy, although their effectiveness is limited.

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- 5–33% of cases have been reported to transform to SCC
  - 5–10% risk in BD, 10–33% in EQ
  - Carries significant risk of death
- Cure can be achieved up to 80% of the time
- All therapies have recurrence rates of 20–30%

COMPLICATIONS

Progression to invasive squamous cell carcinoma

FOLLOW-UP

Patient Monitoring

- BD and EQ surveillance parallels localized, invasive SCC of the penis with clinical exam:
  - Year 1–2, every 3 mo
  - Year 3–5, every 6 mo
  - Year 5–10, every 12 mo
- Consider re-biopsy of recurrent lesions to rule out transformation to invasive SCC

CODES

ICD9

233.5 Carcinoma in situ of penis

ICD10

D07.4 Carcinoma in situ of penis

CLINICAL/SURGICAL PEARLS

- EQ is SCC in situ arising on the glans or inner side of the foreskin.
- BD is SCC in situ of the penile shaft or scrotum.
- 80–90% of cases seen in uncircumcised men.
- Progression to invasive SCC in 5–30%.

BURNS, EXTERNAL GENITALIA AND PERINEUM

Brad Figler, MD
Hunter Wessells, MD, FACS

BASICS

DESCRIPTION

- Burns to the external genitalia and perineum can damage skin, subcutaneous tissue, and surrounding organs and can be due to thermal, electrical, or chemical contact
- Thermal (most common): Includes scalding and immersion injuries, direct contact with flames or hot objects
- Electrical: Passage of an electrical current from 1 point to another through the body
- Chemical: Corrosive and alkali substances found in household and industrial chemicals

EPIDEMIOLOGY

Incidence

- Genital/perineal burns are rarely isolated
- Genitals/perineum involved in 5–13% of burns treated at major burn centers
- Abuse or neglect in 10–15% of childhood burn injuries (higher if < 2 yr of age)

RISK FACTORS

- Age: Very young (scald burns common in abused children) and very old
- Employment: Exposure to flames or caustic substances
- Gender: Women are less likely to experience genital or perineal burns (less exposed)

Genetics

N/A

PATHOPHYSIOLOGY

- Classification (1)
  - 1st-degree (superficial): Epidermis
  - 2nd-degree (partial thickness): Dermis
    - Superficial (involving the superficial, papillary dermis)
    - Deep (involving reticular dermis)
  - 3rd-degree: Underlying subcutaneous tissue
    - Typically not painful due to nerve damage
  - 4th-degree: Bone and muscle
    - Can lead to compartment syndrome
    - Often fatal

ASSOCIATED CONDITIONS

- Child and spousal abuse
- Sexual abuse
- Myoglobinuria (electrical burns)

GENERAL PREVENTION

- Follow occupational-specific safety precautions.
- Handle caustic chemicals with care.

DIAGNOSIS

HISTORY

- Type of burn (thermal, chemical, or electrical)
- Causative agent or heat source (eg, flame vs. water, noxious substance)
- Location and areas involved (Rule of 9s): External genitalia and perineum usually accounts for 1% of body surface area when using “Rule of 9s".
- Possibility of other injuries (eg, fractures from motor vehicle accidents, shrapnel)
- Pediatric considerations
  - Evaluate for scald and immersion injuries

PHYSICAL EXAM

- Complete assessment including ABCD’s of Advanced Trauma Life Support (ATLS). Often associated with concomitant injuries or further burns
  - with electrical burns determine any other entry/exit site of current
- Rule of 9s: Based on total body surface involved. Genitalia/perineum accounts for 1% of body area
- Vital signs (patients with electrical burns will require cardiac monitoring for at least 24 hr)
- Neurologic exam: Evaluate for compartment syndrome, peripheral pulses
- GU: Examine for involvement of phallus, meatus, glans, and scrotum
- Classification:
  - 1st-degree: Characterized by erythema, white plaques, and mild pain
  - 2nd-degree: Characterized by erythema, pain, superficial blisters
  - 3rd/4th-degree: Characterized by eschars, blistering, and absence of pain due to loss of nerve fibers

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Electrolytes: Treatment of burns generally requires large amount of fluid resuscitation
- With electrical burns, monitor creatine kinase and urine myoglobin

Imaging

As indicated by history or physical findings

Diagnostic Procedures/Surgery

N/A

Pathologic Findings

- 3 zones of burns:
  - *Zone of coagulation*: Occurs at point of maximum damage. In this zone, there is irreversible tissue loss due to coagulation of the constituent proteins.
  - *Zone of stasis*: Surrounding zone of stasis is characterized by decreased tissue perfusion. The tissue in this zone is potentially salvageable. The main aim of burn resuscitation is to increase tissue perfusion here and prevent any damage from becoming irreversible. Additional insults – such as prolonged hypotension, infection, or edema – can convert this

zone into an area of complete tissue loss.
- Z*one of hyperemia*: In this outermost zone, tissue perfusion is increased. The tissue here will invariably recover unless there is severe sepsis or prolonged hypoperfusion.

DIFFERENTIAL DIAGNOSIS
- Diagnosis is usually apparent based on history and examination

ALERT
Treat any-life-threatening conditions (ABCD's). IVF: Resuscitation is critical if patient has severe burns.

TREATMENT

GENERAL MEASURES
- Treat any life-threatening conditions (ABCD)
  – Do not attempt to cool wound as this may cause more extensive injury
- Shock may occur; IVF critical
  – >20% total body surface area (TBSA), use modified Brooke formula:
    - 2 mL/kg/TBSA
- Most chemical burns should be copiously irrigated. If agent is known use guidelines:
  – Hydrofluoric acid: Irrigate with calcium gluconate
  – Hydrochloric acid or sulfuric acid: Use bicarbonate irrigation
  – Phenol: No irrigation

MEDICATION
First Line
- Silver sulfadiazine 1%: Apply to affected area
  – Does not penetrate eschar
- Mafenide acetate (Sulfamylon) 11.1%
  – Penetrates eschar
- Pain control
  – Narcotics
  – Anti-inflammatories
- Fluid resuscitation
- Electrolytes as needed
- Tetanus prophylaxis
- Antibiotic prophylaxis not necessary
  – Treat specific infections as they arise.

SURGERY/OTHER PROCEDURES (2,3)
- Most burns, particularly in children, should be managed with conservative treatment and require no surgical intervention.
- Foley catheter or suprapubic drainage may be used, but are often not necessary
- Mainstay of surgical treatment, if needed, is careful debridement.
- Affected areas may require skin coverage:
  – Granulation indicates acceptable graft bed
  – Split-thickness skin grafts have reliable graft take and excellent cosmesis

– Skin grafts can be meshed or unmeshed
– If graft bed health is questionable, can use temporary xenograft
- Wound contractures are not uncommon; treat with z-plasty
- Urethral stricture may develop; should be treated in a delayed fashion (4)
– Catheter drainage may be required in the interim

ONGOING CARE

PROGNOSIS

- Based on degree and extent of burn
- Most burns have matured by 6–12 mo; additional reconstruction may be required at that time

COMPLICATIONS

- Erectile dysfunction
- Scarring/disfigurement
- Urethral strictures

FOLLOW-UP

Patient Monitoring

- Follow-up as indicated

- T21.16XA Burn of first degree of male genital region, init encntr

CLINICAL/SURGICAL PEARLS

- Genital/perineal burns are rarely isolated.
- Favor conservative management initially.
- Excellent functional and cosmetic results are possible with split-thickness skin grafting.

CALYCEAL DIVERTICULA

Yaniv Shilo, MD
Timothy D. Averch, MD, FACS

BASICS

DESCRIPTION

- Calyceal diverticula are nonsecretory, transitional cell epithelium-lined cystic cavities within the renal parenchyma.
- The cavity is usually filled retrograde from urine in the collecting system.
- Mostly unilateral.
- Most prevalent in upper calyces (70%)
- No gender nor laterality predilection
- Bilateral in 3%
- Sometimes called pelvicaliceal diverticula

EPIDEMIOLOGY

Incidence

<1%

Prevalence

Found in up to 0.45% of routine intravenous pyelogram studies.

RISK FACTORS

N/A

Genetics

N/A

PATHOPHYSIOLOGY

- Congenital in origin due to failure of regression of ureteric bud.
- Urine enters diverticulum passively via narrow communication with collecting system.
- Urine trapped in diverticulum predisposes to infection and stone formation.

ASSOCIATED CONDITIONS

- Flank pain
- Calyceal calculi (9–50%)
- Recurrent urinary tract infection (UTI)
- Hematuria

GENERAL PREVENTION

N/A

DIAGNOSIS

HISTORY

- Mostly incidental finding on imaging
- Flank pain

- Microhematuria or macrohematuria
- Recurrent UTI

PHYSICAL EXAM
- Usually not suggestive
- Possible flank pain

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urinalysis
  - Microhematuria and pyuria
- Urine culture
  - Bacterial persistence

Imaging
- Abdominal x-ray (KUB):
  - May demonstrate characteristic radiopaque "milk of calcium," which appears as a half moon or meniscus-shaped calcification
    - Milk of calcium should change its location when changing positioning from erect to lateral decubitus.
  - Case reports of confusion as being diagnosed as rib metastasis
- Ultrasound (US):
  - Provide diagnosis in up to 80% of the cases.
  - Shows cystic lesion with curvilinear, plaque-like calcification along its posterior wall.
  - Exam while changing positioning is needed to differ from complex cyst.
- Intravenous pyelography (IVP):
  - Delayed imaging demonstrates the diverticulum, as it fills retrogradely from its connection to the renal pelvis or calyx.
- CT urography (CTU):
  - Delayed imaging is critical to demonstrate contrast medium within an apparent cystic mass

Diagnostic Procedures/Surgery
- Retrograde pyelogram:
  - Allows greater distension of the collecting system than can be attained with IVP.
  - Delineating anatomy and assist in planning the appropriate treatment approach.

Pathologic Findings
- Lined by nonsecretory transitional epithelium.
- Retrograde reflux of urine from the calyx via the diverticular neck can cause stasis with stones in calyceal diverticula in up to 50% of cases

DIFFERENTIAL DIAGNOSIS
- Calcified tumor
- Complicated renal cyst
- Kidney abscess
- Nephrolithiasis

TREATMENT

GENERAL MEASURES

- In case of uncomplicated, asymptomatic calyceal diverticulum treatment can be conservative with no further imaging follow-up.
- Indications for therapy include pain, recurrent infection, increased calculus growth, hematuria or large size that compresses or progressively damages contiguous renal parenchyma

MEDICATION

First Line

Antibiotic treatment can be used for recurrent UTIs; otherwise no specific role

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Shock wave lithotripsy (SWL):
  - May be suitable for calyceal diverticulum with small calculi and wide infundibulum (1) [B].
  - Can resolve flank pain.
  - Limitations are due to inadequate passage of stone fragments through the infundibulum and lack of anomaly repair.
- Ureteroscopy (URS):
  - Most suitable as initial treatment for calculi <1.5 cm located in the middle or upper pole diverticulum and specifically in the anterior aspect.
  - Involves mechanical dilatation of the diverticular neck and removal of calculi if present.
  - Ablation of diverticular cavity is not a common practice.
- Percutaneous nephrolithotomy (PCNL):
  - Considered to be the definitive surgical treatment specifically for diverticula containing stone burden >1.5 cm in the posterior aspect.
  - Challenging when only thin layer of parenchyma surrounding the diverticula or located anteriorly.
  - Requires direct access to diverticulum and infundibulum widening.
  - Ablation of the calyceal diverticulum cavity is recommended (2)[B].
- Laparoscopic nephrolithotomy (LAP):
  - May be advantageous in cases of anterior diverticula, diverticula covered with thin layer, diverticula containing large calculi or large diverticula (3)[B].
  - Includes unroofing of the diverticulum and calculi removal if present.
  - Ablation of the remaining cavity and neck.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS

- SWL:
  - Stone-free rate is relatively low (up to 60%), however, symptom-free rate is higher (4)[B].
- URS:
  - Stone-free and symptom-free rates can be high when infundibulum is identified
  - In significant number of diverticula the infundibulum cannot be found (4)[B].
- PCNL:
  - Excellent stone-free and symptom-free rates (over 80%).
  - Long-term results remain good.
- LAP:
  - Initial results show high stone-free rate and diverticular ablation.

COMPLICATIONS

- Calyceal diverticula:
  - Secondary infection
  - Chronic pain with stones
  - Compression of surrounding tissue
- SWL:
  - Flank pain
  - Infection
  - Subcapsular or perinephric hematoma
- URS:
  - Bleeding
  - Thermal injury to ureteral wall or renal parenchyma
  - Ureteral perforation
  - Sepsis
- PCNL:
  - Bleeding
  - Urinary extravasation
  - Pneumothorax
  - Hemothorax
  - Collecting system perforation

FOLLOW-UP

Patient Monitoring

- Radiographic imaging with either CTU, IVP, or kidney US should be done 6–8 wk postoperatively.
- Patients with calculi contained in diverticulum may need metabolic evaluation as these patients tend to have metabolic abnormalities similar to patients with nephrolithiasis (5) [B].

CODES

ICD9
- 592.0 Calculus of kidney
- 593.89 Other specified disorders of kidney and ureter
- 753.3 Other specified anomalies of kidney

ICD10
- N20.0 Calculus of kidney
- N28.89 Other specified disorders of kidney and ureter
- Q63.8 Other specified congenital malformations of kidney

CLINICAL/SURGICAL PEARLS
- Usually located on upper calyces.
- Associate disorders include—calyceal calculi, recurrent UTI, and flank pain.
- URS is suitable for anterior midpole or upper diverticula with calculi <1.5 cm.
- PCNL is the treatment of choice in general for calyceal diverticula and specifically for posterior diverticula with thick layer of parenchyma surrounding with calculi >1.5 cm.

- Growing evidence for the effectiveness of LAP approach in cases of anterior diverticula, diverticula covered with thin layer, diverticula containing large calculi or large diverticula.

CATHETERIZABLE STOMA PROBLEMS

Zachary L. Smith, MD
S. Bruce Malkowicz, MD, FACS

BASICS

DESCRIPTION

- Catheterizable stomas (CSs) are utilized in all age groups and provide a means of emptying the native bladder or neobladder.
- Most common indications for CS vary with age groups:
  - Pediatrics: Incontinence related to neurologic or congenital conditions
  - Adults: Urinary diversion following extirpative surgery for malignancy
- Location of CS can vary, but is most often located in the umbilicus or right lower quadrant.
- Catheterizable channels are commonly constructed from a segment of small bowel or the appendix.
- Mechanism of CS continence depends on the type of urinary reservoir.
- Patients with CS often have routine catheterization schedules.
- CS problems can be related to the stoma, catheterizable channel, or urinary reservoir.

EPIDEMIOLOGY

Incidence

- Complications are reported in 10–50% of patients with CSs:
  - Stomal stenosis has been reported in up to 40% of CS
  - Most stomal-related complications are reported within the 1st yr following surgery (1)[C].
  - Incontinence is reported in 1–20% of cases and is associated with the mechanism of continence.
  - Parastomal hernias have been noted in 0–5% of patients.

Prevalence

N/A

RISK FACTORS

- Improper stomal positioning
- Infrequent use of CS
- Multiple prior abdominal procedures
- Obesity
- Surgical technique
- Wound infections

Genetics

N/A

PATHOPHYSIOLOGY

- Stomal stenosis can be attributed to infrequent catheterization, scar formation, ischemia secondary to compromised vascular supply to catheterizable channel, or a nontension-free mucocutaneous anastomosis.

- Difficulty catheterizing the CS channel can be attributed to angulation of a mobile and/or redundant channel.
- Significant weight loss or gain
- Improper creation of continence mechanism
- Incomplete detubularization or augmentation of the urinary reservoir can lead to incontinence secondary to low compliance and small reservoir capacity.
- Pouchitis (lower urinary tract infection) can cause temporary failure of the continence mechanism because of the hypercontractility of the bowel segment; can be caused by inflammation of the mucosa.

ASSOCIATED CONDITIONS
- Urologic, gynecologic, and colorectal malignancies
- Spinal dysraphisms
- Traumatic spinal cord injuries

GENERAL PREVENTION
- Maintenance of a regular catheterization regimen
- Several complications can be prevented at the time of surgery when creating the catheterizable channel:
  - Maintenance of vascular supply to catheterizable channel
  - Minimized redundancy catheterizable channel with fixation and stabilization of the continence mechanism
  - Adequate construction of continence mechanism
  - Tension-free mucocutaneous anastomosis
  - Use of V-flap of skin to prevent stomal stenosis

DIAGNOSIS

HISTORY
- Date of surgery
- Indication for CS:
  - Incontinence (urinary vs. fecal)
  - Malignancy
- Attempt to obtain operative reports
- Type of bowel utilized
- History of CS complications
- Catheterization details:
  - Typical catheterization regimen
  - Type and size of catheter used
  - Technique utilized (direction, amount of pressure, etc.)
  - Normal catheterization volumes
  - Time of last normal catheterization
  - Character of urine at the time of last successful catheterization (color, odor, presence of debris, etc.)
- Status of the bladder neck in patients with native bladder intact:
  - Urethral catheterization can be attempted in patients whose native urethra is intact and

who have an open bladder neck.
- Review of systems should focus on abdominal symptomatology.

PHYSICAL EXAM
- Vital signs may reveal tachycardia, hypotension, and fever in patients with peritonitis secondary to perforation of the catheterizable channel or urinary reservoir.
- Abdominal exam evaluating signs of peritonitis
- Inspection of the stoma, evaluating for:
  – Stenosis
  – Mucosal ischemia
  – Abdominal wall deformity suggestive of parastomal hernia
- Catheterization of CS to:
  – Evaluate patency of stoma
  – Determine capacity of urinary reservoir
  – Evaluate continence mechanism
  – Obtain urine sample
  – Instill contrast for imaging.

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Serum electrolytes:
  – Elevated serum creatinine may be noted in patients with urinary retention from the inability to catheterize.
  – Several metabolic abnormalities may be present in patients with urinary reservoirs, depending on bowel segment utilized:
    - Stomach: Hypochloremic, hypokalemic alkalosis
    - Jejunum: Hyponatremic, hypochloremic, hyperkalemic acidosis
    - Ileum: Hyperchloremic acidosis
    - Colon: Hyperchloremic acidosis
- CBC:
  – Leukocytosis suggestive of infection
- Blood and urine cultures in patients presenting with abdominal pain and fever

Imaging
- Contrast study of catheterizable channel and urinary reservoir to evaluate for perforation
- Cross-sectional imaging of the kidneys assessing for the presence of hydronephrosis

ALERT
Have a low threshold for obtaining a cross-sectional imaging study (CT/MRI) with contrast when a perforation of the CS or urinary reservoir is suspected, especially in patients with neurologic deficits.

Diagnostic Procedures/Surgery
Urodynamics in patients with incontinence may reveal uninhibited contractions or a poorly compliant high-pressure reservoir.

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS

- Perforation of CS channel or urinary reservoir
- Stomal stenosis
- Incontinence
- False passage
- Parastomal hernia
- Fistula
- Inability to catheterize due to redundancy of catheterizable channel

TREATMENT

ALERT
Perforation of CS conduit or urinary reservoir mandates emergent exploratory laparotomy, drainage of urinary extravasation, and repair of urinary reservoir.

GENERAL MEASURES

- Good hygiene
- Routine catheterization of CS
- Early intervention with difficulty

MEDICATION

First Line

- Incontinence related to uninhibited pouch contractions:
  - Anticholinergics (oxybutynin, tolterodine, etc.) (2)[C]
- Pouchitis may sometimes be due to infection and can be treated with appropriate antibiotics.

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Stomal stenosis:
  - Elective surgical revision with V-flap of skin (3)[C]
- Incontinence:
  - Elective surgical revision of continence mechanism
  - Injection of bulking agent into CS
  - Augmentation of urinary reservoir with intestinal patch in cases of high pressures and poor compliance (2)[C]
- Parastomal hernia:
  - Elective hernia repair with or without repositioning stoma site on abdominal wall
  - Surveillance in asymptomatic patients
- Fistula:
  - Elective revision
- Inability to catheterize secondary to false passage or redundancy of CS channel:
  - Elective revision
  - Occasionally, minor false passages can be treated with an indwelling catheter for a short

period to allow healing of channel.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Stomal stenosis:
  - Routine catheterization schedule
  - Dilatation of stenosis
- Inability to catheterize secondary to false passage or redundancy of CS channel:
  - Change type of catheter
  - Change method of catheterization

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Success following stomal revisions for stenosis ranges from 80–95% (1)[C].

COMPLICATIONS

Recurrence of prior complication

FOLLOW-UP

Patient Monitoring

- Maintenance of routine catheterization schedule
- Additional follow-up with enterostomal therapist

Patient Resources

- United Ostomy Associations of America, Inc. www.ostomy.org
- Bladder Cancer Advocacy Network. www.bcan.org

CODES

ICD9

- 596.82 Mechanical complication of cystostomy
- 596.83 Other complication of cystostomy
- V55.5 Attention to cystostomy

ICD10

- N99.512 Cystostomy malfunction
- N99.518 Other cystostomy complication
- Z43.5 Encounter for attention to cystostomy

CLINICAL/SURGICAL PEARLS

- Cathterizable stomas are used for varying reasons throughout one's life. Benign/neurogenic causes most common in children, malignant causes most common in adults.
- Stomal stenosis is by far the most common complication of cathterizable stomas.
- Surgical revision is often required for most cathterizable stomas complications.
- Good technique and cathterizable stomas maintenance with a routine catheterization schedule can prevent most complications.

CHORDEE

Jennifer A. Hagerty, DO

BASICS

DESCRIPTION

- Chordee is ventral penile curvature that occurs with or without hypospadias:
  - Epispadias can occur with dorsal curvature
  - Lateral curvature also can occur with or without hypospadias

EPIDEMIOLOGY

Incidence

The incidence of chordee is unknown

Prevalence

- 44% of fetuses through the 2nd trimester suggesting chordee is a normal part of development (1)[A]
- Chordee occurs without hypospadias in 4–10% of cases of congenital chordee (2)[C]
- Hypospadias occurs in 1 of 250 live births (3)[A]
  - Chordee is identified in 1/3 of these patients (3)[A]

RISK FACTORS

- Congenital
- Prior penile surgery
- Trauma

Genetics

- Found in syndromes associated with hypospadias
- Chromosomal abnormalities found in 22% of individuals with severe hypospadias associated with undescended testicles
- 14% of hypospadias in siblings
- 8% incidence in offspring

PATHOPHYSIOLOGY

- Chordee could be considered an arrest of normal embryologic development
- Different proposed etiologies for chordee without hypospadias (2,4):
  - Class I: Results when corpus spongiosum, dartos, and Buck fasciae are deficient over the involved portion of the urethra; urethra is just below the skin, and the dense fibrous tissue beneath the urethra is responsible for the chordee.
  - Class II: Spongiosum is normal while the dartos and Buck fasciae are dysgenetic.
  - Class III: Only the dartos fascia is deficient.
  - Class IV: Corporeal disproportion.

ASSOCIATED CONDITIONS

- Hypospadias
- Epispadias

- Penile torsion
- Cryptorchidism
- Disorders of sexual development

GENERAL PREVENTION
None known

DIAGNOSIS
HISTORY
- Visualized curvature of the penis with an erection
- Presence of hypospadias

PHYSICAL EXAM
- Observe the individual's erection if possible
- Possible coexisting findings:
  - Hypospadias or epispadias
  - Incomplete foreskin ventrally
  - Penoscrotal webbing
  - Penile torsion
  - Hypoplasia of the ventral shaft skin
  - Cryptorchidism

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Routine lab testing not typically indicated
- Chromosomal testing and/or biochemical testing in the individual with a suspected syndrome or disorder of sexual differentiation

Imaging
- Renal and bladder ultrasound routinely recommended only in individuals with:
  - Severe hypospadias
  - Hypospadias associated with other organ system anomalies

Diagnostic Procedures/Surgery
- Intraoperative artificial erection test at the time of repair
  - Infusion of injectable saline into the corpora with a tourniquet at the base of the penis

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Disorder of sex development
- Epispadias
- Hypospadias
- Normal penile variant
- Penile torsion

TREATMENT

GENERAL MEASURES
Chordee repair is the standard approach

MEDICATION
First Line
None usually indicated specifically for chordee

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Specific surgery dependant on the associated conditions and the severity of the curvature
- Performed typically after 6 mo of age
- General points:
  - Following penile skin release, induce artificial erection. This should be repeated to confirm correction.
  - Chordee without hypospadias often can be corrected by penile degloving with excision of the fibrous tissue superficial to Buck fascia.
  - More moderate chordee requires simple plication and/or excision of ellipses from the site of maximum curvature.
  - In the most severe cases, often associated with hypospadias the urethra may be foreshortened and need to be transected.
  - Chordee secondary to corporeal disproportion involves incising the tunica albuginea on the ventral surface of the penis, transversely over the point of maximal curvature; than covering the defect with either a free dermal, tunica vaginalis or single ply small intestinal submucosal (SIS) graft.
  - It is critical to identify and preserve the neurovascular bundles during dissection and plication.
  - Skin flaps may be required for penile skin coverage after correction of the chordee.

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE
PROGNOSIS
- Excellent prognosis postoperatively with a low complication rate
- There may be progression of chordee after puberty (5)[C]

COMPLICATIONS
Recurrence of chordee

FOLLOW-UP

Patient Monitoring
- Postoperative checkup within several weeks after surgery
- Consider follow-up after puberty

CLINICAL/SURGICAL PEARLS
- Chordee most commonly occurs with hypospadias.
- Repair recommended after 6 mo of age.
- Consider ongoing monitoring after puberty.

CHRONIC KIDNEY DISEASE, ADULT (RENAL FAILURE, CHRONIC)

Shaun G.S. Grewal, MD
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION

- Defined as presence of kidney damage or impaired GFR (< 60 mL/min/1.73 m^2) for > 3 mo (1)
  - if less than 3 months considered acute kidney injury (AKI)
  - Irrespective of cause kidney damage defined as:
    - Pathologic abnormalities
    - Urinary, blood, or imaging abnormalities
    - Kidney transplantation
- Classification based on Kidney Disease Outcomes Quality Initiative (NKF KDOQI):
  - Stage 1: Kidney damage with normal renal function (GFR > 90 mL/min/1.73 m^2)
  - Stage 2: Mild renal dysfunction (GFR 60–89 mL/min/1.73 m^2)
  - Stage 3: Moderate renal dysfunction (GFR 30–59 mL/min/1.73 m^2)
  - Stage 4: Severe renal dysfunction (GFR 15–30 mL/min/1.73 m^2)
  - Stage 5: Kidney failure (GFR < 15 or dialysis mL/min/1.73 m^2)

EPIDEMIOLOGY

Incidence

- Stage 1 or 2 CKD progress to more advanced stages at 0.5% per year
- Stage 3 or 4 progress to end-stage renal disease at 1.5% per year (3)

Prevalence

- 10% in noninstitutionalized adults
  - Corresponds to > 20 million people (4)
  - 398,000 treated by dialysis in 2000, expected to increase to > 2 million people by 2030 (2)
  - Prevalence in US population
    - Stage 1: 1.8%
    - Stage 2: 3.2%
    - Stage 3: 7.7%
    - Stage 4/5: 0.35% (3)

RISK FACTORS

- Diabetes
- Hypertension
- Cardiovascular disease
- Family history
- Age > 60

- Urinary tract obstruction
- Urinary calculi
- Nephrotoxic drugs
- Obesity
- Neoplasia
- Loss of kidney mass
- Race
  - African American, American Indian, Hispanic, Asian, or Pacific Islander

Genetics

- Complex phenotype impacted by various genetic factors in addition to environmental factors and comorbid disease
  - CYP4A11 gene involved in renal vasoconstriction and natriuresis and is associated with increased risk in African Americans (6)
  - APOL1 associated with focal segmental glomerulosclerosis and hypertension associated ESRD (7)

PATHOPHYSIOLOGY

- Heterogenous condition with various causes
  - Diabetic kidney disease
  - Nondiabetic kidney disease
    - Glomerular disease
    - Vascular diseases
    - Tubulointerstitial disease
    - Cystic disease (polycystic kidney disease)
  - Transplant nephropathy
    - Acute rejection
    - Chronic rejection
    - Calcineurin toxicity
    - Glomerulonephropathy

ASSOCIATED CONDITIONS

See risk factors

GENERAL PREVENTION

- Screening and treatment of associated risk factors
  - Screening selected populations:
    - Age >50
    - History of DM (diabetes melitus), HTN (hypertension), or CV (cardiovascular) disease
    - Family history
    - Exposure to nephrotoxins

DIAGNOSIS

HISTORY

- Silent, asymptomatic until late stages
  - Evaluate for symptoms of associated conditions/risk factors

- Symptoms of uremia in ESRD
  - Anorexia
  - Decreased urine output
  - Increased thirst
  - Mental status changes
  - Muscle cramps
  - Nausea
  - Vomiting

PHYSICAL EXAM

- Physical exam findings uncommon until late stages of disease
  - Findings associated with increased risk
    - BP >130/85
    - Obesity/increased waist circumference
  - Manifestations of advanced kidney disease
    - Volume overload/edema
    - Pruritus
    - Visual disturbances
    - Weight Loss
    - Confusion

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Chemistry
  - Elevated creatinine
  - Elevated blood urea nitrogen
  - Hyperkalemia
  - Acidosis
  - Hyperphosphatemia
- Urinalysis with microscopy
  - Hematuria
  - Casts: RBC (glomerulonephritis), WBC (interstitial nephritis)
  - Fat bodies (nephrotic syndrome)
- Hyperparathyroidism
  - Results from altered calcium and phosphorus metabolism
- Anemia
- Proteinuria/albuminuria
  - Albuminuria indicates increased glomerular permeability to macromolecules
  - Albumin to creatinine ratio >30 mg/g indicates increased risk of CKD progression, ESRD, cardiovascular and all cause mortality.
- GFR
  - Estimated GFR (mL/min/1.73 m^2) = $1.86 \times (SCR)^{-1.154} \times (age)^{-0.203} \times$ (0.742 if female) $\times$ (1.1212 if African American)

Imaging

- Broad range of findings depending on etiology and imaging modality (US, CT scan, MRI,

angiography, isotope scans)
  – Hydronephrosis: Potentially reversible
  – Polycystic kidneys
  – Atrophic kidneys
  – Increased echogenicity (on ultrasound)
  – Renal artery stenosis
  – Cortical scarring

Diagnostic Procedures/Surgery

- Renal biopsy is indicated in selected cases and choices can vary greatly with nephrologists
  – Isolated glomerular hematuria with proteinuria
  – Nephrotic syndrome
  – Acute nephritic syndrome
  – Acute/rapidly progressive kidney disease
- Urologic evaluation if gross or microscopic hematuria
  – Cystoscopy
  – Upper tract imaging
- Angiography (CT or MR angiogram) if suspected atherosclerotic renovascular disease (asymmetric renal size)

Pathologic Findings

- *Renal biopsy findings*
  – Reveals tubulointerstitial, glomerular, or vascular disease
  – May also be seen on nephrectomy/partial nephrectomy specimens

DIFFERENTIAL DIAGNOSIS

- Kidney damage with duration >3 mo is diagnostic regardless of cause
- Differentiate from acute kidney disease based on duration and underlying etiology
  – Acute kidney injury
  – Alport syndrome
  – Autosomal dominant polycystic kidney disease.
  – Chronic glomerulonephritis
  – Diabetic nephropathy
  – Goodpasture syndrome
  – Multiple myeloma
  – Nephrolithiasis
  – Nephrosclerosis
  – Rapidly progressive glomerulonephritis
  – Renal artery stenosis
  – Systemic lupus erythematosus
  – Urinary obstruction
  – Wegener granulomatosis

TREATMENT

GENERAL MEASURES

- Use CKD staging to guide management (ie, risk for progression and complications of CKD). See table in Section II "Chronic Kidney Disease (CKD)."
- Goal is reduction of morbidity and mortality from associated comorbidities
  - Patient more likely to die of cardiovascular disease than progress to dialysis (3)
  - Blood glucose control (HbA1c <7)
  - Treatment of proteinuria and hypertension
  - Treatment of dyslipidemia to prevent cardiovascular events
  - Addressing alterations in bone metabolism (hyperphosphatemia, Vitamin D deficiency)
  - Prevention of contrast-induced nephropathy (patient at risk if GFR <60)
  - Avoidance of Gadolinium when GFR <30 to prevent nephrogenic systemic fibrosis

MEDICATION

First Line

- ACE inhibitors (ACE-I) (captopril, enalapril, ramipril, others) or angiotensin II receptor blockers (ARBs) (losartan, olmesartan, telmisartan others)
  - Indicated with random protein to creatinine ratio >200 mg/G
  - Do not use ACE-I and Angiotensin II receptor blockers (*ARBs*) concurrently: Risk of hypotension and worsening renal function
  - Monitor for hypotension, hypokalemia, or worsening renal function
  - Common ACE-I side effects include cough, angioedema, or allergy
- Statin therapy
  - Goal LDL (low density lipids) <100 and triglyceride <150
  - Side effects include myalgia, liver dysfunction, GI disturbance, and rash

Second Line

- Erythropoiesis-stimulating agents
  - Optimal hemoglobin unknown
  - Increased risk of cardiovascular events and death with hemoglobin >11 g/dL
  - Indicated to prevent transfusion-related risks (patient with Hg <10 and rate of decline suggesting need for blood transfusion)
    - Examples include erythropoietin α and darbepoetin α

SURGERY/OTHER PROCEDURES

- Dialysis access as appropriate (vascular or peritoneal)
- Renal transplantation

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Dietary modifications
- Patient education
- Smoking cessation
- Weight loss

Complementary & Alternative Therapies

Avoidance of herbal remedies which may have nephrotoxic effects.

ONGOING CARE

PROGNOSIS

- Variable depending on stage, patient risk factors, and management of comorbidities
  - 10–100 × increased risk of cardiovascular comorbidities in ESRD patients
  - 13–29% 1-yr mortality in patients initiating hemodialysis (5)

COMPLICATIONS

- CKD patients at increased risk of progression, cardiovascular disease, hypertension, anemia, disorders of mineral metabolism, and death
- Degree of proteinuria correlates with risk of progression

FOLLOW-UP

Patient Monitoring

- Stage 1-2
  - Monitor GFR, proteinuria, and blood pressure
    - Clinical abnormalities rare at this stage but patients must be monitored for progression
    - Monitor HbA1c and microalbumin in diabetics
    - Evaluation every 12 mo, at least every 6 mo if proteinuria present
- Stage 3
  - Monitor GFR, proteinuria, blood pressure, HbA1c, serum electrolytes, and hemoglobin
    - Elevations of phosphorous, potassium, and anemia may be seen
    - Evaluation every 3 mo
    - Referral to nephrology when GFR approaches 30 mL/min
- Stage 4
  - Monitor GFR, proteinuria, blood pressure, HbA1c, serum electrolytes, and hemoglobin
    - Significant electrolyte abnormalities common; monthly follow-up with nephrology
- Stage 5
  - Severe electrolyte abnormalities and anemia present: Ongoing follow-up with renal replacement therapy

- Differentiate from acute renal failure based on duration.
- Treat potentially reversible causes (ie, hydronephrosis).

CHRONIC KIDNEY DISEASE, PEDIATRIC (RENAL FAILURE, CHRONIC)

Timothy E. Bunchman, MD
Megan M. Lo, MD

BASICS

DESCRIPTION

- National Kidney Foundation (NKF) defines chronic kidney disease (CKD) as evidence of structural or functional kidney abnormalities (abnormal urinalysis, imaging studies, or histology) that persist for at least 3 mo, with or without a decreased glomerular filtration rate (GFR), as defined by a GFR of <60 mL/min per 1.73 m^2 (1)
  - This definition is not applicable to children younger than 2 yr, because they normally have a low GFR, even when corrected for body surface area
- CKD in pediatrics
  - 70% tubular interstitial disease (TID)
  - 30% chronic glomerular disease (CGD).
- CKD in children is often related to congenital abnormalities. The presentation often can be silent or associated with: Polyuria and polydipsia and failure to grow.
- TID is often congenital and associated with different syndromes: Posterior urethral valves (PUVs), Eagle-Barrett syndrome (EBS), and renal dysplasia (most genetic syndromes are associated with dysplasia).
- CGD is often associated with hypertension, hematuria, proteinuria, and edema.
- The peak age of the diagnoses of end-stage renal disease is about 5 yr of age. The second age of presentation of loss of kidney function is around the age of puberty.

EPIDEMIOLOGY

Incidence

10–15 cases per million per year

Prevalence

50–100 per million per year

RISK FACTORS

- Primary risk factor for dysplasia is associated congenital diseases and/or syndromes.
- Familial renal disease; may present at any age
  - Alport syndrome
  - Benign familial hematuria
  - IgA nephropathy
  - Polycystic kidney disease
- Higher in males, African Americans

Genetics

Diverse based upon cause. For example, mutations in HNF1B are causative for cystic dysplasia of the kidney.

PATHOPHYSIOLOGY

- In interstitial renal disease, the degree of CKD is related to the amount of renal mass. In those patients who were born with small kidneys or have associated obstructive uropathy (PUV, EBS, megaureter syndrome) often will have early progressive loss of renal function.
- Glomerular-based renal disease is more common in the school age and greater population.
  - The clinical presentation of glomerulonephritis is associated with edema, hypertension, as well as blood and protein in the urine; most need a renal biopsy.

ASSOCIATED CONDITIONS

- Hearing loss
- Short stature

GENERAL PREVENTION

- In CKD associated with congenital renal disease there is no true prevention.
- Often the use of prenatal ultrasounds can identify infants at risk but they are not 100% diagnostic.
  - Serial ultrasounds over time may identify lack of interstitial renal disease, primarily looking for renal growth.
  - Further, a low level of amniotic fluid at the time of birth also correlates with poor renal function.
- Prevention from a glomerular-based renal disease is limited as these are usually related to autoimmune diseases. Therefore, the general prevention in all areas of CKD is prevention of complications of CKD.

DIAGNOSIS

- In glomerular-based renal disease the history is associated with grossly bloody urine, hematuria, proteinuria, hypertension, and edema. Tissue pathology is generally needed for diagnosis.
- In the review of systems, the findings of polyuria, polydipsia, and exclusion of diabetes is important. These children also can have associated growth impairment.
- Family history is important in certain renal disease, specifically in the area of the familial renal disease such as IgA nephropathy, Alport, polycystic kidney disease, and rarely benign familial hematuria.
  - In addition, eliciting a history of reflux nephropathy, recurrent urinary tract infections, and congenital renal abnormalities within the family is important.
  - Further a family history of dialysis or transplantation or unexplained hypertension earlier in life may be important.
- In the classic Alport syndrome (a male predominant disease) there is an association with high-frequency hearing loss, often in the 2nd or 3rd decade of life.

PHYSICAL EXAM

- Often these children have a benign exam
  - In TID, the blood pressure and poor growth are important.
  - In CGD, kids often have hypertension.
  - Can have associated edema, ascites, and cardiovascular abnormalities.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Basic metabolic panel, renal function testing
- Regardless of the etiology of CKD, at levels of CKD 3 or greater (roughly 50% kidney function), one can have:
  - Metabolic acidosis (low CO_2)
  - Abnormal parathyroid activity
    - Low calcium, elevated phosphorus, and elevated PTH
  - Anemia that is usually related to a combination of iron deficiency, as well as the lack of natural erythropoiesis.
- C3 C4 complement
  - Decreased in some glomerulonephritis and lupus nephritis
- Urinalysis:
  - In TID, the urine is usually benign with inability to concentrate the urine regardless of the time of day.
  - In CGD, often these patients can have blood and protein and red cell casts.
- Urine protein: Creatinine ratio, rarely 24-hr urine for protein.

Imaging

- In TID the renal imaging is important.
  - Often these patients can have normal to small looking kidneys seen on ultrasound. The echogenic texture will be important. Further, some degree of obstructive uropathy may be seen.
  - Voiding cystourethrogram may be indicated
  - In those patients who have obstructive uropathy, either at a UPJ or UVJ, a diuretic renal scan or MAG3 scan may be important.
- In CGD, renal imaging may show nephromegaly. Otherwise, ultrasound will be nonspecific.

Diagnostic Procedures/Surgery

- In glomerular-based renal diseases renal biopsy is often required.
- Indication for biopsy in patients with CGD is: A normal complementemic glomerulonephritis or a persistent low C3, and a low C4.
- Other indications: Glomerulonephritis associated with an elevated anti-dsDNA (lupus), hemoptysis with associated renal glomerulonephritis (pulmonary, renal disease), and in patients with persistent low C3 without normalization after 12 wk, which excludes postinfectious glomerulonephritis (historically poststreptococcal glomerulonephritis).

Pathologic Findings

- Histologic analysis in interstitial renal disease is not essential.
- In glomerular-based renal diseases, renal biopsy is often required.
- Depending on underlying cause, the pathologic findings are vastly different on H&E, immunofluorescence, and electron microscopy.

DIFFERENTIAL DIAGNOSIS

- As mentioned for TID, polyuria, polydipsia can also be associated with diabetes, which is an easy diagnosis to exclude based on urinalysis and blood work.
- Differential diagnosis of CKD is limited to underlying disease

– Congenital renal anomalies: Obstructive uropathy, renal hypoplasia or dysplasia, reflux nephropathy, polycystic kidney disease
– Glomerular disease: Focal segmental glomerulosclerosis (FSGS).
– Others: Hemolytic uremic syndrome, genetic diseases (cystinosis, oxalosis, Alport syndrome), interstitial nephritis
– Rare in childhood: Diabetic nephropathy and hypertension

TREATMENT

GENERAL MEASURES

- In chronic interstitial renal disease with polyuria/polydipsia, more fluid and sodium are needed to maintain euvolemia.
- In both groups, attention to potassium and phosphorus load is important.
- All NSAIDS should be avoided. Levels of potential nephrotoxins, if measurable such as vancomycin or gentamicin, should be followed at least twice weekly; with an initial level no later than 24–48 hr after starting.
- Damage from CT contrast should be minimized with pre- and postprocedure IV hydration.

MEDICATION

First Line

- Treatment of metabolic acidosis with either liquid form of Bicitra or the pill form of bicarbonate to normalize the CO_2. This will preserve growth as well as bone integrity.
- Treatment of phosphorus restriction, phosphorus binding (nonaluminum binders such as $CaCO_3$, Calcium acetate, or sevelamer products), and institution of vitamin D to preserve and prevent secondary hyperparathyroidism and prevent bone disease.
- Treatment with replacement doses of iron sucrose 1–3 mg/kg per dose and use of erythropoietic agents (epoetin, darbepoetin) are used for anemia.

Second Line

- Those that were mentioned above including antihypertensive agents if indicated.
- Often ACE inhibitors and angiotensin receptor blockers (ARBS) are used for glomerular-based renal disease because of proteinuria but are contraindicated in possible pregnancy (birth defects) and low GFR (renal failure, hyperkalemia)

SURGERY/OTHER PROCEDURES

In TID, patients may require cystoscopy with ablation of PUVs. UPJ or UVJ obstructions may need to be relieved. Reflux may need to be corrected, if high grade and not resolving spontaneously.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Dialysis (peritoneal or hemodialysis) or kidney transplant should be considered when GFR falls into the 20's or growth and metabolic control can no longer be maintained with medical management.

Complementary & Alternative Therapies

- Nutrition is important: At least 2 g/kg/d protein would be needed in order to maintain adequate protein stores and growth.
- Nutrition in CGD is associated with salt and water restriction. Therefore, the nutrition construction may be opposite in terms of the sodium and water load.

ONGOING CARE

PROGNOSIS

- Difficult to predict early in life.
- Lack of renal growth with a creatinine greater than 1 at a year of age, associated hematuria, proteinuria, and hypertension in patients with TID portends the need for future dialysis and transplantation.
- CGD prognosis is directly related to underlying cause.
- Certain diseases such as lupus, Wegener, Goodpasture, membranous nephropathy, and IgA nephropathy can be amenable to therapy.
- Other renal diseases such as focal sclerosis maybe less amenable to therapy.

COMPLICATIONS

- Growth impairment in children is a known complication, independent of the etiology of CKD (2)
- Hypertension is also a risk factor.
- Protein restriction, used in adult CKD to slow disease progression, cannot be used with kids as this would further hinder their growth and development.

FOLLOW-UP

- Newborns and infants should be seen as frequently as every 1–2 wk in order to ensure maintenance of euvolemia.
- Primary care physicians need to be instructed that patients with interstitial disease will get dehydrated more quickly than the average patient; therefore, attention to their care at the time of vomiting and diarrhea is important for these patients will become volume depleted in a hurry.

Patient Monitoring

Glomerular-based renal diseases are associated with salt and water restriction as well as blood pressure control.

- Prune Belly (Eagle-Barrett or Triad) Syndrome

CODES

ICD9

- 582.89 Chronic glomerulonephritis with other specified pathological lesion in kidney
- 585.9 Chronic kidney disease, unspecified
- 753.8 Other specified anomalies of bladder and urethra

ICD10

- N03.9 Chronic nephritic syndrome with unsp morphologic changes
- N18.9 Chronic kidney disease, unspecified
- Q64.79 Other congenital malformations of bladder and urethra

CLINICAL/SURGICAL PEARLS

- Patients with interstitial disease or obstructive uropathy require IV hydration while NPO prior to procedures.
- In contrast to adults, diabetic nephropathy and hypertension are rare causes of CKD in children.
- Small changes in creatinine reflect large changes in GFR for children with CKD.
- Baseline creatinine with attention to any changes after potential renal insult (CT contrast, hypovolemia/hypertension, medications, etc.) is an important measure for monitoring and prevention of progression of CKD.

CHYLOUS ASCITES

Brett S. Carver, MD

BASICS

DESCRIPTION

- Chylous ascites is characterized by the accumulation of chyle in the peritoneal cavity.
- Results from the obstruction or injury of the thoracic duct or cisterna chyli of the lymphatic system.
- Lymphatic leakage from the lymph vessels draining the intestines.
- Characterized as a milky fluid due to the high triglyceride component.
- This section focuses primarily on chylous ascites associated with retroperitoneal lymph node dissection (RPLND) for testicular cancer

EPIDEMIOLOGY

Incidence

Chylous ascites is reported to occur in ~1% of patients undergoing a primary RPLND for testicular cancer and 3% of postchemotherapy RPLNDs.

Prevalence

N/A

RISK FACTORS

- Predisposing factors for chylous ascites associated with RPLND:
  - Surgical resection of the vena cava.
  - Suprahilar dissection.
  - Simultaneous hepatic resection.
  - In addition, patients undergoing reoperative RPLND are at an increased risk.

Genetics

N/A

PATHOPHYSIOLOGY (1)

- Chylous ascites is caused by injury or obstruction of the thoracic duct or cisterna chyli.
- Surgical injury, ligation of the thoracic duct.
- Retroperitoneal tumor associated with obstruction of the thoracic duct.
- Leakage of fat containing lymphatic fluid into the peritoneum.

ASSOCIATED CONDITIONS

- Testicular cancer
- Peritonitis
- Ileus or small-bowel obstruction
- Failure to thrive

GENERAL PREVENTION

- Appropriate ligation of lymphatic vessels during surgery to minimize lymphatic leak.
- Preservation of the thoracic duct.

- Oral diet with low lipid, high medium-chain triglyceride content.

DIAGNOSIS

HISTORY

- Patients often present following RPLND with symptoms of abdominal distention and pain, decreased appetite, nausea, and vomiting.
- Shortness of breath may also be present associated with increased abdominal pressures.
- Secondary infection associated with peritonitis with symptoms of fever, chills, abdominal pain, and lethargy.

PHYSICAL EXAM

The most common finding on physical exam is distension of the abdomen with flank bulging. The abdomen is dull to percussion and may demonstrate a fluid wave upon palpation.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum tumor markers (AFP, HCG, LDH) should be obtained to rule out recurrence.
- Aspiration of the abdominal fluid reveals a milky white fluid, which should be sent for triglyceride testing and culture to rule out a secondary infection.
  - A fluid triglyceride level >110 mg/dL is diagnostic.

Imaging

- CT scan of the abdomen and pelvis is the imaging modality of choice to evaluate for the presence of ascites and rule out retroperitoneal recurrent disease.
- Abdominal ultrasonography may be used to document ascites and guide aspiration.

Diagnostic Procedures/Surgery

Abdominal paracentesis is performed to aspirate the ascites for diagnostic testing.

Pathologic Findings

Chylous ascites is grossly defined as a milky white fluid. Lab testing will reveal elevated triglyceride content.

DIFFERENTIAL DIAGNOSIS

- Chylous ascites can be caused by other conditions beyond RPLND for testicular cancer:
  - Postoperative
    - Abdominal aneurysm repair
    - Peritoneal dialysis catheter placement
  - Infectious/inflammatory
    - Pancreatitis
    - Retroperitoneal radiation
    - Pericarditis
    - Celiac disease
    - Retroperitoneal fibrosis
    - Sarcoid
    - TB
    - Filariasis
    - Mycobacterium avium-intracellulare (AIDS related)

- Neoplasm
  - Lymphoma
  - Kaposi sarcoma
  - Other solid tumors
- Other causes
  - Cirrhosis
  - Carcinoid
  - Nephrotic syndrome
  - Trauma
  - Right-sided heart failure
  - Dilated cardiomyopathy
  - Idiopathic
  - Congenital causes (defects of lacteal formation)

TREATMENT

GENERAL MEASURES

- All patients with abdominal distention following an RPLND should be evaluated for:
  - Ascites (nonchylous)
  - Ileus
  - Small-bowel obstruction
  - Recurrent disease in the abdomen or retroperitoneum.
- The majority of chylous effusions will heal spontaneously. Abdominal paracentesis is diagnostic and often therapeutic in relieving symptoms associated with increased abdominal pressures.

MEDICATION

First Line

- Low lipid, high medium chain triglyceride oral diet.
  - MCT oil supplement
    - 1 tablespoon (15 mL) 3–4 times/d
    - Mix with juices or otherwise incorporated into low-fat diet
    - Do not use in patients with advanced cirrhosis: Risk of narcosis and coma
- Somatostatin analogs have been demonstrated to be effective in reducing lymphorrhagia.
  - Octreotide 100 mcg administered subcutaneously 3 times per day

Second Line

- Total parental nutrition is to be utilized in patients who fail oral diet modifications.
  - Bowel rest may enhance recovery if conservative approaches are not successful

SURGERY/OTHER PROCEDURES

- Abdominal paracentesis, repeated as necessary.
  - Primarily for pain control and dyspnea
- Surgical exploration with direct ligation of lymphatic vessels for persistent chylous ascites (2).
- Peritoneal venous shunts for refractory chylous ascites.

- Direct lymphatic vessel ligation or embolization of large leaking vessels using interventional radiologic techniques.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

Orlistat (Xenical) has been used successfully in a nontesticular cancer case of chylous ascites (3)

ONGOING CARE

PROGNOSIS

The prognosis is excellent for the vast majority of cases as most will respond to conservative management.

COMPLICATIONS

- The complications of chylous ascites related to increased abdominal pressure:
  - Renal failure
  - Venous thrombosis
  - Pulmonary embolism
  - Atelectasis
  - Pneumonia
- The gastrointestinal complications of chylous ascites include ileus and small-bowel obstruction.
  - Malnourishment and failure to thrive may also occur due to protein-losing enteropathy with chronic diarrhea (steatorrhea), malabsorption, and malnutrition

FOLLOW-UP

Patient Monitoring

- Follow-up protocols should be followed according to guidelines established by the National Comprehensive Cancer Network for testicular cancer patients.
- After initial treatment of chylous ascites, patients should be seen in follow-up to monitor for recurrent ascites.

Patient Resources

N/A

- Chylous Ascites Image
- Lymphatic Ascites
- Testis Cancer, Adult General Considerations

CODES

ICD9

- 125.9 Unspecified filariasis
- 457.8 Other noninfectious disorders of lymphatic channels

ICD10

- B74.9 Filariasis, unspecified
- I89.8 Oth noninfective disorders of lymphatic vessels and nodes

CLINICAL/SURGICAL PEARLS

- Chylous ascites occurs in ~1–3% of patients undergoing a RPLND.
- Risk factors include vena cava resection, suprahilar dissections, and concomitant hepatic surgery.
- Initial management includes paracentesis for symptom of pain or pulmonary compromise and low lipid, high medium-chain triglyceride oral diet.

CHYLURIA

Matthew A. Uhlman, MD, MBA
James A. Brown, MD, FACS

BASICS

DESCRIPTION

- Chyluria is the presence of chyle (a combination of lymphatic fluid and triglycerides) in urine
- Presents as milky white urine that can be constant or present primarily after meals
- Often self-limiting or resolves with conservative treatment including dietary changes
- Extended chyluria can lead to malnutrition, vitamin deficiencies, and immunosuppression (due to depletion of fat soluble vitamins) (1)[C]

EPIDEMIOLOGY

Incidence

- 2–10% of patients infected with filariasis can develop chyluria (2)[C]
- Extremely low rates of clinically significant chyluria (1)[C]
  - Clinically significant in $<1\%$ of postsurgical patients
  - Reports of subclinical chyluria based on CT in 3–41% of postpartial nephrectomy or radiofrequency ablation (RFA) patients (2,3)[C][B]

Prevalence

- 120 million people suffer from filariasis worldwide, primarily in Asia, Africa, Pacific Islands, and South America (2)[C]
- Chyluria is a manifestation of chronic infection, most often by *Wuchereria Bancrofti, Brugia malayi,* or *Brugia timori* (2)[C]
- Rare in developed countries
- Nontropical chyluria most often caused by trauma, renal surgery, infection, mass effect (AAA, tumor, abscess), pregnancy, or congenital abnormality (1)[C]

RISK FACTORS

- **Parasitic chyluria**
  - *W. bancrofti*, *B. malayi,* and *B. timori* are primary causes of filariasis. All are transmitted by mosquito. Less common parasitic infections have been reported to cause chyluria (*echinococcus, bilharzias, onchocerca, ascariasis*) (1,2)[C]
- **Nontropical chyluria**
  - Retroperitoneal surgery (most often radical or partial nephrectomy, RFA, or renal tumors) (1,3,4)[C][B]
  - Trauma
  - Mass effect: Retroperitoneal tumors (primary or metastatic) or lymphadenopathy
  - Infectious: TB, abscess
  - Aortic aneurysm
  - Pregnancy

– Congenital fistula or lymphangioma

PATHOPHYSIOLOGY

- **Parasitic**
  - Adult filariasis causes lymphangitis
  - Obstruction of suprarenal lymphatics (thoracic duct or upper retroperitoneal lymph drainage)
  - Results in rupture of lymphatic vessel into calyceal fornix, forming intrarenal lymphatic urinary fistula
  - Lymphatic HTN, with valvular incompetence:
    - With obstruction between intestinal lacteals and thoracic duct, the resulting cavernous malformation opens into the urinary system, creating a fistula
    - Common fistula sites are renal fornix, pelvicalyceal system, trigone, and prostatic urethra
    - Primary causal agents: *W. bancrofti*, *B. malayi,* and *B. timori*
    - Less commonly caused by external compression or trauma
- **Nontropical**
  - Disruption of peripelvic lymphatics during surgery allows backflow into pyelocaliceal system (1)[C]
  - Congenital fistulous connections between urinary tract and lymphatic system have been described, primarily in children

ASSOCIATED CONDITIONS

W. bancrofti, B. malayi, and *B. timori* are considered the three causative agents of lymphatic filariasis. Mosquitos serve as vectors for all 3 nematodes (2)[C]

GENERAL PREVENTION

- Control of mosquito vector that transmits *W. bancrofti*, *B. malayi,* and *B. timori* (2)[C]
- Insect repellant and mosquito nets in endemic areas
- Diethylcarbamazine (DEC) fortified salt
- Annual DEC + albendazole are used to treat asymptomatic filariasis via action on microfilaria

DIAGNOSIS

HISTORY

- Patient complaints of intermittent or continuous milky or cloudy urine
  - If intermittent, most often occurs following meals
- Country of origin of patient:
  - Asia, Africa, Pacific Islands, South America
- Travel to tropical regions
- History of trauma
- History of renal surgery within prior 2 yr
- History of TB exposure/infection
- Significant weight loss, anemia, lower urinary tract symptoms (frequency, urgency, dysuria), hematuria, nutritional deficiency, proteinuria, or signs of immunosuppression
- Heavy chyluria can cause clot colic or, rarely, urinary retention

PHYSICAL EXAM

- Elephantiasis of lower limbs and genitals
- Lymphadenitis/lymphangitis
- Male groin exam may reveal hydrocele or epididymitis
- Palpable abdominal or flank mass
- Chylous output from surgical wound or surgical drain

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis typically positive for albuminuria
- Postprandial urinary triglycerides
- Fat globules in urine identified by Sudan III stain
- Peripheral blood eosinophilia, may indicate parasitic infection
- Evaluate for TB if clinically indicated (tuberculin test, urine stain, and culture for acid-fast bacillus)
- ICT antigen card test (immunochromatographic card test, a commercial assay) is widely used in the diagnosis of *W. bancrofti*
- WB rapid and panLF rapid (2 commercially available assays) tests detect *W. bancrofti, B. malayi,* and *B. timori*

Imaging

- Abdominal/pelvic CT (3,4)[B]:
  - Exclude retroperitoneal mass
  - Fat fluid level seen in the urinary tract
  - Can demonstrate contrast communication between collecting system and perinephric collection but does not show communications between perinephric collection and lymphatics
- Lymphangiography (traditional or magnetic resonance)
  - Demonstrates abnormal lymphatics and entrance of contrast material into renal collecting system
- Lymphoscintigraphy
  - Can be useful in delineating site of fistula, though not as precise as lymphangiography
- Retrograde pyelography
  - Rarely warranted, but may show diffuse pyelolymphatic backflow

Diagnostic Procedures/Surgery

- Blood smear: Examine for microfilariae (early stage in life cycle of nematodes) using Giemsa stain
- Cystourethroscopy: Can help localize site of milky efflux of urine. Rarely, efflux seen from bladder or posterior urethra.
- Retrograde pyelography: Rarely warranted, but may show diffuse pyelolymphatic backflow

Pathologic Findings

Lipid contents of chyluria are mainly chylomicrons, 90% of which are in the form of triglycerides

DIFFERENTIAL DIAGNOSIS

- Filariasis from *W. bancrofti, B. malayi,* or *B. timori*
- Pyelolymphatic fistula
- Phosphaturia, most common cause of cloudy urine
- Pyuria
- Hyperuricosuria
- Nephropathy—urinary sediment can cause cloudy appearing urine
- Enterovesical fistula

TREATMENT

GENERAL MEASURES

- **Nontropical**
  - Up to 50% of cases resolve spontaneously under dietary restriction (1)[C]
  - Bed rest and/or use of abdominal binder to increase abdominal pressure may allow spontaneous closure.
  - Medium-chain triglyceride (MCT) diet (avoidance of long-chain triglycerides)
    - MCTs are transported via portal system, not by chylomicrons through lymphatics
  - Ureteral stent placement to reduce renal pelvis pressure

MEDICATION

Nontropical

Dietary modifications to reduce chylomicrons in diet—recommendations are often for fat-free or very low-fat diet, though this should not be observed for more than several weeks given the body's need for some fats

Parasitic Chyluria

- DEC and albendazole, or ivermectin and albendazole
- DEC fortified salt can be used to treat and prevent lymphatic filariasis

SURGERY/OTHER PROCEDURES

- Procedures of choice involve disconnection of renal pedicle lymphatics (1,5,6)[C][A]
- Nephrolysis:
  - Stripping and ligation of all lymphatic vessels to the kidney and upper ureter; open and laparoscopic techniques described
  - Laparoscopic transabdominal and retroperitoneoscopic approaches described
  - Success rates 80–98%; recurrence rates 3–25%
- Endoscopic coagulation of fistula
- Lymphangiovenous anastomosis with ligation of renal lymphatics
- Renal autotransplantation
- Nephrectomy was described prior to minimally invasive techniques

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Sclerotherapy with various agents instilled into collecting system (1,3)[C][B]

- Povidone iodine (5%) and dextrose (50%) in renal pelvic instillation sclerotherapy; 87% success reported
- Silver nitrate (1–3%) instillation into the affected collecting system causes sclerosis of lymphatic fistulas; 48% success reported
- Case reports of successful sclerotherapy with:
  - N-butyl-2-cyanoacrylate (component of medical cyanoacrylate glues)
  - Radiographic contrast media

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Rarely fatal, with high success rates reported for surgical intervention
- Recurrence rates after surgery reported as high as 25%

COMPLICATIONS

- Hypoalbuminemia and anasarca from massive protein loss (1)[C]
- Immunosuppression from fat soluble vitamin loss in chronic cases (1)[C]
- Underlying filariasis may cause epididymitis, hydrocele, and elephantiasis of the penis/scrotum and lower extremities

FOLLOW-UP

Patient Monitoring

- Treatment failures are readily apparent as urine returns to milky color (1,5)[C][A]
- Re-evaluate if chyluria recurs following treatment; consider the contralateral kidney as the source

Patient Resources

N/A

CODES

ICD9

- 125.0 Bancroftian filariasis
- 125.9 Unspecified filariasis
- 791.1 Chyluria

ICD10

- B74.0 Filariasis due to Wuchereria bancrofti
- B74.9 Filariasis, unspecified
- R82.0 Chyluria

CLINICAL/SURGICAL PEARLS

- Milky or cloudy urine (often after meals) is the most common presentation, though phosphaturia is the most common cause of cloudy urine.
- *W. bancrofti*, *B. malayi,* and *B. timori* are the primary causes of filariasis, the most common cause of chyluria (parasitic chyluria).
- Following renal surgery, incidence of chyluria (up to 41% on CT) is likely much higher than is clinically significant (<<1%).
- Up to 50% of cases of chyluria resolve spontaneously with a medium chain fatty acid or very low-fat diet.
- There is no “best” imaging technique, though lymphangiography can demonstrate entrance of contrast from lymphatics into the collecting system.

CIRCUMCISION, ADULT CONSIDERATIONS

Irvin H. Hirsch, MD

BASICS

DESCRIPTION

- Circumcision involves the removal of the prepuce. This section addresses adult circumcision issues.
- Adult circumcision is indicated for elective treatment of balanitis (glans inflammation), posthitis (prepuce inflammation), removal of preputial lesions, and at patient request for cultural and religious preference.
- Emergent circumcision may be necessary for treatment of paraphimosis after failed attempt at manual reduction.
- Circumcision may be necessary as part of surgical procedures requiring degloving exposure of the penis (penile fracture repair or Peyronie disease).
- Circumcision is the most common operation performed worldwide.
- There is some controversy concerning the need for circumcision and potential effects on sexual satisfaction. This is weighed against the potential health benefits.

EPIDEMIOLOGY

Incidence

N/A

Prevalence

- Male circumcision, largely in newborns, is performed in 77% of US males and in 30% of males worldwide.
- Circumcision rate in newborns has declined from 83% in the 1960s to 77% in 2010.
  - These incidence rates do not include out-of-hospital circumcisions
- Increasingly adult circumcision has been advocated as an important adjunct to STD and HIV prevention in developing countries (1).

RISK FACTORS

- Diabetes mellitus
- Genital lesions

Genetics

N/A

PATHOPHYSIOLOGY

- The prepuce serves as a specialized, junctional mucocutaneous tissue marking the boundary between mucosa and skin; it is similar to the eyelids, anus, and lips.
- Condition that can cause problems:
  - Lack of genital hygiene
  - Chronic balanoposthitis may lead to phimosis

ASSOCIATED CONDITIONS

- Diabetes mellitus
- Balanitis
- Lichen sclerosus/urethral stricture
- Penile condylomata
- Squamous cell carcinoma
- Erectile dysfunction
- Peyronie disease

ALERT
The American Urologic Association (AUA) policy statement now considers circumcision to be of a health benefit, citing a 50–60% risk reduction in HIV transmission in some African nations.

GENERAL PREVENTION
- Local hygiene measures may prevent balanitis and its sequelae.
- Although male circumcision should not be substituted for other HIV risk-reduction strategies, it has been shown to reduce the risk for HIV and some STDs in heterosexual men.
  - Despite these data, male circumcision has not been demonstrated to reduce the risk for HIV or other STDs among men who have sex with men (MSM).
- Good visualization of the glans penis is crucial in all cases of circumcision to limit complications.

DIAGNOSIS
HISTORY
- Penile pain with or without erection
- Dyspareunia
- Postcoital pain

PHYSICAL EXAM
- Inability to retract prepuce (phimosis)
- Inability to reduce prepuce (paraphimosis)
- Preputial erythema or excoriation
- Glans erythema
- Malodorous secretion (smegma)
- Associated penile lesion

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- UA
- Urine culture if indicated
- STD testing if indicated

Imaging
N/A

Diagnostic Procedures/Surgery
N/A

Pathologic Findings
- Acute and chronic inflammation
- Plasma cell infiltrate (Zoon balanitis)
- Lichen sclerosus (BXO blanaitis xerotica obliterans)

DIFFERENTIAL DIAGNOSIS
N/A

TREATMENT

GENERAL MEASURES
Circumcision for balanitis in adults should be performed after exhausting nonsurgical medical approaches.

MEDICATION
First Line
- Topical antibiotics
- Topical steroids
- Topical antifungals

Second Line
N/A

SURGERY/OTHER PROCEDURES
- General anesthesia may be utilized
- Local anesthesia is recommended when tolerated
- Lidocaine/bupivacaine combination is injected at the level of the infrapubic bone and around the base of the penis. Avoid epinephrine.
- Technique is selected based on surgeon's preference: Sleeve technique or dorsal slit circumcision.

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
- For high risk or anticoagulated patients an isolated dorsal slit may be oversewn without circumcision.
- Nonsurgical preputial compression devices are currently under investigation for HPV, HSV, and HIV risk-reduction programs in developing countries (Prepex or Shang Ring). The prepuce sloughs after 7 days.

ONGOING CARE

PROGNOSIS
Patient satisfaction is high

COMPLICATIONS (2)

- The majority of complications relating to circumcision are minor and should be easily treated
- While very infrequent, challenging complications requiring complex reconstructive surgery and should be referred to a center specializing in these reconstructions.
- Early
  - Hematoma and bleeding
  - Infection
  - Urinary retention due to tight bandaging
  - Glans necrosis
  - Removal of inadequate or excessive skin
  - Partial penile amputation
- Late
  - Urethral injury/urethrocutaneous fistula
  - Meatal stenosis
  - Hypesthesia or hyperesthesia of penis
  - Penile scarring and deformity
    - Skin bridges between the glans and penile shaft
  - Concealed/buried penis
  - Inclusion cysts
  - Erectile dysfunction

FOLLOW-UP

Patient Monitoring

- Routine postoperative care.
- Follow for alterations in penile sensation and erectile function.

Patient Resources

- V50.2 Routine or ritual circumcision

ICD10

- N47.2 Paraphimosis
- N48.1 Balanitis
- Z41.2 Encounter for routine and ritual male circumcision

CLINICAL/SURGICAL PEARLS

- These measures reduce risk of neural injury: minimize use of electrocautery and limit excision superficial to Buck fascia.
- Assure hemostasis of frenular artery.

CIRCUMCISION, PEDIATRIC CONSIDERATIONS

Mary Ellen T. Dolat, MD
Harry P. Koo, MD, FAAP, FACS

BASICS

DESCRIPTION

- Circumcision is the surgical removal of the foreskin (prepuce) from the penis.
- One of the oldest surgical procedures
- One of the most commonly performed surgical procedures in practice today
- There is some controversy concerning the need for circumcision and potential effects on sexual satisfaction in adulthood. This is weighed against the potential health benefits.

EPIDEMIOLOGY

- Few data are available to help estimate accurately the number of newborns circumcised worldwide.
  - Country of origin, ethnicity, religious affiliation, and birth in a rural vs. an urban hospital clearly influences a child's likelihood of being circumcised.
  - In addition, lack of (or the type of) health insurance may influence a child's likelihood of being circumcised.
- Most common reasons reported by US parents for choosing circumcision
  - Health/medical benefits including hygiene (40–60%)
  - Social concerns (23–37%)
  - Religious requirements (11–19%)

Incidence

- Circumcision rate in newborns has declined from 83% in the 1960s to 77% in 2010.
  - These incidence rates do not include out-of-hospital circumcisions

Prevalence

- 79% of men surveyed reported being circumcised (range: 42% for Mexican American; 88% for non-Hispanic Caucasian) (1)
  - Prevalence rates are limited by the accuracy of the self-report

RISK FACTORS

- Urinary tract infection
  - An increased risk for UTI in uncircumcised males younger than 1 yr; risk being the greatest toward the 1st 6 mo
  - Given that the risk of UTI in infant males is ~1%, the number needed to circumcise to prevent UTI is ~100
  - The benefits of male circumcision are, therefore, likely to be greater in boys at higher risk for UTI, such as infants with underlying anatomic defects
- Need for future circumcision
  - Future medical complications for boys (and men) who are uncircumcised as newborns include balanitis, severe phimosis, and paraphimosis.

  - For parents, there exists ~2–5% risk that their sons will need a circumcision for a medical indication if they choose not to circumcise their sons as newborns (2)
- Penile cancer (see "Circumcision, Adult Considerations")
  - The relationship among hygiene, phimosis, and penile cancer is uncertain
  - In a Danish study of penile cancer, there was a statistical decline in the rates of penile cancer over a 50-yr period despite a national circumcision rate of 1.6%. These data correlated with better penile hygiene resulting from improvements in sanitary conditions.
  - Based on the low incidence of penile cancer in Israel (high prevalence of circumcision) and in Scandinavian countries (low prevalence of circumcision), 2 ways of preventing penile cancer:
    - Remove the foreskin
    - Practice good penile hygiene
- Sexually transmitted disease (refer to the Chapter, "Circumcision, Adult Considerations")

Genetics

N/A

PATHOPHYSIOLOGY

- Prepuce serves as a specialized, junctional mucocutaneous tissue marking the boundary between mucosa and skin; it is similar to the eyelids, anus, and lips.
- Most neonates have a physiologic phimosis
- During childhood, the growth of the penile body, accumulation of epithelial debris, and intermittent penile erections eventually separate the prepuce from the glans, permitting retraction
- During the 1st 6 mo of life, there are more uropathogenic organisms around the urethral meatus of an uncircumcised male infant than around those of circumcised male infants; this colonization decreases in both groups after the 1st 6 mo (3)
- Boys with vesicoureteral reflux who are uncircumcised have a higher risk of UTI

ASSOCIATED CONDITIONS

- Phimosis
- Paraphimosis

GENERAL PREVENTION

Gentle periodic retraction during the newborn period will help prevent phimosis for the inability to retract foreskin later in life

DIAGNOSIS

HISTORY

- Prior history of posthitis or balanitis
- Prior history of meatitis
- Report of "ballooning" of the distal foreskin during voiding
- Prior history of circumcision
  - Incomplete removal of foreskin
  - Iatrogenic phimosis
- Some parents report "infected whitish pus," which in most instances is due to normal

secretion of smegma

PHYSICAL EXAM

- In newborns, perform a complete male genital exam
  - In rare instances, a well-formed phallic structure in a baby with nonpalpable testes may be due to congenital adrenal hyperplasia
- Look for penile developmental variations that may be a contraindication of a newborn circumcision (see "Differential Diagnosis")
- Some instances with newborns with incomplete foreskin development (ie, does not have natural phimosis), may still be amenable to a newborn clamp circumcision
  - Recommend obtaining a pediatric urology consultation to determine whether the baby would be a candidate for newborn circumcision

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Not necessary unless there is suspicion for intersex anomaly

Imaging

Not necessary unless there is suspicion for intersex anomaly

Diagnostic Procedures/Surgery

Not necessary unless there is suspicion for intersex anomaly

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- The penis should be carefully examined before the procedure to identify the following conditions that may preclude a circumcision
  - Webbed penis
  - Microphallus
  - Chordee
  - Epispadias
  - Hypospadias
  - Megameatus intact prepuce (MIP) variant of hypospadias
    - The foreskin is normally developed; the abnormal urethra is noted after the foreskin has been pulled back (or after the neonatal circumcision has already been performed)

TREATMENT

ALERT

In cases of Disorders of Sexual Development (DSD) with sex assignment concerns or significant anomaly such as hypospadius the infant should not undergo neonatal circumcision.

GENERAL MEASURES

- The AAP states that: The health benefits of newborn male circumcision outweigh the risks but the scientific evidence is not strong enough for the AAP to recommend routine

circumcision of all newborns. The AAP advises parents to learn the facts about circumcision and weigh the risks and benefits.
- Most routine circumcision is performed between 2 and 10 days of life.
- Contraindications to newborn circumcision include:
  - Congenital penile anomalies (see "Differential Diagnosis")
  - Significantly premature infants
  - Blood dyscrasias
  - Babies with a family history of bleeding disorders
  - Disorders of Sexual Development (DSD)
- Relative contraindications to newborn circumcision:
  - Incomplete foreskin development
  - Prominent suprapubic fat pad (retrusive penis)

MEDICATION

First Line

- Analgesia is safe and effective in reducing the procedural pain associated with newborn circumcision
  - Dorsal penile nerve block
    - 1% lidocaine without epinephrine
  - Subcutaneous ring block
    - 1% lidocaine without epinephrine
  - Topical cream may cause a higher incidence of skin irritation in low–birth-weight infants
    - Lidocaine–prilocaine (2.5% lidocaine and 2.5% prilocaine) applied for 30–40 min

ALERT
Epinephrine should not be used for pediatric circumcsion.

Second Line

- Nonpharmacologic techniques (eg, sucrose pacifier) alone are insufficient to prevent pain and are not recommended as the sole method of analgesia
  - Sucrose on a pacifier has been demonstrated to be more effective than water alone for decreasing crying during circumcision (2)

SURGERY/OTHER PROCEDURES

- Common methods for the newborn circumcision
  - Gomco clamp
  - Plastibell
  - Mogen clamp
- After the newborn and infant periods, circumcision is performed under general anesthesia

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

Traditional religious providers perform the procedures in community settings

ONGOING CARE

PROGNOSIS

Some groups believe that circumcision may reduce or increase the sensitivity of the tip of the penis, potentially impacting sexual pleasure later in life. The data are conflicting and mostly these subjective findings are not conclusive.

COMPLICATIONS

- Large US hospital-based studies estimate the risk of a significant acute circumcision complication to be between 0.19–0.22%.
- From neonatal circumcisions using clamp techniques
  - Gomco clamp
    - Mainly related to technical factors
    - Insufficient or inadequate skin removal requiring additional revision procedure
    - Since the met al bell completely covers the glans, glans injury is extremely rare
  - Plastibell
    - Incomplete circumcision
    - Retained Plastibell ring
  - Mogen clamp
    - Potential for injury to glans, including partial amputation
- Immediate complications
  - Significant bleeding (0.08–0.18%)
    - Postcircumcision bleeding may be the 1st manifestation on an underlying bleeding disorder
  - Significant infection (0.06%)
  - Significant penile injury (0.04%)
- Late complications
  - Phimosis (iatrogenic)
  - Adhesions
  - Skin bridges
  - Excess foreskin
  - Insufficient penile skin
  - Penile inclusion cysts
  - Meatal stenosis
  - Penile torsion
  - Urethrocutaneous fistula

FOLLOW-UP

Patient Monitoring

- A small amount of petroleum jelly may help with discomfort due to diaper friction the 1st few days postop.
- Bandaging is optional after the 1st 1–2 days.
- Healing usually take place within 10 days.
- Clean site with warm water and avoid baby diaper wipes.

CODES

ICD9
V50.2 Routine or ritual circumcision

ICD10
Z41.2 Encounter for routine and ritual male circumcision

CLINICAL/SURGICAL PEARLS
- Make sure to carefully inspect the penis for any congenital defects such as hypospadias or chordee before proceeding with neonatal circumcision. It is best to delay circumcision until the primary defect can be repaired as the foreskin may be used in reconstructive procedure.
- The choice of neonatal circumcision is a matter of the physician's personal preference. For circumcisions using a Gomco clamp, or Plastibell, select the correct size of the bell; this would ensure adequate foreskin removal.
- Always consider the cultural and religious beliefs of the family when counseling about newborn circumcision.

CONDYLOMA ACUMINATA (VENERAL WARTS)

Neal Patel, MD
Allen D. Seftel, MD

BASICS

DESCRIPTION

- Anogenital epidermal lesions caused by the transmission of human papilloma virus (HPV)
- The most common viral sexually transmitted infection in the US, they are also called genital warts, or venereal warts
- Most common sites: Penis, vulva, vagina, cervix, perineum, and perianal area.
- Less commonly, urethra, bladder, oropharynx, larynx, and trachea

EPIDEMIOLOGY

Incidence (1)

- Most common STD
- ~1% of sexually active adults in the US

Prevalence

- Highest prevalence: 18–28 yr olds and exceeds 50%
- HPV DNA can be detected in 10–15% of the US population
- HPV 6 and 11 account >90% of visible genital warts.

RISK FACTORS

- Increased risk with number of sex partners, frequency of sexual activity, early coitus, and presence of condyloma on partners
- Age <25
- Immunocompromised status
- Cigarette smoking and oral contraceptives may be associated with an increased risk.
- Onset of sexual activity at an early age

PATHOPHYSIOLOGY

- HPV is a double-stranded, circular DNA genome consisting of ~8,000 base pairs. Subtypes 6 and 11 are associated with the majority of genital warts. Types 16, 18 most often associated with potential for malignancy.
- >80 different subtypes can potentially associate with condylomata.
- HPV subtypes associated with malignancy include: 16, 18, 31, 33, 35, 39, 45, 51, 52, 56, 58, 59, 68, and 82 (2)
- Transmission is by direct sexual contact.
- Less common mode is autoinoculation from nongenital lesions.
- Basal layer of epidermis is invaded by the virus.
- Latent phase can last months to years.

ASSOCIATED CONDITIONS

- Penile cancer
- Anal cancer

- Cervical cancer
- Buschke-Lowenstein tumor

GENERAL PREVENTION
- Sexual abstinence
- Condoms
- Pre-exposure vaccination (Gardasil, Cervarix, Hepatitis B)

DIAGNOSIS
HISTORY
- Age and sex of patient
- History of recent sexual exposure
- Number of partners and frequency of sexual intercourse
- Visible warts usually seen within 2–3 mo after exposure
- Practice of anal intercourse
- Immunocompromised state

PHYSICAL EXAM
- Lesions are pinkish to red-grayish white cauliflower-like lesions found on moist surfaces, often coalescing.
- Lesions appear pearly white and granular
- Larger lesions may be verrucous or flat in configuration
- With magnifications, a central venule can be seen within each projection.
- Male: Examine penis, meatus, scrotum, perineum, suprapubic, and perianal region
- Female: Vagina, introitus, perineum, cervix, and perianal region
- Examine for evidence of coexisting STD (ulcers, discharge, adenopathy).

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- HPV cannot be readily grown in culture.
- Cytologic testing with Pap smear: Exfoliated genital cells are stained and examined for koilocytosis and neoplasia
- Serologic assays not useful in screening for HPV injection, but may provide prognostic information for patients with abnormal Pap smears
- Histologic analysis from biopsy specimens
- Rapid commercial screening tests available and are fairly accurate: ViraPap, ThinPrep Pap, Hybrid capture II
- If necessary, molecular characterization for diagnosis and serotyping (eg, Southern and/or slot blot hybridization, PCR)
- Consider screening for other associated STDs: HIV, GC, chlamydia, syphilis

Diagnostic Procedures/Surgery
- Magnification with colposcope or 10× handheld magnifying lens of the suspected region after application of 3–5% acetic acid-soaked gauze pad for 5 min allows visualization of nonvisible lesions, but has low specificity. (3,4)
  – However, the Centers for Disease Control (CDC) no longer recommends acetic acid soaks

to improve diagnosis. The soaks are associated with many false positives.
- Subclinical lesions may appear shiny white.
- Urethroscopy for any patients with suspected urethral warts, with care to occlude proximal urethra to prevent flushing of virus toward bladder
- Proctoscopy for patients at risk for anal condyloma

Pathologic Findings
- Branching, villous, papillary connective tissue stroma covered by epithelium.
- Superficial hyperkeratosis and thickening of the epidermis (acanthosis).
- Clear vacuolization of the prickle cells (koilocytosis), characteristic of HPV infection, is seen.
- There is no evidence of invasion of the underlying stroma

DIFFERENTIAL DIAGNOSIS
- Bowen disease and erythroplasia of Queyrat
- Bowenoid papulosis
- Buschke-Löwenstein tumor
- Condyloma latum (syphilis)
- Extramammary Paget disease
- Fibroepitheliomas
- Herpes simplex virus
- Malignant melanoma
- Molluscum contagiosum
- Nevi
- Pearly penile papules
- Seborrheic keratosis
- Squamous cell carcinoma/basal cell carcinoma

TREATMENT

GENERAL MEASURES (5)
- Diagnosis usually based on observation of characteristic lesions.
- Main goal of treatment is to remove visual presence of warts.
- Current therapies have an equally low effectiveness in preventing wart recurrence and may not reduce disease transmission.
- Vaccine: HPV quadrivalent recombinant (types 6, 11, 16, and 18): Gardasil (Merck) is currently available for administration to females of ages 9–26 for prevention of condyloma acuminata and associated diseases. HPV bivalent Cervarix (types 16 and 18) (GSK)
- Gardasil can also be used in males aged 9–26 to prevent genital warts. Administration to males prior to start of sexual activity is optimal.
- Topical therapy may take up to 3 mo to observe a response.

MEDICATION
First Line
- Podophyllin (Podoben 25%, Podocon, Podofin):
  – Applied to lesion (concentration 10–25%) by health care worker once weekly for up to 6 wk

- Podofilox (Condylox):
  – Self-application of a 0.5% solution to warts twice daily for 3 days, followed by 4 days without treatment; can be repeated 4–6 times.
- 5-FU (Efudex, Fluoroplex):
  – Topical treatment with 5% cream 1–3 times per week for several weeks, as needed. Maybe also used as an intraurethral instillation but not without irritative complications.
- Trichloroacetic acid (Tri-Chlor):
  – An 80–90% solution of trichloroacetic acid; apply directly to lesions; repeat weekly
- Imiquimod (Aldara):
  – Potent inducer of interferon-α, which enhances cell-mediated cytolytic activity. Available as a 5% cream applied to external lesions 3 times per week up to a maximum of 16 wk

Second Line

Interferon-α IM or intralesional 3 million units 3 times a week for 3 wk

SURGERY/OTHER PROCEDURES

- Electrosurgery (electrodesiccation/loop electrosurgical excisional procedure): To destroy lesions; local anesthesia is usually sufficient
- CO_2 laser therapy: Useful for lesions that have not responded to other therapies and for extensive disease. Magnification necessary to maximize efficacy; may produce less scarring
- Holmium laser can be used to remove intraurethral warts via cystoscopy.
- Surgical excision: Often reserved for extensive disease; also effective for isolated warts
- Cryotherapy: Application of liquid nitrogen on patients without extensive disease. This procedure can be repeated at 1- or 2-wk intervals.

ONGOING CARE

PROGNOSIS

- Subclinical infections are probably not curative.
- Women should still undergo routine Pap smears.
- Cervical cancer is associated with HPV infection. HPV infection is not solely responsible for the malignant transformation of genital cells, but it may be a cofactor in development of malignancy. HPV 6 and 11 are low-risk subtypes, and are seldom associated with malignancy.
- Homosexuals are at 25–50 times greater risk for anal cancer.
- Long-term, increased risk of malignancy secondary to HPV infection (HPV types 16, 18, 31, 33, and 51 are at highest risk of anogenital malignancy).

COMPLICATIONS

Malignant transformation: Penile carcinoma, cervical carcinoma, anal cancer, and Buschke-Löwenstein tumor

FOLLOW-UP

Patient Monitoring

- Educate the patient about self-exam.
- Patients should be examined shortly after therapy, to evaluate initial response rates.
- Encourage use of condoms if sexually active.

- Surveillance urethroscopy is recommended 3–6 mo after treatment of intraurethral lesions.

CODES

ICD9

- 078.11 Condyloma acuminatum
- 079.4 Human papillomavirus in conditions classified elsewhere and of unspecified site

ICD10

- A63.0 Anogenital (venereal) warts
- B97.7 Papillomavirus as the cause of diseases classified elsewhere

CLINICAL/SURGICAL PEARLS

- HPV types 6, 11, 16, and 18 most common subtypes.
- Women who have received the HPV vaccine should still undergo routine screening with Pap smears.
- Eliminating warts may not decrease infectivity or transmission.
- Men along with women may benefit from vaccination.
- Vaccines are not recommended for use in women >26 yr of age.
- In absence of lesions, treatment is not recommended for individuals with subclinical infections.

CONTRAST ALLERGY AND REACTIONS

Edouard J. Trabulsi, MD, FACS
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION

- Allergy reactions to IV contrast used for radiologic imaging are common, can range from mild to moderate, and occasionally life threatening.
- Often an immune system–based response to IV administration of contrast used for common urologic studies such as excretory urography and CT.
- Contrast allergy and reactions can be divided into 3 groups:
  - Idiosyncratic anaphylactoid reactions
  - Nonidiosyncratic reactions
  - Delayed reactions
- Reactions to MRI contrast media are discussed in Section II "Nephrogenic Systemic Fibrosis/Fibrosing Dermatopathy (NSF/NFD)."
- "Contrast Induced Nephropathy" is discussed in Section II.

EPIDEMIOLOGY

Incidence

- Overall rate of ADR (adverse drug reaction) for ionic high-osmolar contrast media (HOCM) is 11–12% and 0.2–3% for nonionic low-osmolar contrast media (LOCM) (1)[B]
- It is estimated that up to 12% of patients may experience a contrast-related reaction.

Prevalence

N/A

RISK FACTORS

- History of asthma/bronchospasm (10 times), previous reaction (5 times), allergy or atopy (2–3 times) (2)[B]
- Other significant risks include: Cardiac disease, dehydration, sickle cell disease, polycythemia, multiple myeloma, pheochromocytoma, renal disease, anxiety, and the use of ionic vs. nonionic contrast material
- Possible risk factors: β-blockers, IL-2, aspirin, NSAIDs
- Concomitant shellfish allergy or iodine allergy, while a common misnomer, does not confer a higher risk of cross-reaction to radiocontrast media (RCM)

Genetics

N/A

PATHOPHYSIOLOGY

- Idiosyncratic anaphylactoid:
  - Not dose dependent
  - Most serious and potentially fatal type of reaction

  - Occurs without warning, previous exposure not a prerequisite, not preventable
  - Not considered anaphylactic due to lack of IgE antibody formation
  - Usually begins with or immediately after injection of RCM (<30 min)
- Nonidiosyncratic:
  - Dose dependent
  - Related to osmolality, chemical composition, volume, and concentration of contrast medium used
  - Idiosyncratic and nonidiosyncratic reactions may be classified as minor, moderate, or severe
  - Minor: Urticaria, nausea and vomiting, sense of warmth, pruritus, diaphoresis
  - Moderate: Faintness, severe vomiting, facial edema, laryngeal edema, mild bronchospasm
  - Severe: Hypotensive shock, pulmonary edema, respiratory arrest, seizures, cardiovascular collapse
- Delayed:
  - Occurs 1 hr to 7 days from injection of RCM
  - Usually mild to moderate, transient, and self-limiting
  - Commonly includes rash, urticaria, pruritus, and erythema

ASSOCIATED CONDITIONS

- Asthma
- Cardiac disease
- Dehydration
- History of allergy or atopy
- Previous adverse drug reaction
- Renal disease
- Sickle cell disease
- Renal insufficiency

GENERAL PREVENTION

- Use of alternative imaging in patients with history of previous ADR
- These measures may decrease likelihood of ADR but will not eliminate all risk (3)[B].
  - Use of nonionic LOCM
  - Antihistamines (diphenhydramine 50 mg 1 hr prior to study). An H_2-blocker can be used in conjunction with H_1, but never without H_1-blockers
  - Preprocedure hydration
- Patients with pre-existing renal impairment should stop metformin 24 hr prior to procedure and be well hydrated to avoid RCM-related biguanide lactic acidosis and contrast-induced nephropathy.
  - In patients with normal renal function on metformin the following comorbidities should prompt discontinuation of metformin before the contrast:
    - Liver dysfunction, alcohol abuse, cardiac failure, myocardial or peripheral muscle ischemia, sepsis
- To limit risk for contrast-induced nephropathy, special arrangements should be made with the radiology department for any patient with a GFR <60 mL/min/1.73 m^2.
- Prevention in patient with known allergy:

– Review radiology department procedures at site where testing scheduled.
– Give methylprednisolone (Medrol) 32 mg PO 12 and 2 hr prior to scheduled test and 50 mg diphenhydramine
– Patients with allergies to other substances (food, medicines), with history of asthma, who are allergic to iodinated contrast, who are receiving gadolinium (or those with allergy to gadolinium who are to receive IV contrast) DO NOT need steroid prep.

DIAGNOSIS

HISTORY (4)

- Previous ADR
- Cardiac or renal disease
- Metformin with chronic renal diisease
- Allergies

PHYSICAL EXAM

- Monitor vital signs (BP, heart rate, respirations)
  – Hypotension and rarely shock
- Observe for:
  – Urticaria, bronchospasm, wheezing, stridor shortness of breath, flushing, pruritus, angioedema

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- In acute setting, no labs are usually needed
- Blood gas may be useful
- The following may be obtained immediately after the reaction to help with the diagnosis: Elevated tryptase or histamine (released from activated mast cells).

Imaging

N/A

Diagnostic Procedures/Surgery

N/A

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

Complex of symptoms immediately after contrast administration supports diagnosis

TREATMENT

GENERAL MEASURES

- Any facility that administers IV contrast should be equipped to treat common reactions noted below as well as initial steps in cardiac/respiratory arrest.
- The American College of Radiology classifies acute contrast reactions and treatment in adults as noted below. Treatment is similar in children with appropriate dose modifications.
  – Hives

- Mild (scattered/transient): Observe or PO diphenhydramine or PO fexofenadine
- Moderate (numerous/bothersome): PO/IM/IV diphenhydramine or PO fexofenadine
- Severe (widespread/progressive): Consider IM/IV diphenhydramine; consider IM/IV epinephrine

– Diffuse erythema: IV access, monitor vitals, pulse oximeter, O_2 mask
- If hypotensive NS or LR IV bolus 1 L
- If no fluid response consider IM/IV epinephrine

– Bronchospasm: IV access, monitor vitals, pulse oximeter, O_2 mask
- Mild: β-agonist inhaler (eg, albuterol); consider rapid response team or ER admit
- Moderate: Consider IM/IV epinephrine; consider rapid response team or ER admit
- Severe: IM/IV epinephrine and rapid response team/911

– Laryngeal edema: IV access, monitor vitals, pulse oximeter, O_2 mask, IM/IV epinephrine; consider rapid response team/911 based on response

– Hypotension (systolic BP <90 mm Hg): IV access, monitor vitals, pulse oximeter, O_2 mask, elevate legs 60°; consider NS or LR IV bolus 1 L
- With bradycardia (pulse <60 BPM [vasovagal] as above; give atropine; consider rapid response team/911
- With tachycardia (pulse >100 BPM [anaphylactoid reaction]) IM/IV epinephrine; consider rapid response team based on response

– Hypertensive crisis (DBP >120 mm Hg; SBP >200 mm Hg; IV access, monitor vitals, pulse oximeter, O_2 mask; IV labet alol or nitroglycerine SL and furosemide; rapid response team/911

– Unresponsive and pulseless: Check for responsiveness; rapid response team/911; initiate CPR; apply AED device; epinephrine IV (10 mL 1:10,000)

– Pulmonary edema: IV access, monitor vitals, pulse oximeter, O_2 mask; elevate head of bed; IV furosemide, IV morphine; rapid response team/911

– Seizures: Protect patient; turn on side to avoid aspiration; suction airway as needed; IV access, monitor vitals, pulse oximeter, O_2 mask; if unremitting rapid response team/911 lorazepam IV

– Hypoglycemia: IV access, O_2 mask; oral 2 sugar packets or 4 oz fruit juice or D50W I amp IV with D5W or D5NS 100 mL/h adjunctively; if no IV glucagon 1 mg IM

– Anxiety/panic attack: Diagnosis of exclusion; monitor for evolving reactions if present; IV access, monitor vitals, pulse oximeter; reassure patient

– Reaction rebound prevention: IV steroids help short-term recurrence but not acute treatment benefit; consider IV hydrocortisone/methylprednisolone with severe allergic reaction prior to transport to ED

MEDICATION

First Line

- Based on guidelines noted above (5):
  – Albuterol: 2 puffs (90 mcg/puff)
  – Atropine 0.6–1 mg slow IV with NS flush up to 3 mg
  – Benadryl

- 25–50 mg PO
- 25–50 mg IV slowly over 2 min

– Epinephrine
- 0.3 mg (0.3 mL 1:1,000 solution) IM
- EpiPen or (equivalent) IM 0.3 mL 1:1,000 solution
- 1 mL 1:10,000 solution slow IV injection over 5 min repeated every 5–10 min as needed for severe reaction

– Furosemide 20–40 mg IV over 2 min
– Fexofenadine: 180 mg PO
– Glucagon: 1 mg IM
– Hydrocortisone 200 mg IV over 2 min
– Labet alol: 20 IV over 2 min; double dose every 10 min PRN
– Lorazepam 2–4 mg IV slow push; 4 mg max
– Methylprednisolone: 40 mg IV over 2 min
– Morphine: 1–3 mg IV, repeat every 5–10 min PRN
– Nitroglycerine: 0.4 mg tablet SL repeat every 5–10 min PRN

Second Line

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
For life-threatening reactions: ABCs of resuscitation, IV fluids, vasopressors for BP support if IV fluids not adequate

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Depends on severity of ADR
- Risk of death of 1 in 170,000 for both ionic HOCM and nonionic LOCM

COMPLICATIONS
- Renal failure occurs in up to 5%
- Generally supportive measures only with renal function returning to normal in a few weeks
- Contrast-induced nephropathy (CIN)

FOLLOW-UP
Patient Monitoring
- Appropriate supportive measures until recovery depending on severity of ADR
- For patients with renal insufficiency on metformin follow-up renal function monitoring

recommended.

CLINICAL/SURGICAL PEARLS

A shellfish or iodine allergy does not correlate with contrast media allergy.

CUSHING DISEASE AND SYNDROME

John B. Eifler, MD
Michael S. Cookson, MD

BASICS

DESCRIPTION

- Cushing disease is hypercortisolism due to an ACTH-secreting pituitary adenoma
- Cushing syndrome is the cluster of symptoms attributable to hypercortisolism
- Pituitary adenomas account for 70% of patients with endogenously elevated cortisol (15% primary adrenal tumor, 15% ectopic ACTH production)
- Iatrogenic supplementation of glucocorticoids is the most common cause of hypercortisolism

EPIDEMIOLOGY

Incidence

N/A

Prevalence

- Cushing disease: 1.2–2.4 per million
- Cushing syndrome 4–5× more common in women than men
- In diabetics, prevalence 2–5%

RISK FACTORS

- Iatrogenic exposure to glucocorticoids
  - Includes steroid creams or nasal sprays

Genetics

- Associated with MEN-1, Carney complex
- GNAS1 gene mutation (McCune-Albright syndrome)

PATHOPHYSIOLOGY

- Elevated serum levels of cortisol, either from exogenous intake or endogenous production
- Hypothalamus-pituitary-adrenal physiology
  - ACTH (anterior pituitary), stimulates cortisol production in zona fasciculate of adrenal cortex
  - ACTH release governed by CRH (hypothalamus)
  - Cortisol—feedback regulation of CRH/ACTH production
- Cushing syndrome causes:
  - Exogenous intake (most common)
  - Cushing disease (70% of endogenous Cushing)
  - Adrenal adenoma/carcinoma (10% of endogenous Cushing)
  - Ectopic ACTH producer (10%): Neuroendocrine tumor (small-cell lung cancer, thymoma, ovarian tumors)
  - Other: ACTH-independent macronodular adrenal hyperplasia, ectopic CRH production

ASSOCIATED CONDITIONS

- Pituitary tumor
- Steroid administration
- Adrenal adenoma/carcinoma

GENERAL PREVENTION

Diligent management of glucocorticoid administration

DIAGNOSIS

HISTORY

- Progressive weight gain
- Fatigue
- Proximal limb weakness
- Skin abnormalities: Easy bruisability, and striae
- Abnormal menses/decreased libido
- Impotence
- New-onset hypertension/diabetes
- Frequent infections
- Osteopenia/osteoporosis
- Visual disturbances due to pituitary impinging optic nerves

PHYSICAL EXAM

- Obesity/weight gain (80%)
- Thin skin with striae (70%)
- Moon facies (75%)
- Buffalo hump (50%)
- Hypertension (75%)
- Truncal obesity (50%)
- Amenorrhea (60%)
- Loss of visual fields

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC, serum glucose, electrolytes, lipids
  - Hyperglycemia, hypokalemia, neutrophilia, lymphopenia, hyperlipidemia consistent with Cushing
- Initial screen: Late-night salivary cortisol and 24-hr urinary free cortisol. (Note: Establishes hypercortisolemia, not etiology)
  - Elevated late-night salivary cortisol: In Cushing syndrome, diurnal variation of cortisol levels is lost → high levels of cortisol suggest Cushing syndrome
  - 24-hr urinary free cortisol × 3 samples: Sensitivity 90–97%, specificity 85–96%
- Second-line tests: Late-night serum cortisol, low-dose DST
- Determining etiology of hypercortisolemia
  - Plasma ACTH concentration
    - Elevated in Cushing disease/ectopic tumor
    - Decreased in adrenal adenoma/carcinoma, nodular adrenal hyperplasia, steroid use
  - High dose DST

- May distinguish pituitary from ectopic ACTH-secreting tumor (failure to suppress cortisol suggests ectopic tumor)

– Inferior petrosal vein sampling: Higher sensitivity and specificity than high-dose DST

Imaging

- Brain MRI if pituitary lesion suspected
- CT abdomen/pelvis adrenal protocol for ACTH-independent hypercortisolism to evaluate for adrenal adenoma/carcinoma

Diagnostic Procedures/Surgery

Inferior petrosal vein sampling to diagnose and localize pituitary adenoma

Pathologic Findings

- Pituitary adenoma
- Adrenal adenoma/carcinoma
- Micronodular/macronodular adrenal hyperplasia

DIFFERENTIAL DIAGNOSIS

- Alcoholism (pseudo-Cushing)
- Anorexia nervosa
- Bulimia
- Depression
- Hypertension
- Obesity
- Polycystic ovarian syndrome

TREATMENT

GENERAL MEASURES

- Multidisciplinary approach: Endocrinologist, neurosurgeon, adrenal surgeon
- Surgical therapy is the mainstay of treatment

MEDICATION

First Line

- Medical therapy only indicated when surgery not possible

– Ketoconazole: Considered medical treatment of choice; not FDA approved for this indication.
  - Inhibits cytochrome p450
  - 200–400 mg 2 or 3 times a day
  - Side effects: Reversible hepatotoxicity, headache, sedation, nausea, and vomiting.
  - Reduced androgen production may lead to gynecomastia, decreased libido, and impotence in males

– Mitotane: Suppresses cortisol production by inhibiting 11β-hydroxylase
  - Primarily used for adrenocortical carcinoma
  - 0.5 g start, gradually increase to 2–3 g/d

– Metyrapone: Inhibits 11β-hydroxylase
  - 500–750 mg 3 or 4 times a day

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Cushing disease:
  - Trans-sphenoidal resection of pituitary adenoma: Gold standard
    - Cure in 60–80% of patients
  - Bilateral adrenalectomy if disease refractory to pituitary surgery or if life-threatening hypercortisolism
- Ectopic ACTH-secreting tumor: Surgical resection
  - Bilateral adrenalectomy reserved for unresectable disease
- Ipsilateral adrenalectomy for primary cortisol-secreting adrenal masses

ADDITIONAL TREATMENT
Radiation Therapy
Pituitary irradiation effective in 15% of refractory cases—not considered primary therapy

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Prognosis good for adrenal adenoma or Cushing disease, worse for adrenocortical carcinoma
- Prognosis for ectopic ACTH-producing tumors typically poor

COMPLICATIONS
- Bilateral adrenalectomy
  - Adrenal insufficiency
  - Osteoporosis
  - Increased infection risk
  - Nelson syndrome (pituitary adenoma)

FOLLOW-UP
Patient Monitoring
- Postoperative monitoring for adrenal insufficiency
- Pre- and postoperative management is complex and should be coordinated by endocrinologist
- Post operative hydorcortisone replacement with prolonged wean to allow pituitary adrenal axis to recalibrate
- After primary treatment (pituitary surgery), any new-onset symptoms → reevaluation

CODES

ICD9
255.0 Cushing's syndrome

ICD10
- E24.0 Pituitary-dependent Cushing's disease
- E24.8 Other Cushing's syndrome
- E24.9 Cushing's syndrome, unspecified

CLINICAL/SURGICAL PEARLS

- Initial diagnostic studies for suspected Cushing syndrome include late-night salivary cortisol and 24-hr urinary free cortisol.
- Most common cause of endogenous Cushing syndrome is a pituitary adenoma.
- Muscle weakness +/− skin hyperpigmentation after bilateral adrenalectomy may be due to pituitary adenoma (Nelson syndrome).

CYSTITIS, GENERAL CONSIDERATIONS

Kelly A. Healy, MD
Demetrius H. Bagley, MD, FACS

BASICS

DESCRIPTION

- Inflammatory process of the bladder
- Occurs more frequently in women.
- In men, isolated cystitis is rare and often associated with prostatitis that results in secondary bacterial infection of the bladder.
- Clinical syndrome of dysuria, frequency, urgency, and suprapubic pain
- Can be caused by infection (bacterial, viral, fungal, less commonly parasitic), radiation, interstitial cystitis (IC) or due to other irritants (drugs), or a complication of another illness
- Geriatric considerations:
  - Bacterial cystitis increases with advancing age.
- Pediatric considerations:
  - Cystitis in children is rare. Bacterial cystitis in an infant necessitates a urologic workup.
  - Eosinophilic cystitis most common in this age group.
- Pregnancy considerations:
  - Bacterial cystitis in pregnancy requires appropriate antibiotic coverage to prevent complications to the mother or fetus.
  - Screening and treatment of asymptomatic bacteriuria in pregnant women is encouraged to prevent the development of cystitis or more severe UTI and fet al harm.

EPIDEMIOLOGY

Incidence

- 33% of women experience an episode of bacterial cystitis by age 24. 50% of women will have an episode in their lifetime (1).
- Annual incidence of 0.5–0.7 infections per patient-year in this group
- Bacterial cystitis in healthy men is rare:
  - Annual incidence $<0.01\%$ in men aged 21–50 yr.
- Hemorrhagic cystitis occurs in 10–15% of patients after bone marrow transplantation while on immunosuppression. The BK virus is present in 80% of population but is reactivated only with immunosuppression (2).
  - Adenovirus in the urine preceding transplantation is greatest associated factor
- Reported rates of IC from 52/100,000 to 67/100,000

Prevalence

N/A

RISK FACTORS

- Bacterial cystitis:
  - Young women: Sexual activity, use of spermicidal condoms or diaphragm, and genetic factors such as blood type or maternal history of recurrent cystitis

– Healthy, noninstitutionalized older women: Postmenopausal changes in the perineal epithelium and vaginal microflora, incontinence, diabetes, and history of cystitis

Genetics
N/A

PATHOPHYSIOLOGY (3)
- Bacterial cystitis in females is usually an ascending infection.
- In males, it occurs in association with urethral or prostatic obstruction, prostatitis, foreign bodies, or tumors.
- Increases in tumor necrosis factor in bladder mucosa
- Increased mast cell degranulation and histamine release
- Changes in purinergic signaling

ASSOCIATED CONDITIONS
See "Differential Diagnosis."

GENERAL PREVENTION
- Infectious: Minimize bacterial exposure, avoid indwelling Foley catheter if possible; intermittent catheterization if prolonged catheter needed
- Hemorrhagic: Avoid radiation or cyclophosphamide/iphosphamide exposure

DIAGNOSIS

HISTORY
- Characterization of symptoms: Frequency, urgency, dysuria, suprapubic pain, perineal or scrotal pain, dyspareunia
- Exposure to radiation:
  – Obliterative endarteritis causing ischemia
  – May occur several years after exposure.
- Exposure to cyclophosphamide/iphosphamide:
  – Common cause of hemorrhagic cystitis thought to be due to acrolein metabolite dwelling in bladder
- History of UTI; previous treatments
- If patient immunosuppressed:
  – Suspect viral or fungal infection
- Use of personal hygiene products that can cause local irritation (douches, vaginal preparations)
- Indwelling catheters
- History of hematuria
- History of fevers, chills
- Symptoms of vaginitis or discharge present

PHYSICAL EXAM
- Vital signs: Fever, tachycardia (from anemia or sepsis), pallor (anemia due to hemorrhagic cystitis)
- Abdomen: Suprapubic tenderness, costovertebral angle tenderness
- GYN: Bladder or vaginal tenderness, vaginal discharge

- GU, male: Tender and/or boggy prostate, testicular tenderness, penile discharge

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis with microscopy
- Urine culture:
  - Anaerobic, aerobic
    - Midstream standard
    - Catheterize sample if concerns about contamination
  - Fungal and viral cultures only if high suspicion
  - A recent study compared catheterized urine with midstream urine cultures in acute cystitis (4)
    - Cultures of voided midstream urine with acute uncomplicated cystitis accurately showed evidence of bladder *Escherichia coli* but not of enterococci or group B streptococci
    - These bacteria which are often isolated with *E. coli* but appear to rarely cause cystitis by themselves (urethral contaminants)
- CBC: Anemia in hemorrhagic cystitis, leukocytosis in infectious cystitis
- Creatinine
- Urine cytology: If patient with symptoms of cystitis, risk factors for urothelial or other bladder cancer, and negative workup for UTI or overactive bladder
- Urine culture for Mycobacterium in presence of sterile pyuria and suspicion for TB
- Vaginal discharge evaluation if present

Imaging

- CT urogram or US:
  - To rule out associated upper-tract pathology
  - May show thickened bladder wall or filling defect such as blood clots or tumor
- Cystogram:
  - To rule out vesicoureteral reflux if considering intravesical formalin treatment for hemorrhagic cystitis

Diagnostic Procedures/Surgery

- Cystoscopy for hematuria workup or if the diagnosis is not apparent
- Cystoscopy with hydrodistention for the diagnosis of IC
- Bladder biopsy: To rule out carcinoma in situ or for tissue culture

Pathologic Findings

- Evidence of acute or chronic inflammation
- Michaelis–Gutmann bodies in malakoplakia

DIFFERENTIAL DIAGNOSIS

- Anxiety
- Balanitis
- Bladder cancer or other malignancy
- Chronic pelvic pain syndromes
- Cystitis cystica, cystitis glandularis
- Diabetes insipidus, excess fluid intake

- Diabetes mellitus
- Diuretics, excessive caffeine, alcohol
- Eosinophilic cystitis
- Epididymitis
- Extrinsic bladder compression (eg, pelvic tumor, radiation-induced fibrosis)
- Genital herpes
- Hemorrhagic cystitis
- Infectious cystitis: Bacterial, viral, parasitic, fungal
- IC (painful bladder syndrome)
- Neurogenic bladder, chronic urinary retention
- Overactive bladder
- Prostatitis
- Prostatodynia
- Pyelonephritis
- Urethral syndrome
- Urethritis (eg, gonorrhea, chlamydia)
- Urinary calculi
- Vulvovaginitis and/or pelvic inflammatory disease

TREATMENT

GENERAL MEASURES

- Encourage adequate hydration.
- Proper toilet hygiene for females to limit urethral exposure to pathogens
  - Cleansing perineum "from front to back" (controversial)
- Encourage voiding immediately before and after sexual activity in females.

MEDICATION

First Line

- Antimicrobials for bacterial cystitis
  - TMP–SMZ for 3 days is a standard therapy for simple uncomplicated bacterial cystitis in females.
  - Other combinations may include cephalexin, 250–500 mg q6h for 1–3 days; ciprofloxacin, 250–500 mg q12h for 1–3 days; nitrofurantoin (macrocrystals), 100 mg q12h for 7 days; ofloxacin, 200 mg q12h for 1–3 days
- Phenazopyridine (Pyridium) for relief of dysuria:
  - Pregnancy category B
  - Contraindicated in glomerulonephritis, renal insufficiency or failure, severe hepatitis, G6PD deficiency
  - Side effects: Orange urine, renal failure, rash, nausea, headache, vertigo, hemolytic anemia, methemoglobinemia
  - Dose:
    - Adults: 200 mg PO TID
    - Pediatric: 4 mg/kg PO TID

Second Line

Based on culture if initial antibiotic not successful in bacterial cystitis

SURGERY/OTHER PROCEDURES
- Cystoscopy with biopsy to diagnose cystitis cystica or glandularis
- Cystoscopy with hydrodistention to diagnose IC; look for characteristic glomerulations.
- Cystoscopy with clot evacuation and electro or laser fulguration for hemorrhagic cystitis
- Cystectomy for refractory hemorrhagic cystitis is rarely necessary

ADDITIONAL TREATMENT

Radiation Therapy

May induce radiation cystitis

Additional Therapies
- Intravesical installations of alum, silver nitrate for hemorrhagic cystitis
- Hyperbaric oxygen for hemorrhagic cystitis.

Complementary & Alternative Therapies

Cranberry tablets for prevention of recurrent bacterial cystitis; evidence that the benefit for preventing UTI is small, cranberry juice cannot currently be recommended for the prevention of UTIs.

ONGOING CARE

PROGNOSIS

Simple bacterial cystitis prognosis is excellent.

COMPLICATIONS
- Depends on etiology of cystitis
- Untreated simple bacterial cystitis can cause pyelonephritis.
- Hemorrhagic cystitis may recur and/or be refractory to therapy, resulting in multiple transfusions or requiring cystoscopy and fulguration.

FOLLOW-UP

Patient Monitoring
- Urinalysis
- History and physical exam
- Females with >3 episodes of cystitis per year should be considered candidates for prophylaxis:
  - Prior to institution of therapy, exclude anatomic abnormality (eg, stones, reflux, fistula).
  - Single dosing at bedtime or at time of intercourse is recommended.
  - Common oral agents are TMP–SMZ (40 mg/200 mg), nitrofurantoin (100 mg), and cephalexin (250 mg).

CODES

ICD9

• 595.82 Irradiation cystitis
• 595.89 Other specified types of cystitis
• 595.9 Cystitis, unspecified

ICD10

• N30.40 Irradiation cystitis without hematuria
• N30.80 Other cystitis without hematuria
• N30.90 Cystitis, unspecified without hematuria

CLINICAL/SURGICAL PEARLS

- Acute cystitis in females is most commonly bacterial and typically responds to a short course of antibiotic.
- Cystitis in the male is much less common and usually indicates a need for further evaluation.

CYSTITIS, HEMORRHAGIC (INFECTIOUS, NONINFECTIOUS, RADIATION)

Ahmad Shabsigh, MD, FACS

BASICS

DESCRIPTION

- Inflammation leading to damage of the bladder's urethelium and blood vessels, causing hematuria and irritative voiding symptoms.
- Hemorrhagic cystitis (HC) is commonly caused by severe infection, cyclophosphamide, and radiation therapy induced.

EPIDEMIOLOGY

Incidence

- Cyclophosphamide-induced HC: 5–7%
- Radiation-induced HC: 10–15% in patients with history of pelvic radiation.
- 7–70% of hematopoietic stem cell transplants.

RISK FACTORS

- No age, sex, or race predilection.
- Infections.
- Exposure to certain industrial chemicals, such as aniline or toluidine derivatives.
- Previous treatment with oxazaphosphorine alkylating agents (for lymphoproliferative disorders, solid tumors, collagen diseases) such as cyclophosphamide, isophosphamide.
- History of prior pelvic radiation (prostate and cervical cancers).
- Reactivation of BK virus (BKV) infection in bone marrow transplant patients.

Genetics

N/A

PATHOPHYSIOLOGY

- Cyclophosphamide: Acrolein enters the urethelium. Activates platelet-activating factor, nitric oxide, tumor necrosis factor-α, and IL-1, eventually forming peroxynitrite that causes damage.
- Radiation-induced cystitis results from a progressive obliterative endarteritis leading to mucosal ischemia, ulceration, and neovascularity.
- Penicillin toxicity is immune-mediated, whereas danazol toxicity is likely from damaging vascular changes.

ASSOCIATED CONDITIONS

See "Differential Diagnosis."

GENERAL PREVENTION

- Patients treated with cyclophosphamide once had a very high incidence of HC (~70%), with high mortality rates (as high as 75%) if it became severe
- IV hydration, frequent bladder emptying, and sometimes indwelling catheters with bladder

irrigations are used to reduce the time toxins are in contact with the bladder wall (1)[A]

- Mercaptoethane sulfonate Na (MESNA) and N-acetylcysteine (Mucomyst) bind to acrolein, creating nontoxic compounds.
- WF-10 (2)[A], sodium pentosan polysulfate (Elmiron), and amifostine (Ethyol) have been investigated in prevention of radiation-induced cystitis.
- Infectious: Minimize bacterial exposure, avoid indwelling Foley catheter if possible; intermittent catheterization if prolonged catheter needed

DIAGNOSIS

HISTORY

- Gross hematuria (with or without pain)
- Frequency, urgency, dysuria
- Urinary retention from clots
- Occasional mucosal sloughing
- Suprapubic pain
- Fevers with chills
- Previous history of cyclophosphamide therapy, pelvic radiation, bone marrow transplant

PHYSICAL EXAM

- Suprapubic pain/mass: Distended bladder, infected and/or clot-filled bladder
- Signs and symptoms of hypovolemia, hemorrhagic shock, or anemia if severe
- Ocular infections: Common with adenovirus infection
- Large hypertrophied tongue: Amyloidosis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine for analysis, cytology, and cultures (including fungal and viral cultures, if indicated)
- Coagulation factors (especially platelets, which can be depleted)
- Serial hematocrits
- Serum creatinine
- Blood tests for collagen disease markers, if indicated

Imaging

- CT urogram:
  - Often done as part of hematuria workup
  - Rules out other urologic abnormalities
  - Usually not able to diagnose HC, but may show clots in the lumen, a thickened irregular bladder wall, and/or small capacity.

Diagnostic Procedures/Surgery

- Cystoscopy ± biopsy, ± clot evacuation
- Consider electro- or laser fulguration if focal bleeding visualized.

Pathologic Findings

- Urothelial damage: Edema, necrosis, ulceration, hemorrhage, leukocyte infiltration, and neovascularization
- May reveal amyloid deposits; eosinophilic inflammatory response of schistosomiasis; IgG,

IgM, and C3 depositions; penicillin toxicity; whitish pseudomembranes or plaques of fungal infections; inclusion bodies of viral infections

DIFFERENTIAL DIAGNOSIS

- Oxazaphosphorine agents (cyclophosphamide and isophosphamide):
  - Most common cause of severe HC
  - Acrolein, a liver metabolite of the agents, is the toxin believed to be directly implicated.
  - Higher dosages, IV route of administration (vs. oral), and increased contact time between the bladder wall and the acrolein (because of dehydration and/or infrequent emptying) all worsen HC.
- Pelvic radiation:
  - Usually initiated by bladder distension, minor trauma, infection, instrumentation
  - Acute episodes wane within 12–18 mo
  - Can occur as late as 15–20 yr after exposure
- Viral infection:
  - Adenovirus 11 and 35, influenza A, CMV, Polyomavirus hominis 1, the BKV, and JC viruses
  - Typically seen in immunocompromised patients after BMT
  - May present dramatically, but usually resolves spontaneously in <2 wk
- Other infections rarely cause severe HC:
  - Bacterial: *Escherichia coli*, *Staphylococcus saprophyticus*, Proteus, Klebsiella, *Mycobacterium tuberculosis*
  - Fungal: Candida, Aspergillus, Cryptococcus, Torulopsis
  - Parasitic: *Schistosoma haematobium*, *Echinococcus granulosus*
- Systemic hematologic disease: Rare; often refractory to fulguration and irrigation
- Systemic amyloidosis associated with rheumatoid arthritis or Crohn disease
- Chemical toxins:
  - Anilines, toluidines, and chlordimeform are common industrial exposures (dyes, pesticides).
  - Overdoses of methenamine mandelate; accidental urethral instillation of gentian violet douche or nonoxynol-9 contraceptive
  - Thiotepa and acetic acid intravesically
- Medications:
  - Penicillin, piperacillin, methicillin, carbenicillin, danazol, bleomycin, allopurinol, busulfan
- Prolonged high-altitude travel (Boon disease)
- Carcinomas of the urinary tract
- Acute UTIs
- Benign prostatic hypertrophy
- Trauma to the urinary system
- Arteriovenous malformation, vascular fistulae

TREATMENT

GENERAL MEASURES

- Catheterization/bladder irrigation with normal saline to clear bleeding and evacuate clots

- Remove the offending toxin.
- Treat the infectious agent.
- Hydration and diuresis
- Blood products transfusion, when necessary

MEDICATION

First Line

- Alum irrigation often considered 1st line:
  - Astringent, forms precipitates over bleeding surface
  - 1–4% solution at 300–1,000 mL/h
  - No need for anesthesia
  - Adverse effects: Spasms, precipitation and clogged catheters, rare encephalopathy from aluminum toxicity
- ε-Aminocaproic acid (Amicar):
  - Inhibits clot lysis by urinary urokinase
  - Can be given orally or parenterally
  - Contraindicated in upper-tract bleeding, as dense clots can lead to ureteral obstruction
- Silver nitrate instillation:
  - 0.5–1% solution in bladder for 10–20 min, followed by saline flush
  - Causes a chemical cauterization
  - Painful, requires anesthesia
  - Adverse effect: Build-up can clog catheters
  - Duration of response is often short
- Prostaglandin instillation:
  - Carboprost tromethamine (synthetic PGF2) 0.1–0.8 mg/dL solution. Dwell for 1–4 hr, 4 times a day for 5–7 days
  - Stabilizes membranes, decreasing edema; causes vasoconstriction and platelet aggregation
  - Low morbidity: No anesthesia required, no precipitate forms, so no clogging of catheters
  - Adverse effects: Cost, requires intensive nursing care, moderate bladder spasms
- Phenol instillation:
  - 30 mL 100% phenol in 30 mL of glycine for 1 min, then ethanol and saline washes
  - Destroys urothelium, not muscularis; less bladder fibrosis than with formalin
  - Painful, requires anesthesia
  - Duration of response is often short
- Low-dose cidofovir (3)
  - 5 mg/kg in 60 mL of 0.9% NaCl intravesical over 15 min.

Second Line

- Hyaluronic acid:
  - Constitutes a protective barrier.
  - Intravesical treatment of 40 mg every week for 4–6 wk. If responds add monthly treatments
- Formalin instillation:
  - 1–4% solution of $\leq$50 mL for 5–30 min, with patient in reverse Trendelenburg to minimize vesicoureteral reflux.
  - Check cystogram before instillation to rule out reflux or extravasation; may need to

occlude ureter with balloon to prevent potentially fatal renal absorption.
  – Hydrolyzes proteins, coagulating mucosa and submucosa; 80% effective
  – Very painful, requires anesthesia.
  – Adverse effects: Reflux could cause ureteral fibrosis and obstruction or papillary necrosis; extravasation causes peritonitis and/or fistulas.
- Pentosan polysulfate 100 mg TID

SURGERY/OTHER PROCEDURES
- Repeated cystoscopic laser ablation or cauterization
- Consider the following after all conservative modalities have failed, and patient is unstable.
  – Bilateral percutaneous nephrostomy tubes with occlusive balloons decrease the exposure of new clots to urokinase, allowing bladder to self-tamponade. Would consider this option prior to formalin instillation.
  – Supravesical urinary diversion, cutaneous ureterostomy, ureterosigmoidostomy, cystectomy in severe retractable cases.

ADDITIONAL TREATMENT

Radiation Therapy

Contraindicated; a recognized cause of HC

Additional Therapies
- Hyperbaric oxygen (4):
  – Promotes granulation tissue and neovascularization, causes vasoconstriction.
  – Better for radiation-induced cystitis.
  – Requires a hyperbaric chamber, which may not always be readily available.
  – May require 30–60 daily treatments.
  – High rate of recurrence.
- Selective hypogastric artery embolization:
  – Under local anesthesia on risky patients.
  – Complications: Gluteal claudication, bladder necrosis, lower limb paralysis, or impotence.
  – Low success, as most bleeding is venous.

Complementary & Alternative Therapies

Supportive care. Blood products, platelets, reverse anticoagulation.

ONGOING CARE

PROGNOSIS
- Related to the successful treatment of etiology of HC.
- Long term increases risk of secondary urothelial malignancy.

COMPLICATIONS
- Anemia, renal failure.
- Bladder fibrosis with small, noncompliant bladder; may need surgical reconstruction.
- Bladder perforation.
- Increased risk for transitional cell carcinoma from radiation, cyclophosphamide, and similar agents; may be years later
- Secondary UTIs from prolonged catheterization.

• Vesicoureteral reflux resulting from bladder fibrosis.

FOLLOW-UP

Patient Monitoring

• Repeated hematocrit, platelets, renal function, urine culture, and sensitivities.
• Maintain sterile urine.
• Continue hydration for many days after bleeding ceases as rebleeding is common.
• Evaluate long-term sequelae after acute episode.
• May need repeat cystoscopy

CODES

ICD9

• 595.4 Cystitis in diseases classified elsewhere
• 595.82 Irradiation cystitis
• 595.89 Other specified types of cystitis

ICD10

- N30.40 Irradiation cystitis without hematuria
- N30.90 Cystitis, unspecified without hematuria
- N30.91 Cystitis, unspecified with hematuria

CLINICAL/SURGICAL PEARLS

Optimum treatment for chemotherapy-induced HC is prevention (aggressive hydration and/or prophylactic mesna therapy).

CYSTOCELE

Alana M. Murphy, MD

BASICS

DESCRIPTION

- Cystocele is prolapse of the bladder into the vagina
- Also referred to as anterior compartment prolapse

EPIDEMIOLOGY

Incidence

11% lifetime risk of surgery for pelvic organ prolapse (POP) or urinary incontinence (UI) (1)

Prevalence

- Difficult to determine due to several factors:
  - Data mostly reported in the context of surgical treatment
  - Cystocele may be asymptomatic
  - Diagnosis requires a vaginal exam
- POP quantification (POP-Q) distribution in an observational study of women 18–82 yr old seeking routine gynecologic care (2):
  - POP-Q stage 0: 6.4%
  - POP-Q stage 1: 43.3%
  - POP-Q stage 2: 47.7%
  - POP-Q stage 3: 2.6%

RISK FACTORS

- Increasing age
- Parity
- Vaginal delivery (nerve, muscle, and connective tissue damage)
  - Instrumented vaginal delivery may be associated with a higher risk of POP compared to spontaneous vaginal delivery
- Race (3)
  - Hispanic women have highest prevalence of POP
- Increased intra-abdominal pressure (obesity, chronic cough, constipation)
- Pelvic surgery (hysterectomy, radical cystectomy)
- Congenital connective tissue disorders (Ehlers–Danlos syndrome)

Genetics

- Connective tissue disorders, bladder exstrophy
- POP prevalence rates differ according to race suggesting a genetic component (3)

PATHOPHYSIOLOGY

- Weakening of supporting and suspending structures: Cardinal ligaments, uterosacral ligaments, endopelvic fascia, pubocervical fascia, levator ani muscles
- Defect location:
  - Central: Attenuation of the pubocervical fascia in the midline

- Lateral: Disruption of lateral attachments of the endopelvic fascia to the arcus tendineus fascia pelvis (ATFP)
- Combined defects

ASSOCIATED CONDITIONS

- Multicompartment POP
  - Always suspect concomitant apical prolapse in the setting of stage ≥3 cystocele
- Storage symptoms/signs: Stress UI, urinary urgency, urgency urinary incontinence (UI)
- Voiding symptoms/signs: Weak urinary stream, urinary hesitancy, elevated postvoid residual (PVR) urine, bladder outlet obstruction, urinary retention

GENERAL PREVENTION

- Reduction of modifiable risk factors
- Additional studies examining the role of prophylactic vaginal support at the time of pelvic surgery (eg, hysterectomy) are needed

DIAGNOSIS

HISTORY

- Symptoms/signs: Pelvic pressure, vaginal pressure, sensation of a vaginal bulge, stress/urgency/ overflow UI, obstructive voiding symptoms, recurrent urinary tract infections (UTIs)
- Previous pelvic/vaginal surgical procedures
- Hormonal status
- Obstetric history
- Comorbidities

PHYSICAL EXAM

- Assessment of POP should be performed during a Valsalva maneuver
- Leading edge of POP should be used for staging purposes
- Examining a patient in a standing position may help determine the maximum extent of POP
- Assessment of the anterior compartment should be performed with support of the apical and posterior compartment to ensure the elimination of potentially distracting apical and posterior POP
- Baden-Walker grading system:
  - Grade 0: No POP
  - Grade 1: Leading edge descends halfway to the hymen
  - Grade 2: Leading edge descends to the hymen
  - Grade 3: Leading edge descends halfway past the hymen
  - Grade 4: Procidentia or vault eversion
- POP-Q staging system:
  - POP described using 9 reference measurements, including 2 measurements specific to the anterior vaginal wall
    - Aa: Distal anterior vaginal wall
    - Ba: Proximal anterior vaginal wall
  - Stage 0: No POP
  - Stage 1: Leading edge is >1 cm above the hymen

– Stage 2: Leading edge is between 1 cm above and 1 cm below the hymen (-1, 0, +1)
– Stage 3: Leading edge is >1 cm below the hymen but less than total vaginal length – 2 cm (TVL – 2 cm)
– Stage 4: Leading edge is below hymen by more than TVL – 2 cm

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- No lab testing is required for the diagnosis of a cystocele
- Urinalysis and urine culture as indicated

Imaging

- No imaging is required for the diagnosis or management of a cystocele
- A cystocele may inadvertently be detected on imaging studies, such as a cystogram
- Dynamic magnetic resonance imaging (MRI) with contrast:
  – Examines pelvic structures in relation to one another during a Valsalva maneuver
  – Aids in differentiation between a cystocele and an enterocele
  – Aids in assessment of multicompartment POP

Diagnostic Procedures/Surgery

- Pelvic exam
  – Employ standardized staging system (POP-Q or Baden-Walker)
- PVR assessment
- Urodynamics
  – Only indicated to characterize associated storage and voiding symptoms/signs

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Cystocele
- Enterocele
- Anterior vaginal wall masses: Urethral diverticulum, Skene gland cyst, epidermal inclusion cyst, leiomyoma, ectopic ureterocele, Bartholin duct cyst, Gartner duct cyst

TREATMENT

GENERAL MEASURES

- Observation
- Pelvic floor exercises (Kegel exercises) (4)[B]
- Vaginal pessary
- Surgical repair

MEDICATION

First Line

There are no data to support systemic or topical estrogen or other medications as a therapy for the treatment of cystocele.

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Preoperative preparation:
  - Optional hormone replacement with topical estrogen
- Perioperative factors:
  - Single dose of preoperative antibiotics
  - DVT prophylaxis with sequential compression devices
  - Optional vaginal packing
  - Optional temporary urethral catheterization
    - Consider in the setting of a multicompartment repair with or without an anti-incontinence procedure
- Transvaginal vs. transabdominal repair:
  - Transvaginal repair:
    - Central defect repair: Plication of pubocervical fascia in the midline with horizontal mattress sutures
    - Lateral defect repair: Reattachment of the endopelvic fascia to the ATFP
    - Transvaginal mesh grafts provide a superior anatomic outcome but are associated with higher complication rates (5)[A]
  - Transabdominal repair:
    - Only repair lateral defects
- Closure of the vagina (colpocleisis):
  - Excellent option for geriatric women who no longer desire the ability to maintain sexual activity
- Perform a simultaneous repair of all POP defects and an anti-incontinence procedure for demonstrable stress UI
- Consider a prophylactic concomitant anti-incontinence procedure in patients with stage ≥ 3 cystocele and/or history of stress UI

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Observation:
  - Appropriate if a patient is not symptomatic
- Pelvic floor exercises (Kegel exercises) (4)[B]
- Vaginal pessary:
  - Good option for poor surgical candidates
  - May be used as a temporary solution
  - Risk of vaginal discharge, vaginal ulceration, vesicovaginal and rectovaginal fistula formation

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Recurrence rates as high as 30–70%
- Close to 30% of women will require reoperation for symptomatic POP (1)

COMPLICATIONS

- Bladder injury
- Ureteral injury/obstruction
- Bleeding
- Dyspareunia
- *de novo* stress UI
- Recurrent cystocele

FOLLOW-UP

Patient Monitoring

Evaluation for recurrent POP should largely be based on symptoms or clinical signs (elevated PVR, urinary retention, recurrent UTIs)

CODES

ICD9

- 618.01 Cystocele, midline
- 618.02 Cystocele, lateral

ICD10

- N81.10 Cystocele, unspecified
- N81.11 Cystocele, midline
- N81.12 Cystocele, lateral

CLINICAL/SURGICAL PEARLS

- Management of a cystocele should largely be based on patient preference and symptoms.
- Always suspect concomitant apical prolapse in the setting of stage ≥ 3 cystocele or a recurrent cystocele.
- Mesh grafts for cystocele repair provide a superior anatomic outcome but they are associated with higher complication rates.

DEEP VENOUS THROMBOSIS AND PULMONARY EMBOLUS, UROLOGIC CONSIDERATIONS

Joshua D. Roth, MD
Michael O. Koch, MD, FACS

BASICS

DESCRIPTION

- Deep vein thrombosis (DVT): Aggregation of platelets and fibrin within a deep vein of the leg or pelvis that may lead to venous obstruction.
- Pulmonary embolism (PE): Blockage of the pulmonary artery or one of its branches by a thrombus that has traveled from elsewhere in the body through the bloodstream. Can be an acute life-threatening illness.
- Venous thromboembolism (VTE or DVT/PE) is the disease process by which a DVT can embolize and become a life-threatening PE.

EPIDEMIOLOGY

Incidence

- DVT
  - 160/100,000/yr (1)
  - Increases with age: 1/100 if age ≥80
- PE (1)
  - 70/100,000/yr, with a 1-wk survival rate of 71%; 25% present with sudden death
  - PE is believed to be the most common cause of postoperative death in the urologic population
- VTE risk in urologic populations (2)
  - Radical cystectomy: 3.7%
  - Percutaneous nephrostomy in patients with/without malignancy: 3.6%/0.8%
  - Nephrectomy with/without malignancy: 2.0%/0.4%
  - Radical prostatectomy: 1.5%
  - Transurethral resection of bladder tumors/prostate: <0.5%
  - Incontinence repair: 0.3%

Prevalence

Prevalence of genetic mutations causing inherited thrombophilia: <1–5%, which cause a 3–10× increase risk of VTE in heterozygous state (3)

RISK FACTORS

- Patient-specific risk factors (1)
  - Surgery
  - Trauma (major or lower extremity)
  - Immobility, paresis
  - Malignancy
  - Cancer therapy (hormonal, chemotherapy, or radiotherapy)

- Previous VTE
- Increasing age (≥60)
- Pregnancy and the postpartum period
- Estrogen-containing oral contraception
- Selective estrogen receptor modulators
- Acute medical illness
- Heart or respiratory failure
- Inflammatory bowel disease
- Nephrotic syndrome
- Myeloproliferative disorders
- Paroxysmal nocturnal hemoglobinuria
- Obesity
- Smoking
- Varicose veins
- Central venous catheterization
- Inherited or acquired thrombophilia

Genetics

- Inherited risk factors for DVT/PE (3)
  - Family history
  - Factor V Leiden mutation
  - Prothrombin G20210A
  - Protein C deficiency
  - Protein S deficiency
  - Antithrombin deficiency
  - Sickle cell trait

PATHOPHYSIOLOGY

- Most PEs arise from DVTs
- DVTs arise from initiating factors of Virchow's triad:
  - Hypercoagulability: Regional activation of coagulation cascade leading to obstruction, edema, pain
  - Stasis: Stagnant hypoxemia causes endothelial injury
  - Injury: Platelet accumulation and fibrin deposition
- Need to differentiate from superficial thrombophlebitis/thrombosis that does not usually lead to DVT/PE

ASSOCIATED CONDITIONS

Paradoxical embolism: Systemic embolisms of venous origin that occur in patients with atrial or ventricular septal defects, which allow the embolus to pass into the arterial circulation

GENERAL PREVENTION

- DVT prophylaxis (ppx)
  - Mechanical (nonpharmacologic) therapies
    - Early postoperative ambulation
    - Graduated compression stockings (GCSs)
    - Intermittent pneumatic compression (IPC)

- Pharmacologic therapies
  - Subcutaneous low-dose unfractionated heparin (LDUH)
  - Subcutaneous low–molecular-weight heparin (LMWH)
- Recommendations (4)
  - Very low–risk surgery (VTE risk <0.5%)
    - No specific pharmacologic (B) or mechanical (C) ppx
  - Low-risk surgery (VTE risk ~1.5%)
    - Mechanical ppx, preferably with IPC (C)
  - Moderate-risk surgery (VTE risk ~3.0%) who are not at high risk for bleeding complications
    - LMHW/LDUH (B), or mechanical ppx, preferably with IPC (C)
  - Moderate-risk surgery (VTE risk ~3.0%) who are at high risk for bleeding complications
    - Mechanical ppx, preferably with IPC (C)
  - High-risk surgery who are not at high risk for bleeding complications
    - LMHW/LDUH (B) and mechanical ppx, with IPC or GCS (C)
  - High-risk patient undergoing cancer surgery who are not at high risk for bleeding complications
    - 4 wk of LMWH (B)
  - High-risk patient who are at high risk for bleeding complications
    - Mechanical ppx, preferably with IPC until the risk of bleeding diminishes
  - High-risk patients with contraindications to LMWH/LDUH who are not at high risk for bleeding complications
    - Low-dose aspirin (C), fondaparinux (C), or mechanical ppx, preferably with IPC (C)
  - Inferior vena cava (IVC) filters should not be used for primary VTE prevention
  - No need for periodic ultrasound surveillance

DIAGNOSIS

HISTORY

- Recent high-risk surgery, or other risk factors for VTE
  - DVT
    - History of prolonged immobilization, postoperative stasis, especially in patient with risk factors
    - Complaint of calf pain, swelling, or discoloration
  - PE
    - High clinical suspicion with above history
    - Acute onset of dyspnea, tachycardia, arrhythmia, hypotension

PHYSICAL EXAM

- DVT: Determined by level of obstruction
  - Inspection: Unilateral edema, discoloration below level of occlusion, dilated superficial veins
  - Palpation: Tender cord or knot, Homans' sign (limitation of passive dorsiflexion of foot, 55% unreliable)
- PE
  - Inspection: Cyanotic, dyspneic, prominent jugular veins, hemoptysis, tachypnea

– Palpation: Tachycardia, arrhythmia
– Auscultation: Pleural rub, rales, S3–S4 heart sounds

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- DVT
  – D-dimers: Sensitivity approaches 95% for ELISA method
- PE
  – ABG: Increased $P(A\text{-}a)O_2$ gradient
  – $PaO_2 < 80$ mm Hg

Imaging

- DVT
  – Central venography (gold standard): Invasive, expensive, not always available, contrast risks
  – Doppler ultrasound (US)/sonography: 90% accurate above knee, versatile, noninvasive, painless
  – Venous duplex ultrasound
    ○ Grayscale US to visualize the structure of the veins and color Doppler US to visualize the flow of blood through the vein; more accurate than Doppler and plethysmography
- PE
  – Chest x-ray (CXR)
    ○ Generally unremarkable, but can sometimes see a small, unilateral effusion
    ○ Westermark sign: Asymmetric vascular markings with segmental or lobar ischemia
  – Ventilation/perfusion scan (V/Q scan)
    ○ A perfusion defect in ≥ 1 pulmonary segment or all unmatched with ventilation defects support a high probability of PE
    ○ Negative result is very predictive
  – Computed tomography (CT)
    ○ Most common test used to diagnose PE

Diagnostic Procedures/Surgery

- Pulmonary Angiography
  – Injection of contrast into the pulmonary circulation, fluoroscopy of the lungs
  – Gold standard for diagnosing PE; rarely done

Pathologic Findings

Thrombi are a woven congealed mass of fibrin and platelets

DIFFERENTIAL DIAGNOSIS

- DVT: Cellulitis, thrombophlebitis, muscle sprain/strain, claudication, lymphedema
- PE: Pneumonitis/pneumonia, pneumothorax, CHF, esophageal perforation, myocardial infarction

TREATMENT

ALERT

DVT and PE are potentially life-threatening and acute decline in status can occur. This condition must be treated/diagnosed quickly and level of suspicion must always be high in postoperative patients.

GENERAL MEASURES

- DVT: Extremity elevation, early ambulation, pain relief
- PE: Oxygen therapy, fluid resuscitation, maintain cardiac output with pressors if needed
- Overall management of anticoagulation and antiplatelet therapy can be found in Section VII: Reference Tables: Anticoagulation and Antiplatelet Therapy in Urologic Practice

MEDICATION

First Line

- DVT proximal to knee anticoagulation with (4):
  - LMWH
  - Fondaparinux
  - Above favored over IV unfractionated heparin (UH) drip (B)
  - Early initiation of oral warfarin, with continued parenteral anticoagulation until INR is reached for >24 hr.
- DVT Distal to knee
  - Without severe symptoms/risk factors: Serial noninvasive imaging for 2 wk over anticoagulation (C). If thrombus extends, recommend therapeutic anticoagulation (B/C).
  - With severe symptoms/risk factors: Anticoagulation (as above) over imaging (C).
- PE (4)
  - Systemic anticoagulation as for DVT (B/C)
  - PEs with hypotension: Systemic thrombolysis with streptokinase is recommended (C).

Second Line

- DVT/PE
  - In patients with heparin-induced thrombocytopenia (HIT), LMW heparin (argatroban, lepirudin, and danaparoid) can be used

SURGERY/OTHER PROCEDURES

- DVT
  - Venous thrombectomy: Rarely needed
  - IVC filter:
    - Used as prophylaxis in high-risk or multitrauma patients
    - Recommended for acute DVT with contradic-tion to anticoagulation (4)[B]
- PE
  - Pulmonary embolectomy: Considered rarely for patient who remains in shock despite medical therapy

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Will need 3 mo of anticoagulation therapy for postsurgical DVT/PE (4)[B]

- Protamine can reverse unfractionated heparin if needed. Protamine is not as effective with LMWH but should be used if excessive bleeding is encountered

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- 10–30% of all patients with VTE suffer mortality within 30 days (3)
- Following anticoagulation therapy, 1/3 of all VTE patients will experience a recurrence within 10 yr (3)
  – Highest risk of recurrence is in the 1st year (3)
- 1/3–1/2 of those with LE DVTs develop postthrombotic syndrome (3)

COMPLICATIONS

- DVT: Pulmonary embolus; postthrombotic syndrome: Destruction of valves leads to chronic pain, swelling, skin necrosis, ulceration
- PE: Death, pulmonary infarction, pain, arrhythmia, shortness of breath
- VTE: Requires anticoagulation with its associated risk factors (increased bleeding risk), increased healthcare costs, prolonged hospitalization, rehospitalizations
- Heparin-induced thrombocytopenia with unfractionated heparin

FOLLOW-UP

Patient Monitoring

- Patients on heparin: Follow aPTT
- If necessary LMWH therapy can be followed by antifactor Xa assays
- Patients on warfarin need close monitoring of their INR for a goal between 2.0 and 3.0 (3) [B]

Patient Resources

- The Coalition to Prevent Deep-Vein Thrombosis http://www.preventdvt.org
- The National Blood Clot Alliance http://www.stoptheclot.org

CODES

ICD9

- 415.11 Iatrogenic pulmonary embolism and infarction
- 453.40 Acute venous embolism and thrombosis of unspecified deep vessels of lower extremity
- 997.2 Peripheral vascular complications, not elsewhere classified

ICD10

- I26.99 Other pulmonary embolism without acute cor pulmonale
- I82.409 Acute embolism and thrombosis of unspecified deep veins of unspecified lower extremity
- T81.72XA Complication of vein following a procedure, NEC, init

CLINICAL/SURGICAL PEARLS

- Prophylaxis can help prevent DVT/PE.
- PE usually develops from a venous thrombus involving the proximal lower extremity.
- DVT/PE are potentially life threatening—have a high index of suspicion.
- Early diagnosis and treatment are key.

DETRUSOR OVERACTIVITY

Lysanne Campeau, MD, CM, PhD, FRCSC
Victor W. Nitti, MD, FACS

BASICS

DESCRIPTION

- Detrusor overactivity (DO) is occurrence of involuntary detrusor contractions during filling cystometry
  - Spontaneous or provoked
  - Contractions produce a wave form on cystometrogram of variable duration and amplitude
  - Phasic or terminal
  - Can be associated with symptoms
  - Neurogenic DO: DO with evidence of a relevant neurologic disorder
  - Idiopathic DO: DO without a neurologic cause

EPIDEMIOLOGY (1,2)

- DO is a common cause of symptoms of overactive bladder (OAB) syndrome, however since it is defined by urodynamics, it may not be documented if urodynamics are not preformed
- Symptoms associated with DO (urgency, frequency, and urgency incontinence) are more commonly treated rather than DO per se
- OAB is a symptom complex and is diagnosed without urodynamics and therefore may be diagnosed in the presence or absence of DO
- Approximately one-third of patients with OAB have incontinence
  - OAB is defined as urinary urgency, usually accompanied by frequency and nocturia, with or without incontinence, in the absence of urinary tract infection (UTI) or other obvious pathology
  - Urinary incontinence accounts for 2% of healthcare cost in the United States

Prevalence

- OAB present in 17% of women and 16% of men
  - Increases with age
- DO present in 33% of women with OAB
- DO is present in 36% of patients with no OAB symptoms

RISK FACTORS

- Neurogenic and idiopathic DO
  - Most neurologic disorders are risk factors for DO (ie, stroke, neurodegenerative disorders, multiple sclerosis)
  - Pelvic surgeries, metabolic syndrome, diabetes, pelvic floor disorders, bladder outlet obstruction

PATHOPHYSIOLOGY

- Increased connectivity and excitability between detrusor muscle and nerves
- Inflammation

- Increased afferent activity
- Neurologic lesions of the CNS above the sacral micturition center

ASSOCIATED CONDITIONS

OAB, pelvic floor disorders, urinary incontinence, bladder outlet obstruction, neurologic lesions above the sacral micturition center, detrusor external sphincter dyssynergia

GENERAL PREVENTION

- Avoiding large fluid intake or the consumption of "bladder irritants" such as caffeine.
- Timed voiding and avoiding bladder overdistension

DIAGNOSIS

ALERT

DO, by definition can only be diagnosed by urodynamics. Therefore it is more practical to talk in terms of diagnosing OAB.

HISTORY (3)

- Past medical and surgical history
- Medications (diuretics, psychoactive drugs)
- Lower urinary tract symptoms survey
- Women with DO and OAB:
  - Are twice as likely to have urge urinary incontinence.
  - Have a higher symptom score on questionnaires
  - Higher episodes of daytime voiding and nocturia
  - Have lower functional bladder capacities

PHYSICAL EXAM

- Rule out the presence of exacerbating conditions
  - Pelvic and vaginal exam
  - Neurologic exam: Peripheral sensation and motor assessment
  - Postvoid residual

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis: Determine presence of infection, hematuria, glycosuria
- Urine culture: Rule out infection
- Urine cytology: Rule out malignancy

Diagnostic Procedures/Surgery

- Urodynamic testing
  - Filling cystometry: Measurement of the pressure/volume relationship of the bladder during filling

Imaging

- Can involve videourodynamics with cystogram and voiding cystourethrogram
  - Renal ultrasound can also rule out the presence of hydronephrosis caused by high bladder pressures

Pathologic Findings
DO is characterized by the presence of contractions that produce a wave form on cystometrogram of variable duration and amplitude

DIFFERENTIAL DIAGNOSIS
- Bladder calculi
- Bladder cancer/carcinoma in situ
- Bladder outlet obstruction/Prostatic hypertrophy
- Congestive heart failure
- Detrusor external sphincter dyssynergia
- Diabetes
- Interstitial cystitis/Painful bladder syndrome
- Pelvic pain syndrome
- Medications
- Neurogenic bladder
- Pelvic organ prolapse
- Polyuria/polydipsia
- Sexually transmitted infection
- Stress incontinence
- Testing artifact during UDS evaluation (false positive)
- Urethral diverticulum
- UTI

TREATMENT

GENERAL MEASURES
- Treatment aimed at inhibiting involuntary detrusor contractions and decreasing intravesical pressures
- There are a number of options used to treat symptoms associated with DO. Only antimuscarinics, botulinum toxin, and augmentation cystoplasy have been proven to actually reduce or eliminate DO
- Behavioral modifications: Timed voiding, decrease fluid intake, avoid caffeine
  – Pelvic floor exercises (Kegel): With or without biofeedback

MEDICATION
- Antimuscarinics: Inhibit the effect of acetylcholine at postjunctional muscarinic receptors on detrusor muscle cells
  – Tolterodine (2–4 mg/d)
  – Trospium XR (60 mg/d)
  – Darifenacin (7.5–15 mg/d)
  – Solifenacin (5–10 mg/d)
  – Oxybutynin (IR 7.5–20 mg/d, XL 5–30 mg/d, patch twice weekly),
  – Fesoterodine (4–8 mg/d)
- β3-adrenergic receptor agonist: Promotes detrusor muscle relaxation

SURGERY/OTHER PROCEDURES

- Intravesical botulinum toxin (OnabotulinumtoxinA) injection:
  - Approved for treatment of neurogenic detrusor overactivity and OAB
- Sacral neuromodulation: Stimulation of S3 nerve root (InterStim)
- Posterior tibial nerve stimulation (PTNS): Urgent PC™
- Augmentation cystoplatsy/Urinary diversion: Increase functional bladder capacity and reduce intravesical pressure
- Pelvic floor reconstruction: If concomitant pelvic floor disorder

Additional Therapies
- Infection prophylaxis
- Clean intermittent catheterization
  - Decrease bladder pressure if urinary retention present

ONGOING CARE

PROGNOSIS
- Stepwise approach to treatment with least invasive pharmacologic options as first line
  - Patient may develop refractory OAB that may require second- or third-line treatment

COMPLICATIONS
- Urinary incontinence: Social and hygienic issues
- UTIs
- Renal deterioration
  - High economic burden

FOLLOW-UP
Patient Monitoring
- Periodic patient follow-up
  - Symptom assessment
  - Treatment compliance
  - Minimize medication side effects
  - Repeat urodynamic evaluation

Patient Resources
- National Association For Continence: www.nafc.org/bladder-health
- National Kidney and Urologic Diseases Information Clearing House: http://kidney.niddk.nih.gov/kudiseases/pubs/urodynamic/

- Incontinence, Urinary, Adult Male
- Overactive Bladder (OAB)
- Urgency, Urinary (Frequency and Urgency)
- Sacral Neuromodulation

CODES

ICD9

- 596.51 Hypertonicity of bladder
- 788.41 Urinary frequency
- 788.63 Urgency of urination

ICD10

- N32.81 Overactive bladder
- R35.0 Frequency of micturition
- R39.15 Urgency of urination

CLINICAL/SURGICAL PEARLS

- OAB is not synonymous with detrusor overactivity; the key symptom of OAB is urinary urgency.
- DO demonstrated on cystometry needs to be correlated with patient's symptoms.
- Treatment indicated if potential complications or patient driven.
- Only antimuscarinics, botulinum toxin, and augmentation cystoplasy have been proven to actually reduce or eliminate DO.

DETRUSOR SPHINCTER DYSSYNERGIA (DSD)

Michael J. Amirian, MD
Patrick J. Shenot, MD, FACS

BASICS

DESCRIPTION

- Detrusor sphincter dyssynergia (DSD) is found in cases of neurogenic lower urinary tract dysfunction
- DSD is contraction of the sphincter mechanism occurring simultaneously with uninhibited involuntary contraction of the bladder detrusor muscle (neurogenic detrusor overactivity [NDO])

EPIDEMIOLOGY

Incidence

- Unknown
  - Depends on incidence of underlying neurologic condition

Prevalence

- Prevalent in those with spinal cord lesions
  - More prevalent at higher levels (cervical) than lower (sacral) injury or disease
- May affect those with multiple sclerosis (MS), spinal cord tumor, traumatic spinal cord injury (SCI), arteriovenous malformation
- Uninhibited involuntary detrusor contraction (ie, NDO) must be present for DSD to occur

RISK FACTORS

- Neurologic processes affecting central nervous system (CNS)
  - Below level of the pons
- Associated with autonomic hyperreflexia

Genetics

None

PATHOPHYSIOLOGY

- DSD causes functional outflow obstruction
  - Dramatic elevation of intravesical pressure
    - Damages urinary tract directly with pressure and poor upper tract drainage
    - Secondarily with infection and urolithiasis
- DSD always associated with NDO
  - NDO may occur with synergic sphincter function (without DSD)
- Pontine mesencephalic reticular formation
  - Coordinates sphincter relaxation with detrusor contraction
    - Spinal cord lesions impair transmission of coordinating influences from the pons during reflex detrusor contraction
    - Uninhibited detrusor contraction stimulates a reflex sphincter contraction, resulting in bladder outflow obstruction

- 10–20% patients have internal (bladder neck) sphincter dyssynergia coexistent with external sphincter dyssynergia

ASSOCIATED CONDITIONS
- SCI
- MS
- Transverse myelitis

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Neurologic disease
  - Date of onset, duration of process
- Urinary voiding symptoms
  - Frequency, urgency, urge incontinence
- Method of urinary management
  - Condom catheter urinary collection
  - Intermittent self-catheterization
  - Indwelling urethral or suprapubic catheter
- Urinary tract infection (UTI)
  - Severity of infection
    - Response to antibiotics
    - Need for parenteral antibiotics
  - Frequency of occurrence of infection
  - Urolithiasis
    - Episodes of lithiasis
    - Surgical intervention

PHYSICAL EXAM
- Fever
- Parenchymal UTI
  - Men
    - Prostate, testes/epididymis, renal
  - Female
    - Renal
- Hypertension
  - During manipulation of GI/GU systems, autonomic hyperreflexia may result
- Generalized edema
  - Severe renal insufficiency
- Palpable flank mass
  - Secondary hydronephrosis
- Flank tenderness
  - Ureteral obstruction
  - Pyelonephritis

- Abdominal mass
  - Distended bladder, urinary retention
- Incontinence of urine
  - Spontaneously
  - With stress maneuvers
  - During abdominal/pelvic palpation
- Testicular mass
  - Epididymo-orchitis/epididymitis
  - Secondary abscess formation
  - Hydrocele from recurrent infection
- Prostate mass/nodule
  - Focal prostatitis
  - Prostate abscess

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Blood studies
  - Serum chemistry
    - Renal function, electrolyte levels
  - Complete blood count
    - Secondary anemia due to decreased renal function or chronic infection
- Urine studies
  - Urinalysis
    - Proteinuria: Renal dysfunction
    - Pyuria, nitrite, leukocyte esterase: Acute or chronic infection
    - Hematuria: Infection or lithiasis

Imaging

- Renal ultrasound (US)
  - Effective in screening for upper urinary tracts
    - Calculus
    - Hydronephrosis
    - Masses
- Excretory urography (ExU)
  - Contraindicated in those with decreased renal function (serum creatinine >2.0)
  - Delayed excretion of contract with high urinary storage pressures
  - Hydroureteronephrosis
    - Marked elevation of intravesical pressure
    - May be due to urinary calculi
- Voiding cystourethrogram
  - Bladder
    - Wall thickening
    - Trabeculation
    - Diverticulum formation
    - Incomplete emptying
  - Ureter

    - Vesicoureteral reflux
    - Hydroureter
    - Hydroureteronephrosis
  - Urethra
    - Prostatic urethral dilated
    - Membranous urethra persistently narrow, stenotic, nonrelaxing
    - Distal urethra normal; rule out stricture
- Nuclear medicine renal scan
  - Objective quantification of GFR
  - Sequential studies can detect deterioration of renal function prior to elevation of serum creatinine

Diagnostic Procedures/Surgery
- Urodynamic evaluation
  - Essential to diagnose detrusor overactivity with detrusor sphincter dyssynergy
- Cystoscopy
  - Normal penile urethral
  - Spastic, nonrelaxing, stenotic membranous urethral
  - Dilated prostatic urethra
  - Bladder trabeculation/diverticula
  - Rule out calculus or bladder tumor

Pathologic Findings
None

DIFFERENTIAL DIAGNOSIS
- Detrusor overactivity and bladder outflow obstruction
  - Benign prostatic hyperplasia
  - Adenocarcinoma of the prostate
  - Urethral stricture disease
  - Urethral tumor
- Urinary retention/incomplete emptying and neurologic disease
  - Impaired detrusor contractility
  - Detrusor areflexia

TREATMENT

GENERAL MEASURES
- Intermittent catheterization
- Decrease intravesical pressure
  - Decrease bladder contractility
    - Low-pressure urinary storage
  - Defeat sphincter function to establish low-pressure urinary drainage per urethra
    - Only option for males
    - No effective external urinary collection device for females

MEDICATION

First Line

- Anticholinergic therapy
  - Effective in improving urinary storage under low pressure
    - Hyoscyamine 0.375 mg PO BID-TID
    - Oxybutynin 5 mg PO TID-QID
    - Oxybutynin extended release 5–40 mg/d PO
    - Tolterodine 2–4 mg PO BID
- α-Adrenergic blockade
  - Decrease internal sphincter function
  - Largely ineffective for external sphincter dyssynergia
    - Alfuzosin 10 mg/d PO
    - Phenoxybenzamine 10 mg PO BID (nonselective)
    - Terazosin 2–5 mg PO daily-BID
    - Doxazosin 2–8 mg/d PO
    - Tamsulosin 0.4 mg PO daily

Second Line

- Botulinum toxin injection into the external sphincter for DSD
  - Short lived
  - Requires repeated injections (1)[B]

SURGERY/OTHER PROCEDURES

- Endoscopic sphincter ablation
  - Only in males as it requires condom catheter urinary collection
    - Electrosurgical or laser sphincterotomy: Incise external sphincter from bulbous urethra to midprostatic urethra
    - Further incision through the prostate and bladder neck may be required if internal dyssynergia is present
- Sphincter stent prosthesis placement
  - Wire mesh stent placed endoscopically
  - Bridges midprostatic to bulbous urethra (2)[A]
    - Maintains caliber of membranous urethra at 42 French
    - Suprapubic tube cystostomy may be required in perioperative period
- Augmentation cystoplasty
  - Bladder is incised in clamshell fashion to disrupt detrusor contraction
  - Gastrointestinal segment used to enlarge bladder, increasing urinary storage with decreased pressure
    - May use large intestine, ileum, or gastric segment
    - Requires intermittent catheterization for urinary drainage
    - Limited dexterity may mandate creation of continent catheterizable stoma for the urinary reservoir, especially in females
- Ileal conduit cutaneous vesicostomy
  - Conduit of ileum connecting dome of bladder to anterior abdominal wall
    - Continuous low-pressure drainage through incontinent ileal conduit urostomy requires stomal appliance for urinary collection

- Useful for those who cannot perform self-catheterization (ie, quadriplegia)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Sacral deafferentation with sacral nerve root stimulation
  - Deafferentation with dorsal rhizotomy abolishes spontaneous detrusor contraction, improving urinary storage
  - Nerve root stimulation allows control over detrusor contraction
  - Obstruction by sphincter may require adjunctive sphincteric ablation

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Excellent prognosis if effectively treated
- Untreated, ~50% of men will develop significant complication

COMPLICATIONS

- Vesicoureteral reflux
- Renal insufficiency
- Urolithiasis
- Urosepsis

FOLLOW-UP

Patient Monitoring

- Annual evaluation
  - Urodynamic testing
    - Assure low intravesical pressure
  - Upper tract imaging (Ultrasound most comonly used; decreasing reliance on excretory urogram)
    - Rule out upper tract changes (calculi, hydroneprhosis)
- Serum chemistry
  - Confirm normal renal function and electrolyte balance

Patient Resources

N/A

CODES

ICD9

- 596.0 Bladder neck obstruction
- 596.54 Neurogenic bladder NOS
- 596.55 Detrusor sphincter dyssynergia

ICD10

- N31.8 Other neuromuscular dysfunction of bladder
- N31.9 Neuromuscular dysfunction of bladder, unspecified
- N36.44 Muscular disorders of urethra

CLINICAL/SURGICAL PEARLS

- DSD is always associated with NDO.
- Anticholinergic therapy and α-Adrenergic blockade are 1st-line medical therapy.
- If left untreated, ~50% of men will develop significant complication.

DIABETES MELLITUS, UROLOGIC CONSIDERATIONS

Thomas M. Facelle, MD
Mark L. Jordan, MD, FACS

BASICS

DESCRIPTION

- Hyperglycemia with secondary metabolic abnormalities
- Two subtypes including insulin deficiency (DM1) and insulin resistance (DM2)

EPIDEMIOLOGY

Incidence

- 30% with DM1 and 10–40% with DM2 will develop kidney failure.
- 59% with DM will have urologic complications/symptoms

Prevalence

8.3% of US population in 2010 was diabetic (1)

RISK FACTORS

- Likely genetic and environmental interplay for DM1
- Genetic predisposition for DM2
  - Environmental: Visceral obesity for DM2

Genetics

- DM1: Approx one-third genetic contribution
  - HLA-DR3, HLA-DR4
- Strong hereditary component for DM2
  - 70% twin concordance after age 40
  - Several loci identified affecting pancreatic B-cell function and propensity to visceral obesity

PATHOPHYSIOLOGY

- Urinary tract infections (UTIs)
  - Neutrophil dysfunction due to hyperglycemia
  - Patients with DM are at increased risk and are classified as “complicated” UTI due to risk of progression to more severe manifestations such as abscess, emphysematous pyelonephritis, and papillary necrosis
  - UTI increased incidence in women with DM but not men
  - 80% have upper tract infections
  - Often atypical organisms, eg, yeast
  - Risk of xanthogranulomatous pyelonephritis (XGP) with stones
- Erectile dysfunction (ED)
  - 3× more common in men with DM
  - 15% at age 30, 55% at age 60 (2)
  - 12% of men diagnosed with DM due to declining sexual function
  - Caused by peripheral neuropathy, arterial insufficiency, changes in cavernous smooth

muscle, and endothelial dysfunction
  – Increased rates of hypogonadism
• Voiding dysfunction
  – Sensory and motor neuropathy
  – Impaired sensation and detrusor function
  – Chronic bladder distension or overactivity
  – Incontinence prevalent in women (3)
• End-stage renal disease (ESRD)
  – DM most common cause (44%)
  – Preceded by onset of proteinuria
• Polyuria
  – In setting of glycosuria—osmotic diuresis
• Infertility
  – ED and androgen deficiency
• Bladder cancer
  – Increased incidence and mortality seen in men and women with DM (4)
  – DM medication pioglitazone associated with increased bladder cancer risk

ASSOCIATED CONDITIONS
• Obesity
• Metabolic syndrome
• New onset diabetes after transplant (NODAT)
  – Seen in up to 30% of nondiabetic renal transplant patients
• Papillary necrosis
• Retrograde ejaculation

GENERAL PREVENTION
• Glycemic control
• Weight reduction

DIAGNOSIS
HISTORY
• General
  – Polyuria, polydipsia
  – Weight loss, malaise
  – Family history
  – ED, especially in younger man
• UTI
  – Recurrent UTI (may be asymptomatic)
  – Fever, nausea, vomiting, flank pain
  – Dysuria, hematuria
• Voiding dysfunction
  – Urgency, frequency, weak stream, retention
• Bladder cancer
  – Hematuria, pioglitazone use

PHYSICAL EXAM

- Flank
  - CVA tenderness
- Abdomen
  - Distended bladder, bladder mass
- External genitalia
  - Phimosis, balanitis, yeast dermatitis
  - Testicular atrophy, varicocele
  - Peyronie plaques
- Rectal
  - Tone, bulbocavernosus reflex
- Prostate
  - Symmetry, nodules, tenderness

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- General
  - Fasting glucose >126 mg/dL
  - Oral GTT, 2-hr value >200 mg/dL
  - Microalbuminuria (30–300 mg/dL) predicts renal disease
- UTI
  - Urinalysis, urine culture, and sensitivities
  - BUN, creatinine
- ED
  - Consider testosterone level, esp if low libido
    - if low, follicle-stimulating hormone (FSH) and luteinizing hormone (LH)
- Voiding dysfunction
  - UA, C&S
  - Urine specific gravity if polyuric: Dilute if <1.007
  - Metabolic panel including serum creatinine
- Infertility
  - Testosterone, FSH, LH, prolactin
  - Semen analysis

Imaging

- UTI
  - Consider CT scan if symptoms severe to rule out urolithiasis and/or emphysematous pyelonephritis especially if flank pain
  - R/O papillary necrosis
- ED
  - Cavernosal Doppler ultrasound (select cases)
- Voiding dysfunction
  - Renal and bladder ultrasound

Diagnostic Procedures/Surgery

- Voiding dysfunction

- Post-void residual (PVR)
  - Via straight cath or bladder scan
  - Generally acceptable if <150 mL
- Voiding diary: Voiding volumes and frequency
- Uroflow
  - Normal 20–25 mL/s in men, 25–30 mL/s in women
  - Diminished if <10 mL/s
- Cystometrogram (CMG): Capacity, voiding pressure, detrusor instability

Pathologic Findings

- Diabetic nephropathy
  - Microangiopathy and glomerulopathy (5)
    - Thickened glomerlular capillary basement membrane; diffuse mesangial sclerosis; nodular glomerulosclerosis
  - Ischemia leads to tubular atrophy and interstitial fibrosis
  - Renal artery atherosclerosis

DIFFERENTIAL DIAGNOSIS

- UTI: Cystitis, pyelonephritis, emphysematous pyelonephritis, emphysematous cystitis, XGP, urolithiasis, papillary necrosis, perinephric abscess, sexually transmitted urethritis
- Voiding dysfunction: Bladder outlet obstruction, urethral stricture, neurogenic bladder, UTI, interstitial cystitis
- Polyuria: Excess fluid intake, diabetes insipidus, renal failure
- Infertility: Ejaculatory obstruction, retrograde ejaculation, varicocele, testicular causes

TREATMENT

GENERAL MEASURES

- Educate patients regarding urologic manifestations of diabetes
- Glycemic control
  - Dietary improvement, weight loss, exercise

MEDICATION

First Line

- UTI
  - DM is an underlying condition that makes any UTI a complicated UTI
  - Antibiotics (oral vs. intravenous)
  - Fluid resuscitation
- ED
  - Oral phosphodiesterase inhibitors (sildenafil, vardenafil, tadalafil, avandafil)
- Voiding dysfunction
  - α-Blockers if outlet obstruction (terazosin, doxazosin, tamsulosin, alfuzosin, silodosin)
    - Add 5α-reductase inhibitor (finasteride, dutasteride) if significant benign prostatic enlargement (eg, >40 g)
  - Anticholinergics for detrusor overactivity
- Ejaculatory failure

  – α-Agonist (pseudoephedrine)
- Diabetic nephropathy
  – ACE inhibitor if proteinuria for renal protection

Second Line
- ED
  – Intraurethral suppository (MUSE)
  – Intracavernosal injection (alprostadil, Bimix, Trimix)
  – Testosterone replacement if androgen deficient
- Voiding dysfunction
  – α3-Agonist (mirabegron) for overactivity

SURGERY/OTHER PROCEDURES
- UTI
  – Retention: Catheter placement, suprapubic tube
  – Urolithiasis: Ureteral stent, nephrostomy tube, ureteroscopy, extracorporeal shock wave lithotripsy
  – XGP: Nephrectomy
- ED
  – Penile prosthesis
- Voiding dysfunction
  – Sacral nerve stimulation (InterStim)—efficacy for overactivity and retention
  – Bladder outlet obstruction: Transurethral resection of prostate, photoselective vaporization of prostate, etc.
  – Urinary diversion (uncommon)
- Infertility
  – Assisted reproduction
- Bladder cancer
  – Transurethral resection, cystectomy

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
- Voiding dysfunction
  – Bladder training, biofeedback, timed voiding
  – Clean intermittent catheterization (CIC) for retention
- Erectile dysfunction
  – Vacuum erection device

Complementary & Alternative Therapies
- UTI
  – Cranberry extract
- Voiding dysfunction
  – Acupuncture to sacral dermatome

ONGOING CARE

PROGNOSIS

- Good with tight glycemic control
- Onset of proteinuria typically heralds future renal failure
- Diabetic cystopathy typically permanent

COMPLICATIONS

- UTI
  - Upper tract infection
  - Staghorn calculi; XGP
  - Renal failure
- Voiding dysfunction
  - UTI
  - Upper tract damage/renal failure
  - Incontinence
  - Bladder stones
  - Atonic bladder
- Diabetic nephropathy
  - ESRD
  - Dialysis dependence

FOLLOW-UP

Patient Monitoring

- General
  - Periodic serum glucose
  - Hemoglobin A1C
  - Creatinine
  - Urine protein and microalbumin
- ED
  - Testosterone replacement: Check serum testosterone, prostate-specific antigen (PSA), serial hematocrit for elevation
- Voiding dysfunction
  - Symptomatology
  - BUN/creatinine
  - PVR
  - Repeat urodynamics as needed

Patient Resources

CODES

ICD9

• 250.40 Diabetes with renal manifestations, type II or unspecified type, not stated as uncontrolled
• 250.41 Diabetes with renal manifestations, type I [juvenile type], not stated as uncontrolled
• 585.6 End stage renal disease

ICD10

• E10.29 Type 1 diabetes mellitus w oth diabetic kidney complication
• E11.29 Type 2 diabetes mellitus w oth diabetic kidney complication
• N18.6 End stage renal disease

CLINICAL/SURGICAL PEARLS

• DM predisposes to urinary infections of greater severity with likely upper tract involvement.
• Most common voiding symptom is overactivity.
• ED may be the presenting sign of DM.
• Tight glycemic control is necessary to reduce progression of symptoms.

DISORDERS OF SEXUAL DEVELOPMENT (DSD)

Luigi Avolio, MD

BASICS

DESCRIPTION

- Congenital condition in which development of chromosomal, gonadal, or anatomic sex is atypical (1)
- Chromosomal sex is inconsistent with phenotypical sex
- DSD is the result of a discordance among the 3 sex determination processes (chromosomal, gonadic, and phenotypic)
- Ambiguous genitalia and intersex disorders are no longer considered correct terms
  - Classification
    - Sex chromosome DSD
    - XX DSD
    - XY DSD

EPIDEMIOLOGY

Incidence

- 1 in 5,000 live births
  - Congenital adrenal hyperplasia (CAH) represents 60–70% of neonatal DSD (1 case per 15,000 live births)

Prevalence

N/A

RISK FACTORS

- Family history of DSD
- In utero exposure to androgens
  - Ovarian tumors
  - Maternal ingestion

Genetics

- XX DSD
  - 21α-hydroxylase deficiency (21OHD), Mendelian Inheritance in Man, MIM #201910 (online reference http://www.ncbi.nlm.nih.gov/omim/)
  - CYP21 gene-chr.6p21.33. Autosomal recessive

  - Leydig cell hypoplasia, MIM#238320, LHCGR gene-chr.2p16.3. Autosomal recessive
  - Steroid 5α-reductase Type 2 deficiency, MIM#264600, SRD5A2 gene-chr.2p23.1. Autosomal recessive
  - Steroidogenic acute regulatory protein, MIM#201710, StAR gene-chr.8p11.23. Autosomal recessive
  - P450 side-chain cleavage deficiency, MIM#613743, CYP11A1 gene-chr.15q24.1. Autosomal recessive
  - 3β-hydroxysteroid dehydrogenase deficiency, MIM #201810, HSD3B2 gene-chr.1p12. Autosomal recessive
  - P450 oxidoreductase deficiency, MIM#613571, POR gene-chr.7q11.23. Autosomal recessive
  - 17α-hydroxylase/17,20-lyase deficiency, MIM#202110, CYP17A1 gene-chr.10q24.32. Autosomal recessive
  - 17β-hydroxysteroid dehydrogenase Type 3 deficiency, MIM#264300, HSD17B3 gene-chr.9q22.32. Autosomal recessive
  - Disorder of the Androgen Receptor (AR), MIM#300068, AR gene-chr.Xq12. X-linked recessive
  - Anti-müllerian hormone (AMH) gene or its receptor, MIM#300068, AMH gene-chr.19p13.3 (type I), AMHR2 gene-chr.12q13.13 (type II). Autosomal recessive (2).

ALERT
The possible risk of an immediate life-threatening adrenal crisis must be considered in case of neonatal salt-wasting CAH and the general status of the child, including hydration, blood pressure, and jaundice, should be documented.

PATHOPHYSIOLOGY

- XX DSD
  - Disorders of ovarian development
    - (ovotesticular DSD): Ovary may contain some testicular tissue (unilateral 50%—ovotestis on one side and normal gonad in the other side; lateral 20%—a testis on one side and an ovary on the other; bilateral ovotestis 30%) that secretes adequate amounts of testosterone and AMH
  - Disorders of androgen excess
    - 21-hydroxylase deficiency is the most common cause of 46XX DSD. Impaired cortisol biosynthesis relieves feedback inhibition and thus increases ACTH secretion, which leads to hyperplasia of the adrenals and to disordered steroidogenesis: As a consequence cortisol precursors are shunted to androgen synthesis.
- XY DSD
  - Disorders of testis development
  - Disorders of androgen synthesis
    - Deficiency of 7-dehydrocholesterol reductase (DHCR7) results in a failure of cholesterol synthesis

- Disorders of androgen action
- Persistent müllerian duct syndrome (PMDS)

ASSOCIATED CONDITIONS
- Turner syndrome, Klinefelter syndrome, Reifenstein syndrome
- Inguinal hernia
- Amenorrhea
- Infertility

GENERAL PREVENTION
- Prenatal treatment of fetuses at risk for CAH with dexamethasone
- Chorionic villus sample
- Amniocentesis

DIAGNOSIS
HISTORY
- Family anamnesis
  - DSDs, genital abnormalities, amenorrhea, sterility, hirsutism
  - Early infant deaths (missed adrenogenital syndrome)
- Maternal exposure to androgens
- History of maternal virilization (androgen-producing tumor)

PHYSICAL EXAM
- External genitalia
  - Phallic structure (length, breadth, and amount of erectile tissue)
    - Normal penile length is ≥ 2.5 cm, and normal penile diameter is ≥ 0.9 cm
    - Normal clitoral width is from 2 to 6 mm; length > 9 mm unusual
  - Position of urethral meatus
  - Number of orifices in the perineum and their characteristics
  - Labioscrotal folds (separated or fused)
  - Asymmetry (ovotesticular DSD can produce virilization on only one side)
- Gonads
  - Palpable gonads (testis, very rarely ovotestis)
- Abdomen
  - Mass referable to enlarged uterus

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Karyotype
- Serum levels of sodium, potassium, and 17-hydroxyprogesterone
- Androgens (testosterone, dihydrotesterone, androstenedione)
- Cortisol, gonadotrophins, and AMH levels
- Stimulation test with human chorionic gonadotropin (suspected defect of androgen production)

Imaging
- Abdominal/Pelvic ultrasound (utero presence)

- Cystogram/genitogram (visualization of vagina, sinus)
- MRI

Diagnostic Procedures/Surgery
- Laparoscopy to define internal anatomy
- Cysto/vaginoscopy to confirm anatomy and level of confluence of urogenital sinus
- Gonadal biopsy to analyze presence of ovarian and/or testicular tissue
- Skin biopsy to obtain cellular lines

Pathologic Findings
Identification of ovarian tissue, testicular tissue, ovotestes, or streak gonads according to related specific disorders

DIFFERENTIAL DIAGNOSIS
- Hypopituitarism
- Hypospadias
- Hydrocele and hernia
- Menstruation disorders
- Microphallus
- Gonadoblastoma

TREATMENT

GENERAL MEASURES
- Gender assignment avoiding hasty decision
- Expert evaluation by an experienced multidisciplinary team

MEDICATION
First Line
- Newborn with salt-wasting CAH
  - Fluid and electrolytes replacement
  - Glucocorticoid and mineralocorticoid replacement
    - Hydrocortisone 10 mg/m^2/d
    - Fludrocortisone 0.1–0.2 mg/d
    - Oral sodium chloride, 1–2 g/d added to formula or breast milk

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Masculinizing genitoplasty (between the ages of 6 and 18 mo)
  - Hormonal treatment with testosterone preparation to stimulate phallus
  - Surgical excision of müllerian structures
  - Phalloplasty (hypospadias repair, chordee correction, scrotal transposition)
  - Orchidopexy
- Feminizing genitoplasty (during the 1st 6 mo of life) (3)
  - Clitoroplasty preserving innervation to reduce the size of the gland and shaft
  - Vaginoplasty and labioplasty to separate vagina and urethra from the common urogenital

sinus
- Gonads
  - 46XX DSD: Normal ovaries, no treatment necessary
  - 46XY DSD:
    - Female gender assigned: Orchiectomy (timing is subject of debate)
    - Male gender assigned: Orchidopexy
  - Ovotesticular DSD:
    - Gonadal biopsy
    - Excision of dysgenetic gonads (streak)
- Müllerian remnants
  - Small asymptomatics are managed conservatively
  - Symptomatic remnants are treated surgically (endoscopic incision or unroofing, laparoscopic/robotic excision)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

Some patient groups strongly advocate to delay any surgical procedures until patients are competent to provide informed consensus

ONGOING CARE

PROGNOSIS

Many patients can remain fertile (CAH, some ovotesticular DSD, XY DSD 5α-RD)

COMPLICATIONS

- Acute adrenal insufficiency in CAH not adequately treated
- Damages to clitoral innervation (clitoroplasty)
- Stenosis of the vaginal introitus (vaginoplasty)
- Meatal stenosis, fistula (hypospadias repair)
- Rectal injury (urogenital sinus mobilization)

FOLLOW-UP

Patient Monitoring

- Sexual function (adequate vaginal introitus, adequate penis reconstruction)
- Risk of gonadoblastoma in gonadal dysgenesis is 12% (occurrence of neoplasia is primarily associated with the Y chromosome containing karyotypes)
- Lifelong psychosocial support mandatory for all patients with DSD

CODES

ICD9

- 255.2 Adrenogenital disorders
- 259.50 Androgen insensitivity, unspecified
- 752.7 Indeterminate sex and pseudohermaphroditism

ICD10

- E25.0 Congenital adrenogenital disorders assoc w enzyme deficiency
- E34.50 Androgen insensitivity syndrome, unspecified
- Q56.4 Indeterminate sex, unspecified

CLINICAL/SURGICAL PEARLS

- DSD should be managed by a specialized multidisciplinary team.

- Gender assignment should be made after thorough investigation by the team.
- DSD is a heterogeneous group of conditions with different underlying molecular causes. Many disease genes remain to be identified.
- Infants with a DSD and who present with truly ambiguous genitalia are a rare occurrence.

DYSFUNCTIONAL ELIMINATION SYNDROME

Jennifer A. Hagerty, DO

BASICS

DESCRIPTION

- Dysfunctional voiding; various symptoms from mild daytime frequency and postvoid dribbling to daytime and nighttime wetting, urgency, urge incontinence, pelvic holding maneuvers, and urinary tract infections (UTIs)
- Sometimes referred to as bowel bladder dysfunction (BBD).
- Dysfunctional voiding often associated with bowel dysfunction; constipation, encopresis, or fecal impaction (1)[C]
  - Constipation and rectal dilation interferes with normal bladder function
  - No identifiable neurologic cause

EPIDEMIOLOGY

Incidence

Constipation is present in up to 50% of children with dysfunctional voiding (2)[C]

Prevalence

20–30% school-aged children have dysfunctional voiding (3)[C]

RISK FACTORS

- UTIs
- Sexual abuse
- Attention deficit/hyperactivity disorder
- Stressors during or after toilet training

Genetics

- Ochoa syndrome, a genetic disorder with an autosomal recessive inheritance pattern
  - Associated with dysfunctional voiding

PATHOPHYSIOLOGY

- Voiding dysfunction (variable etiologies):
  - Small bladder capacity
  - Large bladder capacity secondary to urine holding
  - Discoordinated voiding with difficulty relaxing the sphincter during voiding
- Often associated with constipation
  - Rectum close to posterior wall of bladder
  - Large amount stool:
    - Obstruction by compression of the bladder and bladder neck
    - Or bladder instability leading to urgency and frequency

ASSOCIATED CONDITIONS

- Vesicoureteral reflux (VUR)
- UTIs

- Encopresis
- Incontinence
- VUR
- Urge syndrome

GENERAL PREVENTION
None have been identified

DIAGNOSIS
HISTORY
- Present typically after toilet training
- Diurnal and/or nocturnal enuresis
- Frequency and urgency
- Hesitancy
- UTIs
- Difficulty stooling, hard or infrequent stools
- Encopresis

PHYSICAL EXAM
- Typically normal physical exam
  - Evaluate for neurologic dysfunction
  - Examine the external genitalia for anatomic causes of symptoms
  - Evaluate for a distended bladder and palpable stool
  - Consider rectal exam for fecal retention

DIAGNOSTIC TESTS & INTERPRETATION
Lab
Urinalysis and urine culture; rule out bacteriuria and glucosuria

Imaging
- Renal/bladder ultrasound; evaluate for hydronephrosis, thickened and/or distended bladder, post-void residual, stool in the rectum
- MRI lumbar spine if concern for a neurogenic cause to evaluate for a tethered cord
- Voiding cystourethrogram to evaluate for VUR in patients with febrile UTIs.
  - Also information on bladder capacity and emptying, and appearance of the bladder and urethra
  - Spinning top urethra; widening of the urethra in females during voiding

Diagnostic Procedures/Surgery
- Voiding and stooling diary to assess frequency and volume of voids and stooling frequency and consistency
- Uroflowmetry; evaluate pattern
  - Flow rates different than adults and less reliable; curve more diagnostic
    - Bell shaped—normal
    - Tower shaped—overactive bladder
    - Low flat curve—outlet obstruction
    - Staccato pattern—sphincter overactivity

    - Interrupted flow—underactive bladder
- Urodynamics; patients refractory to conventional therapy
  – Evaluate the filling and emptying phases of the bladder
  – Can be done in conjunction with fluoroscopy

DIFFERENTIAL DIAGNOSIS
- Nonneurogenic neurogenic bladder
- Neurogenic bladder
- Ochoa syndrome
- Overactive bladder
- Giggle Incontinence

TREATMENT

GENERAL MEASURES
- Behavioral modification: Education on voiding patterns
  – Timed voiding
  – Correct positions to void
  – Relaxation techniques
  – Proper hydration
- Bowel Management
  – Education on correlation between the bladder and bowel activity
  – Daily toilet time
  – Dietary modifications; high fiber

MEDICATION

First Line
- *Treatment of constipation prior to medications for bladder symptoms; disimpaction followed by maintenance therapy*
  – *Initial cleanout with laxatives and enemas*
  – *Maintain soft daily stools with a combination of fiber, fluids, laxatives, and softeners*
- Antimuscarinics; overactive bladders
  – Reduce the intensity and frequency of bladder contractions
- α-Adrenergic blockers; bladder neck obstruction
  – Relaxation of the bladder neck to improve bladder emptying
- Prophylactic antibiotics; prevention of recurrent UTIs until dysfunctional elimination improved

Second Line
- Tricyclic antidepressants for urge incontinence
  – Mechanism not known; not FDA approved in children

SURGERY/OTHER PROCEDURES
- Biofeedback
- Transcutaneous electrical nerve stimulation

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Clean intermittent catheterization with impaired bladder contractility

Complementary & Alternative Therapies

- Acupuncture
  – Low utility in children given use of needles
- Probiotics; prevention of UTIs and treatment of constipation
- Cranberry supplements; potential for UTI prevention

ONGOING CARE

PROGNOSIS

Most children have resolution of symptoms in a short period of time with behavioral modifications; however, some children may have persistence requiring more intensive management.

COMPLICATIONS

- UTIs
- Urinary incontinence
- Urinary retention
- Hydronephrosis

FOLLOW-UP

Patient Monitoring

- Voiding/stooling diary
- Uroflowmetry
- Post-void residual monitoring

Patient Resources

- http://kidshealth.org/parent/general/sick/constipation.html
- http://kidshealth.org/parent/medical/kidney/recurrent_uti_infections.html

• Enuresis, Pediatric
• Incontinence, Urinary, Pediatric
• Urinary Retention, Pediatric
• Urinary Tract Infection, Pediatric
• Vesicoureteral Reflux, Pediatric
• Dysfunctional Elimination Syndrome Image

CODES

ICD9
• 599.0 Urinary tract infection, site not specified
• 788.3 Urinary incontinence
• 788.41 Urinary frequency

ICD10
• N39.0 Urinary tract infection, site not specified
• R32 Unspecified urinary incontinence
• R35.0 Frequency of micturition

CLINICAL/SURGICAL PEARLS

• Constipation is often associated with bladder dysfunction in children.
• Treatment of constipation alone may lead to complete resolution of urinary complaints.
• Vesicoureteral reflux may resolve after treatment of voiding dysfunction.
• Education of the correlation between stooling patterns and voiding complaints is a very important part of treatment; if understanding is poor there is often low compliance.

DYSORGASMIA (PAINFUL ORGASM), MALE

John Patrick Mulhall, MBBCh, FACS, FECSM

BASICS

DESCRIPTION

- Dysorgasmia specifically refers to pain that occurs immediately preceding, at or immediately following orgasm.
- The pain is usually located in the penis or testicles but may be present in the lower abdomen, groin, perineum, or elsewhere.
- The severity of pain ranges from mild and of nuisance value to crippling and may last seconds to hours after orgasm.
- The condition is best identified and studied in the postradical prostatectomy setting.
- Ejaculatory pain may be seen in other conditions such as chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS), or NIH category III prostatitis, and is discussed in Section II ("Ejaculation, painful").

EPIDEMIOLOGY

Incidence

- The most frequent correlate of dysorgasmia is radical prostatectomy and this condition occurs in about 10–15% of patients.
- In this population, the pain is usually self-limiting with most sufferers experiencing complete resolution by 2 yr postoperatively

Prevalence

N/A

RISK FACTORS

- Radical prostatectomy
- Prostate radiation
- Chronic pelvic pain syndrome (CPPS)

Genetics

None known

PATHOPHYSIOLOGY

- While unproven one of the postulated mechanisms is that the pain is related to pelvic floor or bladder neck spasm.
  – This is the rationale for the use of α-blockers.
- Dysorgasmia decreases in frequency and degree over time after RP.

ASSOCIATED CONDITIONS

- Chronic pelvic pain syndrome (NIH category III prostatitis)
- Erectile dysfunction (1)
- Prostate cancer

GENERAL PREVENTION

None known

DIAGNOSIS

HISTORY

- Medical history
- Focusing on assessment of orgasmic pain location, severity and duration.
- Prior history of radical prostatectomy, radiation therapy, or CPPS.

PHYSICAL EXAM

- General physical exam
- Genital exam (although often there are no specific findings)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

None are useful

Imaging

None are useful

Diagnostic Procedures/Surgery

None

Pathologic Findings

None

DIFFERENTIAL DIAGNOSIS

- Penile pain:
  - Penile compressive neuropathy
  - Penile trauma
  - Peyronie disease
  - Sexually transmitted infection (STI)
  - Ureteral stone
- Testicular pain:
  - Epididymitis
  - Orchitis
  - Testicular tumor
  - Trauma

TREATMENT

GENERAL MEASURES

Reassurance that the condition is most often self-limiting

MEDICATION

First Line

- α-Blockers (daily initially; if successful attempt on-demand) (2).
- Up to 70% of men using α-blockers will have significant improvement in pain.
- Side effects include syncope, orthostasis, retrograde ejaculation, asthenia, and nasal

congestion
  – Alfuzosin 10 mg/d
  – Doxazosin start 1 mg/d to max 8 mg
  – Silodosin 8 mg/d
  – Tamsulosin start 0.4 mg to max 0.8 mg
  – Terazosin start 1 mg/d to max 20 mg

Second Line
- Centrally acting pain relievers
- Optimum dose and duration not established
- Gabapentin
  – 900 to 1,800 mg/d and given in divided doses (3 times a day) using 300 or 400 mg capsules
- Pregabalin
  – Begin dosing at 150 mg/d, increase to 300 mg/d within 1 wk. Maximum dose of 600 mg/d

SURGERY/OTHER PROCEDURES
Case reports exist of excision of retained seminal vesicle following radical prostatectomy with relief of symptoms (3)

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Recovery is expected following radical prostatectomy.
- At 24 mo, a statistically significant decrease in symptoms was seen in one study (4).
  – 72%, 26%, and 7% of patients still complained of pain at 12, 18, and 24 mo, respectively.

COMPLICATIONS
N/A

FOLLOW-UP
Patient Monitoring
Routine radical prostatectomy follow-up appears most appropriate.

Patient Resources
N/A

- Ejaculation, Painful
- Post-orgasm Illness Syndrome (POIS)
- Prostatitis, Chronic Nonbacterial, Inflammatory and Noninflammatory (NIH CP/CPPS III A and B)

CODES

ICD9

- 607.89 Other specified disorders of penis
- 608.89 Other specified disorders of male genital organs
- 789.09 Abdominal pain, other specified site

ICD10

- N48.89 Other specified disorders of penis
- N50.8 Other specified disorders of male genital organs
- N53.12 Painful ejaculation

CLINICAL/SURGICAL PEARLS

- Dysorgasmia is common after radical prostatectomy.
- It is usually self-limiting.
- It is often responsive to α-blocker therapy.

DYSPAREUNIA, FEMALE

Bradley C. Gill, MD, MS
Sandip P. Vasavada, MD, FACS

BASICS

DESCRIPTION

- Dyspareunia is defined as pain associated with sexual intercourse.
  - Most often used in associated with female sexual dysfunction and is the focus of this section.
- Present since 1st (primary) intercourse or acquired (secondary) thereafter.
- Etiologies can be physiologic and/or psychological.

EPIDEMIOLOGY

Incidence

Lacking disclosure to clinicians and treatment pursuit suggests underestimation

Prevalence

Up to a 60% prevalence in women, but varies widely by sample and definition

RISK FACTORS

- Menopause (physiologic or iatrogenic)
- Physical trauma (physiologic or iatrogenic)
- Psychological trauma (supporting evidence is mixed)
- Tissue irritation (infection, inflammation, malignancy, etc.)
- Urogenital anatomy (congenital)

Genetics

Early menopause should be considered

PATHOPHYSIOLOGY

- Pain results from irritation or trauma to the female reproductive tissues.
- Can be entrance, vaginal, or deep-thrust dyspareunia per the etiology.

ASSOCIATED CONDITIONS

- Vaginal atrophy
- Urogenital malformations
- Posttraumatic stress disorder (prior physical or psychological trauma)
- Pelvic inflammatory disease
- Endometriosis

GENERAL PREVENTION

- Maintenance of vaginal mucosal integrity
- Good hygiene and health maintenance

DIAGNOSIS

HISTORY

- Description of pain
  - Specific localization: Superficial, deep, anterior, posterior
  - Timing and duration: When starting, throughout, after finishing
  - Consistency with intercourse: Occasional; sometimes, always
  - Character: Burning, sharp, aching, throbbing
  - Associations: Discharge, bleeding, urinary symptoms, bowel symptoms
- Factors altering the pain
  - Positioning, specific maneuvers, location
  - Use of lubricants, condoms, sex toys, hygiene products
  - Specific partners or partner-related factors
  - Timing of menstrual cycle
  - Bowel or bladder habits
- Urogenital conditions
  - Sexually transmitted or urinary tract infections
  - Complicated pregnancies
  - Endometriosis
  - Uterine fibroids
  - Inflammatory bowel disease
- Urogenital interventions
  - Surgery or radiation
  - Injections or topical therapy
- Urogenital trauma
  - Vaginal childbirth injuries
  - Difficult or forced intercourse
- Systemic conditions
  - Menopause (physiologic or iatrogenic)
  - Pain disorders or fibromyalgia
  - Cancer
  - Other chronic diseases
- Current or prior abuse
  - Sexual abuse
  - Verbal or physical abuse

PHYSICAL EXAM

- Visual inspection of external genitalia
  - Distribution of pubic hair
  - Diffuse vulvo-vestibulitis
  - Ulcerations, pustules, discharge, or bleeding
  - Inflamed Bartholin or Skene glands
  - Prolapsed urethra, vagina, or cervix
  - Skin or mucosal lesions suspicious for cancer
- Speculum exam
  - Diffuse vaginitis or cervicitis
  - Mucosal rugae, moisture, thinning, or excoriation
  - Ulcerations, pustules, discharge, or bleeding

  - Cystocele, rectocele, or enterocele
  - Vaginal wall masses
  - Mucosal lesions suspicious for cancer
- Diagnostic sampling with cervical surface scrapings, brushings, and culture swabs
  - Ulcerations, pustules, or discharge
  - Masses, skin changes, mucosal changes, bleeding
- Palpation of external genitalia, vaginal sidewalls, pelvic floor muscles, cervix, and ovaries
  - Bartholin or Skene gland tenderness
  - Urethral or vaginal sidewall mass
  - Surgically placed foreign bodies
  - Pelvic floor muscle tension, spasm, or tenderness
  - Cervical motion, ovarian, or adnexal tenderness
  - Vaginal cul-de-sac mass or tenderness

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis and urine culture to screen for infection or cystitis
- Endocervical swabs for gonorrhea, chlamydia, or bacterial vaginosis
- Cervical scrapings or brushings for malignancy and human papilloma virus
- Vaginal pH, wet mount, or whiff test for bacterial or fungal infection

Imaging

- Transvaginal ultrasound for reproductive organ or pelvic masses
- Transabdominal ultrasound for abdominal masses
- Pelvic magnetic resonance imaging for urethral diverticula or pelvic masses

Diagnostic Procedures/Surgery

- Cystourethroscopy for cystitis, urethritis, urethral diverticula
- Double balloon urethrography for urethral diverticula
- Colposcopy for human papilloma virus or uterocervical malignancies
- Colonoscopy for inflammatory bowel disease or colorectal malignancy
- Diagnostic laparoscopy for endometriosis or pelvic masses

DIFFERENTIAL DIAGNOSIS

- Congenital
  - Vaginal agenesis, vaginal malformation, imperforate hymen, rigid hymen, retroverted uterus
- Gynecologic
  - Structural: Hymenal remnant, introital or vaginal stenosis, prolapse, childbirth, adhesions
  - Cellular: Vaginal atrophy, lichen sclerosis, vulvar hyperplasia, cancer
  - Infectious: Sexually transmitted, viral, bacterial vaginosis, fungal, pelvic inflammatory disease
  - Allergic: Contraceptive device, condom, latex, semen, hygiene product, sex toy
  - Reproductive: Endometriosis, fibroids, ectopic pregnancy, adnexal cyst, ovarian cyst
  - Iatrogenic: Implanted mesh erosion, exposed suture, postoperative fistula
- Urologic
  - Urethral prolapse, urethral caruncle, urethral diverticulum, urethral cancer, urethritis,

cystitis
- Colorectal
  – Inflammatory bowel disease, abscess, hemorrhoids, constipation, rectal cancer
- Musculoskelet al
  – Vaginismus, pelvic floor muscle spasm, trauma, chronic pain disorder, fibromyalgia
- Psychological
  – Posttraumatic stress disorder, sexual aversion disorder, genital sexual arousal disorder

TREATMENT

GENERAL MEASURES
- Behavioral (1,2)
  – Identify and eliminate any allergy-related hygienic or sexual practices
  – Encourage using water-based lubrication or hypoallergenic products
  – Utilize infection prophylaxis like postcoital voiding when appropriate for UTI issues
  – Psychological counseling, couples therapy, or relaxation exercises as indicated
- Careful consideration of replacing condoms or other barrier devices with another contraceptive

MEDICATION
First Line
- Ospemifene is an estrogen agonist/antagonist indicated for the treatment of moderate to severe dyspareunia, a symptom of vulvar and vaginal atrophy, due to menopause
  – 1 tablet (60 mg) taken orally once daily with food
  – Do not use estrogens or estrogen agonist/antagonist or fluconazole concomitantly
- Appropriate dose and duration of antibiotics or antifungals for infection
- Topical estrogen for atrophy considering benefits over systemic forms
- Topical corticosteroids for vulvar hyperplasia or testosterone for lichen sclerosis

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Laparoscopic endometriosis excision or ablation
- Laparoscopic lysis of adhesions if indicated
- Laparoscopic sacral colpopexy for problematic retroverted uterus
- Urethral diverticulectomy if indicated
- Excision of implanted mesh, eroded sutures, or other foreign body
- Trigger point injections for muscle spasm

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
- Daily passive dilation with progressive vaginal dilators for stenosis
- Use of pessary for problematic retroverted uterus
- Pelvic floor physiotherapy or biofeedback for muscle spasms

- Ultrasound or electrical stimulation for persistent muscle spasm
- Tibolone (synthetic steroid) is commonly used in Europe in postmenopausal women with desire and arousal disorders

Complementary & Alternative Therapies

- Education, sex therapy, psychotherapy, and cognitive behavioral therapy are also important in the multidisciplinary management of sexual dysfunction including those with a history of sexual abuse.
- Currently there are limited studies on the effectiveness of herbal remedies to aid female sexual dysfunction in general.

ONGOING CARE

PROGNOSIS

- Results vary with etiology and treatment of many is long term
- Multimodal approach to any etiology should be most beneficial

FOLLOW-UP

Patient Monitoring

- Frequent follow-up with initiation of new behavioral or medical therapies is best
- Upon resolution and improved patient satisfaction follow-up may be spaced out

• Do not discount behavioral interventions.
• Topical estrogen can work wonders.
• Changing the hygiene routine can help.

DYSURIA

Mohamed S. Ismail, MBChB, MRCS, PhD
Francis Xavier Keeley, Jr., MD, FRCS

BASICS

DESCRIPTION

- Dysuria is the symptom of discomfort, burning, or pain during micturition.
- It is often associated with other lower urinary tract symptoms.

EPIDEMIOLOGY

Incidence

- Dysuria accounts for up to 15% of visits to family doctors
- In men the incidence increases with age and 5% of men seeks medical help for dysuria

Prevalence

In the United States the reported prevalence of dysuria is 25%

RISK FACTORS

See associated conditions

Genetics

N/A

PATHOPHYSIOLOGY

- Dysuria results from the irritation of the urethra or bladder by inflammation or irritants
- The transient receptor potential subfamily vanilloid type 1 receptor (TRPV1) exists in the urethra
- Inflammatory mediators such as leukotrienes activate TRPV1 and result in pain and burning during voiding

ASSOCIATED CONDITIONS

- Bladder or urethral cancer
- BPH
- Connective tissue diseases
  - Behçet disease
  - Reiter (reactive arthritis) syndrome
- Pregnancy
- STD
- Urethral stricture disease
- Urinary tract infection
- Urolithiasis

GENERAL PREVENTION

- Hydration to flush out the urinary tract
- Women should wipe from front to back after bowel movements
- Women should empty the bladder immediately after intercourse

- Keep the genital area clean and dry
- Avoid irritating soap and vaginal products
- Treat infection with antibiotics

DIAGNOSIS

ALERT
Unexplained dysuria may indicate carcinoma in situ of the bladder.

HISTORY

- The cause of dysuria can be challenging to diagnose
- Dysuria is frequently associated with other lower urinary tract symptoms such as urinary frequency, hesitancy, urgency, and nocturia (1)
- Age and sex (2)
  - Dysuria is more common in women
  - The most common cause in young women is urethritis, in middle age women gynecologic causes, and in elderly women urinary tract infection
  - The most common cause in young men is urolithiasis and in elderly are benign prostatic hyperplasia (BPH) and urinary tract infection
  - Dysuria in children may suggest sexual abuse
- Onset
  - Sudden onset symptoms suggest acute bacterial infection
  - Gradual onset symptoms may suggest Chlamydia trachomatis infection
- Timing of pain
  - At the onset of voiding indicates inflammation such as urethritis
  - At the middle of voiding indicates obstruction such as urethral stricture or BPH
  - At the end of voiding usually indicates bladder pathology such as cystitis
- Location of pain
  - External discomfort associated with vaginal infection or inflammation
  - Internal discomfort indicates bladder or urethral origin
- Associated symptoms
  - Frequency, urgency, and suprapubic pain suggest diagnosis of interstitial cystitis
  - Frequency, nocturia, and reduced flow suggest bladder outlet obstruction or urethral stricture
  - Fever, rigor, and flank pain suggest pyelonephritis or urolithiasis
  - Urethral discharge in young age indicates sexually transmitted diseases
  - Vaginal irritation, discharge, and dyspareunia indicate genital tract infection such as:
  - Vulvo-vaginitis, atrophic vaginitis, or sexually transmitted diseases
  - Dyspareunia + dribbling + dysuria (“3 Ds”) suggests a urethral diverticulum in females
  - The presence of joint or back pain may indicate connective tissue diseases
  - Significant urgency occurs as a result of irritation of the bladder trigone and posterior urethras due to inflammation, bladder stone, or tumor.
  - Oral and genital ulcers, uveitis, vasculitis with dysuria suggest Behçet disease
- History of recent surgery such as urethral instrumentation or continence surgery and history of recent catheterization should be obtained to rule out infection, inflammation, and

urethral erosion.
- Sexual history
  – Sexual behavior
  – The use of contraceptives, diaphragms, condoms, etc.
  – Previous history of sexually transmitted diseases and history of urethral scarring
- Drug history: Drugs associated with dysuria are ticarcillin, penicillin G, cyclophosphamide, saw palmetto, dopamine

PHYSICAL EXAM
- General exam and observation should be recorded
- Abdominal exam
  – Inspection: Look for skin rash and abdominal distension which indicate full bladder
  – Palpation: Feel for loin tenderness, palpable bladder, suprapubic tenderness, abdominal masses, and midline pulsation
  – Percussion: To detect full bladder or any other abdominal mass
  – Auscultation: To rule out other causes of abdominal distension
- Male genital exam
  – Look for any penile lesions, urethral discharge, meatal stenosis, balanitis, perineal bruising, and abnormalities in the foreskin
  – Examine the scrotum for swelling, tenderness, and testicular masses
  – Digital rectal exam to rule out prostatitis, benign prostatic enlargement, and prostate cancer
- Female genital exam (3)
  – Look for vaginal and urethral discharge
  – Vulval lesions such as ulcers, vesicles, and rash
  – Identify urethral lumps that indicate urethral caruncle, diverticulum, or stones. Look for signs of atrophic vaginitis
  – Pelvic exam: Adnexal and cervical tenderness which indicates pelvic inflammatory disease, urethral tenderness, and urethral masses
  – Bimanual exam to look for pelvic masses

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urine dipstick is a useful and easy test to screen for urinary tract infection
  – A positive test for nitrites is suggestive of urinary tract infection. A negative test does not rule out infection
  – A positive leukocyte esterase suggests the presence of white blood cells in the urine which is associated with inflammation. It has 75% sensitivity to detect infection
- Urine microscopy
  – Pyuria is defined by the presence of 3–5 white blood cells per high-power field
  – Hematuria is defined by the presence of 3–5 red blood cells per high-power field
  – Sterile pyuria is present in urolithiasis, transitional cell carcinoma, and atypical microorganisms such as tuberculosis
- Gram staining demonstrate the urinary pathogens
- Urine culture and sensitivity identify the causative microorganism of urinary tract infection and its antimicrobial sensitivities. Bacterial count of more than 1,000 colony forming units

is diagnostic
- Vaginal and urethral smears: Important for the diagnosis of sexually transmitted diseases
- Vaginal PH measurement, potassium hydroxide microscopy, and yeast culture are indicated in patients with unexplained or recurrent dysuria
- Chlamydia: Nucleic amplification testing (NAAT) of vaginal swabs for women or 1st-catch urine for men

Imaging
- Renal ultrasound scan in suspected cases of upper tract pathology, urolithiasis, and bladder abnormalities
- Plain abdominal x-ray in suspected cases of urolithiasis and emphysematous pyelonephritis and cystitis
- Other imaging modalities can be arranged according to the suspected diagnosis such as voiding cystourethrography, retrograde urethrogram, computerized tomogram with intravenous contrast, magnetic resonance imaging

Diagnostic Procedures/Surgery
Cystoscopy: Allows careful assessment of the urethra and bladder.

Pathologic Findings
Based on specific diagnosis

DIFFERENTIAL DIAGNOSIS
- Disease of the urinary tract
  - Urinary tract infection
  - Urolithiasis, bladder calculus, crystalluria
  - Interstitial cystitis
  - Prostatitis (acute, chronic bacterial and chronic pelvic pain syndrome)
  - Malignancy (carcinoma in situ, prostate cancer, urethral cancer)
- Diseases of the genital tract
  - Sexually transmitted disease: Gonorrhea, Chlamydia, and herpes simplex infection
  - Vulvo-vaginitis, cervicitis, pelvic inflammatory disease
  - Epididymitis
  - Urethral diverticulum
- Systemic diseases
  - Connective tissue diseases: Reiter (reactive arthritis) syndrome and Behçet disease
- Local irritants
  - Chemicals irritants: Cyclophosphamide, laundry detergents, bubble baths, intravaginal lubricants
  - Mechanical irritation: Radiation cystitis
- Infants and adolescents
  - Labial adhesions
  - Exploratory sexual activity, masturbation
- Diverticulosis

TREATMENT

GENERAL MEASURES
- Encourage good hydration
- Personal hygiene
- Protective measures against STD
- Treat the primary cause

MEDICATION
First Line
- Mainly directed to relief symptoms and treat the underlying cause
- Symptomatic relief can be achieved by using phenazopyridine hydrochloride 200 mg PO TID
- Urinary tract infections are treated with oral antibiotics according to the causative microorganism. In men presumptive organisms are gram negative. Chronic bacterial prostatitis may require a prolonged course
- Urethritis in males is typically due to Chlamydia or gonorrhea

Second Line
- Associated symptoms of urgency can be treated with antimuscarinic drugs such as solifenacin 5 mg PO OD
- Associated symptoms of bladder outlet obstruction can be treated with α-blockers such as tamsulosin 0.4 mg PO OD

SURGERY/OTHER PROCEDURES
Surgical management is reserved for specific causes such as stones, bladder tumors, urethral diverticulum, and bladder outlet obstruction

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
Interstitial cystitis is treated by replacing the glycosaminoglycan layer in the bladder using sodium hyaluronate

Complementary & Alternative Therapies
Acupuncture, nutritional therapy, pelvic floor exercises, and biofeedback can be useful complementary treatments for dysuria

ONGOING CARE
PROGNOSIS
- Prognosis depend on the causative factor
- Urinary tract infection has a good prognosis

COMPLICATIONS
Based on the primary diagnosis

FOLLOW-UP
Patient Monitoring
Based on the primary diagnosis

• R30.0 Dysuria

CLINICAL/SURGICAL PEARLS

• Unexplained persistent dysuria should NEVER be ignored; must rule out occult malignancy, such as carcinoma in situ of the bladder.
• Persistent hematuria after adequate treatment of dysuria related to UTI must have formal

hematuria workup.

EDEMA, EXTERNAL GENITALIA (LYMPHADEMA, PENO-SCROTAL EDEMA)

Megan M. Merrill, DO

BASICS

DESCRIPTION

Pitting or nonpitting edema of 1 or both sides of the penile shaft and scrotal skin due to the accumulation of transudative fluid in the dartos (scrotal) or subcutaneous layer of the penile skin

EPIDEMIOLOGY

Incidence

The incidence is not well documented

Prevalence

Prevalent condition in nursing home and hospitalized patients

RISK FACTORS

- Chronic liver disease
- Congestive heart failure
- Epididymo-orchitis
- Genital trauma or penile fracture
- Hypervolemia
- Indwelling Foley catheter
- Lymphoma
- Medications known to cause lymphedema
- Paraphimosis
- Pelvic or inguinal surgery
- Peritoneal dialysis
- Radiation to the pelvic or inguinal region
- Retroperitoneal surgery
- Squamous carcinoma of the penis

Genetics

- Fragile X Syndrome—mutation in FMR-1 on X chromosome
  - Physical manifestation of macro-orchidism/scrotal edema that becomes more apparent in puberty (1)

PATHOPHYSIOLOGY

- Accumulation of transudate within the subcutaneous tissue of the penile shaft and scrotal skin
  - May be localized to the genital region or part of more extensive lower extremity edema or massive body edema (anasarca)
    - In generalized edema capillary hemodynamics are altered and fluid moves from vascular

space to interstitium according to Starling's law (2)
Net filtration = LpS × (Δ Hp - Δ Op)
Lp = permeability of capillary wall
S = surface area for fluid movement
Hp = hydraulic pressure
Op = oncotic pressure
- Hypoalbuminemia contributes to change in oncotic pressure and worsens edema (2)

– Transient lymphedema can be seen after pelvic surgery, such as radical prostatectomy or radical cystectomy
– Often is localized to the peno-scrotal region

- Rarely, sexually transmitted diseases (STDs) such as lymphogranuloma venereum (LGV) or donovanosis (granuloma inguinale) may cause lymphangitis and lymphatic genital obstruction resulting in chronic fibrosis (elephantiasis) (3)

ASSOCIATED CONDITIONS

- Advanced prostate cancer
- Anasarca
- Ascites/hepatic failure
- Congestive heart failure
- Fournier gangrene
- Lymphatic obstruction (lymphangitis filariasis)
- Lymphoma
- Pelvic or inguinal surgery (eg, pelvic or ilioinguinal lymphadenectomy)
- Paraphimosis
- Renal insufficiency/peritoneal dialysis
- Retroperitoneal lymphadenectomy
- Testicular torsion

GENERAL PREVENTION

- Maintenance of euvolemia
- Foley catheter care

DIAGNOSIS

ALERT

- Edema of the penis and scrotum in an uncircumcised male may indicate paraphimosis, which requires immediate foreskin reduction to avoid glans penis vascular compromise (3).
- Edema of the scrotum with areas of necrosis or devitalized skin may indicate Fournier gangrene and requires emergent urologic consultation and surgical debridement.

HISTORY

- Acute vs. chronic condition
- Acute scrotal pain in a child or young adult may indicate torsion.
- Circumcision: Severe paraphimosis can compromise the glans penis
- Trauma
- Recent inguinal, pelvic or retroperitoneal surgery

- History of lower extremity lymphedema
- History of STDs
- Peritoneal dialysis: Dialysate can leak through inguinal hernias into the scrotum
- Medication history:
  – Pantoprazole, sirolimus, and mycophenolate can cause lymphedema.
  – Angiotensin-converting enzyme (ACE) inhibitors: Angioedema of the genitals reported
- Indwelling Foley catheter
  – BPH or indwelling Foley catheter patients can develop epididymo-orchitis.

PHYSICAL EXAM
- Examine for anasarca
- Evaluate for lower extremity edema
- Pitting or nonpitting edema of the penile shaft and/or scrotal skin
- Note the presence/correct placement of an indwelling Foley catheter
- Reduce foreskin in uncircumcised males
- Inspect for skin integrity
- Bruising or induration with crepitance seen in Fournier gangrene
- Foul odor associated with Fournier gangrene
- Examine testis and epididymis for signs of epididymo-orchitis
- Examine scrotum/ spermatic cord in supine and standing position for presence of varicocele
- Transilluminate the scrotum for hydrocele
- Examine external inguinal ring for herniation
- Cremasteric reflex test for testicular viability
- Evaluate for the presence of inflatable penile prosthesis (IPP), artificial urinary sphincter (AUS), or other foreign body

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- No specific lab tests
- Urinalysis may suggest infection/epididymo-orchitis
- Elevated brain natriuretic peptide (BNP) associated with hypervolemia
- Fractional sodium excretion may suggest fluid overload
- Albumin/pre-albumin levels assess nutritional status

Imaging
- Scrotal ultrasound (US) confirms thickened subcutaneous tissue and may suggest etiology.
- CT may suggest retroperitoneal etiology.

Diagnostic Procedures/Surgery

Physical exam significant for pitting edema of the genital skin

Pathologic Findings

Edematous subcutaneous tissue of the scrotum and penile shaft with possible areas of devitalized skin or necrosis

DIFFERENTIAL DIAGNOSIS
- Acute idiopathic scrotal edema
- Angioedema of the genital skin

- Cellulitis
- Chemical or allergic dermatitis
- Elephantiasis
- Epididymo-orchitis
- Fournier gangrene
- Hydrocele
- Idiopathic scrotal edema (usually children)
- Inguinal hernia
- Paraphimosis
- Retroperitoneal mass
- Squamous carcinoma of the penis
- Testicular torsion
- Varicocele

TREATMENT

GENERAL MEASURES
- Scrotal elevation
- Genital or scrotal compression NOT recommended
- Meticulous care of skin breakdown
- Correction of hypervolemia
- Dialysis if due to severe hypervolemia
- Evaluate for urinary retention—Foley catheter if indicated
- Immediate postoperative edema usually resolves spontaneously

MEDICATION
First Line
- Limited utility
- Diuretics may be of some utility
- Chemotherapy for lymphoma

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Indicated to address the etiologic process: Testicular torsion, inguinal hernia, penile fracture, or Fournier gangrene
- Manual reduction of foreskin or dorsal slit if necessary to address paraphimosis
- Rarely, radical excision with gracilis flap may be required for severe refractory cases

ADDITIONAL TREATMENT
Radiation Therapy
While this can be a cause of genital lymphedema, it may have a role in primary palliative treatment of prostate, penile, and retroperitoneal malignancies causing scrotal edema.

Additional Therapies
Supportive undergarments/briefs for patient comfort

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
Depends on etiology

COMPLICATIONS
- Skin breakdown/ulceration
- Urinary retention/difficulty voiding
- Genital and scrotal compression is NOT recommended

FOLLOW-UP
Patient Monitoring
- Physical exam for resolution
- Monitor underlying condition, appropriate labs, nutritional status

See Also (Topic, Algorithm, Media)
- Edema, Lower Extremity, Urologic Considerations
- Fournier Gangrene
- Testicular Torsion
- Paraphimosis
- Edema, External Genitalia (Lymphedema, Peno-Scrotal Edema) Image

CODES

ICD9
- 605 Redundant prepuce and phimosis
- 607.83 Edema of penis
- 608.86 Edema of male genital organs

ICD10

- N47.1 Phimosis
- N48.89 Other specified disorders of penis
- N50.8 Other specified disorders of male genital organs

CLINICAL/SURGICAL PEARLS

- Determine the patient's fluid status to rule out hypervolemia as the cause of genital edema.
- Acute scrotal pain, swelling, lack of cremasteric reflex, and a high-riding ipsilateral testis could indicate testicular torsion.
- Evaluate for paraphimosis in uncircumcised males.
- Crepitance, induration, necrosis, and foul odor suggest Fournier gangrene and require emergent surgical debridement.
- Complications of edema may include urinary retention and skin breakdown—these should be evaluated for and treated accordingly.

EJACULATION, PREMATURE (PREMATURE EJACULATION)

Elizabeth K. Peacock, MD
James S. Rosoff, MD

BASICS

DESCRIPTION

- Definition of premature ejaculation (PE) remains controversial:
  - ISSM (2008): Ejaculation within about a minute and inability to delay ejaculation with all or nearly all vaginal penetrations causing negative personal consequences (1)
  - WHO (2004): Inability to delay ejaculation with ejaculation before/soon after starting intercourse (15 s)
  - AUA (2004): Ejaculation sooner than desired, before or shortly after penetration that causes distress to 1/both partners
  - EAU (2001): Inability to control ejaculation for sufficient time before vaginal penetration
  - APA (2001): Persistent or recurrent ejaculation with minimal sexual stimulation
- May also be classified as *primary* (lifelong PE) or *secondary* (acquired PE)
- ICD-10 uses 15 s of intravaginal ejaculatory latency time (IELT) as a cutoff

EPIDEMIOLOGY

Incidence

Unknown

Prevalence

- PE is the most common sexual dysfunction in men < 40
- Approximately 20–30% in this group

RISK FACTORS

- Increased levels of arousal due to new partner or situation
- Low frequency of sexual activity

Genetics

Polymorphism in the serotonin transporter promoter region (5-HTTLPR) may play a genetic role in the etiology and/or treatment of PE, though this is controversial.

PATHOPHYSIOLOGY

- Serotonin receptor stimulation (5-hydroxytryptamine):
  - Serotonin 5-HT_{2c} receptors inhibit ejaculation, 5-HT_{1a} receptors facilitate ejaculation
  - Hyposensitivity of 5-HT_{2c} or hypersensitivity of 5-HT_{1a} may cause PE
  - Increase in serotonin transporter (5-HTT) may play a genetic role in PE
- Consider psychological factors, hormone alterations, penile sensitivity, circumcision status, chronic prostatitis as potential causes though with limited evidence supporting these

ASSOCIATED CONDITIONS

- Erectile dysfunction
- General anxiety

- Situational anxiety
- Depression
- Substance abuse
- Relationship distress
- Prostatitis

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Time to ejaculation is essential
  - Duration/frequency of PE
  - Rate of occurrence of PE
  - Degree of sexual stimulation causing PE
  - Nature/frequency of sexual activity including foreplay, masturbation, and intercourse
- Discuss length of time experiencing PE, perceived lack of control, and resultant sexual dissatisfaction
- Any indication of ED
- Issues with the partner, such as dyspareunia or other medical problems
- Rule out symptoms consistent with cystitis or prostatitis
- Medication history: Consider PE due to withdrawal from narcotics or trifluoperazine (Stelazine)
- Sexual History
  - Global to all sexual encounters, or with specific situations and/or partners
  - Religious upbringing
  - Early sexual experiences
  - Sexual relationships, past and present
  - Conflicts or concerns within current relationship
  - Traumatic sexual experiences

PHYSICAL EXAM
- Complete physical exam with focus to rule out biologic causes including recent pelvic surgery or infectious source
- Rectal exam to assess for prostatitis
- Rare to have findings on exam that would define etiology or change management

DIAGNOSTIC TESTS & INTERPRETATION
Lab
Usually unnecessary

Imaging
N/A

Diagnostic Procedures/Surgery
N/A

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS
- Erectile dysfunction
- Generalized anxiety disorder
- Other anxiety states
- Substance abuse

TREATMENT

GENERAL MEASURES
- Behavioral treatment:
  - Stop–squeeze method (Masters and Johnson) involves removal of penis at point of ejaculation with squeezing of glans or frenulum
  - Start–stop method (Seman) involves a pause in intercourse at point of ejaculation
  - High initial success rates are reported, but poor long-term rates are present due to the time-consuming nature of treatment
- Psychotherapy may be beneficial
- Combination of pharmacotherapy and psychotherapy is suggested as current model for treatment

MEDICATION
First Line
- No medications are approved for treatment of PE in the United States
  - SSRIs:
    - Elevates level of serotonin in synapse that results in prolongation of ejaculatory latency time
    - 1st-line pharmacotherapeutic approach (off-label)
    - Daily treatment with PO paroxetine 20–40 mg (greatest evidence), sertraline 25–200 mg, fluoxetine 5–20 mg
    - Newer agents have not been effective (fluvoxamine/venlafaxine)
    - Dapoxetine approved in Europe only for on-demand dosing for PE
  - Topical agents:
    - EMLA: Lidocaine–prilocaine 2.5% cream
    - TEMPE: Metered-dose aerosol spray with lidocaine 7.5 mg and prilocaine 2.5 mg per spray

Second Line
- Clomipramine:
  - Tricyclic antidepressant
  - Daily treatment with 25–50 mg or on-demand treatment with 50 mg 5 hrs prior to intercourse
- Tramadol (synthetic opioid analgesic) with potential treatment role in PE (little evidence) (2)

SURGERY/OTHER PROCEDURES
CT-guided cryoablation of unilateral dorsal penile nerve (single study, 24 patients) (3)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

European Medicines Agency's Committee for Medicinal Products for Human Use (CHMP) has recommended authorization of a cutaneous spray containing a mixture of 150 mg lidocaine and 50 mg prilocaine per milliliter applied to the glans

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Varies by treatment modality. May have up to 80% success rate with medication and/or behavioral modification

COMPLICATIONS

- Medications carry side effects, but complications of PE are limited
- Rarely, a problem with fertility may exist due to inability to complete intercourse
- May provoke anxiety or depression if PE is severe
- May interfere with development of sexual relationship

FOLLOW-UP

Patient Monitoring

- Ejaculation Premature Algorithm

CODES

ICD9

302.75 Premature ejaculation

ICD10

F52.4 Premature ejaculation

CLINICAL/SURGICAL PEARLS

- Exact definition of PE remains controversial.
- Combination of pharmacotherapy (off-label use) and psychotherapy is likely the most beneficial treatment.

EJACULATORY DISTURBANCES (DELAYED, DECREASED, ABSENT)

Pravin K. Rao, MD

BASICS

DESCRIPTION

- Anorgasmia or delayed orgasm/ejaculation
  - Difficulty/inability to reach orgasm
- Low volume ejaculate
  - Suspect if <1.5 cc ejaculate volume
- Aspermia
  - Orgasm with zero ejaculate volume
- Retrograde ejaculation
  - Sperm seen in post-ejaculatory urine
- Ejaculatory duct obstruction (EDO)
  - Congenital, acquired, iatrogenic
- Failure of emissions
  - Can also cause low/zero volume

EPIDEMIOLOGY

Incidence

- Increased in aging (age 50–80 yr) men with BPH/LUTS (1)[B]
  - 46% decreased ejaculation
  - 5% anejaculation
- Men on tamsulosin 0.8 mg
  - ~90% report decreased ejaculatory volume (2)[B]
- Selective serotonin reuptake inhibitors (SSRIs)
  - 16–37% delayed or difficult orgasm
- Anorgasmia is rare:
  - 0.14–0.4% in general population

Prevalence

N/A

RISK FACTORS

- Age
- Benign prostatic hyperplasia
- Lower urinary tract symptoms
- Prostatitis/Ejaculatory duct stones
- Depression and related medications
- Hypogonadism
- Hypertension medications
- Prostate/Urethral /Bladder neck surgery

- Retroperitoneal lymph node dissection (RPLND)
- Cystic fibrosis
- Neurologic conditions/Diabetes
  - Multiple sclerosis, spinal cord injury (SCI), spina bifida, diabetes
- Rectal surgery
- Radiation therapy

Genetics

N/A

PATHOPHYSIOLOGY

- Normal ejaculation:
  - Central control in multiple brain regions
    - Can promote or inhibit ejaculation
  - Sympathetic (T12–L3):
    - Hypogastric nerve (thoracolumbar)
    - Seminal emission by contraction of epididymis, vas deferens/ampulla, seminal vesicle (SV), and prostate smooth muscle
    - Bladder neck closure preventing retrograde ejaculation
  - Parasympathetic (S2–S4):
    - Pelvic nerve
    - Gland secretions of prostate SV
  - Somatic (S2–S4):
    - Pudendal nerve
    - Efferents from sacral cord
    - Contraction of bulbocavernosal and ischiocavernosal muscles
    - Relaxation of external urethral sphincter
    - Projectile expulsion of ejaculate
  - Sensory
    - Pudendal nerve
    - Tactile stimulation of penis can activate ejaculatory reflex
- Anorgasmia/Delayed orgasm
  - Hypogonadism
  - Medication side effect
  - Psychological/Psychiatric (depression)
- Retrograde ejaculation
  - Damage to ejaculatory nerves/reflexes
  - Bladder neck surgery or dysfunction
  - Medications affecting bladder neck
- Low volume ejaculate
  - Poor development/absence of accessory sex organs
  - Retrograde ejaculation or functional problem
  - Medications affecting accessory glands
  - Decreased prostate and SV secretions seen in hypogonadism
- Ejaculation requires intact, properly developed, and coordinated accessory sex organs, nerves, and muscles

  - Congenital, acquired, iatrogenic, infectious, inflammatory causes can all prevent normal ejaculation
  - Functional causes may lead to the complaint of decreased force of ejaculate
  - Ejaculate volume commonly decreases by ~0.03 mL each year with advanced age

ASSOCIATED CONDITIONS

- Psychological/Psychiatric conditions
- See Risk Factors

GENERAL PREVENTION

- Avoidance of bladder neck procedures
  - Transurethral prostate, bladder neck surgery
- Avoidance/decreased use of medications
  - SSRI, α − blockers, 5α-reductase inhibitors
- Nerve sparing at time of RPLND
- Strict diabetic control

DIAGNOSIS

HISTORY

- Duration of symptoms
- No defined criteria for diagnosis of delayed ejaculation
  - Mostly normal men ejaculate after 4–10 min of penetration
  - Presence of significant distress to patient or partner important to diagnosis
- Presence or absence of orgasm
- Perceived ejaculate volume
- Sources of stress/psychological disturbance
- Past medical history
- Retroperitoneal and genitourinary operations
- Family history of cystic fibrosis
  - See vas deferens, congenital absence
- Medications:
  - Antidepressants/antipsychotics
  - Bladder outlet medications
  - Antihypertensives (clonidine)
  - Methyldopa

PHYSICAL EXAM

- Absence or diminished development of epididymides and vasa deferentia
  - Congenital bilateral or unilateral absence of the vas deferens (CBAVD/CUAVD)
- Enlarged SV
  - EDO
- Hypospadias or epispadias
  - Hypogonadism

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Semen analysis
  - Volume: Suspect if ejaculate volume < 1.5 cc
  - Concentration: Low volume azoospermia suspicious for EDO
  - Absence of seminal fructose suggests EDO
- Post-ejaculatory urinalysis (PEU): > 10–15 sperm/HPF demonstrates retrograde ejaculation

Imaging

- Transrectal ultrasound (TRUS)
  - Usually done for low volume azoospermia
    - For patients with negative PEU
  - Normal SV A-P diameter < 1.5 cm
- MRI
  - Can help identify structural abnormalities

Diagnostic Procedures/Surgery

- TRUS with SV aspiration: Presence of numerous sperm suggests obstruction
  - Rare: Seminal vesiculography

Pathologic Findings

Scar tissue at ejaculatory duct

DIFFERENTIAL DIAGNOSIS

- Anorgasmia
- Retarded/Delayed orgasm
- Erectile dysfunction
  - May present as inability to reach orgasm, or with weak force of ejaculate
- Retrograde ejaculation
- Aspermia
- EDO (ejaculatory duct obstruction)

TREATMENT

GENERAL MEASURES

- Remove/modify correctible causes
  - Medications
    - Alfuzosin 21% vs. tamsulosin 90% of patients reported reduced ejaculatory volume (2) [B]
  - Psychological/Stress factors
- Psychological assessment/counseling
- Treat erectile dysfunction
- Sexual counseling on techniques for optimal arousal

MEDICATION

First Line

- Anorgasmia/Delayed ejaculation
  - No drug treatments FDA approved
  - Medications that can be tried include:

- Pseudoephedrine
- Yohimbine

- See “Retrograde Ejaculation”

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Most procedures reserved for infertility treatment
- Transurethral resection of ejaculatory ducts (TUREDs) for EDO
- Penile vibratory stimulation (PVS)
  - For anorgasmic/anejaculatory men
  - Integration with cognitive-behavioral therapy
  - High success (>75%) in SCI, though usually for fertility purposes
  - Procedure: Apply to ventral/frenular region for 1–3 min at a time, with 1 min rest periods, for up to 15–20 min
  - See images of PVS devices:
    - Ferticare
    - Viberect (dorsal and ventral stimulation)
- Electroejaculation (EEJ) via rectal probe
- Autonomic dysreflexia
  - Risk for SCI lesions above T6
  - Can occur with PVS or EEJ
  - Consider nifedipine 10–20 mg PO 10–15 min before treatment initiated
  - Monitor at-risk patients for hypertension, tachycardia, sweats
- Retrieval of sperm from bladder
  - See “Retrograde Ejaculation”
- Testicular or epididymal sperm retrieval
  - Requires IVF/ICSI
  - Donor sperm or adoption may circumvent the need for IVF/ICSI

ALERT
Men with spinca cord injury (SCI) above the T6 level are at risk of autonomic dysreflexia (3).

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
- Pelvic floor physical therapy for associated symptoms of pain or voiding symptoms
- Cognitive-behavioral sex therapy
- Changing idiosyncratic masturbation style if present

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS

- Depends on the etiology, duration, and severity
- >40% SCI men doing PVS with home insemina-tion can achieve pregnancy (3)[B]

COMPLICATIONS

- Infertility implications
- Relationship stress and difficulty

FOLLOW-UP

Patient Monitoring

Based on response to therapy and needs of specific patient

Patient Resources

N/A

CLINICAL/SURGICAL PEARLS

Inclusion of partner in treatment important if recommending change in sexual practice.

ENURESIS, ADULT

Katie S. Murray, DO
Tomas L. Griebling, MD, MPH, FACS

BASICS

DESCRIPTION

- Enuresis is repeated inability to control urine
  - Primary: Starts in childhood and never resolves and continues into adulthood
  - Secondary: New onset in adulthood
- Nocturnal enuresis (NE) is involuntary urination while asleep after the age at which bladder control usually occurs

EPIDEMIOLOGY

2.3% of adult population affected (1)[A]

RISK FACTORS

- Family history of NE
  - If both parents have NE, children have 80% chance

Genetics

- Possibly hereditary
- Related to site on chromosome 13

PATHOPHYSIOLOGY

- Unknown in most situations
- Recognized hypotheses
  - Obstructive sleep apnea causing diminished vasopressin secretion
  - Disturbance in sensation, cortical arousal, or urinary sphincter function
  - Decreased bladder capacity initiating involuntary voiding reflex
  - Nocturnal polyuria because vasopressin secretion or reduction in renal sensitivity to the antidiuretic (2)[B]
  - Detrusor instability during filling phase
  - Urine production increased in recumbent position in patients with peripheral edema or congestive heart failure
- Normal physiology decreases nighttime, relative to daytime, urinary output. Excess production of urine at night, in the setting of a normal 24-hr urine output, is termed nocturnal polyuria
  - Nocturnal polyuria is nighttime excretion of $>35\%$ of a 24-hr urine volume

ASSOCIATED CONDITIONS

- Benign prostatic hypertrophy
- Daytime urinary incontinence
- Psychological disorders including depression
- Sleep apnea

GENERAL PREVENTION
- Timed voiding
- Complete bladder emptying
- Avoidance of caffeine and alcohol
- Adjust timing of fluid intake

DIAGNOSIS
HISTORY
- Have never achieved nocturnal continence of urine
- Nonspecific urinary symptoms
- Ask about known or potential medical history
- Complete surgical and trauma/incident history
- Obtain record of fluid intake habits
- Review medications and times of administration
- Voiding diaries to evaluate frequency, volume, and patterns
- International prostate symptom score (IPSS) in men

PHYSICAL EXAM
- Full urologic exam (pelvic exam in women and DRE in men)
- Full neurologic exam

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis and urine culture: Rule out urinary tract infection, hematuria, proteinuria, glycosuria
- Creatinine: Rule out renal insufficiency
- Urine cytology (if other symptoms such as irritative voiding symptoms make carcinoma a concern)

Imaging
- Post-void residual bladder scan
- Renal/ureteral imaging to evaluate for abnormalities such as ectopic ureters
  - CT urogram
  - Renal ultrasound

Diagnostic Procedures/Surgery
- Bladder diaries/frequency–volume charts
- Cystoscopy with retrograde pyelograms to evaluate bladder and ureters
- Urodynamic testing (3)[B]
  - Identify anatomical urethral abnormalities
  - Identify anatomical bladder abnormalities
  - Evaluate bladder function for possible neurogenic bladder findings
  - May find abnormalities in up to 90% of patients (4)[B]
- Consider sleep medicine consultation and/or polysomnography if clinical concern for sleep apnea

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Obstructive sleep apnea
- Anxiety or psychological disorders
- Anatomic abnormalities
- Idiopathic detrusor instability
- Neurologic disorders

TREATMENT

GENERAL MEASURES

- Conservative measures have varying success rates
- Education is key when attempting to improve enuresis without medical therapy
- Timed voiding
- Complete bladder emptying
- If associated with BPH in men management with α-blockers for 5α-reductase inhibitors
- Avoidance of caffeine and alcohol
- Adjust timing of fluid intake
  - Restrict fluid intake in evening to reduce urine output at night
  - Take diuretic medications early in a day

MEDICATION

First Line

- If due to prostatic hypertrophy: See Section I "Bladder Outlet Obstruction (BOO)."
- Antimuscarinics or β3-agonists (3)[B]
  - Inhibit the effect of acetylcholine at postjunc-tional muscarinic receptors on detrusor muscle cells
  - β3-Adrenergic agonist promotes detrusor muscle relaxation
  - Varying results (5–40%), depends on whether detrusor instability is root cause of enuresis
  - Side effects: Dry mouth, constipation, blurred vision, confusion
- Antimuscarinics
  - Tolterodine (2–4 mg/d)
  - Trospium XR (60 mg/d)
  - Darifenacin (7.5–15 mg/d)
  - Solifenacin(5–10 mg/d)
  - Oxybutynin (IR 7.5–20 mg/d, XL 5–30 mg/d, patch twice weekly)
  - Fesoterodine (4–8 mg/d)
- β3-adrenergic agonist
  - Mirabegron (25–50 mg/d)

Second Line

- DDAVP (Desmopressin) (5)[B]
  - Not currently FDA approved for this clinical indication (has European regulatory approval)
  - Analog of vasopressin

- Decreases urine production for about 5 hr
- Decreases number of enuresis events but may not eliminate it completely
  - Oral 0.2 mg at bedtime; increase to 0.6 mg to response
  - Intranasal formulations are no longer indicated for the treatment of primary NE due to risk for severe hyponatremia with seizures and death
  - Side effects: Nasal irritation, dry mouth, sleep disruption, water intoxication, seizures, heart failure, electrolyte disturbances, hyponatremic coma
  - Use with extreme caution if at all in geriatric patients (>65 yr) due to risk of severe hyponatremia and other adverse events

• Imipramine (5)[B]
- Tricyclic antidepressant
- Mild anticholinergic effect and α-action to increase internal sphincter tone
- Side effects: Sleep abnormalities, decrease appetite, personality disturbances

SURGERY/OTHER PROCEDURES
• Consideration after all conservative and pharmacologic measures have failed
• If urodynamic testing shows detrusor overactivity, may consider additional interventions
- Botulinum toxin injections
- Sacral neuromodulation
- Posterior tibial neuromodulation
- Augmentation cystoplasty
- Urinary diversion

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
• Psychological counseling
- Assist with coping mechanisms and finding any potential underlying issues

Complementary & Alternative Therapies
• Enuresis (bedwetting) alarms
• Timed voiding through the day and night
• Decrease fluid hydration prior to bed
• Empty bladder to completion prior to bed

ONGOING CARE
PROGNOSIS
• Many patients may eventually become dry
- This is more likely in children

COMPLICATIONS
• Urea dermatitis
• Skin breakdown and superficial ulcers from direct contact of urine on skin
• Psychological effects
- Job changes/decreased work performance

– Depression
– Low self-esteem
– Decreased social activities

FOLLOW-UP

Patient Monitoring

- Long-term follow-up until resolution or satisfaction by the patient
- Psychological counseling and follow-up if necessary

Patient Resources

- The Simon Foundation for Continence (simonfoundation.org)
- National Association for Continence (www.nafc.org)

- Enuresis, Pediatrics
- Incontinence, Adult Male
- Nocturia
- Urge Incontinence
- Urgency, Urinary (Frequency and Urgency)

CODES

ICD9

- 307.6 Enuresis
- 788.30 Urinary incontinence, unspecified
- 788.36 Nocturnal enuresis

ICD10

- F98.0 Enuresis not due to a substance or known physiol condition
- N39.44 Nocturnal enuresis

- R32 Unspecified urinary incontinence

CLINICAL/SURGICAL PEARLS

- Evaluating for underlying conditions is important in new onset enuresis.
- Social implications are common.
- Enuresis raised the risk for nighttime falls in elderly.

ENURESIS, PEDIATRIC

Ellen Shapiro, MD, FACS
Daniel A. Wollin, MD

BASICS

DESCRIPTION

- Terminology based on 2006 (International Children's Continence Society) ICCS standards (1)
  - Enuresis is intermittent incontinence of urine while sleeping usually referred to as nocturnal enuresis (NE).
  - This term is used with or without daytime incontinence or other lower urinary tract symptoms (LUTSs)
- Monosymptomatic enuresis (MNE) is nocturnal incontinence without other LUTSs
  - MNE is abnormal in children ≥ 5 yr of age
- Non-NMNE may coexist with increased/decreased voiding frequency, daytime incontinence, urgency, hesitancy, straining, a weak stream, intermittency, holding maneuvers, a feeling of incomplete emptying, post-void dribble and genital/LUT pain
- Primary enuresis if the child has been dry for <6 mo; secondary if the child has been dry for at least 6 mo

EPIDEMIOLOGY

Incidence

- 15% of normal children have NE at age 5
- Of all children with incontinence:
  - 70% with NE only
  - 15% with daytime incontinence only
  - 15% with daytime incontinence and NE
  - 2–3% have NE into early adulthood without treatment

Prevalence

5–7 million with NE in the United States

RISK FACTORS

NE is multifactorial (see "Pathophysiology"")

Genetics

- Primary NE tends to be familial:
  - Both parents with history of NE—77% of children
  - If one parent with history of NE—44% of children
- Several chromosomes have been linked to NE, including 12q, 13q, 22q
  - 5HTR2A gene (13q14, serotonin receptor) mutation shown to be associated with NMNE

PATHOPHYSIOLOGY

- Complex, involving central nervous system, circadian rhythm (sleep and diuresis), and bladder function abnormalities
- 3 major pathogenic mechanisms:

  - Increased arousal threshold
  - Nocturnal polyuria
  - Detrusor overactivity
- Some children lack normal nocturnal increase in vasopressin secretion leading to nocturnal polyuria, but not all children with polyuria are vasopressin deficient
- Overactive bladder leading to "small for age" bladder volume associated with NMNE

ASSOCIATED CONDITIONS

- Neuropsychiatric disorders (children with attention deficit hyperactivity disorder 2.7 × more likely to have NE)
- Upper airway obstruction and nocturnal sleep apnea. Apneic episodes result in increased secretion of atrial natriuretic factor
- Constipation
- Urinary tract infection

GENERAL PREVENTION

MNE may not be preventable but parents should maintain regular voiding and bowel patterns —may help reduce risk of developing NMNE with LUTS.

DIAGNOSIS

HISTORY

- Detailed history helps determine treatment strategies
- Number of nights per week enuresis occurs?
- Symptoms suggestive of underlying bladder dysfunction:
  - Drops of urine in underclothing before or after voiding
  - Frequency of leakage (intermittent or continuous)
  - Daytime incontinence in child over 31/2 yr of age
  - Sudden urge to void
  - Straining, posturing, holding maneuvers
  - Interrupted micturition
  - History of urinary tract infection
  - Urinary tract malformation
    - Spinal cord or vertebral malformation
- Comorbidities that may predict treatment resistance:
  - Constipation and encopresis
  - Behavioral, psychological/psychiatric problems such as ADHD, ADD, autism
  - Motor and/or learning disabilities or delayed development
  - Pattern of fluid intake (incl. caffeine)
    - Does patient drink during the night?

PHYSICAL EXAM

- Abdominal exam for distended bowel/bladder
- Lower back inspection for stigmata of occult spinal dysraphism/tethered cord (sacral dimple, hair tuft, hemangioma, lipoma or other neurocutaneous signatures, absence of a palpable sacrum, or excess fat overlying the sacral region suggestive of a lumbosacral abnormality)

- Genital exam for congenital anomalies such as ectopic ureter or a urogenital sinus (with incontinence due to pooling of urine in the vagina)
  - Labial adhesions in girls
  - Urethral abnormalities or phimosis in boys
- Gait abnormalities, high arched foot

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Macroscopic urinalysis (dipstick) to determine glucosuria, proteinuria or UTI. If glucosuria present, obtain serum glucose at that time
- Microscopic urinalysis and culture if history of UTI or symptoms suggestive of infection

Imaging

- Children with MNE do not need imaging but a post-void residual (PVR) by bladder scan is useful
  - US: May be considered in male patients, especially those who have failed initial therapy to ensure no anatomic problem
  - Some suggest most males with enuresis should have bladder US to rule out posterior urethral valves
- Children with history of UTI or NMNE should undergo:
  - Renal US
  - PVR
  - VCUG when diagnosis suggests posterior urethral valves or in older males; also used to evaluate for bulbar stricture (unusual)
  - Abdominal x-ray to evaluate for vertebral abnormality; also assesses degree of stool retention although history is usually sufficient
  - MRI of the spine for children suspected of having a neurogenic bladder as etiology, for those patients who are compliant and fail all therapeutic alternatives for NMNE, or who have a neurocutaneous signature or other physical findings on the lower spine or physical exam

Diagnostic Procedures/Surgery

- Uroflowmetry: Assesses bladder outlet obstruction or hypocontractility; evaluates voiding pattern (staccato)
- Urodynamics: Helpful in evaluating bladder compliance and function in children with severe dysfunctional voiding or enuresis due to neurogenic bladder or posterior urethral valves
- Cystoscopy: Routine use should be avoided
  - May be helpful in the assessment of select patients with potential anatomic causes

Pathologic Findings

- Neurogenic bladder
- Ectopic ureter
- Posterior urethral valves
- Urethral stricture

DIFFERENTIAL DIAGNOSIS

- Ectopic ureter in girls, extremely rare in boys

- Giggle incontinence (enuresis risoria)
- Neurogenic bladder
- Nonneurogenic neurogenic bladder
- Posterior urethral valves (boys)
- Tethered cord
- Urethral stricture
- Vaginal voiding

TREATMENT

GENERAL MEASURES (2–6)

- Before embarking on any therapy, the interest and ability of the child and family to comply should be determined
- Patience and compliance should be emphasized because many months may be required to achieve improvement or resolution
- Motivational therapy should be encouraged in almost every case; it is useful in conjunction with other treatments
- Behavioral therapy is prerequisite to medications in most patients with monosymptomatic NE
- Enuresis alarm for MNE works with well-motivated families and children
  - Treatment may take 2–3 mo
  - Mechanism of action for behavioral therapy unclear
  - Initial cure rate as high as 70%; suggest 4 mo of consecutive dryness
  - Relapse can be high, but 50% achieve long-term cure

MEDICATION

First Line

- DDAVP (desmopressin) for NE:
  - 0.2–0.6 mg PO 1 hr before bed. No fluid intake 2 hr before and 8 hr after bedtime
  - Success rate ~20–50%
  - Caution in patients with cystic fibrosis (hyponatremic dehydration)
  - Tapering schedule imperative
  - Give parents copy of FDA warning (Dec 2007) regarding fluid intoxication and seizures (see “Additional Reading”)

Second Line

- Imipramine for NE: Tricyclic antidepressant with anticholinergic effects
  - Success rates of 25–40%, but relapse rates can be high
  - 25–50 mg
  - Tapering schedule imperative

ALERT

Imipramine overdose can result in seizure, hypotension, coma, and fatal arrhythmias; may prolong QT interval.

- Oxybutynin (anticholinergic) for NMNE:
  - 2.5–5 mg BID–QID (0.2 mg/kg/dose) when PVR negligible

- Available in long-acting form (5–10 mg/d)
- Success primarily when the medication is used with a well-organized treatment program including voiding 1st thing in the morning, timed voiding during the day, and regular bowel habits.
- Patients should be seen in 4–6 wk for evaluation including urinalysis and PVR. If elevated PVR, lower the dose and institute double voiding.

• Tolterodine (anticholinergic) for polysymptomatic or daytime incontinence:
- 1–2 mg BID. Also available in long-acting form (2–4 mg/d)
- More success when the medication is used with a well-organized treatment program

• Low-dose prophylactic antibiotics for NMNE:
- Helpful for children with recurrent UTI or bacteriuria with LUTS and voiding dysfunction
- Nitrofurantoin recommended 1–2 mg/kg QHS

SURGERY/OTHER PROCEDURES

• Only in cases of congenital anomalies (ectopic ureter, posterior urethral valves, etc.)
• Neurosurgical intervention for spinal anomalies, tethered cord

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

• Children with dysfunctional voiding/elimination syndromes may benefit from elimination retraining program and selective use of anticholinergic medications
- Use toilet at regular intervals during the day (every 21/2–3 hr)
- Waking children prior to the bedtime of the parents does not promote long-term dryness

• Fluid restriction useful and mandatory especially with dDAVP
• Treat constipation if present—patient should have at least daily bowel movements that are easy for the child to pass

Complementary & Alternative Therapies

• Pediatric biofeedback can be effective in cases of dysfunctional voiding. Most helpful in addition to improved voiding and bowel habits
- Child must have sufficient cognitive ability to understand teaching

ONGOING CARE

PROGNOSIS

• After age 5, spontaneous resolution rate of 15%/yr for bedwetters
• After age 15, <1% have NE
• Over 6.5 yr of follow-up:
- 91% no longer incontinent during the day
- 84% no longer wet at night
- With UTI history UTI, 82% no longer have infections

COMPLICATIONS

• Recurrent UTI
• Persistence of incontinence and LUTS—requires further investigation with VUDs and MRI

- Persistence of enuresis into adulthood (2–3%)
- Social consequences/withdrawal

FOLLOW-UP

Patient Monitoring

- Children with history of UTI or organic causes of enuresis should be followed for the specific condition
- Monitor closely while on medication to treat the enuresis (PVR and urinalysis)

Patient Resources

CLINICAL/SURGICAL PEARLS

The primary therapy for all children with NE should be initial behavioral management before relying on medications.

EPIDIDYMIS, MASS (EPIDIDYMAL TUMORS AND CYSTS)

Ramiro J. Madden-Fuentes, MD
Judd W. Moul, MD, FACS

BASICS

DESCRIPTION
- Small, discernible growth anywhere along the epididymis
- Frequently asymptomatic, discovered on routine genital exam or incidentally by the patient
- Pain may be presenting symptom

EPIDEMIOLOGY
Incidence
- Not well defined
- Epididymal cysts are usually asymptomatic and may occur in up to 30% of asymptomatic males
- Cysts more common with advancing age
- Adenomatoid tumors—benign and most common (1)

Prevalence
Not well defined

RISK FACTORS
- Aging
- Von Hippel–Lindau disease associated with cystadenoma
- DES exposure in utero: Epididymal cysts
- Prior vasectomy

Genetics
Epididymal cystadenoma associated with Von Hippel–Lindau syndrome (hereditary, autosomal dominant)

PATHOPHYSIOLOGY
- Most solid lesions benign (such as adenomatoid tumors)
- Malignant lesions uncommon
- Metastatic disease is rare but reported

ASSOCIATED CONDITIONS
- Von Hippel–Lindau disease
- Young syndrome

GENERAL PREVENTION
- Routine self-exam for identification of scrotal content masses
- Routine genital exam by physician

DIAGNOSIS

HISTORY

- Age: Cystic lesions increase with age
- Timing of identification
- Interval growth
- Associated pain
- Dysuria, hematuria, frequency, urgency, tenderness—consider epididymitis
- Exposure to tuberculosis (TB)
- History of sarcoidosis, histoplasmosis
- History of vasectomy
- History of urinary tract infection (UTI) or sexually transmitted infection
  - History of anal insertive intercourse increases risk of coliform or STD infection
- Recent GU manipulation
  - Bacillus Calmette–Guérin (BCG) instillation
  - Catheterization
  - Transurethral procedure

PHYSICAL EXAM

- Scrotal exam
  - Identify location of mass—single or multiple
  - Compare with contralateral scrotal contents
  - Evaluate if fixed, mobile, indurated, or encroaching on other structures
  - Identify spermatic cord/vas deferens
  - Scars from vasectomy—sperm granuloma, epidermal inclusion cyst
  - Examine testicle for associated masses
- Inguinal exam
  - Evaluate for lymphadenopathy
  - Hernia

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis: to evaluate for UTI. Include urine culture if suspicious for infection.
- Tumor markers if any concern for testicular mass
  - α-Fetoprotein (AFP), β-human chorionic gonadotropin (β-HCG), lactate dehydrogenase (LDH)
- Purified protein derivative (PPD) if TB suspected

Imaging

- Scrotal ultrasound
  - Solid vs. cystic
  - Location—testicular or paratesticular
  - Vascular or avascular
  - Cannot reliably differentiate between malignant or benign
- Chest x-ray if TB suspected
- If rhabdomyosarcoma and >10 yr old—CT scan of the abdomen and pelvic with contrast to evaluate for retroperitoneal nodes (2)[A]

Diagnostic Procedures/Surgery

- Rarely needed for epididymal lesions

- Inguinal approach
- Frozen section for pathology; proceed to orchiectomy with high cord ligation if malignant

Pathologic Findings

- Benign
  - Adenomatoid
  - Epididymal cystadenoma/papillary cystadenoma
  - Spermatocele
- Malignant
  - Rhabdosarcoma
  - Leiomyosarcoma
  - Fibrosarcoma
  - Metastatic carcinoma

DIFFERENTIAL DIAGNOSIS

- Adenomatoid tumor of the epididymis:
  - Most common solid tumor of the epididymis
- Ectopic tissues:
  - Adrenal cortical rests
  - Splenogonadal fusion
- Epidermoid cyst
- Epididymal calcinosis
- Epididymal cystadenoma/papillary cystadenoma:
  - 2/3 associated with von Hippel–Lindau syndrome
  - 1/3 of all epididymal tumors
  - 2/3 associated with VHL syndrome
  - On US, most common appearance is 15–20-mm solid mass with small cystic components.
- Epididymitis:
  - Acute; very tender on exam
  - Chronic; may have secondary calcification
  - Common cause of epididymal pain
- Fibroma of epididymis
- Fibrous pseudotumor
- Funiculitis
- Granulomas: Sarcoidosis, TB, histoplasmosis
- Hernia
- Hydrocele
- Hydrocele of the cord
- Leiomyoma
- Malignant epididymal tumor:
  - Primary (very rare): Liposarcoma, rhabdomyosarcoma (high on differential in children), leiomyosarcoma, adenocarcinoma, lymphoma
  - Metastatic: Prostate, kidney, stomach most common
- Papillary cystadenoma
- Polyorchidism
- Sarcoid

- Sperm granuloma:
  - Seen in 40% postvasectomy or 2.5% idiopathic in general population
  - Granulomatous lesion with few giant cells
  - Consequence of extravasation of spermatozoa generally postvasectomy (of vasectomized men and of general population)
- Testicular tumor
- TB of the epididymis
- Varicocele
- Vasitis and vasitis nodosa (usually associated with epididymitis)
- Young syndrome (obstructive azoospermia, sinusitis, bronchiectasis)

TREATMENT

GENERAL MEASURES

- As most epididymal lesions are benign, observation for asymptomatic cystic lesions
- Epididymitis
  - Consider sexually transmitted infection as source in young men and treat accordingly (See "Sexually Transmitted Infections [STIs] (Sexually Transmitted Diseases [STDs]), General)"
  - Older men more likely to be infected by enteric organisms *Escherichia coli*, other coliforms, and Pseudomonas

MEDICATION

First Line

- Epididymitis (3)[A]
  - < 35 year old: Consider gonorrhea and chlamydia
    - Ceftriaxone IM 500 mg × 1 AND
    - Azithromycin 1 g PO × 1
  - > 35 year old: Enteric organisms
    - Levofloxacin 500 mg PO daily × 10 days
- TB: Treat according to current CDC guidelines (http://www.cdc.gov/tb/)

Second Line

- Epididymitis (3)[A]
  - Doxycycline 100 mg PO BID × 10 days in lieu of azithromycin

SURGERY/OTHER PROCEDURES

- Excision of suspicious lesion via inguinal approach
- Frozen section
- If positive for malignancy, radical orchiectomy
- Further surgical therapy guided by pathology but may include retroperitoneal lymph node dissection if rhabdomyosarcoma

ADDITIONAL TREATMENT

Radiation Therapy

Use of radiation for local control of rhabdomyosarcoma in young patient is controversial

Additional Therapies

- Chemotherapy
  - Vincristine, cyclophosphamide, dactinomycin may have a role in rhabdomyosarcoma depending on extent of disease and oncologist recommendations (4)[A]

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Adenomatoid tumors
  - Benign, excellent prognosis
- Rhabdomyosarcoma
  - In children with low stage disease survival may be as high as 90%. Worst stage (IV), survival is ~5.2% (4)[A]

COMPLICATIONS

- Untreated epididymitis can cause severe systemic illness.
  - More advanced infections can present with testicular swelling and pain (epididymo-orchitis).
- If radiation or chemotherapy needed:
  - infertility, higher risk for secondary neoplasms including lymphoma, leukemia, soft tissue sarcomas

FOLLOW-UP

Patient Monitoring

- Oncologic follow-up if malignant disease
- Teach patient testicular self-exam

Patient Resources

National Cancer Institute.

CODES

ICD9
- 222.3 Benign neoplasm of epididymis
- 608.89 Other specified disorders of male genital organs

ICD10
- D29.30 Benign neoplasm of unspecified epididymis
- D29.31 Benign neoplasm of right epididymis
- N50.8 Other specified disorders of male genital organs

CLINICAL/SURGICAL PEARLS

- Most epididymal lesions are benign and should be followed serially.
- Treatment for epididymitis is guided by risk of STIs as a source.
- Ultrasound is important to delineate a testicular vs. paratesticular origin of the mass.
- Ultrasound cannot reliably differentiate malignant solid tumors from benign tumors.
- Rhabdomyosarcoma predominantly occurs in children.

EPIDIDYMITIS

Jonathan H. Huang, MD
Wayland Hsiao, MD

BASICS

DESCRIPTION

- Epididymitis is an inflammatory condition of the epididymis
  - Acute epididymitis is a clinical syndrome consisting of pain, swelling, and inflammation of the epididymis that lasts < 6 wk
    - Usually infectious but occasionally inflammatory due to trauma or other cause
  - Chronic epididymitis is characterized by a ≥ 6-wk history of symptoms of discomfort and/or pain in the scrotum, testicle, or epididymis
- Infectious epididymitis is often associated with orchitis
  - Left untreated localized infectious epididymitis can lead to more extensive infection to include the testicle
- Thought to be the most common cause of scrotal pain in men

EPIDEMIOLOGY (1)

Incidence

Estimated at 1 in 100 males in the United States

Prevalence

- 42% of cases are in males 20–39 yr old
- Reported from infancy to the elderly population

RISK FACTORS

- High-risk sexual behavior (multiple sexual partners, sex without condoms)
- Poor hygiene
- Being uncircumcised
- Instrumentation or manipulation of the genitourinary tract
  - Catheterization, transurethral surgery
- Urinary tract obstruction (benign prostate hypertrophy, urethral strictures, bladder cancer, prostate cancer)
- Amiodarone usage
- Tuberculosis (TB)
- Treatment with Bacillus Calmette–Guérin (BCG) for superficial bladder cancer
- Systemic inflammatory diseases (Behçet disease, sarcoidosis)

Genetics

N/A

PATHOPHYSIOLOGY

- Acute infectious epididymitis (< 6-wk duration) is often due to retrograde spread of infection toward the epididymis
  - Infants and children

- Associated with congenital genitourinary abnormalities
- Reactive process after a nongenitourinary viral infection

– Sexually active males
- Associated with sexually transmitted diseases (STDs), often *Neisseria gonorrhoeae* and *Chlamydia trachomatis*

– Elderly males
- Associated with urinary stasis from benign prostate hypertrophy and catheterization

• Other infectious causes:
– Bacterial
- *Escherichia coli*, *Salmonella enterica*, *Ureaplasma urealyticum*, *Corynebacterium pseudotuberculosis*, *Mycoplasma genitalium*, *Brucella ovis*, *Pseudomonas* species, *Toxoplasma* species

– Fungal (more common with HIV)
- *Cryptococcus* species

– Filarial
- *Wucheria bancrofti*

– Viral (more common with HIV)
- Cytomegalovirus

• Noninfectious epididymitis
– Trauma
– Amiodarone usage
- Antiamiodarone antibodies interact with the elevated concentration of amiodarone in the epididymis, leading to inflammation

– Behçet disease
- Etiology of epididymitis is unclear

– Sarcoidosis
- Noncaseating granulomas in the epididymis lead to inflammation

• Chronic epididymitis (>6-wk duration)
– Inadequately treated acute epididymitis
– Postvasectomy syndrome
- Reported in 1 in 100 males

• TB
– Suspected to be due to hematogenous spread; usually a chronic granulomatous reaction

• BCG treatment for superficial bladder cancer can lead to epididymitis

ASSOCIATED CONDITIONS

• Orchitis
• Hydrocele
• Immunosuppression

GENERAL PREVENTION

• Condom usage
• Proper hygiene
• Avoiding unnecessary instrumentation of the genitourinary tract

ALERT

Emergency evaluation for testicular torsion is indicated when the onset of pain is sudden, pain is severe, or the test results available during the initial examination do not support a diagnosis of infection.

DIAGNOSIS

HISTORY

- Testicular pain
  - Gradually worsens in epididymitis
  - Rapid onset and intense in testicular torsion
- Sexual intercourse without condom including anal receptive unprotected sex
- Instrumentation of the genitourinary tract
- Review of systems may help elucidate other causes (ie, amiodarone usage, TB, Behçet disease, sarcoidosis)
- Chronic Epididymitis Symptom Index (CESI) has been described for cases that last >3 mo

PHYSICAL EXAM

- Epididymal tenderness
  - Positive in 90–97% of patients
  - Ipsilateral and contralateral testicle may be involved
  - Spermatic cord may be involved
- Erythema of the scrotum
- Fever
- Genital exam
  - Lesions related to STDs
  - Urethral discharge
  - Ulcerations from Behçet disease
  - Hydrocele
    - A reactive process sometimes related to the epididymal inflammation
- Prostate exam
  - Rule out prostatitis, especially in males with chronic epididymitis
- Prehn sign
  - Used to rule out testicular torsion
  - Alleviation of pain, with elevation of the testicle, is more consistent with epididymitis (negative Prehn sign)
  - Only positive in 8% of children with epididymitis

DIAGNOSTIC TESTS & INTERPRETATION

Lab (3)

- Used to rule in a source of infection
- Urethral exudate
  - Gram stain with at least 5 white blood cells (WBC) per oil immersion field
    - Gram-negative bacilli is suggestive of *E. coli* infection and underlying cystitis
    - Intracellular gram-negative diplococci suggests a diagnosis of *N. gonorrhoeae* infection
    - Findings of only WBC are suggestive of *C. trachomatis* in 2/3 of cases
  - Send for culture and sensitivity

- Urine analysis
  - Assess for leukocyte esterase or at least 10 WBC per high power field
- Urine culture (midstream clean catch)
  - Send for culture and sensitivity
- C-reactive protein
  - Acute phase protein that is elevated in epididymitis
  - Sensitivity of 96.2%; specificity of 94.2%
- When an STD is suspected, the patient should be screened for other STDs, including human immunodeficiency virus (HIV)

Imaging (4,5)

- Color Doppler scrotal ultrasound (US)
  - Hyperemia and swelling in epididymitis
    - Sensitivity of 70%; specificity of 88%
    - Negative US, when positive clinical findings, should not necessarily alter management
  - Decreased blood flow in testicular torsion
    - Sensitivity of 100%
  - May identify an abscess
- Radionuclide imaging with Tc-99m pertechnetate
  - High sensitivity and specificity in differentiating testicular torsion from epididymitis
  - Rarely used in the United States

Diagnostic Procedures/Surgery

- Testicular exploration
  - Not used as 1st-line diagnostic procedure
  - Used when clinical suspicion for testicular torsion is high
- In infants and children with epididymitis, up to 75% have genitourinary abnormalities
  - Renal ultrasound and voiding cystourethrography are recommended when there are clinical signs of epididymitis and a positive urine culture

Pathologic Findings

- Inflammation
- Infection
- Possible fibrosis

DIFFERENTIAL DIAGNOSIS

- Abscess
- Chronic pelvic pain syndrome
- Epididymitis (acute vs. chronic)
- Interstitial cystitis
- Orchitis
- Partial spermatic cord torsion
- Prostatitis
- Referred pain (inguinal hernia renal colic, aneurysm, hip pain, lower back pain)
- Spermatocele
- Testicular cancer
- Testicular torsion

- Varicocele

TREATMENT

GENERAL MEASURES

- Acute epididymitis
  - Treat infections
  - Decrease inflammation (NSAIDs)
  - Pain control (NSAIDs, prescription pain medications)
  - Scrotal support
  - Ice/heat based on response
  - Avoid sexual activity for at least 1 wk following the initiation of therapy and until symptoms resolved
- Chronic epididymitis
  - Course of antibiotics is appropriate initially; if no relief observation and reassurance are recommended for mild symptoms
  - Scrotal support
  - Avoid aggravating activities
  - Local heat therapy/Sitz baths

MEDICATION (1)

First Line

- For infections tailor therapy to age and history
  - Ciprofloxacin and other quinolones are no longer recommended for gonococcal/nongonococcal infections due to resistance
- Empiric therapy to treat *N.* gonorrhea and *C. trachomatis* should be initiated pending lab results
  - Ceftriaxone 250 mg intramuscularly in a single dose along with either
    - Azithromycin 1 g PO × 1 dose OR
    - Doxycycline 100 mg orally BID for 10 days
- Epididymitis due to enteric organisms
  - Levofloxacin 500 mg orally once daily for 10 days or ofloxacin 300 mg orally twice daily for 10 days
- Epididymitis due to TB
  - Systemic antibiotics based on most current CDC guidelines or local guidelines if available local guidelines
- Epididymitis due to intravesical BCG
  - Fluoroquinolone (eg, levofloxacin 500 mg once daily)

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Drainage if abscess present
- Epididymectomy (2)
  - Not used as 1st-line treatment

  – Reserved for severe acute or chronic epididymitis/epididymalgia
  – Patient needs to understand that there is only at best a 50% chance of pain relief
  – Outcomes appear improved in the setting of postvasectomy chronic epididymitis
  – Fertility issues need to be addressed
- Testicular denervation
  – Not widely used
  – Reserved for patients who failed conservative management
  – Pain relief noted in 71% of cases

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Scrotal elevation
- Limitation of activity
- Ice packs

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Pain often improves within 48–72 hr after treatment of acute epididymitis
  – Induration may remain for up to 4 wk
- Chronic cases can be difficult to treat

COMPLICATIONS

- Chronic or recurrent epididymitis
- Epididymal and/or testicular abscess
- Infertility
- Testicular atrophy
- Fournier gangrene

FOLLOW-UP

Patient Monitoring

- Patients should follow up within 3–7 days after initiation of treatment, especially if symptoms have not improved
- Infants and children may need to be assessed for genitourinary abnormalities
- Elderly males may need to be assessed for urinary tract obstructions
- Screening and treatment of partners for STDs

CODES

ICD9

- 016.40 Tuberculosis of epididymis, unspecified
- 098.0 Gonococcal infection (acute) of lower genitourinary tract
- 604.90 Orchitis and epididymitis, unspecified

ICD10

- A18.15 Tuberculosis of other male genital organs
- A54.23 Gonococcal infection of other male genital organs
- N45.1 Epididymitis

CLINICAL/SURGICAL PEARLS

- In men <35-yr-old STI/STD with *C. trachomatis* and *N. gonorrhoeae* are the most common organisms responsible for bacterial epididymitis.
- In older men suspect coliform bacteria.
- Testicular torsion needs to be ruled out in cases of acute scrotal pain (clinical exam and Doppler US as appropriate).

EPISPADIAS

Sarah M. Lambert, MD
Pasquale Casale, MD, FACS
Paul H. Noh, MD, FACS, FAAP

BASICS

DESCRIPTION

- Congenital anomaly characterized by a dorsal opening of the urethra, resulting in dorsal chordee and widely displaced corporeal bodies.
- Often associated with the so-called "exstrophy–epispadias complex" a wide spectrum of abnormalities that can include classic bladder exstrophy, epispadias, and cloacal exstrophy.
  – Each of these anomalies is considered to arise from the same basic embryologic defect.

EPIDEMIOLOGY

Incidence

- 1 in 117,000 newborn males (1)[A]
- 1 in 484,000 newborn females (1)[A]
- Male > Female (3:1–5:1) (1)[A]

Prevalence

N/A

RISK FACTORS

None identified

Genetics

None sporadic

PATHOPHYSIOLOGY

- On the same spectrum of exstrophy
- Failure of medial migration of mesenchyme between the ectodermal and endodermal layers of the cloacal membrane due to premature rupture of the cloacal membrane
- The mesenchyme that forms the genital tubercles at the 5th wk of gestation fails to migrate completely toward the midline, resulting in a defect in the dorsal urethral wall

ASSOCIATED CONDITIONS

- Exstrophy
- Urinary incontinence
- VUR: Incidence of 30–75% (1)
- Inguinal hernias: Incidence of 33% (1)
- 2.8% concomitant renal anomalies, duplicated collecting system most common
- Concomitant colorectal anomalies with 1.8% (exstrophy/epispadias), imperforate anus most common

GENERAL PREVENTION

N/A

DIAGNOSIS

HISTORY

- Usually recognized at birth
- Less severe forms, especially in females, may go unrecognized until the child experiences persistent urinary incontinence after toilet-training or UTIs
- Urinary incontinence due to open bladder outlet and absence of urinary sphincter. The more proximal the urethral meatus, the greater the degree of incontinence
- There may be a family history of exstrophy–epispadias, although rare

PHYSICAL EXAM

- Males:
  - Displaced meatus, ranging from glans to penile shaft to peno-pubic region to subsymphyseal location
  - Open urethral plate visible on dorsum of phallus
  - Divergent peno-pubic attachments due to public diastasis, resulting in splaying of corpora cavernosa and a short, pendular penis with dorsal chordee, similar to that seen in exstrophy
  - Ventral hood of foreskin
  - Assess position of testes
- Females:
  - 3 degrees of female epispadias, according to Davis (1)
    - I: Urethral orifice appears patulous
    - II: Urethra split dorsally along most of urethra
    - III: Urethra open dorsally along its entire length into the bladder neck, rendering patient incontinent. Most common female type
  - Bifid clitoris
  - Mons pubis depressed and covered in glabrous skin
  - Labia minora poorly developed and terminated anteriorly at clitoris
  - Vagina and internal genitalia usually normal
- Other:
  - Should assess for any degree of bladder prolapse or exstrophy
  - Low-set umbilicus with exstrophy
  - Public diastasis due to outward rotation of innominate bones, usually not as wide as in exstrophy–epispadias complex
  - Evaluate for inguinal hernias

DIAGNOSTIC TESTS & INTERPRETATION

Lab

CBC, renal profile

Imaging

- Plain x-ray to assess orientation of pelvic bones; osteotomies should be done if pubic diastasis is >4 cm.
- Renal/bladder US to assess presence/absence of 2 kidneys and presence/absence of hydronephrosis, due to increased risk of renal agenesis, ectopic renal location, and VUR.
- Voiding cystourethrogram to assess bladder capacity, bladder outlet, presence/absence of

VUR.

Diagnostic Procedures/Surgery
Cystourethroscopy to assess length of urethra, presence/competency of sphincter, bladder capacity/quality, location/quality of ureteral orifices.

Pathologic Findings
- N/A

DIFFERENTIAL DIAGNOSIS
- Varying degree of epispadias
- Classic bladder exstrophy

TREATMENT

GENERAL MEASURES
- Usually managed along with bladder exstrophy, which is commonly present.
- Complete continence may not be achieved for months to years after initial surgery.
- In males, continence may not occur until puberty with maturation of prostate.

MEDICATION
First Line
Anticholinergic therapy may help with bladder development and modeling to promote increased capacity with good compliance once surgery has increased outlet resistance.

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Goals:
  - Protection of upper tracts, including correction of VUR and maintenance of a low-pressure system
  - Achieve urinary continence
  - Reconstruction of external genitalia for optimal functional and cosmetic results
- 1st stage:
  - Bladder closure between 3 to 6 mo of age. Patient is left with an epispadias
  - Can also be done as a single stage with bladder closure and urethral reconstruction known as the “Complete Primary Repair of Exstrophy.” Higher incidence of glanular loss than staged repair
  - Osteotomies are needed if the pubic diastasis is 4 cm or greater on plain x-ray. It was once thought that if the surgery was done in the 1st 48 hr of life that osteotomies are not needed. Current management favors osteotomies to maximize continence
  - Patients need to be immobilized after surgery to allow pelvic bone healing if osteotomies are needed
- 2nd stage:
  - Typically performed 6 mo to a year after 1st stage
- Males:
  - Administer testosterone stimulation preoperatively if penile length not adequate.

  - At 6 to 12 mo of age, perform modified Cantwell–Ransley epispadias repair, involving tubularization of intact urethral plate with reverse meatal advancement and transposition of urethra ventral to corpora cavernosa
  - Also must correct dorsal chordee by division of suspensory ligaments, freeing attachments from undersurface of inferior public ramus, and medially rotating the corpora cavernosa, and occasionally performing cavernostomy
- Females:
  - At 12–18 mo of age, perform genitoplasty and urethroplasty
  - Edges of urethra approximated for tubularization
  - Clitoris and labia minora reapproximated
  - Mons may be reconfigured
- 3rd stage:
  - Most commonly, Young–Dees–Leadbetter bladder neck reconstruction affords best chance at continence
  - Often, ureters must be reimplanted at same time due to proximity to bladder neck or VUR. Cohen technique usually preferred

ADDITIONAL TREATMENT

Further surgery may be necessary to correct complications of initial surgery or to achieve improved cosmesis or complete continence.

Additional Therapies

N/A

Complementary & Alternative Therapies

Psychological: If signs of self-esteem or sexual dysfunction arise, psychological therapy plays a crucial role and should be implemented early on in diagnosis of emotional issues.

ONGOING CARE

PROGNOSIS

- Continence rates after bladder neck reconstruction range from 70% to 87% (2 – 5).
- Satisfactory cosmesis after penile reconstruction ranges from 55% to 84% (6,7).
- Erectile function is almost universally preserved.
- The ability to participate in satisfactory intercourse and to have children is difficult to assess, as this requires long-term follow-up. Most reports seem to indicate the majority of patients can have intercourse and many males have even fathered children.

COMPLICATIONS

- The most common is fistula formation, with an incidence of 4–40% after urethroplasty in males, although many of these will close spontaneously (2,4,7).
- Other less common complications are stricture, meatal stenosis, wound infection, diverticulum, and ureteral obstruction.
- If there is tension on the closure, dehiscence is a major complication that might result.

FOLLOW-UP

Patient Monitoring

- After epispadias repair:

  – Remove urethral catheter 1–2 wk after surgery
  – Regular cystoscopy to assess urethra and bladder capacity
  – Regular upper tract monitoring with renal/bladder US to ensure healthy upper tracts.
- After bladder neck repair:
  – Initiate suprapubic tube capping trials a few weeks after surgery
  – Can remove SP tube once PVRS are minimal
  – Continuation of prophylactic antibiotics until resolution of VUR confirmed and child voiding well
  – Regular upper tract monitoring with US
  – Urodynamics may be necessary with cystometrogram and urethral pressure profilometry in cases of persistent incontinence or infection

- Epispadias Image ☼
- Exstrophy, Bladder (Classic Exstrophy)
- Exstrophy, Cloacal
- Exstrophy–Epispadias Complex

CODES

ICD9

- 752.62 Epispadias
- 753.5 Exstrophy of urinary bladder
- 753.8 Other specified anomalies of bladder and urethra

ICD10

- Q64.0 Epispadias
- Q64.10 Exstrophy of urinary bladder, unspecified

CLINICAL/SURGICAL PEARLS

- Female epispadias is not well recognized. It often presents after birth because of complaints of incontinence.
- Antenatal ultrasonography may be suggestive of exstrophy–epispadias complex: Findings of abnormal genitalia, low set umbilical cord, inability to identify bladder on ultrasound.

ERECTILE DYSFUNCTION, FOLLOWING PELVIC SURGERY OR RADIATION

Boback M. Berookhim, MD, MBA

BASICS

DESCRIPTION

- Erectile dysfunction (ED), defined as the inability to achieve or maintain an erection for sexual activity, is very common after major pelvic surgery or radiation.
- Curative therapy for prostate cancer, particularly radical prostatectomy (RP) and radiation therapy (RT), are well-defined causes of ED.
- ED after pelvic surgery is sudden in onset with gradual improvement within 24 mo postoperatively.
- ED after pelvic RT has an insidious onset, with a "honeymoon" period of 1 yr following treatment and significant worsening between 3–5 yr.

EPIDEMIOLOGY

Incidence

Not reported

Prevalence

- Rates of ED post-RP/RT vary widely due to definitions, patient populations, and time-point following treatment
- 30–90% after RP
- 6–90% after RT, including brachytherapy (BT)
- Prospective, multicenter, cohort study reported 2-yr ED rates: (1)[B]
  - 65% post RP
  - 63% post external beam RT
  - 57% post BT

RISK FACTORS

- Age
- Pretreatment erectile function
- Quality of nerve sparing
- Surgeon experience and volume
- Concomitant androgen deprivation therapy (ADT) with RT
- RT dose and duration
- Cardiovascular disease and risk factors

Genetics

- Single nucleotide polymorphisms (SNPs) have been identified that are associated with ED following RT but require validation.
- Genetics of cavernous nerve regeneration following RP are under investigation.

PATHOPHYSIOLOGY

- Pelvic Surgery/RP:
  - Injury to cavernosal nerves leading to neuropraxia and lethal axonal damage.
  - Apoptosis of smooth muscle and endothelium within the penis.
  - Potential end-organ failure with corporal smooth muscle fibrosis leading to cavernous venocclusive dysfunction over time.
  - Role of arterial injury is not well defined.
    - Data suggests preservation of accessory pudendal arteries may help prevent post-op ED.
- RT:
  - Endothelial cell and microvascular arterial injury leading to arterial insufficiency and ultimately ischemia.
  - Small likely role of cavernous nerve injury following RT.
  - RT-induced corporal tissue fibrosis leading to cavernosal vono-occlusive dysfunction (CVOD aka venous leak).

ASSOCIATED CONDITIONS

Treatment effects are generally dependent upon the modality used and are discussed elsewhere.

GENERAL PREVENTION

- Pelvic surgery/RP:
  - Cavernous nerve sparing surgery
  - Sparing of accessory pudendal arteries intraoperatively
- RT:
  - Reducing volume of tissue irradiated is postulated to reduce likelihood of ED
  - No definitive evidence supporting use of intensity-modulated radiation therapy (IMRT), BT, or proton beam RT to reduce ED
  - Treatment plans limiting RT to the corpora cavernosa may have a beneficial effect
- Penile rehabilitation:
  - Signals from studies suggesting early rehabilitation (phosphodiesterase Type 5 Inhibitors [PDE5i], intracavernosal injections) can impact posttreatment erectile status after RP and RT
  - Goals: Cavernosal oxygenation, preservation of endothelial function, prevention of corporal smooth muscle fibrosis
  - Optimal regimen for rehabilitation is not understood

DIAGNOSIS

HISTORY

- Medical history: Risk factors for general ED
  - Cardiovascular disease
  - Diabetes mellitus
  - Smoking
  - Peripheral neuropathy
  - Depression
  - Alcoholism
- Surgical history

  – Type and date of surgery
  – Nerve sparing status (if RP or radical cystectomy)
- Radiation history
  – Dose, template, radiation modality, and date
  – Use of ADT
- ED history
  – Validated questionnaires, ie, International Index of Erectile Function (IIEF)
  – Onset and severity of ED
  – Consistency of erectile quality
  – Presence of nocturnal erections
  – Prior use of therapy and response

PHYSICAL EXAM
- General physical exam
- Penile exam focusing on presence of tunical plaques and penile compliance
- Testicular volume and consistency as screening for hypogonadism

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Generally noncontributory.
- If evidence of hypogonadism, check early morning serum testosterone.

Imaging
- Duplex Doppler ultrasound of the penis
  – Can be used to evaluate for presence of vasculogenic ED
  – Peak systolic velocity <30 cm/s indicative of arterial insufficiency
  – End diastolic velocity >5 cm/s indicative of CVOD

Diagnostic Procedures/Surgery
N/A

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Hyperprolactinemia
- Medication induced: Antihypertensives, psychotropics, antiandrogens
- Neurogenic ED
- Profound hypogonadism
- Psychogenic ED
- Vasculogenic ED

TREATMENT

GENERAL MEASURES
- Perform cardiovascular risk assessment to evaluate fitness for sexual activity prior to treatment.
- Patient and partner should be informed of relevant treatment options, risks, and benefits.

MEDICATION

First Line

- PDE5i (2)[A]
  - Likely to be ineffective immediately after surgery given cavernosal nerve injury
  - Daily dosing frequently used in rehabilitation regimens
  - When used on-demand only, decreased response noted 2–3 yr after RT
  - Medications:
    - Sildenafil 50–100 mg: Onset 15–60 min, duration of action 4 hr
    - Vardenafil 10–20 mg: Onset 15–60 min, duration of action 2–8 hr
    - Tadalafil 10–20 mg: Onset 15–120 min, duration of action 24–36 hr
    - Avanafil 100–200 mg
  - Contraindications to PDE5i use:
    - Absolute contraindications: Use of nitrates
    - Sildenafil: Should be postponed for 4 hr after taking α-adrenergic antagonists
    - Vardenafil: Should not be taken with type 1A or type 3 antiarrhythmics or patient with long QT syndrome
  - Side effects: All associated with headache, dyspepsia, facial flushing
    - Tadalafil: Backache, myalgia
    - Sildenafil: Blurred/blue vision—reacts with PDE6 in retina

Second Line

- Intracavernosal injection therapy
  - Highly efficacious with up to an 89% response rate post-RP (3)[C]
  - Risks include priapism, penile pain, ecchymosis
  - Used in a variety of formulations
    - Single agent: Prostaglandin E_1
    - Bimix: Papaverine and phentolamine
    - Trimix: Papaverine, phentolamine, and prostaglandin E_1
- Intraurethral prostaglandin E_1 suppository (MUSE)
  - Variable efficacy
  - Penile pain frequently reported, especially in the immediate postoperative period

SURGERY/OTHER PROCEDURES

- Vacuum constriction devices
  - Low patient satisfaction given cumbersome application
  - Cooler, cyanotic appearance of vacuum-assisted erection appears “unnatural” to some
- Penile prosthesis implantation
  - Definitive therapy for patients failing or refusing 1st- and 2nd-line treatments
  - Generally, postponed until 2-yr post-RP as regeneration of cavernous nerves during this time may preclude need for surgical therapy
  - High patient satisfaction in appropriately selected population
  - Implant infection and malfunction risk must be discussed with patient preoperatively

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Limited data on combining modalities has been reported
  - Level 3 evidence: PDE5i + either transurethral or intracavernosal injection therapy generate better efficacy rates than either monotherapy alone
  - Level 4 evidence: Enhanced efficacy with the combination of vacuum-erection therapy + either PDE5i or transurethral PGE1 or intracavernosal injection therapy

Complementary & Alternative Therapies

- Data does not support use of trazodone, yohimbine, and herbal therapies. These medications are not recommended for use in ED by the American Urological Association
- Testosterone therapy
  - May be useful in aiding erectile function recovery only in patients with documented hypogonadism
  - Controversial; must discuss risks/benefits of androgen supplementation before initiating therapy, particularly in patients with a history of prostate cancer

ONGOING CARE

PROGNOSIS

- Improvement in erectile function can be noted after pelvic surgery, with maximal improvement noted between 18 and 24 mo postoperatively.
- Low likelihood of improvement in erectile quality after 2 yr postoperatively.
- Nadir of erectile function 3 to 5 yr after RT.
- Penile rehabilitation likely improves the prognosis of postsurgical/post-RT ED. Definitive data are pending.

COMPLICATIONS

- Significant effect on patient quality of life
  - Noted to be strongest predictor of patient satisfaction after prostate cancer therapy
- Depression

FOLLOW-UP

Patient Monitoring

- Variable dependent upon patient response to treatment.
- Close follow-up is recommended in patients on rehabilitation protocols to evaluate for erectile recovery.

CODES

ICD9

607.84 Impotence of organic origin

ICD10

• N52.31 Erectile dysfunction following radical prostatectomy
• N52.32 Erectile dysfunction following radical cystectomy
• N52.39 Other post-surgical erectile dysfunction

CLINICAL/SURGICAL PEARLS

• ED after pelvic surgery and RT is highly prevalent and frequently underestimated in physician marketing materials.
• ED after pelvic surgery is immediate in onset with 18- to 24-mo time to maximal recovery.
• ED after RT has an insidious onset, with nadir of erectile function at 3- to 5-yr post-RT.
• Data on penile rehabilitation is conflicting but increasingly shows an improvement in posttreatment erectile recovery.
• The majority of postpelvic surgery/RT ED patients are effectively treated with PDE5i ± intracavernosal injection therapy.

ERECTILE DYSFUNCTION/IMPOTENCE, GENERAL CONSIDERATIONS

Nathaniel Readal, MD
Trinity J. Bivalacqua, MD, PhD

BASICS

DESCRIPTION

Consistent or recurrent inability to attain and/or maintain an erection sufficient for satisfactory sexual activity

EPIDEMIOLOGY

Incidence

- Crude incidence: 26 cases/1,000 man years
  - Incidence increases with each decade above 40
    - 12 cases/1,000 man years: 40–49 yr
    - 30 cases/1,000 man years: 50–59 yr
    - 46 cases/1,000 man years: 60–69 yr

Prevalence

- Increases universally with age and medical comorbidities (cardiovascular disease, hypertension, smoking, inactivity, obesity)
  - Prevalence by age
    - Below age 40: 1–9%
    - 40–59 yr: 20–30%
    - 60–69 yr: 20–40%
    - >70 yr: 50–75%

RISK FACTORS

- Probability of ED increases with presence of each risk factor
  - Diabetes mellitus
    - Prevalence of ED 3 times higher in diabetic men
    - ED occurs at earlier age and increases with disease duration
    - Associated with 14 times increased risk of cardiovascular morbidity and mortality
  - Cardiovascular disease (hyperlipidemia, hypertension, peripheral vascular disease)
  - Lower urinary tract symptoms/Benign prostatic hyperplasia (BPH)
  - Chronic renal failure, chronic liver disease
  - Endocrinopathies (hypogonadism, Cushing disease)
  - Prior abdominal/pelvic/penile surgery, radiation or trauma
  - Priapism, Peyronie disease
  - Neurologic disease (Parkinson disease, dementia, prior stroke)
  - Depression/Psychological disorders
  - Long-distance cycling
  - Smoking

- Medications
  - Antihypertensives (thiazide diuretics, β-blockers, α_2-agonists)
  - ACE inhibitors, angiotensin receptor blockers, and calcium channel blockers cause less ED/may improve erectile function
  - Psychotropics (monoamine oxidase inhibitors, selective serotonin reuptake inhibitors, lithium)
  - Antiandrogens
  - Miscellaneous (digoxin, cimetidine, spirolactone, marijuana)
  - Tobacco smoking

Genetics

- Several gene polymorphisms linked with ED
- Angiotensin-converting enzyme (ACE) polymorphisms may be risk factors for vasculogenic ED and endothelial nitric oxide synthase (eNOS) polymorphisms alone or in combination with other genetic polymorphisms implicated in ED

PATHOPHYSIOLOGY

- Mechanism of erection
  - Relaxation of cavernosal smooth muscle (contracted in flaccid state inhibiting inflow of blood)
    - Mediated by NO release from pelvic nerves and endothelial cells
    - Increased cyclic GMP (cGMP) and cyclic AMP (cAMP) trigger signaling pathways leading to decreased intracellular calcium causing smooth muscle relaxation, increased penile blood flow, and tumescence
    - Smooth muscle relaxation further promoted due to inhibition of Rho-kinase
    - Veno-occlusive mechanism prevents outflow of blood from penis and maintains erection
    - cGMP degraded by phosphodiesterase type 5 (PDE5)
- Organic ED
  - Vasculogenic
    - Arteriogenic—atherosclerotic lesions decrease arterial inflow to penis
    - Venogenic—failure of corporal vasoocclusion
  - Neurogenic—Alzheimer disease, Parkinson disease, injury to central nervous system, spinal cord, or peripheral nerves
  - Anatomic
  - Endocrinologic (hyperprolactinemia, hyper or hypothyroidism, adrenal disorders/Cushing syndrome)
- Psychogenic ED
  - Only accounts for 10% of ED
  - More common in men <35 yr old
    - May result from lack of interest in partner, performance-related anxiety, negative mood, life stressors

ASSOCIATED CONDITIONS

- Atherosclerosis
- Diabetes mellitus
- Hypertension, stroke

- Depression
- Parkinson disease, multiple sclerosis
- Priapism
- Peyronie disease
- Prostate cancer

GENERAL PREVENTION
- Avoidance of tobacco use
- Optimal medical management of commonly associated conditions
- Increase exercise/weight loss
- Split bicycle seat for long-distance cycling

DIAGNOSIS
HISTORY
- Medical history—comorbid conditions, medications, alcohol, tobacco, recreational drug use, history of cycling
- Surgical history
- Psychosexual history
  - Status of current relationship
  - Level of libido/interest in sex
  - Quality of erection
  - Duration of ED
  - Onsent of ED (sudden vs. gradual)
  - Presence of nocturnal/early morning erections
  - Presence of penile curvature, plaque, pain
  - International Index of Erectile Function Questionnaire (IIEF-5)
    - 5 questions scored individually from 0–5 (maximum of 25 points, higher score indicated better function)
    - Classifies ED into severe (5–7), moderate (8–11), mild to moderate (12–16), mild (17–21), and no ED (22–25)

PHYSICAL EXAM
- Neurologic: Stroke, CNS disease, visual field defects, neuropathy, perineal sensation
- Endocrinologic: Atrophic testes, gynecomastia, loss of secondary sexual characteristics
- Cardiovascular: Blood pressure, femoral/pedal pulses, lower extremity ischemia
- Penile: Curvature, Peyronie disease plaques
- Rectal exam

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Complete blood count
- Serum chemistries
- Fasting glucose level, hemoglobin A1C
- Lipid profile
- Serum total testosterone
- Thyroid function tests (optional)

- PSA (suspect prostate pathology)
- Urinalysis (glucose as indicator of diabetes)

Imaging

- Duplex penile ultrasound—most reliable and least invasive modality for assessing ED
- Provides imaging evaluation and quantification of penile blood flow

Diagnostic Procedures/Surgery

ALERT

A trial of oral pharmacotherapy is warranted prior to an invasive procedure/test

- Specialized testing indicated for:
  - Young men < 40 yr old
  - Men with previous perineal/pelvic trauma
    - Combined intracavernosal injection and stimulation (CIS) with duplex ultrasound (US): Intracavernosal injection of vasodilator with genital/audiovisual sexual stimulation and measurement of erection/blood flow—provides objective measurement of vascular parameters
    - Penile angiography: Reserved for young patient with ED secondary to traumatic arterial disruption/compression to evaluate for revascularization
    - Nocturnal penile tumescence (RigiScan®): Automated, portable measurement of presence of nocturnal erections—can confirm integrity of neurovascular axis, diagnose psychogenic ED

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

Psychogenic erectile dysfunction, depression, possible early sign of cardiovascular disease

TREATMENT

GENERAL MEASURES

- Treatment choice should be made among physician, patient, and partner after evaluation of risk/benefits of all treatment choices
- Cardiovascular risk assessment should be performed before initiating therapy
  - Low risk: Asymptomatic, < 3 risk factors—may proceed with treatment
  - Intermediate risk: Asymptomatic, ≥ 3 risk factors, stable angina, or mild heart failure—requires full cardiovascular assessment to reclassify as high vs. low risk
  - High risk: Unstable angina, recent myocardial infarction, uncontrolled hypertension, advanced heart failure or valvular disease—defer until cardiac condition stabilized

MEDICATION

First Line

- PDE5 inhibitors (PDE5i): Inhibit breakdown of smooth muscle cGMP promoting smooth muscle relaxation. > 50% of patients will respond
  - Drugs:
    - Sildenafil 50–100 mg : Onset 15–60 min, duration of action 4 hr

- Vardenafil 10–20 mg: Onset 15–60 min, duration of action 2–8 hr
- Tadalafil 10–20 mg: Onset 15–120 min, duration of action 24–36 hr
- Avanafil 100–200 mg

– Contraindications to PDE5i use:
- Absolute contraindications: Use of nitrates
- Sildenafil: Should be postponed for 4 hr after taking α-adrenergic antagonists
- Vardenafil: Should not be taken with type 1A/type 3 antiarrhythmics or with long QT syndrome

– Side effects: All associated with headache, dyspepsia, facial flushing
- Tadalafil: Backache, myalgia
- Sildenafil: Blurred/blue vision—reacts with PDE6 in retina

Second Line

• Intracavernous injection therapy
– Mechanism: Self-injection of vasoactive agent into corpora cavernosa producing rapid erection
– Drugs:
- Alprostadil (PGE1)
- Bimix: Papaverine and phentolamine
- Trimix: Papaverine, phentolamine, and prostaglandin E_1

– Side effects: Fibrosis, priapism, painful erection, hematoma
– Contraindications: Monoamine oxidase medication usage, decreased manual dexterity
– Efficacy: 80–90% effective in wide range of patients

• Intraurethral therapy
– MUSE:Medicated urethral system for erection
– Mechanism: Insertion of alprostadil containing pellet into distal urethral, absorbed into corpora cavernosa production erection within 30 min
– Side effects: Penile/vaginal pain, dysuria
– Contraindications: Priapism risk
– Efficacy: $<50\%$ effective

• Vacuum constriction device
– Effective 2nd-line treatment and represents an alternative/adjunct to pharmacotherapy
– Pursued prior to surgical intervention
– Produces negative penile pressure, engorging corpora with blood
– Constrictive ring at the base of penis maintains tumescence
– Side effects: Penile ischemia when duration of use >30 min, pain, abnormal color of penis

SURGERY/OTHER PROCEDURES

• IPP
– Indications: Failed 1st- and 2nd-line pharmacotherapy or vacuum erection device
– Mechanism: Definitive ED treatment with placement of inflatable cylinders into corpora cavernosa
– Complications: Infection (1–3%), erosion ($<5\%$), mechanical malfunction (5–10%)

• Penile revascularization
– Reserved for select young patients with clearly documented arterial occlusion

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Psychosexual therapy: Referral for sex therapy in patients with psychogenic ED. Cognitive behavioral intervention identifies sexual stressors and refocus maladaptive thought processes

Complementary & Alternative Therapies

No FDA-approved dietary supplements or herbal medications for ED but gingko biloba, red ginseng, yohimbine reportedly improve ED

ONGOING CARE

PROGNOSIS

Excellent if reduction of cardiovascular risk factors, weight loss, exercise, smoking cessation

COMPLICATIONS

N/A

FOLLOW-UP

Patient Monitoring

- Patients to be reevaluated periodically with following considerations:
  - Response to initial therapy
  - Need for dose titration
  - Patient education on proper medication use (specific PDE5i on empty stomach, use of local injection therapy)
  - Need for progression to 2nd-line therapy/surgery based on therapeutic effectiveness and patient satisfaction

- Erectile Dysfunction/Impotence, General Considerations Image
- Penile Rehabilitation

CODES

ICD9

- 302.72 Psychosexual dysfunction with inhibited sexual excitement
- 607.84 Impotence of organic origin

ICD10

- F52.21 Male erectile disorder
- N52.9 Male erectile dysfunction, unspecified
- N52.39 Other post-surgical erectile dysfunction

CLINICAL/SURGICAL PEARLS

- ED is a symptom of multiple underlying diseases that affect the following: penile nerve, artery, endothelial or smooth muscle function.
- Cardiac risk assessment should occur prior to initiation of therapy.
- Surgical therapy (penile prosthesis) is an essential therapy when medical treatment has failed or is contraindicated.

EXSTROPHY, BLADDER (CLASSIC EXSTROPHY)

Grahame H.H. Smith, MBBS

BASICS

DESCRIPTION

- Classic bladder exstrophy is a major genitourinary anomaly characterized by the bladder laying open on the abdominal wall with an associated lower midline abdominal wall hernia. The defect extends from the umbilicus to the distal end of the phallus, resulting in coexistent epispadias in males and a bifid clitoris in females.
- Classic exstrophy is considered midway in severity between cloacal exstrophy and epispadias, as part of exstrophy–epispadias complex.

EPIDEMIOLOGY

Incidence

- 1 in 10,000–50,000
- Male > Female (2:1)

Prevalence

N/A

RISK FACTORS

Genetics

- Multifactorial etiology without definite genetic link (1)
  - May be associated with p63 gene dysregulation
  - Chromosomal regions 4q31.21–22, 19q13.31–41, and 22q11.21 may harbor genes associated with exstrophy
- Risk in sibling is 1 in 100; risk in offspring is 1 in 70

PATHOPHYSIOLOGY

- Incompletely understood, 2 predominant theories
- 1st theory postulates that an incomplete ingrowth of mesoderm is unable to reinforce cloacal membrane, which results in premature rupture and subsequent failure to develop ectoderm and mesoderm. The timing of the rupture determines cloacal (earlier) vs. classic exstrophy vs. epispadias (later)
- 2nd theory describes an overgrowth of cloacal membrane preventing medial migration of mesenchymal tissue. Bladder smooth muscle cells in exstrophy patients show lower intracellular calcium concentrations and enhanced migration

ASSOCIATED CONDITIONS

- Usually healthy without any other major organ system defects
- Subsequent inguinal hernia common
- Rarely may be associated with duplication of bladder or urethra, colorectal abnormalities (2%), cleft lip and palate, subsequent testis tumors
- In contrast, cloacal exstrophy has much more extensive anomalies

GENERAL PREVENTION
N/A

DIAGNOSIS

HISTORY
Any family history of exstrophy

PHYSICAL EXAM
- Bladder exposed on abdominal wall
- Bladder plate size
- Lateral ureteric orifices
- Males have an open bladder neck and prostate, the short and broad phallus is open dorsally with dorsal chordee
- Females have an open bladder neck and urethra, bifid clitoris lateral to urethra and anteriorly situated vagina
- Low-set umbilicus with foreshortened distance to pubis
- Pubic diastasis with external rotation of pelvis

DIAGNOSTIC TESTS & INTERPRETATION
- Antenatal
  - May be diagnosed on antenatal ultrasound study due to absence of the bladder (1st trimester) or reduced umbilical to pubic length (2nd trimester)

Lab
- Full blood count, electrolytes, creatinine
- Blood type and cross-match in preparation for surgery

Imaging
- Renal ultrasound
- Pelvic x-ray to document pubic diastasis

Diagnostic Procedures/Surgery
N/A

Pathologic Findings
- Exstrophic bladders may have more type III collagen and fewer myelinated nerve fibers
- If left untreated and exposed, the urothelium undergoes squamous metaplasia as a response to acute and chronic inflammation

DIFFERENTIAL DIAGNOSIS
- Cloacal exstrophy
- Omphalocele
- Gastroschisis
- Epispadias

TREATMENT

GENERAL MEASURES

- Antenatal
  - Consider MRI assessment and *karyotyping*. Options for termination may be discussed
- Immediate postnatal care:
  - 2-0 silk suture on umbilical cord as close to abdominal wall as possible
  - Cover bladder with a nonadherent dressing (eg, Saran Wrap) to prevent excoriation
  - Irrigate with normal saline and apply a new dressing with each diaper change

MEDICATION

First Line

No medical treatment is available to close the bladder wall

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Ideally the extrophy is closed on next elective list with two senior staff in attendance:
  - Requires an adequate bladder plate but the minimum size is not defined
  - If unable to easily approximate pubis, then may need pelvic osteotomy
  - Pelvic osteotomy may reduce the incidence of dehiscence and subsequent prolapse in females
- Avoid latex exposure to prevent latex allergy
- 3 contemporary closures (2)
- Classic repair involves 3 stages:
  - Immediate bladder closure
  - Epispadias repair at 6 mo
  - Bladder neck repair at 5 yr:
    - Requires >100-cc bladder capacity and motivation for continence
- Complete primary repair of bladder exstrophy (CPRE):
  - Epispadias repaired along with bladder as neonate with penile disassembly (if male)
- Kelly repair:
  - Soft tissue mobilization away from pelvic sidewall with midline closure without the need for pelvic osteotomy
- Associated surgery
  - Prophylactic inguinal hernia repair in males is advised
  - Ureteric reimplantation may be required subsequently

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Delayed closure in the case of a late presentation
- All need osteotomy with option of external fixation
- Inadequate bladder plate:
  - Delay closure with osteotomies, once adequate
  - If remains inadequate consider augmentation at time of closure
- Postoperative:

- Ensure maximal urinary drainage with ureteric stents, suprapubic tube, and urethral catheter
- With our without pelvic immobilization (traction, Buck, Bryant; Mermaid dressing; spica cast)
  - Optimal duration of immobilization not established
- Remove stents one at a time; suprapubic only removed after ensuring appropriate bladder emptying

Complementary & Alternative Therapies

N/A

ONGOING CARE

- Subsequent operative treatment options:
  - Bladder neck plasty (failure rate 50%)
  - Bladder neck closure (failure rate 2%) with augmentation and Mitrofanoff conduit
  - Ureterosigmoidostomy (plus or minus Mainz II pouch)
  - Umbilicoplasty
  - Radial forearm flap phalloplasty (males)
  - Vaginoplasty, clitoroplasty (females)

PROGNOSIS

- Life expectancy normal
- Urinary continence in 50–90%; definition of continence disputed; most common definition of continence is dry with voiding or catheterization every 3 hr (3)
- May require multiple surgeries
- Quality-of-life scores are less than the normal. Functional results seem to be the most likely predictive factor of health-related QOL score

COMPLICATIONS

- Failure of primary closure; 10%
- Failure to store (urinary incontinence secondary to incompetent outlet plus or minus poor bladder compliance)
- Failure to empty (after closure or after bladder neck procedure)
- Upper tract damage and renal failure due to high bladder pressures and or high outlet resistance
- Developmental psychopathology
- Male: Infertility, retrograde ejaculation, urethrocutaneous fistula, loss of phallus (complete penile disassembly, Kelly repair), inadequate phallus, testis tumors
- Female:
  - Vaginal stenosis, requiring vaginoplasty
  - Degree of diastasis association with risk of uterine prolapse
  - Enterocystoplasty may lead to false-positive pregnancy test
  - Normal fertility possible, Cesarean delivery suggested
- Increased risk of adenocarcinoma of bladder
- Increased risk of colonic adenocarcinoma after ureterosigmoidostomy

FOLLOW-UP

Patient Monitoring

- After discharge:
  - Antibiotic prophylaxis to prevent urinary tract infections
  - Regular ultrasound to assess for hydronephrosis, residual volume, and bladder volume
  - Yearly colonoscopy starting 10 yr after ureterosigmoidostomy

CODES

ICD9

753.5 Exstrophy of urinary bladder

ICD10

- Q64.11 Supravesical fissure of urinary bladder
- Q64.19 Other exstrophy of urinary bladder

CLINICAL/SURGICAL PEARLS

- Achieving normal urinary continence with normal voiding after repair is uncommon. It is almost always possible to achieve continence if the patient is willing to undertake clean intermittent catheterization.
- Males will tend to be unhappy about the length of their penis. However, what they lack in length they gain in width.

- For the inexperienced clinician it is sometimes difficult to identify the gender of a newborn baby with bladder exstrophy. Boys almost always have bilateral palpable gonads.

EXSTROPHY, CLOACAL

Jason C. Fisher, MD
Harry P. Koo, MD, FAAP, FACS

BASICS

DESCRIPTION

- Cloacal exstrophy, or vesicointestinal failure, is a congenital abnormality of the infraumbilical abdominal wall. Its presentation is highly variable, but key features include an exomphalos with an exstrophied cecum flanked by two hemibladders
- Ureteral orifices present on each hemibladder. Cecal plate has orifices to three structures:
  - Appendix
  - Blind-ending hindgut (colonic remnant)
  - Ileum, often prolapsed elephant-trunk deformity
- Most severe anomaly along epispadias–exstrophy complex (EEC) spectrum
- When neurospinal defects and omphalocele occur with cloacal exstrophy, it is termed OEIS complex (omphalocele, exstrophy, imperforate anus, spinal defects)

EPIDEMIOLOGY

Incidence

- One of the rarest urologic anomalies
- Widely quoted historic incidence of 1:200,000 to 1:400,000 based on statistical estimates
- More accurate and contemporary international registries now estimate 3:100,000 to 8:100,000.
- Male ≥ Female (1:1–2:1)

RISK FACTORS

- No well-defined causative factors; statistical analysis of large registries identifies the following:
  - Bimodal risk of maternal age: <20 year old or >30 year old
  - Intrauterine fet al demise of twin pregnancy
  - In vitro fertilization

Genetics

- Most cases are sporadic
- Some cases reported with genetic causation:
  - Unbalanced translocation of 9q and Yq
  - Homeobox mutations at HLXB9 and HOX

PATHOPHYSIOLOGY

- Traditionally postulated embryologic theories:
  - Premature cloacal membrane rupture (8 wk)
  - Failed cloacal partition by lateral folds of Rathke
  - Incomplete descent of a cloacal septum
- Current understanding of cloacal exstrophy embryogenesis (1)[B]:

– Disrupted cellular proliferation and apoptosis of dorsal cloacal wall and infraumbilical mesenchyme—this disrupts the infraumbilical body wall, everts the cloacal cavity, and wedges the pubic bones and genital tubercles apart

ASSOCIATED CONDITIONS

- Upper genitourinary anomalies:
  - Unilateral renal agenesis (33%)
  - Pelvic kidney (33%)
  - Hydronephrosis (33%)
  - Horseshoe kidney
  - Fusion anomalies
  - Ureteral anomalies
- Lower genitourinary anomalies:
  - Separation or absence of clitoral/phalic halves
  - Separation of scrotum or labia
  - Undescended testicles/bilateral hernias
  - Uterine and vaginal duplication anomalies
- Gastrointestinal anomalies:
  - Omphalocele (88–100%)
  - Short-gut (25%; source of major morbidity)
  - Intestinal malrotation
  - Intestinal duplication
  - Imperforate anus/anal atresia
- Central nervous system anomalies:
  - Tethered spinal cord
  - Myelomeningocele
  - Aberrant pelvic autonomic nerve anatomy
  - Impaired continence, ambulation, erectile function
- Musculoskelet al anomalies:
  - Symphysis pubis diastasis
  - Sacral dysplasias and vertebral anomalies
  - Scoliosis
  - Hip subluxation and acetabular dysplasia
  - Lower limb anomalies
- Serious cardiovascular and pulmonary anomalies are uncommon with cloacal exstrophy

DIAGNOSIS

Cloacal exstrophy is a major congenital anomaly. Prompt referral and coordination with a variety of specialists including pediatric urology, pediatric general surgery, pediatric orthopedics, neonatology, pediatric gastroenterology, pediatric neurosurgery, endocrinology, genetics, and social work is needed.

HISTORY (ANTENATAL)

- Major diagnostic criteria (2)[A]:
  - Nonvisualization of the bladder (91%)

  - Large midline infraumbilical anterior abdominal wall defect or cystic anterior abdominal wall structure (82%)
  - Omphalocele (77%)
  - Lumbar myelomeningocele (68%)
- Prolapsed ileal segment can be pathognomic

PHYSICAL EXAM

- The classic collection of findings include:
  - Exstrophy of the bladder
  - Complete phallic separation
  - Wide pubic diastasis
  - Cecal plate everted between 2 hemibladders
  - Blind-ending hindgut; no well-formed colon
  - Omphalocele
- Thorough assessment for associated anomalies (see "Associated Conditions"):
  - Spinal and vertebral defects
  - Lower extremity malformations
  - Patency and position of anus
  - Presence of descended testicles
- Detailed exam of exstrophy:
  - Males: Divided corpus cavernosum and glans
  - Females: Divided clitoris, duplicated vagina
  - Additional müllerian anomalies
  - Identification of ureteral orifices: Two exstrophied hemibladders are on either side of the exstrophied intestinal segment. Each half usually drains the ipsilateral ureter
  - Identification of intestinal orifices: Appendix, hindgut, ileum (often prolapsed)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Karyotype
- CBC, basic metabolic panel:
  - At risk for nongap metabolic acidosis due to absorption of urine chloride by intestinal mucosa
  - Type and cross blood for surgery

Imaging

- Plain CXR, sacral and spinal x-rays
- Ultrasounds of abdomen, kidneys, head, spine
- Consider MRI to detect occult spinal lesions if no obvious dysraphism and US nondiagnostic
- Skelet al and bony films of pelvis and lower extremities as needed
- Echocardiogram: Low incidence of associated cardiac lesions, but advisable in the preop setting

DIFFERENTIAL DIAGNOSIS

- Unique appearance makes it unlikely to confuse with other conditions
- Exists along EEC spectrum
- Consider isolated bladder exstrophy, giant isolated omphalocele, large epispadias

TREATMENT

GENERAL MEASURES

- Assessment of newborn with anomaly:
  - Immediate cardiopulmonary stabilization
  - Neonatology management of prematurity
  - IV access: UA and UV lines not possible
- Protection and prevention maneuvers:
  - Ligate umbilical cord with silk tie (avoid plastic clip which will irritate bladder mucosa)
  - Lower half of infant in bowel-bag initially
  - Cover exstrophic tissue with plastic wrap
  - Protect omphalocele: Minimal handling
  - Assess for open spinal cord defects
  - Place nasogastric tube for decompression
  - Prophylactic antibiotics (ampicillin and gentamicin)
- Contact specialists (see under “diagnosis" heading above) immediately.
- Detailed exam to assign gender
  - Identification of phallus, labia/scrotum, testes
  - Consistent with the karyotype if possible

MEDICATION

First Line

- IVF support: Adjust for fluid losses across exstrophied mucosa
- At risk for hyperchloremic metabolic acidosis
- Generally not candidates for epidural anesthesia due to spinal dysraphism

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Open spinal anomaly: Prompt neurosurgical repair required before addressing exstrophy.
- Exstrophy repair at 48–72 hrs of life if stable
  - Combined pediatric urology and general pediatric surgery
  - Usually staged approach vs. single stage
- Multistage approach (3)[B]: Creates classic bladder exstrophy anatomy at conclusion of initial surgery described above; preferred for most cases. General principles of Stage 1:
  - Separate hemibladders from cecal plate
  - Revert any prolapsed terminal ileum
  - Mobilize, rescue, and preserve any hindgut
  - Tubularize the cecum to bring terminal ileum, cecum, and hindgut into closed continuity
  - Create end colostomy from distal hindgut
  - Assess and preserve müllerian anatomy
  - Excise and close omphalocele if possible
  - Anastomose hemibladders in midline
- Single-stage approach (4)[B]: In highly select patients, can proceed with bladder and abdominal wall closure and phallic reconstruction which may avoid osteotomies, minimize

bladder scarring. Otherwise, Stage 2 is performed in late infancy, mirroring a classic bladder exstrophy repair:
  – Mobilize bladder plate and posterior urethra deep into pelvis: Yields incontinent bladder.
  – Orchiopexy with repair of inguinal hernias
  – Reconstruct gender-based external genitalia
  – Pubic reapproximation +/– pelvic bone osteotomies with fixation and traction for 4–6 wk
- Stage 3 involves procedures aimed at continence and genital cosmesis and is addressed in older children, often involving bladder augmentation and catherizable conduits
- Surgical pitfalls to avoid:
  – Injury to ureteral orifices: Place stents
  – Overaggressive closure of a large omphalocele defect leading to compartment syndrome
  – Excising/discarding diminutive male phalic remnants and assigning female gender: Controversial and still occurs with unclear long-term consequences
  – Excising/discarding the hindgut even if short
  – Primary perineal pull-through of the hindgut (can be performed in highly select patients)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Large omphaloceles not amenable to primary closure can be treated with Silvadene-mediated epithelialization of sac followed by delayed closure, or by excision of sac and placement of a silo with gradual staged reduction of viscera
- Consider gastrostomy tube placement and/or tunneled central line during initial repair if patient appears at risk for short-gut syndrome

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Survival >90% over last 20 yr
- Nutrition and growth is the most important determinant of early survival and morbidity
  – 30–50% will have failure to thrive before age 5
  – Important to avoid using any bowel for GU reconstruction procedures until child is thriving
- After 3 yr, quality-of-life issues outweigh nutritional concerns
  – Urinary continence: Rarely achieved; dependent on a compliant reservoir and continent catherizable conduit
  – Fecal continence: Usually managed by enema regimen, rarely are perineal pull-through maneuvers associated with any continence
  – Gender assignment and reconstruction, especially for genetic males raised as females
  – Ambulation impairments
  – Gynecologic issues after onset of menarche
  – Psychosexual problems

COMPLICATIONS

- Infection and breakdown of repair
- Abdominal compartment syndrome
- Short-gut syndrome
- Vesicoureteral reflux and hydronephrosis
- Hirschsprung-type enterocolitis in the dysmotile hindgut, even after colostomy formation

FOLLOW-UP

Requires a multidisciplinary team (see "Diagnosis") to coordinate regular follow-up through all stages of surgical repair, with careful attention to nutrition and growth in infancy, and both surgical and psychological support for the multiple quality of life issues which begin in childhood and persist into adulthood

CODES

ICD9

753.5 Exstrophy of urinary bladder

ICD10
Q64.12 Cloacal extrophy of urinary bladder

CLINICAL/SURGICAL PEARLS

- Meticulous assessment of associated anomalies can prevent early clinical and surgical mishaps, particularly with regard to spinal defects.
- A multidisciplinary team is critical to the short- and long-term outcomes of these children.
- A staged surgical repair remains the preferred approach for most children with cloacal exstrophy.
- Do not underestimate the impact of early gender assignment: Avoid irreversible surgical resection of structures that may be useful for genital reconstruction.
- Save as much bowel as possible, especially the short hindgut, to maximize nutritional capability.

FERTILITY AND CANCER THERAPY, UROLOGIC CONSIDERATIONS

James M. Hotaling, MD, MS
Craig S. Niederberger, MD, FACS

BASICS

DESCRIPTION

- 2006 ASCO Guidelines recommend that all patients in their reproductive years undergoing cancer therapy be offered fertility preservation options (1)
- Mainstay of fertility preservation in men is referral to a reproductive specialist and sperm cryopreservation
- Sperm cryopreservation is often not covered by insurance but Livestrong Foundation and Fertile Hope offer financial support (2)

EPIDEMIOLOGY

Incidence

- 1.4 million people are diagnosed with cancer every year
- 10% of those diagnosed with cancer are <44 yr old (3)
- Testicular cancer is one of the most common cancers seen by men in their reproductive years and typically presents to urologists

Prevalence

Advances in cancer treatment have led to increased survival rates of 75–80% for those diagnosed <50 yr old (4)

RISK FACTORS

Men with male factor infertility (azoospermia) are significantly more likely to develop testis cancer

Genetics

N/A

PATHOPHYSIOLOGY

- Men presenting with cancer often have reduced semen quality (3)
- Radiation at doses of 2.5 Gy to the testis causes prolonged azoospermia
- Radical pelvic surgery can cause erectile and ejaculatory dysfunction
- Certain common chemotherapeutic agents cause prolonged azoospermia (1)
  - Cisplatin (500 mg/m^2)
  - Chlorambucil (1.4 g/m^2)
  - Cyclophosphamide (19 g/m^2)
  - Procarbazine (4 g/m^2)
  - Melphalan (140 mg/m^2)
  - Others shown to be gonadotoxic:
    - Busulfan, carmustine, cytarabine, ifosfamide, lomustine, nitrosoureas

ASSOCIATED CONDITIONS

- Hematologic malignancies
  - Whole-body radiation used before bone marrow transplant usually causes life-long infertility
- Prostate cancer can directly impact fertility through sperm impairment and indirectly through erectile dysfunction (5)
  - Radical prostatectomy and its effect on fertility should be disclosed to the patient preoperatively
  - Brachytherapy does not give a large dose of radiation to the testicles, and most men will remain fertile or recover sperm production
  - External radiation is more likely to cause permanent infertility, even if the testicles are shielded
- Testicular cancer
  - More than half of the patients with testicular germ cell cancer showed impaired fertility
  - Retrograde ejaculation following retroperitoneal lymphadenectomy

GENERAL PREVENTION

- Radiation to the testicles can cause permanent loss of sperm production
- Unless the cancer is in the testicles, attempt to protect them from radiation by using a shield called a clam shell (5)

DIAGNOSIS

HISTORY

- Thorough reproductive history
  - Gonadotoxin exposure?
  - Previous difficulty with conception?
  - Use of exogenous steroids?
  - Varicocele surgery?
  - Diagnosis of cystic fibrosis?
- Discussion of desire for future paternity
- Assessment of onset of puberty in adolescent patients
  - Nocturnal emissions?
  - Sexually active?

PHYSICAL EXAM

- Assessment of Tanner stage in adolescent males
- Focused testicular exam
  - Longitudinal testicular axis
  - Presence of vas deferens
  - Presence of epididymis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Evaluation of baseline FSH, LH, estradiol, total testosterone, sex hormone binding globulin (SHBG), and albumin (to calculate bioavailable T)
- Values for optimal spermatogenesis

  - Bioavailable T >155 ng/dL
  - FSH <4.5
  - Total testosterone:estradiol ratio > 10:1
- Semen analysis by a high-volume lab: WHO 5th edition lower limits of normal
  - Sperm concentration >39 million/mL
  - Motility >40%
  - Total motile count >15 million
  - Morphology >4% normal by Kruger strict criterion

Imaging

N/A

Diagnostic Procedures/Surgery

If men are found to be azoospermic on semen analysis consider microsurgical testicular sperm extraction (microTESE)

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

N/A

TREATMENT

GENERAL MEASURES

- Semen analysis with cryopreservation of ejaculated sperm by a high-volume lab
  - Men with testis cancer or Hodgkin disease should bank multiple times given known lower recovery rates (3,6)
  - Any sperm obtained from semen analysis should be banked
  - Patients should abstain from ejaculation for 2 days before banking sperm but not more than 3 days
  - At least 2–3 samples should be banked for each patient
  - A frank discussion with the patient regarding the ongoing costs of cryopreservation and methods for patient contact in the future is vital
- Attempts to obtain and bank seminiferous tubules from prepubertal males for use in future-assisted reproductive technologies should only be done under an IRB-approved research protocol (4)
- All discussions for adolescents and children should involve both the patient and their parents
- Electroejaculation or vibratory stimulation may be used for patients with a spinal cord injury

MEDICATION

First Line

- To convert a retrograde ejaculation to an antegrade ejaculation
  - In the United States, ephedrine is most often used
  - In Europe, imipramine is also used
- α-adrenergic agents (dosing highly variable)

– Pseudoephedrine 60 mg
– Ephedrine 25–50 mg
– Imipramine 25–50 mg (may cause dizziness and nausea); commonly used in Europe
– Frequency ranges from QD to QID
– Duration ranges from 2 to 14 days
– Side effects: HTN, tachycardia

Second Line
N/A

SURGERY/OTHER PROCEDURES
In men who are azoospermic, aspiration of seminiferous tubules from the testis, sperm from the epididymis or microTESE with extraction of sperm and cryopreservation is a viable option and should be offered

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
Roughly 30% of men who receive gonadotoxic chemotherapy or radiotherapy will remain azoospermic permanently

COMPLICATIONS
N/A

FOLLOW-UP
Patient Monitoring
- Men should have a repeat interrogation of their male endocrine axis and another semen analysis by a reproductive health specialist when they desire paternity
- Some men may be hypoandrogenic after completion of treatment and referral to a reproductive health specialist is essential to ensure that they are offered medication other than testosterone for androgen repletion

CODES

ICD9

- 186.9 Malignant neoplasm of other and unspecified testis
- 606.8 Infertility due to extratesticular causes
- V26.82 Encounter for fertility preservation procedure

ICD10

- C62.90 Malig neoplasm of unsp testis, unsp descended or undescended
- N46.024 Azoospermia due to radiation
- Z31.84 Encounter for fertility preservation procedure

CLINICAL/SURGICAL PEARLS

- <10% of men who bank sperm retrieve it for use in assisted reproductive technologies.
- Referral to a reproductive specialist and sperm cryopreservation prior to initiation of gonadotoxic chemotherapy, radiation, or radical oncologic surgery is essential.
- Cost of sperm cryopreservation typically ranges from $200 to $500 initially usually with an annual maintenance fee.

FILLING DEFECT, UPPER URINARY TRACT (RENAL PELVIS AND URETER)

Scott G. Hubosky, MD

BASICS

DESCRIPTION

- Radiographic diagnosis of a radiolucent entity occupying the confines of the upper urinary tract including the intrarenal collecting system or ureter, as seen against contrast within the intraluminal space
- The finding itself is nonspecific but may represent malignant or benign processes
- Ureteroscopic evaluation is the gold standard to establish definitive diagnosis

EPIDEMIOLOGY

Incidence

- Difficult to define given the nonspecific nature of the radiographic finding
  - Upper tract urothelial carcinoma (UTUC)
    - Estimated 5,900–7,300 new cases in USA in 2014 (1)[C]

Prevalence

- Nephrolithiasis
  - Reported prevalence of kidney stones in USA between 1976 and 1994 was 13% in men and 7% in women (2)[C]

RISK FACTORS

- For UTUC
  - History of smoking
  - History of urothelial carcinoma of the bladder
  - Gene carrier or family history of Lynch syndrome (hereditary nonpolyposis colorectal cancer)
- For nephrolithiasis
  - Previous stone history
  - Chronic dehydration
  - Dietary factors
    - Elevated sodium intake
    - Purine gluttony
- For sloughed papilla
  - NSAID overuse
  - Sickle cell disease or trait
  - History of diabetes
- For fungus ball
  - Immunosuppression

Genetics

N/A

PATHOPHYSIOLOGY
Depends on underlying etiology

ASSOCIATED CONDITIONS
- Hematuria
  - Gross
  - Microscopic
- Flank pain

GENERAL PREVENTION
- Depends on underlying etiology
  - UTUC
    - Smoking cessation/avoidance
  - Nephrolithiasis
    - Adequate hydration
    - Diet and lifestyle modification to prevent future stone formation

DIAGNOSIS
HISTORY
- Flank pain or renal colic
- Hematuria
  - Gross
  - Microscopic
- Pre-existing malignancy
- History or urinary diversion
- Prior urinary tract manipulation (stent, stone treatment, etc.)

PHYSICAL EXAM
- Costovertebral angle tenderness
- Patient may by asymptomatic

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis
- Urine cytology may suggest malignancy
- Urine culture including fungal cultures
- Serum creatinine/BUN

Imaging
- Filling defects are found in imaging modalities which utilize contrast that fills the intrarenal collecting system
  - Intravenous injection of contrast
    - CT urogram
    - MR urogram
    - IVP
    - Invasive arteriograms (cardiac catheterization, aortogram, etc.)
  - Intraluminal administration of contrast

- Retrograde pyelogram
- Antegrade nephrostogram
- Cystogram (if reflux present)

Diagnostic Procedures/Surgery

Ureteroscopic evaluation is required to obtain definitive diagnosis and provides for direct visual inspection with relatively low morbidity (3)[C]

Pathologic Findings

Depends on underlying etiology

DIFFERENTIAL DIAGNOSIS

- Malignant lesions
  - UTUC
  - Rare primary cancers of the upper urothelial surface
    - Squamous cell carcinoma (often associated with chronic untreated infected staghorn calculi)
    - Adenocarcinoma
    - Inverted papilloma (about 15% have malignant components)
    - Sarcoma
    - Leiomyosarcoma
    - Angiosarcoma
    - Small cell carcinoma
  - Metastatic carcinoma
    - Melanoma
    - Renal cell carcinoma
- Benign lesions
  - Air: Iatrogenic, infectious, fistula
  - Blood clot
  - Fibroepithelial polyp
  - Fungus ball
  - Hemangioma
  - Inflammatory lesions: Granuloma, malakoplakia, TB
  - Inverted papilloma
  - Calculus (usually radiolucent)
  - Benign tumors (rare): Leiomyoma, neurofibroma, cholesteatoma
  - Extrinsic compression of the ureter
  - Mucous (urinary diversion patients)
  - Protein matrix
  - Ureteritis or pyelitis cystica
  - Vascular impression
  - Fibroepithelial polyp
  - Papilla
    - Prominent papilla (ectopic or end on; normal anatomic variant)
    - Sloughed papilla (may cause obstruction or hematuria)
  - Foreign body

- Stent fragment (retained)
- Staple/clip (more likely with urinary diversion)

TREATMENT

GENERAL MEASURES

- If any doubt exists about the etiology of the filling defect then diagnostic ureteroscopy is indicated
- Prominent papilla may appear as filling defects in the very peripheral aspect of renal calyces in an "end on" position

MEDICATION

First Line

- For stones composed purely of uric acid manifesting as filling defects, alkalization of the urine can be attempted and if pH of 6.5 or greater is achieved then uric acids may dissolve over time
  - Potassium citrate
  - Sodium bicarbonate

Second Line

N/A

SURGERY/OTHER PROCEDURES

- UTUC
  - For low-grade UTUC which can be reached ureteroscopically and completely ablated, 5-yr survival is equal to radical nephroureterectomy (4)[C]
    - After complete ablation, local recurrence can be seen in up to 75% of patients if followed for at least 5 yr.
    - Progression of low-grade to high-grade disease occurs in about 15% of cases
    - These points should be stressed to patients when counseling on the management of UTUC
  - For high-grade UTUC or very large-volume low-grade UTUC, radical extirpative surgery is considered the gold standard for cancer control
    - Nephroureterectomy (open or laparoscopic)
    - Segmental ureterectomy
- Nephrolithiasis
  - Ureteroscopy with laser lithotripsy
  - ESWL with or without retrograde pyelogram to assist with localization or with ultrasound guidance
  - PCNL
- Sloughed papilla
  - Ureteroscopy confirms diagnosis
    - Papilla can be removed primarily with ureteroscopic grasper or basket
    - Coagulation with cautery or laser will achieve hemostasis
    - Avoid overuse of NSAIDs
- Fibroepithelial polyp

  - Can be removed with ureteroscopy using laser or grasper
- Fungus ball
  - Can be removed with ureteroscopy or percutaneous approach
  - Antifungals

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- UTUC
  - Neoadjuvant chemotherapy is currently under investigation for suspected high-stage disease with preliminary data suggesting down staging on pathologic specimens

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Depends on underlying etiology
  - Prognosis usually excellent for benign conditions
  - UTUC (prognosis depends on pathologic staging) (5)[C]. TNM pathologic staging and prognosis is as follows:
    - pTo, pTa, and pTis have 93% and 89% cancer-specific survival at 5 and 10 yr
    - pT1 has 91% and 85% cancer-specific survival at 5 and 10 yr
    - pT2 has 75% and 70% cancer-specific survival at 5 and 10 yr
    - pT3 has 54% and 45% cancer-specific survival at 5 and 10 yr
    - pT4 has 12% and 6% cancer-specific survival at 5 and 10 yr

COMPLICATIONS

N/A

FOLLOW-UP

Patient Monitoring

- UTUC
  - For those undergoing ureteroscopic conservative treatment, regular surveillance including cystoscopy and ureteroscopy is required given high chance of local recurrence
  - Cross-sectional imaging (CT or MRI) is recommended to check for locally advancing disease
  - For those undergoing radical nephroureterectomy (NU), surveillance cystoscopy and cross-sectional imaging are also needed on a regular basis
- Nephrolithiasis
  - Renal ultrasound, serum electrolyte testing
  - For patients at high risk for stone recurrence, 24-hr urine electrolyte evaluation

CODES

ICD9
- 189.1 Malignant neoplasm of renal pelvis
- 189.2 Malignant neoplasm of ureter
- 793.5 Nonspecific (abnormal) findings on radiological and other examination of genitourinary organs

ICD10
- C65.9 Malignant neoplasm of unspecified renal pelvis
- C66.9 Malignant neoplasm of unspecified ureter

- R93.4 Abnormal findings on diagnostic imaging of urinary organs

CLINICAL/SURGICAL PEARLS

- Up to 40% of patients with an upper tract urothelial carcinoma will develop urothelial carcinoma of the bladder.
- Ureteroscopy can be both diagnostic and therapeutic.

FLANK PAIN, GENERAL

Taylor B. Vaughan, MD
James S. Rosoff, MD

BASICS

DESCRIPTION

- Flank pain refers to pain or discomfort in the side of the abdomen between the last rib and the hip.
- Sometimes referred to as loin pain, it is often associated with urologic conditions, although not exclusively.

EPIDEMIOLOGY

Incidence

True incidence is difficult to ascertain, as it is a common symptom associated with many medical conditions.

Prevalence

- Many medical conditions can cause flank pain, the prevalence is high.
- Up to 12% of the adult US population will suffer from urolithiasis at some point.

RISK FACTORS

Risk factors are dependent upon etiology

Genetics

NA

PATHOPHYSIOLOGY

- Flank pain caused by urologic pathology is usually due to sudden stretch of the renal capsule, generally from inflammation or distal obstruction.
- The severity of the pain is directly related to the acuity of the obstruction and not to its degree.
- Flank pain from renal inflammation has a gradual onset and is often not as severe as renal colic due to acute obstruction.
- Flank pain from chronic obstruction is generally less severe, or may be absent.

ASSOCIATED CONDITIONS

Pregnancy Considerations:

- Flank pain during pregnancy may be a symptom of an obstructing ureteral stone or pyelonephritis, as well as hydronephrosis of pregnancy which may be present in 60–100% of women (more commonly on the right).

GENERAL PREVENTION

- Strategies depend on the etiology of the pain.
- Preventive strategies for calculous disease may include dietary modification and medical management to reduce recurrent stone formation.
  – Dietary modifications include increasing fluid intake, and reducing intake of sodium,

animal protein, and oxalate-rich foods.
  – Drugs such as citrate, allopurinol, and thiazide diuretics may be necessary depending on the underlying metabolic abnormality.
  – Calcium reduction has not been shown to affect the likelihood of recurrent stone formation in most patients.

DIAGNOSIS

HISTORY

- Age and sex of patient
- Pain characteristics
  – Location: Flank(s)/abdomen
  – Quality: Dull/sharp
  – Duration: How long have symptoms been present
  – Severity: Use visual analog pain scales
  – Timing: Constant/intermittent, onset (sudden vs. gradual)
  – Radiation: Pain radiating from the flank down into the testicle or labia may suggest renal colic caused by passage of stone or clot down the ureter
  – Moderating factors: Medications, rest, position
  – Aggravating factors: Movement, cough
  – Associated symptoms: Fever, chills, dysuria, nausea, vomiting
- Prior medical history
  – History of nephrolithiasis (stone recurrence rates: 10%, 1 yr; 35%, 5 yr; 50%, 10 yr)
  – Diabetes mellitus, patients have higher predisposition to papillary necrosis and infections, including xanthogranulomatous pyelonephritis (XGP) and emphysematous pyelonephritis
  – GYN history (pregnancy/STDs)
  – History of trauma (penetrating vs. blunt)
- Prior surgical history
  – General surgical, urologic, and gynecologic abdominal and pelvic procedures involving a potential risk of ureteral injury and obstruction (TAH/BSO, vascular bypass, AAA repair, colectomy, ureteral manipulation)
- Social history
  – Smoking is a risk factor for development of urothelial carcinoma
- Family history
  – Polycystic kidney disease
  – Renal cell carcinoma

PHYSICAL EXAM

- Vital signs
  – Temperature: Fever is usually associated with infectious etiologies
  – Blood pressure
    ◦ Hypotension: Suspect sepsis or hemorrhage (eg, ruptured angiomyelolipoma (AML), aortic aneurysm), may need immediate intervention
    ◦ Hypertension: May reflect response to pain. Rule out renal parenchymal, renal cystic, or vascular disease
- Abdominal exam

  - Inspect for scars, skin changes, or signs of trauma
  - Bruit with aneurysm
  - Palpate abdomen and flanks to evaluate for masses, organomegaly, or tenderness
  - Fist percussion of flank: CVA tenderness suggests renal etiology
- Peripheral pulses with aneurysm

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis
  - Initial diagnostic step in the management of flank pain. Ensure proper specimen collection: Clean catch or catheterized specimen.
  - Dipstick test is performed to evaluate for the presence of blood and/or infection. If abnormal, it should be followed by microscopic analysis and sent for culture and sensitivities.
  - Presence of epithelial cells suggests a contaminated sample.
  - Hematuria suggests insult to the urologic system.
  - Urinary pH: >7.6 should raise suspicion for the presence of urea-splitting organisms.
  - A pH <5 is often associated with the formation of uric acid calculi.
  - Nitrite and/or LE positivity: Indicates presence of infection or inflammation. Nitrite positivity is more specific for infection than LE positivity.
- Urine and blood cultures: Collect prior to administration of antibiotic therapy.
- CBC: Elevated WBC suggests infectious or inflammatory process. Low Hgb/Hct may suggest hemorrhage.
- Chemistry profile: Assess renal function and electrolytes; elevated BUN/creatinine and reduced creatinine clearance suggest renal insufficiency/failure.
- Liver function panel: Rule out malignant hepatic processes.
- Other tests may be ordered depending on clinical presentation and judgment.

Imaging (1)

- Plain radiograph. Historically, a kidney ureter bladder abdominal flat plate plain film (KUB) was the initial radiograph done for the evaluation of flank pain to rule out urolithiasis. However, KUB may be unable to demonstrate small or radiolucent (eg, uric acid, indinavir) calculi. May show nephrocalcinosis. Overall sensitivity for stone detection is 59%.
- Excretory urogram/IVP
  - Once the standard for urologic evaluation of flank pain, IVP is very accurate, with the diagnosis of calculous disease able to be established in 96% of cases.
  - Aids in quantifying severity of obstruction.
  - Contraindications to the use of IV contrast media include renal insufficiency and previous reaction to contrast media.
  - Limitations include the complexity and length of time needed to perform the series of images.
- CT
  - Low-dose, noncontrast-enhanced CT has largely replaced KUB and IVP as the standard imaging modality for the workup of acute flank pain from suspected urolithiasis. It has been shown to be very sensitive and specific (97% and 96%, respectively) in detecting calculi.

- It can detect secondary signs of obstruction (hydronephrosis, renal enlargement, perinephric stranding), and can also be used to assess nonrenal causes of flank pain (appendicitis, pancreatitis, tubal pregnancy, etc.).
- Renal/ureters/bladder US
  - Can diagnose hydronephrosis with a sensitivity of 85–94% and a specificity of 100%.
  - Disadvantages: Sensitivity for detecting stones only 24–57%, limited in obese patients, and operator-dependent.
- Nuclear scan: Helps to evaluate differential renal function, degree of obstruction, and presence of renal scarring.
- MRI: Not usually indicated for initial workup unless CT is contraindicated. It may be helpful for evaluation of renal masses or in the evaluation of suspected spinal cord pathology.

Diagnostic Procedures/Surgery

These are dependent upon etiology

Pathologic Findings

These are dependent upon etiology

DIFFERENTIAL DIAGNOSIS

- There are many causes of flank pain. It is useful to differentiate between urologic and nonurologic causes. Renal/ureteral etiologies are the most common and those that usually require urologic intervention. Some of the most common causes are listed below (2).
  - Urologic
    - Calculi: Mostly ureteral; however, renal pelvic and calyceal stones (obstructing infundibulum) can cause flank pain
    - Acute cortical necrosis
    - Acute papillary necrosis
    - Ptotic kidney
    - Polycystic kidney disease
    - Acute/chronic pyelonephritis
    - Renal infarction (renal artery thrombus or dissection)
    - Renal cyst (especially hemorrhagic; benign cysts rarely cause flank pain)
    - Renal neoplasm
    - Renal trauma
    - Renal vein thrombosis
    - Retroperitoneal bleed or mass
    - Ureteropelvic junction obstruction
    - Calyceal diverticulum
    - Medullary sponge kidney
    - Other ureteral obstruction (extrinsic compression, blood clot, necrotic material, etc.)
  - Nonurologic
    - Appendicitis
    - Abdominal aortic aneurysm
    - Diabetes
    - Diverticulitis
    - Herpes zoster

- Musculoskelet al (muscle spasm, costochondritis, strain)
- Myocardial infarction
- Ovarian torsion
- Pancreatitis
- Peripheral nerve compression or trauma
- Peripheral neuropathy
- Pleuritis
- Tubal pregnancy
- Vertebral or spinal cord/nerve root irritation (herniated disc, sciatica, vertebral body fracture, or collapse)

TREATMENT

GENERAL MEASURES (3)

- Treatment varies based on etiology.
  - Rest and physical therapy may be recommended for flank pain cause by muscle spasms.
  - NSAIDs are excellent 1st-line agents to control pain secondary to inflammation, but caution must be used in the presence of acute ureteral obstruction or in patients with advanced renal disease as they can decrease intrarenal blood flow.

MEDICATION

First Line

- Acute pain control (NSAIDs, opioids)
- Antiemetics, antipyretics, antibiotics as appropriate
- IV fluids if sepsis/hypovolemia. May also help with passage of stones

Second Line

α-antagonists and calcium channel blockers may help with expulsion of ureteral stones.

SURGERY/OTHER PROCEDURES

- Prior to any diagnostics or intervention, the patient must be stabilized.
- Surgical management may be required in some cases depending on the etiology and the patient's medical condition.
- Examples of surgical management: If the collecting system is infected and obstructed or renal abscess is present, percutaneous drainage and antibiotics are the mainstays of treatment. If dealing with a ruptured AML, embolization should be considered. Renal tumors should be treated on an elective basis. Emergent nephrectomy for ruptured AML or XGP/emphysematous pyelonephritis may be necessary.

ADDITIONAL TREATMENT

Radiation Therapy

NA

Additional Therapies

NA

Complementary & Alternative Therapies

NA

ONGOING CARE

- Follow-up for flank pain will also be dictated by the etiology and acuity of the clinical presentation. Repeat imaging or other lab studies may be required depending on response to initial therapy.
- If clinical picture fails to improve or worsens, a change in therapy should be instituted (ie, different antibiotic, PCN, surgical intervention).

PROGNOSIS

In general, for nephrolithiasis, the prognosis is good but this may vary for other etiologies.

COMPLICATIONS

Longstanding ureteral obstruction can cause permanent loss of renal function.

FOLLOW-UP

Patient Monitoring

Periodic renal imaging, urinalysis, or 24-hr urine may be indicated for patients with stone disease. Follow-up may be more or less intensive based on etiology.

CODES

ICD9

- 592.9 Urinary calculus, unspecified
- 788.0 Renal colic
- 789.09 Abdominal pain, other specified site

ICD10

- N20.9 Urinary calculus, unspecified

- N23 Unspecified renal colic
- R10.9 Unspecified abdominal pain

CLINICAL/SURGICAL PEARLS

- Flank pain associated with fever and chills may represent urinary tract infection (pyelonephritis).
- Abdominal aortic aneurysm is a potentially life-threatening cause of flank pain.

FOLEY CATHETER PROBLEMS (INSERTION AND REMOVAL)

James Kearns, MD

BASICS

DESCRIPTION

- The terms "urethral catheter" and "Foley catheter" are often used interchangeably. Urethral catheter is a general description of a tube that traverses the urethra whereas a Foley catheter refers to a urethral catheter with a retention balloon.
- Common types of urethral catheter include:
  - Foley: rounded tip with balloon
  - Council: hole at distal tip to allow for passage over wire or on the end of a stylette
  - Coude': angulated distal tip to allow for navigating past large prostates or elevated bladder necks
- 2-way catheters have a single drainage port and a balloon port
- 3-way catheters have a drainage port, an infusion port, and a balloon port
  - NOTE: Drainage channel is larger in a 2-way catheter than 3-way catheter of the same size
- Size measured in Charrier or French (Fr) scale
  - Fr = D × 3, where D = diameter in mm
  - Common sizes include 5–10 Fr in the pediatric population and 16–24 Fr in the adult population
- Common materials include latex and silicone
  - Latex appropriate for short-term (< 1 mo)
  - Silicone better for longer-term or latex allergy
- Hydrophilic coatings may facilitate easier passage of catheter
- Problems can occur with insertion, drainage, or removal

EPIDEMIOLOGY

Incidence

Unknown but very common in hospitalized patients

Prevalence

N/A

RISK FACTORS

Hospitalized patient requiring strict documentation of urine output, BPH, urethral stricture disease, bladder neck contracture, previous urethral or prostate surgery, trauma, immobility, obesity

Genetics

N/A

PATHOPHYSIOLOGY

Indications for urethral catheterization include need for bladder decompression, need for accurate monitoring of urine output, immobility during postoperative setting, diversion of urine from wounds, instillation of therapeutic agents, and facilitation of certain diagnostic

studies (eg, urodynamics, VCUG, cystogram)

ASSOCIATED CONDITIONS

- BPH
- Balanitis xerotica obliterans (BXO)
- UTI
- Urinary retention
- Neurogenic bladder
- Liver failure, heart failure—edema

GENERAL PREVENTION

- Minimization of unnecessary urethral catheterization
- Removal of urethral catheter as soon as clinically indicated
- Proper insertion technique prevents false passages and potential bladder neck or urethral strictures
  - Catheter should always be placed without undue force, using copious lubrication
    - Excess force may lead to false passage creation

ALERT

Do not inflate foley balloon unless the catheter is confirmed in the bladder.

- Look for urine return and insert catheter until "hub" reaches urethral meatus.
- If no urine return with "hubbed" catheter, irrigate normal saline into the bladder with a catheter-tipped syringe; 120 mL is often necessary before fluid can be aspirated.
- Inflation in urethra or prostate may lead to significant hematuria or future urethral stricture as well as inability to place another catheter:
  - Always inflate balloon with water as saline may crystallize and is usually not necessary to test balloon prior to insertion

DIAGNOSIS

HISTORY

- Previous difficulty with catheterization
- Urethral instrumentation in the past
- Episodes of urethral catheterization
- Prior pelvic radiation or brachytherapy
- History of urinary symptoms
  - Quality of urinary stream, urinary frequency, sensation of emptying, history of urinary retention
- Circumcision may lead to meatal stenosis

PHYSICAL EXAM

- Abdominal examination for palpable bladder, dullness to percussion over lower abdomen
- DRE feels for evidence of prostate cancer (nodularity or hardness), prostatic abscess (tender prostate), urethral disruption (high-riding or nonpalpable prostate)
- Bimanual examination to evaluate for bladder or pelvic masses
- Palpate penis for strictures
  - Both location and length of stricture important

- Blood at meatus suggests trauma/urethral disruption

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Electrolytes and creatinine to evaluate for renal function
  - Decreased renal function in an obstructed patient is risk factor for postobstructive diuresis

Imaging

- Generally unnecessary
- Retrograde urethrogram can demonstrate urethral disruption, injury, or stricture
- Cystourethroscopy, if needed

Diagnostic Procedures/Surgery

- Catheterization is both diagnostic and therapeutic
  - See treatment section

Pathologic Findings

If performed in OR, may consider biopsy of strictures

DIFFERENTIAL DIAGNOSIS

- Difficulty placing catheter
  - Urethral sphincter spasm
  - BPH
  - Urethral stricture
  - Bladder neck contracture
  - Urethral disruption
  - Urethral false passage
  - Phimosis
  - Meatal stenosis
  - Penile/foreskin edema
  - Obesity/buried penis
  - Retracted meatus in women
  - Urethral stone or foreign body
- Problems with drainage
  - Clot retention
  - Bladder debris (tumor or stone)
- Difficulty removing catheter
  - Improper coupling of syringe to balloon port
  - Obstructed balloon port
  - Encrustation of balloon or catheter
  - Catheter sutured in place

TREATMENT

GENERAL MEASURES

- Assess need for urethral catheterization
- For difficult placement, start with an 16–18-Fr Foley and note location of difficulty
  - If stricture suspected, attempt 1 pass with 12–16-Fr Foley

- If BPH suspected, attempt 1 pass with 18–22-Fr coude
- Choose proper catheter size for pediatric population
  - Newborns/neonates based on body weight (no retention balloon)
    - <1000 gm: 3.5 Fr
    - 1000–1800 gm: 5 Fr
    - 1800–4000 gm: 6.5 Fr
    - >4000 gm: 8 Fr
  - Children
    - Age <5 yr, 5–8 Fr
    - Age 5–10 yr, 8–10 Fr
    - Age 10–14 yr, 10 Fr
    - Age >14 yr, 10–14 Fr

MEDICATION

First Line

Intraurethral lidocaine jelly may be useful in difficult catheter placement

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Urethral sphincter spasm
  - Provide reassurance and ask patient to relax and take slow, deep breaths
  - Intraurethral lidocaine jelly may not decrease pain (1)
  - Instruct patient to attempt to void when encountering the sphincter
- BPH
  - Use a coude catheter to help navigate the prostate
    - Bend of catheter always facing up toward ceiling (often matches a raised area on balloon port)
  - Larger (ie, 20–22 Fr) preferable because less likely to bend on itself
- Urethral stricture/bladder neck contracture
  - If unable to pass 14 Fr or larger catheter, dilation likely necessary
  - General principle is to place catheter over a wire into the bladder using Seldinger technique
  - Flexible cystoscopy is ideal
    - Advance scope to level of stricture
    - Pass 0.038” wire through stricture into bladder
  - If cystoscope unavailable, consider filiforms with followers, or blindly pass 0.038” soft-tip wire into bladder and confirm location of wire in bladder
    - Portable pelvic x-ray
    - Insert 5-Fr open-ended catheter over wire and aspirate; presence of urine indicates bladder location of wire

ALERT

Never dilate urethra unless wire in bladder.

- Wire rigid enough to potentially undermine bladder neck or enter rectum:
  - Dilate over wire using serial Amplatz-type renal dilators to 1 size larger than desired

catheter (ie, 22 Fr for 20-Fr catheter)
- If dilators unavailable, serial silicone catheters may be rigid enough for dilation:
  - Insert Council catheter over wire until return of urine and inflate balloon
- If Council unavailable, use 14-gauge Angiocath to thread wire into Foley.

- Urethral disruption
  - Retrograde urethrogram generally necessary for diagnosis, but consider blind passage of catheter in trauma patient without pelvic fracture or signs of urethral injury (ie, blood at meatus, perineal hematoma, high-riding prostate) (2)
  - Consider cystoscopically inserting catheter
  - Low threshold for suprapubic catheter
- Urethral false passage
  - False passage generally down, so use coude with tip pointed up
  - If unable to pass coude, use cystoscope to place wire in bladder and place catheter over wire
- Phimosis
  - Attempt to retract foreskin
  - If able to visualize meatus, attempt to place Foley through meatus normally
  - If unable to visualize meatus, perform dorsal slit in foreskin under local anesthesia
- Meatal stenosis
  - Inject lidocaine gel
  - Serial dilation with Van Buren sounds
- Penile/foreskin edema
  - Manually compress edematous skin to minimize edema
  - Place catheter once meatus visible
- Retracted female meatus
  - Inserting a finger into the vagina may bring meatus forward
  - Manually direct catheter into meatus
- Urethral stone or foreign body
  - Cystoscopically remove stone/foreign body
- Clot retention with no catheter output
  - Ensure at least 20-Fr 2-way catheter in place
  - Manually irrigate catheter
  - If urine does not remain clear after irrigation, consider placing 3-way catheter (22 or 24 Fr) for continuous irrigation

ALERT
If outflow from catheter stops while on continuous bladder irrigation (CBI), immediately stop inflow.
- Decreased catheter output from bladder debris:
  - Manually irrigate
  - Consider insertion of larger catheter
- Inability to remove catheter:
  - Place syringe on balloon port for 30 min
  - Cut balloon port and wait for fluid output
  - Insert stiff end of wire through balloon port to attempt to unclog the port

– If still unable to remove catheter:
  ◦ Under US guidance, spinal needle may be inserted into balloon percutaneously
  ◦ In women, transvaginal US and needle placement may be preferable
  ◦ If balloon palpable in bulbar or pendulous urethral, transcutaneous placement of a 22-gauge needle may decompress balloon
– If catheter sutured in place and suture resorbable, consider waiting before removing catheter
– Open cystotomy with retrograde removal is a final resort

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

If unable to place urethral catheter, suprapubic catheterization may be necessary

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

N/A

COMPLICATIONS

- False passage
- Hematuria
- Catheter-associated UTI
  – Many catheters have antimicrobial coatings, which may not be beneficial (3)

FOLLOW-UP

Patient Monitoring

- Before removing difficult Foley, ensure no foreseeable indication for recatheterization
- Consider removing catheters at midnight so a failed voiding trial can be managed early during the day

Patient Resources

N/A

CODES

ICD9

- 996.64 Infection and inflammatory reaction due to indwelling urinary catheter
- 996.76 Other complications due to genitourinary device, implant, and graft
- V53.6 Fitting and adjustment of urinary devices

ICD10

- T83.51XA Infect/inflm reaction due to indwell urinary catheter, init
- T83.89XA Other specified complication of genitourinary prosthetic devices, implants and grafts, initial encounter
- Z46.82 Encounter for fitting and adjustment of non-vascular catheter

CLINICAL/SURGICAL PEARLS

- Proper initial catheter placement will prevent many subsequent problems.
- A calm patient and proper equipment are critical for success.
- If dilation is necessary, always confirm wire in bladder before dilating.
- Perform voiding trials at times that allow for reinsertion of difficult catheter at a convenient time.
- Suprapubic catheterization is a reliable method of bladder drainage, if needed.
- Remove catheter as soon as possible to reduce risk of catheter-associated UTI.

FOURNIER GANGRENE

Brad Figler, MD
Bryan Voelzke, MD, MS

BASICS

DESCRIPTION

- Necrotizing soft tissue infection arising in the genitalia and/or perineum
- Rapidly progressive and life-threatening with a high mortality rate
- Much more common in men than women

ALERT
Fournier gangrene is a urologic emergency, causing progressive tissue destruction with significant potential for soft tissue loss, sepic shock, and death. Prompt debridement is mandatory.

EPIDEMIOLOGY

Incidence

- 1.1 per 100,000 patients are admitted for treatment of Fournier gangrene nationally (1)
- Most common in 5th and 6th decades of life
- Male > Female (10:1)
- Limited to 60 case reports in children

Prevalence

Unknown

RISK FACTORS

- Alcoholism
- Diabetes mellitus
- Genital skin trauma
- Impaired immunity
- IV drug abuse
- Recent penile, perineal, or perirectal surgery
- Urethral stricture

PATHOPHYSIOLOGY

- Primary insult is a breach in the integrity of the GI or urethral mucosal lining
- Infection is frequently polymicrobial (aerobic and anaerobic, gram-positive and gram-negative)
- Pathogens differs from nonnecrotizing infection: Higher frequency of virulent organisms such as group A streptococci, community-associated methicillin-resistant *Staphylococcus aureus* (CA-MRSA), and Clostridium spp (2)
- Obliterative endarteritis leads to thrombosis, ischemia, and necrosis, which allows for further bacterial proliferation
- Process extends along Dartos and Colles fascia, potentially involving perineum, abdomen, thighs, ischiorectal fossa, and retroperitoneum

- Rates of spread as high as 2–3 cm/h have been reported
- Deep structure (corpus cavernosum, corpus spongiosum, and testicles) are typically not affected

ASSOCIATED CONDITIONS
- Perianal/scrotal abscess
- Immunosuppression
- Obesity
- Urethral stricture
- Paraplegia
- Malignancy
- Septic abortions, vulvar abscesses, and episiotomy (in women)

GENERAL PREVENTION
- Early recognition/treatment of infection
- Early and aggressive management of underlying immunosuppressive conditions

DIAGNOSIS

HISTORY
- Presentation is typically abrupt with severe pain in the perineum, abdominal wall and thighs, however a prodrome of several days of fever and lethargy can be seen
- Perineal or genital trauma (including bites)
- Urethral instrumentation
- Perirectal/scrotal/perineal abscess or wound
- Urinary tract infection or STD
- Urethral stricture disease
- Anal fissure, fistulae, or hemorrhoids
- Alcohol or IV drug abuse
- Malignancy
- Diabetes mellitus
- Steroid use
- HIV

PHYSICAL EXAM
- Altered mental status
- Pain out of proportion with physical exam
- Tachycardia and tachypnea
- Fever or hypothermia
- Cellulitis
- Dusky, erythematous or frankly necrotic, skin
- Foul odor described as strong or feculent
- Crepitus
- Edema of the involved skin
- Purulent drainage
- Rectal exam essential. Assess for:
  – Tumor

– Perirectal abscess

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC: Leukocytosis/leukopenia, anemia
- Serum chemistry: Hyponatremia, hypocalcemia, elevated serum creatinine, hyperglycemia, metabolic acidosis
- Myonecrosis may elevate CK levels
- Coagulopathy
- Glucosuria and pyuria
- Wound culture (aerobes, anaerobes, fungi)
  – Aspiration of subcutaneous skin at the point of demarcation for Gram stain and culture may be useful
  – Deep tissue cultures at the time of surgery should be obtained
- Urine and blood culture. In spite of severe clinical findings blood cultures are rarely positive

Imaging

- Plain radiography or ultrasound may show subcutaneous emphysema; less sensitive than CT
- CT helpful in identifying nidus of infection and/or subcutaneous emphysema
- MRI can be used to define affected areas, but should not delay prompt surgical intervention

Diagnostic Procedures/Surgery

- Immediate surgical debridement
- Incision should be extended until normal appearing tissue is encountered
- Infection presumed present as far peripherally as swelling, erythema exist, watery pus, or necrotic fascia are found

Pathologic Findings

- Intact epidermis with dermal necrosis
- Vascular thrombosis
- Acute PMN infiltrate

DIFFERENTIAL DIAGNOSIS

- Cellulitis
- Balanitis
- Epididymitis/orchitis
- Hidradenitis suppurativa
- Pyoderma gangrenosum
- Strangulated inguinal hernia
- Testicular torsion

TREATMENT

GENERAL MEASURES

- Immediate and aggressive surgical therapy with debridement of necrotic tissue
- Aggressive fluid resuscitation (isotonic fluid)
- Inotropic support is frequently necessary
- Correct coagulopathy

- Quadruple antibiotics
- ICU support until clinically stable

MEDICATION

First Line

- Antibiotics should include gram-positive, gram-negative, and anaerobic coverage in full therapeutic dosages
- Modify antibiotics as needed, based on Gram stain, culture, and sensitivity
- Appropriate empiric therapy typically consists of:
  - Penicillin G 3–5 million international units IV q6h (Gram-positive coverage)
  - Imipenem 500–1,000 mg IV q6h (polymicrobial coverage)
  - Clindamycin 600–1,200 mg/d, divided dose (anaerobic coverage)
  - Vancomycin 1 g IV BID (MRSA)

Second Line

- Potential single-agent regimens include:
  - Imipenem/cilastatin
  - Meropenem
  - Ertapenem
  - Piperacillin/tazobactam
  - Ticarcillin/clavulanic acid
  - Tigecycline
- Intravenous immunoglobulin may be a useful adjunct in treatment of staphylococcal or streptococcal infections with signs of toxic shock syndrome (TSS)

SURGERY/OTHER PROCEDURES

- Immediate and aggressive wide surgical debridement and irrigation with bacteriocidal solution minimizes progression of necrosis.
- All affected tissues should be debrided; questionable involvement can be treated with incision and drainage and observation.
- Repeat exam under anesthesia and possible debridement at 24-48 hr
- Fascia and muscle are rarely involved and do not typically require wide resection.
- Testicles and tunica vaginalis are rarely involved; when possible, tunica vaginalis should be left intact to facilitate future application of skin graft
- Consider cystoscopy if there is concern for urethral nidus
- Consider proximal urinary diversion (suprapubic tube, percutaneous nephrostomies) if the penis is extensively involved
- If perirectal disease is identified, exam with proctoscopy under anesthesia is necessary
- Postoperative care
  - If a vacuum assist closure (VAC) dressing is not used, wet-to-dry dressing changes are performed BID-TID
  - EUA after 24–48 hr to assess for and debride newly necrotic tissue
  - Follow cultures for sensitivities and adjust antibiotic therapy accordingly
  - Nutritional support (preferably enteral) should be instituted early to correct the negative nitrogen balance associated with profound sepsis

ADDITIONAL TREATMENT

- VAC may result in earlier wound granulation compared to simple wet-to-dry dressing changes, but may be difficult to apply to the perineum and genitalia (Level I) (4)
- If a VAC closure is not possible, the wound should be packed with fine-mesh gauze soaked in normal saline, Dakin (25%) solution, or Clorpactin
- Diverting colostomy may help keep perineal or peri-anal wounds clean
- Reconstruction can be performed after the patient has stabilized and the wound demonstrates adequate granulation
- When health of graft bed is uncertain, xenograft is an inexpensive and useful method for temporary wound coverage and is helpful in assessing suitability of graft bed for autologous skin grafting. Xenograft should be removed within 2 wk
- If $<50\%$ of scrotum is resected, can be reconstructed primarily
- Split-thickness skin grafts (meshed or unmeshed for penis; meshed for scrotum) are useful for covering small or extensive wounds, with excellent long-term results (4)
- Thigh pouches for testicles are effective, but can cause pain and interfere with testicular exam

Complementary & Alternative Therapies
- Whirlpool therapy for micro-debridement
- Hyperbaric oxygen may be helpful if used early as an adjunct to radical debridement (3)
- Dakin's solution, Sulfamylon solution, or Silvadene cream can be applied during each dressing change

ONGOING CARE

PROGNOSIS
- Historically, Fournier gangrene carried a $>50\%$ mortality rate
- Modern mortality rates average 5–20%, which is highly dependent on prompt diagnosis and tight coordination of definitive care (1)

COMPLICATIONS
- Coagulopathy
- Death from sepsis
- Disfiguring skin and soft tissue loss
- Infertility
- Multi system organ failure
- Renal failure
- Urethral stricture

FOLLOW-UP
Patient Monitoring
Prolonged critical care may be required.

- Urosepsis (Septic Shock)
- Fournier Gangrene Images

CODES

ICD9

- 608.83 Vascular disorders of male genital organs
- 616.89 Other inflammatory disease of cervix, vagina and vulva

ICD10

- N49.3 Fournier gangrene
- N76.89 Other specified inflammation of vagina and vulva

CLINICAL/SURGICAL PEARLS

- Signs of local infection with pain out of proportion to physical exam is highly suspicious for a diagnosis of Fournier Gangrene.
- Prompt and radical debridement is mandatory.
- Infections are typically polymicrobial, so broad-spectrum antibiotics are critical.

FUNGAL INFECTIONS, GENITOURINARY

Daniel C. Parker, MD
Michael A. Pontari, MD

BASICS

DESCRIPTION

- Primary fungal infection of the genitourinary (GU) tract is common with Candida, but uncommon with other fungi.
- Other fungal infections are found in the GU tract but are seen more commonly with immunocompromised patients or in setting of systemic disease.

EPIDEMIOLOGY

Incidence

- Difficult to determine because most cases are not reportable
  - Estimated 1–2 new cases per 100,000 population per year involving the GU tract

Prevalence

Difficult to estimate as cases are not reportable

RISK FACTORS

- Urinary tract drainage catheter
- Prior antibiotics
- Diabetes/glucosuria
- Urinary tract pathology
- Malignancy
- Increased age
- Neonates
- Female sex
- Prior surgical procedures
- Immunosuppression

Genetics

No heritable form of transmission

PATHOPHYSIOLOGY

- Funguria to fungemia:
  - Can occur with obstruction, reflux, or instrumentation
- Fungemia to funguria:
  - Disseminated disease seeds GU tract
    - Multiple microabscesses develop in the renal cortex, with subsequent penetration into the glomeruli and shedding into the urine from the proximal tubules

ASSOCIATED CONDITIONS

- Immunocompromised state:
  - Diabetes

  - AIDS
- Anatomic GU abnormalities:
  - Strictures
  - Prostatic hypertrophy
  - Diverticula
  - Indwelling tubes
  - Stones

GENERAL PREVENTION

- Remove unnecessary catheters/tubes
- Narrow antibiotic coverage
- Improve nutritional status
- Control hyperglycemia

DIAGNOSIS

HISTORY

- Immunocompromised state:
  - Fungi are ubiquitous in the environment and can overwhelm those with weakened immune systems
  - Those receiving chemotherapy, with AIDS, or afflicted with diabetes
- Recent antibiotic use:
  - Risk of candiduria is 6× after use of broad-spectrum antibiotics
- Indwelling GU tubes or prosthesis:
  - Risk of candiduria 12× with catheterization
- GU tract abnormalities:
  - Risk of candiduria 6× with abnormalities (1)[A]
- Occupation:
  - Exposure to aerosolized soil; spelunkers; bird handler
- Recent travel or recreation (see image):
  - Blastomycosis found in Ohio, Missouri, and Mississippi river basins; Great Lakes; Canada
  - Coccidioidomycosis found in semiarid regions of the Western US, Mexico, Central and South America
  - Histoplasmosis found in Midwestern and Southern US in areas of high-nitrogen soil such as chicken coops and bat caves
  - *Cryptococcus* thrives with birds
- UTI symptoms:
  - Only 4–14% with symptomatic candiduria

PHYSICAL EXAM

- CVA tenderness
- Abdominal tenderness
- Boggy or firm prostate
- Firm testicular or epididymal masses
- GU tubes present
- Manifestations of disseminated disease

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Candida:
  - No studies have established the importance of pyuria or quantitative urine culture in diagnosing *Candida* UTI (2)[A]
  - Presence of pyuria helpful in those without catheter, however, up to 25% with candiduria also have bacteriuria/pyuria
  - Urine cultures positive for candiduria in otherwise asymptomatic patients should be repeated with a clean catch sample to rule out contamination (2)[B]
  - >10,000 CFU/mL could mean infection; 10,000–100,000 CFU/mL could mean colonization
  - Check urine microanalysis looking for casts containing yeast: Very specific, not sensitive
- Aspergillosis:
  - Culture in Sabouraud medium or stain tissue with methenamine silver or Periodic acid–Schiff stain (PAS); can PCR
- Cryptococcosis:
  - Culture; stain tissue with India ink, PAS, methenamine silver; perform latex agglutination
- Phycomycosis:
  - Stain tissue
- Blastomycosis:
  - Stain tissue and visualize secretions
- Coccidioidomycosis/histoplasmosis:
  - Culture and stain tissue

Imaging

CT abdomen with contrast and delayed imaging vs. US may elucidate bezoars, perinephric pathology, renal destruction

Diagnostic Procedures/Surgery

- Cystoscopy/retrograde urogram
- Urine culture
- Tissue biopsy

Pathologic Findings

Positive histology staining for fungi in tissue

DIFFERENTIAL DIAGNOSIS

- Blood clots in collecting system
- Cystitis
- GU TB
- Nephrolithiasis
- Squamous cell carcinoma (SCC)
- Urothelial carcinoma (transitional cell carcinoma)

TREATMENT

GENERAL MEASURES

- Infectious Diseases Society of America recommends treatment of candiduria in (3)[A]:
  - Infants with low birth weight
  - Patients who will have GU procedures
  - Neutropenic patients
  - Symptomatic patients
- Treat UTI symptoms empirically for funguria only if the patient is unable to vocalize or perceive symptoms
- Asymptomatic candiduria: Assess for risk factors (3)[A]

MEDICATION

First Line

- Aspergillosis:
  - Amphotericin B 1–1.5 mg/kg/d for 10 wk
- Blastomycosis:
  - Itraconazole 200 mg PO BID for 6–12 mo
- Candidiasis:
  - Clotrimazole, miconazole, tioconazole, terconazole topical for 1 wk
- Candidemia (treat for 2 wk after afebrile and Cx negative):
  - Fluconazole 400–800 mg/d IV, then PO
- Candiduria:
  - Fluconazole 200 mg/d IV/PO for 1–2 wk
- Coccidioidomycosis:
  - Itraconazole 200 mg PO BID. for 1 yr
- Cryptococcosis:
  - Amphotericin B 0.5–1 mg/kg/d IV + flucytosine 100 mg/kg/d PO for 2 wk
    - Then fluconazole 400 mg/d PO for 8 wk OR
    - Then Itraconazole 200 mg PO BID for 8 wk
  - For cryptococcal suppression:
    - Fluconazole 200 mg/d PO OR
    - Amphotericin B 0.5–1 mg/kg IV every week
- Histoplasmosis:
  - Itraconazole 200 mg PO BID for 6–18 mo
  - For histoplasmosis suppression:
    - Itraconazole 200 mg/d PO BID OR
    - Amphotericin B 0.5–1 mg/kg IV every week
- Mucormycosis:
  - Amphotericin B 1–1.5 mg/kg/d IV for 6–10 wk

Second Line

- Aspergillosis
  - Voriconazole 6 mg/kg q12h for 2 days, then 4 mg/kg q12h (IV or oral) for 10 wk OR
  - Itraconazole 200 mg IV BID for 4 days, then 200 mg/d IV for 12 days, then 200 mg PO BID for 10 wk OR
  - Itraconazole 200 mg PO TID for 9 days, then 200 mg PO BID for 10 wk
- Blastomycosis

  – Amphotericin B 0.5–1 mg/kg/d for 6–12 wk OR
  – Fluconazole 400–800 mg/d PO for 6–12 mo
- Candidiasis
  – Fluconazole 150 mg in 1 dose
- Candidemia (treat until 2 wk after afebrile and Cx negative):
  – Caspofungin 70 mg/d IV in 1 dose, then 50 mg/d OR
  – Amphotericin B 0.5–1 mg/kg/d
- Candiduria:
  – Amphotericin B 0.3–0.5 mg/kg/d IV for 1–2 wk OR
  – Flucytosine 25 mg/kg/d PO for 1–2 wk
- Coccidioidomycosis:
  – Fluconazole 400–800 mg/d PO for 1 yr OR
  – Amphotericin B 0.5–0.7 mg/kg/d IV for 1 yr
- Histoplasmosis:
  – Fluconazole 400–800 mg/d PO for 6–18 mo OR
  – Amphotericin B 0.5–1 mg/kg/d IV for 10–12 wk

SURGERY/OTHER PROCEDURES
- Obstructions from fungal bezoars require drainage.
- Access to upper tracts can facilitate drainage, antifungal irrigation, and extraction if needed.
- Perinephric abscess can be drained percutaneously, but may require operative drainage if multiple loculations are present.
- Severe aspergillus kidney infections may require nephrectomy.
- Treatment of fungal prostatitis may require surgical intervention for prostate resection or drainage of abscess in addition to medical therapy (4)[B].

ADDITIONAL TREATMENT

Radiation Therapy

None

Additional Therapies
- Irrigation may be necessary in aggressive infections when systemic medication is not excreted into the urine
  – Amphotericin B GU tract irrigation
    - 50 mg in 1,000-mL water at 40 mL/hr (over 24 hr) for 5–7 days
  – In children, renal irrigation with 10–24 mg/d
- Removing catheter may eradicate funguria in 40% of cases

Complementary & Alternative Therapies

None

ONGOING CARE

PROGNOSIS
- Candiduria does not predict development of candidemia in most people
  – Rates 1.3–10.5%
  – No different in renal transplant population: 5%

- Aspergillosis mortality 40–90% with treatment
- Phycomycosis (mucormycosis, zygomycosis) mortality 90% if untreated, 24% with nephrectomy and amphotericin B

COMPLICATIONS
- Bezoar formation
- Emphysematous pyelonephritis
- Obstruction, fungemia, death
- Papillary necrosis
- Perinephric abscess
- Renal scarring

FOLLOW-UP

Patient Monitoring
- Surveillance cultures can be obtained to document clearance of infection.
- Prostate can be fungal reservoir for recurrent infection.

Patient Resources

CODES

ICD9

- 112.1 Candidiasis of vulva and vagina
- 112.2 Candidiasis of other urogenital sites
- 116.0 Blastomycosis

ICD10

- B37.3 Candidiasis of vulva and vagina
- B37.4 Candidiasis of other urogenital sites
- B40.89 Other forms of blastomycosis

CLINICAL/SURGICAL PEARLS

- When fungal infections are found in the GU tract in patients without risk factors, a search for systemic disease is warranted.
- Disseminated fungal disease can seed the GU tract through the development of renal microabscesses.
- Fungal infections are encountered in varying geographic locales based on type.
- Treat candiduria in infants with low birth weight, those undergoing GU procedures, neutropenic patients, and symptomatic patients.
- Surgical drainage of fungal infections is indicated in cases of urinary tract obstruction.

GLOMERULONEPHRITIS, ACUTE

Christopher E. Keel, DO
Raju Thomas, MD, MHA, FACS

BASICS

DESCRIPTION

- Inflammation of the glomerulus mediated through humoral and cell-mediated immune mechanisms including immunoglobins, complement, and circulating T cells usually in response to an infection (typically streptococcal).
- The inflammation and immunologic response results in immune deposits in the glomerulus.
- Onset of symptoms is usually acute and includes oliguria, hypertension, hematuria, proteinuria, and renal impairment.
- Poststreptococcal acute GN is the onset of GN after a preceding group A β-hemolytic streptococcal infection, most commonly of the pharynx or skin.
  – Most common glomerulonephritis affecting children.
- Synonym(s): Acute nephritic syndrome; Postinfectious glomerulonephritis.

EPIDEMIOLOGY

Incidence

- Poststreptococcal GN, the most common form, occurs most frequently in children between 2 and 10 yr of age but can occur at any age with a slight predominance of males over females
  – 10% cases are in adults >40 yr of age
  – 20/100,000/yr

Prevalence

- Most patients have a complete recovery, with resolution of clinical signs within a few weeks.
- The reported incidence of chronic renal insufficiency is 0–20%.

RISK FACTORS

- Occurs with infection of specific types of group A β-hemolytic streptococci, and these vary by site of infection. It occurs more commonly after pharyngitis than pyoderma:
  – Pharyngitis is associated with types 1, 3, 4, 12, 25, 49 with the more common sporadic variety following infection with type 12.
  – Pyoderma is associated with types 2, 49, 55, 57, 60.

Genetics

N/A

PATHOPHYSIOLOGY

- Tends to occur with impetigo in the late summer and with streptococcal pharyngitis in the winter.
- Note that cases of postinfective GN have also been reported from other bacteria (Pneumococcus, Staphylococcus, Meningococcus) and after viral infections (chickenpox, hepatitis).
- The exact mechanism of renal injury from poststreptococcal GN is not clear. IgG and C3

deposits are found at the capillary wall and in the mesangium. It is unclear if the inflammatory response is due to circulating immune complexes, complexes in situ, or both.
  – The antigen or antigens activate the alternative complement pathway and result in renal damage.

ASSOCIATED CONDITIONS
- Pharyngitis
- Hematuria
- Hypertension
- UTI
- Acute renal failure
- Rapid decrease in renal function heralds the syndrome of rapidly progressive glomerulonephritis

GENERAL PREVENTION
No specific prevention measures; prompt treatment of strep infections may reduce risk

DIAGNOSIS
HISTORY
- Recent episode of pharyngitis or skin infection.
- Pharyngitis usually precedes renal disease by 8–14 days.
- Time between purulent skin disease and acute nephritis is widely variable.
- Severity varies from asymptomatic microhematuria to anuric renal failure.
- Gross hematuria occurs in 30–50%.
- Volume overload occurs in up to 2/3 of patients and may be severe enough to cause congestive heart failure and pulmonary edema.
- Hypertension occurs in up to 80%. Severity may not correlate with the degree of volume overload.
- Hypertensive encephalopathy (seizures, confusion, coma) is the presenting feature in 5%.
- Often patient has contact with individuals complaining of similar symptoms.

PHYSICAL EXAM
- Patients may have periorbital edema, peripheral edema, HTN
- Transient oliguria will be present in half of patients

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Throat swabs are rarely positive.
- Urinalysis (1):
  – Hematuria may be microscopic or gross and is present in all cases.
  – Microscopic analysis shows dysmorphic red blood cells and red cell casts.
  – >30% of red blood cells having dysmorphic features is a highly sensitive test for glomerular disease.
  – Red blood cell cast present after acute pharyngitis episode is pathognomic for poststreptococcal GN.
- Proteinuria may also be present and is usually mild (no more than 2+ on dipstick), but

some may have proteinuria to the nephrotic range.
- Evaluate proteinuria with a spot urine protein-to-creatinine ratio:
  – Normal <0.2.
  – Nephrotic range proteinuria being >2.0.
- Basic chemistry profile may reveal elevated BUN and creatinine consistent with ARF.
  – Urea can be raised disproportionately to creatinine.
- Mild normochromic, normocytic anemia due to hemodilution.
- Hyponatremia may be present due to volume overload.
- Acidemia and hyperkalemia may occur in those with severely depressed renal function.
- ESR will be elevated.
- Serum complement levels, in particular, C3 will be depressed early in the disease in 90%:
  – Normalizes 2–6 wk after onset.
  – Prior penicillin therapy may attenuate the fall in C3.
  – If C3 remains depressed beyond this interval, look for other causes.
- Antistreptolysin-O and antihyaluronidase titers may be obtained and may be elevated in poststreptococcal GN (2).
- Not all strains of streptococci will cause these elevations and site of infection may affect which is present.

Imaging
- No imaging is indicated to identify poststreptococcal GN.
- CXR may identify fluid overload.

Diagnostic Procedures/Surgery
- Renal biopsy *not* indicated in poststreptococcal GN unless symptoms persist or renal function deteriorates due to progressive disease
- Renal biopsy, thus, indicated if:
  – Persistently low C3 beyond 8 wk
  – Persistent heavy proteinuria after 6 mo
  – Atypical presentation—nephrotic syndrome, severe acute renal failure with estimated GFR <30 mL/min/1.73 m^2
  – Atypical course—failure of renal function to improve after initial improvement during the acute phase which usually lasts no more than 2 wk

Pathologic Findings
- IgG and C3 deposits are found at the capillary wall and in the mesangium on renal biopsy.
- Rapidly progressive GN is characterized pathologically by crescents forming from the cells of Bowman capsule.
- Typically $>50\%$ of glomeruli should have crescents to be called rapidly progressive GN. This may result from any of the immunologically mediated types of GN, but most frequently occurs with antiglomerular basement membrane disease, antineutrophil cytoplasmic antibody GN, and Henoch–Schönlein purpura nephritis.

DIFFERENTIAL DIAGNOSIS
- Anaphylactoid purpura
- IgA nephropathy
- Alport's disease

- Membranoproliferative glomerulonephritis
- Other postinfective glomerulonephritis
- Infective endocarditis
- Rapidly progressive glomerulonephritis
- Systemic lupus erythematosus

TREATMENT

GENERAL MEASURES
- Supportive care and reassurance.
- Monitor weight and serum sodium daily during acute phase.
- Bed rest does not influence rate of recovery.
- Antibiotics do not change the course of illness once established but should be given to reduce infection-related morbidity.
- Restrict protein until azotemia clears.

MEDICATION
First Line
- Treatment is supportive for this condition and directed at the effects of renal insufficiency and HTN.
- Sodium and water restriction is indicated in patients who show signs of fluid overload (400 $mL/m^2/d$).
- Loop diuretics, calcium channel blockers, and vasodilators are mainstays in the treatment of resultant HTN.
  - Furosemide 2–4 mg/kg/dose IV
    - Titrate dose based on clinical response.

Second Line
- Patients should be treated with a 10-day course of penicillin antibiotics to prevent the spread of the nephritogenic organisms. This will not alter the course of the disease.
- Erythromycin is substituted if penicillin allergic.
- Family members of patients with acute GN should be cultured for group A β-hemolytic streptococci and treated if positive.

SURGERY/OTHER PROCEDURES
Renal biopsy if indicated (see evaluation)

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS

- Most patients have a complete recovery, with resolution of clinical signs within a few weeks.
- The reported incidence of chronic renal insufficiency is 0–20%.
- Microscopic hematuria may persist for months up to 2 yr, and mild proteinuria may persist for years following an episode of poststreptococcal GN.

COMPLICATIONS

- Rarely does poststreptococcal GN progress to crescentic or rapidly progressive GN resulting in ESRD. Most cases resolve with no sequelae. Chronic renal failure or marked decline in glomerular filtration rate is very rare
- It is rare to result in severe HTN, seizures, anuria, hyperkalemia, or death.
- Hypertensive retinopathy or encephalopathy
- Rapidly progressive glomerulonephritis
- Microhematuria may persist for years
- Nephrotic syndrome (10%)
- Obesity may increase risk for residual renal injury

FOLLOW-UP

Patient Monitoring

- Subsequent urinalysis to ensure hematuria has resolved
- Periodic BP monitoring

Patient Resources

See Also (Topic, Algorithm, Media)

- Acute Kidney Injury, Adult (Renal Failure, Acute)
- Acute Kidney Injury, Pediatric (Renal Failure, Acute)
- Glomerulonephritis, Chronic

CODES

ICD9

- 446.21 Goodpasture's syndrome
- 580.4 Acute glomerulonephritis with lesion of rapidly progressive glomerulonephritis
- 580.9 Acute glomerulonephritis with unspecified pathological lesion in kidney

ICD10

- M31.0 Hypersensitivity angiitis
- N00.9 Acute nephritic syndrome with unsp morphologic changes
- N01.9 Rapidly progr nephritic syndrome w unsp morphologic changes

CLINICAL/SURGICAL PEARLS

- Dysmorphic RBC on microscopic urinalysis suggest the diagnosis.
- Prior pharyngitis or skin infection suggests diagnosis of acute glomerulonephritis.
- With supportive care, recovery is usually rapid and complete with an excellent prognosis.

GLOMERULONEPHRITIS, CHRONIC

Eric Langewisch, MD
John M. Barry, MD, FACS

BASICS

DESCRIPTION

- Chronic glomerulonephritis is the loss of renal function caused by damage to glomeruli
- Often mediated by inflammation and cellular proliferation
- Frequently associated with hematuria and proteinuria
- Many forms of glomerulonephritis (GN) present acutely. Progression from acute to chronic GN is variable
- IgA nephropathy is the most common type of GN

EPIDEMIOLOGY

Incidence

- 4/100,000 people in the United States (US)
- 20–50% of patients with acute GN will develop chronic GN

Prevalence

- GN is the 3rd leading cause of end-stage renal disease (ESRD) in the United States after diabetes mellitus and hypertension (1)
  – Accounts for about 10% of dialysis patients

RISK FACTORS

- The cause of many forms of chronic GN is unknown
- Acute GN (focal segmental glomerulosclerosis, hemolytic uremic syndrome, IgA nephropathy, membranous GN)
- Autoimmune diseases (systemic lupus erythematosus (SLE), Goodpasture's syndrome, systemic vasculitis)
- Infections (β-streptococci, human immunodeficiency virus (HIV), Hepatitis B, Hepatitis C)
- Other systemic diseases (diabetes mellitus, multiple myeloma, amyloidosis, Henoch–Schönlein purpura, polyarteritis nodosa, Wegener's granulomatosis)
- Family history of hereditary GN (Alport syndrome, thin basement membrane disease)

Genetics

Some cases of hereditary GN or nephritis (Alport syndrome caused by a mutation of *COL4A5* gene, usually X-linked and more severe in men; thin basement membrane disease)

PATHOPHYSIOLOGY (2)

- Damage to glomeruli, often mediated through immune/inflammatory mediators, leads to decreased filtering surface and nephron mass
- Remaining glomeruli are subjected to increased filtering pressure. This results in hyperfiltering by remaining glomeruli.
- Increased glomerular pressure causes progressive sclerosis of glomeruli and interstitial fibrosis and progressive loss of functioning glomeruli

ASSOCIATED CONDITIONS
See Risk Factors

GENERAL PREVENTION
- Early nephrology consultation can improve outcomes
- Treat active GN, eg, immune suppressing/modulating agents for active lupus nephritis
- Control blood pressure
  - Target <125/75 in patients with >1 g proteinuria
  - Target <130/80 in patients with <1 g proteinuria
- Treat comorbid conditions
  - Dyslipidemia
  - Diabetes
  - Infectious disease
  - Malignancy
- Dietary protein restriction
  - Must balance protein restriction with risk of malnutrition
- Avoid NSAIDs, aminoglycosides, and contrast media as they may further impact on the renal insufficiency

DIAGNOSIS

HISTORY
- Often asymptomatic
- Past acute kidney disease
- Symptoms of uremia
  - Decreased energy
  - Met allic taste in mouth
  - Poor appetite
  - Pruritus
  - Slowed cognition

PHYSICAL EXAM
- May be unremarkable
- Weight loss
- Hypertension
- Volume overload
  - Elevated jugular venous pressure, pulmonary rales, pedal edema
- Signs of uremia
  - Asterixis
  - Pericardial rub

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Elevated plasma creatinine from loss of renal function (3)
  - Prior plasma creatinine values may help determine rate of renal function deterioration
- Serologies may help identify etiology
  - Antistreptolysin O, antinuclear antibody (ANA), antineutrophil cytoplasmic antibody

(ANCA), C3, C4, HIV, Hep B, Hep C
- Urinalysis
  - Proteinuria
  - RBC casts
    - Considered diagnostic for GN or vasculitis
  - Dysmorphic RBC
    - Isomorphic RBCs appear similar to erythrocytes in the circulation (small, anucleated cells; biconcave discs)
    - Dysmorphic RBC criterion varies; membrane protrusions such as seen with peripheral acanthocytes are 1 described criterion
- Urine protein measurement
  - 24-hr urine (normally <100 mg)
  - Random urine microalbumin/ creatinine ratio (normally <20 μ/mg)
  - Random urine protein/creatinine ratio (normally <0.2)
- With significant chronic kidney disease
  - Anemia from decreased erythropoietin production
  - Hyperkalemia from decreased potassium clearance
  - Hyperphosphatemia from decreased phosphorous excretion
  - Acidemia from decreased acid buffering

Imaging
- Renal ultrasound to assess kidney size and cortical volume
  - Advanced disease is associated with decreased renal size, increased echogenicity, and cortical thinning
  - Kidneys usually normal sized with diabetic nephropathy

Diagnostic Procedures/Surgery
- Renal biopsy can potentially diagnose different glomerular diseases
  - Biopsy may not be helpful in advanced disease

Pathologic Findings
- Renal biopsy may determine type of glomerular disease by pattern of injury and immune complex staining
  - With advanced disease and small kidneys on ultrasound, biopsy frequently shows advanced sclerosis/scarring and may not be able to determine etiology

DIFFERENTIAL DIAGNOSIS
- Aristocholic acid (for weight control)
- Chronic interstitial nephritis
- Diabetic nephrosclerosis
- Diuretic abuse
- Hypertensive nephrosclerosis
- Nephrotoxin exposure
- Obstructive uropathy
- Prerenal disease
- Renal artery stenosis

TREATMENT

GENERAL MEASURES

- See GENERAL PREVENTION
- Referral to nephrology
- Treat specific glomerular disease (eg, prednisone or other immunosuppressive agents)
- Control blood pressure (4)
- Renal replacement therapy may be necessary long term

MEDICATION

First Line

- Angiotensin-converting enzyme inhibitors (ACEIs) and angiotensin receptor blockers (ARBs) slow the decline of the glomerular filtration rate (GFR) in patients with diabetic and nondiabetic proteinuric nephropathies
  - ACEIs: Benazepril, captopril, enalapril, fosinopril, lisinopril, moexipril, quinapril, ramipril, others
  - ARB: Candesartan, eprosartan, irbesartan, losartan, telmisartan, valsartan
  - Use may be limited by drug-induced hyperkalemia, increased plasma creatinine due to decreased glomerular pressure, or anemia

Second Line

- Diuretics to treat volume overload
- Additional antihypertensive agents to reach blood pressure goals
  - β-Blockers, calcium channel blockers, central α2-agonists (eg, clonidine), α1-antagonists, and direct vasodilators

SURGERY/OTHER PROCEDURES

- Access for dialysis
  - AV fistula or graft
  - Hemodialysis access or peritoneal dialysis catheter
- Renal transplantation
  - Preemptive transplantation before dialysis results in better survival than transplantation after the initiation of dialysis

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Oral calcium supplements (1 g/d) and vitamin D (400–800 IU/d) for prophylaxis against osteoporosis.
- Sodium bicarbonate has been shown to slow progressive kidney damage.

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Progression of glomerular disease to ESRD is variable and dependent upon cause and response to treatment
- Prognosis has negative correlation with higher blood pressure and degree of proteinuria

COMPLICATIONS

- ESRD
  - Uremia
  - Volume overload
  - Hyperkalemia
  - Anemia
  - Acidosis
- Increased risk of cardiovascular disease
- Increased risk of mortality

FOLLOW-UP

Patient Monitoring

- Lab monitoring
  - Estimate glomerular filtration rate (eGFR): BUN, plasma creatinine
  - Basic metabolic panel + phosphorous
  - Random urine protein/creatinine ratio
  - 24-hr urine protein
- Blood pressure
- Signs or symptoms of uremia

Glomerulonephritis, Acute

CODES

ICD9

- 582.1 Chronic glomerulonephritis with lesion of membranous glomerulonephritis
- 582.89 Chronic glomerulonephritis with other specified pathological lesion in kidney
- 582.9 Chronic glomerulonephritis with unspecified pathological lesion in kidney

ICD10

- N03.2 Chronic nephritic syndrome w diffuse membranous glomrlneph
- N03.9 Chronic nephritic syndrome with unsp morphologic changes
- N11.9 Chronic tubulo-interstitial nephritis, unspecified

CLINICAL/SURGICAL PEARLS

- Many cases of acute GN can progress to chronic GN.
- ACEIs and ARB can slow the decline of the GFR in patients with proteinuric nephropathies.

GONORRHEA

Arpeet Shah, MD
Ahmer V. Farooq, DO

BASICS

DESCRIPTION

- A sexually transmitted disease (STD) caused by the gram-negative diplococcal bacteria *Neisseria gonorrhea*
  - Clinical manifestations range from asymptomatic disease to disseminated infection
  - In men, can cause urethritis, prostatitis, and epididymitis
  - In women, can cause cervicitis, salpingitis, endometritis, and pelvic inflammatory disease
  - Anorectal and pharyngeal infections may also occur depending on sexual practices
  - *Pediatrics:* Vertical transmission to newborn may result in infection of conjunctiva, rectum, or respiratory tract; rule out sexual abuse in infections of young children
  - Disseminated gonococcal infection may occur secondary to distinct strains or host factors and may result in a variety of clinical manifestations including skin lesions, arthritis, pericarditis, endocarditis, and meningitis

EPIDEMIOLOGY

Incidence

- In the United States, gonorrhea remains the 2nd most commonly reported bacterial STD
- The Center for Disease Control and Prevention (CDC) estimates 820,000 new cases per year with over half occurring in young adults ages 15–24
- In 2011, CDC reported the rate of gonorrheal infections to be 104.2/100,000 persons
- Rates in the United States have drastically declined since the 1970s due to the public health measures
- More recently, the rate decreased 11.7% during 2007–2011

RISK FACTORS

- Multiple sexual partners
- Unsafe sexual practices
- Alcohol and substance abuse
- Men have a 20–30% chance and women have a 70–80% chance after having 1 exposure

Genetics

Individuals with inherited or acquired deficiency of complement components C5–C9 are more susceptible to local and systemic gonorrheal infections

PATHOPHYSIOLOGY

- *N. gonorrhea* is not part of the normal flora of the genitourinary tract (1)
- Bacteria are introduced to the mucosal epithelial surface after direct contact with an infected individual
- Attachment of the bacteria to the mucosal epithelium is mediated by pili (PilC1 and PilC2) and Opa proteins

- Penetration of the organism into submucosal tissue usually takes 24–48 hr
- Invasion of the epithelial triggers a strong response by neutrophils causing sloughing of epithelium, submucosal microabscesses, and purulent drainage

ASSOCIATED CONDITIONS
- Always recommend testing for other STDs
- Commonly associated with concomitant infection with *Chlamydia trachomatis*

GENERAL PREVENTION
- Delaying onset of sexual activity and reducing the number of new partners
- Consistent condom use

DIAGNOSIS
HISTORY
- Obtain detailed history of sexual activity and partners
- Incubation period of 3–14 days
- Approximately 50% of infections in men are asymptomatic or minimally symptomatic; most common symptoms include dysuria and mucopurulent discharge
- Approximately 50% of women have asymptomatic infection; most common symptoms include vaginal/cervical discharge, dysuria, urinary frequency, abdominal pain, and abnormal menstrual bleeding
- Pregnancy does not change clinical presentation, but does lower incidence of pelvic inflammatory disease (PID)
- Anorectal infection is usually asymptomatic but can produce symptoms of pruritus, tenesmus, rectal bleeding, and discharge
- Pharyngeal infection is usually asymptomatic but can cause sore throat
- Approximately 50–75% of those with disseminated gonococcal infection (DGI) have skin lesions characterized by papules and pustules with surrounding erythema

PHYSICAL EXAM
- In men, mucopurulent urethral discharge may be seen; other signs include testicular/epididymal tenderness
- In women, pelvic exam with speculum may demonstrate mucopurulent cervical discharge; other signs include cervical erythema, edema, and friability as well as cervical motion and adnexal tenderness
- If suspecting anorectal infection, external inspection may reveal few or no signs of infection and anoscopy may be indicated with collection of specimens for culture
- Pharyngeal cases may demonstrate exudative pharyngitis and cervical adenitis
- Conjunctival cases demonstrate severe purulent discharge with crusting and lid edema

DIAGNOSTIC TESTS & INTERPRETATION
Lab (2)
- Gram stain of urethral or endocervical discharge with a swab.
  - Considered positive if neutrophils with intracellular gram-negative diplococci are visualized. Sensitivity and specificity of the Gram stain varies depending on the site of infection and the presence of symptoms.

- Culture has long been considered the gold standard for diagnosis.
  - Advantages include high specificity and the ability to test for antibiotic sensitivity.
  - Disadvantages include strict transport and storage requirements, specific environmental variables needed for growth (Thayer–Martin agar in CO_2 incubator), and delays in obtaining results. Culture is the test of choice for extragenital sites of infection.
- Nucleic acid amplification test (NAAT) use molecular techniques to amplify specific DNA and RNA sequences.
  - Optimal specimens are urine samples for males and vaginal swabs for females.
  - Advantages include higher sensitivities and comparable specificities of culture, minimal delay in results, noninvasive and self-collected samples, and identification of coinfections.
  - Disadvantages include inability to screen for antimicrobial sensitivity. CDC now recommends NAAT as the 1st-line diagnostic test for uncomplicated urogenital gonorrheal infection.

Imaging

- Not indicated in uncomplicated cases
- Computed tomography or pelvic ultrasound if pelvic inflammatory disease (PID) or pelvic abscess suspected
- Retrograde urethrogram if urethral stricture suspected

Pathologic Findings

Gram stain demonstrates gram-negative diplococci found inside of polymorphonuclear cells

DIFFERENTIAL DIAGNOSIS (3)

- Other genitourinary infections including *C. trachomatis, Trichomonas vaginalis, Mycoplasma genitalium, and Ureaplasma urealyticum*, herpes simplex virus, bacterial vaginosis, and candidiasis
- Also consider noninfectious sources such as foreign body, chemical irritation, allergic reaction, trauma, carcinoma, and leukorrhea of pregnancy
- For women who present with suspected PID, must rule out ectopic pregnancy and other intra-abdominal processes such as appendicitis

TREATMENT

GENERAL MEASURES

- Patients with suspected active infection should abstain from sex until diagnostically excluded or adequately treated
- All sexual partners who have contacted the infected patient within 60 days of diagnosis should also be evaluated
- Treatment with penicillins and tetracycline are not effective due to the high level of penicillinase-producing bacteria and plasmid-mediated high-level tetracycline-resistant bacteria
- Over the last decade, increasing mean minimum inhibitory concentrations of selective cephalosporins have indicated decreasing susceptibility and have impacted current treatment recommendations
- Fluoroquinolone resistance has impacted treatment options and is most prevalent in the

states of California and Hawaii
- Macrolide resistance has also been reported

MEDICATION

First Line (4)

- For uncomplicated cases of urethral and endocervical gonorrheal infection, patients must also be treated for concomitant chlamydia infection unless diagnostically excluded
- Ceftriaxone 250 mg IM in 1 dose PLUS azithromycin 1 g PO in 1 dose is the current gold standard
- Ceftizoxime 500 mg IM in 1 dose, cefotaxime 500 mg IM in 1 dose, or cefoxitin 2 g IM with probenecid 1 g PO in 1 dose are alternatives for ceftriaxone
- If an injectable cephalosporin is not an option, alternatives include cefixime 400 mg PO in 1 dose or cefpodoxime 400 mg PO in 1 dose. However, patients who receive these options should return in 1 wk for microbiologic test of cure with culture
- Doxycycline 100 mg BID PO for 7 days is an alternative for azithromycin

Second Line

- The management of those with a penicillin allergy depends on clinical suspicion of true allergy and the severity of the allergy. Most patients with documented penicillin allergy are not found to have an allergy after further testing and only 2% of those with a penicillin positive skin test cross react with cephalosporins. Thus, the physician must decide whether to give a cephalosporin vs. an alternative therapy
- Azithromycin 2 g PO in 1 dose monotherapy treats gonorrhea and chlamydia; however, due to GI side effects and growing macrolide resistance, it is not a preferred regimen unless the patient has a severe penicillin allergy
- Spectinomycin 2 g IM in 1 dose is a safe and effective alternative therapy for those with severe penicillin allergies, but is only available outside the United States
- Quinolones were once a 2nd-line therapy, but due to drug resistance in 10–100% of strains depending on location, they are no longer recommended for the treatment of gonorrhea

SURGERY/OTHER PROCEDURES

- Chronic gonorrheal infection may lead to bulbar urethral strictures requiring urologic intervention
- Gonorrheal abscesses may require incision and debridement procedures

ADDITIONAL TREATMENT

- Patient counseling regarding safe sex practices and abstinence for 7 days following treatment initiation
- Patients should also be offered additional STD testing and pregnancy testing
- Pregnancy considerations
  - 1st line still remains ceftriaxone 250 mg IM in 1 dose PLUS azithromycin 1 g PO in 1 dose
  - Doxycycline should be avoided during pregnancy
  - If the patient has a penicillin allergy, desensitization procedures or 2nd-line treatments such as azithromycin monotherapy are alternatives
  - Microbiologic test of cure with culture is recommended
- Ophthalmia neonatorum
  - Prevented by routine screening for endocervical infection during pregnancy and

prophylactic use of erythromycin ophthalmic solution

ONGOING CARE

PROGNOSIS

>95% of uncomplicated genitourinary gonorrheal infections are cured by 1 course of treatment

COMPLICATIONS

- In males, may lead to bulbar urethral stricture and sterility
- In females, can cause PID leading to chronic pelvic pain, ectopic pregnancy, and sterility
- Genital abscesses may occur in either sex requiring surgical intervention
- Fitz–Hugh–Curtis Syndrome – perihepatitis characterized by acute right or bilateral upper quadrant tenderness – may occur in either sex
- Ocular infection with gonorrhea in adults may lead to corneal scarring and vision loss
- The most common complication of DGI is septic arthritis and arthritis–dermatitis syndrome; extreme cases may lead to destruction of articular surfaces
- Hematogenous spread may lead to endocarditis and meningitis

FOLLOW-UP

- All patients diagnosed with gonorrhea should be tested to rule out repeat infection 3–4 mo after treatment
- All patients who undergo PO cephalosporin therapy and all pregnant patients should undergo microbiologic test for cure using a Gram stain and culture 7 days after treatment

CODES

ICD9

- 098.0 Gonococcal infection (acute) of lower genitourinary tract
- 098.11 Gonococcal cystitis (acute)
- 098.12 Gonococcal prostatitis (acute)

ICD10

- A54.00 Gonococcal infection of lower genitourinary tract, unsp
- A54.01 Gonococcal cystitis and urethritis, unspecified
- A54.22 Gonococcal prostatitis

CLINICAL/SURGICAL PEARLS

- Maintain a high degree of suspicion for gonorrhea, especially in patients who are in their 20s.
- Most common symptoms include mucopurulent discharge and dysuria.
- Culture has been the gold standard for diagnosis, however, NAAT is now being widely used as a 1st-line diagnostic modality.
- 1st-line treatment includes ceftriaxone 250 mg IM in 1 dose PLUS azithromycin 1 g PO in 1 dose.
- Antibiotic susceptibilities continue to change and vary by geographical location.
- Always council patients regarding safe sex practices.

GROIN/INGUINAL MASS, MALE AND FEMALE

Edouard J. Trabulsi, MD, FACS

BASICS

DESCRIPTION

- A palpable bulge in the groin region that can be benign or malignant. The groin has 2 distinct anatomic areas:
  - Inguinal canal
  - Femoral triangle

EPIDEMIOLOGY

Incidence

- Hernia:
  - Estimated that ~5% of population will develop hernia at some point in their lifetime.
- Cryptorchidism:
  - 3–5% in newborn and 0.7–1% by the end of 1st yr.

Prevalence

N/A

RISK FACTORS

- Hernia:
  - Low birth weights (<1,500 g)
  - Incidence increases with aging as well as complications.
  - Full-term newborn has 3.5–5% chance
- Cryptorchidism:
  - Low birth weights (<2,500 g)
  - Prematurity 30%
  - Factors that may lead to late testicular descent include black or Hispanic ethnicity; a family history, low birth weight, and preterm birth delivery; and cola consumption during pregnancy

Genetics

Some connective tissue disorders are inherited and can be associated with a groin hernia (see "Groin Hernia, Adult and Pediatric")

PATHOPHYSIOLOGY

- The contents of the groin include skin, subcutaneous tissue, the inguinal canal and contents, femoral triangle and contents (including vessels, nerves, and lymph nodes), and musculoskelet al structures (1)
- Lymphadenopathy:
  - Infection with STD, skin infection in the lower extremities
  - Malignancy such as melanoma, lymphoma, other
- Hernia:
  - Persistence of patent processus vaginalis

  - Chronic increased intra-abdominal pressure
  - Connective tissue disorder altering collagen formation can predispose to hernia
  - Prematurity
- Cryptorchidism:
  - Endocrine abnormality
  - Absence or abnormalities of the gubernaculum
  - Reduced intra-abdominal pressure
  - Pronounced impairment in germ cell development

ASSOCIATED CONDITIONS
- Chronic increased intra-abdominal pressure.
- STDs associated with lymphadenopathy
- Penile cancer

GENERAL PREVENTION
- Avoid chronic increase in intra-abdominal pressure that may encourage hernia formation.
- Avoid STIs.

DIAGNOSIS
HISTORY
- Onset of the mass (age, activity) and any associated symptoms
- Family history of cryptorchidism
- Symptoms of malignancy (fevers, weight loss)
- Birth history: Premature or low birth weight (for congenital hernia and cryptorchidism)
- History of presence or absence of testes in the scrotum, contralateral testis
- Alteration in the size of the mass with cough or abdominal straining suggests hernia or varicocele.
- Fever, a lesion on genitalia or lower extremity, and weakness may suggest infection and lymphadenitis.
- Surgical history of previous hernia repair

PHYSICAL EXAM
- General:
  - Evidence of adenopathy elsewhere, to suggest more systemic disease such as lymphoma
- Groin:
  - Patient should be examined in standing position as well as supine, and Valsalva maneuver should be done during exam
    - A cough impulse usually suggests an inguinal hernia. Erythematous skin suggests infection or strangulated hernia. Pulsatile mass may suggest arterial aneurysm
    - A finger in the external ring can help to differentiate direct and indirect hernias
    - Groin tenderness: Likely infection is the etiology
- Genitalia:
  - Evaluate for masses, lesions, ulcers
    - Malignancy may result in groin adenopathy
    - Ulceration may suggest a sexually transmitted infection
- Scrotum:

- Absent testis suggests undescended testes
- Tender testis suggests epididymitis, testicular torsion, and epididymitis
- Transillumination test, if positive, may suggest a hydrocele/hydrocele of the spermatic cord

• Lower extremity exam:
- Any source of infection or malignancy such as melanoma

DIAGNOSTIC TESTS & INTERPRETATION

Lab

• Blood tests:
- Full blood count and ESR
- Renal function tests and electrolytes
- Syphilis serology, if indicated
- HIV serology, if indicated
- LGV (lymphogranuloma venereum) serologic test, if suspected

• Swab and culture the base of any lesions to diagnose genital herpes, syphilitic ulcer, chancroid (*Haemophilus ducreyi*)

Imaging (2)

• US can confirm hernia and can help to see the testes within the inguinal canal. Not sensitive for intra-abdominal testis.
• Doppler US for vascular conditions (Valsalva maneuver should be performed during exam).
• CT/MRI can help to diagnose obscure hernias. Also can identify related lymphadenopathy.
• Arteriography may help diagnose femoral artery aneurysm.
• Venography or Doppler US will help diagnose saphenous varix.

Diagnostic Procedures/Surgery

• Laparoscopy: Can be diagnostic and therapeutic for hernia and intra-abdominal testes.
• Exploratory surgery is necessary in many cases for both diagnosis and treatment.
• Lymph node biopsy or fine needle aspiration (FNA) for definitive diagnosis of lymphadenopathy.
• Chromosomal and hormonal analysis in situation with bilateral undescended testes.

Pathologic Findings

• Cryptorchidism:
- Decreased number of Leydig and Sertoli cells
- Failure to develop primary spermatocyte
- Peritubular fibrosis

• Lymphadenopathy:
- Can identify neoplastic or inflammatory cause

DIFFERENTIAL DIAGNOSIS

• The mnemonic "**MINT**" can be used to remember the possibilities (Malformations, Inflammatory, Neoplasms, Trauma):
- **M**alformations:
  - Hernia (inguinal or femoral), usually presents with a mass
  - Hydrocele

- Hydrocele of the canal of Nuck
- Cryptorchidism (undescended, maldescended, or retractile testicles)
- Testicular torsion
- Femoral artery aneurysm
- Varicocele
- Spermatocele

• **I**nflammatory Lesions:
  – Inguinal lymphadenitis (a mass found during exam):
    - Acute secondary to venereal disease (chancroid, gonorrhea herpes, or syphilis) or skin disease, infection in the groin area, drug reaction, and viral infections
    - Chronic secondary to TB
  – Cellulitis
  – Psoas abscess secondary to TB
  – Thrombophlebitis of the saphenous or femoral vein (especially postpartum)
  – Osteomyelitis
• **N**eoplasms:
  – Lymphadenopathy (penile cancer, melanoma, lymphoma, or metastatic tumor)
  – Paratesticular tumors
  – Skin tumor, lipoma and sarcoma of the bone
• **T**rauma:
  – A perforation of the femoral vein or artery
  – Contusion and fracture, or dislocation of the hip

TREATMENT

GENERAL MEASURES

Management is based on the cause of the mass and can vary from antibiotic therapy, biopsy, or further imaging for more extensive adenopathy.

MEDICATION

First Line

• Lymphadenopathy:
  – Infection requires treatment with specific antibiotics.
  – For STD-related adenopathy, see specific chapter.
  – Malignancy with either requires chemotherapy or lymph node dissection based on the etiology.
  – For penile cancer with lymphadenopathy, a course of antibiotics is indicated.

Second Line

N/A

SURGERY/OTHER PROCEDURES

• Cryptorchidism:
  – Treatment started at 6–12 mo
  – Hormonal treatment efficacy is $<20\%$ and is dependent on testis location
  – Surgery is the gold standard for management

- Hydrocele:
  - Communicating hydrocele with patent processus vaginalis will require surgery
- Testicular Torsion:
  - Manual detorsion followed by orchiopexy
- Hernias:
  - Congenital hernias are repaired by ligating the processus vaginalis at the internal inguinal ring (60% chance of having a contralateral defect)
  - Strangulated, incarcerated hernias require emergency intervention
  - Elective surgical repair for hernia is recommended based on surgeon preference

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

- Lymphadenopathy: Requires follow-up for chronic infection, response to treatment.
- Cryptorchidism: Requires follow-up for:
  - Malignancy: Increased risk of malignancy in undescended testis, and patient is required to perform monthly self-exam for any abnormality (corrective surgery does not reduce the chances of malignancy).
  - Increased risk of trauma and torsion.
  - Requires follow-up for fertility.
- Hernia: Follow for recurrences and possible occurrence on the other side in young children.

PROGNOSIS

Depends on the etiology of the mass

COMPLICATIONS

- Cryptorchidism:
  - Infertility
  - Malignancy
  - Increased risk of trauma and torsion
  - Hernia
- Hernia:
  - Nonreducible and incarceration
  - Obstruction
  - Strangulation
- Lymphadenopathy can erode into femoral vessels and cause exsanguination and death

FOLLOW-UP

Patient Monitoring

- Cryptorchidism:
  – Requires follow-up for fertility
  – Self-exam for testicular masses
- Hernia, for recurrence

Patient Resources
N/A

- Cryptorchidism
- Groin Hernia
- Groin Inguinal Mass Image ☼
- Penis Cancer, General
- Sexually Transmitted Infections (STIs) (Sexually Transmitted Diseases [STDs]), General

CODES

ICD9
- 550.90 Inguinal hernia, without mention of obstruction or gangrene, unilateral or unspecified (not specified as recurrent)
- 752.51 Undescended testis
- 789.39 Abdominal or pelvic swelling, mass, or lump, other specified site

ICD10
- K40.90 Unil inguinal hernia, w/o obst or gangr, not spcf as recur
- Q53.9 Undescended testicle, unspecified
- R19.09 Other intra-abdominal and pelvic swelling, mass and lump

CLINICAL/SURGICAL PEARLS
- The differential diagnosis varies greatly by the age of the patient.
- If the mass is reducible, strongly suggests a hernia.

GYNECOMASTIA

Samuel Walker Nickles
James S. Rosoff, MD

BASICS

DESCRIPTION

- Gynecomastia (GM) is benign enlargement of the male breast due to proliferation of ductal elements.
- Pseudogynecomastia/lipomastia is an increase in breast adipose tissue. This can be distinguished by careful physical exam of subareolar tissue and comparison to adjacent adipose tissue.

EPIDEMIOLOGY

Incidence (1)

Approximately 2,000 cases of male breast cancer are diagnosed in the United States annually

Prevalence

- 30–65% of men have palpable breast tissue and at autopsy 40–55% of men have histologic evidence of GM
- Age related: Asymptomatic GM is 60–90% in neonates, 50–60% in adolescents, and up to 70% in men aged 50–69 yr

RISK FACTORS

- Alcoholism
- Endocrinopathies
- Medications
- Obesity
- Renal failure

Genetics

- Klinefelter syndrome (47, XXY) is strongly associated with GM
- An increased risk of male breast cancer has been reported in families with a BRCA2 mutation

PATHOPHYSIOLOGY

- Male breast tissue has both androgen and estrogen receptors.
- Androgens inhibit breast development and estrogens stimulate it. GM develops when there is an imbalance of these two influences (ie, androgen deficiency or excess estrogen) or lack of tissue response to them.

ASSOCIATED CONDITIONS

- Prostate cancer
- Testicular tumors
- Cirrhosis
- Renal failure

GENERAL PREVENTION
With hormonally induced GM, prophylactic breast irradiation may reduce GM

DIAGNOSIS

HISTORY
- Age of patient and onset of symptoms (pubertal, GM of aging)
- Associated fevers or chills, breast trauma, nipple discharge
- Medical conditions (cirrhosis, chronic kidney disease, HIV, hyperthyroidism)
- Medications/drugs
- History of cryptorchidism
- Sexual history: Sexual maturation, changes in libido, erectile dysfunction, infertility

PHYSICAL EXAM
- General appearance, weight, amount of adipose tissue (contains aromatase capable of peripheral conversion of androgens to estrogen)
- Secondary sexual characteristics such as body hair distribution and phallus size
- Thyroid exam
- Breast exam: Special attention should be paid to distinguish true GM from pseudogynecomastia; unilateral vs. bilateral (if unilateral should be concerned for potential male breast cancer), firm and mobile vs. fixed, skin dimpling, any nipple discharge, palpation of axillary lymph nodes
- Genitourinary exam with special attention to the testicular exam

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Basic studies: Creatinine, LFTs, thyroid function tests, serum testosterone
- Further testing as needed:
  - Serum estrogens (estradiol, estrone)
  - LH, FSH, prolactin
  - Tumor markers: AFP, β-hCG
  - Adrenal androgens, serum DHEA, urinary 17-ketosteroids

Imaging
- Testicular US if abnormal tumor markers
- CT of the abdomen and pelvis/chest if abnormal levels of adrenal androgens
- Mammography if cancer suspected

Diagnostic Procedures/Surgery
Breast biopsy for suspected breast cancer

Pathologic Findings
- Proliferation of ductules embedded in a connective tissue stroma
- Over about 12 months, the breast tissue evolves into a quiescent stage, in which the amount of stroma and fibrosis increasesand the ductules become less prominent. glandular acini are rare (2)

DIFFERENTIAL DIAGNOSIS
- Physiologic GM: Normal in neonatal boys secondary to maternal estrogen exposure.

  - Occurs in 60–90% of neonatal boys and resolves within several weeks after delivery.
  - Pubertal GM results from the earlier rise of estrogens in early puberty. As the normal ratio of estrogen to testosterone is restored later in puberty the GM resolves.
  - 50–70% of boys develop GM during puberty.
  - 20% of men still have GM at 20 yr of age.
- GM of aging:
  - The hypothalamic–pituitary–testis axis is variable in age-related decline. Some men will have elevated gonadotropins while others will be normal.
  - Adiposity increases with age which leads to increasing peripheral conversion.
  - Sex hormone–binding globulin (SHBG) levels rise with age and decreasing bioavailable testosterone.
  - Medications may also play a part in GM in older men.
- Estrogen secreting tumors:
  - Leydig cell tumors are rare tumors of the testis; 85–90% are benign, most are nonpalpable. Some Leydig cell tumors can directly secrete estradiol. This increases estrogen levels and inhibits LH secretion, suppressing testicular production of testosterone.
  - Sertoli cell tumor: Converts androgens to estrogens leading to a direct increase in circulating levels of estrogens.
  - Feminizing adrenal cortical tumors are generally malignant and poorly differentiated. These cancers directly secrete estrogens as well as steroid precursors that may be aromatized to estrogens in peripheral tissues. Increased estrogen suppresses LH-mediated production of testosterone as well.
- hCG-secreting tumor such as choriocarcinoma stimulates Leydig cells to preferentially secrete estradiol. Many HCG-secreting tumors also will take up steroid precursors such as DHEA and convert them to active estrogens.
- Increased peripheral aromatization to estrogens: Familial aromatase excess syndrome. The enzyme aromatase (P450 aroma or CYP19A1) catalyzes the conversion of steroid precursors to estrogens.
- Estrogen receptor agonists:
  - Therapeutic administration of estrogens such as DES (diethylstilbestrol) may be used to treat men with prostate cancer and can lead to GM. Estrogens may also be used to stimulate breast development in male-to-female transsexuals.
  - Unintentional exposure may occur transcutaneously by sexual intercourse with a partner that uses topical estrogen. Occupational exposure is also possible. Estrogens can be found in hair creams, embalming creams, and in the production of medicinal estrogen products.
  - Marijuana smoke, digitoxin, testosterone, or other aromatizable androgens.
- Androgen deficiency or resistance:
  - Primary or secondary hypogonadism: Testicular failure from any cause may result in GM. Testosterone deficiency leads to elevated LH, which increases estradiol production by remaining Leydig cells. Increased estrogens lead to elevated levels of SHBG, further decreasing free testosterone.
  - Klinefelter syndrome is the most common genetic disorder associated with hypogonadism and infertility in men. GM is present in 50–70% of cases. Klinefelter syndrome is the only cause of GM with an established risk of breast cancer (20-fold increase).

  - Defects in genes critical for testosterone production may also lead to decreased testosterone production.
- Androgen resistance disorders:
  - In both partial and complete androgen insensitivity syndrome, cellular response to androgens is inadequate (elevated gonadotropins and increased serum testosterone) due to lack of negative feedback.
- Refeeding associated GM:
  - Recognized after WWII when imprisoned men resumed normal diets and developed tender GM. Starvation is associated with hypogonadotrophic hypogonadism. With resumption of a healthy diet and regaining weight the hypothalamic–pituitary–testis axis returns to normal, resulting in transient estrogen excess. May also explain GM associated with several chronic diseases.
- Renal failure:
  - Many men with chronic kidney disease develop GM upon initiation of hemodialysis. Before initiation of dialysis men are often nauseated, anorexic, and on protein-restricted diets. The pathogenesis is thought to be similar to refeeding GM.
- Cirrhosis:
  - Studies have shown that the prevalence of GM in cirrhotics is no different than hospitalized age-matched controls. Hormonal changes in chronic liver disease may increase the risk of GM.
  - Patients with cirrhosis have decreased clearance of androstenedione, which provides more substrate for peripheral conversion via aromatase.
  - SHBG may also be increased, decreasing free testosterone.
  - Alcohol has a direct toxic effect on gonadal function, and cirrhotics may have testicular atrophy and hypogonadism.
- Hyperthyroidism:
  - 10–40% of men with thyrotoxicosis may have GM. Due to the increased peripheral conversion of androgens to estrogens. There is also an increase in SHBG in hyperthyroidism. Restoration of euthyroid state resolves associated GM in 1–2 wk.
- HIV:
  - Multifactorial. Use of illicit drugs (heroin or marijuana) may also be seen in this group. Other chronic disease states may also be present such as Hep C, Hep B, and alcoholic liver disease. Some men on HAART therapy have hypogonadotropic hypogonadism.
- Diabetes Mellitus:
  - Diabetic mastopathy presents as a discrete lump or diffuse nodularity. The lesions are composed of B-cell infiltration of mammary ducts and lobules with fibrosis and vasculitis. Can be seen in Hashimoto thyroiditis and lupus.
- Medications:
  - Androgen deprivation therapy (ADT) in prostate cancer is often associated with breast pain, tenderness, and enlargement.
  - Rates of GM in men treated with ADT vary depend on the type employed.
- Miscellaneous medications may be responsible for as much as 25% of new cases of GM in adults.
  - Destruction of Leydig cells: Chemotherapy with cytotoxic agents.

  - Decreased testosterone or DHT production: Spironolactone, ketoconazole, metronidazole, finasteride, dutasteride.
  - Androgen receptor blocker: Flutamide, bicalutamide, nilutamide, cimetidine, marijuana, spironolactone.
  - Increased serum prolactin: Antipsychotic agents, metoclopramide.
  - Possible: Refeeding GM, isoniazid, digoxin.
  - Unknown: HAART, human growth hormone, amiodarone, calcium channel blockers, amphetamines, diazepam, antidepressants (tricyclics and SSRIs).
- Breast cancer:
  - Rare in men; symptoms are similar to those of female breast cancer.
  - A hard fixed mass, ulceration, bloody nipple discharge, or lymphadenopathy should raise suspicion.
  - Suspicious lesions should be biopsied.
  - Except in the setting of Klinefelter syndrome, GM does not increase the risk of breast cancer.

TREATMENT

GENERAL MEASURES

Removal of the offending drug or exogenous source of estrogen if possible

MEDICATION

First Line

- SERMs have been used to block the effects of estrogen excess on breast tissue. Tamoxifen, 10 and 20 mg/d, for 3–9 mo with 90% resolution. Additionally, raloxifene and clomiphene citrate have also been used.

Second Line

- Aromatase inhibitors such as testolactone and anastrazole have been used but not proven as effective as tamoxifen.
- Testosterone replacement therapy in androgen-deficient men may result in partial regression of GM, especially if breast enlargement is of recent onset.

SURGERY/OTHER PROCEDURES

- With longstanding GM, or those that refuse medical treatment, cosmetic surgical excision and reconstruction may be performed
- Testicular cancer: Orchiectomy
- Adrenal tumors: Adrenalectomy

ADDITIONAL TREATMENT

Radiation Therapy

- Prophylactic breast irradiation has been used prior to initiation of estrogens or androgen blockade for blockade for prostate cancer patients
  - Dose: 12 Gy in 2 fractions to 20 Gy in 5 fractions

Additional Therapies

Radioactive iodine ablation or propylthiouracil for hyperthyroidism

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Generally favorable prognosis.
- Patient main concerns: Ruling out breast cancer and cosmetic correction

COMPLICATIONS
Psychological stress

FOLLOW-UP
Patient Monitoring
No regular follow-up is necessary for patients who have physiologic GM and are untroubled by their symptoms and do not have symptoms suggestive of malignancy.

Patient Resources
N/A

CODES

ICD9
- 278.00 Obesity, unspecified
- 611.1 Hypertrophy of breast
- 758.7 Klinefelter's syndrome

ICD10
- E66.9 Obesity, unspecified
- N62 Hypertrophy of breast

- Q98.4 Klinefelter syndrome, unspecified

CLINICAL/SURGICAL PEARLS

- Breast cancer is rare in males, representing $<1\%$ of all cases of breast cancer.
- Klinefelter syndrome is the only cause of gynecomastia with an established risk of breast cancer.

HEMATOSPERMIA

Robert L. Segal, MD, FRCS(C)
Arthur L. Burnett, II, MD, MBA, FACS

BASICS

DESCRIPTION

- Hematospermia (sometimes referred to as hemospermia) as the presence of visible blood (fresh or altered) in the ejaculate (not specified with regard to how many episodes or overall duration).
- Semen can be described as bright red, coffee-colored, rusty, or darkened; appearance may change as blood ages.
- May occur as a single episode or persist chronically.
- Usually a self-limited and benign condition.

EPIDEMIOLOGY

Incidence

- Accounts for 0.02% (1/5,000) new patient visits to a urology clinic; seen in 0.5% of men presenting for prostate cancer screening (1)
- Mean presenting age of 37 yr old
- Mean duration is 1–24 mo
- In men <40 yr old, cause is always almost due to an inflammatory or infectious process.
- Only 2.4–3.5% of cases of hematospermia result in the diagnosis of a malignancy, typically >40 yr old.

Prevalence

Not truly known

RISK FACTORS

- Recent genitourinary trauma, surgery (prostate biopsy), infection
- Prostatitis, bacterial
- Prolonged abstinence from or frequent ejaculation
- Use of anticoagulant medication
- Systemic coagulopathy/bleeding disorder
- Renal agenesis (associated with seminal vesicle [SV] cysts)

Genetics

None

PATHOPHYSIOLOGY

- Often occurs in isolation
- Pathophysiologic causes include:
  - Inflammation and infection
  - Ductal obstruction and cysts of the accessory sexual glands
  - Neoplasms
  - Vascular abnormalities

- Systemic factors
- Iatrogenic factors

ASSOCIATED CONDITIONS
- Nonmalignant prostatic disease (26%)
- Hypertension (HTN) (5%)
- Genital tuberculosis (TB) (1%)
- Prostate cancer (1%)

GENERAL PREVENTION
None known

DIAGNOSIS
HISTORY
- Duration and amount of bleeding
- Sexual history/frequency
  - Hematospermia often associated with long periods of abstinence or after frequent ejaculation
- Associated voiding disorders
  - Hematuria
  - Dysuria
  - Urethral discharge
  - Lower urinary tract symptoms (LUTS)
- Pain (pelvic, perineal)
- Systemic symptoms:
  - Fever
  - Weight loss
- Travel history to endemic areas:
  - TB
  - Schistosomiasis
  - Hydatid disease (Echinococcus)
- Medications
  - Aspirin
  - Oral anticoagulants
  - Atomoxetine (approved for the treatment of attention deficit hyperactivity disorder [ADHD])
- Recurrent trauma, surgery, or infection:
  - Transrectal ultrasound (TRUS) biopsy
  - Brachytherapy
  - Microwave hyper thermia
  - Cryoablation
  - Radiation therapy
  - High-intensity focused ultrasound (HIFU)
  - Sexually transmitted infection
  - Vasectomy

- Medical conditions
  - HTN
  - Liver disease
  - Bleeding disorders
  - Hyperuricemia in one series
- Rule out partner as a source (ie, vaginal bleeding)
  - If uncertainty exists, consider having the patient ejaculate into a condom for objective verification

PHYSICAL EXAM

- Assess blood pressure (BP)
- Abdominal exam for masses
- Penis/urethra
  - Meatal lesions/masses
  - Discharge
  - Condylomata
  - Meatus should be checked for bloody discharge after rectal exam
- Scrotum, epididymides, and testes:
  - Palpate vas deferens:
    - Induration may indicate TB
    - Absence may explain infertility
  - Assess for masses/fluctuance or tenderness
- Prostate
  - Nodularity: Tenderness, masses
  - Palpate for midline cystic structures
  - SV fullness can be associated with schistosomiasis (egg burden)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis and cultures:
  - Urine culture (for acid-fast bacilli and parasites if indicated)
- Serum white cell count and coagulation profile (platelets/PT/PTT)
  - Complete blood count (CBC) if blood dyscrasia
- Suspected
  - INR for patients on coumadin
- Tuberculin skin test should be considered, particularly in patients with exposure history or if originate from or recent travel to endemic areas.
- Semen analysis can be used to confirm diagnosis of true hematospermia and, in cases of schistosomiasis, eggs may be noted. If performed, semen culture should also be sent.
- Urethral swabs/urine studies for the diagnosis of sexually transmitted infection if indicated
- In patients >40 yr or with risk factors for prostate or bladder malignancy:
  - Prostate serum antigen (PSA)
  - Urine cytology

Imaging

- Trans rectal ultrasound (TRUS) of the prostate:

  - To evaluate the prostate, seminal vesicles (SV's), and possible Müllerian duct remnants
  - Identifies etiology in ~95% of cases
    - Prostatic calcifications (43%)
    - Ejaculatory duct calculi (39%)
    - SV calcifications (11%)
    - Dilated SV (22%)
    - Ejaculatory duct cyst (11%)
  - Facilitates diagnostic procedures such as biopsy, puncture
  - Should be 1st imaging study for hematospermia
- Magnetic resonance imaging (MRI)
  - Abnormal signal intensity may represent hemorrhage
  - Should be used if TRUS is not diagnostic or if TRUS is equivocal
  - Cross-sectional or endorectal coil MRI may be obtained

Diagnostic Procedures/Surgery
- Prostate biopsy
  - Indicated if clinical suspicion of prostate cancer is high
- Cystourethroscopy
  - Allows visualization of urethral inflammation and opening of ejaculatory ducts
  - Critical for ruling out urothelial carcinoma

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Inflammation/infection
  - Calculi of SVs, prostate, or urethra
  - Prostatitis
  - Urethritis
  - Seminal vesiculitis
  - Viral:
    - Herpes simplex
    - Cytomegalovirus
    - Human papilloma virus/condylomata
  - Bacterial:
    - TB
    - Chlamydia trachomatis
    - Gonorrhea
    - Syphilis
  - Parasitic:
    - Schistosomiasis
    - Hydatid disease (Echinococcus)
- Ductal obstruction and cysts of accessory glands:
  - Ejaculatory duct cyst
  - SV diverticulum
  - Urethral stricture

  - Utricular cysts
  - Wolffian duct cysts
  - Prostatic cysts
- Neoplasms:
  - Benign
    - BPH
    - Leiomyoma of the SV
    - Urethral adenoma
  - Malignant
    - Bladder: Urothelial carcinoma
    - Prostate: Adenocarcinoma, ductal adenocarcinoma, sarcoma, stromal tumor, lymphoma, malakoplakia
    - SV: Adenocarcinoma, sarcoma, squamous cell carcinoma, malakoplakia, metastases to prostate or SVs (metastatic melanoma to the SVs or prostate, may result in melanospermia)
    - Urethra
    - Testis
    - Epididymis: Mesothelioma
- Vascular abnormalities
  - Arteriovenous malformations
  - Prostatic varicosities
  - Hemangioma
- Systemic factors
  - Hematologic conditions
  - Hemophilia
  - Von Willebrand disease
  - HTN
  - Chronic liver disease
  - Amyloidosis of the SVs
- Iatrogenic causes
  - Prostate biopsy (most common)
  - Genitourinary (GU) instrumentation
  - Extracorporeal shock wave lithotripsy (ESWL) of distal ureteral stones
  - Brachytherapy (occurs in 28% of seed cases)
  - Prostate radiation
  - HIFU
  - Postvasectomy (vasovenous fistula)
  - Postorchiectomy

TREATMENT

GENERAL MEASURES

- If an underlying cause is identified (ie, bleeding disorder, GU TB, schistosomiasis), initiate appropriate medical management.
- Patients should be made aware that this is very common after prostate biopsy

- Spontaneous hematospermia is rarely associated with malignancy
- Most commonly a benign condition that resolves spontaneously and reassurance is appropriate

MEDICATION

First Line

- In men < 40 yr old without an obvious cause of hematospermia after workup (normal physical exam, negative urine studies):
  - Reassurance and expectant management
  - Empiric antibiotic therapy with doxycycline or fluoroquinolone
  - Trial of 5α-reductase inhibitor (finasteride, dutasteride) for 3 mo (3)[C]
- While a similar approach can be taken in men > 40 yr old, diagnostic workup should be more exhaustive and prostate biopsy should be considered if PSA or DRE indicates.

Second Line

None

SURGERY/OTHER PROCEDURES

- Prostatic calculi: Transurethral incision
- Cystoscopic resection of any lesions seen on exam
- Cyst puncture and drainage should be considered in selected cases when indicated
  - Can be performed via TRUS guidance, transperineal or transurethral approaches
- Transurethral cannulation of ejaculatory ducts to perform seminal vesiculoscopy with a ureteroscope and perform therapeutic interventions (dilation, stone extraction, biopsy) has been described (2)[C]

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Patients should be reassured, as should their partners.
- A significant number of cases remain idiopathic even after a full workup.
- Hematospermia following prostate biopsy may take several months to clear.

COMPLICATIONS

N/A

FOLLOW-UP

Patient Monitoring

Follow PSA in older patients, as per prostate cancer screening recommendations

Patient Resources
N/A

CODES

ICD9
• 286.9 Other and unspecified coagulation defects
• 601.9 Prostatitis, unspecified
• 608.82 Hematospermia

ICD10
• D68.9 Coagulation defect, unspecified
• N41.9 Inflammatory disease of prostate, unspecified
• R36.1 Hematospermia

CLINICAL/SURGICAL PEARLS
• Hematospermia is usually a benign and self-limited condition, particularly in men < 40 yr old.
• Will often resolve spontaneously in all age groups.
• Work-up only indicated if persistent or if other associated symptoms (such as hematuria).
• Expected symptom following prostate biopsy and can last for several weeks.
• Treatment should be directed toward underlying cause if identified.

HEMATURIA, GROSS AND MICROSCOPIC, ADULT

Megan M. Merrill, DO
Surena F. Matin, MD, FACS

BASICS

DESCRIPTION

- Hematuria may be gross (GH) (visible) or microscopic (MH)
- It can originate from any part of the urinary tract

ALERT

- Hematuria of any degree should not be ignored, as it may be a sign of serious renal or urologic disease, including malignancy.
- Urologic malignancy associated with microscopic hematuria in 1–3% (1).
- GH has a 5 times higher incidence of serious urologic disease compared to MH (2).

EPIDEMIOLOGY

Incidence

- Incidence of various disorders in patients who present with MH or GH: (3)
  - No diagnosis – 60.5%
  - UTI – 13%
  - Bladder cancer – 12%
  - Renal disease – 9.8%
  - Stone disease – 3.6%
  - Renal cancer – 0.6%
  - Prostate cancer – 0.4%
  - Upper tract cancer – 0.1%

Prevalence

Prevalence of asymptomatic MH varies with age and gender, and ranges from 0.19–21% (4).

RISK FACTORS (5)

- Age >35
- Male gender
- Current or past smoking history
- Recent trauma
- Urinary tract surgery or instrumentation
- Prostatic enlargement (BPH or BPE)
- Chronic indwelling Foley
- Family history of renal disease
- Renal calculi
- Pelvic radiation
- Recent febrile illness
- History of irritative voiding symptoms
- UTI

- Occupational exposure to chemicals or dyes
  - Benzenes or aromatic amines
- Medications
  - Cyclophosphamide
  - Analgesic abuse

Genetics

Familial hematuria (Alport syndrome or hereditary nephritis)—glomerulonephritis (GN), end-stage kidney disease, and hearing loss (2)

PATHOPHYSIOLOGY

- Macroscopically:
  - Blood clots that have a vermiform (worm-like) appearance suggest the origin of hematuria to be the upper tract
  - Blood clots that are amorphous suggest the origin to be the lower urinary tract—bladder or prostate
- On microscopic analysis: (2)
  - RBCs in the urine that are isomorphic and have smooth, round membranes and even hemoglobin distribution suggests urologic disease
  - RBCs that are dysmorphic with irregular shapes and uneven hemoglobin distribution suggests glomerular disease

ASSOCIATED CONDITIONS

- Neoplasms
- UTI
- Urolithiasis
- Glomerulonephritis
- Anatomic abnormalities of urinary tract (eg, UPJ [uretero-pelvic junction obstruction])
- Benign prostatic enlargement

GENERAL PREVENTION

- Adequate fluid intake, especially for patients with history of calculi
- Smoking cessation
- Treat/prevent underlying cause

DIAGNOSIS

HISTORY

- Age and sex: Age >35, bladder cancer is the most common cause of hematuria, urologic cancer is more common in males; females may have vaginal bleeding (4)
- Timing of GH during urinary stream:
  - Initial hematuria—anterior urethral pathology
  - Terminal hematuria—bladder neck, prostate, or urethra inflammation/pathology
  - Hematuria throughout—vesical or upper-tract origin
- Associated pain:
  - Painless hematuria suggests bladder cancer
  - Flank pain, GH, and abdominal mass is pathognomonic of renal cell carcinoma

  - Ureteral colic/flank pain can be caused by calculi (most common), tumor, or blood clot
  - UTI/prostatitis can cause hematuria associated with dysuria, urgency, and frequency
- Presence of clot—indicates significant degree of hematuria and higher probability of significant pathology
  - Amorphous clots—bladder/prostate origin
  - Vermiform clots—upper tract origin
- Lower urinary symptoms (frequency, urgency, etc.):
  - BPH can cause hematuria
  - Incomplete bladder emptying can predispose to bladder stones and infection
  - Straining to urinate or spraying of urinary stream can indicate a urethral stricture
- Activity/exercise-induced hematuria should be excluded
- Trauma—significant crush injury or burn may result in myoglobinuria; abdominal or pelvic trauma may cause urinary tract injury
- Recent upper respiratory infection—associated with GN or immunoglobulin A (IgA) nephropathy
- Medical or surgical history:
  - Renal or urologic disease or surgery
  - Recent urethral instrumentation (including catheterization)
  - Sexually transmitted diseases (STDs)
  - History of tuberculosis (TB)
  - History of pelvic radiation
  - History of autoimmune diseases and bleeding disorders
- Current medications
  - Anticoagulants
  - Analgesic abuse
  - Cyclophosphamide
- History of smoking tobacco
- Menstrual history: Vaginal bleeding can be mistaken for hematuria
- Family history
  - Primary renal disease
  - Hypertension (HTN)
  - Adult polycystic kidney disease
  - Alport syndrome
  - Urolithiasis
  - Urologic malignancy
- Occupational risk factors:
  - Exposures to chemicals or dyes (aromatic amines, benzenes) in rubber, petroleum, and dye industries—risk of urothelial carcinoma

PHYSICAL EXAM

- Vital signs
  - If hypertensive evaluate for renal parenchymal disease, chronic kidney disease (CKD) or renal failure, renal cystic disease or renal vascular disease; may be hypotensive if hematuria persistent/severe
- Pallor

  – Anemia may be associated with SLE, hemolytic anemia, and CKD or renal failure
- Rashes
  – Consider Henoch–Schönlein purpura, SLE, and vasculitis
- Generalized edema
  – Associated with nephrotic syndrome or renal failure
- Hearing loss: Alport syndrome
- Heart murmurs: Subacute bacterial endocarditis
- Palpable abdominal or flank masses
  – Hydronephrosis, renal cystic disease, renal tumors, distended bladder
- Flank tenderness:
  – Pyelonephritis or urolithiasis
- Flank lacerations, contusions or rib fractures—underlying renal injury
- Pelvic exam:
  – Urethral caruncle or vaginal prolapse, vaginal bleeding
- Digital rectal exam (DRE)
  – Boggy, tender, warm prostate suggests acute prostatitis
  – Nodularity suggest cancer
  – High-riding prostate suggests urethral disruption in presence of pelvic fracture

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis: Must include standard urine dipstick and microscopic evaluation:
  – MH is defined as ≥3 RBCs/high-powered field (hpf) in urinary sediments from 2 of 3 properly collected urine specimens (catheterized sample if vaginal contamination or phimosis) (5)[C]
  – Color
    ◦ Bright red: Suggests recent or ongoing bleeding with urologic/anatomic origin
    ◦ Brown (tea-colored): Suggests old blood/clots or medical renal disease (GN)
  – Dipstick (4)
    ◦ Specific gravity: Poorly concentrated urine—low specific gravity (<1.007) suggests hydronephrosis with renal impairment or intrinsic renal disease
    ◦ Proteinuria: Heavy (3–4+) suggests GN or renal disease
    ◦ Leukocyte esterase and/or nitrite positive (pyuria) suggests infection
    ◦ False-positive dipsticks for blood: Oxidizing agents (betadine, bacterial peroxidases), myoglobinuria, hemoglobinuria (microscopic analysis is negative)
    ◦ False-negative dipsticks for blood: Reducing agents (high-dose vitamin C), urine pH <5.1
  – Microscopy
    ◦ Pyuria – suggests infection
    ◦ Red cell casts – pathognomonic of glomerular bleeding
    ◦ Crystalluria – suggests urolithiasis
- Phase-contrast microscopy or urinary sediment: Differentiates glomerular (renal) and nonglomerular bleeding based on the presence of distorted RBCs (80%) in glomerular bleeding; sensitivity of 95% and specificity 100% (2)
- Urine culture:

- If urinalysis suggests infection
- Urinary cytology
  - Recommended for all patients with risk factors or irritative voiding symptoms. Not recommended as part of routine evaluation for asymptomatic MH (5)[C].
  - Sensitivity for detecting bladder cancer 40—76% (1) (Better at detecting high-grade urothelial carcinoma and CIS)
    - Negative result does not rule out malignancy
    - Atypical cells can be seen with calculi or inflammation
  - NMP22, BTA stat, and UroVysion are alternatives; not considered standard of care but can be useful in some cases of bladder cancer
- Renal function tests (creatinine and BUN)
- CBC – anemia may be due to GH or chronic renal disease. Elevated white blood cell count (WBC) with a left shift suggests infection
- Coagulation profile studies (PT, PTT, INR) to identify coagulopathy
- Other lab tests as clinically indicated
  - Streptozyme (antistreptolysin O titer), serum complement, and antinuclear antibody (ANA), total serum proteins, and albumin: Globulin ratios for GN
  - Urinary calcium: Creatinine ratio (for hypercalciuria), peripheral smear (for sickle cell disease/trait), TB skin test, and urinary mycobacterial cultures (for TB)
  - If in bone marrow transplant patient, consider cytology to look for typical changes associated with polyoma virus

Imaging

- Plain abdominal imaging: Limited utility in initial evaluation of hematuria, may be useful in long-term follow-up of radiopaque stones
- Intravenous pyelography (excretory urography)
  - Traditional imaging for the detection of stones, masses, or obstruction, largely replaced by CT urogram (CTU)
  - Has utility for papillary necrosis and medullary sponge kidney
- Computerized tomographic urogram (CTU) (with and without IV contrast)
  - The current gold standard for surveying the genitourinary (GU) tract for causes of hematuria; can detect stones (on noncontrast imaging), hydronephrosis and other anatomic abnormalities, renal masses, collecting system filling defects, lower urinary tract pathology (contraindicated in serum creatinine >2 mg/dL) (5)[C]
  - Noncontrast CT scanning is the procedure of choice to evaluate kidney stones but should not be used in the initial evaluation of hematuria.
- MRI
  - Alternative imaging modality when CT scanning is not advised (contrast allergy, renal insufficiency, met allic implants)
  - Provides excellent visualization of small renal masses and arteriovenous malformations but has less utility for stones
  - Gadolinium contrast is avoided in patients with creatinine >2 mg/dL (eGFR <30 mL/min), due to risk of progressive systemic fibrosis (nephrogenic systemic fibrosis [NSF])
- Renal US

- Detects renal cystic disease, renal masses, hydronephrosis
- Less sensitive for detecting stone disease but useful in children and pregnancy, when radiation is contraindicated
- Operator dependent, large body habitus can limit utility

• Bladder US
- Useful to assess postvoid residuals, can detect larger bladder tumors, bladder calculi and diverticuli, although less sensitive than CT scan

• VCUG
- Not routinely performed in work-up of hematuria in adults
- May be done in children if hematuria is felt to be in conjunction with febrile UTI, concern for urethral obstruction, or other lower urinary tract abnormalities

• Nuclear renal scans
- Limited utility in the initial evaluation of hematuria

• Renal arteriography and venography
- Useful for renal artery stenosis and renal vein thrombosis and preoperative elucidation of anatomy for surgical planning

• Retrograde urethrogram (RUG), cystogram as clinically indicated

Diagnostic Procedures/Surgery

• Cystoscopy (5)[C]
- Should be performed in all patients >35 yr old with MH or GH
- Patients <35 yr; cystoscopy performed if significant risk factors for urologic malignancies present (irritative voiding symptoms, tobacco history, chemical exposures, etc.)

• Retrograde pyelograms +/− ureteroscopy to evaluate the upper tract when IV contrast is contraindicated (ie, contrast allergy/elevated creatinine) or when upper tract pathology is suspected but not seen on less invasive imaging

• Renal biopsy
- As directed by nephrologist when suspected glomerulonephritis (GN)

Pathologic Findings

Based on primary cause

DIFFERENTIAL DIAGNOSIS

• Pseudohematuria
- Drugs:
  - Reddish color: Pyridium, doxorubicin, phenytoin, salicytes, senna, others
  - Brown color: Cascara, iron supplements, nitrofurantoin, others
- Vegetables: Beets
- Dyes or pigments
- Myoglobin and free hemoglobin
- Menstrual period contamination
- Dysfunctional uterine bleeding

• Congenital/inherited:
- Cystic renal disease
  - Polycystic kidney disease
  - Medullary sponge kidney

    - Medullary cystic disease
  - Benign familial hematuria or thin basement membrane nephropathy
  - Alport syndrome
  - Inherited renal tubular disorders that can lead to urolithiasis
    - Renal tubular acidosis type I
    - Cystinuria
    - Oxalosis
- Hematologic abnormalities
  - Bleeding dyscrasias
  - Sickle hemoglobinopathies
- Anatomic causes
  - Urethral and ureteric strictures
  - Phimosis
  - Posterior urethral valves
  - Urethral caruncle
  - Diverticula
  - UPJ obstruction
  - Obstructive uropathy: Hydronephrosis
  - Vesicoureteric reflux
- Vascular malformations: Hemangiomas
- Traumatic
  - Abdominal and pelvic injury
  - Degree of hematuria is a poor indicator of injury severity
  - Iatrogenic trauma after abdominal, pelvic, or urinary tract surgery
- Exercise-induced hematuria
- Foreign bodies: Catheters, stents, self-introduced, etc.
- Inflammatory
  - UTI/prostatitis and specific infections (schistosomiasis, TB, etc.)
  - GN: IgA nephropathy most common (4%)
  - Radiation: Radiation cystitis and nephritis
- Metabolic
  - Urinary calculi
  - Hypercalciuria
  - Hyperuricosuria
- Neoplastic: Any benign or malignant GU lesion
- Drug-induced
  - Nephrotoxic drugs
  - Analgesic abuse
  - Cyclophosphamide
  - Overanticoagulation
- Miscellaneous
  - BPH
  - Renal vessel disease
    - Arterial emboli or thrombosis

- Renal vein thrombosis
- Endometriosis of the urinary tract—female with cyclic hematuria
- Benign essential hematuria

TREATMENT

GENERAL MEASURES

- The standard urologic evaluation should include urinalysis, urine culture, cytology if risk factors, CTU and cystoscopy as outlined above (See also "Hematuria Algorithm")
- Treatment depends on etiology
- Consider and rule out pseudohematuria or medical causes of hematuria based on presentation, history, lab data, or if evaluation for anatomic lesion is negative
- Gross hematuria
  - If patient is urinating without difficulty and has no blood clots can treat conservatively—increase oral fluid intake
  - For patients with clots/urinary retention: Place a large-bore 3-way Foley catheter (large-bore 2-way or rigid catheter may be more effective to clear clots) and hand irrigate out all clots, followed by continuous bladder irrigation (CBI) with sterile saline or water
  - More severe hematuria or hemodynamic instability may require surgery—cystoscopy with clot evacuation/fulguration
- Microscopic hematuria
  - Work-up can be done in the office setting and usually requires no immediate monitoring or treatment unless associated with trauma

MEDICATION

First Line

- Not treated primarily by medications.
- Aminocaproic acid (Amicar)—for intractable gross hematuria (6)
  - Inhibitor of fibrinolysis
  - Rare but serious side effects of thrombotic events and renal failure
- Finasteride may be effective for prostatic hemorrhage

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Transfuse RBCs if indicated for extreme acute blood loss
- Continuous bladder irrigation (CBI) with normal saline for persistent hematuria with clots
- Consider bladder irrigation with 1% Alum if GH persists (6)
- Cystoscopy, clot evacuation, fulguration if conservative treatment fails
- If intractable GH despite all other measures consider formalin bladder instillation (6)
  - Performed under anesthesia
  - Must rule out vesicoureteric reflux 1st—contraindicated if positive
  - Side effects: Renal failure, bladder contracture/decreased capacity, incontinence, ureteral stenosis
- For life-threatening hemorrhagic cystitis or recurrent/refractory hemorrhagic cystitis

stabilize patient then consider
– Unilateral selective arterial embolization
– Urinary diversion with or without cystectomy

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

Hyperbaric oxygen therapy (HBO) has been shown to be effective in hematuria caused by radiation-induced cystitis if delivered within 6 mo of initiation of hematuria

ONGOING CARE

PROGNOSIS

Based on etiology of the hematuria

COMPLICATIONS

Hypotension and anemia may result on degree and chronicity of blood loss

FOLLOW-UP

Patient Monitoring

- Monitor hemodynamic status if severe gross hematuria persists or if associated with trauma
  – Serial hemoglobin and hematocrit

Patient Resources

CODES

ICD9

- 599.0 Urinary tract infection, site not specified
- 599.71 Gross hematuria
- 599.72 Microscopic hematuria

ICD10

- R31.0 Gross hematuria
- R31.2 Other microscopic hematuria
- N39.0 Urinary tract infection, site not specified

CLINICAL/SURGICAL PEARLS

- Gross or microscopic hematuria in any patient should be evaluated, especially when significant risk factors are present (age >35, smoking history, exposure to chemicals/dyes, irritative voiding symptoms).
- Risk of urologic malignancy is 5 times higher in patients who present with gross hematuria.
- Cytology is recommended for patients with risk factors; however, a negative result does not rule out malignancy.
- CTU is the imaging test of choice for evaluating hematuria from the upper tract.
- Cystoscopy should be performed on any patient >35 yr of age presenting with unexplained MH or GH.

HEMATURIA, GROSS AND MICROSCOPIC, PEDIATRIC

Douglas W. Storm, MD, FAAP, FACS
Christopher S. Cooper, MD, FAAP, FACS

BASICS

DESCRIPTION

- Hematuria can be macroscopic or microscopic
  - Macroscopic: Grossly red/pink-tinged urine
  - Microscopic: >5–10 RBC/hpf
  - Common pediatric urology referral
  - Approach is different in children compared to adults
    - Low risk of malignancy as cause in children
    - Medical causes more frequent than surgical

EPIDEMIOLOGY

Incidence

- Microscopic hematuria more frequently encounte-red than gross hematuria (1,2)[A]
- Microscopic hematuria
  - 0.41% (41 in 1,000 pediatric visits)
  - 0.32% school-aged girls
  - 0.14% school-aged boys
- Macroscopic hematuria
  - 0.13% (1.3 in 1,000 pediatric visits)
  - 80% of cases involve males; 20% females

Prevalence

Exact prevalence is unknown

RISK FACTORS

- Alport syndrome
- Anaphylactoid purpura
- Benign familial hematuria
- Dysfunctional voiding
- Glomerular bleeding
- Glomerulonephritis (GN)
- Hemophilia
- Henoch–Schönlein purpura (HSP)
- Genitourinary anatomic anomaly
- Kidney stones
- Medications
- Recent upper respiratory illness
- Recent strep throat
- Renal papillary necrosis

- Sexual abuse
- Sickle cell disease or trait
- Systemic lupus erythematosus (SLE)
- Trauma
- UTI
- Vigorous exercise

Genetics
- Benign familial hematuria: Autosomal dominant
- Sickle cell anemia: Autosomal recessive
- Alport syndrome: X-linked

PATHOPHYSIOLOGY
- Depends on source of the bleeding:
  - Glomerular source (most common)
  - Renal tubular source
  - Interstitial source
  - Vascular source
  - Urinary tract

ASSOCIATED CONDITIONS
Depends on the bleeding source

GENERAL PREVENTION
Must understand the source of the bleeding and tailor prevention accordingly

DIAGNOSIS

HISTORY
- Age of child and timing of onset:
  - Poststreptococcal GN occurs 14–28 days after the sore throat
  - IgA nephropathy hematuria occurs at the time of or shortly after the respiratory illness
  - HSP hematuria occurs 1–3 mo after the rash
- Characterize the pattern of hematuria
  - Gross pink/red urine suggests a urologic cause
    - Initial or terminal hematuria suggests lower urinary tract source
    - Total hematuria suggests upper tract source
    - Idiopathic urethrorrhagia seen in prepubertal boys with blood spotting at the end of urinary stream
  - Gross brown, tea-colored, or cola-colored suggests glomerular origin
  - Microscopic suggests nephrologic cause
- Any precipitating events
  - Recent viral illness, strep throat, skin rash
  - Trauma, strenuous exercise, foreign bodies, sexual abuse, or bleeding/coagulation disorders
- Associated lower urinary tract symptoms (urgency, frequency, dysuria) and/or flank and abdominal pain suggests UTI, stone disease, or dysfunctional voiding component

- Family history of renal disorders, stones, end-stage renal disease, neurosensory hearing loss, HTN, or coagulopathy
- Current medications

PHYSICAL EXAM

- Blood pressure (BP)
  - High BP is suggestive of glomerular disease, especially when accompanied with edema
- Presence of fever and costovertebral angle (CVA) tenderness suggests stone and/or pyelonephritis
- Presence of palpable abdominal or flank mass, bruit, or abdominal tenderness
- Skin rashes and arthritis may suggest HSP and SLE
- Hearing loss suggests Alport disease
- Examine the genitalia for meatal stenosis, urethral prolapse, ureterocele, trauma, sexual abuse
- Edema suggestive of nephrotic syndrome

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Microscopic hematuria considered clinically significant if >5–10 RBC/hpf
  - Recommend that 2 of 3 urinalyses show microscopic hematuria over 2–3 wk before work-up initiated (1,2)[A]
    - False-negative results occur with high urine specific gravity or with high ascorbic acid concentration
    - False-positive results occur in presence of myoglobin, medications (eg, rifampin, pyridium, etc.), bile pigments, and oxidizing agents (eg, household bleaches)
- Urinalysis
  - Proteinuria
    - If 1+– or 2+ child should be evaluated for postural proteinuria
    - 2+ or greater proteinuria child should be evaluated for glomerulonephritis and nephrotic syndrome
  - RBC casts are highly specific for glomerulonephritis
  - Dysmorphic RBCs predict glomerular bleeding with a sensitivity of 93–95% and a specificity of 95–100%
  - WBCs, bacteria, leukocyte esterase, nitrates suggest UTI
    - Recommend urine culture to verify UTI and identify bacteria causing the infection
- Other blood tests:
  - Serum creatinine, BUN, electrolytes (if renal insufficiency noted)
  - Complete blood count CBC)
  - antistreptolysin O titer/streptozyme panel (indicative of poststreptococcal GM)
  - C3/C4 levels (may be lowered in cases of SLE and GN)
  - plasma IgA levels (may be increased with IgA nephritis and HSP)
- Other urine tests:
  - urine calcium to creatinine ratio (varies by age, but generally <0.18; if >0.18 suggests high 24-hr excretion of calcium >4 mg/kg/d)
- Other lab tests:

- throat culture (to rule out strep throat)

Imaging

- Renal and bladder sonography
  - Evaluates for renal parenchymal disorders, stones, tumors, renal artery stenosis, and anatomic abnormalities
- Voiding cystourethrogram (VCUG)
  - Not routinely performed in work-up of hematuria
  - May be done if hematuria is felt to be in conjunction with febrile UTI, concern for urethral obstruction, or other lower urinary tract abnormalities
- CT
  - Selectively used in pediatrics secondary to radiation exposure
  - May be used to evaluate for stone disease or anatomic abnormality or after recent trauma

Diagnostic Procedures/Surgery

- Renal biopsy
  - Heavy proteinuria and worsening renal function are the main indications for biopsy. Only performed if the results will alter therapy.
- Cystoscopy
  - Rarely performed in children
  - Performed if bleeding source thought to originate from the lower urinary tract
  - May inspect efflux of urine from each ureteral orifice to lateralize source of bleeding
  - May perform retrograde ureteropyelogram to look for upper tract source (eg, fibroepithelial polyp)
- Hearing test
  - Alport syndrome

Pathologic Findings

Dependent on the cause of the bleeding

DIFFERENTIAL DIAGNOSIS

- Divided into categories, based on the source of the bleeding
  - Glomerular sources
  - Interstitial and tubular sources
  - Urinary tract source
  - Vascular source
- Glomerular source
  - IgA nephropathy or Berger disease (recurrent gross, painless hematuria, often following a mild fever, upper respiratory illness, viral illness, or exercise)
  - Benign familial hematuria (usually microscopic hematuria also found in parent without hearing loss or renal insufficiency)
  - Alport syndrome (usually microscopic hematuria, proteinuria, progressive renal insufficiency, high-frequency hearing loss, family history of renal disease)
  - Acute poststreptococcal glomerulonephritis (PSGN) (usually acute onset edema, tea-colored urine, history of antecedent illness 2–4 wk prior, elevated BP, urinalysis with RBC casts, and proteinuria)
  - Membranoproliferative glomerulonephritis

  - SLE
  - Rapidly progressive glomerulonephritis (pediatric nephrology emergency, presents with signs and symptoms similar to PSGN, renal function though shows renal insufficiency, may progress to end-stage renal disease in a few weeks)
  - Henoch–Schönlein purpura (rash on dependent parts of the body, renal manifestations may include: No involvement, HTN, active glomerulonephritis, nephrotic syndrome, and acute renal failure)
  - Goodpasture syndrome (pulmonary hemorrhage associated with severe and progressive glomerulonephritis)
- Interstitial and tubular source
  - Acute pyelonephritis
  - Renal tuberculosis
  - Sickle cell disease or trait
  - Acute interstitial nephritis
  - Nephrocalcinosis
  - Metabolic (eg, Fabry disease)
  - Nephrotoxins (eg, analgesics, NSAIDs)
  - Renal cystic disease
  - Acute tubular necrosis
- Urinary tract source
  - Dysfunctional voiding and elimination
  - Papillary necrosis
  - HIV, hepatitis
  - Infestations (eg, schistosomiasis)
  - Nephrolithiasis
  - Anatomic abnormality (eg, ureteropelvic junction obstruction, fibroepithelial polyp)
  - Hemorrhagic cystitis (eg, viral, chemical, radiation)
  - UTI
  - Urethritis
  - Hypercalciuria
  - Tumor
  - Drug-induced cystitis (eg, chemotherapy, antibiotics, Coumadin, etc.)
  - Menstruation
  - Foreign bodies (eg, urinary catheter)
  - Exercise
  - Trauma
- Vascular source
  - Trauma
  - Sickle cell disease/trait
  - Renal vein thrombosis
  - Renal artery thrombosis (20% of gross hematuria in 1st months of life)
  - Arteriovenous malformation
  - Nutcracker syndrome
  - Vasculitis (eg, C3 arteriolar deposition)

– Coagulopathy
– Thrombocytopenia

TREATMENT

GENERAL MEASURES

- Establish diagnosis and treat any underlying medical problems causing the hematuria
- Prompt evaluation must be provided to a child with any of the following in addition to the hematuria (1,2)[A]
  – HTN
  – Edema
  – Oliguria
  – Significant proteinuria (2+ or greater)
  – RBC casts

MEDICATION

Based on underlying cause of hematuria

OTHER PROCEDURES

Based on clinical diagnosis and etiology of the hematuria

ADDITIONAL TREATMENT

Additional Therapies

Based on clinical diagnosis and etiology of the hematuria

Complementary & Alternative Therapies

Based on clinical diagnosis and etiology of the hematuria

ONGOING CARE

PROGNOSIS

Based on underlying cause of the hematuria (3)

COMPLICATIONS

Based on the underlying cause of the hematuria and any interventions delivered

FOLLOW-UP

Patient Monitoring

- Current recommendation of American Academy of Pediatrics is screening urinalysis at age 5 yr
- Annual measurements of height, weight, and BP measurements after age 3 yr

Patient Resources

  – Unstable BP, renal insufficiency, fevers

HEMORRHAGE FOLLOWING TURP OR TURBT

Frank M. Nezu, MD
Mohamed T. Ismail, MD

BASICS

DESCRIPTION

Significant gross hematuria with or without clot retention that occurs following transurethral resection of the prostate (TURP) or transurethral resection of bladder tumor (TURBT)

EPIDEMIOLOGY

- Occurs in up to 11% of patients, typically within the 1st 3 mo after TURP (1)[B]
- TURP is associated with a 2.9% transfusion rate (2)[B]
- 2.2–3.3% of patients require recatheterization, clot evacuation, or return to OR for bleeding after TURP (3)[A]

RISK FACTORS

- Excessive Valsalva/straining/constipation
- Inadequate hemostasis/coagulation of bleeding vessels
- Infection
- Medications: Warfarin, heparin, low molecular weight heaprins, aspirin, thienopyridine (clopidogrel), etc.
- Trauma
- Undermining of bladder neck

Genetics

Patients with deficiencies in the clotting cascade (eg, hemophilia) or other coagulopathies are more prone to hemorrhage.

GENERAL PREVENTION

- Obtain sufficient hemostasis intraoperatively
- Stop anticoagulants or other blood-thinning medications prior to surgery
- Delay starting anticoagulant medications postoperatively if possible, although this practice has been questioned (4)[B]
- Gentle postoperative catheter traction
- 5α-reductase inhibitors, taken pre operatively reduce surgical blood loss intraoperatively (5)[A]
- 5α-reductase inhibitors, do not decrease rates of postoperative clot retention (6)[A]

PATHOPHYSIOLOGY

- Anesthetic technique (regional or general) appears to have no impact on TURP-related bleeding
- Inadequate hemostasis/coagulation of bleeding vessels
- Narcotics may cause constipation and increased intra-abdominal pressure
- NSAIDs are not contraindicated after TURP, they do not increase risk of postoperative

adverse events (7)[A]

- Due to the sloughing of necrotic tissue in prostatic fossa or bleeding at the bladder neck
- Size of tissue resected, duration of resection, or presence of prostate cancer does not correlate with the incidence of hematuria post-TURP (1)[B]
- Studies suggest that there is transient change in platelet count, prothrombin time, and fibrinogen and serum sodium concentrations postoperatively, which can be explained on the basis of dilution of the blood
- Prostate cancer is known to trigger disseminated intravascular coagulation (DIC), and this should be kept in mind when performing resection in the face of known advanced prostate cancer
- In the absence of prostate cancer, up to 6% of patients undergoing TURP may develop mild subclinical intravascular coagulopathy
- Urinary fibrinolysis is a normal physiologic process. Plasminogen is converted to plasmin by plasminogen activators
- The presence of a clot in the bladder causes the release of additional plasminogen activators. Evacuation of clot in the bladder is essential to stopping the bleeding

ASSOCIATED CONDITIONS

- BPH
- Bladder cancer
- Prostate cancer

DIAGNOSIS

HISTORY

- Color of urine, presence of clots
- Patient is not able to void (clot retention)
- History of TURP TURBT—timing, complications, catheter removal
- Use of anticoagulation or similar medications
- Excessive straining or trauma; last bowel movement
- History of clotting disorder
- History of prostate cancer

PHYSICAL EXAM

- General: Pallor, dehydrated, acutely ill
- Vitals: Hypotensive or tachycardic
- Abdomen: Bladder distended or palpable
- Genitalia: Edematous; ecchymotic

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC to assess for anemia
- Creatinine level for obstruction
- Urinalysis, urine culture
- Coagulopathy screen (platelets, PT/PTT) particularly if there is suggestion of bleeding from other sites

Imaging
Bladder US or pelvic CT to evaluate for large organized clot within bladder

Diagnostic Procedures/Surgery
Bladder drainage and irrigation with large-caliber hematuria catheter

DIFFERENTIAL DIAGNOSIS
- Bleeding from lower GU tract source: Urethra, prostate, bladder
- Bleeding from upper GU tract source: Ureter, renal pelvis, kidney

TREATMENT

GENERAL MEASURES
- Limit physical activity, encourage bed rest
- Limit Valsalva and avoid constipation through stool softeners
- Adequate hydration; IV fluid resuscitation
- Bladder drainage and clot evaluation with large-caliber hematuria catheter
- Continuous bladder irrigation (CBI) via 3-way Foley catheter to clear clots and prevent new clots from forming in the bladder
- Foley traction, additional inflation of Foley balloon
- Cessation of anticoagulants or blood-thinning medications
- Check CBC and coagulation profile
- PRBC transfusions if necessary, vitamin K and/or FFP if coagulopathic
- CBI with intravesical alum or silver nitrate
- These are reported but rarely necessary:
  - Hyperbaric oxygen
  - Aminocaproic acid (Amicar) antifibrinolytic
  - Hormonal manipulation: LHRH agonists
  - Urinary diversion with bilateral PCNs
  - Salvage radical prostatectomy
  - Selective arterial prostatic embolization (SAPE) (8)[A]

MEDICATION
First Line
- Antibiotics if infected
- Stool softeners
- 5α-reductase inhibitors such as finasteride or dutasteride (although will not have an acute effect)

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Transurethral clot evacuation with fulguration and cauterization (laser or electrocautery) of prostate if bleeding does not subside within a reasonable time frame
  - Typical Findings: Visible bleeding arterial vessel or discrete/nondiscrete venous bleeding
- Post-TURBT hemorrhage, more expeditious clot evacuation and fulguration

ONGOING CARE

PROGNOSIS

- The mortality rate for hemorrhage after TURP and TURBT is unknown
- Whether hemorrhage after TURP increases the risk of future prostatic bleeding has not been described in the literature
- Use of stool softeners and avoidance of constipation for several weeks after TURP and TURBT seems advisable

COMPLICATIONS

Severe anemia and/or hypovolemic shock can lead to syncope and/or MI

FOLLOW-UP

Patient Monitoring

- Can be managed on the floor setting with staff who are accustomed to managing catheters and CBI
- Serial CBCs, blood transfusions as necessary
- Monitor coagulation profile, FFP if needed

Patient Resources

N/A

- Hemorrhagic Cystitis
- Urine, Abnormal Color

CODES

ICD9

- 599.71 Gross hematuria
- 998.11 Hemorrhage complicating a procedure

ICD10

- N99.820 Postproc hemor/hemtom of a GU sys org fol a GU sys procedure
- R31.0 Gross hematuria

CLINICAL/SURGICAL PEARLS

- Proper patient selection, identify patients at risk for bleeding with attention to medications.
- Attention to detail at the end of TURP/TURBT, complete hemostasis and evacuation of specimen.
- Avoid constipation postoperatively.
- In patient with clot retention a large-bore catheter is used to evacuate all clots and start continuous bladder irrigation (CBI) immediately.

HERPES SIMPLEX, GENITAL

Michael Perrotti, MD

BASICS

DESCRIPTION

- Herpes simplex is a common sexually transmitted virus infection
- Herpes simplex virus (HSV)
  - HSV-2 is the most common cause of genital herpes
  - Can be caused by HSV-1 (oral sex during HSV-1 outbreak)
- An increasing proportion of anogenital herpetic infections in some populations has been attributed to HSV-1 infection

EPIDEMIOLOGY

Incidence

0.5–1 million new cases of genital herpes per year in US

Prevalence

~45 million people in US have genital herpes

RISK FACTORS

- Sexual contact with an infected person
- Unprotected sexual intercourse
- Multiple sexual partners

PATHOPHYSIOLOGY

- Transmission can occur by anal, vaginal, or oral sex
- Primary infection if patient was HSV-seronegative for both HSV-1 and HSV-2
- Secondary infection if patient with pre-existing HSV-1 immunity
- Most persons infected with HSV-2 have not been diagnosed with genital herpes. Many have mild or unrecognized infections and shed virus intermittently in the genital tract. As a result, the majority of genital herpes infections are transmitted by persons who are unaware that they have the infection or who are asymptomatic when transmission occurs (2).
- Asymptomatic viral shedding is more frequent in genital HSV-2 infection than genital HSV-1 infection and is most frequent during the first 12 mo after acquiring HSV-2.

ASSOCIATED CONDITIONS

- HIV
- Other STDs

GENERAL PREVENTION

- Monogamous seronegative partner
- Condom use
- Randomized trials have demonstrated that male circumcision (MC) reduces heterosexual acquisition of various STI/STD including HSV type 2, and it reduces genital ulcer disease among female partners (1)

DIAGNOSIS

HISTORY

- Patients may experience a prodrome before the appearance of lesions
  - Tingling, pruritus, paresthesias
- Fever
- Malaise
- Headache
- Painful genital lesions
- Dysuria

PHYSICAL EXAM

- Multiple shallow genital ulcers that may be vesicular
  - However, these classical painful multiple vesicular or ulcerative lesions may be absent in some.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Viral culture
- Polymerase chain reaction
- Direct fluorescence antibody
- Type-specific serology testing
  - Both lab-based assays and point-of-care tests that provide results for HSV-2 antibodies from capillary blood or serum.
    - The sensitivities of these glycoprotein G type-specific tests for HSV-2 antibody vary from 80–98%, are false-negative at early stages of infection. The specificities are ≥96%. False-positive results can occur, especially in patients with a low likelihood of HSV infection

Imaging

MRI in suspected CNS disease

Diagnostic Procedures/Surgery

- Unroofing of vesical to obtain fluid for viral culture
- Lumbar puncture in meningitis

DIFFERENTIAL DIAGNOSIS

- Acute UTI
- *Neisseria gonorrhoeae*
- Treponema pallidum
- Drug eruption
- Behçet's disease

TREATMENT

GENERAL MEASURES

- No cure is available
- Encourage safe sex practices to reduce transmission (ie, condom use); however, lesions can

sometimes spread outside of the coverage area
- Common concerns regarding genital herpes include the severity of initial clinical manifestations, recurrent episodes, sexual relationships and transmission to sex partners, and ability to bear healthy children. The misconception that HSV causes cancer should be dispelled.
- Avoidance of sexual activity during recurrences
- Antiviral medications can prevent or shorten outbreaks.
- Daily suppressive therapy can reduce recurrences and the likelihood of transmission to partners.
- Topical therapy with antiviral drugs offers minimal clinical benefit.
- Treatment guidelines based on most current CDC recommendations (2)
- Acyclovir, valacyclovir, and famciclovir are safe for use in immunocompromised patients in the doses recommended for treatment of genital herpes.

MEDICATION

First Line

- Recommended regimens for 1st episode (extend treatment if healing is incomplete after 10 days of therapy).
  - Acyclovir 400 mg PO TID for 7–10 days OR 200 mg PO 5 times a day for 7–10 days
  - Famciclovir 250 mg PO TID for 7–10 days
  - Valacyclovir 1 g PO BID for 7–10 days

Second Line

- Suppressive therapy for recurrent genital herpes
  - Acyclovir 400 mg PO BID (3)[A]
  - Famciclovir 250 mg PO BID
  - Valacyclovir 500 mg or 1,000 mg PO once daily
    - Valacyclovir 500 mg once a day might be less effective than other valacyclovir or acyclovir dosing regimens in patients who have very frequent recurrences (ie, ≥10 episodes per year).
- Episodic therapy for recurrent genital herpes (2)
  - Requires initiation of therapy within 1 day of lesion onset or during the prodrome that precedes some outbreaks.
  - Provide patient with a supply of drug or a prescription for the medication with instructions to initiate treatment immediately when symptoms begin.
    - Acyclovir 400 mg TID for 5 days OR 800 mg PO BID for 5 days OR 800 mg PO TID for 2 days
    - Famciclovir 125 mg PO BID for 5 days OR 1,000 mg PO BID for 1 day OR 500 mg once, followed by 250 mg BID for 2 days
    - Valacyclovir 500 mg PO BID for 3 days OR 1 g PO QD for 5 days

SURGERY/OTHER PROCEDURES

- Sitz baths
- Foley catheter for retention of urine associated with sacral nerve root involvement

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- In complicated HSV infection (central nervous system disease, disseminated HSV), the Centers for Disease Control recommend intravenous acyclovir (5–10 mg/kg) every 8 hr for 2–7 days or until clinical improvement
- Suppressive or episodic therapy with oral antiviral agents is effective in decreasing the clinical manifestations of HSV among HIV-positive persons.

Complementary & Alternative Therapies

None noted to be effective

ONGOING CARE

PROGNOSIS

- Symptoms may last 2–4 wk if untreated
- Symptoms less severe in nonprimary compared to person without pre-existing HSV immunity
- Treatment during primary infection lessens morbidity (1)[A]

COMPLICATIONS

- Aseptic meningitis
- Encephalitis
- Transverse myelitis
- Hepatitis
- Pneumonitis
- Disseminated HSV
- HIV transmission
  - When the sores come into contact with the mouth, vagina, or rectum during sex, they increase the risk of HIV transmission if either partner is HIV-infected.
- Some HSV-infected persons might express anxiety concerning genital herpes that does not reflect the actual clinical severity of their disease; the psychological effect of HSV infection frequently is substantial.

FOLLOW-UP

Patient Monitoring

- Patient's education concerning the natural history of the disease, potential for recurrent episodes, asymptomatic viral shedding, and the risks of sexual transmission.
- At 1st episode of genital herpes, advise the patient that suppressive therapy is available and effective in preventing symptomatic recurrent episodes
- Encourage patients to inform their current sex partners that they have genital herpes and to inform future partners before initiating a sexual relationship.
- The risk for HSV-2 sexual transmission can be decreased by the daily use of valacyclovir by the infected person. Episodic therapy does not reduce the risk for transmission and its use should be discouraged for this purpose among persons whose partners might be at risk for HSV-2 acquisition (4).
- Symptomatic sex partners should be evaluated and treated in the same manner as patients

who have genital lesions. Asymptomatic sex partners of patients who have genital herpes should be questioned concerning histories of genital lesions and offered type-specific serologic testing for HSV infection.

CODES

ICD9

- 054.10 Genital herpes, unspecified
- 054.11 Herpetic vulvovaginitis
- 054.19 Other genital herpes

ICD10

- A60.00 Herpesviral infection of urogenital system, unspecified
- A60.04 Herpesviral vulvovaginitis
- A60.9 Anogenital herpesviral infection, unspecified

CLINICAL/SURGICAL PEARLS

- It is estimated that 1 in 5 adults in US is infected with HSV, but that many are asymptomatic and do not know that they are infected with the virus.
- Most infected individuals have recurrent episodes of painful genital ulcers.
- The 1st episode usually occurs a few weeks following initial infection with the virus and may last 2–3 wk.
- HSV recurrences generally decrease in frequency over time.

HESITANCY AND INTERMITTENCY

Patricia Lewandoski, MD
Akhil Das, MD, FACS

BASICS

DESCRIPTION

- Hesitancy is the delay in the start of micturition.
- Intermittency is the involuntary stopping and starting of the urinary stream during voiding.
- Hesitancy and intermittency are commonly characterized as obstructive (emptying) symptoms. These spectrum of symptoms also include:
  - Postvoid dribbling
  - Straining to void
  - Decreased force of stream
  - Incomplete bladder emptying

EPIDEMIOLOGY

Incidence

- Obstructive urinary symptoms and age are highly correlated.
- Patient symptom reporting is influenced by sociodemographic and cultural factors.
- Hesitancy and intermittency is primarily related to BPH and occurs mostly in men.

Prevalence

- Age-stratified prevalence of moderate-to-severe Lower Urinary Tract Symptoms (LUTS) in men:
  - 40–50 yr old: ~20%
  - 50–60 yr old: ~30%
  - 60–70 yr old: ~40%
  - 70–80 yr old: ~56%

RISK FACTORS

- Bladder outlet obstruction:
  - In men, primarily related to benign prostatic hypertrophy (BPH), bladder neck contracture, bladder stones, urethral valves, urethral stricture disease, and prostate cancer.
  - In women, primarily caused by pelvic floor prolapse/large cystocele, bladder stones, and urethral stricture disease (rarely)
- Detrusor underactivity:
  - Idiopathic
  - Neurogenic: Diabetes, Parkinson disease, etc.
  - Non-neurogenic: Dysfunctional voiding
- Obesity is associated with a higher incidence of LUTS

Genetics

N/A

PATHOPHYSIOLOGY

- Bladder outlet obstruction: Increased resistance to urinary flow due to various etiologies (BPH, stricture, etc.) requires the bladder to generate higher voiding pressures which delays the initiation of micturition and may cause intermittency.
- Inadequate detrusor contraction due to various etiologies delays the start of voiding and may cause intermittency.

ASSOCIATED CONDITIONS
BPH and erectile dysfunction in men

GENERAL PREVENTION
Adequate treatment of LUTS

DIAGNOSIS
HISTORY
- Quantification of lower urinary tract symptoms
  - AUA/IPSS symptom index should be used.
  - Other obstructive voiding symptoms should be assessed.
  - Consider voiding diary if history is unclear.
- Assess for irritative voiding symptoms:
  - Cystitis/prostatitis: Can present with acute, severe obstructive symptoms.
- History of hematuria:
  - Urethral stricture
  - Bladder/kidney stones
  - Bladder mass
- Certain pelvic procedures can result in detrusor underactivity.
  - Other medical conditions:
    - Certain neurologic conditions and diabetes can cause detrusor underactivity.
    - Prior pelvic irradiation can affect bladder contractility.
- History of STD may predispose patients to urethral stricture disease.
- Medications:
  - Certain over the counter (OTC) medications for colds or sinusitis may contain phenylephrine which may exacerbate LUTS.
  - Antimuscarinics may lead to obstructive symptoms.

PHYSICAL EXAM
- Abdominal exam: Palpate for a distended bladder.
- Focused neurologic exam should be performed. The following should be assessed:
  - General mental status
  - Ambulatory status
  - Lower extremity neuromuscular function
  - Anal sphincter tone
- Digital rectal exam (DRE) should be performed:
  - Prostatic nodularity, if present, may be a sign of prostate cancer and should be worked up accordingly
  - Size should be assessed, although DRE tends to underestimate size
  - Bogginess or tenderness: Consistent with prostatitis

- In men, circumcision status, assess for urethral stenosis
- In women:
  - Pelvic exam should be performed to assess for masses, pelvic floor prolapse, and/or cystocele.
  - Urethral lesions should also be assessed.
- Pediatric considerations:
  - Meatal stenosis should be considered in young boys who present with hesitancy and intermittency

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis by dipstick testing or microscopic exam of the sediment should be performed to screen for hematuria and UTI.
  - If UTI suspected: Urine culture.
- Serum PSA should be assessed in men with at least a 10-yr life expectancy.
- Renal function tests (BUN and creatinine) are NOT recommended in the initial evaluation of men with LUTS, such as hesitancy or intermittency according to the AUA guidelines for BPH.

Imaging

- Upper tract evaluation (CT scan, IVP, or US) is not recommended as part of the initial work-up of hesitancy and intermittency unless warranted by history, exam, or lab evaluation.
- If urethral stricture disease is suspected, retrograde urethrography (RUG) may be helpful
- Transrectal US should be reserved for patients with an increased suspicion of prostate cancer undergoing prostate needle biopsy

Diagnostic Procedures/Surgery

- Urinary flow rate should be considered:
  - May be helpful in patients with complex medical history.
  - Should be performed in patients who are to undergo invasive therapy, as this may predict response to surgery.
- Catheterized or scanned PVR should also be considered:
  - Will indicate which patients need immediate catheterization for acute urinary retention.
  - Helps in diagnosis of voiding dysfunction or in patients with neurologic disease.
- Cystourethroscopy should be considered in patients with possible urethral stricture.
- Urodynamics (pressure flow) study should be considered in certain patients with complicated histories that imply neurologic disease.

Pathologic Findings

BPH findings on pathologic exam include proliferation of the stroma and epithelium.

DIFFERENTIAL DIAGNOSIS

- Bladder outlet obstruction
  - BPH—common cause of hesitancy and intermittency in men
  - Bladder neck contracture (ie, after prostate surgery)
  - Urethral stricture disease
- Bladder stone

- Foreign body
- Cancer (prostate, bladder, urethral)
- Prostatitis
- UTI
- Bladder neck dyssynergia
- Detrusor-sphincter dyssynergia
- Pelvic organ prolapse
- Detrusor underactivity (more common cause of hesitancy and intermittency in women):
- Diabetes mellitus
- Parkinson disease
- Multiple sclerosis
- Interstitial cystitis
- Radiation cystitis
- Spinal cord injury/lumbosacral disk disease
- Medications: Noradrenergic drugs are less likely than selective serotonin reuptake inhibitors (SSRIs) to cause sexual dysfunction but more likely to cause urinary hesitancy

TREATMENT

GENERAL MEASURES

- When the effect of LUTS on quality of life was studied, most important factors for seeking treatment were the severity and degree of bother.
- Treatments are tailored to the degree of bother and the severity of the disease
- Review medications (anticholinergics, sympathomimetics, and opioids) to determine if any are potential cause; consider alternatives
- Mild symptoms: Watchful waiting and conservative measures
  - Limit fluid intake
  - Avoid diuretics
  - Avoid coffee, tea, alcohol which may irritate the bladder

MEDICATION (2)

First Line

- For patients with evidence of infection, appropriate antibiotic therapy should be initiated.
- For men with hesitancy and intermittency presumably due to BPH/BOO:
  - α-adrenergic antagonists (alfuzosin, doxazosin, tamsulosin, terazosin, silodosin) reduce resistance at the bladder outlet and provide symptom relief.
  - At maximal doses, all agents are felt to be equally effective.
  - Side effect profiles may include syncope, orthostatic hypotension, retrograde ejaculation, asthenia, and nasal congestion.
- 5α-reductase inhibitors (5ARIs) (finasteride 5 mg/d and dutasteride 0.5 mg/d) reduce prostate volume, prevent progression of BPH, and improve symptoms in clinical trials.
  - These drugs can cause decreased libido, sexual dysfunction, and reduce PSA by ~50% and are of little use in men without evidence of clinical BPH.
- Combination therapy: MTOPS study showed a 67% 5-yr risk reduction in BPH progression in men on combination therapy (doxazosin and finasteride) compared to placebo and better

than either agent alone (39% and 34%, respectively).

Second Line

- Combination therapy combining an 5ARI with an α-blocker may be useful
- If ED and BPH/BOO coexist daily tadalafil (2.5–5 mg PO QD) can be used

SURGERY/OTHER PROCEDURES

- Urethral stricture disease and/or bladder neck contractures should be addressed using appropriate endoscopic or open procedures.
- Cystocele and/or pelvic floor prolapse in women should be addressed surgically if indicated.
- For men with hesitancy and intermittency presumably due to BPH/BOO who do not respond to medical management:
  - Transurethral resection of the prostate (TURP) remains the gold standard surgical approach in patients who do not respond to medical management to BPH.
    - Can be combined with various laser techniques to facilitate tissue hemostasis and removal
- Transurethral laser vaporization or enucleation.
- Transurethral microwave heat treatment (TUMT): Minimally invasive therapy is somewhat effective in the treatment of LUTS due to BPH.
  - Simple open prostatectomy is often reserved for patients with large prostates (>100 cc) who are not candidates for TURP.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Behavioral interventions, such as timed voiding or double voiding

Complementary & Alternative Therapies

Saw palmetto (*Serenoa repens*) has been reported to improve LUTS due to BPH/BOO. Randomized clinical studies have produced contradictory results.

ONGOING CARE

PROGNOSIS (3)

- 25% of untreated patients with moderate-to-severe LUTS presumably due to BPH/BOO experience clinical progression of symptoms within 5 yr.
- Randomized clinical trials of patients receiving α-blocker therapy indicate that >1/2 will report a >25% improvement in symptoms within 3 mo of initiating treatment.
- 5–10% of men with moderate-to-severe LUTS will fail medical therapy and will require surgical intervention for their condition.

COMPLICATIONS

- Patients with disease progression who do not receive appropriate treatment may experience the following complications:
  - Renal insufficiency
  - UTI

– Stone formation
– Acute urinary retention
– Secondary bladder dysfunction

FOLLOW-UP

Patient Monitoring

- After appropriate treatment has been initiated and patients report improvement, annual follow-up should include:
- History and physical exam, urinalysis, PSA
  – Uroflowmetry and postvoid residual urine as needed

CODES

ICD9

- 788.61 Splitting of urinary stream
- 788.64 Urinary hesitancy
- 788.69 Other abnormality of urination

ICD10

- R39.11 Hesitancy of micturition
- R39.13 Splitting of urinary stream
- R39.19 Other difficulties with micturition

CLINICAL/SURGICAL PEARLS

- Hesitancy and intermittency is often associated with BPH and generally represents LUTS associated with an obstruction.
- Increasing hesitancy may be seen before an episode of retention.
- In men, the incidence increases with age.
- Pressure-flow studies are helpful in determining obstruction vs. detrusor underactivity.

HIV/AIDS, UROLOGIC CONSIDERATIONS

Daniel C. Parker, MD
Michael A. Pontari, MD

ALERT
The American Urological Association (AUA) policy statement now considers circumcision to be of a health benefit, citing a50–60% risk reduction in HIV transmission in some African nations.

BASICS

DESCRIPTION
- HIV disease results from the acquired deficiency of cellular immunity caused by the human immunodeficiency virus (HIV).
  - Hallmarks
    - Reduction of the helper T-lymphocytes in the blood and the lymph nodes
    - Development of opportunistic infections (*Pneumocystis carinii* pneumonia, cytomegalovirus infections, tuberculosis, candida infections, cryptococcosis, others)
    - Development of malignant neoplasms (non-Hodgkin lymphoma and Kaposi sarcoma)
- A spectrum of HIV infections range from asymptomatic seropositivity to AIDS
- Urologic manifestations of HIV/AIDS
  - Bacterial and nonbacterial infections
  - Urolithiasis
  - Increased risk of malignancy
  - Renal impairment
  - Voiding dysfunction

EPIDEMIOLOGY
Incidence
40–50,000 new cases per year in US

Prevalence
- 0.5% of US adults <50 are infected
  - 2.6% of African American men and 1.5% of African American women were HIV positive from 1999 to 2006
- 33.2 million people worldwide with HIV/AIDS
- 2.1 million deaths due to HIV/AIDS in 2007

RISK FACTORS
- Unprotected intercourse, anal or oral sex
- IV drug abuse and needle sharing
- Transfusion of blood products
- Concomitant STD/STI
- Uncircumcised phallus

- Transmission of mother to infant at birth or via breast milk
- Health care workers
  - Risk for HIV after percutaneous exposure to HIV infected blood is 0.3%; after mucous membrane exposure 0.09%.

Genetics

- 3 groups of HIV viruses: M, N, and O
  - Most infections are by class M
    - 9 subtypes of M exist
  - 15–20% genetic variation between viruses

PATHOPHYSIOLOGY

- HIV-1 binds to cells expressing CD4, leading to decline in CD4 cells and immune function.
- Immunosuppression allows opportunistic/unusual infections, decreases host defense against malignancy.

ASSOCIATED CONDITIONS

- UTI
  - Greater if CD4 count $<500/mm^3$
  - Associated with typical bacteria (*Escherichia coli*, *Enterococcus*) and atypical pathogens such as fungi, mycobacteria, and viruses
- Epididymitis/orchitis
  - Chlamydia, gonorrhea, salmonella, toxoplasmosis
- Fournier gangrene
- Prostatitis
  - Up to 14% in patients with AIDS
  - Greater risk in AIDS patients for developing prostatic abscess
- Urolithiasis
  - Risk with use of indinavir or from metabolic abnormalities
- Hepatitis B virus (HBV)
- Malignancies
  - Non-Hodgkin lymphoma
    - Usually B cell
    - May involve kidneys in 6–12% of AIDS patients
  - Kaposi sarcoma
    - Up to 20% of untreated patients
  - Testicular tumors
    - Usually seminoma
    - Up to 50 times more common
  - Renal cell carcinoma
    - Up to 8-fold increased risk vs. noninfected individuals
- HIV associated nephropathy (HIVAN)
  - Proteinuria >3.5 g/d, edema, and HTN
  - Associated with focal segmental glomerulosclerosis (FSGS) on renal biopsy
  - Progression to dialysis in <10 mo.
- Voiding dysfunction

– Can be retention, detrusor overactivity, and sphincter dyssynergia

GENERAL PREVENTION

- Barrier protection during sex (male and female condoms)
  – Lab studies indicate that the female condom is an effective mechanical barrier to viruses, including HIV, and to semen.
- Avoid high-risk sexual behavior
- Male circumcision
  – Although male circumcision should not be substituted for other HIV risk-reduction strategies, it has been shown to reduce the risk for HIV and some STDs in heterosexual men.
  – Despite these data, male circumcision has not been demonstrated to reduce the risk for HIV or other STDs among men who have sex with men.
- Use of precautions by health workers
- Treating STDs

DIAGNOSIS

HISTORY

- Voiding history (1)[A]
  – Dysuria
  – Frequency
  – Incontinence
  – Urethral discharge
  – Pelvic or testicular pain
  – Flank pain
- Neurologic history
  – Numbness
  – Dysesthesias
- Social history
  – Sexual history
  – IV drug use
  – Blood product transfusions
- Generalized lymphadenopathy, fever, weight loss, and chronic diarrhea are common symptoms.
- Review of systems (ROS): Constitutional symptoms, skin lesions, confusion, urticaria

PHYSICAL EXAM

- General: Skin lesions, adenopathy
- Neurologic exam: Numbness, alterations in sensation
- GU exam: Urethral discharge, testicular/epididymal exam for masses, prostate exam for nodule or tenderness
- Penile lesions of Kaposi sarcoma present as red/brown/purple nodules, macules, or patches

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- HIV testing

- Screening HIV-1 antibody titer
  - If positive, need confirmation by Western blot or immunofluorescence.
  - Need separate consent for HIV testing.
- UA, urine C + S
  - May show rectangular crystals from indinavir
  - Common bacterial pathogens in HIV-infected patients are *E. coli, Enterobacter* (enterococci), *Pseudomonas aeruginosa*, *Proteus* spp., *Klebsiella, Acinetobacter, Staphylococcus aureus*, group D *Streptococcus, Serratia*, and *Salmonella* spp.
  - If UTI suspected and C&S negative, consider atypical organisms: Fungi, parasites, viruses
- CBC
- BUN/creatinine
- Specific testing for STD if urethral discharge present

Imaging

- With flank pain: Noncontrast CT
  - Indinavir stones may not show on CT: Consider contrast study or retrograde pyelogram if renal impairment.
- Scrotal US for palpable lesions
- Prostate abscess: CT scan

Diagnostic Procedures/Surgery

- Measure PVR urine
- Urodynamics for voiding dysfunction or retention.
  - Distinguishes bladder outlet obstruction from acontractile bladder if in retention
    - Bladder hypocontractility was seen in 35–45% at time of urinary retention (2)[A]
  - Common urodynamic findings:
    - Hypo- and hyperreflexia
    - Acontractile hypoactive bladder
    - Detrusor-sphincter dyssynergia

Pathologic Findings

- Testicular tumors: Usually seminoma
- Lymphoma: B-cell non-Hodgkin lymphoma (NHL)
- Penile lesions: Kaposi sarcoma from lymphatic endothelial cells vs. squamous cell carcinoma

DIFFERENTIAL DIAGNOSIS

- Other systemic disease that cause fatigue: Chronic fatigue syndrome, others
- *Salmonella* epididymitis pathognomonic for HIV

TREATMENT

GENERAL MEASURES

- Refer to neurology, nephrology, infectious diseases when appropriate
- Patient education about risk factors, transmission

MEDICATION

First Line

- Highly active antiretroviral therapy (HAART)
  - Combination therapy to combat the ability of HIV to generate drug-resistant mutants (3) [A].
  - 10 million people now on antiretroviral therapy according to the WHO
  - HIV therapy should be started in patients with:
    - AIDS
    - New WHO guidelines recommend starting therapy when CD4 count $<500/mm^3$ (previous guidelines were $<350/mm^3$)
    - Pregnant women
    - Patients with HIV nephropathy
    - Coinfection with HBV regardless of CD4 count.
    - New WHO guidelines also call for some people to begin treatment as soon as they test positive for HIV, regardless of CD4 count

Second Line

- General urologic conditions such as UTI, voiding symptoms, calcium stones treat as per general practice.
  - *Salmonella* epididymitis
    - 2–4 wk of doxycycline 100 mg PO BID plus Cipro 500 mg PO BID
    - If difficult to eradicate may need lifelong suppression.
- Kaposi sarcoma
  - If focal, local radiation, cryosurgery, or retinoids.
  - If disseminated use chemotherapy (doxorubicin) or immunotherapy with interferons

SURGERY/OTHER PROCEDURES

- Indinavir and other protease inhibitor (PI) stones
  - Stop indinavir
  - Hydration
  - Stent if necessary
    - Stones are soft and may pass after stenting.
- Surgical drainage of prostatic abscess
- Stenting for ureteral obstruction from retroperitoneal NHL

ADDITIONAL TREATMENT

Radiation Therapy

Indicated in some cases of focal Kaposi sarcoma

Additional Therapies

- For health care worker exposure
- Post-Exposure Prophylaxis (PEP)
  - Occupational PEP (“oPEP”), healthcare worker potentially exposed to material infected with HIV
  - Non-occupational PEP (“nPEP”), someone is potentially exposed to HIV outside the workplace (eg, from sexual assault, unprotected sex, needle-sharing injection drug use).
  - begin within 72 hrs of exposure; 2–3 antiretorviral medications for 28 days
- Pre-Exposure Prophylaxis (PrEP)

– For people who are HIV-negative and at substantial risk for HIV infection (relationship with HIV infected partner, gay or bisexual man who has had sex without a condom or been diagnosed with a sexually transmitted infection within the past six months, others
– Along with other prevention methods like condoms, PrEP can offer good protection against HIV if taken daily

Complementary & Alternative Therapies
None

ONGOING CARE

PROGNOSIS
Much improved prognosis leading to longer life expectancies, primarily due to newer drug combination therapies

COMPLICATIONS
- Antiretroviral therapy
  – Risk of nephrotoxicity, crystal precipitation leading to stones, hypocalcemia
  – Erectile dysfunction and decreased libido (caused by increased estradiol) may be associated with HAART therapy
- Drugs used for the treatment of HIV-infected patients have become the most frequent cause of drug-containing urinary calculi.
  – Among these agents, PIs are well known to induce kidney stones, (indinavir, atazanavir, darunavir).

FOLLOW-UP
Patient Monitoring
- CD4 counts
- Serum creatinine

Patient Resources
- CDC HIV/AIDS Fact Sheets. http://www.cdc.gov/hiv/library/factsheets/index.html

CODES

ICD9

- 042 Human immunodeficiency virus [HIV] disease
- 599.0 Urinary tract infection, site not specified
- 592.9 Urinary calculus, unspecified

ICD10

- B20 Human immunodeficiency virus [HIV] disease
- N20.9 Urinary calculus, unspecified
- N39.0 Urinary tract infection, site not specified

CLINICAL/SURGICAL PEARLS

- Urologic considerations in patients with HIV/AIDS include bacterial infections, urolithiasis, malignancy, renal impairment, and voiding dysfunction.
- Urolithiasis is associated with patients taking indinavir and other protease inhibitors (PI's).
- HIV associated nephropathy (HIVAN) increases the patient's risk of dialysis.
- Salmonella epididymitis is pathognomonic for HIV.
- Highly active antiretroviral therapy (HAART) increases estradiol and can lead to symptoms of erectile dysfunction and decreased libido.

HOT FLUSHES/VASOMOTOR INSTABILITY IN MALES

Tara K. Ortiz, MD
Judd W. Moul, MD, FACS

BASICS

DESCRIPTION

- Hot flushes are typically described as a feeling of intense heat with associated flushing, sweating, rapid heart rate, and anxiety
- Sometimes called "hot flashes"
- Common side effect of androgen ablation therapy in men with metastatic or locally advanced prostate cancer
- Flushing can be associated with wide ranges of other conditions and medications
- This section primarily discusses this condition in males

EPIDEMIOLOGY

Incidence

Occurs in 50–80% of men on androgen deprivation therapy (1)

Prevalence

N/A

RISK FACTORS

- Age, race and ethnicity, educational level, smoking, cardiovascular risk including body mass index, and genetics
- Prostate cancer

Genetics

N/A

PATHOPHYSIOLOGY

- Exact mechanism unknown; majority of theories based on studies in postmenopausal women
- Hot flushes in prostate cancer patients result from decreased feedback of testosterone to the hypothalamus.
- Central control of thermoregulation is preoptic/anterior area in the brain
- Increases in internal and/or skin temperature sensed in the anterior pituitary results in cutaneous vasodilatation (flushing) and sweating.
- Thermoregulatory zone is disrupted:
  - Reduced thermoneutral zone between an upper threshold for sweating and a lower threshold for shivering
- Alterations in glucose transport across blood–brain barrier theorized to be a trigger:
  - Hot flushes are counterregulatory attempts to increase cerebral blood flow and cerebral glucose levels.
- Decreased plasma sex hormones results in loss of negative feedback, thus increasing hypothalamic norepinephrine (NE) levels
- NE decreases thermoneutral zone

– Thermoregulatory center in hypothalamus is anatomically close to the GnRH-secreting neurons
– These neurons are stimulated by NE to secrete GnRH
– Increased GnRH stimulation, by being in close proximity to the thermoregulatory center, might activate heat-losing mechanisms (flushing, sweating).

ASSOCIATED CONDITIONS
- Osteopenia, osteoporosis
- Erectile dysfunction/loss of libido
- Metabolic syndrome (insulin resistance, unfavorable lipid profile, increased fat mass)
- Gynecomastia
- Normocytic, normochromic anemia
- Fatigue

GENERAL PREVENTION
- Identification of triggers
  – Avoid hot beverages, spicy foods, alcohol, abrupt change in ambient temperature
- Keep environment cool

DIAGNOSIS
HISTORY
- Abrupt onset of warmth, frequently followed by profuse sweating requiring change of clothes
- More likely to occur at night
- Sensation typically affects the face and trunk
- Attacks normally last 1–5 min, but can persist for up to 20 min
- Can occur occasionally or multiple times daily:
  – Majority of patients have daily episodes
- Frequently experienced at night
- Onset is typically seen within the 1st yr after androgen ablation:
  – 1/3 of men will develop symptoms within the 1st mo

PHYSICAL EXAM
- During acute episode, facial flushing common
- Perspiring frequently present
- Mild tachycardia secondary to vasodilation or anxiety
- Slight increase in oral and forehead temperature
- Usually normal exam in between hot flush episodes
- May have gynecomastia, increased fat mass secondary to androgen deprivation

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- No routine lab evaluation indicated
- No pattern of characteristic changes in testosterone, follicle-stimulating hormone (FSH), leuteinizing hormone (LH), or prolactin

Imaging

N/A

Diagnostic Procedures/Surgery
N/A

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Febrile states or hyper thermia
- Emotional blushing
- Systemic illness:
  - Carcinoid syndrome
  - Pheochromocytoma
  - Medullary thyroid tumors
  - Pancreatic islet cell tumors
  - Renal cell carcinoma
- Other illness:
  - Rosacea
- Neurologic disorders
- Medications:
  - Phosphodiesterase 5 inhibitors (sildenafil, vardenafil, tadalafil, avanafil),
  - Any vasodilatory agent (nitroglycerine, etc.)
  - Nicotinic acid
  - Calcium channel blockers most commonly nifedipine, nisoldipine, amlodipine
  - Opiates
  - Tamoxifen
  - Antibiotics (vancomycin, amphotericin B)
  - IV contrast media
- Dietary
  - Ethanol ingestion
  - Monosodium glutamate or other food additives

TREATMENT

GENERAL MEASURES
- For flushing related to androgen deprivation therapy
  - Reassurance if symptoms mild
  - Attempt to identify and avoid lifestyle triggers
  - Keep environment cool
  - Many men will experience resolution after several years without therapy

MEDICATION
First Line
- For androgen deprivation therapy related hot flushes most are hormonal agents
- Megestrol acetate (Megace) 20 mg/d:
  - Synthetic derivative of progesterone

- 1 study demonstrated complete resolution of symptoms in 90% of patients, >50% improvement in 25% (2)[B]
- Side effects include chills, weight gain, nausea, carpal tunnel–like syndrome, disease progression

• Medroxyprogesterone acetate (Depo Provera) 400 mg/d IM:
- 91% with symptomatic improvement (1)[B]
- 46% have complete response as defined as total elimination of hot flushes.
- Side effects could include weight gain, congestive heart failure exacerbation, loss of bone mineral density, disease progression

• Transdermal estrogen patch 0.05 or 0.1 mg/d (1,3)[B]:
- 3 studies with over 70% of men reporting complete resolution
- Side effects include breast swelling, nipple tenderness

• Diethylstilbestrol (DES): 0.30–1 mg/d:
- 70–90% of men achieve excellent results (1)[B]
- Side effects include painful gynecomastia.
- At low doses, thromboembolic events are not a significant problem.
- Generic drug, inexpensive though difficult to obtain in US.

• Cyproterone acetate (Androcur) 100 mg/d
- Not approved for use in US
- Steroidal antiandrogen, antigonadotropin with progestin-like activity
- May interfere with ADT regimen
- 1 study demonstrated resolution of symptoms in 84% of patients, >50% improvement in 37% (2)[B]
- Side effects include fatigue, increased risk of thrombosis, anemia, potential hepatotoxicity, gynecomastia

Second Line (Nonhormonal Therapy)

• Venlafaxine (Effexor) 12.5 mg/d PO:
- Antidepressant of the serotonin-norepinephrine reuptake inhibitor (SNRI) type
- Median weekly hot flush scores decreased 54% from baseline after 1 mo (2)[B]
- Side effects include lack of sexual desire, delayed orgasm, and increase in suicidal ideation.

• Paroxetine (Paxil-CR) 12.5–37.5 mg/d:
- Antidepressant of the selective serotonin reuptake inhibitor (SSRI) class
- In 1 study, daily hot flushes decreased from 6.2–2.5. (4)[B]
- Side effects include sexual dysfunction, somnolence

• Ergotamine/belladonna/phenobarbital (EBP): 1 tablet PO BID:
- Ergot alkaloid used primarily to treat migraine headache
- Use with caution with patients on monoamine oxidase inhibitors (MAOIs), central nervous system (CNS) depressants, anticholinergic agents
- Generally not recommended for the treatment of hot flushes in men

• Gabapentin (Neurontin) 900 mg/d (300 mg TID, titrated) (5)[B]
- Anticonvulsant/treatment of neuropathic pain

– Modest 46% reduction in hot flush symptom score at target dose of 900 mg
– Side effects include nausea, vomiting, dizziness, and somnolence

- Clonidine (Catapres) 0.1–1 mg/d (PO or patch formulations):
  – Centrally acting α-adrenergic agonist used for treatment of hypertension (HTN)
  – 1/3 of men will report a partial response although similar to placebo (1)[B].
  – Side effects include hypotension, dry mouth, skin irritation from patches.

SURGERY/OTHER PROCEDURES

N/A

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Behavioral therapy: Slow, deep breathing may reduce frequency of hot flushes

Complementary & Alternative Therapies

- Acupuncture:
  – 10–12 wk (twice weekly × 2 wk then once weekly × 8–10 wk)
  – 43–78% reduction in frequency of flushes, average 9-mo duration of effect (1)[B]
- Vitamin E:
  – 30% reduction vs. 22% of women receiving placebo in 1 study *(not studied in men)*
  – May increase the risk of prostate cancer; unclear effect on existing cancer (1)[B]
- Soy products:
  – Contain phytoestrogens which might decrease severity of hot flushes (1)[C]
  – Also have shown benefit with regard to cardiac and bone health
- Black cohosh:
  – Has been used in some postmenopausal women for treatment of hot flushes
  – Mechanism is unknown
  – In 1 trial, no difference found with men taking placebo (1)[C]

ONGOING CARE

PROGNOSIS

- Most men have symptom improvement with medical or complementary therapy.
- At 8 yr of treatment with ADT over 40% of men still had flashes.
- In 1 study, 72% of patients noted that hot flashes interfered with sleep and 59% reported they interfered with the quality of life.

COMPLICATIONS

Some men have side effects from medications taken to alleviate hot flushes (bloating, weight gain, hypertension)

FOLLOW-UP

Patient Monitoring

- Ask patients on androgen deprivation at each follow-up clinical evaluation about the presence and severity of hot flushes:

– Inquire about side effects from therapy
– Intermittent cessation of treatment can be used if side effects become bothersome.
  ○ May have positive effect on quality of life, but may decrease survival

Patient Resources
N/A

CODES

ICD9
- 780.2 Syncope and collapse
- 780.8 Generalized hyperhidrosis
- 782.62 Flushing

ICD10
- R23.2 Flushing

- R55 Syncope and collapse
- R61 Generalized hyperhidrosis

CLINICAL/SURGICAL PEARLS

- Symptoms are usually reversible with cessation of ADT usually within 3–4 mo of stopping treatment.
- Most effective treatment is hormonal therapy with estrogen or progesterone derivatives.
- There are limited data to support alternative/complementary therapies.

HYDROCELE, ADULT & PEDIATRIC

Costas D. Lallas, MD, FACS
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION

- A hydrocele is a collection of serous fluid in some part of the processus vaginalis, usually in the tunica. Can be congenital or acquired
- Translucent swelling in the scrotum or inguinal canal or both
- Aside from congenital hydrocele, it is possible to get examining fingers above the swelling realted to a hydocoele.
- Demonstrated fluctuation in size in congenital hydrocele (also called communicating hydrocele)

EPIDEMIOLOGY

Incidence

- More common in childhood
- 1% of adult males; prevalence: 1,000 in 100,000
- No racial predilection

Prevalence

N/A

RISK FACTORS

- The hydrocele is produced by:
  - Connection with the peritoneal cavity (PPV); also known as congenital hydrocele
  - Defective absorption of fluid by tunica vaginalis; eg, primary hydrocele (common in adults)
  - Excessive production of fluid within the sac; (eg, secondary hydrocele) due to epididymitis, orchitis, testicular torsion causing a “reactive” hydrocele
  - Trauma with bleeding (technically a hematocele)
  - Lymphatic obstruction; eg, filariasis, scrotal surgery (varicocele), renal transplantation, pelvic radiation, malignancy
  - Migration of ventriculoperitoneal (VP) shunt
- Prematurity, low birth weight are risk factors

Genetics

N/A

PATHOPHYSIOLOGY

- Congenital: The PV does not close after testicular descent.
  - 80–90% of newborns have patent processus vaginalis with most closing by age 2
- 4 anatomic variants:
  - Vaginal (PV around the testis)
  - Infantile (PV around testis and cord)

  – Congenital communicating (PV communicates with the peritoneal cavity)
  – Hydrocele of the cord (PV patent with obliteration above and below)
- Acquired: Can be primary (idiopathic) or secondary to disease of the testis. Secondary hydroceles may present acutely or chronically.
- The hydrocele of the canal of Nuck is comparable in females. The cyst is in relationship with the round ligament and located in the inguinal canal.
- Hydrocele fluid characteristics:
  – Amber colored; specific gravity of 1.022–1.024
  – Components: Water, inorganic salts, 6% albumin, and fibrinogen
  – Nonclotting, unless a drop of blood added
  – Chronic hydrocele: Cholesterol-rich
  – Occasionally, tyrosine crystals are present

ASSOCIATED CONDITIONS
- Ehlers–Danlos syndrome
- Exstrophy of the bladder
- Indirect inguinal hernia
- Hydrocephalus (with VP shunt)
- Peritoneal dialysis
- Testicular tumors or epididymo-orchitis in secondary hydrocele
- Undescended testicle with patent procesus vaginalis (PPV)
- Varicocele surgery

GENERAL PREVENTION
None other than repair of indirect hernia defect in infants/children

DIAGNOSIS
HISTORY
- Symptoms of epididymitis, UTI, or acute pain:
  – Secondary hydrocele with infection, torsion, and trauma usually painful
- Usually not painful
- Sensation of heaviness or discomfort in the scrotum
- Change in size of the swelling (ie, size varies throughout day):
  – Suggests congenital communicating hydrocele
- Birth history:
  – Hydrocele more common in premature and low–birth-weight infants
- Medical or surgical history:
  – Varicocelectomy, renal transplant, VP shunt, trauma to the genitalia can be causes
  – Recent inguinal hernia repair (1)

PHYSICAL EXAM
- Transilluminate scrotum:
  – If transilluminates, favors simple hydrocele, but is *not* diagnostic
- Palpation of testes bilaterally:
  – Especially in children, need to rule out undescended testicle. Adults, attempt to feel for testicular mass

- Spermatoceles are always located superior to the testis and are palpated as distinct from the testis, which differentiates them from hydroceles.
- Positive pinch test in a secondary hydrocele (ability to pinch the tunica)
- Examine the groin for inguinal hernia.
- Lymphedema of external genitalia or lower extremities:
  – Tissue edema can be mistaken for the hydrocele.
- On abdominal exam, concomitant presence of a mass may indicate an abdominoscrotal hydrocele

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis and urine culture if epididymo-orchitis suspected
- Tumor markers (bhCG, AFP) if tumor suspected

Imaging

- Transscrotal US in adults with hydrocele to detect underlying testicular abnormality (ie, tumor) and confirm the nature of the mass as a hydrocele.
- Nuclear scan or Doppler US exam in cases of torsion

Diagnostic Procedures/Surgery

N/A

Pathologic Findings

Fibrous wall lined by mesothelial single layer cuboidal or flattened mesothelial cells; may contain benign mesothelial proliferations

DIFFERENTIAL DIAGNOSIS

- Cord lipoma
- Epididymo-orchitis
- Hydrocele of the spermatic cord
- Inguinal/femoral hernia
- Lymphedema of the external genitalia
  – Retroperitoneal process with obstruction of lymphatics (ie, malignancy, lymphatic filiariasis)
  – Nephrotic syndrome
  – Anasarca (protein-loosing enteropathy, cirrhosis)
- Spermatocele
- Testicular or paratesticular tumors
- Torsion (testis or appendix testis)
- Traumatic injury to the testis (hematocele)
- Varicocele (large)

TREATMENT

GENERAL MEASURES

- Adults:
  – No treatment is necessary unless the hydrocele causes discomfort or cosmetic concerns or there is a significant underlying cause present, such as a tumor.

– Communicating hydroceles in older patients may have increased risk of incarceration
- Children:
  – Most will resolve in 1st yr of life.
  – For newborns and children <1 yr supportive care is indicated
  – Persistence beyond age 1 suggests the presence of a patent indirect hernia sac that should be repaired.

MEDICATION

First Line

N/A

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Children:
  – Inguinal incision between internal and external rings.
  – High ligation of the processus vaginalis and excision of the sac.
  – In hydrocele of the cord, the sac can be completely removed. It is imperative that the hydrocele sac be opened when the anatomy is confusing or the sac is very thickened. Failure to do so may result in disastrous consequences if bowel, bladder, or ovary is contained in the sac and not recognized.
- Adults:
  – Scrotal approach with drainage of the hydrocele and resection of the tunica vaginalis; scrotal drain for 24–48 hr
    - Bottle procedure (thin hydrocele sac): Also called Andrews procedure; incise anteriorly, wrap sac back around testicle
    - Jaboulay–Winkelmann procedure (thick hydrocele sac): Hydrocele sac resected and edge wrapped posteriorly around cord structures (resected edges can also simply be oversewn)
    - Lord procedure (thin hydrocele sac): Radial sutures used to gather sac posterior to testis

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Aspiration of the hydrocele, with or without the injection of sclerosing agents is not usually recommended
- Nonseptated hydrocele aspiration and sclerotherapy with doxycycline has been reported to have an 84% success rate with a single treatment (2)
- Aspiration may have a role in postoperative hydroceles such as after inguinal hernia repair.

Complementary & Alternative Therapies

Scrotal support may provide relief of discomfort

ONGOING CARE

PROGNOSIS

Many hydroceles do not enlarge and can be observed if confirmed that there is no underlying pathology (based on ultrasound confirmation).

COMPLICATIONS

- Rupture: Usually traumatic
- Hernia of the hydrocele sac: Tension causes herniation through the Dartos muscle.
- Calcification of the wall: May occur with longstanding cases
- Hematocele: Following trauma or aspiration, or presents chronically simulating a neoplasm
- Infection
- Postoperative:
  - Testicular atrophy or infarction after repair due to damage to vascular supply to the testicle
  - Infection
  - Recurrence

FOLLOW-UP

Patient Monitoring

- Periodic follow-up (baseline US) suggested if managed by observation; return for any acute changes in symptoms
- Parents of a newborn with a hydrocele should be instructed in the natural history of the condition in children.
- Following surgical repair, edema may take several weeks to resolve.

Patient Resources

N/A

CODES

ICD9

- 603.8 Other specified types of hydrocele
- 603.9 Hydrocele, unspecified
- 778.6 Congenital hydrocele

ICD10

- N43.2 Other hydrocele
- N43.3 Hydrocele, unspecified
- P83.5 Congenital hydrocele

CLINICAL/SURGICAL PEARLS

- Tenderness, fever, or other symptoms such as nausea, vomiting, abdominal pain associated with an acute hydrocele requires immediate evaluation to rule out other scrotal pathology.
- The inability to transilluminate a hydrocele could be due to a thick-walled or septated hydrocele, another cause of an enlarged scrotum such as tumor or hematocele or the presence of bowel in a large hernia defect.

HYDROCOLPOS AND HYDROMETROCOLPOS, PEDIATRIC

Sarah M. Lambert, MD
Pasquale Casale, MD, FACS

BASICS

DESCRIPTION

- Hydrocolpos and hydrometrocolpos are congenital anomalies of the female reproductive tract due to an imperforate hymen or less commonly due to a transverse vaginal septum.
  - Hydrocolpos: Gross distension of the vagina with fluid
  - Hydrometrocolpos: Gross distension of vagina and uterus with fluid. May also be associated with vaginal or cervical atresia, stenosis, urogenital sinus, or cloacal anomalies
- Hematocolpos: bloody fluid in vagina
- Hematometrocolpos: bloody fluid in vagina and uterus
- Can be an infrequent cause of an abdominal mass in a newborn female

EPIDEMIOLOGY

Incidence

0.1–3.8% of live female births

Prevalence

N/A

RISK FACTORS

- Imperforate hymen
- High/low transverse vaginal septum
- Urogenital sinus/cloacal abnormality

Genetics (1)

- *McKusick*–Kaufman syndrome
  - Autosomal recessive multiple malformation syndrome
  - Characterized by vaginal atresia with hydrometrocolpos, polydactyly, congenital heart defects, nonimmune hydrops fet alis
- Bardet–Biedl syndrome
- Langer–Giedion syndrome
- Herlyn-Werner-Wunderlich (HWW) syndrome

PATHOPHYSIOLOGY

- Hydrocolpos: Congenital obstruction of the female genital tract leading to accumulation of vaginal secretions and distension of the vagina
- Hydrometrocolpos: Same as hydrocolpos but the pressure now is transmitted past the cervix into the uterus causing distention of both vagina and uterus.
  - The most frequent cause of hydrometrocolpos is the presence of imperforate hymen due to failure of partial resorption of this membrane during the embryonic development
  - Hymen fails to rupture during the 8th wk of gestation

ASSOCIATED CONDITIONS
- Vaginal atresia
- Cloacal anomalies
- Urogenital sinus
- Other malformations, such as imperforate anus, bifid clitoris, polycystic kidney.
- Pediatric considerations:
  – The diagnosis should be considered in the pubertal female with amenorrhea.

GENERAL PREVENTION
Early diagnosis may prevent urinary retention, hydronephrosis, and upper urinary tract complications.

DIAGNOSIS
HISTORY
- Sonolucent mass on prenatal ultrasound (US)
- Stranguria due to bladder outlet obstruction
- Intestinal obstruction with larger mass
- Amenorrhea in pubertal females if the problem was not diagnosed before menarche. In these rare cases, chronic cyclic lower abdominal pain may be present.

PHYSICAL EXAM
- Imperforate hymen with bulging cystic vaginal introitus. The hue is typically bluish if there is trapped blood.
- Palpable suprapubic mass due to distended bladder if associated with outlet obstruction
- Lower extremity lymphedema due to decreased venous return
- Examine for stigmata of Mckusick–Kaufman syndrome (see above)

DIAGNOSTIC TESTS & INTERPRETATION
Lab
Electrolytes and creatinine if significant bilateral upper urinary tract dilation

Imaging
- Abdominal US:
  – Large sonolucent cystic mass displacing bladder anteriorly and rectum posteriorly
  – May see layering of debris
  – Hydronephrosis or ureteral ectasia may be present
  – Prenatal sonogram can detect Hydrometrocolpos as an antenatal diagnosis but usually cannot identify the etiology
- IVP:
  – May see hydroureteronephrosis and a distended bladder
- VCUG:
  – May see an anteriorly displaced bladder
- MRI/MRU:
  – Maybe useful for further delineation of pelvic anatomy when US is equivocal
  – MR urography provides dynamic images that may identify underlying etiologies such as ureteral ectopia

Diagnostic Procedures/Surgery
N/A

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS (2)
- Dermoid cyst
- Hematometrocolpos:
  – Accumulation of menstrual blood products in vaginal and uterus
- Mucocolpos
- Ovarian cyst
- Periurethral cyst:
  – Eccentric smooth mass displacing urethral meatus
- Prolapsed ureterocele:
  – May see necrotic tissue, asymmetric urethral meatus
- Prolapsed urethra:
  – Donut-shaped urethral meatus in the center of a normal vaginal introitus
- Rhabdomyosarcoma:
  – Cluster of grapelike masses protruding from vaginal introitus

TREATMENT

GENERAL MEASURES (3)
- Incision of the hymen if due to imperforate hymen. If an imperforate hymen is present and no mass or hydronephrosis is present, surgical correction is sometimes delayed until tissues become more estrogenized. However, the correction of the imperforate hymen must take place before there is development of hydrocolpos.
- Address vaginal or cervical issues as the anatomic pathology presents

MEDICATION
First Line
N/A

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Simple incision of the imperforated hymen. A cruciate incision with resection of excess tissue tags as necessary
- Cloacal anomalies require a coordinated surgical team and planned intervention.
- Vaginal septum if present needs to be incised either endoscopically or through open surgery

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
Excellent, especially with early diagnosis and treatment

COMPLICATIONS
- Renal compromise or acute kidney injury with severe hydronephrosis
- Abdominal ascites
- Urinary retention and voiding difficulty
- Reports of increasing rates of infertility based upon level of obstruction
- Respiratory compromise in neonates due to massive abdominal distension
- At menarche, retrograde flow may predispose patient to endometriosis

FOLLOW-UP
Patient Monitoring
Usually none necessary. Follow for resolution of hydronephrosis if present.

Patient Resources
N/A

- Q52.3 Imperforate hymen
- Q52.11 Transverse vaginal septum

CLINICAL/SURGICAL PEARLS

The diagnosis should be considered in the pubertal female with amenorrhea.

HYDRONEPHROSIS/HYDROURETERONEPHROSIS (DILATED URETER/RENAL PELVIS), ADULT

Kelly A. Healy, MD
Demetrius H. Bagley, MD, FACS

BASICS

DESCRIPTION

- Hydronephrosis includes dilation of the renal pelvis and calyces while hydroureteronephrosis is dilation of the renal pelvis, calyces, and ureter
- Both can result from obstructive and nonobstructive causes
- Intrinsic and extrinsic obstructive process can affect the entire urinary tract
- Obstructive uropathy indicates impedance of urinary flow anywhere along the urinary tract, upper or lower and damage to the renal parenchyma due to obstruction at any site

EPIDEMIOLOGY

Incidence

Asymptomatic, unilateral hydronephrosis occurs in ~3% of population

Prevalence

- 3.1% prevalence in historic autopsy series of 59,000 patients
  - Age 20–60 more common in women, secondary to pregnancy/gynecologic conditions
  - Age >60 yr obstruction more common in men (6.2% vs. 2.9%) attributed to prostatic diseases
- A similar 2.5% prevalence of asymptomatic unilateral hydronephrosis in radiologic series among potential renal donors
  - More women than men (86% vs. 14%)
  - No association with potential donor age

RISK FACTORS

- Urolithiasis is most common cause of upper urinary tract obstruction, prevalence between 10–15% by age 70 yr
- Ureteropelvic junction (UPJ) obstruction can occur from anatomic-crossing vessel, high insertion, or secondary conditions (impacted stone)
- Lower urinary tract disorders can result in hydroureteronephrosis, often bilateral
- Benign prostatic enlargement is the most common affecting 70% of men by age 70
- Hydronephrosis can develop with obstructive lesions at essentially any level.
- Kidney:
  - Benign lesions including peripelvic cysts
  - Malignant neoplasms with renal cell carcinoma and urothelial carcinoma
  - Renal pelvic calculi
  - UPJ obstruction
  - Infection tuberculosis
  - Renal artery aneurysm

  - Hilar lymphadenopathy
- Ureter:
  - Neoplasms: Benign papilloma, fibroepithelial polyp, ureteritis cystica; malignant urothelial carcinoma
  - Ureteral calculi or stricture
  - Ureterocele or congenital megaureter
  - Infection (tuberculosis, schistosomiasis)
  - Retroperitoneal lymphadenopathy (lymphoma, other malignancy)
  - Inflammatory (retroperitoneal fibrosis and arterial aneurysms)
  - Gynecologic: Ovarian vein syndrome, endometriosis, GYN malignancy, pregnancy
  - Pelvic lipomatosis
  - Retrocaval ureter
- Bladder/urethra:
  - Malignant neoplasms: eg, urothelial carcinoma locally advanced carcinoma of the prostate
  - Bladder neck contracture
  - Prostatic obstruction
  - Detrusor dysfunction
  - Increasing intravesical storage pressure
  - Urethral stricture; meatal stenosis
  - Phimosis

Genetics

Nonobstructive hydronephrosis occurs with several congenital syndromes, usually diagnosed in infancy (see “Hydronephrosis/Hydroureteronephrosis, Pediatric”)

PATHOPHYSIOLOGY

- Effective hydroureteronephrosis on renal function depends on whether it is totally or partially obstructive and unilateral or bilateral
- Effects of obstruction of the kidney are time dependent. Within several hours, changes are evident but (1)
  - 1–2 wk—glomerular destruction, tubular atrophy, and interstitial fibrosis occur
  - By 6–8 wk irreversible damage occurs

ASSOCIATED CONDITIONS

Numerous causal conditions can be associated. See “Risk Factors” above.

GENERAL PREVENTION

Hydronephrosis may be disease related and prevention then must be individualized

DIAGNOSIS

HISTORY

- Signs and symptoms vary dependent on the etiology and chronicity of the condition
- Acute obstruction can cause abdominal flank and/or back pain; may be associated with anorexia, nausea, vomiting
- Gradual ureteral obstruction more typically presents with vague complaints or may be asymptomatic

- Insidious obstruction of solitary kidney or bilateral can present with symptomatic obstructive uropathy or evidence of renal compromise
- Complete urinary history is essential
- Site of obstruction, upper vs. lower urinary tract may relate to presentation
  - Upper urinary tract—flank pain and costovertebral angle tenderness with acute obstruction
  - Lower urinary tract maybe associated with obstructive voiding symptoms

PHYSICAL EXAM

- General condition—pain or localized symptoms
- Hypertension can be related to obstruction
- Abdominal, flank, or pelvic mass
- Flank tenderness can occur with acute obstruction and with calculi or infection (pyelonephritis, pyelonephrosis, retroperitoneal abscess)
- Vaginal exam
  - Ureteral prolapse
  - Ureterocele through urethra
- Digital rectal exam
  - Enlarged prostate, nodularity suggestive of prostate cancer

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis for hematuria, pyuria, crystalluria
- Urine culture
- Renal function studies:
  - BUN & creatinine
- CBC
  - Anemia—associated with chronic renal insufficiency
  - Elevated white blood cell count with infection
- Serum chemistries, special attention to potassium
- Serum prostatic-specific antigen (PSA)
- Urine cytology for urothelial carcinoma

Imaging (2)

- Several modalities are available. They differ in their degree of anatomic and functional information and may distinguish the presence and extent of obstruction.
- Renal ultrasound: Inexpensive, widely available, no ionizing radiation, and no contrast (3)
  - Excellent to define hydronephrosis
  - Should include imaging through the bladder to assess for distal hydroureter, ureteral jets, bladder wall thickening, and postvoid residual
  - Renal cortex can be evaluated
- Color Doppler renal ultrasound (4):
  - Help distinguish obstructive vs. nonobstructive hydronephrosis
  - Resistive index (RI) = (PSV – EDV)/PSV (peak systolic velocity end diastolic velocity)/peak systolic velocity
    - RI $\geq$0.7 suggested of obstruction (92%) sensitivity and (88%) specificity

- RI is time dependent and decreases >48 hr after obstruction. Thus, less useful for chronic vs. acute obstruction

- Noncontrast CT scan:
  - Imaging of choice for acute renal colic
  - Visualizes entire urinary tract and adjacent structures; best for urolithiasis and may not detect soft tissue masses or filling defects
  - Secondary signs of acute obstruction include perinephric stranding and nephromegaly
  - Normal ureter on unenhanced CT is considered to be 3 mm in adults
- CT urogram
  - Good for incidental hydronephrosis
  - Noncontrast phase for ureterolithiasis
  - Contrast phase-delayed nephrogram suggested obstruction
  - Defined parenchymal masses, evaluate for crossing vessels with UPJ obstruction
  - Delayed (excretory) phase may look like site of obstruction and rule out filling defect depending on degree of renal impairment
- Excretory urogram:
  - Generally replaced by CT urogram
- Magnetic resonance imaging (MRI)
  - Lack of ionizing radiation advantageous for children, pregnant patients, and those with renal insufficiency or contrast allergy
  - More time consuming, expensive, does not effectively image urolithiasis
- Pyelography: Antegrade or retrograde
  - Can be used with ultrasound or noncontrast CT in patients with contrast allergies or renal insufficiency; but invasive
- Functional studies to differentiate obstructive vs. nonobstructive uropathy
  - Whitaker test: 1st described in 1980
    - Indwelling percutaneous nephrostomy tube
    - Percutaneous puncture renal pelvis
    - Upper urinary tract is perfused at a rate of 5–10 mL per minute with saline or contrast media
    - Serial pressure recording is made in renal pelvis and bladder; spot films aid in evaluation
    - Pressure gradient: Obstruction >22 cm H_2O; equivocal 15–22 cm H_2O; normal <15 cm H_2O
  - Nuclear renography:
    - Primary noninvasive study to distinguish obstructive vs. nonobstructive uropathy
    - DTPA: Freely filtered by glomerulus. Neither secreted nor resorbed by renal tubules
    - MAG-3: Almost exclusively limited by proximal tubule secretion without resorption distally
    - Preparation of patient, maintain hydration, place a Foley catheter if concern for lower urinary tract dysfunction or obstruction
    - Furosemide 20–40 mg given 20 min after radiotracer administration to induce diuresis
    - Half time ($T_{½}$ clearance). Time it takes to eliminate 50% of radiotracer: Obstruction >20 min; equivocal >10–20 min; normal <10 min; false positives: More commonly with severe dilation or poor function

- Endoluminal ultrasound (ELUS):
  - Evaluate periureteral anatomy, vessels of high insertion and UPJ obstruction, define ureteral stricture
  - Study of choice for submucosal calculi
- Voiding cystourethrogram (VCUG):
  - Evaluate for reflux
  - Patients with recurrent urinary tract infections, flank pain, nonobstructive hydronephrosis

Diagnostic Procedures/Surgery

Cystoscopy, retrograde ureteropyelogram

Pathologic Findings

Nephropathy related to obstruction (see above)

DIFFERENTIAL DIAGNOSIS

- Obstructive vs. nonobstructive hydroureteronephrosis
- See also “Risk Factors”

TREATMENT

GENERAL MEASURES

- Management is highly dependent on underlying condition and the timing (acute vs. chronic)
- Urgent decompression is needed with:
  - Severe pain
  - Active urinary tract infection and acute kidney insufficiency
  - Retrograde ureteral stent or percutaneous nephrostomy can provide equally effective drainage
- Hydronephrosis lower urinary tract etiology is typically bilateral and patients may be asymptomatic
- May warrant catheter drainage or endoscopic treatment

MEDICATION

First Line

- Patients with infection and hydronephrosis require antibiotic therapy and drainage
  - Renal failure and electrolyte abnormalities should be corrected in conjunction with drainage

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Catheter drainage of obstructed system with percutaneous nephrostomy or ureteral stent is guided by the severity of the illness
  - Hydronephrosis and fever may be ominous signs requiring early drainage
  - Other surgical procedures can be guided by the findings on imaging studies

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies
Hemodialysis may rarely be needed in the acutely ill patient

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
Cause specific

COMPLICATIONS
- Progressive renal deterioration
- With vesicoureteral reflux, scarring and hypertension can occur
- Postobstructive diuresis seen only with bilateral obstruction or solitary functioning kidney

FOLLOW-UP
Patient Monitoring
- The etiology for hydronephrosis will determine the appropriate surveillance regimen
- Consider renal ultrasound and renal scan at 3 mo after treatment
- Postoperative imaging may demonstrate the dilatation persists despite relief of obstruction

Patient Resources
N/A

CODES

ICD9

- 591 Hydronephrosis
- 592.0 Calculus of kidney
- 600.00 Hypertrophy (benign) of prostate without urinary obstruction and other lower urinary tract symptom (LUTS)

ICD10

- N13.2 Hydronephrosis with renal and ureteral calculous obstruction
- N13.30 Unspecified hydronephrosis
- N40.0 Enlarged prostate without lower urinary tract symptoms

CLINICAL/SURGICAL PEARLS

- Hydronephrosis and fever especially sepsis may require immediate drainage.
- Hydronephrosis may be nonobstructive.
- Generally hydronephrosis in an adult can be considered a sign of a process that must be defined and possibly treated.

HYDRONEPHROSIS/HYDROURETERONEPHROSIS (DILATED URETER/RENAL PELVIS), PEDIATRIC

Ahmad H. Bani-Hani, MD, FAAP, FACS

BASICS

DESCRIPTION

- Refers to dilatation of any part of the collecting system, single or combined:
  - Pelviectasis (renal pelvis)
  - Caliectasis (calyces)
  - Pelvocaliectasis (both renal pelvis and calyces)
  - Ureterectasis (ureter)
  - Hydroureteronephrosis (entire collecting system is dilated)
- Society of Fet al Urology (SFU) grading of infant hydronephrosis (1)[A]:

SFU grade	Pattern of renal sinus splitting on renal ultrasound
0	No splitting
1	Urine in pelvis barely splits sinus
2	Urine fills *intrarenal* pelvis and/or urine fills *extrarenal* pelvis *major* calyces dilated
3	SFU Gr 2 *and minor* calyces uniformly dilated *and* parenchyma preserved
4	SFU Gr 3 *and* parenchyma thin

EPIDEMIOLOGY

- Prenatal hydronephrosis is detected in about 1.4% of total prenatal ultrasound performed in US
- The true incidence is difficult to determine secondary to many asymptomatic, undetected cases

RISK FACTORS

- Family history of hydronephrosis, maternal type I diabetes mellitus (associated with infant sacral agenesis)
- Genetic syndromes: Downs, trisomy 13, trisomy 18, CHARGE, Ehlers–Danlos, Menkes, Prune belly, etc
- Horseshoe kidney/pelvic kidney
- Duplication renal anomalies
- Neurogenic bladder secondary to tethered spinal cord, myelodysplasia, sacral agenesis

Genetics

No specific genetic abnormalities except if associated with specific genetic syndromes as outlined above

ALERT

Hydronephrosis is not a specific diagnosis but a finding or sign. The cause of the

hydronephrosis is the diagnosis and indicates the appropriate treatment.

PATHOPHYSIOLOGY

- Physiologic hydronephrosis: Unclear etiology but typically improves with serial renal ultrasound monitoring
- Pathologic hydronephrosis
  - Vesicoureteral reflux: Reflux can be primary or secondary to conditions that raises the intravesical pressures (eg, bladder outlet obstruction and neurogenic bladder)
  - Ureteropelvic junction (UPJ) obstruction (2)[A]:
    - Defined as obstruction to the flow of urine from the renal pelvis to the proximal ureter
    - Considered to be the commonest cause of prenatal hydronephrosis
    - Obstruction can be caused by an intrinsic narrowing at the UPJ or by an extrinsic compression by a lower pole anteriorly crossing vessel
    - Examples of intrinsic obstruction can include: Narrow segment with muscular discontinuity, ureteral valves, mucosal folds, or ureteral polyps
  - Ureterovesical junction (UVJ) obstruction:
    - Primary: Called primary obstructive megaureter. The most common finding is a distal adynamic ureteral segment that affects the free efflux of urine resulting in a functional obstruction
    - Secondary: Distal stone, hypertrophy of the distal ureter and trigone in neurogenic bladder or posterior urethral valves
  - Ureterocele:
    - Defines as cystic dilatation of the distal ureteral segment
    - More common in females and can cause obstruction to the distal urine flow
    - Often associated with duplication anomalies of the kidneys particularly involving the upper pole moiety
  - Ectopic ureter:
    - Occurs when the distal opening of the ureter is not in the normal location at the corner of the trigone
    - Ureter can enter the bladder neck, urethra, and, in female, the vestibule, vagina, and rarely the uterus
    - Ectopic ureters opening outside the bladder or urethra tend to be obstructed and often associated with nonfunctioning renal moiety
    - Commonly involves the upper pole moiety in duplicated renal anomalies
  - Posterior urethral valves:
    - The most common cause of congenital lower urinary tract obstruction in males (1/4,000 to 1/7,500 births)
    - Varies in severity and can result in deterioration of fet al renal function, and progressive oligohydramnios, which may lead to pulmonary hypoplasia with a high risk of perinatal morbidity and mortality
  - Other causes:
    - Anterior urethral valves
    - Urethral atresia
    - Nonneurogenic neurogenic bladder (Hinman syndrome)

ASSOCIATED CONDITIONS

Hydronephrosis can by physiologic or pathologic associated with many condition as noted above

DIAGNOSIS

HISTORY

- Detailed prenatal history of:
  - Timing of 1st detection of hydronephrosis in relation to gestational age
  - Unilateral vs. bilateral
  - Gender of the baby
  - Maternal diabetes mellitus, particularly type I (associated with fet al sacral agenesis)
  - Family history of renal anomalies
  - Amniotic fluid volume
  - Paternal allergy to penicillin
- Detailed postnatal history:
  - Circumcision status
  - Birth weight
  - Jaundice
  - Urinary tract infections
  - Progression with potty training
  - Incontinence
  - Hypertension, failure to thrive

PHYSICAL EXAM

- Vital signs, particularly blood pressure
- Weight
- Jaundice
- Abdominal masses
- Is bladder palpable?
- Cutaneous manifestations of spina bifida occulta (hairy patch, sacral dimple, lipoma, asymmetric or short gluteal fold)
- Genital/anorectal exam

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Basic metabolic panel
- Urine analysis and culture if indicated

Imaging

- Renal and bladder ultrasound (RUS):
  - Should be 1st-line imaging study
  - Will give excellent idea about the laterality and severity of hydronephrosis, associated bladder pathology such as ureterocele, are ureters dilated too?
  - Bladder pathology such as abnormal bladder wall thickness, key hole sign in posterior urethral valves
  - Indirect way to assess overall renal function by looking at echogenicity and thickness of

renal parenchyma
- Abdominal kidney-ureter-bladder (KUB) x-ray:
  – Displaced bowel pattern from hydronephrosis or bladder distension
  – Stool load and distribution to help in management
- Voiding cystourethrogram:
  – Assess presence of reflux
  – During early filling, a ureterocele can be identified
  – Assess the entire urethra for evidence of posterior or anterior urethral valves
- Diuretic renal scan (MAG-3 with Lasix):
  – Evaluates differential renal function and drainage curves from each kidney.
  – Very useful for the diagnosis and evaluation of possible UPJ/UVJ obstruction
- MR urogram:
  – Can provide useful information such as renal function and anatomic details when evaluating conditions such as ectopic ureter location

Diagnostic Procedures/Surgery
- Usually reserved for treatment of certain conditions such as posterior urethral valve ablation
- Cystoscopy and retrograde pyelogram can be used to define the anatomy of the collecting system and placement of a drainage stent

Pathologic Findings
Depends on the underlying pathology responsible for the hydronephrosis

DIFFERENTIAL DIAGNOSIS
- Prominent extrarenal pelvis
- Multicystic dysplastic kidney
- Polycystic renal disease
- Renal cysts

TREATMENT

GENERAL MEASURES
Depends on underlying pathology responsible for the hydronephrosis

MEDICATION
First Line
- Antibiotic prophylaxis may be needed in severe cases of hydronephrosis and/or presence of reflux
  – Prophylactic daily antibiotics to keep urine sterile, preferentially given at bedtime to maximize urinary retention
    - < 2 mo age: Amoxicillin 20 mg/kg/d
    - ≥ 2 mo of age: Trimethoprim–sulfamethoxazole 2 mg/kg/d (concentrates in urine); nitrofurantoin is an alternative, but liquid is expensive and bad-tasting

Second Line
- Anticholinergics in cases of an overactive bladder and/or raised intravesical pressures
- β-blockers in some cases of bladder outlet obstruction

SURGERY/OTHER PROCEDURES

- Vesicoureteral reflux: Antibiotic prophylaxis vs. surgical correction
- UPJ obstruction: Pyeloplasty
- UVJ obstruction: Distal ureterectomy and ureteral reimplant
- Ureterocele: Several options available including observation, intravesical puncture, ureteroureterostomy, and partial nephrectomy
- Ectopic ureter: Several options available including heminephrectomy and ureteroureterostomy
- Posterior urethral valves: Endoscopic ablation

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Clean intermittent catheterization in cases of neurogenic bladder
- Biofeedback in some patients with voiding dysfunction

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

Varies and depends on underlying pathology and its severity (3)[A]

COMPLICATIONS

- Hypertension
- Kidney/bladder stones
- Multiple UTIs
- Reflux
- Renal insufficiency
- Renal scarring
- Urinary incontinence

FOLLOW-UP

Patient Monitoring

- Patients need meticulous follow-up once hydronephrosis is diagnosed before and after treatment
- Referral to pediatric urology/nephrology for full assessment and treatment

CLINICAL/SURGICAL PEARLS

- Hydronephrosis is not a diagnosis but a sign.
- Renal ultrasound, VCUG, and diuretic renal scan can establish the underlying etiology of hydronephrosis.

HYDRONEPHROSIS/HYDROURETERONEPHROSIS (DILATED URETER/RENAL PELVIS), PRENATAL

Bruce J. Schlomer, MD
Laurence S. Baskin, MD, FACS, FAAP

BASICS

DESCRIPTION

- In utero dilation of fet al renal collecting system
- May represent a normal developmental variant or a pathologic anomaly
- Prenatal hydronephrosis (PN) may be observed early in pregnancy but the diagnosis usually cannot be made with certainty until 18wk of gestation
- Severity based on anterior–posterior renal pelvis diameter (APD) (1)
  - Mild: 4 to <7 mm (2nd trimester); 7 to <9 mm (3rd trimester)
  - Moderate: 7 to ≤ 10 mm (2nd trimester); 9 to ≤ 15 mm (3rd trimester)
  - Severe: >10 mm (2nd trimester); >15 mm (3rd trimester)

EPIDEMIOLOGY

Incidence

- 1–5% of fetuses are observed to have PN (2)
  - Mild: 57–88%
  - Moderate: 10–30%
  - Severe: 2–13%
- Risk of clinically significant PN increases with severity. Risk of undergoing surgery $<10\%$ with mild and $>50\%$ with severe.

Prevalence

None

RISK FACTORS

- Family history of renal abnormalities or vesicoureteral reflux
- Previous fet al loss due to urinary tract causes

Genetics

None

PATHOPHYSIOLOGY

- Transient hydronephrosis (most common, physiologic dilation of the ureter is seen in 41–88% of cases of PN)
  - $\sim 90\%$ of mild PN will be transient
- Ureteropelvic junction (UPJ) obstruction (most common pathophysiology)
- Ureterovesical obstruction (megaureter, obstructed and nonobstructed)
- Bladder outlet obstruction (posterior urethral valves (PUVs), urethral atresia)
- Nonobstructive processes: Vesicoureteral reflux, nonrefluxing nonobstructed megaureter, and prune belly syndrome

- Severe PN with oligohydramnios may cause pulmonary hypoplasia

ASSOCIATED CONDITIONS
Congenital hydronephrosis is associated with many syndromes.

GENERAL PREVENTION
None

DIAGNOSIS
HISTORY
- Timing of prenatal detection; earlier detection implies more severe condition.
- Presence of calyectasis and renal cortical thinning indicate more severe condition.
- Presence of cortical cysts may indicate dysplasia.
- Unilateral vs. bilateral renal involvement is a critical determination for diagnosis and prognosis.
- Change in dilation in relation to bladder filling may indicate vesicoureteral reflux.
- Presence of oligohydramnios important: Suggests severe comprise of renal function.
  - Associated with severe obstructive uropathy due to PUVs, congenital urethral stricture, or ureterocele obstructing bladder outlet
  - Associated with pulmonary hypoplasia and fet al or neonatal death

PHYSICAL EXAM
N/A

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Maternal α-feto protein may be elevated in some cases of fet al renal anomalies
- Assessment of pulmonary maturity in patients with oligohydramnios (lecithin-to-sphingomyelin ratio)
- Amniotic fluid studies:
  - Volume: Composed mostly (90%) of fet al urine after the 16th wk of gestation
  - Correlates with fet al renal function
- Fet al karyotype (may indicate gender or important genetic information)
- Assessment of fet al urinary electrolytes:
  - Generally only done with oligohydramnios
  - Good prognosis: Sodium <100 mg/dL; osmolarity <210 mOsmol/dL; chloride <90 mg/dL (remember dilute urine is better in the fetus)
- Postnatal serum electrolyte assessment:
  - Nadir creatinine (<0.7 mg/dL in 1st yr holds good prognosis)
  - CO_2: Acidosis has a poor prognosis.
- Urinalysis and urine culture as needed

Imaging
- Prenatal US in 3rd trimester: Based upon severity of PN in 2nd trimester(1)
  - Mild: Consider 3rd trimester US
  - Moderate: 3rd trimester US
  - Severe: US in 3–4 wk

- Additional prenatal US in 3rd trimester: Based upon severity of PN in 3rd trimester (1)
  - Mild: Postnatal evaluation
  - Moderate: Postnatal evaluation
  - Severe: US in 2–3 wk
- Postnatal evaluation: Controversial. Society of Fet al Urology (SFU) recommendations based on severity of PN (1)
- Unilateral mild PN
  - Postnatal US at 2–4 wk
  - Consider VCUG at 2–4 wk if hydro present on postnatal US
  - Consider diuretic nuclear renal scan (MAG-3) at 4 wk if hydro present on postnatal US
- Unilateral moderate-severe PN
  - Postnatal US at 2–4 wk
  - VCUG at 2–4 wk if hydro present on postnatal US
  - Consider diuretic nuclear renal scan (MAG-3) at 4 wk of hydro present on postnatal US
- Bilateral moderate-severe PN
  - 1st postnatal US 1–3 days after birth
  - VCUG 1–7 days after birth
  - Males: Early VCUG to rule out PUVs
  - Consider diuretic nuclear renal scan (MAG-3) at 4 wk
- Special situations: Bladder/urethral abnormalities, decreased amniotic fluid
  - Early evaluation similar to severe bilateral PN
- Postnatal US within 48–72 hr after birth may underestimate degree of hydronephrosis
- Rare cases of pulmonary compromise from mass effect require emergent drainage

Diagnostic Procedures/Surgery

Fet al urinary electrolyte bladder aspiration in cases of oligohydramnios

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Urinary conditions:
  - Autosomal recessive polycystic kidney disease
  - Duplication anomalies
  - Ectopic ureter
  - Megacystis-megaureter microcolon syndrome
  - Multicystic dysplastic kidney
  - PUVs
  - Prune belly syndrome
  - Transient hydronephrosis
  - UPJ obstruction
  - UVJ obstruction
  - Vesicoureteral reflux
- Intestinal disorders:
  - Cloacal exstrophy
  - Duodenal atresia

  - Imperforate anus
  - Intestinal duplication
  - Mesenteric cysts
  - Ovarian cysts
  - Persistent cloaca
- Tumors:
  - Congenital mesoblastic nephroma
  - Neuroblastoma

TREATMENT

GENERAL MEASURES

- Prenatal management: Assessment of hydronephrosis, oligohydramnios:
  - Unilateral cases: Serial prenatal US if severe; deliver at term
  - Bilateral cases
    - No oligohydramnios: Observation, deliver at term
    - Oligohydramnios: Termination, early delivery, prenatal treatment for pulmonary immaturity
- Postnatal management:
  - Pulmonary support if respiratory compromise
  - Antibiotic prophylaxis if moderate-severe unilateral or bilateral PN
  - Bilateral hydronephrosis with dilated bladder: Place catheter to drain bladder
  - All hydronephrosis: US, VCUG, MAG-3 renal scan as indicated (see above for SFU recommendations)

MEDICATION

First Line

- No specific antenatal medications exist
- Prophylactic antibiotics controversial.
  - Recommended by SFU with moderate-severe PN, bladder/urethral abnormalities, dilated ureter, oligohydramnios(1)
  - Amoxicillin (20 mg/kg/d—1 dose per day)
- Surfactant to assist lung function after birth with pulmonary hypoplasia

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Fet al intervention (cases with oligohydramnios only):
  - Controversial(3)
  - Tapping of fet al bladder
  - Percutaneous shunting: Vesicoamniotic drain
- Surgery is seldom necessary in the neonatal period with the exception of severe bilateral obstruction due to bladder outlet obstruction or severe UPJ or UVJ obstruction.
- Need for postnatal surgery based upon diagnosis and correlated with severity of PN
  - Mild: $<10\%$

– Severe: ~50%

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Most neonates have an excellent prognosis. Prognosis depends on etiology of the dilated system and other associated anomalies.
- Severe bilateral hydronephrosis is associated with obstruction and oligohydramnios early in gestation predicts an adverse outcome.
- Fetuses with bilateral hydronephrosis, a distended bladder, and oligohydramnios are at highest risk of neonatal demise or pulmonary complications.
- Risk of UTI correlated with severity of PN
  – Mild: ~10%
  – Moderate-severe: ~30%

COMPLICATIONS

- Pulmonary hypoplasia with severe oligohydramnios
- Renal impairment
- UTIs

FOLLOW-UP

Patient Monitoring

- Based on initial evaluation, subsequent imaging may be necessary (1)
- Most centers employ serial renal US every 3–6 mo for the 1st yr of life
- If febrile UTI, consider VCUG and/or MAG-3 renal scan

CODES

ICD9

- 753.6 Atresia and stenosis of urethra and bladder neck
- 753.20 Unspecified obstructive defect of renal pelvis and ureter
- 753.29 Other obstructive defects of renal pelvis and ureter

ICD10

- Q62.0 Congenital hydronephrosis
- Q64.31 Congenital bladder neck obstruction
- Q62.39 Other obstructive defects of renal pelvis and ureter

CLINICAL/SURGICAL PEARLS

- Majority of prenatal/fet al hydronephrosis (especially mild) is transient with no clinical significance.
- VCUG is not recommended for unilateral mild hydronephrosis.
- Prophylactic antibiotics have not been shown to be effective. Not recommended in mild cases.
- Emergent evaluation by urologist should occur with:
  - Severe bilateral prenatal hydronephrosis
  - Severe unilateral prenatal hydronephrosis in solitary kidney
  - Prenatal hydronephrosis with dilated bladder consistent with posterior urethral valves
  - Severe prenatal hydronephrosis with pulmonary compromise from mass effect (rare)

HYPERALDOSTERONISM, PRIMARY (ALDOSTERONISM, CONN SYNDROME)

Mark W. Ball, MD
Arthur L. Burnett, II, MD, MBA, FACS

BASICS

DESCRIPTION

- Primary hyperaldosteronism or Conn syndrome is characterized by HTN, hypokalemia, hypernatremia, alkalosis, and suppressed renin, due to excess production of aldosterone.
- It classically refers to an aldosterone-producing adenoma (APA) of the adrenal gland that is usually small (< 3 cm), unilateral, and renin-unresponsive.
- APA subtype of primary hyperaldosteronism accounts for 30–60% of primary hyperaldosteronism.
- Secondary hyperaldosteronism is usually related to HTN and/or edematous state disorders such as CHF, cirrhosis, and nephrotic syndrome.
- Pseudohypoaldosteronism can be due to ingestion of large amounts of licorice or Liddle syndrome

EPIDEMIOLOGY

Incidence

Incidence data is lacking.

Prevalence

- 5–13% of hypertensive population (recent increased prevalence of primary aldosteronism due to improved diagnostic testing)
- Peak incidence during 4th and 5th decades
- 20% primary aldosteronism in resistant hypertensives (elevated BP despite 3 antihypertensive medications)
- Adrenal adenoma is more common in women.

RISK FACTORS

No known risk factors for primary hyperaldosteronism

Genetics

- Hereditary pattern for more common APAs unclear
- A rare form of autosomal dominant primary hyperaldosteronism is glucocorticoid-remediable aldosteronism (GRA).
- Gene for aldosterone synthase (CYP11B2) recently identified

PATHOPHYSIOLOGY

- The biochemical hallmark of the disease is increased aldosterone after sodium (Na) loading and low plasma renin activity (PRA) during Na depletion
- Autonomous aldosterone secretion leads to inappropriate Na and water reabsorption from the cortical collecting tubule:

  - Electrical gradient created favors secretion of potassium (K), resulting in hypokalemia.
  - Extracellular fluid volume (ECF) volume causes mild hypertension (HTN).
- Renal escape limits Na retention and prevents significant edema:
  - Occurs after ~1.5 kg of extracellular fluid (ECF) is absorbed, or a weight gain of ~3 kg.
  - Spontaneous diuresis then occurs, lowering the ECF.
  - Increased Atrial natriuretic peptide (ANP), decreased thiazide-sensitive Na-Cl cotransporter, and pressure natriuresis are factors that may contribute to renal escape.

ASSOCIATED CONDITIONS
- Adrenal cancer (rare)
- Essential HTN

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- HTN, often refractory to medical therapy
  - Headaches secondary to HTN
- Symptomatic hypokalemia:
  - Muscle cramps, paresthesias, tetany, nocturia, polyuria

PHYSICAL EXAM
- No specific findings
- Mild-to-moderate HTN, not usually distinguishable from essential HTN
- Malignant HTN rare
- Lack of edema

DIAGNOSTIC TESTS & INTERPRETATION
- Consider screening the following patients (1):
  - Hypertensive and hypokalemic:
    - HTN with K <3 highly suspicious of an aldosterone-producing adenoma (APA).
    - Hypokalemia is thought to be a late manifestation of aldosterone excess.
    - If patient is on restricted Na diet, severe hypokalemia often absent; only test patients if adequately salt loaded.
    - Hypokalemia can be induced with oral Na loading.
    - 20% of patients with hyperaldosteronism are normokalemic; more often seen in adrenal hyperplasia.
  - Inappropriate kaliuresis on initiation of diuretic
  - HTN resistant to multidrug treatment
  - Family history of early HTN or stroke
  - Adrenal incidentaloma
- Diagnosis may be difficult in those with normal serum K levels and those being treated with antihypertensives or diuretics

Lab
- Hypernatremia, hypokalemia, metabolic alkalosis, impaired glucose tolerance

- Plasma renin activity (PRA) low in primary hyperaldosteronism; if plasma renin >1, diagnosis unlikely
- Screening: Plasma aldosterone concentration (PAC)/plasma renin activity (PRA) in the upright position; obtain when K is corrected. Positive if:
  - PAC/PRA >20 with PAC ≥15 ng/dL *OR*
  - PAC/PRA >40 with PRA >0.2 ng/mL/h
  - Diuretics, ACE inhibitors, ARBs can falsely elevate PRA.
- Confirmatory studies:
  - Na-loading test with:
    - Saline infusion: PAC at baseline and 4 hr (positive test PAC >10 ng/dL)
    - Oral Na: 24-hr urine Na and aldosterone on days 3 and 4 (positive if aldosterone <12 mg/d) and (Na >200 mmol/d)
    - Fludrocortisone suppression
- All confirmatory tests should be used with care in patients with compromised left ventricular cardiac function.

Imaging

- CT with thin cuts through the adrenals is the preferred noninvasive test:
  - Used to identify surgically curable disease and differentiate the subtypes once primary aldosteronism is confirmed
  - aldosterone-producing adenomas (APA's) usually uniform, round, and hypodense with Hounsfield unit ≤10
  - 6% probability of identifying an adrenal mass on CT
  - Lacks overall accuracy to distinguish between unilateral and bilateral disease:
    - Bypass adrenal vein sampling only if clear adrenal mass (>1 cm) is identified in the younger patient (<40) with highly suspicious biochemical findings
- MRI is not more sensitive than CT
- Adrenal scintigraphy using Iodine-131-6-iodomethyl-19-nor-cholesterol is rarely available in US, cumbersome to perform, and depends heavily on the size of the adenoma.

Diagnostic Procedures/Surgery

- Adrenal vein sampling (AVS) for aldosterone is the gold standard in localizing the site of excess production:
  - Aldosterone and cortisol samples obtained from peripheral veins, IVC, right and left adrenal veins after corticotrophin infusion
  - 44% of patients with bilateral renal masses had a unilateral source of aldosterone secretion.
  - Cure also reported after adrenalectomy in patients with AVS-proven unilaterality despite normal adrenals on CT scan.
- Postural tests, historically used to distinguish adenoma from bilateral hyperplasia have become less useful with the discovery of angiotensin-responsive APAs.

Pathologic Findings

- Solitary, well-demarcated mass with the typical mottled yellow color of adrenal cortex
- Without diffuse thickening of the zona glomerulosa or hyperplastic nodules
- May compress the nonneoplastic uninvolved adrenal gland

• Histopathology: Foamy lipid-laden clear cells, in sheets or nests

DIFFERENTIAL DIAGNOSIS

• Other causes of HTN. In Cushing disease, aldosterone and renin will both be low. In renal artery stenosis, there will be high renin and high aldosterone.
• Other causes of HTN and hypokalemia, such as:
  – Overingestion of licorice
  – Use of chewing tobacco
  – Hyperdeoxycorticosterones
• Other subtypes of primary hyperaldosteronism:
  – Bilateral adrenal hyperplasia: Idiopathic
  – GRA due to aldosterone-producing, renin-responsive adenoma. Familial hyperaldosteronism type I, autosomal dominant
  – Familial occurrence of APA or bilateral idiopathic hyperplasia or both
  – Adrenal cancer producing aldosterone: Extremely rare
• Liddle syndrome: Autosomal dominant disorder. Mimics hyperaldosteronism and involves problems with excess resorption of Na and loss of K.

TREATMENT

GENERAL MEASURES

• Treatment selected based on etiology of hyperaldosteronism
• Control HTN

MEDICATION

First Line (2)

• Mineralocorticoid receptor antagonist used in those with bilateral adrenal hyperplasia and unilateral hyperplasia or APA who are not surgical candidates:
  – Spironolactone: Limited due to affinity for androgen and progesterone receptors. Can cause gynecomastia, sexual dysfunction, menstrual irregularities
  – Eplerenone: No active metabolites, shorter half-life than spironolactone, 50–75% as potent as spironolactone but less adverse effects
• Thiazide diuretics, ACE inhibitors, calcium channel antagonists, angiotensin blockers

Second Line

Amiloride, an epithelial Na channel blocker and K-sparing diuretic, may also be used, especially if spironolactone or eplerenone are intolerable. More often used in conjunction with the above.

SURGERY/OTHER PROCEDURES

• Unilateral adrenalectomy is indicated in patients with hyperaldosteronism due to an adenoma.
• HTN is cured or improved significantly in up to 90% of such cases. Usually takes 3–6 mo to see an effect.
• Adequate control of BP (see “Medications”) for several weeks and correction of metabolic abnormalities should be done before surgery.
• Obtain PAC after surgery to confirm cure

- Monitor K closely postoperatively

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Emerging therapies include developing drugs that inhibit actions of aldosterone synthase enzyme, encoded on the CYP11B2 gene

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Patients with primary hyperaldosteronism have higher rates of prior stroke (12.9% vs. 3.4%) compared to those with essential HTN.
- Nonfatal MI (4% vs. 0.6%)
- Atrial fibrillation (7.3% vs. 0.6%)

COMPLICATIONS

- Related to HTN (left ventricular hypertrophy, coronary artery disease, heart failure, stroke, intracerebral hemorrhage, etc.)
- Related to low K (tetany, headache, arrhythmias, etc.)

FOLLOW-UP

Patient Monitoring

BP and serum electrolytes should be evaluated postoperatively and following medical therapy.

CODES

ICD9

- 255.10 Hyperaldosteronism, unspecified
- 255.12 Conn's syndrome
- 255.14 Other secondary aldosteronism

ICD10

- E26.01 Conn's syndrome
- E26.1 Secondary hyperaldosteronism
- E26.09 Other primary hyperaldosteronism

CLINICAL/SURGICAL PEARLS

- Hypertension (HTN) with serum K < 3 meq/L is highly suspicious of an aldosterone-producing adenoma (APA).
- Treatment selection is based on etiology of hyperaldosteronism.
- Surgical excision provides excellent control of hypertension in aldosterone-producing adenoma (APA).
- Control of the adrenal vein is the most important step during adrenalectomy.

HYPERPROLACTINEMIA, UROLOGIC CONSIDERATIONS

Mark W. Ball, MD
Arthur L. Burnett, II, MD, MBA, FACS

BASICS

DESCRIPTION

- Hyperprolactinemia (HPRL) refers to serum prolactin levels that exceed the normal range <25 mg/L (~ 500 mIU/L) in women and <20 mg/L (~ 400 mIU/L) in men.
- It is the most common endocrine abnormality due to hypothalamic–pituitary disorders.
- It may result in hypogonadism, erectile dysfunction, infertility, galactorrhea, and osteoporosis.
- Most common causes are pregnancy, medications, hypothyroidism, and prolactin-secreting pituitary tumors (prolactinomas)

EPIDEMIOLOGY

Incidence

- Peak incidence occurs in women of age 25–34, at 23.9/100,000/yr.
- Incidence data in men is lacking

Prevalence

- Lifetime prevalence of prolactinoma is 30/100,000 in woman and 10/100,000 in men.
- Pituitary microadenomas are found in 10.9% of autopsies, with 44% prolactinomas.
- In men with sexual dysfunction, $\sim 1\%$ have HPRL.
- 90% of prolactinomas occur in women of reproductive age.
- 40% of pituitary adenomas are prolactinomas

RISK FACTORS

- Female sex
- Pregnancy
- Prolactinomas
- Medications (antipsychotics, antidepressants, verapamil, opiates, GI motility drugs, estrogens)
- MEN-1 syndrome

Genetics

- Most prolactinomas are sporadic (1)
- Present in about 20% of adults with MEN-1, who have an autosomal dominant mutation in the MEN-1 tumor suppressor gene on chromosome 11
- Can rarely occur as part of familial isolated pituitary adenomas

PATHOPHYSIOLOGY

- Prolactin is produced in the anterior pituitary
- Secretion is pulsatile and increases with stress and sleep
- Tonically suppressed by dopamine via D2 receptors
  – Medications that inhibit dopamine secretion raise prolactin levels

- Elevated prolactin suppresses GnRH, with subsequent reductions in LHRH, FSH, and sex steroid levels.
  - Low testosterone can cause decreased libido, erectile dysfunction, infertility, and gynecomastia in men.
  - Low estrogen can cause oligomenorrhea, decreased libido, anovulation, and galactorrhea in women
  - Decreased bone mineral density can occur in both sexes secondary to low sex steroid levels.
- Prolactinomas: Pituitary microadenomas (<10 mm) and macroadenomas (>10 mm) can be seen in some patients as the cause of the elevated levels.
  - Macroadenomas can have mass effect symptoms, including headache and visual disturbance by optic nerve compression
- Rarely, chest wall injury can increase prolactin levels.
- Macroprolactinemia is caused by an abnormal binding of the molecule to circulating IgG.

ASSOCIATED CONDITIONS

- Amenorrhea and/or galactorrhea in women
- Hypogonadism and/or ED in men
- Hypothyroidism: Increased thyrotropin-releasing hormone can stimulate prolactin secretion.
- Renal failure can result in reduced clearance.
- Cirrhosis
- Herpes zoster (particularly involving the chest wall)

GENERAL PREVENTION

Discontinuation of medication causing symptomatic HPRL (asymptomatic prolactin elevations need not be treated)

DIAGNOSIS

HISTORY

- Women: Often presents early in disease course.
  - Infertility (including pregnancy history)
  - Amenorrhea/menstrual irregularities
  - Galactorrhea
- Men: Often presents late in disease course.
  - Complaints of sexual dysfunction
    - Decreased libido
    - Erectile dysfunction (ED)
  - Gynecomastia
- General
  - Headache
  - Visual field defects
- Psychiatric history and antipsychotic medication use
- Alcohol abuse
- Medication use:
  - Antipsychotics: Butyrophenones (eg, haloperidol), phenothiazines (eg, chlorpromazine),

thioxanthenes (eg, thiothixene), risperidone and others: Metoclopramide, sulpiride, pimozide, methyldopa, reserpine
  - Others reported: Antiandrogens, cimetidine, cyproheptadine, danazol, estrogens, INH, tricyclic antidepressants, opiates, verapamil

PHYSICAL EXAM
- Breast exam for gynecomastia, galactorrhea
- Evidence of chest wall trauma or herpetic lesions
- Signs of hypogonadism
- Signs of hypothyroidism
- Visual field abnormalities

DIAGNOSTIC TESTS & INTERPRETATION

Lab (2)
- A single serum measurement > upper limit of normal makes the diagnosis of HPRL
- Serum PRL >500 µg/L is diagnostic of a macroprolactinoma
- Women of reproductive age should have a pregnancy test.
- In men presenting with ED, a testosterone level should be checked. If low, further evaluation of prolactin should be performed.
- With medication-induced HPRL, prolactin levels are usually <50 mg/L and almost always <100 mg/L.
- After stopping suspected medication, prolactin levels usually return to normal within 4 days.

Imaging
- Pituitary MRI is the test of choice. Should be obtained in all cases where prolactin is persistently elevated and no cause is apparent.
- DEXA scanning to evaluate for possible bone mineral density problems
- In women, pelvic US to assess for uterine or ovarian pathology

Diagnostic Procedures/Surgery

Formal visual field assessment should be done in patients with macroadenomas.

Pathologic Findings

Prolactinoma: Glands composed of cuboidal cells. May be either eosinophilic or chromophobic.

DIFFERENTIAL DIAGNOSIS
- Hypothyroidism
- Lab error or macroprolactinemia (abnormal prolactin molecule)
- Medication-induced
- Nonprolactin-secreting pituitary or hypothalamic tumor
- Polycystic ovary syndrome (PCOS)
- Pregnancy
- Prolactinoma
- Renal failure

TREATMENT

ALERT
Do not treat women until pregnancy is excluded.

GENERAL MEASURES (3)

- Women of reproductive age should have a pregnancy test 1st.
- Treat underlying cause or stop offending drug if possible
- Asymptomatic HPRL secondary to medication use does not require treatment.

MEDICATION

First Line

- Cabergoline or bromocriptine (dopamine agonists):
  - Usually will lower prolactin levels, regardless of cause, and shrink prolactinomas
  - In general, both cabergoline and bromocriptine are effective. Cabergoline is usually better-tolerated, more convenient, and more effective than bromocriptine, whereas bromocriptine is less expensive and has been used longer.
  - Use dopamine agonists with caution in patients on psychotropic drugs that inhibit dopamine action.
    - Cabergoline dosing (0.5-mg tablets): Start with 0.25–0.5 mg once or twice weekly and increase the dose at monthly intervals until prolactin normalizes (>3 mg/wk is rarely needed).
    - Bromocriptine dosing (2.5-mg tablets): Start with 0.625 or 1.25 mg with food before bedtime and gradually increase at weekly intervals until prolactin level is controlled (usually 2.5 mg BID–TID).
  - Side effects include nausea and postural hypotension
- Pregnancy considerations
  - More experience with bromocriptine.
  - Neither bromocriptine nor cabergoline has been associated with teratogenicity.
  - Nevertheless, either drug is usually stopped at the 1st evidence of pregnancy, except in patients with macroadenomas in whom previous mass effects may recur if tumor enlarges.
  - Significant enlargement of microadenomas is uncommon during pregnancy.
  - Lactation: Dopamine agonists will inhibit lactation.

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Often performed transsphenoidally
- For microadenomas, generally reserved for patients intolerant of drug therapy. Tumors may recur.
- Only indicated for pituitary macroadenomas when medical therapy is ineffective, including persistent visual field abnormalities:
  - Usually not curative

ADDITIONAL TREATMENT

Radiation Therapy

Usually only indicated for pituitary macroadenomas that have failed medical therapy, and where response to surgery is inadequate or surgery is contraindicated.

Additional Therapies
Men with ED or persistent hypogonadism may require additional therapies.

Complementary & Alternative Therapies
Vitex agnus-castus extract can be tried in cases of mild HPRL

ONGOING CARE

PROGNOSIS
- 90–95% of prolactin-secreting pituitary microadenomas will not grow further, even without medical therapy.
- Medical therapy is usually successful in normalizing prolactin levels, normalizing menses, reducing or stopping galactorrhea, inducing ovulation, and shrinking pituitary tumors.
- >90% of microadenomas do not grow significantly during pregnancy, even after medical therapy is stopped.
- Some microadenomas disappear with time (especially after menopause) or do not recur after medical therapy.
- Pituitary macroadenomas usually do not disappear completely with medical therapy and require continuous medical therapy.

COMPLICATIONS
- Dopamine agonists can worsen underlying psychiatric problems in patients taking psychotropic medications.
- Pituitary macroadenomas can secrete other hormones or become resistant to medical therapy.

FOLLOW-UP
Patient Monitoring
- Drug-induced HPRL:
  - Prolactin should normalize after switching medications and no further follow-up is needed.
- Microadenomas:
  - Some microadenomas resolve spontaneously.
  - Measure prolactin every 6–12 mo to ensure continued drug efficacy.
  - No need for repeat pituitary MRI unless prolactin increases markedly on therapy.
  - Consider stopping dopamine agonist after at least a year of successful therapy; some microadenomas do not recur
- Macroadenomas:
  - If prolactin normalizes, repeat pituitary MRI after 3–6 mo to ensure tumor shrinkage and establish new baseline.
  - No consensus on frequency of further MRIs in patients whose prolactin is well-controlled medically.
  - Repeat prolactin measurements every 3–6 mo.
  - Follow visual fields in patients who have visual field defects at baseline.
  - Some macroadenomas resolve spontaneously.

- 256.39 Other ovarian failure
- 257.2 Other testicular hypofunction

ICD10

- E22.1 Hyperprolactinemia
- E28.39 Other primary ovarian failure
- E29.1 Testicular hypofunction

CLINICAL/SURGICAL PEARLS

- Women present early in the disease course, while men present late.
- Dopamine agonists are the 1st-line treatment of prolactinomas.
- Surgical excision is reserved for refractory cases.
- All women should be screened for pregnancy before initiating treatment.

HYPOSPADIAS

Steve J. Hodges, MD
Anthony Atala, MD

BASICS

DESCRIPTION

- Common congenital disorder of male external genitalia characterized by a ventrally displaced urethral meatus
  - Associated conditions may include:
    - Ventral chordee
    - Incomplete foreskin with dorsal hood and ventral deficiency
  - May be an isolated defect or may be associated with a significant underlying abnormality
  - Classification:
    - Anterior (distal) 50%: Glandular, coronal, subcoronal, megameatus intact prepuce
    - Middle (midshaft) 30%
    - Posterior (proximal) 20%: Penoscrotal, scrotal, perineal

EPIDEMIOLOGY

Incidence

- 1 in 250–300 live male births
- 1 in 80–100 in family history of hypospadias

Prevalence

Prevalence in US for hypospadias ranges between 2.01 and 56.17 per 10,000

RISK FACTORS

- 5× incidence in IVF births compared to controls
- Environmental:
  - Because of increases in rates in certain areas an association with chemicals with estrogenic or antiandrogenic effects has been suggested
  - Examples include environmental chemicals such as bisphenol A (BPA) and hormones used during pregnancy such as progesterone.
  - Genetics (see below)

Genetics

- <5% of cases have genetic cause (2)
- Can be seen in isolated and syndromic genetic abnormalities
- Caused by mutations of genes controlling development of male gonads or penis (eg, homeobox, FGF, and Sonic hedgehog genes)
- 5α-reductase mutations
- Familial propensity
  - 10% have affected 1st–3rd degree relative
  - 14% of male siblings affected
  - 27% concordance in monozygotic twins

PATHOPHYSIOLOGY

- Normal penile development:
  - Urogenital folds form on either side of the cloacal membrane, and fuse anteriorly at the genital tubercle
  - Lateral labioscrotal folds fuse posteriorly and separate the urogenital and anal membranes
  - Under influence of testosterone and DHT, phallus elongates and the genital folds fuse in the midline to enclose urethral proximally to distally
  - Canalization of the glans occurs distally, fusing with urethra
  - Process complete by 20th wk of gestation
- Glandular hypospadias likely represents failure of distal canalization
- Proximal hypospadias due to failure of fusion of genital folds
- Scrotal or perineal variants result in cleft scrotum

ASSOCIATED CONDITIONS

- Growth restriction (low birth weight and length, small head circumference) has been associated with hypospadias
- Associated anomalies are more common in cases of severe hypospadias
  - Cryptorchidism (7–9%)
  - Inguinal hernia/hydrocele (9–16%)
  - Syndromes:
    - 49 described in which hypospadias is frequent or occasional (Aniridia-Wilms tumor association, Beckwith–Wiedemann, Smith–Lemli–Opitz, Trisomy syndromes [4p, 9p, 13, 18], VACTERL association, XXY, Zellweger, and many others)
    - 78% of these have associated micropenis, cryptorchidism, and/or scrotal anomaly
    - In presence of hypospadias and cryptorchidism must rule out intersex condition (15% with palpable undescended testicle, 50% with nonpalpable)
- 2–12% have upper tract anomalies (horseshoe kidney, renal ectopia, duplicated ureters, others)
- Enlarged prostatic utricle can be associated with severe cases and may increase risk of UTI or prostatic utricle stone formation

GENERAL PREVENTION

Not possible except by avoidance of environmental agents or medications with estrogenic effects by pregnant women (see “Risk Factors”)

DIAGNOSIS

HISTORY

- Family history of hypospadias
  - Any associated congenital anomalies
    - Exposure of mother to hormonally active agents during pregnancy
- IVF may increase risk of hypospadias

PHYSICAL EXAM

- Determine location of urethral opening
- Evaluate for chordee
- Evaluate foreskin

- Evaluate presence of inguinal hernia, hydrocele, or cryptorchidism
- Severely proximal hypospadias may be associated with bifid scrotum and/or penoscrotal transposition
  – Look for other congenital anomalies

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Karyotype and hormonal evaluation to rule out intersex is needed in cases of severe hypospadias and cryptorchidism

Imaging

- No routine imaging necessary for routine hypospadias evaluation
  – In setting of intersex evaluation, genitogram or pelvic US may be performed
  – VCUG in proximal hypospadias may demonstrate prominent prostatic utricle

Diagnostic Procedures/Surgery

N/A

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- In cases of proximal hypospadias associated with an undescended testicle differential should include:
- Congenital adrenal hyperplasia
- Mixed gonadal dysgenesis
- Partial androgen insensitivity
- True hermaphroditism

ALERT

Do not perform circumcision in the setting of hypospadias. Hypospadias in the presence of cryptorchidism may signal an intersex disorder.

TREATMENT

GENERAL MEASURES (3)

The general tenets of repair are to move the urethral meatus to an orthotopic location, straighten the penis (repair chordee), and either remove or modify the foreskin to give the appearance or a normal circumcised or uncircumcised penis

MEDICATION

First Line

- There is no specific medical therapy for hypospadias
  – Preoperative hormonal therapy (testosterone injections or creams, or HCG injections) may be used to enlarge penile size to aid in repair in cases of small phallus (4)
  – However, although a preference for the use of preoperative hormonal therapy is observed in the literature, the exact protocol and benefit is not conclusively determined
  – 25–50 mg of testosterone propionate given IM weekly for 3 wk preoperatively is one such approach

SURGERY/OTHER PROCEDURES

- Indications of repair (1):
  - Goals are to create a cosmetically normal appearing penis with orthotopic meatus, and straight phallus so the child can in the future void while standing, have sexual intercourse, and effectively inseminate.
  - Timing of repair is ideal at 4–6 mo of age, surgeries should be complete by 2 yr (the age of genital awareness)
  - Techniques dictated by meatal location, degree of chordee, and skin availability
  - Chordee should be repaired 1st (orthoplasty)
  - Distal hypospadias: MAGPI, Thiersch–Duplay, tubularized incised plate urethroplasty, Mathieu (perimeatal-based flap)
  - Midshaft hypospadias: Tubularized incised plate urethroplasty, Mathieu, onlay island flap
  - Proximal hypospadias: 1 stage—Thiersch–Duplay, incised plate urethroplasty, onlay island flap; 2 stage—1st stage repair chordee, second stage 6 mo after 1st (Thiersch–Duplay, incised plate urethroplasty)
    - In cases of lack of skin may use buccal mucosal graft
    - Hypospadias revision: Meatoplasty, fistula repair

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Patient may need revisions for chordee, meatal issues, or recurrent chordee at later dates

Complementary & Alternative Therapies

Psychosocial support for patient and family if needed long term

ONGOING CARE

PROGNOSIS

Most patients have normal penile function for voiding, sexual performance, and insemination

COMPLICATIONS

- Early:
  - Bleeding/hematoma—treated with compression or surgical exploration; infection—treated with antibiotics or incision and drainage;
  - UTI—treated with appropriate antibiotics;
  - Wound dehiscence—requires reoperation 6 mo later
- Late:
  - Residual/recurrent chordee—treated with reoperation,
  - Meatal stenosis—treated with meatal dilation or meatoplasty
  - Urethral stricture—treated with dilation or urethroplasty;
  - Urethrocutaneous fistula or urethral diverticulum—treated with excision and repair;
  - Hair in urethral repair—treated with endoscopic laser or cauter or excision and repair;
  - Lichen sclerosis or balanitis xerotica obliterans—treated with complete excision and buccal graft

FOLLOW-UP

Patient Monitoring

- Follow-up for observation of penile development and complications noted above
  - Children may present after toilet training or even as late as adolescence with newly diagnosed complications from repair as an infant

Patient Resources

Urology Care Foundation http://www.urologyhealth.org/urology/index.cfm?article=130

- Hypospadias Image ☼
- Penoscrotal Transposition

CODES

ICD9

- 752.61 Hypospadias
- 752.63 Congenital chordee
- 752.69 Other penile anomalies

ICD10

- Q54.0 Hypospadias, balanic
- Q54.1 Hypospadias, penile
- Q54.9 Hypospadias, unspecified

CLINICAL/SURGICAL PEARLS

- More severe cases (proximal) more likely to be associated with an intersex disorder.
- All members of the health care team must clearly understand that circumcision should not be performed if hypospadias is present.

IMMUNOCOMPROMISED PATIENTS, UROLOGIC CONSIDERATIONS

Nathan Roberts, MD
Patrick J. Shenot, MD, FACS

BASICS

DESCRIPTION

- Immunocompromised patients have attenuated immune responses caused by:
  - Immunosuppressive drugs (chemotherapy)
  - Radiation (bone marrow irradiation)
  - Hematopoietic stem cell transplant
  - Malnutrition
  - Disease processes (HIV, lymphoma, congenital immune deficiencies, autoimmune disorders)
- Immunocompromised patients are at risk for opportunistic infections
- Hematopoietic stem cell transplant
  - Need preparative regimens to prevent rejection of transplanted graft: Complete myeloablative, Nonmyeloablative or +/– chemotherapy
- Miliary tuberculosis
  - Hematogenous dissemination of Mycobacterium tuberculosis
  - HIV coinfection is common; 38% with military TB patients also have HIV

EPIDEMIOLOGY

Incidence

- HIV infections
  - 2.7 million new HIV infections worldwide
- Tuberculosis
  - 11,182 reported cases in US in 2010
  - 22% of cases were extrapulmonary
  - 2.7% were miliary TB

Prevalence

HIV/AIDS: 1.2 million Americans

RISK FACTORS

- Hemorrhagic cystitis (HC) (1)
  - Increased degree of immunosuppression
    - BK virus Hemorrhagic cystitis (HC)
  - Early onset Hemorrhagic cystitis (HC)
    - Conditioning regimen used for Hematopoetic stem cell transplant (HSCT) with cyclophosphamide, busulfan, or with antithymocyte globulin (4)
    - Donor–recipient gender mismatch
  - Late onset Hemorrhagic cystitis (HC)

- Allogenic HSCT transplant
- Graft versus host disease (GVHD)
  - Use of corticosteroids or cyclosporine for GVHD
- Use of T-cell depleted grafts
- Need for blood transfusions

- HIV/AIDS
  - Unprotected high-risk sexual contact
  - Blood transfusion
  - Uncircumcised Men
  - Occupational exposure
- Tuberculosis
  - HIV infections: 14% of TB patients have HIV

PATHOPHYSIOLOGY

- Cyclophosphamide/busulfan
  - Metabolized in the liver to acrolein
    - toxic to urothelium; prolonged exposure in the bladder causes increased inflammatory mediators: Bladder mucosal edema, vascular dilation, and increased capillary fragility
    - Long-term increased bladder cancer risk
- Polyoma virus–related hematuria (see Polyoma virus [BK, JC]), urologic considerations
- HIV/AIDS
  - Virus targets CD4+ T cells
    - Virus targets CCR5 expressing CD4+ cells; with decreased CD4 lymphocyte count. Mucosal tissues preferentially targeted, leads to immunosuppression
- TB genitourinary involvement
  - Hematogenous spread → renal capillaries → renal cortex → immune response → chronic inflammation → granuloma with central caseous necrosis → inflammation into renal tubules and medulla → renal papilla sloughing → calyceal ulceration → fibrosis from healing → calyceal infundibular narrowing or UPJ scarring → hydronephrosis
  - Tubercles can also form in distal ureter leading to stricture

ASSOCIATED CONDITIONS

- HIV/AIDS; indinavir calculus
- TB
- Any cause requiring bone marrow transplant
- Urethritis: Reiter syndrome, arthritis

GENERAL PREVENTION

- HIV/AIDS: Protection during sexual activity; universal precautions for healthcare professionals
- Miliary tuberculosis: Treatment of latent TB can prevent miliary TB

DIAGNOSIS

HISTORY

- HC

  - Ranging from pink urine to clot retention
  - Can also have bladder pain and or lower urinary tract symptoms (LUTS)
- HIV/AIDS (2)
  - Increased risk of transmission and acquisition of sexually transmitted infections
    - Atypical and prolonged course; genital lesions do not respond to normal treatments
    - Can present with symptomatic genitourinary tract infections
    - Testicular pain: Epididymitis/orchitis are common findings
    - Can be positive for LUTS with prostatitis
    - Cystitis: Increased risk of bladder infections
    - Urolithiasis: Can present with typical complaints of ureteral calculus (flank pain, nausea, vomiting, dysuria, increased frequency, urgency)
    - Can present with voiding dysfunction
    - Commonly present with urinary retention
    - Detrusor hyperreflexia, LUTS for bladder outlet syndrome
- Miliary tuberculosis
  - Failure to thrive, fever of unknown origin and night sweats, anorexia, weight loss
    - Subacute or chronic presentation more common; can have dysfunction of one or more organ system
    - 50% have pulmonary disease with dyspnea or cough
  - Genitourinary involvement
    - Hematuria; small percentage may be passing material in urine (caseous material)
    - Flank pain, symptoms of cystitis, LUTS (storage symptoms), scrotal pain, male infertility workup; hematospermia

PHYSICAL EXAM

- HC
  - May present with palpable bladder if in clot retention
- HIV/AIDS
  - Most common intrascrotal pathology in AIDS is testicular atrophy
    - Secondary to endocrine imbalances, febrile episodes, malnutrition, testicular infections, and toxic effects of therapeutic agents
  - Prostatitis
    - Boggy prostate
  - Scrotal swelling/testicular pain
    - Epididymitis/orchitis caused by common and uncommon organisms (Candida, CMV, toxoplasmosis)
  - Voiding dysfunction
    - May have enlarged prostate
- Miliary tuberculosis
  - Pulmonary: Course breath sounds on auscultation, may have lymphadenopathy
  - Genitourinary involvement
    - Possible costovertebral angle tenderness
    - Epididymal/prostate tenderness

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- HIV/AIDS
  - HIV ELISA for anti-HIV-1 and 2
    - >99% sensitivity; Western blot to exclude false-positive but also to confirm HIV diagnosis
  - Plasma HIV RNA
    - Detectable by day 12; antibodies detected day 21
    - Used to assess treatment response/failure HIV-associated nephropathy: Proteinuria-increased creatinine
- Tuberculosis
  - PPD; may be false negative
  - Mycobacterial blood cultures
    - Urinalysis: Sterile pyuria, possible hematuria
    - Urine acid fast bacilli (AFB) culture

Imaging

- HC
  - CT with and without contrast: Can show clot, filling defect, calculus
- HIV/AIDS
  - Urolithiasis
    - CT non contrast may be associated with minimal findings with indinavir calculus
  - Kidney infection
    - CT scan: Can see striated nephrogram in pyelonephritis, abscess
- Tuberculosis
  - Chest radiograph (miliary disease)
    - Faint, reticulonodular infiltrate distributed fairly uniformly throughout the lungs
  - GU findings: Disparity in renal size. Larger may indicate caseous lesions or shrunken and fibrotic from autonephrectomy
    - Autonephrectomy: Diffuse, uniform, extensive parenchymal, putty-like calcification, a lobar cast of the kidney
    - Calcifications in 30–50% of cases (seen in caseating lesions)
    - Calculi may also be seen in the collecting system or ureter secondary to stricture formation
    - Ureteral calcifications are rare and are characteristically intraluminal
    - Bladder wall calcifications are not very common except in late cases of bladder contraction
    - Calcifications of the prostate and seminal vesicles are seen in 10% of cases
  - Contrast-enhanced computed tomography
    - Renal parenchymal masses and scarring
    - Thick urinary tract walls
    - Tuberculoma: Renal mass coalescing caseating granulomas
    - Can see hydronephrosis
    - Sensitive in seeing the calcifications
    - Contrast can evaluate function of the kidney
  - Ultrasound: Limited in diagnosis, Can be used for monitoring disease progression

Diagnostic Procedures/Surgery

- HC
  - Cystoscopy, possible ureteroscopy
- HIV/AIDS
  - Kidney biopsy: Help to diagnose HIV-associated nephropathy (HIVAN)
  - Voiding dysfunction
    - May warrant UDS, may uncover neurogenic voiding dysfunction
    - Post-void residuals, cystoscopy
- Tuberculosis
  - Biopsy of the following can demonstrate granulomas and be used for culture: lung, bone marrow, lymph nodes, bones, joints, liver, brain, and other tissues
  - Cystoscopy/retrograde pyelograms
    - Limited in diagnosis: Stricture, acute UO inflammation, acute tuberculous ulcer. Golf hole ureter: Circular and often excessively lateral ureteral orifice

Pathologic Findings

- Tuberculosis
  - Granulomatous inflammation
    - Contain epithelioid macrophages, Langhans giant cells, and lymphocytes
    - Contain caseation necrosis
    - Organisms may or may not be seen with acid fast staining
- HIV
  - HIV-associated nephropathy (HIVAN)
    - Collapsing form of focal segmental glomerulosclerosis
    - Dilated tubules and interstitial inflammation

DIFFERENTIAL DIAGNOSIS

- HC
  - Infectious source
    - Bacterial
    - Viral BK vs. adenovirus, CMV, JC, and herpes
- HIV
  - Voiding dysfunction
    - Patient may have underlying neurologic opportunistic infection

TREATMENT

GENERAL MEASURES

- Reduction of immunosuppression (if possible) can help to reduce clinical sequelae
- HIV patients have higher risk of bladder infections than non-HIV patients
  - Associated with typical uropathogens
  - Salmonella is of particular concern due to high-risk fatal recurrence (may need chronic suppression)

MEDICATION

First Line

- HC

- Increased hydration
- Catheter placement with clot evacuation
- Continuous bladder irrigation (CBI)

• HIV/AIDS
- Antiretroviral therapy (ART)

• Miliary TB (3)
- Standard pulmonary therapy
- Often directly observed therapy
- Isoniazid (INH), rifamycin (rifampin), pyrazinamide, and ethambutol for 2 mo
- Isoniazid and rifamycin for additional 4 mo

Second Line

• HC
- Conjugated estrogens
  - Act by stabilization of microvasculature
  - Oral vs. intravenous administration
- Intravesical instillation of Alum
  - An astringent precipitates protein over bleeding surface
  - 1% Alum solution in continuous bladdder irrigation (CBI)
  - Can be used in presence of vesico ureteral reflux (VUR)
- Intravesical instillation of silver nitrate
  - Chemical coagulation and eschar at bleeding sites
  - 0.5–1% instilled for 10–20 min
  - VUR may lead to renal failure due to precipitation and obstruction of upper tracts
- E-aminocaproic acid
  - Inhibits fibrinolysis preventing activation of plasminogen to plasmin
  - Given orally, parenterally, or intravesically
  - Patients can form hard clots that are difficult to flush from the bladder
- Intravesical instillation of prostaglandin
  - PGE2: May encourage platelet aggregation and induce vasoconstriction
  - PGE2: 0.75 mg in 200 mL of normal saline and left indwelling
  - May cause bladder spasms
- Intravesical instillation of formalin (40% formaldehyde)
  - Hydrolyzes proteins and coagulates tissue on superficial level
  - Painful and needs to be done with general anesthesia
  - Should not be done with VUR. Can fibrose the ureters, cause obstruction, hydronephrosis and also papillary necrosis
  - Can result in small contracted bladder

• HIV/AIDS
- Urinary tract infection (UTI)
  - Can treat with prolonged 7–10-day course of antibiotics
  - If patients do not respond to empiric antibiotics attention should be turned and patients screened for atypical and opportunistic infections (ie, fungi, parasites, TB, and viruses)
- Prostatitis/Epididymitis/Orchitis
  - Should be treated with antibiotics

- Opportunistic infections should be suspected if not resolving
- Voiding dysfunction
  - Individualized for the patient
  - Males: α-blockers possibly 5α-reductase inhibitors
  - Irritative symptoms: Anticholinergics if low PVR's

Surgery

- HIV/AIDS
  - Kidney infection abscess (Aspergillus and toxoplasma)
    - Percutaneous or open drainage
    - Nephrectomy
  - Prostatic abscess
    - Percutaneous (transperineal vs. transrectal aspiration)
    - Transurethral unroofing (TUR)
  - Testicular and epididymal infections
    - If intractable pain may warrant epididymectomy or orchiectomy
- Tuberculosis
  - Often will proceed 3–6 wk after medications
    - Abscess drainage
    - Ureteral stenting for strictures (41% successful)
    - PCN: TB fistula can form
    - Nephrectomy: If kidney is nonfunctioning, there is extensive disease involving the whole kidney, coexisting renal carcinoma
    - Partial nephrectomy
    - Epididymectomy: Caseating abscess that has not responded to medical therapy or firm swelling that has remained unchanged or increased in size with medial therapy
    - Augmentation cystoplasty (<100 cc capacity) vs. orthotopic bladder substitution (20 cc capacity)

SURGERY/OTHER PROCEDURES

- HC
  - Hyperbaric oxygen therapy
    - 100% oxygen in a hyperbaric chamber at 2.5 atmospheres absolute for 90 min 5 days a week.
  - Cystectomy if refractory life-threatening cases
  - Selective embolization
    - Vesical or internal iliac artery

ADDITIONAL TREATMENT

Additional Therapies

- Oxazaphosphorine (cyclophosphamide)-induced HC
  - Mesna
    - Binds to acrolein and inactivates it
  - Supra hydration
  - Prophylactic Continuous bladder irrigation (CBI)
    - Often occurs within 72 hr

ONGOING CARE

PROGNOSIS

- HIV/AIDS
  - Greatly improved in the era of HAART therapy
  - Cancer
    - Penile: 8-fold higher incidence
    - Testicular cancer: 2-fold increase in seminoma
- Miliary tuberculosis
  - Greatly improved with the introduction of antibiotics
  - Mortality previously 100% (preantibiotics) now 20%

COMPLICATIONS

- Increased risk for malignancy in immunosuppressed patients
- HIV/AIDS
  - 3.5% of HIV-infected patients will experience HIV-associated nephropathy
    - Caucasian patients 12:1 risk
    - Intravenous drug use and men who have sex with men association
- Tuberculosis
  - Percutanous nephrostomy (PCN)
    - Tuberculosis fistula formation
  - Ureteral stenting
    - Limit high-pressure contrast injection during retrograde pyelogram may disseminate infection

FOLLOW-UP

Patient Monitoring

- Hemorrhagic cystitis (HC)
  - Cyclophosphamide
    - 9-fold increase in urothelial carcinoma
    - 10-yr latency period

CODES

ICD9

- 279.9 Unspecified disorder of immune mechanism
- 279.49 Autoimmune disease, not elsewhere classified
- 279.50 Graft-versus-host disease, unspecified

ICD10

- D89.9 Disorder involving the immune mechanism, unspecified
- D89.813 Graft-versus-host disease, unspecified
- M35.9 Systemic involvement of connective tissue, unspecified

CLINICAL/SURGICAL PEARLS

- Recurrent UTI in the absence of infections in other organ systems, is not a typical presentation of an immunocompromised patient.
- Most common intrascrotal pathology in AIDS is testicular atrophy.

INCONTINENCE, URINARY, ADULT FEMALE

Debra L. Fromer, MD
Drew A. Freilich, MD

BASICS

DESCRIPTION

- Incontinence is broadly defined as the loss of urine that is objectively demonstrable and is of social and hygienic concern
- Stress urinary incontinence (SUI): Involuntary loss of urine on effort of physical exertion
- Urgency incontinence (UI): Involuntary loss of urine associated with urgency
- Mixed incontinence (MI): Lost of urine associated with urgency and also with effort
- Overflow incontinence (OI): High residual or chronic urinary retention leads to urinary spillage from bladder overdistention
- Functional incontinence: Loss of urine due to deficits of cognition and mobility
- Coital incontinence: leakage urine during intercourse
- Continuous incontinence: Continuous involuntary loss of urine

EPIDEMIOLOGY

Incidence

N/A

Prevalence

- Affects 30–50% of adult women
- Stress urinary incontinence is the most common (49%), followed by mixed (29%) and urge (21%) incontinence

RISK FACTORS

- Advanced age
- Cognitive impairment
- COPD
- Menopause
- Obesity
- Pelvic organ prolapse
- Pelvic surgery or radiation
- Pregnancy
- Smoking
- Vaginal childbirth

Genetics

Evolving data to support genetic predisposition

PATHOPHYSIOLOGY

- Stress incontinence: Occurs with increased intra-abdominal pressure without detrusor contraction. 2 types:
  – Anatomic: Due to urethral hypermobility from lack of pelvic support

- Hammock theory: Normally, the suburethral support contributed by the endopelvic fascia and anterior vaginal wall provides a stable backboard against which the urethra is compressed while intra-abdominal pressure rises. When this suburethral support layer is lax and mobile, any effective compression is not achieved, causing leakage
  - Intrinsic sphincter deficiency (ISD): Impairment of urethral mucosal seal and inherent closure from collagen, fibroelastic tissue, smooth and striated muscles. May be lost secondary to surgical scarring, radiation, or hormonal and senile changes
- Urge incontinence: Detrusor overactivity (may be secondary to detrusor myopathy or neuropathy)
- OI: Urinary retention (usually from lower motor paralytic neurogenic bladder in women)
- Total incontinence: Constant loss of urine. Ectopic ureters in females usually open in the urethra distal to the sphincter or in the vagina, causing continuous leakage
  - Suspect fistula if pneumaturia or fecaluria in history of radiation
- Coital incontinence: Up to 60% of women who report incontinence appear to leak urine during intercourse

ASSOCIATED CONDITIONS

- Pelvic organ prolapse
- Diabetes
- Neurologic disease (ie, multiple sclerosis, Parkinson)

GENERAL PREVENTION

- Weight loss
- Optimization of medical health (ie, diabetes)
- Smoking cessation

DIAGNOSIS

HISTORY

- Parity: Weakness of the pelvic floor is more likely in multiparous women leading to SUI
- Amount and frequency of leakage
- Continuous slow leakage in between regular voiding indicates ectopic ureter, urinary fistula, etc.
- Pain: Suprapubic pain with dysuria implies urinary infection, interstitial cystitis, etc.
- Medical history:
  - Cerebrovascular accidents, Parkinsons disease, multiple sclerosis, myelodysplasia, diabetes, spinal cord injury
  - Radiation to pelvic and vaginal areas: Causes ISD, urgency, and low bladder compliance
- Medications
- Surgical history: Pelvic and vaginal surgeries can weaken the pelvic floor support

PHYSICAL EXAM

- General neurologic exam:
  - Mental status, speech, intellectual performance
  - Motor status: Gait, generalized or focal weakness, rigidity, tremor
  - Sensory status: Impairment of perineal-sacral area sensation helps localize the level of neurologic deficit

  - Reflex: A bulbocavernous reflex implies contraction of the anal sphincter in response to squeezing the clitoris. This reflex tests the integrity of S2–S4 spinal cord segments
- Urologic exam:
  - Abdomen: Scars of previous surgeries
  - Suprapubic tenderness: May indicate cystitis
  - Palpable bladder: Chronic urinary retention
- Pelvic exam:
  - The patient is asked to cough or strain to reproduce incontinence or demonstrate urethral hypermobility (Q-tip test positive if >30 degrees)
  - Assess for atrophic vaginitis
  - Examine vaginal for cystocele, enterocele, rectocele, or uterine descensus

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine analysis
- Urine culture: Assess for infection

Imaging

- CT urogram: Determines status of upper urinary tract, duplicated systems for ectopic ureters, and associated pathologies (indicated only when upper tract issues are suspected)
- Voiding cystourethrogram: Preferably done in combination with videourodynamic studies

Diagnostic Procedures/Surgery

- 24-hr voiding diary to assess frequency, timing, volume of symptoms
- Cystoscopy: If concern for fistula or malignancy
- Urine cytology: If hematuria and urgency (concern for carcinoma in situ)
- Urodynamic studies:
  - Filling cystometry: Pressure/volume relationship during bladder filling
    - Assess 1st sensation, desire to void, strong desire to void, capacity, detrusor overactivity
    - Assess Valsalva leak point pressure: Determines the intra-abdominal pressure at which leakage is observed at the meatus or by fluoroscopy; low leak point pressure (<60 mm H_2O) implies ISD
    - Assess detrusor leak point pressure: Lowest detrusor pressure at which leakage of urine occurs in absence of detrusor contraction and increase abdominal pressure (>40 cm H_2O risk or renal deterioration)
  - Voiding cystometry: Pressure/volume relationship during micturition
    - Assess urinary flow rate, postvoid residual, detrusor sphincter synergy
  - Videourodynamic studies: Combination of fluorocystourethrography and urodynamic studies mentioned above
    - Most useful in patients at risk for neurogenic bladder to assess for detrusor sphincter dyssynergia which is risk for renal deterioration

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Stress incontinence: Due to urethral hypermobility or ISD, although in the majority it is

mixed or due to both of the factors
- Urgency incontinence: Can be due to urinary infection, interstitial cystitis, carcinoma in situ, bladder calculi, detrusor overactivity, or neurogenic detrusor overactivity. Most often idiopathic
- Nocturnal enuresis: Idiopathic, neurogenic, cardiogenic, or obstructive causes
- Continuous leakage: Ectopic ureter, urinary fistulas, exstrophy–epispadias complex
- Postvoid dribbling: Urethral diverticulum, idiopathic or iatrogenic
- Mobility or cognitive impairment post stroke
- Coital or mixed incontinence

TREATMENT

GENERAL MEASURES (1)
- Nonsurgical management (helps ~50–65% patients with milder symptoms)
- Treat correctable causes (Atrophic vaginitis, constipation, UTI, fistula, etc.)
- Encourage weight loss in obese patients
- Biofeedback and pelvic floor exercises (Kegel exercise) (3)
- Behavioral therapy: Voiding at progressively increasing predetermined intervals

MEDICATION
First Line (2)
- Stress incontinence: Activation of α-adrenergic receptors in the internal urethral sphincter increases the urethral resistance to urinary flow with sympathomimetic drugs, estrogen, and tricyclic agents (not used commonly due to side effects and interaction concerns and potential-limited efficacy)
- Urge incontinence: Anticholinergic, antispasmodic, and tricyclic antidepressant medications have been used to treat overactive bladder symptoms
  - Mirabegron is a 1st in class β_3-agonist for treatment of urge incontinence. When compared to anticholinergic medications much less dry mouth and constipation, but risk of hypertension
    - Mirabegron (25–50 mg/d)

Second Line
Other antichlonergic agents oxybutynin, ect.

SURGERY/OTHER PROCEDURES
- Stress urinary incontinence
  - Vaginal pessary
  - Surgical management: Provides more successful and sustained outcome (5)
    - Periurethral injection of bulking agents: Calcium hydroxylapatite/sodium carboxymethylcellulose and hyaluronic acid
    - Pubovaginal sling suspension: Used for coaptation and compression of the incontinent urethra, using autologous fascia or xenograft or allograft materials
    - Midurethral sling: Controversial as to if retropubic (TVT) or transobturator (TOT) better for urethral hypermobility and ISD patients
      - Postoperative de novo urgency, urge incontinence, voiding difficulty, and urinary

retention, necessitating intermittent self-catheterization or take-down of the suspension, remain as concerns in up to ~20% of patients
  - Artificial urinary sphincter (not FDA approved for female incontinence)
- Refractory overactive bladder (failed 1st- and 2nd-line therapies including anticholinergics):
  - Sacral neuromodulation: Efficacy ~50% of patients who have failed other treatments
  - Percutaneous tibial nerve stimulation
  - Intravesical botulinum toxin for neurogenic detrusor overactivity or refractory UI
    - Efficacy: Up to ~75% improved/cured in those refractory to other medical treatment
    - Side effects: UTI (~25%), Urinary retention (~10%) (patients must be counseled about possible need for postoperative intermittent catheterization)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Reduction or avoidance of spicy foods, citrus, or chocolate; limiting excessive fluid intake and caffeine can improve symptoms of urinary incontinence (especially if overactive bladder)

Complementary & Alternative Therapies

No high-level data to support

ONGOING CARE

PROGNOSIS

Excellent prognosis for many patients with awareness of this condition, combined with advances in diagnosis and management to minimize associated morbidity of this condition.

COMPLICATIONS

- Prolonged exposure to urine causes skin breakdown and dermatitis, which may lead to ulceration and secondary infection (4)
- Catheter-related complications can result from long-term indwelling catheters, such as recurrent UTIs, skin infections, and urethral erosion

FOLLOW-UP

Patient Monitoring

- Initial postoperative assessment after midurethral sling: Evaluate voiding function with estimation of postvoid residual and need for intermittent catheterization
- Periodic long-term follow-up with validated outcome-based questionnaire surveys

Patient Resources

National Kidney and Urologic Diseases Information Clearinghouse (NKUDIC)

CODES

ICD9

• 625.6 Stress incontinence, female
• 788.30 Urinary incontinence, unspecified
• 788.31 Urge incontinence

ICD10

• N39.3 Stress incontinence (female) (male)
• N39.41 Urge incontinence
• R32 Unspecified urinary incontinence

CLINICAL/SURGICAL PEARLS

• Recent FDA Alerts regarding vaginal mesh applies to prolapse repair and not midurethral sling. Mesh for stress incontinence has been supported in multiple randomized controlled trials.

- Consider reduction of pelvic organ prolapse as part of evaluation for incontinence.
- Consider referral to neurologist in young patients with refractory idiopathic overactive bladder as 1st presenting symptom of multiple sclerosis is isolated urinary urgency in ~15%.

INCONTINENCE, URINARY, ADULT MALE

Michael J. Amirian, MD
Patrick J. Shenot, MD, FACS

BASICS

DESCRIPTION

Defined by International Continence Society, urinary incontinence is the involuntary loss of urine that presents a social or hygienic problem

EPIDEMIOLOGY

Incidence

No published reports on incidence

Prevalence

- 3–11% overall prevalence rate of incontinence in male population
- NOBLE study
  - Urge incontinence
    - 2.6% American men of all ages
  - After age 64, prevalence rose sharply
    - ~10% in men ≥75 (1)
  - Reaches 31% in men ≥85 (2)
- Stress incontinence in men is rare
  - Unless attributable to prostate surgery, neurologic disease, or trauma
- Incontinence after prostatectomy ranges from 1% after transurethral resection to 2–57% after radical prostatectomy
- Incontinence in male of all ages is ~1/2 as prevalent as it is in women

RISK FACTORS

- Age
- Neurologic disease
- Prostate surgery
- Pelvic trauma

Genetics

N/A

PATHOPHYSIOLOGY

- Incontinence secondary to bladder abnormalities
  - Detrusor overactivity results in urge urinary incontinence (UUI)
    - Associated with bladder outlet obstruction from benign prostatic hyperplasia (BPH)
- Incontinence secondary to outlet abnormalities
  - Sphincteric damage
    - Secondary to pelvic surgery or radiation
  - Sphincteric dysfunction
    - Secondary to neurologic disease

- Mixed incontinence is due to abnormalities of both bladder and the outlet

ASSOCIATED CONDITIONS
- Neurologic disease
  - Parkinson disease, multiple sclerosis
- Pelvic radiation
- Pelvic trauma
- BPH
- Prostate surgery

GENERAL PREVENTION
None

DIAGNOSIS
HISTORY
- Voiding symptoms
  - Duration and characteristics of incontinence
  - Stress, urge, total
  - Precipitants and associated symptoms
  - Use of pads, briefs, diapers
  - Fluid intake
  - Alteration in bowel habits
  - Previous treatments and effect on incontinence
- Diabetes mellitus
- Associated conditions
  - Neurologic disease
- Medication use
  - Diuretics
- Alcohol and drug use including caffeine
- Radical pelvic surgery or radiation
  - Abdominoperineal resection
  - Radical prostatectomy

PHYSICAL EXAM
- Abdominal exam
  - Suprapubic mass
    - Suggests retention
  - Suprapubic tenderness
    - Suggests UTI
  - Surgical scars suggesting pelvic surgery
  - Skin lesions associated with neurologic disease
    - Neurofibromatosis and café au lait spots
- External genitalia
- Prostate
- Spine/back
- Skelet al deformities

- Scars from previous spinal surgery
- Sacral abnormalities may be associated with neurologic bladder dysfunction
  - Cutaneous signs of spinal dysraphism
    - Subcutaneous lipoma
    - Vascular malformation, tuft of hair, or skin dimple on lower back
  - Cutaneous signs of sacral agenesis
    - Low, short gluteal cleft
    - Flattened buttocks
    - Coccyx not palpable
- Focal neurologic exam
  - Motor function
    - Inspect muscle bulk for atrophy
    - Tibialis anterior (L4–S1): Dorsiflexion of foot
    - Gastrocnemius (L5–S2): Plantar flexion of foot
    - Toe extensors (L5–S2): Toe extension
- Sensory function
- Reflexes
  - Anal reflex (S2–S5)
    - Gently stroke mucocutaneous junction of circumanal skin
    - If visible contraction (wink) absent, suggests peripheral nerve or sacral (conus medullaris) abnormality
  - Bulbocavernosus reflex (BCR) (S2–S4)
    - Elicited by squeezing glans to cause reflex contraction of anal sphincter
    - Absence of BCR suggests sacral nerve damage

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Creatinine
  - If significant retention suspected
- Urinalysis
  - Glucosuria, infection

Imaging

None usually indicated

Diagnostic Procedures/Surgery

- Urodynamics
  - Useful for confirming bladder outlet obstruction as a possible cause of detrusor overactivity

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Urge incontinence
  - Loss of urine accompanied by urgency; often related to triggers such as sounds of running water, cold weather, passing a restroom

- Stress incontinence
  - Urinary leakage associated with exertion, lifting, coughing, sneezing
- Mixed incontinence
  - Urinary leakage associated with both stress and urge incontinence
- Low bladder compliance resulting in overflow incontinence
- Continuous urinary incontinence is the continuous loss of urine
- Post micturition dribble
  - The involuntary loss of urine immediately after he has finished passing urine, usually after leaving the toilet
- Mobility or cognitive impairment post stroke

TREATMENT

GENERAL MEASURES

- Bladder diaries are invaluable
  - Help patients understand patterns of incontinence
- Time voiding
  - Avoids significant bladder distention
- For postradical prostatectomy incontinence see Section I: Incontinence, urinary, following radical prostatectomy

MEDICATION

First Line

- Urge incontinence
  - Antimuscarinics: Inhibit the effect of acetylcholine at postjunctional muscarinic receptors on detrusor muscle cells
    - Tolterodine (2–4 mg/d)
    - Trospium XR (60 mg/d)
    - Darifenacin (7.5–15 mg/d)
    - Solifenacin (5–10 mg/d)
    - Oxybutynin (IR 7.5–20 mg/d, XL 5–30 mg/d, patch twice weekly)
    - Fesoterodine (4–8 mg/d)
  - β_3-adrenergic agonist agent: Promotes detrusor muscle relaxation
    - Mirabegron (25–50 mg/d)
- Stress incontinence
  - No generally accepted drug therapy
  - Tricyclics sometimes used
    - Imipramine 10–25 mg PO BID-TID

Second Line

- Urge incontinence
  - Tricyclic antidepressants
    - Imipramine 10–25 mg PO BID-TID
  - DDAVP for nocturnal symptoms
    - 0.1–0.5 mg PO or intranasal QHS (off label)
    - Avoided in patients with cardiac disease and older patients

- Risk of significant hyponatremia
- Intradetrusor botulinum toxin injections

SURGERY/OTHER PROCEDURES

- Urge incontinence
  - Sacral neuromodulation
  - Augmentation cystoplasty
- Stress incontinence
  - Urethral bulking agent
  - Male sling procedure
    - Promising short-term results
    - No long-term studies (3)[B]
  - Artificial urinary sphincter
    - Excellent long-term continence rates (4)[A]

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Pelvic floor exercise (Kegels)
  - Significantly improve SUI/UUI
- Biofeedback
- Timed voiding in UUI
- Overflow incontinence due to poor bladder contractility with urinary retention
  - Indwelling catheter
  - Intermittent catheterization
  - Evaluate for outlet obstruction

Complementary & Alternative Therapies

- Penile clamps, condom catheters, and pads are occasionally used
- They should be reserved for minor degrees of incontinence or in patients who have multiple other comorbidities in whom surgery may be thought inappropriate (5)
- Penile compression clamps
  - Applied externally to the penis to exert nonsurgical compression of the urethra, thereby preventing leakage of urine
  - 3 types of commercially available penile incontinence clamps (C3, U-Tex Male Adjustable Tension Band and Cunningham clamp) have been studied in a small trial (6)
  - No device completely eliminated leakage when applied at a comfortable pressure
  - Complications of penile clamps can include edema, pain, urethral erosion, and obstruction
  - Penile clamps should not be used for more than 4 hrs at a time
- Absorbent products (pouches, absorbant pants, small pads) were evaluated in a multi-center, multi-crossover study (7)
  - The conclusion was that no one product suits every patient although small pads came closest
  - Washable absorbant pants for men with light incontinence have economic advantages

ONGOING CARE

PROGNOSIS

Continence can be improved in almost all patients

COMPLICATIONS

- Candidiasis
- Dermatitis
- Skin breakdown

FOLLOW-UP

Patient Monitoring

Monitor post-void residual in patients on anticholinergic medications

Patient Resources

CLINICAL/SURGICAL PEARLS

• Prevalence of incontinence in males is 50% that of women.
• Continence can be improved in almost all patients.
• An Artificial urinary sphincter has excellent long-term continence rates.

INCONTINENCE, URINARY, FOLLOWING RADICAL PROSTATECTOMY

Robert L. Segal, MD, FRCS(C)
Arthur L. Burnett, II, MD, MBA, FACS

BASICS

DESCRIPTION

- Post-prostatectomy incontinence (PPI) is a well-recognized complication of radical prostatectomy (RP) whether performed openly (perineal retropubic) or laparoscopically with or without robotic assistance.
- The definition of continence following RP in the literature varies widely, with the strictest definition of continence being no pads used.

EPIDEMIOLOGY

Incidence

- The incidence of PPI depends on the interval of time following surgery, the definition and methodology for assessing continence, and the experience of the surgeon.
- The overwhelming majority of men have some degree of PPI immediately after catheter removal.
- If PPI is defined as no pads/small protective pad or total control/occasional dribbling, experienced surgeons consistently report continence rates exceeding 95% at 1–2 yr after RP.
- Recent evidence suggests that PPI may improve after 2 yr.

Prevalence

Approximately 6% of men will undergo a procedure for the management of PPI at a median of 20 mo after RP (1)

RISK FACTORS (2)

- Body mass index (BMI) ≥ 25
- Compromised sexual potency (IIEF-EF < 10)
- Enlarged prostate volume
- Increasing age (> 65 yr)
- Nerve-sparing status (non vs. unilateral vs. bilateral)
- Presence of preoperative incontinence/lower urinary tract symptoms (LUTS)
- Previous TURP
- Surgeon inexperience

Genetics

N/A

PATHOPHYSIOLOGY

- PPI results primarily from injury to the rhabdosphincter resulting in SUI.
- Pre-existing detrusor instability (DI) is a less likely etiology of PPI.
- An anastomotic stricture may be the cause, or exacerbate PPI.

ASSOCIATED CONDITIONS
- Anastomotic stricture/bladder neck contracture
- Detrusor Instability (DI)/Overactive bladder (OAB)
- Sphincteric incompetence

GENERAL PREVENTION
- Achieving a bloodless surgical field following anatomic ligation of the dorsal venous complex is required to meticulously divide the prostatourethral junction.
- Maximal preservation of the rhabdosphincter is felt to minimize PPI.
- Encourage Kegel exercises—may accelerate continence recovery.
- Preoperative pelvic floor muscle training with biofeedback has not resulted in improved postoperative continence recovery (3)

DIAGNOSIS
HISTORY
- Assess the severity of LUTS and incontinence preoperatively.
  – The International Prostate Symptom Score (IPSS).
- Inquire about the use of α-blockers because these agents may exacerbate PPI.
- Ascertain if the PPI is exacerbated by physical activity.
- Determine the severity of PPI by: Number of pads, degree of bother, and frequency of incontinence episodes.
- Assess the severity of LUTS.
- Inquire if PPI is improving, stable, or deteriorating:
  – Deterioration of continence together with increasing voiding symptoms suggests an anastomotic stricture.

PHYSICAL EXAM
- Observe for skin excoriation secondary to PPI.
- Observe degree of pad saturation.
- Observe degree of incontinence when transferring from the sitting to standing position.
- Observe caliber of urinary stream.

DIAGNOSTIC TESTS INTERPRETATION (C)
Lab
Urinalysis to exclude urinary tract infection

Imaging
Sonographic post-void residual (PVR)

Diagnostic Procedures/Surgery
- Uroflowmetry
- 24-hr pad test to quantify PPI
- Urodynamics evaluation with or without fluoroscopy will help define the etiology for PPI
- Pressure flow study is useful for evaluating a possible obstructive anastomotic stricture

Pathologic Findings
None

DIFFERENTIAL DIAGNOSIS

- Anastomotic stricture
- Detrusor Instability (DI)/Overactive bladder (OAB)
- Stress urinary incontinence (SUI)
- Urge incontinence
- Overflow incontinence
- Mixed incontinence

TREATMENT

GENERAL MEASURES

- Kegel exercises should be encouraged as soon as urinary catheter removal
- Discontinue α-blockers
- Limitation of fluid intake
- Timed voiding
- Voiding before strenuous activity
- Counsel patient that incontinence following RP is the norm and that with time most patients will improve

MEDICATION

First Line

- α-Agonists generally not effective for SUI
- Imipramine (a tricyclic antidepressant) promotes external urethral sphincter muscle tone and may improve mild SUI (off-label use)
  - Typical off-label starting dose is 25–50 mg PO QHS
- Anticholinergic agents may improve PPI secondary to DI
  - Options include: Oxybutynin, tolterodine, darifenacin, solifenacin, fesoterodine, trospium

Second Line

Periurethral bulking agents (bovine glutaraldehyde cross-linked collagen polydimethylsiloxane elastomer) are costly; they require multiple injections and have limited durable success in this setting.

SURGERY/OTHER PROCEDURES

- Surgical intervention should not be pursued until at least 1 yr post-prostatectomy because of the temporal improvements in the condition
- Surgical intervention should not be contemplated at 1–2 yr if there is evidence of progressive improvement
- Imperative to exclude anastomotic stricture and DI before embarking on surgical correction of SUI
- Surgical options:
  - The specific surgical procedure is dictated by severity of PPI.
  - More severe cases best managed with an artificial urinary sphincter (AUS)
  - In many cases, surgery achieves marked improvement in PPI but some degree of SUI may persist
    - Male slings

- Artificial urinary sphincter (AUS)

ADDITIONAL TREATMENT

Radiation Therapy

Although there is no role in the treatment of PPI, data suggest that radiation administered in the adjuvant setting following RP may not worsen incontinence but may limit resolution of continence particularly if the radiation is administered before continence returns.

Additional Therapies

- Urethral dilation should be performed if evidence of bladder outlet obstruction and anastomotic stricture.
- Transurethral incision of the stricture may be required if stricture reoccurs despite multiple dilation(s).
- In Europe duloxetine, a serotonin-norepinephrine reuptake inhibitor is approved for stress incontinence (US approval is only for neuropathic pain and depression).

Complementary & Alternative Therapies

Biofeedback may have a role in selected patients in strengthening pelvic musculature.

ONGOING CARE

PROGNOSIS

- The overwhelming majority of men will spontaneously regain urinary continence following RP.
- The small subset of men with persistent SUI will improve, providing the appropriate surgical procedure is performed.
- The worst prognosis exists for cases with severe refractory anatomic strictures (bladder neck contractures) who must 1st be made totally incontinent with subsequent placement of an AUS.
- PPI secondary to DI likely to improve with anticholinergic agents.

COMPLICATIONS

- Dermatitis
- Diminished self-esteem:
  - Limitation of physical activity
  - Withdrawal from sexual activity
  - Complications of treatment for PPI

FOLLOW-UP

Patient Monitoring

- Pad use
- Impact of PPI on quality of life

Patient Resources

http://www.webmd.com/urinary-incontinence-oab/mens-guide/urinary-incontinence

• Bulking Agents, Injectable
• Incontinence, Urinary, Adult Male
• Stress Urinary Incontinence, Male

CODES

ICD9

• 788.39 Other urinary incontinence
• 997.5 Urinary complications, not elsewhere classified

ICD10

• N39.498 Other specified urinary incontinence
• N99.89 Oth postprocedural complications and disorders of GU sys

CLINICAL/SURGICAL PEARLS

• Post prostatectomy incontinence (PPI) is very common, with the vast majority (95%) resolving 6–12 mo postoperatively.
• Kegel exercises should be instituted immediately after catheter removal postoperatively.
• It is crucial to determine the exact pattern of urinary leakage.
• If conservative measures fail, treatment for bothersome SUI requires surgery.
• Type of surgery is dictated by severity of SUI.

INCONTINENCE, URINARY, PEDIATRIC

Steve J. Hodges, MD
Anthony Atala, MD

BASICS

DESCRIPTION

- Incontinence: Involuntary leaking of urine due to any cause
- A "wet" child is the most common problem seen by pediatric urologists. Most wetting children will appear to no inciting cause, and some will improve spontaneously
- Enuresis: Involuntary leaking of urine while sleeping
  - "Nocturnal" enuresis implies night wetting alone, "diurnal" implies day and night, although these terms are outdated according to International Childrens Continence Society (ICCS)
  - Primary enuresis: Child was always wet at night
  - Secondary enuresis: Child has had a dry interval for at least 6 mo before wetting again

EPIDEMIOLOGY

Prevalence

- Day or night wetting occurs in up to 25% of 4–6 yr old children (daytime incontinence is present in approximately 5–10%)
- Resolution rates of approximately 15% a year
- At 12 yr of age 4% of children are enuretic at least once a week, at 15 yr old it is 2%
- Enuresis is 3× more common in boys than girls, however daytime incontinence is more common in females in all age groups

RISK FACTORS

- Spinal dysraphism
- Urinary tract anomalies
- Developmental delay
- Family history of enuresis
- Attention deficit disorder
- Urinary tract infection
- Constipation

Genetics

- Children whose parents were not bed-wetters have a 15% incidence of bedwetting. When one or both parents were bed-wetters, the rates jump to 44% and 77%, respectively.
- Genetic research shows that bedwetting is associated with the genes on chromosomes 13q and 12q (possibly 5 and 22 also).

PATHOPHYSIOLOGY

- Daytime control attained before nighttime
- Constipation plays a major role in urinary continence
- Normal bladder control involves 3 basic components: Intact neurologic system, normal

anatomy, and a mature, motivated child
- Normal urinary control occurs in stages:
  - Infantile voiding (0–6 mo) low-pressure filling, reflex detrusor contractions, simultaneous relaxation of external sphincter, complete emptying, uninhibited voids
  - Transitional voiding (1–2 yr) conscious sensation of bladder filling, continence achieved by controlling external sphincter, increasing bladder capacity (60 cc at birth + 30 cc/yr till 12 yr old)
  - Adult voiding: Supraspinal inhibition of voiding reflex, voluntary inhibition/initiation of voiding
- Delayed voiding/defecation lead to bladder overactivity, constipation
- Bladder overactivity/constipation compounded by dyssynergy of pelvic floor, with failure to relax pelvic floor completely with emptying

ASSOCIATED CONDITIONS
See risk factors

GENERAL PREVENTION
- Aggressively prevent and treat constipation
- Ensure an environment where children are not delaying micturition or defecation

DIAGNOSIS

ALERT
Incontinence in the presence of an abnormal back exam may signal a neurologic abnormality.

HISTORY
- Child's age—more common in young
- Child's sex—bedwetting is more common in boys, daytime wetting more common in girls
- When did the symptoms begin? What is the pattern? Severity?
- Primary enuresis is highly associated with constipation
- Secondary nocturnal enuresis implies an acquired cause or stressor
- Dribbling upon standing or activity in girls may imply vaginal voiding
- Determine associated daytime symptoms (urgency, frequency, weak or intermittent stream, or infrequent voiding)
- History of UTI? Functional constipation?
- History of large or firm bowel movements, or encopresis, may signify constipation even in setting of normal frequency of bowel movements
- Does child show holding behavior? (curtsey or squatting in girls, holding genitals in boys)
- History of neurologic disorder?
- Family history of incontinence? UTIs? Enuresis?

PHYSICAL EXAM
- Level of physical and emotional development
- Abdominal exam—rule out masses, constipation
- Back exam—rule out signs of occult spinal dysraphism (dimples, short sacrum, spinal defect, hairy patches)

- Flattened buttocks, low gluteal cleft, or nonpalpable coccyx suggest sacral agenesis
- GU exam, rule out genital or perineal sensation disorders, signs of abuse, hypospadias, or epispadias
- Rule out urine in vaginal vault or labial adhesions in girls
- Ectopic perineal ureteral orifice can be cause of constant wetness in girls
- Rectal exam to rule out rectal stool, evaluate normal sensation and tone
- Neurologic exam
- Measure or observe urinary stream for force, caliber, straining, duration (may obtain flow/PVR)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis
  - Rule out UTI, microhematuria, proteinuria, glucosuria
- If any of above discovered, require thorough evaluation and treatment
- Urine culture if UA shows signs of infection

Imaging

- KUB to rule out spinal anomalies and rule out occult constipation
- Renal US to evaluate for normal GU anatomy
- VCUG only needed in the setting of febrile UTI (or any UTI in boys), hydronephrosis; allows evaluation of urethra in males
- MR urography may be needed when concerned for ectopic ureter
- Renogram rarely needed to evaluate for urinary obstruction, renal function

Diagnostic Procedures/Surgery

- Urodynamics indicated in setting of known neurologic disorder
- Cystoscopy only needed if evaluation demonstrated anatomic abnormality such as posterior urethral valves

Pathologic Findings

- Incontinence classified as structural, neurogenic, complicated, or uncomplicated
- Structural—anatomic cause of incontinence (eg, ectopic ureter in girls)
- Neurogenic—incontinence due to spinal dysraphism or other neurologic cause
- Uncomplicated—nocturnal enuresis in appropriate age group in the presence of no obvious causes on diagnostic and physical exam (least common—almost all cases have cause if look closely)
- Complicated—functional voiding disorders; significant incontinence without anatomic or neurologic cause
- Need KUB and renal/bladder US, urodynamics optional
- Other pediatric bladder disorders:
  - Lazy bladder syndrome (infrequent voider)—rare voids, 2–3× a day, may have infections, associated with constipation
  - Bladder overactivity—typically associated with delayed voiding and constipation, typified by uninhibited bladder contraction with no neurologic lesion
  - Hinman-Allen syndrome—nonneurogenic neurogenic bladder, may be due to constipation as well

- Daytime frequency syndrome—frequent urination in a child with no other identifiable abnormalities, usually do have constipation on KUB
- Giggle Incontinence—rare form of incontinence where wetting only occurs with laughing, may be centrally mediated (brain), treated with Ritalin

DIFFERENTIAL DIAGNOSIS

- Structural incontinence:
  - Ectopic ureter
  - Exstrophy-epispadias complex
  - Fibrotic bladder (postoperatively or postradiation)
  - Imperforate anus
  - Labial adhesions
  - Posterior urethral valves
  - Urethral duplication
  - Urogenital sinus
  - Vesical fistula
- Neurogenic:
  - Anterior sacral meningocele, caudal tumor
  - Intradural lipoma, diastematomyelia
  - Myelodysplasia
  - Occult dysraphism
  - Sacral agenesis, spinal cord trauma, myelitis cerebral palsy
  - Tight filum terminale, dermoid cyst/sinus
  - Isolated nocturnal enuresis: Constipation, sleep arousal disorder, nocturnal polyuria
- Complicated incontinence:
  - Giggle incontinence
  - Hinman-Allen syndrome
  - Lazy bladder syndrome
  - Overactive bladder

TREATMENT

GENERAL MEASURES

- Behavioral measures—timed voiding, constipation therapy
- Biofeedback—physical therapy to relax external sphincter
- Diet—avoid bladder irritant, caffeine
- Perineal hygiene—voiding positioning

MEDICATION

First Line

- Treat UTI if present
- Overactive bladder
  - Anticholinergic medications
    - Oxybutynin: Safety and efficacy of oxybutynin chloride administration have been demonstrated for pediatric patients 5 yr of age and older
    - Tolterodine (off label in children)

- Consider β_3-agonist (mirabegron off label in children)

- Constipation
  - PEG 3350, enemas or suppositories, Senna laxatives, fiber supplements

SURGERY/OTHER PROCEDURES

- Structural—alleviate structural cause of incontinence
  - Neurogenic—low compliance bladder may require enterocystoplasty, urethral dilation, neural stimulation, or botulinum toxin injection
  - Overactive bladder—may benefit from neural stimulation, botulinum toxin injection in bladder or sphincter, rarely urethral dilation

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Aggressive constipation management for severe cases may require chronic enemas or antegrade continence enema (ACE) creation

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Most patients do resolve over time as they grow, and gain more mature toileting habits
- Severe cases may lead to pelvic floor disorders (such as pelvic pain syndrome, dyspareunia) in future, so aggressive therapy indicated

FOLLOW-UP

Patient Monitoring

- Follow-up for observation of progress, adjusting medications as needed
  - Structural and neurogenic causes need routine evaluations to rule out upper tract injury and monitor progress

Patient Resources

- National Kidney and Urologic Diseases Information Clearinghouse (NKUDIC)
  http://kidney.niddk.nih.gov/kudiseases/pubs/uichildren/

CODES

ICD9
- 788.30 Urinary incontinence, unspecified
- 788.36 Nocturnal enuresis
- 788.91 Functional urinary incontinence

ICD10
- F98.0 Enuresis not due to a substance or known physiol condition
- N39.44 Nocturnal enuresis
- R32 Unspecified urinary incontinence

CLINICAL/SURGICAL PEARLS
- Aggressive constipation therapy is needed.
- Enemas are most effective in treating incontinence.
- Incontinence in children is never normal and is a sign of treatable pathology.

INFERTILITY, UROLOGIC CONSIDERATIONS

Craig S. Niederberger, MD, FACS
Mark C. Lindgren, MD

BASICS

DESCRIPTION

- Infertility is the inability to achieve pregnancy after 1 yr of regular unprotected intercourse
- Couples achieve pregnancy by intercourse at a rate of approximately 20–25% per month, 75% by 6 mo, and 90% by 1 yr

EPIDEMIOLOGY

Incidence

- 15% of couples have infertility
- In approximately 30%, infertility is due to a significant male factor alone
- An additional 20% of couples have both male and female factors present

Prevalence

N/A

RISK FACTORS

- Anatomic: Varicocele; bilateral cryptorchidism; hypospadias; testicular trauma; testicular torsion; thermal exposure (hot baths, saunas); spinal, inguinal, or retroperitoneal surgery
- Medications: Cancer and cancer treatments (chemotherapy, radiation); recreational drugs (marijuana, cocaine); prescription meds (exogenous testosterone [T], GnRH agonists/antagonists, α-blockers, antibiotics, sulfasalazine, cimetidine, spironolactone, Ca channel blockers, colchicine, opioids, psych meds)
- Others: Heavy alcohol use; GU infections; chromosomal abnormalities; neurologic disease; endocrine disorders

Genetics

- Most common defects and % of men with nonobstructive azoospermia (NOA) or obstructive azoospermia (OA) with each:
  - Klinefelter syndrome 47,XXY (10% NOA)
  - Cystic fibrosis transmembrane conductance regulator protein (CFTR) found abnormal in 80% of patients with congenital bilateral absence of the vas deferens (CBAVD) (6% OA)
  - Azoospermia factor (AZF) a, b, and c:
    - AZFa (1% NOA) predictive of testicular sperm extraction (TESE) failure
    - AZFb (1–3% NOA) predicts TESE failure
    - AZFc (13% NOA) best prognosis, can be oligospermic, if azoospermic 2/3rds have sperm on TESE

PATHOPHYSIOLOGY

3 categories:

- Pretesticular: Endocrine abnormality
- Testicular: Abnormal sperm production

- Posttesticular: Abnormal sperm transport

ASSOCIATED CONDITIONS

- Pretesticular:
  - Hypogonadotropic hypogonadism: Low follicle stimulating hormone (FSH), luteinizing hormone (LH), and testosterone (T) with normal prolactin
  - Hypothyroidism
  - Medication use: See Risk Factors
  - Elevated estradiol from morbid obesity, tumors, or hepatic dysfunction
  - Kallmann syndrome: X-linked, absent GnRH secretion, absent puberty, anosmia
  - Pituitary/cranial trauma, infection, or tumor
  - Hyperprolactinemia: Prolactin inhibits LH action on Leydig cells. Brain MRI to evaluate for macroadenoma (>1 cm)
    - Macroadenoma: Refer for possible resection
    - Microadenoma: May respond to dopamine agonist (1st line: Cabergoline, 2nd: Bromocriptine)
- Testicular:
  - Varicocele: 15% of all men, 35–40% of men with primary infertility, 70–80% of men with secondary infertility
  - Bilateral cryptorchidism
  - Testicular cancer—pretreatment sperm density and motility are significantly decreased
  - Gonadotoxins: Radiation, chemotherapy, medications, environmental endocrine disrupting chemicals (eg, phthalates used in plastics)
  - Immunologic: Antisperm antibodies; febrile infections can decrease sperm production for 3 mo; postpubertal mumps orchitis
  - Sertoli-cell only syndrome: Absent germ cells
  - Maturation arrest: Spermatogenesis halted at a certain stage
  - Genetic/chromosomal factors:
    - Klinefelter: 47,XXY; small, firm testes; often azoospermic, however, mosaicism (47,XXY/46,XY) allows spermatogenesis. Up to 69% have sperm found from TESE
    - Y microdeletions: AZFa, b and c: See Genetics
    - Androgenization disorders: Defects in synthesis of T, androgen receptor, and 5α reductase
    - 47,XYY: Usually fertile due to mosaicism with XYY cells arresting in meiosis and XY cells producing mature sperm
    - 46,XX with male phenotype: No spermatogenesis, donor sperm/adoption
    - Primary ciliary dyskinesia (Kartagener syndrome): Immotile sperm; frequent respiratory infections; situs inversus
    - Globozoospermia (round-headed sperm): Severe teratospermia in which sperm lack acrosomes giving the heads a round appearance
- Posttesticular:
  - Obstruction of epididymis or vas deferens: Congenital or acquired (eg, vasectomy)
  - CBAVD: 80% have CFTR mutations—genetic testing must be performed for male and female
  - Ejaculatory dysfunction:

- Anejaculation: Caused by retroperitoneal surgery, neuropathic disorders, α-blockers and psychiatric medications
- Retrograde ejaculation: Transurethral prostate and bladder neck procedures as well as the same causes of anejaculation (above)

– Ejaculatory duct obstruction (EDO): Low-volume azoospermia; causes include previous infection, iatrogenic trauma, and congenital

GENERAL PREVENTION

See “Risk Factors”

DIAGNOSIS

HISTORY

• Mnemonic **TICS:**

– **Toxic:** Varicocele, chemotherapy, radiation exposure, thermal exposure to testes, testicular injury, heavy alcohol use, recreational drugs (marijuana, cocaine), surgical history, medications, and other medical illnesses

– **Infectious:** Sexually transmitted disease, urinary tract infections, epididymitis, recent febrile illness, and postpubertal mumps

– **Congenital:** Bilateral cryptorchidism, testicular torsion, family history of difficulty conceiving or miscarriages, family history of cystic fibrosis

– **Sexual:** Length of time attempting to conceive, previous pregnancies with current or previous partner, frequency of intercourse, lubricant use, erectile dysfunction, age at puberty, libido, exogenous T use, energy level

PHYSICAL EXAM

• General: Degree of virilization, Tanner stage

• Penile exam: Location of urethral meatus, buried penis

• Scrotal exam:

– Measure testicles by long access length or orchidometer volume (nL ≥4 cm or 20 mL)

– Testicular consistency, including careful evaluation for testicular masses

– Epididymal exam—note presence of caput, corpus, and cauda as well as possible induration or fullness suggestive of obstruction

– Cord structures: Evaluate for varicocele in standing position, note presence or absence of vasa deferentia as well as continuity or malunion

DIAGNOSTIC TESTS & INTERPRETATION

Lab

• Semen analysis:

– Minimum of 2 specimens due to variability

– World Health Organization (WHO) 2010 5th edition reference values:

- Volume >1.5 mL normal, if low, obtain post ejaculatory urinalysis to distinguish between retrograde ejaculation and EDO
- Concentration >15 million/mL
- Total sperm count >39 million/mL
- Total Motility >40%
- Morphology >4%

  - Azoospermia:
    - Distinguish between obstructive and NOA
    - If FSH <7.6 mIU/mL and testicular long axis >4.6 cm then 96% probability of OA
    - If FSH ≥ 7.6 and testicle ≤ 4.6 cm then 89% probability of NOA (1)[B]
- Further specialized semen testing may aid decision-making but not routinely obtained
- Endocrine workup obtained if abnormal semen analysis, impaired sexual function or findings indicative of endocrine abnormality:
  - Obtain T, sex hormone binding globulin (SHBG), albumin to calculate bioavailable T and FSH, LH estradiol for all patients needing workup
  - Consider prolactin and others as indicated
- Genetic testing
  - CBAVD: Patient and partner should have genetic counseling and CFTR mutation testing
  - Karyotyping is indicated in patients with NOA or severe oligospermia (<5 million sperm/mL)
  - Consider Y chromosome microdeletion testing if azoospermic

Imaging

- Transrectal ultrasound—use in azoospermic patients with palpable vasa and low-volume ejaculate. Seminal vesical dilatation (normal <2 cm) indicative of EDO
- Scrotal ultrasound—only used in patients with difficult or inadequate scrotal exams
- Renal ultrasound—recommended if unilateral absent vas or CBAVD with no CFTR mutations to evaluate for renal abnormalities

Diagnostic Procedures/Surgery

Testicular biopsy is typically unnecessary

Pathologic Findings

- Seminiferous tubules findings include:
  - Normal spermatogenesis—indicative of OA
  - Maturation arrest ($\sim 20\%$ of NOA)—can be “early” or “late”
  - Sertoli-cell-only syndrome ($\sim 60\%$ of NOA)—germinal cell aplasia
  - Hypospermatogenesis ($\sim 20\%$ of NOA) or germ cell hypoplasia
  - Tubular hypoplasia—possible hypogonadotropic hypogonadism
  - Seminiferous tubule sclerosis
  - Testis cancer

DIFFERENTIAL DIAGNOSIS

See “Associated Conditions”

TREATMENT

GENERAL MEASURES

- The goal is to address the underlying problem to allow natural conception, if possible.
- Female evaluation by a reproductive specialist and coordinated care is crucial for optimal outcomes.

MEDICATION

First Line

- Clomiphene citrate 50 mg every other day: Used for hypoandrogenism. Stimulates GnRH resulting in increased T and spermatogenesis. Less than 10% of men with azoospermia and hypoandrogenism have return of sperm to ejaculate after T normalizes using clomiphene citrate (2)[B]. Note: Exogenous T decreases fertility
- Pseudoephedrine 60 mg 1–2 hr prior to sex: For retrograde ejaculation
- Anastrozole 1 mg daily: Men with abnormal semen parameters and low testosterone to estradiol ratio (<10:1)

Second Line

- hCG and/or recombinant FSH: If hypoandrogenism unsuccessfully treated with clomiphene citrate
- Alternatives for retrograde ejaculation: Imipramine 25 mg, ephedrine 25 mg

SURGERY/OTHER PROCEDURES

- MicroTESE: Performed for NOA, superior to other sperm-retrieval techniques with 20–30% improvement in yield up to 67%
- Vasectomy reversal: Time since vasectomy is the best predictor of success (3)[B]
- MicroTESE, vasovasostomy, or vasoepididymostomy should be performed by microsurgical specialist
- OA, if patient does not desire reconstruction or it is not possible: TESE, testicular sperm aspiration (TESA), percutaneous or microsurgical epididymal sperm aspiration (PESA or MESA)
- Varicocelectomy: Recommended for men with infertility, palpable varicocele, abnormal semen parameters, elevated FSH, and female partner with normal/potentially correctable infertility (4)[A]
- Transurethral resection of ejaculatory ducts: For EDO
- Neurostimulatory ejaculation: Men with spinal cord injury may be able to retrieve sperm via ejaculate with penile vibratory stimulation or, electroejaculation or via microTESE

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Assisted Reproductive Technologies (ARTs), Intrauterine insemination (IUI), In Vitro Fertilization (IVF) and Intracytoplasmic Sperm Injection (ICSI)

Complementary & Alternative Therapies

Coenzyme Q10 is used

ONGOING CARE

PROGNOSIS

- Pregnancy rates are highly dependent on the age of the female partner
- MicroTESE for NOA: 67% sperm-retrieval rate
- IUI: ~15% pregnancy rate per cycle

- IVF: ~30% pregnancy rate per cycle
- IVF with ICSI: ~35–45% pregnancy/per cycle

COMPLICATIONS
- Scrotal surgery: Hematoma, bruising, pain
- ART: Multiple gestations, passing genetic defects to offspring

FOLLOW-UP

Patient Monitoring

Spermatogenesis takes approximately 64 days; semen analysis 3 mo after starting treatment

- 606.8 Infertility due to extratesticular causes
- 606.9 Male infertility, unspecified

ICD10
- N46.029 Azoospermia due to other extratesticular causes

- N46.129 Oligospermia due to other extratesticular causes
- N46.9 Male infertility, unspecified

CLINICAL/SURGICAL PEARLS

Testis biopsy is rarely indicated in the evaluation of male infertility.

INTERSTITIAL CYSTITIS (IC)/PAINFUL BLADDER SYNDROME (PBS)

Nikhil Waingankar, MD
Sonia Bahlani, MD
Robert M. Moldwin, MD, FACS

BASICS

DESCRIPTION

- Interstitial cystitis (IC) or Painful Bladder Syndrome (PBS) is an unpleasant sensation (pain, pressure, discomfort) perceived to be related to the bladder, associated with lower urinary tract symptoms (LUTS) for more than 6 wk duration, and in the absence of other identifiable causes (1,2)
- 92% of patients also complain of frequency (>10–12× daily); nocturia is common
- 84% complain of constant/persistent urgency
- Dysuria is uncommon
- Symptoms can be associated with a wide range of diseases (see "Differential Diagnosis")
- Two forms of IC/BPS:
  - "Classic": Associated with Hunner lesions on cystoscopy (formerly known as Hunner ulcer)
  - "Nonclassic": No inflammatory lesions identified upon cystoscopy
- Nomenclature change from IC to IC/PBS due to the lack of gross inflammatory bladder wall changes found in most patients
- Median age of onset 30–40 yr
- Female: Male ~ 5:1
- 5–10% of patients have Hunner lesions

EPIDEMIOLOGY (3)

Incidence and prevalence vary widely

Incidence

0.6–1.6 per 100,000 people

Prevalence

Ranges from 1.6 to 2,600 per 100,000 people

RISK FACTORS

No known risk factors beyond a possible genetic predisposition

Genetics

Adult female 1st-degree relatives of IC patients have a prevalence 17× greater than that of the general population

PATHOPHYSIOLOGY

- Multifactorial etiology with a number of proposed mechanisms
  - Epithelial permeability
  - Antiproliferative factor

  - Mast cell activation
  - Neurogenic inflammation
  - Infectious
  - Autoimmunity
  - Urinary abnormality: Toxic, allergic, immunologic

ASSOCIATED CONDITIONS

- Myalgia of pelvic floor: Most commonly identified comorbid condition
- Irritable bowel syndrome
- Fibromyalgia
- Chronic fatigue syndrome
- Multiple allergies
- Sjögren syndrome
- Chronic headaches
- Depression/anxiety/panic disorder
- In females: Vulvodynia, endometriosis
- In males: Chronic prostatitis/chronic pelvic pain syndrome, BPH, prostate cancer

GENERAL PREVENTION

No definitive prevention strategies, although dietary changes and medical therapy may mitigate symptom flares

DIAGNOSIS

HISTORY

- IC patients 10× more likely to have childhood bladder problems
- Symptoms unrelated to any identifiable cause (infection, STD, cancer, radiation, overactive bladder (OAB), diverticula, vaginitis, stones)
- Chronic pelvic pain, pressure
- Abdominal/supra-pubic pain
- Pain associated with bladder filling and/or emptying
- Premenstrual flares
- Urinary frequency, urgency, nocturia
- Urinary frequency based upon need to decrease level of pelvic discomfort/pain
- Helpful evaluation/monitoring tools:
  - Symptom evaluation with voiding diary
  - O'Leary-Sant Symptom and Problem Score
  - Visual analog scale (pain score)
  - PUF (Pelvic Pain & Urgency/Frequency) Questionnaire
  - Bladder Pain/Interstitial Cystitis Symptom Score

PHYSICAL EXAM

- General:
  - Abdominal exam to assess for supra-pubic tenderness
  - Focused neurologic exam
- Females:
  - Q-tip test to assess for vulvodynia

  - Bimanual exam with palpation of bladder, urethra, and pelvic floor muscles to assess presence of muscle tenderness/banding
- Males:
  - Digital rectal exam with palpation of prostate and pelvic floor musculature
  - External genitalia exam

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis and urine culture
- Urine cytology in high-risk groups

Imaging

No recommended imaging for the diagnosis of IC/PBS

Diagnostic Procedures/Surgery

- Urodynamics:
  - Normal detrusor function on cystometry; may have increased sensitivity (pain) on filling and decreased capacity.
  - Late stages of "classic" IC/PBS may be associated with significant decrease in capacity and bladder compliance
- Cystoscopy:
  - Used selectively to exclude other bladder pathology and identify Hunner lesions
- Cystoscopy with hydrodistention under general/spinal anesthesia:
  - Findings may include: Glomerulations (small foci of hemorrhage), Hunner lesions, decreased anesthetic capacity, mucosal tears; low sensitivity and specificity
  - Hunner lesion (ulcer) is described as circumscript, reddened area with small vessels radiating toward a central scar. Fibrin deposit/coagulum can be attached to this area. With bladder distention the site ruptures with petechial blood oozing from the lesion and mucosal margins (5)
- Potassium sensitivity testing (KCl test):
  - Low sensitivity and specificity; positive result provokes pain
- Residual urine/flow in males

Pathologic Findings

- Histologic findings can vary widely and none are truly pathognomonic
- Bladder biopsy
  - Indicated only to rule out other disease processes
  - Hunner lesions demonstrate pan-mural inflammation

DIFFERENTIAL DIAGNOSIS

- Bacterial cystitis
- Bladder cancer (including CIS)
- Bladder effects of chemotherapy
- Bladder outlet obstruction/urinary retention
- Bladder/lower ureteral stone
- Genital herpes
- Overactive bladder

- Pelvic floor muscle dysfunction
- Pudendal nerve entrapment
- Radiation cystitis
- Females:
  - Cervical/uterine/ovarian cancer
  - Urethral diverticulum
  - Pelvic organ prolapse
  - Endometriosis
  - Vaginal candidiasis
- Males: BPH, prostate cancer, prostatitis

TREATMENT

GENERAL MEASURES

(Adapted from AUA guidelines 2011) (6)

- Patients should be aware that no single treatment has been found effective
- 1st line
  - Stress reduction
  - Exercise
  - Warm baths
  - Stool softeners
  - Biofeedback
  - Avoidance of spicy foods, caffeine, alcohol, artificial sweetener, acidic beverages
- 2nd line
  - Pelvic floor physical therapy/massage
  - Multimodal pain management
  - Amitriptyline
  - Cimetidine
  - Hydroxyzine
  - Pentosan polysulfate
  - Intravesical instillation: Author's preferred "cocktail": Lidocaine, gentamicin, heparin, triamcinolone
  - Intravesical: 50% DMSO
  - Intravesical: 4% alkalinized lidocaine
- 3rd line
  - Cystoscopy with hydrodistention (low pressure/short duration)
  - Fulguration of Hunner lesions
  - Submucosal injection of Hunner lesions with triamcinolone
- 4th line
  - Neuromodulation (InterStim, etc.)
- 5th line
  - Cyclosporine A
  - Intradetrusor botulinum toxin A
- 6th line
  - Urinary diversion +/– cystectomy: May eliminate urinary frequency but does not

necessarily eliminate the pain component

MEDICATION

First Line

See above

Second Line

See Above

SURGERY/OTHER PROCEDURES

See above

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

See General Measures

Complementary & Alternative Therapies

See General Measures; myofascial physical therapy may help (4)

ONGOING CARE

PROGNOSIS

Spontaneous remission rate of 50% at mean of 8 mo

COMPLICATIONS

N/A

FOLLOW-UP

Patient Monitoring

Follow symptoms

CODES

ICD9

- 595.1 Chronic interstitial cystitis
- 599.70 Hematuria, unspecified
- 788.41 Urinary frequency

ICD10

- N30.10 Interstitial cystitis (chronic) without hematuria
- N30.11 Interstitial cystitis (chronic) with hematuria
- R35.0 Frequency of micturition

CLINICAL/SURGICAL PEARLS

- IC/PBS is more common in women than in men.
- This is primarily a clinical diagnosis based upon the presence of characteristic symptoms and the exclusion of other causes.

LATEX ALLERGY, UROLOGIC CONSIDERATIONS

Ahmad H. Bani-Hani, MD, FAAP, FACS

BASICS

DESCRIPTION

- Localized or systemic reaction to latex, a natural substance from the sap of the rubber tree, *Hevea brasiliensis* (1)[A].
- Latex is a common ingredient in many medical and dental products (eg, bladder catheters, blood pressure cuffs, face mask, gloves, endotracheal tubes, IV infusion sets, etc.)
- Patients with spina bifida or congenital urogenital abnormalities have the highest risk.
- Mild forms include pruritus and swelling. The most severe form of allergic reaction is anaphylaxis: A severe, life-threatening, generalized or systemic hypersensitivity reaction characterized by rapidly developing life-threatening airway and/or breathing and/or circulation problems usually associated with skin and mucosal changes.

ALERT

All patients with neurogenic bladder should be considered for latex precautions.

EPIDEMIOLOGY

Incidence

- Latex sensitivity (assessed by serum latex IgE or skin prick test) in the general population is <1%
  - Spina bifida population is 18–72%
- Latex allergy (eg, anaphylactic symptoms) is rare in healthy population.
- Healthcare community: Up to 12.1% which fell to 4% with the introduction of powder-free gloves
- Exposure to multiple surgeries: 1/3–2/3 of children who underwent surgeries in the 1990s developed latex sensitivity; this risk decreased dramatically since the implementation of latex avoidance in hospitals and products

Prevalence

N/A

RISK FACTORS

- Occupational exposure:
  - Healthcare
  - Food handlers/restaurant workers
  - Hairdressers
  - Construction workers
  - Painters
  - First responders
  - Security personal
  - Gardeners
- Atopic disease

- People with food allergies mainly to kiwi, strawberry, banana, avocado, chestnut
- Multiple surgeries at young age
- Children with anorectal or urologic malformations (5)[A].
  - Spinal dysraphism
  - Bladder exstrophy/cloacal anomalies
  - Patients on clean intermittent catheterization

Genetics

- Genetic factor might be indicated.
- Latex allergy is less frequent in adults with spinal cord injury and multiple surgical procedures than in children with similar conditions.
- Interleukin-13 (IL-13) and IL-18 promoter polymorphisms more likely to be found in healthcare workers in comparison to nonatopic controls or patients with anorectal/urologic malformations.

PATHOPHYSIOLOGY

- Presensitization with Hevea latex allergens is prerequisite to initiate an allergic response.
- A number of proteins found in the cytoplasm of *H. brasiliensis* are known potent allergens that can elicit human IgE antibody, leading to sensitization in exposed patients and a spectrum of allergic reactions upon subsequent exposure (4)[A].
- Symptoms of delayed (type IV) hypersensitivity usually develop within 1–2 days of exposure. Immediate (type I) hypersensitivity causes symptoms within minutes of exposure.
- Immediate hypersensitivity reactions to latex (type I) are caused by cross-linking of latex protein-specific IgE antibody with mast cells and basophils.
- Cross-reactivity between various proteins is responsible for the clinical associations between latex allergy and allergic responses to a number of fruits and vegetables.
- Type IVc (T-cell–mediated type), delayed hypersensitivity reaction can occur and usually manifest as contact dermatitis 24–96 hr after exposure.

GENERAL PREVENTION

- Facility:
  - Avoidance is the most effective and least expensive method.
  - Establishment of a latex-safe environment should be a priority for institutions by replacing all Hevea latex–containing products with non–Hevea-based synthetic products or powder-free latex products.
  - Synthetic alternatives to rubber include butyl rubber, a petroleum-based product with no allergenic protein, neoprene, and copolymers of butadiene and acrylonitrile.
  - Non-Hevea source of natural rubber is the guayule plant (Yulex). Yulex-based products pose no risk to individuals allergic to Hevea latex and is approved by the Food and Drug Administration (FDA).
- Individuals with latex allergy:
  - Should wear a medical alert bracelet indicating latex allergy
  - Should be encouraged to have self-injectable epinephrine if they have a clinical history of systemic reaction to latex
  - Should avoid latex-containing products
  - Should report their allergies prior to any medical or surgical procedure

DIAGNOSIS

HISTORY

- Detailed clinical history of allergic reactions that are temporarily associated with exposure to Hevea latex–containing products (eg, prior history to anaphylaxis and/or intraoperative shock, itching, redness, or swelling following dental, rectal, or pelvic exam; itching or swelling with condoms, diaphragms, or latex sexual aids)
- Detailed history of associated risk factors: Healthcare workers, hair dressers, rubber handling, eczema/hay fever, multiple surgeries, food allergies, etc.
- 30–80% of patients with latex allergy also have food allergy
- Allergic symptoms can include the following symptoms:
  - Dizziness
  - Dyspnea
  - Pruritus
  - Rhinitis
  - Tearing
  - Swelling at the site of contact
  - Abdominal cramps
- In the most extreme cases, anaphylaxis can develop

ALERT
Use caution when examining any child for dysfunctional voiding especially if the child has neurologic symptoms or suspected spina bifida.

PHYSICAL EXAM

- Use nonlatex exam gloves
  - Mucocutaneous manifestations:
    - Erythema
    - Edema
    - Papules, macules, urticaria
    - Allergic rhinitis
    - Allergic conjunctivitis
    - Angioedema
  - Cardiopulmonary manifestations:
    - Tachypnea
    - Stridor, wheezing
    - Tachycardia
    - Hypotension
    - Shock

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Routine resuscitation lab studies (blood gas, etc.) if during acute anaphylaxis

Imaging

N/A

Diagnostic Procedures/Surgery

- These are performed on a routine basis and not during an acute event
- Prick skin test:
  - Extracts of Hevea latex, at least 3
  - Commercial extracts are available
  - Test involves performing a puncture with a lancet device through a drop of latex extract at sequential concentrations ranging from 0.001–1 mg/mL of protein
  - Results are read after 15 min and compared with the positive histamine and negative saline controls
  - Small risk of anaphylaxis
- Serology:
  - An alternative test for confirming sensitization when commercial skin test reagents are not available
  - Involves measuring serum Hevea latex–specific IgE antibodies
  - Diagnostic sensitivity and specificity: 80% and >95%, respectively

Pathologic Findings

- Biopsy of skin lesions (type IV hypersensitivity):
  - Perivascular cuffing of CD4 cells identified using anti-CD4 antibody staining
  - Vesicular dermatitis with dermal and epidermal mononuclear infiltrates

DIFFERENTIAL DIAGNOSIS

- Systemic allergic reaction to another allergen, including medications or food products.
- Mild allergic manifestations:
  - Allergic rhinitis
  - Asthma
  - Atopic dermatitis (ie, eczema)
  - Conjunctivitis
  - Contact dermatitis to other allergens (ie, nickel products)
- Severe life-threatening manifestations:
  - Anaphylactic shock
  - Cardiogenic shock
  - Septic shock
  - Hypovolemic shock

TREATMENT

GENERAL MEASURES

- Latex avoidance is by far the most-effective method of prevention (2,3)[A].
- Institutional policy changes in the use of Hevea products are needed to reduce occupational and patient exposure.
- Always seek the use of nonlatex alternative products (eg, silicone urethral catheters)
- Synthetic and Yulex, non-Hevea rubber, are safe alternatives in Hevea-sensitized individuals.
- Additional measures recommended for patients with latex allergy include carrying nonlatex gloves, wearing medical alert bracelets, and having auto-injectable epinephrine available.
- For acute anaphylaxis, standard shock management.

MEDICATION

First Line

- For the management of anaphylaxis
  - Remove latex source
  - Basic life support principles (Airway, Circulation, Breathing)
  - Injectable epinephrine in severe anaphylaxis
    - 0.3–0.5 mL of a 1:1000 solution IM (adult)
    - 0.15–0.3 mL of a 1:000 solution IM (children)
  - Epinephrine autoinjectors:
    - EpiPen, Adrenaclick (0.3 mg) in adults
    - EpiPen Jr., Adrenaclick (0.15 mg) in children
- Supportive medications cannot be substituted for epinephrine in the emergent management of anaphylaxis because they do not prevent or relieve respiratory failure or shock, but can be useful after initial resuscitation
  - Antihistamines (diphenhydramine)
  - Bronchodilators (albuterol)
  - Steroids (hydrocortisone)
  - H_2 blockers (ranitidine)

Second Line

N/A

SURGERY/OTHER PROCEDURES

N/A

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

- Most healthcare facilities have banned latex helium–filled balloons and are striving to become latex-free.
- There is no desensitization available, but several including sublingual and other immunotherapies are under study.

ONGOING CARE

PROGNOSIS

- Depends on severity of symptoms and timely identification of responsible agents.
- High index of suspicion and immediate treatment are essential to good outcome.
- Individuals with severe latex allergy should be provided with epinephrine autoinjections.
- Patients with type I hypersensitivity: Risk of fatal anaphylaxis and/or respiratory compromise

COMPLICATIONS

- Death can result from anaphylactic shock
- Secondary bacterial wound infections in cases of severe contact dermatitis

FOLLOW-UP

Patient Monitoring

- Some patients experience a biphasic or late stage reaction several hours after the initial anaphylactic event. Patients should be observed for at least 4 hr after the initial event.
- Avoidance should extend outside of the hospital to items such as latex balloons, rubber bands, toys, etc.
- Inpatient admission may be necessary until cardiopulmonary risk is reduced.
- Allergy identification band, “MedicAlert" bracelet
- Avoid foods with latex cross-reactivity:
  – Banana, kiwi, chestnut, avocado

Myelodysplasia (Spinal Dysraphism), Urologic Considerations

CODES

ICD9

- 596.54 Neurogenic bladder NOS
- 753.9 Unspecified anomaly of urinary system
- V15.07 Allergy to latex

ICD10

- N31.9 Neuromuscular dysfunction of bladder, unspecified
- Q64.9 Congenital malformation of urinary system, unspecified
- Z91.040 Latex allergy status

CLINICAL/SURGICAL PEARLS

- Natural rubber latex allergy is caused by sensitization to proteins found in *H. brasiliensis*, the rubber tree.
- The highest prevalence of latex allergy (up to 68%) is in patients with spina bifida or congenital urogenital abnormalities.
- The mainstay of management of latex allergy is avoidance of latex products as there is no cure for latex allergy.

LIBIDO, DIMINISHED, FEMALE

Bradley C. Gill, MD, MS
Sandip P. Vasavada, MD, FACS

BASICS

DESCRIPTION

- Diminished libido, low sexual drive, or hyposexuality are defined by a lack of desire for sexual activity.
- Hypoactive sexual desire disorder or subjective sexual arousal disorder may be implicated.

EPIDEMIOLOGY

Incidence

- More common with advancing age and especially following menopause
- A congenital syndrome may be causative at a young age.

Prevalence

Estimated prevalence of 25–75% of women varies by study sample and assessment

RISK FACTORS (1)

- Low testosterone (physiologic or iatrogenic)
- Advanced age
- Menopause (physiologic or iatrogenic)
- Pelvic floor disorder (incontinence or prolapse)
- Physical or psychological trauma (sexual assault, physical abuse, or verbal abuse)
- Pregnancy (multifactorial per hormonal, emotional, and physical changes)

Genetics

Early onset menopause may be implicated

PATHOPHYSIOLOGY (2,3)

- Testosterone drops 50% from age 30 to 60 years and is linked to low libido as are other androgens.
- Estrogen can increase sex hormone–binding globulin concentrations and lower free testosterone.
- Progesterone may lower mood and decrease sex drive as seen with some contraceptives.
- Follicle-stimulating and luteinizing hormone reduction by contraceptives lowers androgen creation.
- Serotonin level alterations from certain antidepressants can decrease sex drive.

ASSOCIATED CONDITIONS

- Vaginal atrophy
- Congenital syndromes
- Posttraumatic stress disorder (prior physical or psychological trauma)

GENERAL PREVENTION

Exercise, balanced diet, healthy lifestyle

DIAGNOSIS

HISTORY

- Details of low libido
  - Acquired or lifelong problem
  - Always or intermittently present
  - With only specific sexual partners
  - After a new diagnosis or procedure
  - Following use of a new medication
  - Association with life events
- Reproductive information
  - Age of menarche or onset of menses
  - Pregnancies and deliveries
  - Contraception use and type
  - Infertility and treatment
- Other sexual information
  - Sexually transmitted infection
  - Pain or discomfort with sexual activity
  - Problems with sexual function of the partner
- Current or prior abuse
  - Sexual
  - Verbal or physical
- Symptoms of androgen insufficiency
  - Dysphoria, fatigue, low sense of well-being
  - Reduced sexual receptivity and pleasure
  - Decreased vaginal lubrication despite estrogen treatment
- Signs of androgen insufficiency
  - Bone loss, decreased muscle mass, less strength
  - Memory changes and altered cognitive function
- Other endocrine disorders
  - Hypothyroidism
  - Cushing syndrome
  - Diabetes
- Urogenital conditions
  - Urinary incontinence or fecal incontinence
  - Pelvic organ prolapse
- Medications
  - Oral contraceptives, estrogens, progestins, gonadotropin-releasing hormone agonists
  - Antidepressants, amphetamines, anticonvulsants, antiepileptics, psychotropics
  - Antihypertensives, antilipidemics, antiarrhythmics
  - Steroids, narcotics
- Chronic medical conditions
  - Psychiatric conditions
  - Substance abuse

PHYSICAL EXAM

- Assessment of nongenital sexual characteristics
  - Breast development
  - Axillary hair
- Signs of endocrinologic disorder
  - Cushingoid appearance
  - Hypothyroid skin and hair changes
  - Diabetic neuropathy
- Visual inspection of the external genitalia
  - Distribution of pubic hair
  - Ulcerations, pustules, discharge, or bleeding
  - Prolapsed urethra, vagina, or cervix
- Speculum exam
  - Mucosal rugae, moisture, thinning, or excoriation
  - Ulcerations, pustules, discharge, or bleeding
  - Cystocele, rectocele, or enterocele
  - Vaginal wall masses
- Palpation of the external genitalia, vaginal sidewalls, pelvic floor muscles, cervix, and ovaries
  - Urethral or vaginal sidewall masses
  - Surgically placed foreign bodies
  - Pelvic floor muscle tension, spasm, or tenderness
  - Cervical motion, ovarian, or adnexal tenderness
  - Vaginal cul-de-sac mass or tenderness

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Estrogens: Estradiol and estrone
- Androgens: Dehydroepiandrosterone, androstenedione, testosterone, and dihydrotestosterone
- Proteins: Sex hormone–binding globulin (SHBG) with free testosterone and total testosterone
- Adjunctive: Thyroid-stimulating hormone, glycosylated hemoglobin

Imaging

Brain magnetic resonance imaging to assess the hypothalamus and pituitary gland

DIFFERENTIAL DIAGNOSIS

- Hormonal
  - Decreased free testosterone or increased sex hormone–binding globulin
  - Decreased androgen
  - Hypogonadotropic hypogonadism
  - Adrenal insufficiency or adrenal suppression
  - Adrenal suppression or glucocorticoid excess
  - Hypothyroidism or hyperthyroidism
- Psychological
  - Hypoactive sexual desire disorder, subjective sexual arousal disorder, sexual aversion disorder

  – Sexual dysfunction in a partner
• Iatrogenic
  – Medication side effect
• Gynecologic
  – Dyspareunia, pelvic organ prolapse, sexually transmitted infection
• Urologic
  – Urinary incontinence
• Colorectal
  – Fecal incontinence
• Congenital syndrome

TREATMENT

GENERAL MEASURES (1)

• Behavioral
  – Identify and eliminate any libido-reducing behaviors, habits, or addictions
  – Psychological counseling, couples therapy, or sex therapy as indicated
  – Encourage a healthy lifestyle with balanced diet, exercise, work, and sleep

MEDICATION

First Line

• Testosterone alone or in combination has been used off-label to increase drive
  – Postmenopausal women with decreased libido who are not receiving estrogen therapy have modest success using an experimental testosterone patch delivering 300 µg/d testosterone
• If possible elimination or replacement of medications that may reduce libido
• Adjunctive treatment of vaginal atrophy with topical estrogen can be helpful
• Also consider appropriate goal-directed treatment of other medical conditions

Second Line

N/A

SURGERY/OTHER PROCEDURES

Appropriate treatment of possibly causative medical (ie, endocrine tumor) conditions

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

• Results vary with etiology and treatment for many is long-term

- Multimodal approach to any etiology should be most beneficial

COMPLICATIONS

Loss of libido can result in depression, infertility

FOLLOW-UP

Patient Monitoring

- Frequent follow-up with initiation of new therapy is best with regular lab work if hormones are used.
- If using testosterone, monitor for signs of testosterone excess (acne, hirsutism, male pattern baldness, hyperlipidemia)

Patient Resources

- 302.71 Hypoactive sexual desire disorder

ICD10

- F52.0 Hypoactive sexual desire disorder
- N95.1 Menopausal and female climacteric states
- R68.82 Decreased libido

CLINICAL/SURGICAL PEARLS

- A good social history is essential.

- Sexual dysfunction in partners can cause this.
- Overall physical health helps maintain libido.

LIBIDO, DIMINISHED, MALE

Daniel Box, MD
Anish K. Shah, MD

BASICS

DESCRIPTION

- Diminished libido (hyposexuality) is the lack of desire to engage in sexual experience.
- Hypoactive sexual desire disorder is characterized by reduced libido and interest in sexual activity causing distress in women.
- This section primarily focuses on decreased libido in men.

EPIDEMIOLOGY

Incidence

- 10–15% of men
- 20–25% of women

Prevalence

N/A

RISK FACTORS

- Therapy for prostate cancer
- Congenital absence of the testicles
- Inflammatory insults to the testicles
- Surgical injury or removal of the testicles
- Metabolic syndrome

Genetics

- Loss of libido may be associated with some of the genetic disorders/syndromes, listed below:
  - 17α-Hydroxylase deficiency
  - Autoimmune polyendocrine syndrome
  - Klinefelter syndrome
  - Inactivation of the luteinizing hormone (LH)-receptor gene
  - Mutations of steroid 5α-reductase gene

PATHOPHYSIOLOGY

- Psychological causes of diminished libido
  - Libido (sexual drive) is mediated by the cerebral cortex.
  - Psychological disturbances of all degrees, from anxiety to major psychiatric disorders
  - May be secondary to medical conditions (ie, congenital anomaly, disfiguring injury, etc.)
  - Erectile dysfunction may cause loss of libido
- Hormonal causes of diminished libido
  - Hypogonadism: Androgen deficiency, particularly testosterone, whether primary (testicular defect) or secondary to hypothalamic–pituitary dysfunction, Cushings syndrome
  - Hyperprolactinemia with or without pituitary lesion (1)[B]
  - Thyroid: Both hyper- and hypothyroidism can lead to diminished sexual desire

- Drugs: β-blockers, clonidine, diuretics, lithium, major tranquilizers, methyldopa, sedatives, ketoconazole, α-blockers, dihydrotestosterone inhibitors, cimetidine, antiandrogens, androgen analogs, selective serotonin reuptake inhibitors
- Temporal lobe epilepsy
- Prostatitis
- Chronic and serious diseases can lead to loss of libido through psychological or physiologic effects

ASSOCIATED CONDITIONS

- Erectile dysfunction (ED) and infertility may be associated with loss of libido and vice versa (2)[B].
- Hypothyroidism
- Alcoholism
- Syndromes, listed above in the Genetics section

GENERAL PREVENTION

N/A

DIAGNOSIS

HISTORY

- Sexual history:
  - Frequency and level of sexual desire
  - Difficulty in achieving or maintaining an erection
  - Evidence of ejaculation disorder, overall satisfaction with sexual life
  - If semen volume is normal, it is unlikely that endocrine factors are responsible for loss of libido
  - Sexual Health Inventory of Men (SHIM) score
- History of psychiatric illness
- Symptoms to suggest decreased testosterone: ED, increased irritability or depression, fatigue, reduced muscle mass and strength, inability to concentrate, decreased bone density/osteoporosis
- Previous/current medication
- History of endocrine disorder
- Therapy for prostate cancer
- Chronic alcoholism may result in decreased serum testosterone, testicular atrophy, and decreased libido.

PHYSICAL EXAM

- Assessment of secondary sexual characteristics.
  - Absence of secondary sexual characteristics suggests hormonal etiology.
- Detailed exam of external genitalia for abnormalities
- Assessment of testicular volume and atrophy

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum testosterone

- Serum prolactin
- If any disturbances of the above, then serum follicle-stimulating hormone and LH
- Serum-free T4 and TSH
- Serum GH and IGF-1 (primarily in children)
- Evlauation for increased cortisol if Cushing's is suspected

Imaging

MRI of the brain if prolactin is elevated

DIFFERENTIAL DIAGNOSIS

- Psychiatric disturbances
- Hormonal disturbances
- Drug induced
- Chronic and serious diseases

TREATMENT

GENERAL MEASURES

- Determine the cause and correct, if possible.
- Identify potential medications causing libido issues.
- Psychiatric consultation/sexual function therapist
- Endocrinology consultation

MEDICATION

First Line

- Decreased testosterone (3)[B]
  - Hormonal supplementation. For replacement dosing, see chapter on "Testosterone, decreased (hypogonadism)."
- Patients interested in sustaining fertility: Avoid exogenous testosterone; stimulate with human chorionic gonadotropin.
- If sexual dysfunction is identified as the cause: Phosphodiesterase inhibitors (sildenafil, tadalafil, etc.) are potentially useful 1st-line therapies
- Bromocriptine for prolactin-secreting tumors

Second Line

N/A

SURGERY/OTHER PROCEDURES

Only useful for pituitary adenomas causing hyperprolactinemia or in cases of Cushing's disease

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

L-arginine and yohimbine are touted but not proven

ONGOING CARE

PROGNOSIS

The prognosis is good when there is a treatable underlying cause for loss of libido. Otherwise it can be permanent.

COMPLICATIONS

Loss of libido can result in depression, infertility, and erectile dysfunction.

FOLLOW-UP

Patient Monitoring

Men treated with androgens should be followed closely with digital rectal exam and prostate-specific antigen every 6 mo

See Also (Topic, Algorithm, Media)

- Andropause (Late Onset Male Hypogonadism)
- Erectile Dysfunction
- Female Hypoactive Sexual Desire Disorder
- Testosterone, Decreased (Hypogonadism)

CODES

ICD9
- 302.71 Hypoactive sexual desire disorder
- 752.89 Other specified anomalies of genital organs
- 799.81 Decreased libido

ICD10
- F52.0 Hypoactive sexual desire disorder
- Q55.0 Absence and aplasia of testis
- R68.82 Decreased libido

CLINICAL/SURGICAL PEARLS
- Decreased libido can be from a number of causes (medications, hormonal or psychiatric disorders, etc.).
- A thorough history (including sexual history and SHIM score) and physical exam (assessment of secondary sex characteristics and testicular volume) are critical and can often point to a diagnosis.
- It is very important to distinguish decreased libido from other disorders of sexual function (arousal, erectile dysfunction, premature ejaculation, orgasm, and sexual pain disorders) but patients can often have multiple issues simultaneously.
- Surgery is usually designated for pituitary adenomas (ie, prolactinomas), which can be found on brain MRI.

LOWER URINARY TRACT SYMPTOMS

Matthew J. Resnick, MD
David F. Penson, MD, MPH

BASICS

DESCRIPTION

- The lower urinary tract infection (LUTS) complex includes both obstructive and storage urinary symptoms.
  - Obstructive urinary symptoms include urinary hesitancy, intermittency, post-void dribbling, and straining to void.
  - Storage urinary symptoms include urinary frequency, nocturia, and urinary urgency.
- While benign prostatic hyperplasia (BPH) frequently contributes to the development of LUTS, there are numerous other etiologies that must be considered in patients presenting with new urinary symptoms.
- LUTS may result from structural or functional abnormalities of the genitourinary tract.

EPIDEMIOLOGY

Incidence

- There is a well-described relationship between age and the development of LUTS.
- A few data specifically address the incidence of LUTS, given the basically negligible low case-fatality rate and the often slow onset of symptoms.

Prevalence

- Disease prevalence is highly variable due to differences in disease definition.
- The Olmsted County Study revealed age-dependent increases in the prevalence of moderate-to-severe LUTS from 26% (40–49 yr) to 46% (70–79 yr)
- 21.1% of patients in the National Health and Nutrition Examination Survey (NHANES) reported at least one symptom of LUTS.
- Various community-based studies estimate the age-stratified prevalence of moderate–to-severe LUTS in men as follows:
  - 40–50 yr old: ~20%
  - 50–60 yr old: ~30%
  - 60–70 yr old: ~40%
  - 70–80 yr old: ~50–60%

RISK FACTORS

- Bladder outlet obstruction (BOO; male)
  - Benign prostatic hyperplasia
  - Urethral stricture disease/bladder neck contracture
  - Prostate/bladder cancer
  - Bladder calculi
- BOO (female)
  - Pelvic organ prolapse
  - Bladder calculi

  - Urethral stricture disease
- Bladder (detrusor) hypocontractility
  - Idiopathic
  - Neurogenic
- Obesity, diabetes, and caffeine intake all have been associated with increased risk of LUTS

Genetics
- Increased risk of moderate-to-severe LUTS in men with a family history of BPH.
- The precise contribution of genetic and environmental factors to the development of LUTS remains largely unknown.

PATHOPHYSIOLOGY
- BOO necessitates generation of higher bladder pressures to overcome outlet resistance.
- Bladder "remodeling" secondary to longstanding outlet obstruction results in overactive bladder syndrome, storage symptoms, and over time, decreased contractility.
- LUTS may result from numerous conditions of the central and peripheral nervous systems.
- Result in either detrusor overactivity (storage symptoms) or detrusor hypocontractility (urinary retention/inadequate emptying).

ASSOCIATED CONDITIONS
Erectile dysfunction

GENERAL PREVENTION
NA

DIAGNOSIS

HISTORY
- Essential to quantify LUTS for both diagnosis and treatment planning
  - Use the validated AUA Symptom Score (AUASS) often referred to a the AUA Symptom Index [AUA-SI]) or International Prostate Symptom Score (I-PSS) (1–7 mild; 8–19 moderate; 20–35 severe)
  - Attention should be paid to nature (obstructive/storage) and duration of LUTS
- Consider voiding diary (frequency/volume charts) if the patient is unable to elaborate the nature of his or her symptoms
- Elicit history of prior urinary tract infection or prostatitis
- Elicit history of prior hematuria (gross or microscopic)
- Elicit history of prior urologic/pelvic surgery
  - Prior lower urinary tract intervention predisposes to stricture/bladder neck contracture
  - Disruption of pelvic plexus with pelvic surgery may result in detrusor hypocontractility
- Elicit history of other medical conditions
  - Neurologic disease—overactivity or bladder hypocontractility
  - Diabetes—bladder hypocontractility
  - History of sexually transmitted infection(s)—urethral stricture disease
  - History of pelvic radiation—urethral stricture disease or bladder hypocontractility
- Elicit family history of genitourinary disease (BPH/LUTS, prostate cancer, prostatitis)
- Review medications as certain antihistamines, antimuscarinics, sympathomimetics, and

bronchodilators may exacerbate LUTS.
- Elicit history of sexual dysfunction
- Evaluate overall fitness to undergo invasive procedure(s)

PHYSICAL EXAM
- Abdominal exam to assess suprapubic region for bladder distension
- Focused neurologic exam should be performed with particular attention to:
  - General mental status
  - Ambulatory status
  - Motor and sensory function of the lower extremities and perineum
  - Anal sphincter tone
- In men:
  - Inspection of the urethral meatus should be performed to rule out meatal stenosis
  - Digital rectal exam (DRE) should be performed to evaluate for:
    - Prostatic enlargement
    - Nodularity or firmness suggestive of prostate cancer
    - Bogginess or tenderness suggestive of prostatitis
    - Anal sphincter tone, abnormalities of which suggest neurologic disease
- In women:
  - Speculum exam should be performed to evaluate for mass, prolapse, and urethral abnormalities

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urinalysis should be performed to evaluate for urinary tract infection or hematuria.
- Serum PSA should be considered as a diagnostic test (as opposed to a screening test).
- Serum creatinine is not recommended in the evaluation of routine LUTS associated with BPH.

Imaging
- Imaging with CT or ultrasound (US) is not recommended as routine procedure.
- Upper tract imaging with either CT or US may be considered in the context of:
  - Acute symptom onset
  - History of upper urinary tract infection or stone disease
  - History of renal insufficiency
  - Recent onset of nocturnal enuresis
- Prostate imaging with transrectal or transabdominal US may provide information for treatment planning and is considered optional

Diagnostic Procedures/Surgery
- Assessment of post-void residual urine with US imaging or catheterization is optional.
  - May aid in the noninvasive assessment of bladder function
- Assessment of urinary flow rate is optional that may predict response to invasive therapy.
- Pressure flow urodynamic studies are not indicated in the evaluation of the uncomplicated patient with LUTS
  - May be useful in patients with mixed symptoms or neurologic disease to develop a therapeutic strategy

- Cystourethroscopy is not recommended for the uncomplicated patient with LUTS.
  - May be helpful to assess prostate configuration as it relates to invasive therapies
  - May be useful in patients with mixed symptoms or neurologic disease to develop a therapeutic strategy
  - May be useful in patients with a history suggestive of urethral stricture/bladder neck contracture

Pathologic Findings

Histopathology of BPH reveals proliferation of both stromal and glandular prostatic elements.

DIFFERENTIAL DIAGNOSIS

- BOO:
  - Urethral Stricture/bladder neck contracture
  - Bladder stone
  - Cancer (prostate, bladder, urethral)
  - Prostatitis
  - Urinary tract infection
  - Detrusor-sphincter dyssynergia
  - Pelvic organ prolapse
- Detrusor hypocontractility
  - Diabetes mellitus
  - Parkinson disease
  - Multiple sclerosis
  - Radiation cystitis
  - Spinal cord injury
  - Lumbosacral disc disease
  - Bladder stone

TREATMENT

GENERAL MEASURES (1,2)

- Treatment should be offered to men with moderate to severe symptoms (AUASS or IPSS ≥ 8) who are bothered enough to consider therapy.
- Men with demonstrable sequelae of BPH/BOO (renal failure secondary to obstruction, bladder calculi, etc.) should be counseled on benefits of treatment.
- Treatment is tailored to symptom type (obstructive, storage, mixed).

MEDICATION

First Line

- α-Adrenergic blockers: relax prostatic/bladder neck smooth muscle tone and improve symptoms (all appear to have equal effectiveness)
  - Alfuzosin 10 mg/d
  - Doxazosin start 1 mg/d to max. 8 mg
  - Silodosin 8 mg/d
  - Tamsulosin start 0.4 mg to max. 0.8 mg
  - Terazosin start 1 mg/d to max. 20 mg

  - Side effects include syncope, orthostasis, retrograde ejaculation, asthenia, and nasal congestion
- 5α-Reductase inhibitors: reduce prostatic volume
  - Finasteride or dutasteride
  - Side effects include decreased libido and sexual dysfunction
  - Reduce PSA by ~50% and correction should be used when evaluating risk for cancer
- Combination therapy (α-adrenergic blocker + 5α-reductase inhibitor) should be considered in men with moderate to severe symptoms and prostatic enlargement.
- Tadalafil 2.5–5 mg/d can treat combined LUTS and erectile dysfunction (ED).
- Antimuscarinic agents can be used alone or in combination for overactivity/storage symptoms

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Urethroplasty or directly visualized incision of urethral stricture (DVIU) should be considered for stricture/bladder neck contracture
- Prolapse repair should be considered for women with urinary symptoms and prolapse
- Numerous surgical options exist for men with BPH/BOO. Some of these include:
  - Transurethral resection of the prostate (TURP)
  - Transurethral microwave therapy (TUMT)
  - Transurethral laser vaporization of the prostate
  - Transurethral laser enucleation of the prostate
  - Simple open or laparoscopic prostatectomy (generally reserved for men with prostate volume > 80–100 cc)
- There are a few high-quality comparative-effectiveness data upon which clinical decisions can be based
  - Patients and physicians must weigh potential benefits and harms of treatments.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Behavioral interventions including timed voiding, double voiding, and biofeedback may improve symptoms.

Complementary & Alternative Therapies

Saw palmetto is widely used to treat LUTS with little benefit in randomized trials (CAMUS trial) (3).

ONGOING CARE

PROGNOSIS

- 20% of men with untreated LUTS experience progression within 5 yr (MTOPS trial). Options for men with BPH/BOO include:
  - Combination therapy reduces risk of progression by 66% (2).

• 5–10% of men with moderate-to-severe LUTS will require surgical intervention (MTOPS).

COMPLICATIONS

• Complications of BPH/LUTS include:
  – Recurrent UTIs
  – Renal insufficiency
  – Bladder stone formation
  – Urinary retention
  – Secondary bladder dysfunction

FOLLOW-UP

Patient Monitoring

• Monitoring with serial AUASS or IPSS to quantify symptom intensity and bother
• Urinalysis, serum PSA, urinary flow rate, and post-void residual as clinically indicated

Patient Resources

Urology Care Foundation. http://www.urologyhealth.org/urology/index.cfm?article=59&display=1

CODES

ICD9

• 788.41 Urinary frequency
• 788.64 Urinary hesitancy

- 788.99 Other symptoms involving urinary system

ICD10

- R35.0 Frequency of micturition
- R39.9 Unsp symptoms and signs involving the genitourinary system
- R39.11 Hesitancy of micturition

CLINICAL/SURGICAL PEARLS

- Quantification of symptoms is paramount in the management of LUTS.
- Treatment should be offered to men with moderate to severe symptoms (AUASS ≥ 8).
- Treatment should be tailored to symptoms and prostate volume and may include behavioral intervention, medical management, or surgical intervention.

LYMPHADENOPATHY, INGUINAL

Michael E. Woods, MD
Raj S. Pruthi, MD, FACS

BASICS

DESCRIPTION

- Clinically evident inguinal lymphadenopathy can be secondary to infection, inflammation, or malignancy.
- Lymph nodes (LNs) are generally considered enlarged if >1 cm.
- There is a <1% annual incidence of unexplained peripheral (including inguinal) lymphadenopathy.
- 14% of all abnormal lymphadenopathy present in inguinal region

EPIDEMIOLOGY

Incidence

- Malignancy
  - Penile cancer (1)[A]
    - 0.4–0.6% of male cancers in USA
    - Median age at diagnosis: 68 yr
    - 50% of enlarged LN secondary to cancer
  - Lymphoma: ~80,000 cases/yr in USA
- Infectious (STD/STI) (2)[A]
  - Approximately 15 million new Sexually Transmitted Infections (STI) cases/yr in USA
  - Chancroid (*Haemophilus ducreyi*)–24 cases reported to the CDC in 2010
  - Herpes simplex–775,000 cases/yr, 16% of 14–49-yr olds infected with HSV-2
  - Lymphogranuloma venereum (LGV)–relatively rare; rise in USA and UK associated with men who have sex with men and persons with HIV
  - Syphilis–In 2011, USA, men 8.2/100,000; women 1/100,000
  - HIV–1.1 million people in USA infected
  - Gonorrhea: 2nd commonest STI in USA
- Infectious (soft tissue of the leg/foot)
  - Common causes: β-hemolytic streptococci and *Staphylococcus aureus*

RISK FACTORS

- Penile Cancer
  - Circumcision (neonatal circumcision is protective)
  - Poor genital hygiene; phimosis
  - Number of sexual partners
  - Human papilloma virus (HPV) infection (type 16 and 18)
  - Incidence of LN metastases related to grade, stage, and lymphovascular invasion
- STI: High-risk sexual practices (ie, nonuse of condom, multiple partners, men who have sex with men)

PATHOPHYSIOLOGY

- Inguinal lymph nodes (ILNs) serve at the primary lymphatic drainage for the penis, scrotum, urethra, vulva, vagina, perineum, gluteal region, lower abdominal wall, lower anus, and lower extremities.
- ILNs lie within the femoral triangle (inguinal ligament, sartorius, and adductor longus) and are separated into superficial and deep groups by the fascia lata of thigh.
- Penile squamous cell carcinoma (SCC) cancer spreads by a relatively reliable pattern: From superficial pelvic LNs to deep pelvic LNs

ASSOCIATED CONDITIONS

- Balanitis
- Phimosis
- Additional sexuallt transmitted infections (STI's)

GENERAL PREVENTION

- Prepubertal circumcision is protective against penile cancer
- Good genital hygiene
- STD education and safe sexual practices
- Sun protection against melanoma
- HPV vaccination may reduce risk (unproven)

DIAGNOSIS

HISTORY

- Constitutional symptoms: Weight loss, night sweats
- Age: Penile cancer is more likely in older individuals, STI more common in younger patients
- Sexual history: Number and sex of partners, condom use
- Travel: International travel is common source of STI and other endemic diseases.
- Ethnicity: Higher penile cancer in South America
- History of other diseases, malignancy, lower extremity trauma, animal exposure

PHYSICAL EXAM

- Cachexia: Suggests systemic illness
  - HIV, lymphoma
- Generalized lymphadenopathy (neck, axilla)
  - Signs of systemic process (HIV, lymphoma)
- Abdominal exam
  - Palpable masses, splenomegaly
- Lower extremities bilaterally for lesions
- Inguinal exam
  - Size, fixation of LNs
  - Erythema, tenderness, warmth, drainage/purulence
- Genital exam
  - Penis, glans, foreskin, scrotum for lesions
  - Erythema, drainage, purulence, abscess
  - Ulcers (can be secondary to herpes, chancroid, granuloma inguinale, syphilis, neoplasias); vesicles with herpes

- Formal pelvic exam in women

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Suspected malignancy
  - CBC, basic metabolic panel, liver function testing (LFT's)
- Infectious/STD (2)
  - Gonococcus
    - Nucleic acid amplification testing (ie, polymerase chain reaction [PCR]) of vaginal samples, urine, urethral samples—98% sensitive
    - Culture–72–95% sensitive, perform if drug resistance is suspected
  - Syphilis
    - Darkfield microscopy of primary chancre, screen with nontreponemal test (RPR, VDRL) confirm with treponemal test (FTA-ABS)
  - Herpes simplex
    - Viral culture of active lesion (50% sensitive)
    - PCR of specimen from genital ulcer
    - Direct fluorescent antibody of specimen
    - Serology for HSV-1/2 (90% and 95% sensitivity and specificity, respectively)
  - LGV: Culture *Chlamydia trachomatis* from ulcer or LN aspirate
    - Serologic identification with complement fixation or microimmunofluorescence; PCR
  - Chancroid: *H. ducreyi* culture (75% sensitive)
    - PCR >95% sensitive/specific (non-FDA approved)
  - HIV: Serology for IgG antibody to HIV-1 antigens (positive test confirmed via western blot assays)

Imaging

- CT abdomen/pelvis: Extent of disease
  - Evaluates other sites of lymphadenopathy lymphoma
- CT chest/CXR: Staging in setting of malignancy
- Inguinal US: Evaluate solid vs. cystic lesions; identify abscess

Diagnostic Procedures/Surgery

- Excisional biopsy of abnormal LN or primary lesion (preferred)
- Percutaneous biopsy/aspiration of abnormal LN
- Bone marrow biopsy (lymphoma workup)

DIFFERENTIAL DIAGNOSIS

- Nonspecific lymphadenitis
- Malignancy: In a historic study of over 200 patients the order of malignancy in inguinal lymphadenopathy was: Cutaneous malignancy of lower extremity (melanoma), cervical, vulva, cutaneous malignancy of the trunk, rectum/anus, ovary, and penile cancer.
- Infectious
  - Soft-tissue infection of the lower extremity (ie, *Staphylococcus*)
  - STD (HIV, gonococcus, herpes simplex, chancroid, LGV, syphilis)
- With more generalized lymphadenopathy consider a systemic disease
  - Infections: Epstein–Barr, toxoplasmosis, cytomegalovirus, mycobacteria (TB, etc.),

mononucleosis
  - Lymphoma, lupus
- Medications: Cephalosporins, others

TREATMENT

GENERAL MEASURES

- Generalized lymphadenopathy should be referred for global evaluation.
- A period of observation for localized lymphadenopathy is reasonable if there are no other clinical findings.
- Penile cancer requires treatment of primary lesion (based on size and location), followed by inguinal lymphadenectomy if indicated.
- Infectious etiologies need to be accurately diagnosed so appropriate treatment can be initiated (see below).
- Gynecologic malignancies have a high predisposition for inguinal spread.

MEDICATION

First Line

- STD (2)[A]
  - Chancroid: Azithromycin 1 g PO ×1 or ceftriaxone 250 mg IM ×1 or ciprofloxacin 500 mg PO BID ×3 days or erythromycin base 500 mg PO TID ×7 days
  - Herpes simplex (primary): Acyclovir 400 mg PO TID ×7–10 days or acyclovir 200 mg PO 5×/day ×7–10 days or famciclovir 250 mg PO TID ×7–10 days or valacyclovir 1 g PO BID ×7–10 days
  - LGV: Doxycycline 100 mg PO BID ×21 days OR erythromycin base 500 mg PO QID ×21 days
  - Syphilis (primary and secondary): Benzathine penicillin G 2.4 million units IM ×1
  - Syphilis (late latent): Benzathine penicillin G 2.4 million units 1×/wk ×3 wk
  - Gonococcus: Ceftriaxone 400 mg IM ×1 plus azithromycin 1 g PO ×1 or doxycycline 100 mg PO BID ×7 days OR cefixime 400 mg PO ×1 plus azithromycin 1 g PO ×1 or doxycycline 100 mg PO BID ×7 days; if cephalosporin allergy: Azithromycin 2 g PO ×1
  - HIV: Antiretroviral drug regimens (see Section 1 “HIV/AIDS, Urologic Considerations” and latest CDC guidelines)

SURGERY/OTHER PROCEDURES

- Penile cancer (1)[A]
  - Management of primary lesion (local excision, partial penectomy, total penectomy)
  - Non-palpable ILNs
  - Up to 50% of all enlarged ILNs are benign in patients with newly diagnosed penile cancer. Treated with 6 wk of antibiotics (currently controversial) prior to consideration of inguinal lymph node dissection (ILND) or undergo a fine aspiration of the node in question if the primary tumor is low risk.
  - Occult metastases ~25%
    - TaG1-2/T1G1—surveillance
    - T1G2—surveillance vs. ILND or dynamic sentinel node biopsy (DSNB)
    - ≥T2 or any G3—ILND or DSNB

- Palpable ILNs
  - Low risk—consider fine-needle aspiration to confirm malignancy; Intermediate/high risk—ILND

- Inguinal lymphadenectomy techniques
  - Dynamic sentinel node biopsy (DSNB)
    - Use of blue dye + γ-emission (radio nuclide tracer)
    - False-negative 5%; expertise required
  - Superficial ILND
    - Removal of LN above fascia lata
    - If lymph positive on frozen section, then compete ILND needed
    - Option for prophylactic ILND
  - Modified ILND
    - Appropriate for prophylactic ILND
    - Decreased morbidity
    - Limited template (lateral border femoral artery, caudal border fossa ovalis)
    - Includes deep nodes medial to femoral vein
    - Smaller incision; preserve saphenous vein
    - Avoids transposition of sartorius muscle
    - Positive on frozen, then standard ILND
  - Radical/standard ILND
    - Indicated for patient with metastatic disease to the ILNs
    - Larger template including tissue lateral femoral artery and distally to apex of the femoral triangle
    - Routine division of saphenous vein and sartorius transposition; higher morbidity
- Infectious etiology
  - Fine-needle aspiration for culture
  - Incision and drainage of abscess
- Lymphoma
  - Excisional biopsy of ILN (may consider other site if generalized lymphadenopathy is present)

ADDITIONAL TREATMENT

Radiation Therapy

Penile Cancer: Palliation of bulky, unresectable inguinal lymphadenopathy

Additional Therapies

- Penile cancer
  - Patients with fixed ILN or pelvic LNs should receive cisplatin-based chemotherapy followed by consolidative surgery when appropriate (3)[C]
    - Paclitaxel, ifosfamide, cisplatin—50% complete response (CR) or partial response (PR) and ~75% underwent planned surgery

ONGOING CARE

PROGNOSIS

- Penile Cancer

– Node negative: 46–100% 5-yr survival (mean ~75%)
– Node positive: 0–86% 5-yr survival based on nodal burden (average ~60%)

COMPLICATIONS

- ILND
  – Seroma, lymphedema, wound infection, skin necrosis
  – 25–50% risk

FOLLOW-UP

Patient Monitoring

- Penile Cancer (1)[A]
  – Nx (surveillance)
    ◦ Q3mo yr 1–2 then Q6mo yr 3–5
  – N0, N1
    ◦ Q6mo yr 1–2 then Q12mo yr 3–5
  – N2, N3
    ◦ Q3–6mo yr 1–2 then Q6–12mo yr 3–5
- Infectious (2)[A]
  – Chancroid–3–7 days after initiating treatment
  – LGV–evaluate for clinical resolution, timing variable
  – Syphilis–clinical and serologic evaluation at 6 and 12 mo
  – Gonorrhea–none if symptoms resolve

Patient Resources

CODES

ICD9

- 187.4 Malignant neoplasm of penis, part unspecified
- 202.80 Other malignant lymphomas, unspecified site, extranodal and solid organ sites
- 785.6 Enlargement of lymph nodes

ICD10

- C60.9 Malignant neoplasm of penis, unspecified
- C85.90 Non-Hodgkin lymphoma, unspecified, unspecified site
- R59.0 Localized enlarged lymph nodes

CLINICAL/SURGICAL PEARLS

- Differentiate inguinal adenopathy from more generalized LN involvement.
- The viability of the skin flaps developed during an inguinal dissection are based on the anastomotic vessels within the superficial fatty layer of Camper's fascia which course lateral to medial along the skin lines. This is a key anatomic dissection plane as the lymphatic drainage of the penis lies beneath Camper's fascia allowing this superficial fatty layer to remain attached to the skin flaps.
- Use a modified technique in a clinically negative groin to decrease morbidity. The key components: Shorter incision (~10 cm), preserve saphenous vein, minimize dissection lateral to the femoral artery, and avoid transposition of the sartorius muscle.

LYMPHADENOPATHY, PELVIC AND RETROPERITONEAL

Carrie L. Fitzgerald, DO, MPH
James A. Brown, MD, FACS

BASICS

DESCRIPTION

- Enlarged nodal tissue in the pelvis and/or retroperitoneum
- Can be regional or generalized
- Definitions vary, but include solitary node ≥1–1.5 cm in short axis, any rounded node >8 mm or multiple nodes >1 cm (1).
- Pelvic lymph nodes (LNs) are generally considered abnormal if >1.3 cm.
- Often discovered incidentally or with imaging performed for tumor staging.
- Usually nonacute, but potentially life threatening.

EPIDEMIOLOGY

Incidence

- Lymphoma is the most frequent malignant tumor in the retroperitoneum. Non-Hodgkin lymphoma (93.7%) occurs more commonly than Hodgkin lymphoma (6.3%).
- Other common causes of retroperitoneal lymphadenopathy are malignancies, infections of retroperitoneal and pelvic organs and external genitalia.

Prevalence

No consistency in literature

RISK FACTORS

- Tumor-associated syndromes:
  - Renal cancer:
    - von Hippel–Lindau (VHL)
    - Hereditary papillary renal carcinoma (HPRC)
    - Hereditary leiomyomatosis and renal cell cancer (HLRCC)
    - Birt–Hogg–Dube (BHD)
    - Hereditary paraganglioma and pheochromocytoma (HPP)
    - Tuberous sclerosis complex (TSC)
- Adrenal cancer:
  - Gardner syndrome
  - Beckwith–Wiedemann syndrome (associated with hemihypertrophy)
  - Multiple endocrine neoplasia type 1
  - SBLA syndrome (Sarcoma, Breast, Lung, Adrenal carcinoma)
  - Li–Fraumeni syndrome
- Urothelial cancer
  - Hereditary nonpolyposis colorectal cancer (HNPCC)
  - Hereditary retinoblastoma
  - Costello syndrome
  - Possibly Apert syndrome

- **Prostate cancer**
  – Hereditary breast and ovarian syndrome (HBOS)
- Patients with primary tumors of GI, GU, and GYN tracts and associated risk factors for these malignancies
- Smoking, age, family history, HPV
- Immunosuppression (HIV, autoimmune)
- Lymphadenitis seen with inflammatory/infectious conditions of the pelvis

Genetics
- Ureteral obstruction
- IVC compression +/– lower extremity edema
- DVT
- Await genetics consult for others
- VHL: 3p25-26
- HPRC: 7q31
- HLRCC: Long arm of chromosome 1
- BHD: 17p11.2
- Hereditary paraganglioma and pheochromocytoma (HPP)
- Tuberous sclerosis complex: TSC, TSC1, 9q34.13; TSC2, 16p13.3

PATHOPHYSIOLOGY
- Most adenopathy incidental; may be regional or generalized
- Usually one of five causes: Malignant, infectious, autoimmune, inflammatory (reactive), iatrogenic

ASSOCIATED CONDITIONS
See risk factors

GENERAL PREVENTION
Resolution of primary source

DIAGNOSIS

HISTORY
- Constitutional: Weight loss, night sweats (especially with lymphoma), fatigue, fever
- Local compressive symptoms: Bowel obstruction, hydronephrosis/pyelonephritis/uremia, lower limb edema (vascular/lymphatic compromise)
- Severe infection on perineum/pelvis may result in inguinal/pelvic adenopathy
- History of primary GU, GI, or GYN tumor
- Paraneoplastic syndromes (ie, breast tenderness, anemia, etc.)
- Immunocompromised states raise risk of mycobacterial infection, lymphoma, or Kaposi sarcoma

PHYSICAL EXAM
- Evaluate for peripheral lymphadenopathy (neck, supraclavicular, inguinal, axillary)
- Chest: Clear breath sounds, breast tissue, or tenderness
- Abdominal/pelvic exam: Meta/menorrhagia, palpable mass, bruits, thrills
- GU/GI exam: Testicular mass, right-sided varicocele, penile lesions, digital rectal exam

(DRE), perineal cellulitis/abscess, fecal occult blood testing, hematuria, pelvic exam in females
- Skin: Rash, lesions (malignant, benign), ie, melanoma
- Lower extremity edema

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC, ESR, exam of peripheral smear
- Creatinine (for imaging and to check renal function)
- Urinalysis for hematuria
- Urine cytology
- Tumor markers:
  - PSA: Prostate cancer
  - AFP, β-hCG, LDH: Testicular cancer
  - CA-125: Ovarian cancer
  - CEA: Colon cancer

Imaging

- May diagnose cause of adenopathy (ie, renal mass)
- Ultrasound: Can pick up larger masses; false-negatives are significant
- CT/MRI: More sensitive than US (1)[A]
  - Nodes <7–10 mm considered reactive
  - CT generally considered best; use MRI if contrast contraindicated
- PET: Evaluate fibrosis from metabolically active nodes, ie, postchemotherapy testicular cancer, seminoma (2); expanding role (3)
  - Some studies show PET can define testicular relapse before CT.
- SPECT: Advances in lymphoscintigraphy have advanced opportunity for LN resection in select GU malignancies (1).
- Bipedal lymphangiography largely replaced by CT and MRI.

Diagnostic Procedures/Surgery

- Nodal tissue exam unless diagnosis is clear (ie, testicular or prostate tumor), then size or function and physiology becomes important (1).
- CT-guided biopsy best way to obtain nodal tissue.
  - Not always feasible (ie, proximity to major vessels), open/laparoscopic in select cases
- CT/MRI or SPECT imaging

Pathologic Findings

Numerous, depends on cause (see below)

DIFFERENTIAL DIAGNOSIS

- Tumor
  - Primary lymphatic: Lymphoma (non-Hodgkin, Hodgkin, others)
  - Secondary: Adrenal, renal, urothelial and nonurothelial bladder or upper tract cancer, prostate, urethral, penile, germ cell, cervical, ovarian, uterine, GI (carcinoid, lymphomas), colorectal, melanoma, Kaposi sarcoma
- Infectious/inflammatory

  - Granulomatous: TB, sarcoidosis, histoplasmosis, lymphogranuloma venereum, Castleman disease (angiofollicular LN hyperplasia associated with HIV and human herpesvirus 8 [HHV-8]).
  - Nongranulomatous: Viral, bacterial (if abscess in local areas), sinus histiocytosis, retroperitoneal fibrosis
- Other: Neoplastic, non-neoplastic, and cystic retroperitoneal masses (lymphocele, urinoma, hemorrhage) aneurysms

TREATMENT

GENERAL MEASURES
- Wide variety, based on diagnosis of primary disease
- Image-guided needle biopsy, as a 1st-line investigation, is useful in the diagnosis of space-occupying lesions of the retroperitoneum
- Routine lymphadenectomy usually indicated for GU malignancy

MEDICATION
First Line
Based on diagnosis of primary disease

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Open or laparoscopic nodal sampling may be required in select cases
- Lymphadenectomy at time of organ-specific resection indicated in many cases of GU, GYN, and GI malignancy

ADDITIONAL TREATMENT
- Underlying cause must be treated appropriately
- Benign reactive lymphadenopathy can be seen in the presence of malignancy and improves with appropriate treatment
- Lymphadenectomy for malignant lymphadenopathy does not always affect overall survival (4).

Radiation Therapy
For certain causes such as seminoma

Additional Therapies
- In select cases, reimaging for signs of growth or assessing therapeutic response, eg, hormonal therapy for prostate cancer, antibiotics for penile cancer
- Notification of partners if HIV-positive (3)[A]

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS

Widely variable

COMPLICATIONS

- Severe lymphadenopathy can result in lower extremity edema, varicocele
- Potential surgical complications of retroperitoneal lymphadenectomy include vascular injury, lymphocele, chylous ascites, ejaculatory dysfunction, and GI complications (pancreatitis, bowel injury/obstruction)

FOLLOW-UP

Patient Monitoring

Based on primary disease

Patient Resources

N/A

- Lymphadenopathy, Pelvic and Retroperitoneal Images ☼
- Retroperitoneal Mass and Cysts

CODES

ICD9

- 202.80 Other malignant lymphomas, unspecified site, extranodal and solid organ sites
- 567.9 Unspecified peritonitis
- 785.6 Enlargement of lymph nodes

ICD10

- C85.90 Non-Hodgkin lymphoma, unspecified, unspecified site
- K65.9 Peritonitis, unspecified
- R59.0 Localized enlarged lymph nodes

CLINICAL/SURGICAL PEARLS

- General malignancies (testis, penile) have predictable lymphadenopathy pattern of spread.
- Pelvic organ malignancies may have skip lesions to the retroperitoneum.
- Lymphadenectomy may be curative for many urologic and nonurologic malignancies.
- Urinary, bowel, and vascular obstruction possible with advanced lymphadenopathy.
- Inflammatory and infectious conditions may lead to reactive lymphadenopathy.

LYMPHOCELE, PELVIC

Rafael E. Yanes, MD
Fernando J. Bianco, Jr, MD

BASICS

DESCRIPTION

- A lymphocoele is a localized encapsulated collection of lymphatic fluid created by disruption of lymphatic vessels.
- A collection of lymph fluid in a cavity that is not lined by epithelium
- Generally occurs following surgery such as pelvic or retroperitoneal lymphadenectomy or renal transplantation

EPIDEMIOLOGY

Incidence (1)

- Incidence: 0.6–18% after renal transplant
- Clinical incidence: 1–10% after pelvic lymphadenectomy
  - May be up to 20–25% if all patients were imaged postoperatively
- After robot-assisted laparoscopic lymphadenectomy (RA-PLND) is about 5%, half becoming symptomatic

RISK FACTORS

- Recent pelvic surgery (ie, PLND, open or laparoscopic), renal transplant, retroperitoneal lymph node dissection (RPLND), RA-PLND, gynecologic procedures:
  - Extended PLND > conventional PLND
  - Extraperitoneal > transperitoneal procedures
  - Risk increases linearly with the number of nodes retrieved.
- Prior radiation or chemotherapy
- Anticoagulation or antiplatelet therapy may increase risk
- Long-term use of steroids
- Presence of involved lymph nodes

PATHOPHYSIOLOGY

- Lymphatic fluid collects in the extraperitoneal space due to continued lymphatic leakage.
- Transperitoneal pelvic lymphadenectomy is less commonly associated with the development of a lymphocele but can occur.
- Fluid is chylous in nature.
- Occurs in up to 20% of kidney transplant recipientscaused by leakage from lymphatic vessels transsected during the transplant surgery

ASSOCIATED CONDITIONS

- Bladder cancer
- Gynecologic malignancy
- Penile cancer
- Prostate cancer

- Renal cancer
- Renal insufficiency with transplantation
- Retroperitoneal metastasis

GENERAL PREVENTION

- Meticulous lymphadenectomy with clips on proximal end of lymphatic vessels.
  - Monopolar electrocoagulation may not adequately seal lymph channels.
  - Bipolar or harmonic devices have been shown to be effective (bipolar devices created seals that were fivefold to 10-fold stronger than the harmonic devices)
    - These vessel-sealing devices (VSDs) may reduce risk.
  - Use of FloSeal or other hemostatic products after lymphadenectomy may reduce the number of symptomatic lymphoceles.
- Some reports that the use of anticoagulants (eg, subcutaneous heparin) postop may increase lymphocele risk.
  - Use of low-dose heparin in this setting when injected in the upper arm may reduce lymphocele risks.
- Use of suction drains does not appear to impact the development of lymphoceles.

DIAGNOSIS

HISTORY

ALERT

Lymphoceles can occur after transperitoneal laparoscopic, robot-assisted surgery.

- Recent pelvic surgery, particularly involving lymphadenectomy
- Prior chemotherapy or pelvic radiation
- Timing of onset of symptoms:
  - Urine leak (urinoma), hematoma, abscess, and peritonitis typically present early
  - Lymphocele can present early in the postop period, but may present several weeks or months after surgery
- Urinary frequency (if compressing bladder)
- Sensation of pelvic fullness
- Constipation
- Flank or abdominal pain (40%)
- Lower-extremity pain/swelling (37%)
- Ileus
- Fever (47%)

PHYSICAL EXAM

- Palpable abdominal mass or lower abdominal tenderness
- Lower-extremity edema
  - Painful leg swelling suggests deep venous thrombosis (DVT).
  - Lymphocele-related, lower-extremity swelling is usually not painful.
- Peno-scrotal or labial edema

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum creatinine, BUN (especially to follow renal function in transplant patient)
- Aspirated fluid creatinine and BUN, Gram stain and culture
- Lymphatic fluid typically contains protein, BUN, creatinine, electrolytes, and, occasionally, lipids as serum
- In contrast, urinoma has markedly elevated creatinine; lymphocele creatinine = serum creatinine

Imaging
- Key to diagnosis, but cannot distinguish between lymphocele and urinoma
- US: Imaging, lymphoceles appear as anechoic cystic structures that may contain thin septations and debris.
  - Pelvic: To identify fluid collection that is separate from the bladder, adjacent to renal allograft
  - Retroperitoneal: To evaluate hydronephrosis, if suspected
  - Ideal for follow-up of resolution
  - Duplex study of the lower extremities: To evaluate for DVT
- Pelvic CT: Best definition of size and location of lymphocele
  - Seen as thin-walled hypodense lesions
  - Negative Hounsfield units
  - Thickened, enhanced wall suggest infection
- IVP: May show displacement of ureter and compression of bladder, but is seldom necessary

Diagnostic Procedures/Surgery
- Lymphangiography/lymphoscintigraphy: If other studies unclear, historic value
- Diagnostic aspiration with count and cultures

Pathologic Findings
Lymph fluid in a fibrous cavity not lined by epithelium-containing lymphatic fluid.

DIFFERENTIAL DIAGNOSIS
- Abscess
- Cystic malignancy
- Hematoma
- Lymphocele
- Urinoma due to urinary leakage
- Seroma

TREATMENT

GENERAL MEASURES
- Treat DVT if present.
- Foley catheter if the patient has significant voiding dysfunction
- Asymptomatic small lymphoceles should be monitored (<100–150 mL volume). Many will resolve spontaneously.

MEDICATION
First Line
- Lymphocele management is primarily interventional with limited role for medications unless

associated with infection or sclerosis (see below) (2).
- Systemic antibiotics (with percutaneous drainage) if lymphocele is infected.

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Treatment of symptomatic or large lymphoceles is immediate percutaneous drainage (3).
  - Reported success rates with aspiration and drainage tube are approaching 80%, with a mean drainage duration ranging from a few days to several months.
  - Increased risk of infection, especially in immunocompromised (transplant) patients.
- Sclerosis therapy can be used to treat extraperitoneal lymphoceles
  - Sclerotherapy (povidone–iodine, 95% ethanol, tetracycline 0.5–2 g in 50 mL NS, bleomycin 1 U/mL, fibrin glue):
  - Cavity is aspirated, then filled gently with a sclerosing agent.
  - Sclerosis is usually contraindicated.
    - Multiseptated lymphoceles: Drainage, lack of access to all chambers
    - When the ureter is in close contact with a wall of the lymphocele (periureteral fibrosis, ureteral obstruction)
    - Incomplete lymphoceles should not be treated by sclerosis.
- Transperitoneal laparoscopic marsupialization (4)
  - If unsuccessful sclerosis or not amenable to percutaneous drainage
  - Three transperitoneal ports provide access for excision of the peritoneal window and optional omental wick placement to keep peritoneal window open.
  - Success: 77–100%
- Open marsupialization (internal drainage) into the peritoneum is the historic gold standard:
  - A window of peritoneum is excised, allowing the lymph to be reabsorbed by the peritoneum.
- Infected lymphoceles require percutaneous or open surgical drainage.
- Omentoplasty:
  - Placing a portion of omentum in the window decreases recurrence maintaining patency.
  - Success: 75–100%

ONGOING CARE

PROGNOSIS
- Most smaller asymptomatic lymphoceles resolve spontaneously.
- >90% success with marsupialization

COMPLICATIONS
- DVT/PE
- Lymphostasis of the lower extremity
- Infection
- Ureteral obstruction
- Bowel obstruction

FOLLOW-UP

Patient Monitoring
Repeat imaging: Ultrasound or CT in 2–4 mo after treatment to detect recurrence.

Patient Resource

- Urinoma (Perinephric Pseudocyst)

CODES

ICD9
457.8 Other noninfectious disorders of lymphatic channels

ICD10
I89.8 Oth noninfective disorders of lymphatic vessels and nodes

CLINICAL/SURGICAL PEARLS
- Use of clips on identifiable lymphatic channels can minimize the occurrence of postoperative lymphoceles.
- A transperitoneal approach for lymphadenectomy is not protective against the formation of a lymphocele because loculation of lymphatic fluid can still occur.
- Symptomatic lymphoceles may require percutaneous or laparoscopic drainage.

MEDULLARY CYSTIC KIDNEY DISEASE (MCKD)

Scott G. Hubosky, MD

BASICS

DESCRIPTION

- Medullary cystic kidney disease (MCKD) is a rare congenital, cystic disease of the kidneys which results in progressive renal deterioration and to eventual end-stage renal disease (ESRD)
- Symptoms develop insidiously and diagnosis is not common until renal insufficiency is detected and initiates evaluation (1)[C]

EPIDEMIOLOGY

Incidence

Less than 1: 100,000

Prevalence

N/A

RISK FACTORS

Positive family history

Genetics

- Mode of inheritance is autosomal dominant (2)[C]
  - Medullary cystic kidney disease-1 (MCKD1)
    - Mutation in MCKD1 gene localized to chromosome 1q21
  - MCKD2
    - Mutation in MCKD2 gene localized to chromosome 16p12

PATHOPHYSIOLOGY

- Unlike other renal cystic diseases such as autosomal dominant polycystic kidney disease (ADPKD), there is no clear correlation between genetic mutation and identifiable protein product responsible for the MCKD phenotype (3)[C]

ASSOCIATED CONDITIONS

- Hyperuricemia and gouty arthritis are associated with MCKD2
- In contrast to juvenile nephronophthisis, MCKD does not have many extrarenal manifestations

GENERAL PREVENTION

N/A

DIAGNOSIS

HISTORY

- Polyuria
  - Usually the 1st clinical manifestation
  - Occurs due to reduced urinary concentrating ability of the kidney

- Polydipsia
- Family history of ESRD, or renal cysts

PHYSICAL EXAM

Hypertension may be noted with disease progression

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis
  - Proteinuria and hematuria are usually absent
- CBC
  - Anemia present in advanced cases due to lack of erythropoietin
- Serum electrolytes
  - Elevated creatinine
  - Hyperkalemia or metabolic acidosis in later stages due to renal insufficiency

Imaging

- Renal ultrasound
  - Kidneys may be atrophic depending on stage of disease
  - Cysts may be visible at the corticomedullary junction in later disease but are usually not detectable in early stages
  - Increased parenchymal echogenicity from tubulointerstitial fibrosis
- CT scan
  - Can detect cysts at the corticomedullary junction better than ultrasound
  - Need for IV contrast is suboptimal in patients with ESRD

Diagnostic Procedures/Surgery

Percutaneous renal biopsy confirms the diagnosis

Pathologic Findings

- Gross findings
  - Initially before disease progression, the kidneys are of normal size
  - Cortical atrophy with progression
  - Cysts develop at the corticomedullary junction and range in size from 1 to 10 mm.
  - With disease advancement the kidneys become very small and demonstrate a granular exterior surface
- Microscopic findings
  - Interstitial nephritis
  - Dilated, atrophic tubules
  - Inflammatory cell infiltrates

DIFFERENTIAL DIAGNOSIS

- Juvenile nephronophthisis
  - Clinically and anatomically similar to MCKD
  - Autosomal recessive inheritance
  - ESRD usually manifests as early as age 13 yr
  - Extrarenal manifestations are common
    - Retinal disorders (retinitis pigmentosa)

    - Hepatic fibrosis
    - Bardet–Biedl syndrome (obesity, retinitis pigmentosa, mental retardation, polydactyly)
- Polycystic kidney disease
  – Autosomal recessive polycystic kidney disease (infantile form)
  – Autosomal dominant polycystic kidney disease (adult form)
- Multicystic dysplastic kidney
- Benign multilocular cyst (cystic nephroma)
- Medullary sponge kidney

TREATMENT

GENERAL MEASURES

- Same as for any patient with renal insufficiency
  – Control hypertension if present
  – Monitor fluid balance/daily weights
  – Monitor serum electrolytes

MEDICATION

First Line

- None for primary treatment
- Antihypertensive regimens sometimes necessary

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Dialysis when ESRD develops
- Renal transplant
  – Allograft is not affected by MCKD after transplantation

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- MCKD1 patients manifest with ESRD at median age of 62 yr
- MCKD2 patients manifest with ESRD at median age of 32 yr

COMPLICATIONS

Similar to any patient with renal insufficiency or ESRD

FOLLOW-UP

Patient Monitoring
Close nephrology follow-up is essential

Patient Resources

- 753.16 Medullary cystic kidney
- 788.42 Polyuria

ICD10
- N18.6 End stage renal disease
- Q61.5 Medullary cystic kidney
- R35.8 Other polyuria

CLINICAL/SURGICAL PEARLS
- MCKD has an insidious disease onset.
- Symptoms usually not present until patient has renal insufficiency documented on serum testing.
- Polyuria is commonly the 1st clinical manifestation.

MEDULLARY SPONGE KIDNEY (MSK)

Demetrius H. Bagley, MD, FACS
Kelly A. Healy, MD

BASICS

DESCRIPTION

Medullary sponge kidney (MSK) consists of developmental abnormalities of the kidneys with ectatic or dilated terminal collecting ducts and associated medullary cysts

EPIDEMIOLOGY

Incidence

N/A

Prevalence

- Estimated at 1 in 5,000–20,000 in the general population
- Occurs more frequently in stone formers ranging from 5 to 20%
- Identification and therefore recognized incidence of MSK may be decreasing since it depends on radiographic contrast studies to detect the dilated collecting ducts

RISK FACTORS

N/A

Genetics

Many cases may be sporadic:

- Increasing evidence suggests inheritability of the disorder, possibly of an autosomal dominance based on familial studies
- Mutations in glial cell–derived neurotropic factor (GDNF) account for roughly 12% of MSK cases (1)[B]

PATHOPHYSIOLOGY

- Dilated collecting ducts and medullary pyramidal cysts which may actually represent ectatic ducts
- Dilated ducts may be filled with calcium apatite crystal
- Distal renal tubular acidosis (DRTA) (33–40%)
- Hypercalciuria (9–100%)
- Hypocitraturia (19–83%)

ASSOCIATED CONDITIONS

- Renal calculi
- Urinary tract infections (UTIs)
- Hypocitraturia and hypercalciuria (as noted above)
- Reduced bone density (2)[B]

GENERAL PREVENTION

- This developmental condition cannot be prevented
- Secondary complications (infections, urolithiasis) can be prevented by appropriate measures

DIAGNOSIS

HISTORY

- Many patients are asymptomatic and are diagnosed incidentally on contrast studies
- Pain associated with renal/ureteral calculi
- Pain without associated obstructing calculi
- Hematuria, microscopic or gross

PHYSICAL EXAM

- May be normal without associated findings
- May have flank tenderness, especially among those with episodes of pain

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum electrolytes usually are normal except with significant distal renal tubular acidosis (DRTA) in which serum bicarbonate and potassium may be low
- Urinary study
  - Urinalysis
    - Microhematuria or pyuria
  - 24-hr urine collections
  - May show hypercalciuria (9–100%)
  - Hypocitraturia in 19–83%
- Stone composition commonly calcium oxalate in 33% (pure) to 63% (mixed)
- Most common mineral
  - Calcium oxalate monohydrate
- Calcium phosphate predominate in 63–67%

Imaging

- Diagnosis based on blush or “paint brush” appearance of dilated collecting ducts after contrast administration
- Intravenous urogram (IVU) or excretory urogram (EXU)
  - Multiple calcifications may appear in dilated ducts as nephrocalcinosis. Often seen on scout film and appear to reside within renal parenchyma
  - Plain film may be useful to detect the appearance of new calcifications
  - Typically bilateral but can occur on one side or in a single renal pyramid
- CT
- Noncontrast CT (NCCT) has largely replaced contrast studies (IVU, EXU) in the diagnosis urinary calculus disease
  - May demonstrate multiple calcifications and possibly localize them to the renal pyramids (3)[B]
  - CT urogram (CTU) may be most useful imaging study
  - After the injection of contrast for CTU, a blush of the involved papillae may be seen
- Renal ultrasonography (RUS)
  - Nondiagnostic for MSK in adults
  - Does not accurately distinguish intraparenchymal from intraluminal calcifications
  - May be used to detect obstruction in the symptomatic patient

Diagnostic Procedures/Surgery

- Endoscopy, specifically ureteroscopy differentiates intraluminal from intraparenchymal calcifications (4)[B]
- 24-hr urine studies to identify metabolic abnormalities

Pathologic Findings

- Typical sponge appearance of the medulla results from the dilated intrapapillary collecting ducts and small medullary cysts
  - Calcifications may be found in the dilated collecting ducts

DIFFERENTIAL DIAGNOSIS

- Dent disease
- Other rare abnormalities of calcium phosphate metabolism
- Primary hyperparathyroidism
- RTA

TREATMENT

GENERAL MEASURES

- Majority of asymptomatic patients can be observed
- General stone clinic measures including high fluid intake should be maintained
- Alkalinization with potassium citrate appears to be of value
- Other abnormalities such as hypercalciuria which do not resolve should be treated specifically
- Treat UTIs as necessary

MEDICATION

- Potassium citrate is employed in patients with hypocitraturia (5)
- Thiazide diuretics are used in patients with stones and nonresponsive hypercalciuria
- Specific antibiotics are indicated for the treatment of UTIs
  - Suppressive antibiotics may be necessary in patients with persistent or multiply recurrent UTIs

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Shock wave lithotripsy has been utilized for treatment of collecting duct stones that can be distinguished from nephrocalcinosis as well as symptomatic intraluminal calculi
- Endoscopy with ureteroscopy or occasionally percutaneous nephrostolithotomy can treat collecting system stones and unroof mucosa to remove obvious and accessible collecting duct stones
- SWL and endoscopy have been advocated to reduce the frequency of symptomatic episodes but is unproven

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Urinary calculi are the most common risk but can be followed and also may be controlled with medical treatment
- Recurrent UTIs can usually be treated
- Development of renal failure is very uncommon

COMPLICATIONS
- Stone formation and subsequent obstruction
- Recurrent/chronic flank pain
- UTI

FOLLOW-UP
Patient Monitoring
- Imaging at every 6–12 mo in stone formers to evaluate for change in existing stones or appearance of new ones
- In some patients, renal ultrasound (RUS) can be used to monitor stones and avoid radiation
- 24-hr urine collections are used to monitor stone risk factors during treatment for urinary abnormalities
- Serum studies are used to monitor changes related to medication

CLINICAL/SURGICAL PEARLS

• Be suspicious of MSK in patients with multiple papillary calculi.
• Use contrast study for diagnosis.
• Search for metabolic defects.
• Treat metabolic factors in stone formers.
• Consider treatment of renal stones in patients with recurrent symptomatic stones.
• Significant benefit in endoscopic inspection and treatment.

MEGAURETER, CONGENITAL

Ahmad H. Bani-Hani, MD, FAAP, FACS

BASICS

DESCRIPTION

- Megaureter is a ureter that is dilated out of proportion to the rest of the urinary tract
- Most consider ureters measuring ≥7 mm in diameter by ultrasound a megaureter
- Four types of megaureter are described:
  - Refluxing megaureter
  - Obstructed megaureter
  - Refluxing and obstructed megaureter
  - Nonrefluxing-nonobstructed megaureter
- Each of the above groups further categorized as either primary (defect lies in the ureter itself) or secondary (another disorder leading to megaureter such as urethral obstruction)
- Primary megaureter represents the 2nd most common cause of hydronephrosis in the newborn, with ureteropelvic junction obstruction the most common cause

EPIDEMIOLOGY

Incidence

- Varies depending on etiology
  - Vesicoureteral reflux (VUR): 0.4–1.8% in children
  - Primary obstructive megaureter (POM): 1 per 10,000 population
  - VUR is more common in females
  - POM is more common in males with predilection for the left kidney
  - Bilateral involvement in up to 40%

Prevalence

N/A

RISK FACTORS

- Posterior urethral valves
- Neurogenic bladder
- Diabetes insipidus

Genetics

- No specific genetic factors can be identified in the majority of patients with megaureters
- VUR can be familial

PATHOPHYSIOLOGY

- Refluxing megaureters
  - Caused by congenital abnormality of the intravesical ureter secondary to abnormal insertion of the ureter into the bladder or the intravesical portion of the ureter is not long enough to enable closure of the ureter during bladder filling
- POM:
  - Exact etiology is unclear, however, the most common finding is a distal adynamic ureteral

segment that affects the free efflux of urine resulting in a functional obstruction
- Refluxing, obstructed megaureter:
  - This paradox of pathology was 1st reported by Weiss and Lytton. The muscle cells in the intravesical and juxtavesical sections of the distal ureter are so lacking that they become incapable of adequate transmission of urine. On VCUG, delayed emptying of the refluxing contrast/sharp cut-off distally is highly suggestive of the diagnosis
- Nonrefluxing, nonobstructed megaureter
  - Transient dilatation of the ureter and/or renal pelvis. Renal parenchyma is preserved. Can be primary (idiopathic) or secondary to urosepsis (bacterial toxins can paralyze the ureteral muscle and produce atonic ureter) or polyuric kidney that lost its concentration ability, eg, following ablation of posterior urethral valves

ASSOCIATED CONDITIONS
- Posterior urethral valves
- Prune belly syndrome

DIAGNOSIS
HISTORY
- Most megaureters are diagnosed currently prenatally with ultrasound (asymptomatic)
- For late diagnosis, patients may present with abdominal pain, UTIs, or kidney stones

PHYSICAL EXAM
- Abdominal mass
- Abdominal pain and costovertebral angle tenderness with pyelonephritis

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urine analysis and culture if UTI is suspected
- Serum electrolytes, BUN, and creatinine
- C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) for pyelonephritis

Imaging
- Normally best to perform ultrasound imaging several days after birth to allow relative newborn dehydration to equilibrate
- Renal and bladder ultrasound:
  - Establishes the diagnosis of megaureter, assesses renal parenchyma and may provide clues on possible etiology eg, thickened bladder wall secondary to urethral valves
- Voiding cystourethrogram:
  - Will evaluate for the presence of VUR and urethral abnormalities such as anterior or posterior urethral valves
- Diuretic renal scan:
  - 99mTc-mercaptotriglycylglycine (MAG-3 scan)
  - Assesses renal function and presence of obstruction to the flow of urine
  - Furosemide washout correlates with the degree of obstruction
  - In general, a washout of >20 min after furosemide suggests obstruction

Diagnostic Procedures/Surgery

- Whitaker test (perfusion-pressure test):
  - More invasive as it requires percutaneous renal access
  - Will provide valuable information if the diuretic renal scan is equivocal
- Endoscopy: Invasive test as it requires anesthesia. Can be combined with transurethral resection of urethral valves if present

Pathologic Findings

- Varies with etiology
- With electron microscopy, the muscle population and the size of smooth muscle cells of megaureters can be measured
  - In obstructed megaureters, muscle hypertrophy and hyperplasia are expected. These changes are absent or minimal in refluxing megaureters and ureters associated with prune belly syndrome
  - Collagen fiber derangements can also be seen in primary obstructed megaureter (Increased collagen types I and III deposition)

DIFFERENTIAL DIAGNOSIS

- Bowel segment misinterpreted as dilated ureter
- Posterior/anterior urethral valves
- Prune belly syndrome
- Retrocaval/retroiliac ureter
- Ureteral stone
- Ureterocele
- Ureterovesical junction obstruction
- VUR

TREATMENT

GENERAL MEASURES

- Serial renal and bladder ultrasounds to monitor progress/resolution of megaureter is important
- Workup of megaureter to assess the presence or absence of reflux and/or obstruction will guide further treatment options
- Prenatally discovered megaureter
  - Unilateral obstructed megaureter has a good prognosis
    - These patients can be followed expectantly in the prenatal period, without further intervention or early delivery
    - Bilaterally obstructed megaureter findings require close monitoring for the development of oligohydramnios

MEDICATION

First Line

- Treat active UTI with culture appropriate antibiotics
- Consider prophylactic antibiotics in refluxing and obstructed megaureter variants (eg, Amoxicillin)

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Refluxing megaureters:
  - Antibiotic prophylaxis and monitor progress with renal ultrasound (RUS) and VCUG
  - Ureteral reimplant in cases of breakthrough UTIs, renal scarring, or noncompliance with medications
- Primary obstructed megaureter (1)[A]:
  - Excision of the distal adynamic ureteral segment and ureteral reimplant. Ureteral tapering maybe required
- Refluxing, obstructed megaureter:
  - Excision of the distal ureteral segment and ureteral reimplant. Often requires ureteral tapering
- Nonrefluxing, nonobstructed megaureter: Observation with serial ultrasound is all that is needed

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

- If the child is newborn or infant, temporizing the obstructing variant of megaureter can be achieved with:
  - Ureteral stent insertion
  - Cutaneous ureterostomy

ONGOING CARE

PROGNOSIS

- Depends on the baseline renal function (2)[A]
- Surgical correction of obstructing megaureters carries a high success rate
- Most nonobstructive, nonrefluxing megaureters will resolve with time
- Outcomes can be poor with concomitant renal anomalies such as renal hypoplasia and dysplasia

COMPLICATIONS

- UTIs
- Ureteral obstruction, mainly technical inattention to details during ureteral reimplant that will cause either:
  - Ureteral kinking at the bladder insertion site
  - Compromised blood supply to the distal ureter associated with excisional ureteral tapering
- Nephrolithiasis

FOLLOW-UP

Patient Monitoring

- Serial RUS (3)[A]
- Serial serum chemistry to monitor renal function

Patient Resources

CODES

ICD9

753.22 Congenital obstruction of ureterovesical junction

ICD10

Q62.2 Congenital megaureter

CLINICAL/SURGICAL PEARLS

- Wide spread use of prenatal ultrasound helps identify patients with megaureters at an early stage, commonly prenatally.
- It is important to classify megaureters based on their refluxing and/or obstructing status with the aid of VCUG and diuretic renal scan.
- Long-term follow-up in patients with megaureter is important for best outcome.

MESOBLASTIC NEPHROMA, CONGENITAL (BOLANDE DISEASE)

Lauren N. Hendrix, MD
Stephen E. Strup, MD, FACS

BASICS

DESCRIPTION

- Congenital mesoblastic nephroma (CMN) is a renal tumor arising from nephrogenic mesenchyme
- Usually a solid lesion, but cystic varieties have been reported
- Majority are benign with a favorable prognosis
- First reported in 1967, referred to in older literature as Bolande's tumor or Bolande disease

EPIDEMIOLOGY

Incidence

- Most common real tumor in children <6 mo of age, usually diagnosed prior to 3 mo
- Accounts for 3–10% of all pediatric renal neoplasms (1)
- More common in males (1)
- Usually unilateral
- Often detected prenatally by ultrasound

Prevalence

N/A

RISK FACTORS

Genetics

- ETV6-NTRK3 gene fusion
  - Results from translocation t (12;15) (p13;q25)
  - Found only in the cellular variant
  - Also found in congenital fibrosarcoma (2,3)

PATHOPHYSIOLOGY

- Tumor classification
  - Stage I: Tumor limited to kidney without involvement of capsule or hilar vessels
  - Stage II: Tumor extends beyond capsule with invasion into perinephric fat or blood vessels, but margins of resection are negative
  - Stage III: Tumor not completely resectable, tumor spillage occurs at time of resection, or tumor was biopsied preoperatively
  - Stage IV: Hematogenous metastases or lymphatic spread outside of abdomen
  - Stage V: Bilateral tumors

ASSOCIATED CONDITIONS

- Polyhydramnios
- Hydrops fet alis

DIAGNOSIS

HISTORY

- History of prenatal ultrasound finding of unilateral renal mass
- History of polyhydramnios
- Neonate with abdominal mass
- Hematuria, jaundice, hypertension, anemia, hypercalcemia

PHYSICAL EXAM

- Palpable abdominal mass
- Hematuria
- Jaundice

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Complete blood count
- Basic metabolic panel
  - Serum creatinine
  - Serum calcium
- Urinalysis

Imaging

- Abdominal ultrasound
  - Preferred modality
  - "Ring pattern"
    - Hypoechoic mass with hyperechoic rim signifying vessels at the tumor periphery
    - Seen only in the classic variant
  - Homogeneous or heterogeneous solid mass seen in cellular variant
- CT
  - Homogeneous mass
  - May have peripheral enhancement or focal enhancement at sites of hemorrhage or necrosis
- MRI
  - Signal similar to normal parenchyma with exception of areas of hemorrhage (4)

Diagnostic Procedures/Surgery

- Biopsy
  - The role of biopsy in pediatric renal tumors is controversial as nephrectomy is the mainstay of treatment and preoperative biopsy upstages to stage III

Pathologic Findings

- Three histologic subtypes
  - Classic
    - 1/3 of cases
    - Similar macro- and microscopically to leiomyoma
    - Entrapped nephrons and blood vessels seen at the tumor periphery
    - Not associated with metastasis
  - Cellular

- 2/3 of cases
- More aggressive than classic with high mitotic index and atypical growth pattern
- Associated with local invasion/recurrence and metastasis

– Mixed (3)

DIFFERENTIAL DIAGNOSIS

- Solid renal mass
  – Wilms tumor
  – Rhabdoid tumor
  – Metanephric adenofibroma
  – Renal cell carcinoma
  – Angiomyolipoma
  – Clear cell sarcoma
  – Multilocular cystic nephroma
- Autosomal recessive polycystic kidney disease
- Cross-fused ectopia
- Renal vein thrombosis
- Solitary kidney with compensatory hypertrophy
- Beckwith–Weidemann syndrome
- Adrenal mass
- Retroperitoneal mass (3)

TREATMENT

GENERAL MEASURES

- Management of associated features
  – Hypertension
  – Hypercalcemia
  – Jaundice
  – Anemia
- Chemotherapy reserved for patients >3 mo with cellular variant, tumor spillage at resection, microvascular invasion, metastatic disease, and inoperable tumors

MEDICATION

First Line

- Vincristine, cyclophosphamide, and doxorubicin (VCD)
- Vincristine, doxorubicin, and actinomycin D (VDA)

Second Line

- Isophosphamide, carboplatin, etoposide (ICE)
  – Has considerable nephrotoxicity (3)

SURGERY/OTHER PROCEDURES

- Radical nephrectomy
  – Gold standard
  – Allows for appropriate staging
  – Decreased risk of local recurrence

- Partial nephrectomy
  - Has been reported with success in Wilms tumors but not CMN

ADDITIONAL TREATMENT

Radiation Therapy

No defined role

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Radical nephrectomy generally curative
- Classic variant favorable
- Metastases and local recurrence possible with cellular type, but rare
- Risk factors for recurrence: Cellular variant, older patient age, tumor spillage during resection, and positive surgical margins (3)

COMPLICATIONS

- Prenatally
  - Polyhydramnios
  - Hydrops fet alis
  - Intrauterine fet al demise
- After birth
  - Hypertension
  - Hemodynamic instability
  - Respiratory distress

FOLLOW-UP

Patient Monitoring

Regular abdominal ultrasound for 1 yr in classic variant and longer in cellular variant

CODES

ICD9

236.91 Neoplasm of uncertain behavior of kidney and ureter

ICD10

- D41.00 Neoplasm of uncertain behavior of unspecified kidney
- D41.01 Neoplasm of uncertain behavior of right kidney
- D41.02 Neoplasm of uncertain behavior of left kidney

CLINICAL/SURGICAL PEARLS

- Most common solid renal tumor <6 mo of age.
- Radical nephrectomy is generally curative.

MICROPENIS (MICROPHALLUS)

Bruce J. Schlomer, MD
Laurence S. Baskin, MD, FACS, FAAP

BASICS

DESCRIPTION

- A micropenis refers to a stretched newborn penis that is <2.5 standard deviations below the normal mean in length (1)
- Full-term newborn micropenis would be <1.9 cm in length (1)
- Typical normal mean stretched penile length in a newborn is 3.5 cm
- The penis is normally formed but small, ie, no hypospadias (2)
- Scrotum usually normal but can be smaller
- Testicles usually descended but may not function normally
- A micropenis is generally not considered to be associated with ambiguous genitalia since the penis is normal in configuration, the scrotum is normal and the testes are usually descended.
- Micropenis is a finding with many causes

EPIDEMIOLOGY

Incidence

~1.5/10,000

Prevalence

None

RISK FACTORS

- Maternal exposure to antiandrogen medications during pregnancy
- Advanced maternal age: Nondisjunction during meiosis can lead to Down syndrome, Klinefelter syndrome, and polysomy X syndromes

Genetics

- X-linked recessive, autosomal recessive, autosomal dominant have all been identified
- Idiopathic spontaneous mutations noted
- Specific known genetic conditions:
  - Kallmann syndrome
  - Prader–Willi syndrome
  - Laurence–Moon–Biedl syndrome
  - Polysomy X (Klinefelter)
  - Translocation, deletion, trisomy of chromosome 8, 13, 18, and 21
  - Partial androgen-insensitivity syndrome (PAIS)
  - 5α-reductase deficiency
  - Noonan syndrome
  - Rud's syndrome

PATHOPHYSIOLOGY

- Normal penile growth and development is both androgen dependent and independent.
- 1st trimester: Maternal hCG stimulates testicle Leydig cells to produce Testosterone (T). T is converted to dihydrotestosterone (DHT) by 5α-reductase in genital tubercle. Penis and urethra are completely formed by end of 1st trimester by influence of DHT.
- 2nd trimester: Fet al hypothalamus and pituitary drive T production by fet al testis which causes penile growth.
- Micropenis believed to be due to inadequate fet al T production or action after the 1st trimester (1).

ASSOCIATED CONDITIONS

- Hypogonadotropic hypogonadism:
  - Most common cause of micropenis
  - Kallmann syndrome: Anosmia, deficit in GnRH secretion, autosomal dominant
  - Prader Willi syndrome: Short stature, hyperphagia, hypotonia, diabetes mellitus, behavior problems, hypogonadism
  - Laurence–Moon–Biedl syndrome
  - Rud's syndrome
- Primary testicular failure:
  - Gonadal dysgenesis
  - Anorchia
  - Klinefelter's and polysomy X syndromes
  - Luteinizing hormone (LH) receptor defects
  - Defects in T steroidogenesis
  - Noonan syndrome
  - Robinow syndrome
  - Laurence–Moon–Biedl syndrome
  - Trisomy 8, 13, 18, and 21
- Defects in T action
  - PAIS
  - 5α-reductase deficiency
- Idiopathic form:
  - Normal hypothalamic–pituitary–testicle axis
  - Hypothesized to be due to delayed onset of fet al gonadotropin stimulation

GENERAL PREVENTION

Avoid maternal exposure to antiandrogens

DIAGNOSIS

HISTORY

- History of genetic syndrome (eg, Kallman)
- Maternal history: Medications during pregnancy, antenatal US, prior stillbirths, decreased fet al activity, or hypotonia at birth
- Family history: Genitourinary anomalies, hypospadias, cryptorchidism, infertility, major congenital anomalies

PHYSICAL EXAM

- Facies suggestive of midline cranial defect, mental retardation:
  - Microcephaly, hypertelorism, low-set ears, small mouth, high-arched palate
- Weight and body habitus: Prader–Willi syndrome, growth hormone abnormality
- Skin: Nevi, ichthyosis
- Hearing: Deafness
- Smell: Anosmia suggests Kallmann syndrome
- Retinal pigment changes on funduscopic exam
- Penis:
  - Always depress fat pad during exam
  - Prepuce, meatus location, general appearance
  - Stretched penile length (SPL): Measure from tip of glans to pubic symphysis
  - Use physiologic age when comparing SPL with standard nomograms
  - Penile girth usually normal and proportional to length
  - Exclude other diagnoses such as hidden penis or buried penis (beware of a large suprapubic fat pad that may distort a normal penis)
- Scrotum: Size, symmetry, and appearance
- Gonads: Size, shape, and position

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Karyotype
- Genetic testing if history consistent with known syndromes such as Prader–Willi or Kallman
- Differentiate between hypogonadotropic hypogonadism and primary testicular failure
  - Pituitary assessment: ACTH, GH, TSH, LH, FSH. Low levels suggest hypogonadotropic hypogonadism
  - High prolactin suggests hypothalamus defect vs. low prolactin suggests pituitary defect
  - Elevated levels of LH, FSH, and T are normal during 1st 6 mo of life. Low T during this time suggests testicular failure. Confirm with hCG stimulation test. LH, FSH should elevate but T will remain low in testicular failure
  - hCG stimulation test: Assesses testicle for T biosynthesis: 1,000 U of hCG IV or IM for 3 days, measure serum T and DHT levels on days 0 and 4. If T at day 4 $>$100 ng/dL, response is normal. If no response, suggests primary testicular failure
  - From 6 mo to puberty, levels of LH, FSH, and T are low. LH, FSH elevate with hCG stimulation test but serum T low in testicular failure
  - For patients who have undergone or started puberty, LH and FSH are normally elevated as may be serum T. LH, FSH, and T are usually low in micropenis. Do hCG stimulation test and look for response; assess pubertal changes to be sure it is not constitutional pubertal delay
  - Antimüllerian hormone is produced by functional sertoli cells and can be used to detect functional testis tissue
- Identifying defects in T action
  - LH, FSH, T normal, or elevated with PAIS
  - PAIS diagnosis often given after excluding other diagnoses
  - Penis may grow with trial of T IM in PAIS
  - Increased T/DHT ratio with hCG stimulation test or postpubertal suggests 5α-reductase

deficiency
  – AR gene mutation only found in 20% of PAIS

Imaging

- MRI of head: Assess hypothalamus, pituitary, brain, craniofacial anomalies, optic chiasm, 4th ventricle, corpus callosum
- Renal imaging: Assess kidneys and bladder; VCUG and MAG3 renal scan if US suggest renal or bladder anomaly or ectopia

Diagnostic Procedures/Surgery

- Laparoscopy to assess nonpalpable undescended testicles, look for müllerian duct structures, biopsy any dysgenetic tissue
- Genitogram indicated if dysgenetic gonads, ovotestis, müllerian duct structures are found or if androgen insensitivity is suspected

Pathologic Findings

- Newborn penis is proportional but <1.9 cm
- Kallmann syndrome: Anosmia, GnRH deficiency: 10% KAL1 gene defect on Xp22.3, 10% KAL2 on 8p12, 70% autosomal dominant with no identified gene defect
- Prader–Willi syndrome: Short stature, hyperphagia, mental retardation, diabetes, hypotonia, behavioral problems; lacking expression of gene SNRPN or necdin on 15q of paternal origin
- Laurence–Moon–Biedl syndrome: Obesity, retardation, pigmented retinopathy, polydactyly

DIFFERENTIAL DIAGNOSIS

- Concealed penis: Large suprapubic fat pad
- Webbed penis: Prominent penoscrotal web
- Postcircumcision cicatrix:
  – Residual foreskin scarred above glans tip
- Hypospadias with and without chordee
- Chordee
- Disorders of sex differentiation:
  – Female DSD: Congenital adrenal hyperplasia, gonads not palpable in labia/scrotum
  – Male DSD
- Hypothalamic–pituitary axis dysfunction (50% of cases):
  – Syndromes: Kallmann, Prader–Willi, Laurence–Moon–Biedl, Rud's
- Isolated hormone deficiency:
  – GnRH deficiency without Kallmann syndrome
  – LH deficiency
  – GH deficiency or growth hormone receptor defect (Laron dwarfism)
- Primary testicular failure:
  – Hypergonadotropic hypogonadism (25% of cases)
  – Testicular dysgenesis (Klinefelter syndrome, 47XXY)
  – Laurence–Moon–Biedl syndrome
  – Polysomy X syndromes
  – Anorchia; intrauterine testicular torsion
- 5α-reductase deficiency: Rare
- PAIS (Partial androgen insensitivity syndrome)

- CNS abnormalities:
  - Anencephaly, congenital pituitary aplasia, agenesis of corpus callosum, malformation of fourth ventricle
- Chromosome defects:
  - Polysomy X syndromes
  - Translocation, deletion, and trisomy of chromosomes 8, 13, 18, and 21
- Rare syndromes: Rud, Robinow, Martsolf, Fanconi anemia, Smith–Lemli–Opitz syndromes
- Idiopathic: Normal hypothalamic pituitary axis:
  - Virilize normally at puberty

TREATMENT

GENERAL MEASURES

- Generally coordinated with an endocrinologist
- Correct any metabolic disturbances
- Specific treatment based upon cause
- Adrenal insufficiency: Treat with hydrocortisone supplementation and IV saline to correct hypovolemia

MEDICATION

First Line

- Testosterone therapy: Diagnostic and therapeutic: 25–50 mg testosterone enanthate IM Q monthly × 3 mo in infancy or prepubertal
- Long-term cortisol replacement, growth hormone, and thyroid hormone if pan-hypopituitarism present
- For gonadal deficiency: Induce puberty later in life with T IM injection or transdermal patch/gels
- For central deficiency: Administer hCG injection or GnRH therapy

Second Line

None

SURGERY/OTHER PROCEDURES

- Manage cryptorchidism with orchiopexy or orchiectomy (if dysgenetic) as needed
- Penile surgery for length or bulk has not been shown to be effective

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Familial genetic counseling and screening
- Prenatal care:
  - Amniocentesis or chorionic villous sampling for chromosomal anomalies and sex determination
  - Fet al US to look for genitourinary and central nervous anomalies

Complementary & Alternative Therapies

Gender reassignment: Generally not done any more for micropenis and is of only historical interest

ONGOING CARE

PROGNOSIS

- Overall good, but long-term effects depend on underlying cause
- Most have stable male gender identity
- Generally good response to 3-mo course of T IM with 100% increases in length seen (3)
- Final adult penis size with treatment usually < mean, but within 2.5 standard deviations (3)

COMPLICATIONS

- Relate to endocrine abnormalities if present
- Side effects of testosterone:
  - Premature closure of epiphyseal plates; limits long-bone growth
  - Behavioral changes: More aggressiveness
  - Early stimulation of penile growth does not affect ultimate penile length
- Psychosocial issues:
  - Most patients have a stable male gender identify but some dissatisfied with penis length

FOLLOW-UP

Patient Monitoring

- Psychological support and psychiatric therapy as needed:
  - Reassure concerns about penile size, function, gender, potency
  - Address behavioral and psychosocial problems
- Hormone biochemical monitoring:
  - Follow pituitary and gonadal hormone therapy
  - Assess growth, vital signs, electrolytes, serum glucose, renin, ACTH, GH, LH, FSH, and T.
- Physical monitoring: Serial penile measurements

Patient Resources

None

CODES

ICD9
752.64 Micropenis

ICD10
Q55.62 Hypoplasia of penis

CLINICAL/SURGICAL PEARLS

- Micropenis is a condition with many causes, most of which are either a form of hypogonadotropic hypogonadism or primary testicular failure.
- Thought to be due to deficient T synthesis or action after the 1st trimester.
- Watch out for large suprapubic fat pad leading to incorrect diagnosis.
- Surgery generally not indicated except for associated cryptorchidism.

MULTICYSTIC DYSPLASTIC KIDNEY

Ellen Shapiro, MD, FACS
Daniel Wollin, MD

BASICS

DESCRIPTION

- Multicystic dysplastic kidney (MCDK) is a congenital renal anomaly with a kidney comprised of cysts of varying sizes; no identifiable renal parenchyma—"bunch of grapes" with a paucity of stroma between cysts; no large central or medial cyst
- No reniform appearance of the involved kidney
- Usually unilateral; bilateral incompatible with life
- Most common type of renal cystic disease and 2nd most common cause of abdominal mass in neonates and infants after hydronephrosis

EPIDEMIOLOGY

Incidence

- 1 in 4,300 live births (unilateral)
- Slight male predominance
- Slightly greater occurrence on the left
- Bilateral MCDK
  - 1 in 10,000—fet al demise due to oligohydramnios or postnatal demise due to pulmonary hypoplasia

Prevalence

N/A

RISK FACTORS

- Possible association with in utero urinary obstruction
- Possible association with teratogens (in utero viral infections, medications such as maternal antiepileptics)
- Maternal diabetes

Genetics

- MCDK seen in disorders of known genetic etiology such as renal cysts and diabetes syndrome (RCAD) which involves mutations in hepatocyte nuclear factor-1β
- Genes such as PAX2, EYA1, SIX1, WNT, WT-1, GNF, and AT2 have an important role in ureteral bud formation and mutations have been identified in human syndromes such as:
  - Branchio-oto-renal (BOR) syndrome with mutations in the EYA1 or SIX1 genes
  - Renal-coloboma syndrome (RCS) with mutations in the PAX2 gene
- Linking genetic mutations with renal dysplasia suggest bud theory as the pathogenesis in MCKD

PATHOPHYSIOLOGY

- Ureteral bud theory:
  - If ureteral bud is atretic or connects abnormally with the metanephric blastema or forms

abnormal distal ureteral connections to the bladder, MCDK will result.
– Prerequisite is the normal reciprocal induction between a normal ureteral bud and normal metanephric mesenchyme.

ASSOCIATED CONDITIONS
- Prenatal hypertrophy of the contralateral kidney (24–46%)
- About 1/3 will have associated congenital anomalies of kidneys and urinary tract (CAKUT)
- Contralateral vesicoureteral reflux (~20%); of those with reflux, 40% will have grades III–V
- Contralateral UPJ obstruction (3–12%) and UVJ obstruction (6%)
- Dilated nonobstructed contralateral renal pelvis (common)
- Anomalies of the ipsilateral internal duct structures (15%) including seminal vesicle cyst, Gartner's cyst, obstructed hemivagina
- Large series show no increased incidence of Wilms tumor or hypertension (see Patient Monitoring)
- Ureterocele or ectopic ureter associated with single system or upper pole of duplex system
- Horseshoe kidney

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
At least 65% are detected prenatally

PHYSICAL EXAM
- Abdominal mass palpable in 13%
- Elevated BP (rare)

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis
- Urine microalbuminuria

Imaging
- US: Multiple noncommunicating cysts of variable size, scant, or no renal parenchyma
- Dilated renal pelvis in hydronephrotic form
- VCUG not absolutely recommended with normal contralateral kidney and bladder despite 20% having contralateral reflux
- Renal scan (DMSA): Confirms absence of function, or rarely minimal function especially in hydronephrotic form or in smaller more solid dysplastic kidneys

Diagnostic Procedures/Surgery
- VCUG: To evaluate for contralateral VUR if hydronephrosis or other contralateral upper tract abnormality on US
  – If the contralateral kidney is normal, performing a VCUG remains controversial

Pathologic Findings
- Renal maldevelopment with large cysts tend to have a small amount of stroma (thin septa of

fibrous tissue) and primitive dysplastic elements
  – Primitive ducts (a duct encircled by a collar of fibromuscular cells)
  – Immature cartilage and remnants of early metanephros can be present
- Kidneys with smaller cysts tend to have more solid components
- Hydronephrotic form
- Small to no vascular pedicle
- Ureter totally or partially atretic; renal pelvis may be absent
- Microscopic communication between cysts
- Often involute—circumscribed rims of calcifications may be seen in the renal fossa on plain film of adults

DIFFERENTIAL DIAGNOSIS
- Acquired renal cysts
- Autosomal dominant kidney disease
- Cystic congenital mesoblastic nephroma
- Cystic Wilms tumor
- Cysts of the medulla
- Hydronephrosis
- Multilocular cystic nephroma
- Neuroblastoma (calcifications)
- Renal cysts, isolated or associated with syndromes (tuberous sclerosis, von Hippel–Lindau, etc.)
- Ureteropelvic junction obstruction (UPJO)
- Vesico ureteral reflux (VUR)

TREATMENT

GENERAL MEASURES
- Educate parents about the signs and symptoms of UTI in infancy and childhood especially if reflux status unknown
- The use of nephrectomy to manage MCDK is controversial

MEDICATION
First Line
N/A

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Mostly nonoperative:
  – 25% totally involute
  – 60% regress
  – 15% remain stable
  – A very small number may increase in size
- Indications for nephrectomy:
  – Kidneys which remain large, increase in size, or show an increased amount of solid tissue

(especially with function)
  - Kidneys easily removed (especially laparoscopically) or cysts may be sequentially decompressed
  - Hypertension: Uncommon (5%) in childhood and not likely caused by MCDK
    - May persist after nephrectomy depending on the patient age at onset of hypertension and the presence of CAKUT (see Prognosis)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Usually excellent in unilateral disease
- KIMONO study (1) reports renal injury (hypertension, albuminuria and/or the use of renoprotective medication) present in 32% at young age (mean age 9.5 yr).
  - Increased renal injury in individuals with a solitary functioning kidney in later life when CAKUT present.
  - Study suggests long-term clinical follow-up for hypertension and microalbuminuria especially into puberty and adulthood.
  - These findings are supported by an early study (2).

COMPLICATIONS

- Malignant transformation extremely low with only 15 cases of tumors reported
- Rare hypertension; usually associated with contralateral renal injury

FOLLOW-UP

Patient Monitoring

- Renal US to document involution and contralateral renal growth
  - Every 6 mo in the 1st 3 yr and then every 1–2 yr to assure appropriate renal growth until puberty
  - Protocol personal preference of physician since there is no consensus; some follow patients every 3–12 mo. No frequency of follow-up has been shown to be beneficial or cost-effective
- As of 2012, the American Academy of Pediatrics states that contact-sport participation is generally OK for children who have only one functional kidney. In a very large published series, none of the kidney injuries were catastrophic or needed surgery
- Long-term follow-up for hypertension and microalbuminuria by informed pediatrician or family physician; referral to nephrology for renoprotective medications when indicated

Patient Resources

- National Kidney and Urologic Diseases
- Information Clearinghouse (NKUDIC)

- Renal Cysts
- Renal Dysplasia, Hypodysplasia, and Hypoplasia

CODES

ICD9

- 593.70 Vesicoureteral reflux unspecified or without reflux nephropathy
- 753.15 Renal dysplasia
- 753.19 Other specified cystic kidney disease

ICD10

- Q61.4 Renal dysplasia
- Q62.7 Congenital vesico-uretero-renal reflux
- Q62.39 Other obstructive defects of renal pelvis and ureter

CLINICAL/SURGICAL PEARLS

- MCDK occurs as a result of renal maldevelopment due to possible mutation(s) in genes responsible for ureteral bud formation.
- Large cysts of varying sizes present with no identifiable parenchyma; ureter usually atretic.
- Most involute or become significantly smaller; rare enlargement.
- Almost none require nephrectomy; consider for functioning solid component or increasing size.
- Not associated with increased risk of hypertension during childhood or Wilms tumor in large series.
- Long-term follow-up recommended for hypertension and microalbuminuria especially at puberty and in adulthood.

MULTIPLE SCLEROSIS, UROLOGIC CONSIDERATIONS

Alana M. Murphy, MD

BASICS

DESCRIPTION

- Multiple sclerosis (MS) is a neurologic disease causing focal demyelination of white matter in the brain and spinal cord that can impact urinary tract functioning.
- Plaques visible on magnetic resonance imaging (MRI) are inflammatory and often lead to scar tissue deposition. They interfere with conduction of electrical signals resulting in loss of central inhibition of reflex activity and dysfunctional conduction of sensory and motor signals.
- Neurologic impairment can vary from mild to severe.
- Urologic manifestations include urinary frequency, urgency incontinence, voiding symptoms, urinary retention, and sexual dysfunction.
- Detrusor sphincter dyssynergia (DSD) and detrusor overactivity (DO) are common dysfunctions noted on urodynamic studies (UDS).

EPIDEMIOLOGY

Incidence

- Most commonly presents between ages 20 and 50 yr old
- Females have 1.5–3 times greater incidence than males

Prevalence

- 1 in 750 lifetime risk of developing MS in USA
- Marked variations in worldwide prevalence
- More common in Caucasians and above 40° latitude

RISK FACTORS

- Caucasian ethnicity
- Primary relative with MS
- Live about 40° latitude

Genetics

- Increased risk if MS is present in a 1st-degree relative
- Primary relative with MS confers 20 times risk
- Identical twin: 300 times increased risk if other twin develops MS
- Unknown pattern of inheritance

PATHOPHYSIOLOGY (1)

- Autoimmune attack on the central nervous system (CNS) myelin:
  - Focal demyelination with relative axon sparing
  - Histopathology shows perivenular lymphocytic infiltrates, macrophages within the white matter, gliosis, and scarring
- Urologic pathophysiology:
  - MS affects the cervical spinal cord in the pyramidal and reticulospinal tracts, affecting

innervation of the bladder and external urethral sphincter, causing DO and DSD
  – MS can affect the sacral cord and may lead to bladder areflexia and elevated post-void residual (PVR) volumes

ASSOCIATED CONDITIONS
- DSD leading to urinary retention, recurrent UTIs, and impairment in renal function
- Urolithiasis due to urinary stasis from incomplete bladder emptying and recurrent UTIs

GENERAL PREVENTION
No proven methods for prevention

DIAGNOSIS
HISTORY
- Presence of neurologic symptoms:
  – Vision changes, balance problems, discoordination, numbness, or paresthesias
- Urologic history: All patients with MS should be screened for urologic problems
  – Recurrent UTIs
  – Urinary frequency
  – Urgency incontinence
  – Voiding symptoms
  – Urinary retention

PHYSICAL EXAM
- Urologic exam:
  – Testicular and prostate exam in males to rule out neoplasm or infection
  – Pelvic exam in females to assess pelvic support and rule out urethral or vaginal pathology
- Focused neurologic exam:
  – Bulbocavernosus reflex to assess function of sacral nerves (absent in up to 30%)
  – Deep tendon reflexes, proprioception, Babinski reflex, and cranial nerve exam

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urinalysis: Concomitant infection or hematuria
- CSF for initial MS diagnosis (oligoclonal IgG bands)

Imaging (2,3)
- MRI:
  – The most useful tool for diagnosing MS; diagnostic in 70–95% of cases
  – Increased signal intensity on T2-weighted images in areas of demyelination
- Upper urinary tract imaging:
  – Rule out presence of hydronephrosis
  – Renal ultrasound (US) is a good screening test
  – Important in patients with known DSD or in patients with indwelling catheters
- Lower tract imaging less commonly performed:
  – Fluoroscopy during UDS can assess for bladder pathology (stones, trabeculation), vesicoureteral reflux, and DSD

Diagnostic Procedures/Surgery

- PVR
  - Large (>275–300 cc) PVR on 2 separate occasions should initiate clean intermittent catheterization
- UDS done by urologic specialists to assess bladder capacity, compliance, detrusor function, continence, and detrusor–sphincter coordination:
  - Routinely performed with fluoroscopy in MS patients
  - Absolutely necessary to characterize voiding dysfunction in MS patients
  - Assess risk for upper tract deterioration (elevated storage and voiding pressures)
  - May suggest diagnosis of MS in patient with few other neurologic symptoms
  - Need follow-up UDS with change in clinical symptoms

Pathologic Findings

Detrusor hypertrophy with trabeculation

DIFFERENTIAL DIAGNOSIS

- Idiopathic overactive bladder
- Dysfunctional voiding
- Detrusor underactivity or acontractile detrusor

TREATMENT

GENERAL MEASURES

- Remissions can occur spontaneously, making management difficult
- Physical therapy and exercise to help prevent muscle atrophy and loss of postural tone
- Avoid stressors
- Disease-modifying medications specific to MS can reduce relapses and control some symptoms: β interferons, glatiramer acetate, fingolimod, natalizumab, and teriflunomide
- Bladder emptying in cases of detrusor underactivity or DSD with urinary retention:
  - Intermittent catheterization preferred over indwelling catheter
  - Consider a suprapubic catheter if intermittent catheterization is not possible
  - Patients on intermittent catheterization or with an indwelling catheter should not be treated with antibiotics for asymptomatic bacterial colonization of the urinary tract
- Urinary frequency and urgency incontinence treatment should include behavioral modification with avoidance of bladder irritants and management of fluid intake

MEDICATION

First Line

- Medical therapy is primarily aimed at urinary frequency and urgency incontinence
  - Antimuscarinic medications: Most common side effects include dry mouth and constipation
    - Fesoterodine 4–8 mg QD
    - Hyoscyamine ER release 0.375 mg BID
    - Oxybutynin 5 mg BID-TID
    - Oxybutynin transdermal patch 3.9 mg/d
    - Oxybutynin XL 10–15 mg/d
    - Oxybutynin, topical gel 10% apply 1 sachet QD to dry skin

- Solifenacin 5–10 mg/d
- Tolterodine LA 1–2 mg BID
- Tolterodine LA 2–4 mg/d
- Trospium XR 60 mg/d

– β_3-agonist: Most common side effects include an increase in blood pressure and palpitations
- Mirabegron 25 mg/d increase to 50 mg/d after 8 wk PRN

Second Line (4)

• Botulinum toxin injection into the detrusor:
– Decreases the force and frequency of neurogenic DO
– Well-tolerated office-based therapy performed under local anesthesia
– Neurogenic DO treated with cystoscopic injection of 200–300 units botulinum toxin type A [onabotulinumtoxinA] into 10–25 sites within the bladder muscle
– Treatment effect lasts 3–9 mo
– Risk of temporary urinary retention requiring intermittent catheterization

SURGERY/OTHER PROCEDURES

• Suprapubic catheter placement:
– If unable to perform intermittent catheterization; avoids urethral erosion; reduces incidence of UTIs, epididymitis, and prostatitis
– Drawbacks include risk of bladder calculi and development of squamous cell carcinoma (usually in >10 yr).
• Augmentation cystoplasty: To address significantly impaired bladder compliance or when conservative management of incontinence from DO has failed
• Urinary diversion: Ileal conduit, ileovesicostomy, or catheterizable stoma

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

Stress reduction therapies and acupuncture have been associated with symptom reduction

ONGOING CARE

PROGNOSIS

With proper urologic follow-up, renal function can be preserved in most patients

COMPLICATIONS

• Hydronephrosis and impairment in renal function due to elevated bladder storage or voiding pressure
• Urolithiasis due to urinary stasis, indwelling catheters and infection
• Recurrent UTIs
• Urethral erosion from indwelling catheters

FOLLOW-UP

Patient Monitoring

- Upper urinary tract screening is especially important in men, since men with MS often develop high bladder storage pressure and urinary stasis without developing overt urologic symptoms such as incontinence.
- Incontinence, especially in women, can become problematic as the severity of MS progresses.
- Patients with bladder dysfunction secondary to MS can be stratified into low- and high-risk:
  - High-risk patients: Incontinence, recurrent infections, DSD, elevated storage pressures >40 cm H_2O, indwelling catheters
    - Follow closely for upper tract deterioration, development of squamous cell carcinoma of the bladder, and other problems associated with long-term indwelling catheters.
  - Low-risk patients: Those with normal continence, no UTIs, and complete bladder emptying. These patients do not require frequent upper tract imaging.
- All patients should undergo periodic urodynamic testing, especially if there is a change in symptoms, an increase in infections, or an overall worsening of their MS.

- Detrusor Overactivity
- Detrusor Sphincter Dyssynergia
- Neurogenic Bladder, General Considerations

CODES

ICD9

- 340 Multiple sclerosis
- 788.31 Urge incontinence
- 788.41 Urinary frequency

ICD10

- G35 Multiple sclerosis
- N39.41 Urge incontinence
- R35.0 Frequency of micturition

CLINICAL/SURGICAL PEARLS

- Medical therapy and behavioral modification remain the 1st-line treatment for urinary frequency and urgency incontinence.
- Cystoscopic injection of botulinum toxin should be used for refractory neurogenic detrusor overactivity.
- Adequate management of lower urinary tract function will lead to preservation of renal function.

MYASTHENIA GRAVIS, UROLOGIC CONSIDERATIONS

Robert L. Segal, MD, FRCS(C)
Arthur L. Burnett, II, MD, MBA, FACS

BASICS

DESCRIPTION

- Myasthenia gravis (MG) is a chronic autoimmune disorder characterized by weakness and early fatigability of the skelet al muscles due to antibody-mediated loss of nicotinic acetylcholine (Ach) receptors (1,2)
- Involvement of the external striated urethral sphincter is rare but may be vulnerable to dysfunction after transurethral resection of the prostate (TURP), explaining the relatively high incidence of post-TURP incontinence in this group (3)
- Although smooth muscle is generally not affected, there are rare reports of detrusor areflexia (4)
- Urologic complaints are uncommon but may include incontinence, urgency, retention, or erectile dysfunction

EPIDEMIOLOGY

Incidence

Published estimates of 2–21 cases per million people per year (1,2)

Prevalence

- In patients < 40 yr:
  – Female > Male (7:3)
- In the 5th decade, new cases of MG are evenly split between the genders
- After the 5th decade:
  – Male > Female (3:2) (1,2)

RISK FACTORS

- Thymic hyperplasia is observed in 65–75% of patients (1,2)
- MG has been described as a paraneoplastic syndrome related to renal cell carcinoma (RCC) (5), as well as other malignancies (thymoma, lymphoma, lung cancer, Kaposi's sarcoma) (6)

Genetics

- Congenital myasthenia syndromes, a subset of MG, stem from genetic mutations resulting in abnormal neuromuscular transmission (1,2)
- HLA types B8 and DR3 are associated with MG

PATHOPHYSIOLOGY

- Autoantibodies develop against Ach nicotinic postsynaptic receptors (1,2).
- The autoantibodies mechanically block the neuromuscular junction binding site and eventually destroy them.
- Cholinergic nerve conduction to striated skelet al muscle is thus impaired.
- Clinical symptoms begin to develop when the number of Ach receptors is reduced to ~30% of the normal level.

- Smooth and cardiac muscle are not affected.
- The role of the thymus in MG is unclear, but it is suspected to be a site of autoantibody formation.
- A majority of patients with MG have thymic hyperplasia or thymoma.
- Many patients improve clinically following thymectomy.

ASSOCIATED CONDITIONS
- Neonatal MG is a transitory disorder resulting from passive maternal antibody transfer to the fetus.
- Congenital myasthenic syndromes result from genetic mutations that lead to abnormal neuromuscular transmission.
- Ocular MG refers to weakness limited to the extraocular muscles and eyelids.

GENERAL PREVENTION
None

DIAGNOSIS
HISTORY
- Reduced exercise tolerance that improves with rest and worsens with warm temperature (eg, after a hot bath)
- The natural history of MG usually follows a characteristic pattern that initially involves weakness of eyelids and extraocular muscles.
- Difficulty climbing stairs is typical of generalized weakness in MG.
- Weakness is variable and fluctuating, but tends to be worse later in the day.

PHYSICAL EXAM
- Muscle fatigability can be tested for many muscles by repeated action: Ptosis, diplopia, dysphagia, and peripheral muscle weakness
- "Dropped head syndrome"

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serology tests demonstrate anti-ACh receptor antibodies in ~90% of patients
- ~50% of patients who test negative for anti-ACh receptor antibodies have antibodies against the MuSK protein.

Imaging
- Chest computed tomography (CT) to rule out thymoma
- If level of suspicion is high, CT abdomen to rule out RCC (5)

Diagnostic Procedures/Surgery
- Edrophonium chloride test: Positive for MG if IV administration unequivocally yields improved strength
- Repetitive nerve stimulation
- Single-fiber electromyography
- Complete urodynamic evaluation if urologic symptoms are present (4)
- Urodynamics:
  – If bladder dysfunction present, resembles lower motor neuron pattern with variable

areflexia or atonia
  – In one UDS series 63% failing to empty completely due to hypocontractile bladders and 6% had complete areflexia

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Acute inflammatory demyelinating polyradiculoneuropathy
- Botulism
- Lambert–Eaton syndrome

TREATMENT

GENERAL MEASURES
- Intermittent catheterization for rare cases of refractory detrusor areflexia (4)
- Adjust mealtimes to take advantage of daily periods of relative strength
- Install railing in household places where it will be needed for support in rising, such as adjacent to the bathtub and toilet
- Use electric toothbrushes and can openers to conserve strength
- Generalized muscle weakness in the acute setting should prompt careful attention to the possibility of respiratory failure
- Patients with MG have symptoms worsened with high core or ambient temperature; therefore, muscle strength will likely improve when a fever is treated with antipyretics
- Urinary tract symptoms, if present, may respond favorably to therapy for MG

MEDICATION
First Line
- Cholinesterase inhibitors (neostigmine, pyridostigmine) provide temporary strength improvement in patients with MG.
- Corticosteroids can produce rapid improvements in MG but are associated with numerous dose-dependent side effects

Second Line
- Plasmapheresis is reserved for short-term treatment in response to myasthenic exacerbations or crises.
- Intravenous immunoglobulin (IgG) also provides short-term improvements in strength during myasthenic exacerbations or crises as an alternative for patients who are poor plasmapheresis candidates because of vascular access issues.
- Immunosuppressive agents (azathioprine, cyclophosphamide, cyclosporine, methotrexate, mycophenolate mofetil, rituximab, tacrolimus) for steroid-sparing protocols, or for refractory disease (6)

SURGERY/OTHER PROCEDURES
- If surgical intervention for bladder outlet obstruction secondary to benign prostatic hyperplasia (BPH) is being considered, some advocate suprapubic prostatectomy to reduce risk of incontinence (3)
- Thymectomy results in complete remission in 35% of cases and clinical improvement in 85%

of patients
- If MG presents as paraneoplastic syndrome associated with RCC, effective treatment for RCC may resolve MG symptoms (5)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

β-Agonist and anticholinergic bronchodilators can reduce bronchospasm and respiratory distress resulting from cholinergic medications.

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Most (96%) of patients have normal lifespan when appropriate medical care involving cholinesterase inhibitors, plasmapheresis, and immunosuppressive agents is given.
- Thymectomy results in complete remission in about 1/3 of patients, but the postsurgical prognosis is otherwise highly variable.

COMPLICATIONS

- Post-TURP incontinence
- Respiratory failure
- Cholinergic crisis from excessive use of cholinesterase inhibitors
- Multiple complicating effects may result from chronic steroid use, including poor wound healing and opportunistic infection

FOLLOW-UP

Patient Monitoring

Patients with MG should be followed by a neurologist with urology referral as needed.

Neurogenic Bladder, General

CODES

ICD9

- 358.00 Myasthenia gravis without (acute) exacerbation
- 788.30 Urinary incontinence, unspecified
- 788.63 Urgency of urination

ICD10

- G70.00 Myasthenia gravis without (acute) exacerbation
- N39.41 Urge incontinence
- R32 Unspecified urinary incontinence

CLINICAL/SURGICAL PEARLS

- Patients with MG may develop voiding dysfunction, most commonly detrusor areflexia resulting in urinary retention.
- Urinary incontinence may develop after TURP.
- Urologic symptoms may be improved by systemic MG therapy, although specific therapy for urologic complications, such as urinary retention or incontinence, may need to be instituted.

MYELODYSPLASIA (SPINAL DYSRAPHISM), UROLOGIC CONSIDERATIONS

Blake A. Wynia, MD, MPH
Ellen Shapiro, MD, FACS

BASICS

DESCRIPTION

- Myelodysplasia (spinal dysraphism, neural tube defect) is a very broad term encompassing a large heterogeneous group of congenital vertebral column defects that result from defects that occur during neural tube closure.
- Group of developmental abnormalities that can be open (meningocele, myelomeningocele, lipomyelomeningocele) or closed (spinal bifida occulta, posterior meningoceles, lipomyelomeningocele, and myelocystocele).
- Primary functional deficits can be lower limb paralysis and sensory loss, bladder and bowel dysfunction, and cognitive dysfunction.
- Affected children often have varying degrees of neurogenic bladder dysfunction.

ALERT
Patients with myelodysplasia have a high incidence of latex allergy. From birth, parents need to be educated in latex precautions.

EPIDEMIOLOGY

Incidence

- Spinal dysraphism:
  - 1 per 1,000 births in USA previously
  - 2.5 times more common in Caucasians than blacks
  - Incidence decreasing over past 20 yr due to prenatal diagnosis and use of folic acid

Prevalence

- Open spinal dysraphism: 60,000 cases estimated in USA
- Spina bifida occulta: 5–10% of the general population; most cases are found incidentally

RISK FACTORS

- Maternal folate deficiency during pregnancy
- Family history: Incidence for mother with one affected child is 20–50/1,000 live births; also 2nd and 3rd degree affected relative
- Prepregnancy obesity or diabetes
- Exposure to high temperatures in early pregnancy (fever or hot tub)
- Intrauterine exposure to valproate or carbamazepine
- Low vitamin B-12 levels
- Chromosome trisomies 13 and 18, triploidy, and single-gene mutations.

Genetics

Genes involved in folate-homocysteine metabolism and transport (see Risk Factors)

PATHOPHYSIOLOGY

- Increased maternal blood AFP (α-feto protein) at 16 wk can indicate the presence of an NTD (neural tube defect).
- Spinal cord begins normal development on day 18 of gestation:
  - The canal closes in a cephalocaudal direction; complete closure day 35 of gestation
  - Exact mechanism of dysraphism undefined
- Myelodysplastic states can be subdivided:
  - Spina bifida occulta: The mildest form. No overt signs of spinal abnormality; may be associated with tethering of the spinal cord and often associated with a low-lying conus (below L2–L3); usually detected by plain x-ray, demonstrating open vertebral bodies
  - Posterior meningoceles, myelocystocele, and lipomyelomeningocele are closed defects associated with a skin-covered back mass
  - Meningocele: The meninges or dural sac, but no neural elements, extend beyond the vertebral canal. Mostly normal lower extremity
  - Myelomeningocele: The nerves and spinal cord are exposed through an opening in the spinal column, meninges, and skin. Significant neurologic defects (paralysis, urinary incontinence) are usually associated.
  - Lipomyelomeningocele: Fatty tissue along with cord structures extend with protruding sac.
- Myelomeningocele account for >90% of spinal dysraphism:
  - Arnold–Chiari malformation in 85% of children with myelomeningocele:
    - Cerebellar tonsils herniated through foramen magnum
    - The 4th ventricle is obstructed leading to hydrocephalus if shunting is not performed

ASSOCIATED CONDITIONS

- Cloacal anomalies/Cloacal exstrophy
- Hydrocephalus/Arnold–Chiari malformation
- Imperforate anus
- Latex allergy
- Sacral agenesis
- VACTERL syndrome (Vertebral defects, anal atresia, cardiac defects, tracheoesophageal fistula, renal anomalies, and limb abnormalities)

GENERAL PREVENTION

- Folic acid 0.4 mg/d in all women of childbearing age; 4.0 mg/d in women with previous NTD-affected pregnancy
  - Begin 2 mo before planned conception
- Prenatal surgery for meningomyelocele at special centers by 26 wk gestation.
  - Outcomes encouraging with shunt placement in only 68% vs. 98% who underwent postnatal repair; also results in improved mental development and motor function at 30 mo of age
  - Has not been shown to impact on urologic outcomes

DIAGNOSIS

HISTORY

- Review medical and developmental history
- Most patients now diagnosed prenatally
- Older patients commonly present with urinary and bowel incontinence:
- Change in bowel habits or gait, onset of leg or back pain, presence of seizures or other neurologic symptoms may suggest subsequent spinal cord tethering

PHYSICAL EXAM

- Assess general appearance, body habitus, gait, dexterity, muscular, and neurologic development
- Genitalia: Presence or absence of hypospadias, cryptorchidism, labiovulvar abnormalities
- Rectal exam: Perianal sensation, rectal tone, fecal impaction
- Back exam for open (obvious exposed neural tissues) or closed defects. Stigmata that may be associated with occult spinal dysraphism include:
  - Dimples or sinuses, subcutaneous mass, skin tags, hemangiomas, abnormal hair patches, pigmentation, or abnormal gluteal cleft.
- Neurologic exam:
  - Gait, balance, muscular development/tone

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Urinalysis, urine culture, basic metabolic panel with high-grade reflux or hydronephrosis

Imaging

- 15–20% of neonates have abnormality of upper tract when 1st studied
- Plain abdominal x-rays:
  - May show structural vertebral anomalies or evaluate for partial or complete sacral agenesis
  - May visualize stones or fecal impaction
- Renal US (ultrasound):
  - Determine baseline of urinary tract; should be performed shortly after birth; important to repeat after back closure prior to discharge
  - Assess for hydronephrosis, hydroureter, and PVR (postvoid residual) if patient voids spontaneously
- Voiding cystourethrogram (VCUG):
  - Assess for vesicoureteral reflux, bladder wall appearance, bladder capacity, PVR
- Dimercaptosuccinic acid (DMSA) renal scan in select cases including: High-grade reflux, renal scarring, and solitary functioning kidney
- Magnetic resonance imaging (MRI):
  - Assess spinal cord and vertebral anomalies in patients with suspected occult spinal dysraphism or a “closed” lesion. Spinal sonogram useful in children <3 mo of age prior to boney ossification.

Diagnostic Procedures/Surgery

- Urodynamic studies (UDS): Fill rate based on average bladder capacity in milliliters: (24.5 $\times$ age $+$ 62) divided by 10 is the rate of filling the bladder with warm saline
  - Often with video (video urodynamic studies or VUDS)
  - Performed 2–3 mo after back closure or at time of diagnosis of occult spinal dysraphism

– Assess bladder capacity, volume, and pressure at abdominal and detrusor leak points (compliance), pressure when reflux, if present, is observed, detrusor overactivity, detrusor sphincter dyssynergia (DSD)
– Findings: Synergic (26%), dyssynergic with or without poor detrusor compliance (37%) and complete denervation (36%)

Pathologic Findings
See Pathophysiology

DIFFERENTIAL DIAGNOSIS
- Other causes of neurogenic bladder (see Chapter on Neurogenic Bladder, general)
- Tethered cord syndrome

TREATMENT

GENERAL MEASURES (1,2,3)
- Urgent neurosurgical intervention is critical for open defects which may lead to hydrocephalus.
- Upper tract preservation is the primary goal with the achievement of continence at an appropriate age.
- Incomplete bladder emptying or significant upper tract hydronephrosis/high-grade reflux before and after repair of the back defect
- Clean intermittent catheterization (CIC) for detrusor filling pressures of >30–40 cm H_2O. May often require the addition of anticholinergic therapy (see Medication)
- Cutaneous vesicostomy or urethral dilation to lower emptying pressures not usually performed

MEDICATION
First Line
- Anticholinergics: Decrease detrusor overactivity, increases bladder compliance and functional capacity
  – Oxybutynin 0.2 mg/kg BID-TID; should be initiated early in life when indicated to prevent upper tract deterioration secondary to poor detrusor compliance and DSD
  – Tolterodine 0.01 mg/kg BID to a maximum of 0.4 mg/kg BID; long-acting forms when older
  – Almost always used in conjunction with CIC
  – Side effects: Headaches, dry mouth, flushing of skin, abdominal discomfort, blurred vision
- Prophylactic antibiotics considered for reflux

Second Line
- α-sympathomimetic, α-sympatholytic, β-sympatholytic, smooth muscle relaxants
- Imipramine 0.7 mg/kg BID with maximum dosing of 1.2 mg/kg TID; consider pretreatment EKG

SURGERY/OTHER PROCEDURES
- When pharmacotherapy and CIC do not result in favorable bladder dynamics and/or continence in older patients, consider:

  - Cystoscopy and botulinum-A toxin injection
  - Bladder augmentation usually with creation of continent catheterizable stoma since many of the children are wheelchair bound; wait until the child is 4–5 yr old for continence if upper tracts not deteriorating and bladder is not hostile
  - Anti-reflux procedure for high-grade reflux
  - Bladder neck reconstructions: Young-Dees-Leadbetter, Kropp, Pippi–Salle modification, bladder neck closure
  - Fascial sling or artificial urinary sphincters
- Bowel incontinence:
  - If oral laxatives, enemas/irrigation, and rectal suppositories do not result in social bowel continence consider MACE procedure selectively

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

- Neuromodulation of the bladder via intravesical electrical stimulation, sacral nerve stimulation, transcutaneous stimulation, and biofeedback; all of unproven efficacy
- Tissue-engineered bladder augmentation (experimental)
- Artificial somatic-autonomic reflex pathway procedure (experimental)

ONGOING CARE

PROGNOSIS

- Self-performance of CIC is likely in school-aged children with supervision.
- Regular monitoring for silent upper tract deterioration including renal sonogram and VUDs
- Erectile and ejaculatory dysfunction
- Delivery concerns especially at the end of gestation in myelodysplasia patients with bladder/bladder neck reconstruction

COMPLICATIONS

- Incontinence with resulting skin ulceration due to ammonia burns; consider delaying circumcision until continence program instituted since the prepuce provides protection for the glans
- Renal insufficiency
- Symptomatic UTIs
- Shunt failure or infections
- Seizure disorders
- Musculoskelet al problems (scoliosis, club foot, others)

FOLLOW-UP

Patient Monitoring

Close follow-up with pediatric urology and neurology from infancy and throughout childhood is required to avoid upper tract deterioration and achieve urinary and bowel continence.

Annual US and VUD when continent with stable upper tracts.

Patient Resources

CODES

ICD9
- 238.75 Myelodysplastic syndrome, unspecified
- 596.54 Neurogenic bladder NOS
- 788.30 Urinary incontinence, unspecified

ICD10
- D46.Z Other myelodysplastic syndromes
- N31.9 Neuromuscular dysfunction of bladder, unspecified
- R32 Unspecified urinary incontinence

CLINICAL/SURGICAL PEARLS

- Affected children often have varying degrees of neurogenic bladder and bowel dysfunction.
- 1st-line treatment consists of CIC for elevated PVR and anticholinergics when VUD testing suggests poor detrusor compliance and/or detrusor overactivity with or without upper tract deterioration. Botulinum-A toxin injections, bladder augmentation, antireflux procedures and /or bladder neck procedures performed to protect upper tracts and achieve urinary continence.

NEPHROCALCINOSIS, ADULT

Jennifer E. Heckman, MD, MPH
Stephen Y. Nakada, MD, FACS

BASICS

DESCRIPTION

- Disorder characterized by deposition of calcium salts in the renal parenchyma
  - Calcium oxalate (CaOx)
  - Calcium phosphate (CaPhos)
- May be intratubular or interstitial
- May cause renal injury or be incidentally detected
- Associated with multiple conditions
  - Renal prognosis dependent on underlying cause
  - Often associated with severe metabolic defects
- Can be classified by location:
  - Renal medulla (medullary nephrocalcinosis)
  - Renal cortex (cortical nephrocalcinosis)
- Can also be classified as:
  - Molecular: Measurable increase in intracellular calcium concentration, but not visible microscopically or radiographically
  - Microscopic: Visible microscopically
  - Macroscopic: Visible radiographically
- Distinct entity from nephrolithiasis (calcifications in collecting system)
- Neonatal nephrocalcinosis is discussed in Section II "Nephrocalcinosis, Neonatal"

EPIDEMIOLOGY

Incidence

Unclear secondary to wide range of etiologies

Prevalence

- Primarily diagnosed in:
  - Adults
  - Low–birth-weight neonates (60% of preterm infants, frequently caused by loop diuretics)
- Medullary nephrocalcinosis (97–98%), cortical nephrocalcinosis (2–3%)

RISK FACTORS

- Disorders that cause:
  - Hypercalcemia
  - Hyperphosphatemia
  - Hypercalciuria
  - Hyperphosphaturia
  - Hyperoxaluria
  - Hypocitraturia

Genetics
Inherited disorders may lead to risk factors for nephrocalcinosis development (eg, autosomal dominant hypocalcemia, familial hyperoxaluria)

PATHOPHYSIOLOGY
- Caused by increase in urinary excretion of calcium, phosphate, and/or oxalate (1)
  - May occur with or without hypercalcemia
  - CaOx and CaPhos crystals result from urinary supersaturation
    - CaOx and CaPhos crystals precipitate, aggregate, and move to interstitium
    - May result in acute or chronic renal damage and/or lead to calculus formation
    - Renal ischemia or injury may augment nucleation of CaOx or CaPhos crystals

ASSOCIATED CONDITIONS
- Nephrolithiasis
- Hypercalciuric states:
  - Primary hyperparathyroidism (most common cause in adults)
  - Sarcoidosis
  - Vitamin D intoxication
  - Multiple myeloma
  - Tuberculosis
  - Milk-alkali syndrome
  - Distal renal tubular acidosis
  - Medullary sponge kidney
  - Inherited tubular defects (eg, Bartter syndrome)
  - Chronic hypokalemia (eg, primary aldosteronism)
  - Chronic immobilization
- Hyperphosphaturic states:
  - Tumor lysis syndrome
  - Inherited tubular defects
- Hyperoxaluric states:
  - Primary oxaluria
  - Secondary oxaluria (increased intake or enhanced absorption)
  - Fat malabsorptive disorders (eg, pancreatic insufficiency, inflammatory bowel disease)
- Chronic pain

GENERAL PREVENTION
- Avoid hypercalciuric, hyperphosphaturic, and hyperoxaluric states
- Avoid medications that enhance calcium loss (eg, loop diuretics)

DIAGNOSIS
HISTORY
- Most cases are asymptomatic (incidental finding on imaging)
- Occasionally present with symptoms related to underlying cause or associated condition
  - Nausea, decreased appetite, abdominal pain, myalgias, polydipsia, lethargy (hypercalcemia)
  - Fatigue, edema, mental status changes, seizures (renal failure)

  – Renal colic, hematuria (nephrolithiasis)
• Review past medical history and medications

PHYSICAL EXAM
• Nonspecific, many patients are asymptomatic
• Physical findings otherwise a manifestation of underlying disorder

DIAGNOSTIC TESTS & INTERPRETATION
Lab
• Used to identify underlying causative disorder
• Serum studies:
  – Calcium, phosphate, albumin
  – Electrolytes
  – BUN, Cr
  – Parathyroid hormone (PTH) levels
  – Thyroid-stimulating hormone (TSH) levels
  – CBC
• Urine studies:
  – Urinalysis with microscopy +/– urine culture (if indicated)
  – 24-hr urine collection

Imaging
• Can be detected on:
  – Abdominal radiograph
    ◦ Usually only if attenuation >100 Hounsfield units and size >2 mm
    ◦ Medullary nephrocalcinosis: Stippled calcifications in renal pyramids
    ◦ Cortical nephrocalcinosis: Thin peripheral band with perpendicular extension; thin, peripheral calcific tracts; or diffuse punctuate calcifications
  – Ultrasound
    ◦ Hyperechoic areas with or without acoustic shadowing
  – Computed tomography
    ◦ Most sensitive and specific
• Pattern and distribution may be suggestive of etiology
• Imaging extent of calcium deposition unrelated to renal functional impairment or prognosis
• Regardless of imaging modality, can be difficult diagnosis, with low levels of intra-observer concordance (2)[B]

Diagnostic Procedures/Surgery
• Radiographic diagnosis (usually incidental finding)
• Rarely, diagnosed on renal biopsy

Pathologic Findings
• Primary histologic finding on renal biopsy:
  – Tubular, intracellular, and interstitial basophilic calcifications
• (+) von Kossa stain of calcifications diagnostic of CaPhos

DIFFERENTIAL DIAGNOSIS
• Nephrolithiasis

- Renal calcifications, associated with:
  - Chronic ureteropelvic junction obstruction or ureterocele
  - Renal infarction
  - Renal mass
- Dystrophic calcifications, associated with:
  - Renal tuberculosis
  - Congenital cystic kidney
- Renal artery calcifications
- Calcification associated with spinal injury

TREATMENT

GENERAL MEASURES

- Treatment directed at underlying etiology
- No specific treatment prevents progression
- Early treatment of reversible causes of renal injury important
- Reduce urinary concentration and increase solubility of calcium, phosphate, and/or oxalate
  - Increase fluid intake
    - Goal urine output >2 L/d
  - If hypercalciuria:
    - Restrict animal protein intake (<0.7 g/kg)
    - Restrict sodium intake (<100 mEq/d)
  - If hypocitraturia and urine pH <7:
    - Potassium citrate (titrate to normal urinary citrate)

MEDICATION

First Line

Must be tailored to underlying etiology (eg, for hyperparathyroidism, resection of adenoma, treatment of renal tubular acidosis, etc.)

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Surgical intervention may be required, particularly if calcification obstructs collecting system
  - Endourologic management
    - May use in diagnosis (direct visual inspection) (3)[C]
    - May treat with flexible ureteroscopy/nephroscopy with laser or electrohydraulic lithotripsy (4)[C]
    - Ureteroscopic laser papillotomy may be safe and effective in patients with chronic flank pain (5)[C]
  - Extracorporeal shockwave lithotripsy (ESWL)
    - Poor fragmentation and evacuation

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Depends on underlying etiology
- Most do not progress to end-stage renal failure

COMPLICATIONS
- Nephrolithiasis
- Obstructive uropathy
  - May be associated with sepsis
- Renal infection
- Renal scarring
- Defects in renal tubular function
- Acute renal failure
- Chronic renal failure

FOLLOW-UP
Patient Monitoring
- Urinalysis, 24-hr urine collection
- Renal function testing
- Serum Ca
- Labs to monitor known metabolic abnormalities
- Imaging if symptomatic

CODES

ICD9

- 275.3 Disorders of phosphorus metabolism
- 275.42 Hypercalcemia
- 275.49 Other disorders of calcium metabolism

ICD10

- E83.52 Hypercalcemia
- E83.59 Other disorders of calcium metabolism
- N29 Oth disorders of kidney and ureter in diseases classd elswhr

CLINICAL/SURGICAL PEARLS

- Important to distinguish nephrocalcinosis from nephrolithiasis.
- Management directed at underlying cause of disorder.
- Primarily a radiographic diagnosis, does not typically require surgical intervention.

NEPHROTIC SYNDROME

Michael Perrotti, MD

BASICS

DESCRIPTION

- Neoprotic syndrome refers to a specific renal disease with a distinct constellation of clinical and laboratory features:
  - Proteinuria (>3.5 g/d)
  - Hypoalbuminemia (<3 g/dL)
  - Peripheral edema
  - Hyperlipidemia and thrombotic disease frequently seen
- Nephrotic syndrome (NS) can be caused by specific renal diseases or systemic diseases such as diabetes, lupus and others.

EPIDEMIOLOGY

Incidence

- Uncommon Disease
  - Children: 2/100,000 new cases / year
  - Adult: 3/100,000 new cases / year

Prevalence

N/A

RISK FACTORS

- Primary renal disease (minimal change disease predominant cause in children)
- Underlying systemic disease in 30% of adults with NS including diabetes mellitus, amyloidosis, systemic lupus erythematosus
- Infection: Streptococcus, hepatitis, mononucleosis, syphilis, tuberculosis, HIV
- Medications: NSAIDs, interferons, bisphosphonates, lithium, gold, captopril, penicillamine, tyrosine kinase inhibitors
- Malignancy

Genetics

- Rare cause
  - 2–8% of cases are familial
  - Finnish type congenital nephritic syndrome is inherited as autosomal recessive

PATHOPHYSIOLOGY

- Severe proteinuria is due to abnormal permeability of the glomerular basement membrane (GBM) (1).
  - GBM normally restricts passage of proteins >70 kd.
- Signs/symptoms of NS worsen as serum albumin falls below 2.5 g/dL.
- Proteinuria can be selective or nonselective.
- Edema results from primary salt retention and secondary decreased plasma oncotic pressure.
- Hyperlipidemia is secondary to increased hepatic synthesis from low oncotic pressure and

urinary loss of regulatory proteins.
- Hypercoagulable state is likely due to loss of antithrombin III in urine.

ASSOCIATED CONDITIONS
- Membranous nephropathy (24%)
- Minimal change disease (15%)
- Lupus (14%)
- Focal segmental glomerulosclerosis (12%)
- Membranoproliferative glomerulonephritis (7%)
- Amyloidosis (6%)
- IgA nephropathy (6%)

GENERAL PREVENTION
- Avoidance of risk factors
- Treating conditions that may cause NS

DIAGNOSIS
HISTORY
- Symptoms of fluid/sodium retention:
  - Periorbital edema, especially on awakening
  - Peripheral edema, especially at end of day
  - Dyspnea/orthopnea secondary to pleural effusion
- Anorexia
- Oliguria, foamy urine
- Weight gain
- Foamy appearance of urine

PHYSICAL EXAM
- Along with signs of fluid retention, patients may have signs of systemic disease causing NS
- Vital signs: BP, temperature, weight
- Skin exam: Rash (eg, butterfly rash of SLE), pallor, edema, lymphadenopathy
- Ophthalmic exam: Uveitis in sarcoid, diabetic retinopathy
- Heart/lung exam: Endocarditis, pleural effusion
- Abdominal exam: Masses, ascites
- Neurologic exam: Diabetic neuropathy, CNS lesion, mononeuritis multiplex

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Blood chemistry: BUN, Cr, comprehensive metabolic panel, CBC
  - Hypoalbuminemia (<3 g/dL)
- Serum lipids: Cholesterol, triglycerides often elevated
- Urine analysis and microscopy
  - Marked proteinuria causes urine to foam.
  - Albuminuria detected by dipstick; all proteinuria detected by SSA; Protein is precipitated in urine by the addition of sulfosalicylic acid (SSA). Performed to confirm positive protein reactions seen on a urine dipstick.

  – Positive SSA and negative dipstick: Nonalbumin proteinuria (multiple myeloma)
  – Characteristic dipstick reading of 3+ to 4+ in NS patients
  – Glycosuria: Suggests diabetes mellitus as possible cause of NS
  – Hematuria common (usually microscopic)
  – Lipiduria: Maltese crosses seen microscopically
  – Microscopic: Oval fat bodies, fatty casts, hyaline casts, cellular casts
- 24-hr urine
  – Protein > 3.5 g/24 h, mostly albumin
- Additional testing as needed to rule out other nonrenal causes
  – Fasting blood sugar/glucose tolerance
  – Hepatitis B and C antibodies
  – Antinuclear antibody
  – Syphilis serology
  – HIV
  – Multiple myeloma

Imaging
- Renal ultrasound: Increased echogenicity of renal parenchyma
- Screening for underlying malignancy with CT scan

Diagnostic Procedures/Surgery
Renal biopsy

Pathologic Findings
- Minimal change glomerulopathy
- Membranous glomerulopathy
- Focal segmental glomerulonephritis
- Mesangioproliferative glomerulonephritis
- Membranoproliferative glomerulonephritis
- Diabetic glomerulosclerosis
- Fibrillary glomerulonephritis
- Light chain deposition disease

DIFFERENTIAL DIAGNOSIS
- Congestive heart failure
- Cirrhosis
- Malnutrition
- Protein losing enteropathy

TREATMENT

GENERAL MEASURES
- Sodium restriction (2 g/d)[A]
- Protein restriction
- BP control
- Maintenance of fluid balance

MEDICATION

First Line

- ACE inhibitors (captopril, enalapril, ramipril, others) or Angiotensin II receptor blockers (losartan, olmesartan, telmisartan others) (2)
  - Indicated with random protein to creatinine ratio >200 mg/G
  - Should not be used concurrently due to risk of hypotension and worsening renal function
  - Monitor for hypotension, hypokalemia, or worsening renal function
  - Common ACE-I side effects include cough, angioedema, or allergy
- Statin therapy
  - Goal LDL <100 and triglyceride <150
  - Side effects include myalgia, liver dysfunction, GI disturbance, and rash
- Corticosteroids for primary idiopathic or minimal change disease (3)[A]

Second Line

Cytotoxic agents (cyclophosphamide, chlorambucil, cyclosporine): Minimal change disease unresponsive to steroids, membranous glomerulonephritis with poor prognosis

SURGERY/OTHER PROCEDURES

- Dialysis
- Renal transplantation

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Anticoagulation for thrombosis

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Prognosis depends on age, race, pathology, presence of HTN, underlying systemic disease, degree of renal dysfunction, and degree of proteinuria.
- Minimal change disease in children has an excellent prognosis.
- Prognosis of the other glomerulopathies much more variable.
- Prognosis of secondary NS depends on the systemic diseases causing the NS.

COMPLICATIONS

- Acute kidney failure
- Atherosclerosis, hyperlipidemia, cardiovascular disease
- Chronic kidney disease
- Congestive heart failure
- Heart disease
- Malnutrition
- Pneumococcal pneumonia and other infections

- Pulmonary edema
- Arterial and venous thrombosis (particularly deep vein and renal vein thrombosis)
- Pulmonary emboli

FOLLOW-UP

Patient Monitoring

- Assess response to treatment with 24-hr urine protein measurement
- Monitor BP and renal function
- Monitor for treatment toxicity

Patient Resources

- Medline Plus http://www.nlm.nih.gov/medlineplus/ency/article/000490.htm

CODES

ICD9

- 250.40 Diabetes with renal manifestations, type II or unspecified type, not stated as uncontrolled
- 250.41 Diabetes with renal manifestations, type I [juvenile type], not stated as uncontrolled
- 581.9 Nephrotic syndrome with unspecified pathological lesion in kidney

ICD10

- E10.21 Type 1 diabetes mellitus with diabetic nephropathy
- E11.21 Type 2 diabetes mellitus with diabetic nephropathy

- N04.9 Nephrotic syndrome with unspecified morphologic changes

CLINICAL/SURGICAL PEARLS

- NS is a constellation of signs and symptoms caused by different disorders that damage the kidneys.
- The hallmark of NS is excess protein in the urine and edema.
- The most common cause in children is minimal change disease.
- The most common cause in adults is membranous glomerulonephritis.
- Treatment is directed toward the underlying disorder, symptom reduction, and prevention of complications and preservation of renal function.
- Most patients are given an ACE inhibitor or an angiotensin II receptor blocker to slow the loss of kidney function.

NEUROBLASTOMA

Nilay M. Gandhi, MD
Arthur L. Burnett, II, MD, MBA, FACS

BASICS

DESCRIPTION

- Heterogeneous malignancy arising from neural crest elements along the sympathetic chain with a broad spectrum of clinical behavior
- International Neuroblastoma Staging System (INSS) (1)
  - Stage 1: Localized tumor, completely excised, ipsilateral lymph nodes (LN) (–)
  - Stage 2a: Localized tumor, incompletely excised, ipsilateral LN (–)
  - Stage 2b: Localized tumor with/without complete excision, ipsilateral LN (+), enlarged contralateral LN (–)
  - Stage 3: Unresectable unilateral tumor crossing midline or localized unilateral tumor with contralateral LN (+)
  - Stage 4: Any primary tumor with metastasis to distant LN, bone, liver, skin, or bone marrow
  - Stage 4s: Localized primary tumor (stage 1, 2a, 2b) metastasis limited to liver, skin, and/or bone marrow in infant <1 yr

EPIDEMIOLOGY

Incidence

- 3rd most common childhood cancer (after leukemia and brain tumors)
  - Most common solid extra-cranial tumor in children
  - Most common cancer in infants <1 yr of age
- Comprises 6–10% of all childhood neoplasms
  - 1 in 7,000 live births
  - 750 new cases/yr
    - 50% incidence in children <2 yr of age (highest incidence in 1st yr of life)
    - Peak age 0–4 yr (median 18–24 mo)
    - More common in Caucasian male infants

Prevalence

- 10.5 per 1 million children <15 yr of age
- Accounts for 15% of all pediatric cancer fatalities

RISK FACTORS

- Risk in sibling or offspring is <6%
- Maternal factors:
  - Folate deficiency (increased incidence)
  - Gestational diabetes mellitus
- Environmental factors implicated but not confirmed (2)
  - Paternal exposure to electromagnetic fields
  - Prenatal exposure to alcohol, pesticides, or phenobarbital

  – Potential relationship with assisted pregnancies
- Genetic factors:
  – Increased incidence in Turner's syndrome

Genetics
- Majority are sporadic
  – 1–2% familial (autosomal dominant 20%)
    ○ 20% bilateral adrenal or multifocal tumors
    ○ Germline mutation in *ALK* gene
- Aneuploidy = favorable prognosis
- N-*MYC* amplification (20% patients), chromosome 1p deletion (25–35%), loss of 11q heterozygosity (35–45%) = adverse prognosis

PATHOPHYSIOLOGY
- Determined by tumor site origin, metastasis, and presence of paraneoplastic syndromes
- Likely failure of persistent primitive ganglion cells to respond to normal signals
- Spinal cord, sympathetic ganglia involvement:
  – Urinary retention, constipation, extremity paresis, Horner syndrome
- Presence of metastasis:
  – Fever, lethargy, weight loss, bony pain, pallor
- Bone metastasis (older children)
- Liver metastasis (younger children)
- Active biochemical products:
  – 90% produce catecholamines
    ○ Paroxysmal hypertension (HTN), palpitation, flushing, headache
  – Homovanillic acid (HVA) in poorly differentiated tumors
  – Vanillylmandelic acid (VMA) in well-differentiated tumors

ASSOCIATED CONDITIONS
- Other disorders of neural crest derived cells
  – Hirschsprung disease
  – Neurofibromatosis type 1
  – Congenital central hypoventilation syndrome

GENERAL PREVENTION
- Screening with urinary catecholamines is not effective (Japan, Canada, Germany)
  – Increased diagnosis, no impact on survival
  – Majority low-grade, spontaneously resolve
- Genetic counseling indicated if family history

DIAGNOSIS

HISTORY
- Early satiety, poor appetite, vomiting
  – Possible partial bowel obstruction due to intra-abdominal mass
- Unexplained weight loss, anorexia, fever, pallor, irritability suggests metastatic disease

- Urinary frequency/retention, constipation:
  - Extrinsic compression of pelvic organs/nerves from presacral mass
- Poor truncal balance, jerky muscle movements, or uncontrolled eye movement
  - Acute myoclonic encephalopathy (2%)
    - Toxic byproducts/autoimmune phenomenon
- Extremity weakness, sensory deficits
  - Paravertebral tumor compressing spinal cord
- Pain in skull and long bones from metastasis
- Pallor/anemia (bone marrow involvement in 50% of patients)
- Bleeding diathesis (from liver metastasis)
- Paroxysmal HTN, sweating, headaches, palpitations
  - $<5\%$ patients (catecholamines sequestered within intracellular vacuoles)
- Watery diarrhea, hypokalemia due to VIP secretion

PHYSICAL EXAM
- Abdominal mass
  - 65% retroperitoneal, 40% adrenal
- HTN (rare, due to catecholamine release)
- Metastasis present in 70% at diagnosis
  - Raccoon's eyes
    - Upper eyelid hemorrhage (periorbital metastasis)
  - Bluish/erythematous subcutaneous nodules
    - Skin metastasis, "blueberry-muffin" spots
- Acute myoclonic encephalopathy
  - Rapid eye movements (opsoclonus), jerky extremities (myoclonus)
  - Cerebellar ataxia, dysphasia, intellectual deficit
  - Autoimmune phenomenon
  - 70–80% with prolonged neurologic impairment (ACTH/steroid therapy)
- Unilateral Horner's syndrome
  - Ptosis, loss of papillary dilation, unilateral anhydrosis
  - Tumor compression on sympathetic ganglia
- Extremity paresis, sensory deficits
  - Paravertebral tumor compressing spinal cord

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- 24-hr urinary VMA and HVA
  - Elevated in 90–95% of patients
- CBC: Anemia suggests bone marrow involvement
- PT/PTT: Elevation suggests liver involvement
- Ferritin: Elevation in advanced disease
  - 40–50% of patients (must be >3 standard deviations)

Imaging
- Ultrasound (1st choice for children with palpable abdominal mass)
- Whole-body CT

  – Evaluate primary tumor, regional extent, distant metastasis
  – Intratumoral calcification and/or vascular encasement distinguishes from Wilms tumor
• Whole-body MRI
  – Evaluate intraspinal tumor extension, delineate major vessels
• Bone scan (radionuclide, not skelet al)
• Iodine^{123} MIBG
  – Determine extent of disease, assess tumor recurrence

Diagnostic Procedures/Surgery
• Open/laparoscopic biopsy for pathologic tissue diagnosis
• Bone marrow aspirate/biopsy
  – 2 marrow aspirates (bilateral iliac crests) + 2 core biopsies recommended
  – 70% positive aspirates
    ◦ Future research into neuroblastoma-specific immunocytology of marrow aspirates

Pathologic Findings
• Gross: Solid/cystic vascular, poorly encapsulated purple mass
• Histology:
  – Small round blue cells
    ◦ Mitosis-Karyorrhexis index is prognostic
  – Homer–Wright pseudorosettes
• Histopathologic markers:
  – N-*MYC*
  – DNA ploidy
  – Shimada classification (stroma poor/rich)
    ◦ Stroma-poor (based on age, histologic maturation, mitotic rate)
    ◦ Stroma-rich (nodular, intermixed, well differentiated)
• Neuron-specific enolase (NSE) staining is specific for neuroblastoma
• Periodic acid-Schiff (PAS) staining can distinguish sarcomas

DIFFERENTIAL DIAGNOSIS
• Ganglioneuroma (benign form)
• Ganglioneuroblastoma (intermediary between ganglioneuroma and neuroblastoma)
• Intra-abdominal mass in childhood:
  – Wilms tumor
  – Pheochromocytoma
  – Rhabdomyosarcoma
  – Lymphoma
  – Teratoma
  – Ewing sarcoma
  – Rare primary neoplasms of liver and pancreas

TREATMENT

GENERAL MEASURES
• Multimodal treatment approach involving surgery, chemotherapy, radiotherapy, and/or

bone marrow or stem cell transplantation
- Nearly all stage 4s patients spontaneously resolve (observation)
- INSS surgical stage and more recently the International Neuroblastoma Risk Group (INRG) pretreatment system dictates treatment (3)

MEDICATION

First Line (4)

- Low risk: None unless surgical failure
  – Cyclophosphamide, Adriamycin, and Cisplatin/VM-26 in low-dose cycles
- Intermediate risk: Induction with Cyclophosphamide and Adriamycin with or without radiotherapy
- High risk: Cyclophosphamide, Adriamycin, VM-26, Doxorubicin, Cisplatin, Etoposide in various combinations

Second Line

- Intermediate risk: Cisplatin/VM-26
- High risk: Alternative use of above-listed combinations

SURGERY/OTHER PROCEDURES

- Low risk (stages 1, 2, or 4s with age <1 yr or >1 yr with favorable pathology):
  – Surgery is curative
  – Chemotherapy indicated if recurrence, N-*MYC* amplification, or unfavorable histology
- Intermediate risk (stage 3 age <1 yr or >1 yr with favorable pathology, or stage 4 <1 yr):
  – Surgery + multiagent chemotherapy
- High risk (stage 2 with age >1 yr with unfavorable histopathology, or stage 3, 4, 4s with N-*MYC* amplification regardless of age):
  – Intensive chemotherapy with or without bone marrow ablation and repeated surgery

ADDITIONAL TREATMENT

Radiation Therapy

- Reserved for primary or secondary chemotherapy failures in low-risk patients
- Utilized for local control in bulky stage 3 or advanced stage 4
  – Avoid if spinal cord compression due to adverse effects on spine growth
- Intraoperative radiation therapy not better than external beam irradiation

Additional Therapies

Bone marrow transplantation

Complementary & Alternative Therapies (5)

- 13-cis-retinoic acid improves 5-yr overall survival (OS) in children with advanced stage disease after transplantation or intensive chemotherapy
- Iodine^{131} MIBG targeted delivery for metastatic disease
- Anti-GD2 antibodies (research pending)

ONGOING CARE

PROGNOSIS

- Dependent on risk status

  - Low risk: Resection is curative, 97% 5-yr OS
  - Intermediate risk: neoadjuvant chemo followed by >50% resection, 70–90% 5-yr OS
  - High risk: Neoadjuvant chemo 4 cycles (restage after 2 cycles), >50% resection, radiation, peripheral stem cell transplant, monoclonal Ab, 20–40% 5-yr OS
- Better survival in nonadrenal primary tumors
- Shimada classification
  - Stroma-poor: <10% survival

COMPLICATIONS

- Dumbbell neuroblastoma with spinal cord compression
  - Best treated with chemotherapy
  - Neurosurgical intervention only for emergent decompression
- Associated with tumor presentation and with treatment modalities

FOLLOW-UP

Patient Monitoring

- Low risk:
  - Imaging + lab markers 1–2 mo after therapy, every 6 mo for 5 yr, then annually after 5 yr
- Intermediate risk:
  - Imaging + lab markers 1–2 mo after therapy, every 1–3 mo for 1st yr, then every 4–6 mo for 2–5 yr, then annually after 5 yr
- High risk:
  - Imaging + lab markers 1–2 mo after therapy, every 1–3 mo for 5 yr, every 6 mo after 5 yr

CODES

ICD9

- 194.0 Malignant neoplasm of adrenal gland
- 197.7 Malignant neoplasm of liver, secondary
- 198.5 Secondary malignant neoplasm of bone and bone marrow

ICD10

- C74.90 Malignant neoplasm of unsp part of unspecified adrenal gland
- C78.7 Secondary malig neoplasm of liver and intrahepatic bile duct
- C79.52 Secondary malignant neoplasm of bone marrow

CLINICAL/SURGICAL PEARLS

- Most common malignancy in infants <1 yr.
- INSS stage determines optimum treatment modality.
- Urine HVA and VMA are diagnostic.
- N-*MYC* associated with poor prognosis.
- Neuroblastoma requires a minimum of 5-yr follow-up.

NEUROGENIC BLADDER, GENERAL CONSIDERATIONS

Alana M. Murphy, MD

BASICS

DESCRIPTION

Neurogenic bladder (NGB) is a general term used to describe dysfunction of the urinary bladder due to disease of the central nervous system (CNS) or peripheral nerves involved in the control of urine storage and micturition

EPIDEMIOLOGY

Incidence

Difficult to determine incidence due to multiple etiologies

Prevalence

- Prevalence of voiding dysfunction by specific conditions:
  - Cerebrovascular accident: 20–50%
  - Parkinson disease: 35–70%
  - Multiple sclerosis: 50–90%
  - Diabetes mellitus: 5–60%

RISK FACTORS

- Neurologic disease, injury, or congenital malformation
- Diabetes mellitus
- Radical pelvic surgery

Genetics

Genetic diseases that may be associated with NGB include muscular dystrophy, hereditary spastic paraplegia, neurofibromatosis, and familial dysautonomia

PATHOPHYSIOLOGY

- CNS lesions (1):
  - Suprapontine:
    - Function: Inhibits sacral micturition center
    - Detrusor overactivity (DO) due to loss of inhibition of sacral micturition center
  - Pontine micturition center:
    - Function: Coordinates sphincter relaxation during bladder contraction
    - Lesions between pontine and sacral micturition centers are associated with DO and detrusor sphincter dyssynergia (DSD)
  - Sacral micturition center:
    - Function: Mediates reflex and voluntary bladder contraction
    - Detrusor underactivity or acontractility
- Peripheral lesions (1): Variable voiding dysfunction
  - Detrusor underactivity
  - Impaired bladder sensation
  - Impaired sphincteric function

ASSOCIATED CONDITIONS

- CNS diseases:
  - Cerebrovascular accident
  - Multiple sclerosis
  - Normal-pressure hydrocephalus
  - Parkinson disease
  - Spinal cord injury
  - Transverse myelitis
- Peripheral nerve disease:
  - Following radical pelvic surgery:
    - Abdominoperineal resection
    - Radical hysterectomy
  - Diabetes mellitus
  - Intervertebral disk disease
  - Spinal stenosis
  - Guillain–Barré syndrome
- Neural tube defects
- Cerebral palsy

GENERAL PREVENTION

- Tight glycemic control with diabetes mellitus
- Prevention aimed at preventing secondary complications
  - Infections
  - Incontinence
  - Skin breakdown
  - Urolithiasis

DIAGNOSIS

HISTORY

- Neurologic disease: Onset, duration
- Diabetes mellitus
- Congenital disorders:
  - Neural tube defects
  - Cerebral palsy
- History of radical pelvic surgery
- Voiding symptoms
- Storage symptoms
  - Urinary frequency
  - Incontinence
- Method of urinary management:
  - Volitional or reflex voiding
  - Condom catheter urinary collection
  - Intermittent self-catheterization
  - Indwelling urethral or suprapubic catheter
  - Credé or Valsalva voiding

- UTI:
  - Severity of infection: Febrile, hospitalization, IV antibiotics required
  - Frequency of recurrence
- Urolithiasis episodes, surgical intervention, calculus composition
- Autonomic dysreflexia (AD): Associated with spinal cord lesion at or above T6
  - Occurs with manipulation of the urinary or gastrointestinal tract

PHYSICAL EXAM

- Flank tenderness: Ureteral obstruction, pyelonephritis
- Abdominal mass: Distended bladder, urinary retention
- Incontinence of urine:
- Testicular exam:
  - Epididymo-orchitis/epididymitis; secondary abscess
- Digital rectal exam:
  - Prostate size: BPH may coexist with NGB
  - See neurologic exam
- Evaluate for sacral abnormalities:
  - Sacral dimple, skin tag, discoloration or tuft of hair may suggest occult spinal dysraphism
  - Sacral agenesis
- Focused neurologic exam:
  - Sacral root
  - Perianal sensation
  - Anal tone, sphincter control

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Blood studies:
  - Serum chemistry: Renal function, creatinine
  - CBC: Elevated WBC, secondary anemia due to decreased renal function or chronic infection
- Urinalysis:
  - Proteinuria: Renal dysfunction
  - Pyuria, nitrite, leukocyte esterase: Acute or chronic infection
  - Hematuria: Infection or urolithiasis

Imaging

- Imaging is most important in patients with risk factors for upper tract compromise:
  - DSD (especially males who void reflexively)
  - Impaired bladder compliance
- Renal ultrasound (US): To screen for calculus, hydronephrosis, or mass
- Excretory urography:
  - Delayed excretion of contrast with high urinary storage pressures
  - Hydroureteronephrosis:
    - Marked elevation of intravesical pressure or calculi
- Nuclear medicine renal scan:
  - Assess for obstruction

– Sequential studies detect deterioration of renal function

Diagnostic Procedures/Surgery

- Urodynamics (UDS): Necessary to determine effective urologic management for all patients with neurogenic lower urinary tract dysfunction
- Neurogenic DO (NDO):
  – Loss of CNS inhibition
- DSD (abnormal reflexive sphincter contraction during involuntary or voluntary detrusor contraction):
  – Functional bladder outflow obstruction with elevated intravesical pressure
  – Secondary damage: Pressure, infection, urolithiasis
  – 10–20% of patients have internal (bladder neck) sphincter dyssynergia with external sphincter dyssynergia.
  – Elevated intravesical pressure >40 cm H_2O responsible for sequelae of NDO–DSD
- Detrusor underactivity or acontractility:
  – Interruption of sacral reflex arc; no detrusor contraction
  – Typically low-pressure storage
  – Adrenergic overgrowth: May result in decreased bladder compliance, elevated storage pressure

Pathologic Findings

Bladder wall thickening with fibrosis and trabeculation

DIFFERENTIAL DIAGNOSIS

- Idiopathic overactive bladder
- Dysfunctional voiding

TREATMENT

GENERAL MEASURES (2)

- UDS is essential to determine lower urinary tract function/dysfunction and to plan urologic management.
- Maintaining low intravesical pressure protects upper urinary tracts
- Urinary drainage: Intermittent catheterization or external collection appliance
- Indwelling catheterization:
  – Associated with recurrent UTIs, urethral erosion, urolithiasis
- Intermittent self-catheterization: Most effective treatment; requires low storage pressure
- Surgical intervention is indicated when other therapies fail to protect the upper urinary tract or provide continence.

MEDICATION

First Line

- Antimuscarinics aimed at decreasing urinary storage pressure and reducing NDO. Most common side effects include dry mouth and constipation
  – Fesoterodine 4–8 mg QD
  – Hyoscyamine extended release 0.375 mg BID
  – Oxybutynin 5 mg BID-TID

  - Oxybutynin transdermal patch 3.9 mg/d
  - Oxybutynin XL 10–15 mg/d
  - Oxybutynin, topical gel 10% apply 1 sachet QD to dry skin
  - Solifenacin 5–10 mg/d
  - Tolterodine LA 1–2 mg BID
  - Tolterodine LA 2–4 mg/d
  - Trospium XR 60 mg/d
- β 3-agonist: Most common side effects include an increase in blood pressure and palpitations
  - Mirabegron 25 mg/d increase to 50 mg/d after 8 wk PRN
- *α*-Adrenergic blockers: Decrease internal sphincter resistance, lower voiding pressure; ineffective for DSD.
  - Alfuzosin 10 mg/d
  - Doxazosin start 1 mg/d to max 8 mg
  - Silodosin 8 mg/d
  - Tamsulosin start 0.4 mg to max 0.8 mg
  - Terazosin start 1 mg/d to max 20 mg

Second Line

- Botulinum toxin type A (onabotulinumtoxinA) injection into the external sphincter for DSD
  - Short-lived; requires repeat injections
- Botulinum toxin injection into the detrusor for NDO
  - Duration of action is 3–9 mo
  - Requires repeated injections

SURGERY/OTHER PROCEDURES

- Endoscopic sphincter ablation or stenting:
  - Only males with DSD; requires condom catheter
- Augmentation cystoplasty using an intestinal segment to enlarge the bladder
  - Goal is to increase bladder volume and decrease bladder pressure
  - Intermittent catheterization for urinary drainage
  - Limited dexterity mandates construction of a continent catheterizable stoma for the urinary reservoir, especially in females
- Ileovesicostomy
  - Useful for those unable to perform self-catheterization (ie, quadriplegia)
- Cystectomy with continent urinary reservoir
  - Ileal or colon pouch; continent catheterizable stoma (appendix or tapered ileum)
- Cystectomy with ileal conduit

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Neuromodulation, sacral nerve stimulation and posterior tibial nerve stimulation are not FDA approved for the treatment of NDO but may have some benefit.

Complementary & Alternative Therapies

Acupuncture has been reported to improve symptoms of neurogenic bladder.

ONGOING CARE

PROGNOSIS

Proper urologic management greatly improves quality of life in patients with NGB dysfunction.

COMPLICATIONS

- Recurrent UTIs
- Urinary retention
- Hydroureteronephrosis
- Neoplastic transformation: Associated with chronic catheter
- Urethral erosion

FOLLOW-UP

Patient Monitoring

- Annual evaluation in high-risk patients may include (3):
  - UDS
  - Imaging: Typically renal US
  - Serum creatinine

Patient Resources

- N32.81 Overactive bladder

CLINICAL/SURGICAL PEARLS

Adequate management of lower urinary tract function is essential to avoid upper urinary tract compromise and preservation of renal function.

NOCTURIA

Garjae D. Lavien, MD
Michael J. Naslund, MD

BASICS

DESCRIPTION

- Nocturia is a symptom describing an individual who awakens at night one or more times to void. Each void is preceded and followed by sleep.
- Can negatively impact quality of life.
  - Can be associated with depression, daytime fatigue, and increased orthopedic morbidity among the elderly.
- Underlying etiologies of nocturia
  - Nocturnal polyuria:
    - The rate of urine output is excessive only at night and total 24-hr output is within normal limits.
  - Reduced bladder capacity
  - 24-hr polyuria
  - Sleep disorder

EPIDEMIOLOGY

Incidence

- The incidence of nocturia and total number of voiding episodes increases with age
  - Overall: 28%
  - Age >60: 41%
- Body mass index >29: 36%
- Black and Hispanic > White

Prevalence

- Higher prevalence in women than men among young adults
- Higher prevalence in men than women among elderly population groups

RISK FACTORS (1)

- Advanced age
- Diuretic usage
- Lower urinary tract dysfunction
- Cardiac disease
- Obesity, sleep apnea

Genetics

None

PATHOPHYSIOLOGY

- 24-hr polyuria:
  - Excessive total urine production where the total 24-hr urinary volume >40 mL/kg)
  - Diabetes mellitus:

    - Secondary to polydipsia and osmotic diuresis from hyperglycemia
  - Diabetes insipidus:
    - Under-secretion (central) or impaired response (nephrogenic) to ADH
  - Medications:
    - Lithium, diuretics, caffeine, nephrotoxic medications
  - Hypercalcemia: Can cause osmotic diuresis
  - Hyperaldosteronism
  - Psychogenic polydipsia
- Nocturnal polyuria
  - Relative increased production of urine at night that is often offset by lowered daytime urine production resulting in normal 24-hr urine volume.
  - Age-related loss of the normal diurnal secretion of vasopressin, resulting in increased nocturnal urine output.
  - Peripheral edema:
    - Fluid that accumulates in the lower extremities when upright during the day is mobilized when supine at night, due to an increase in GFR and excretion.
    - Conditions: CHF, liver disease, nephrotic syndrome, hypoalbuminemia, venous insufficiency, lymphedema, lower extremity injury/swelling.
  - Sleep apnea:
    - Transient periods of hypoxia lead to increased pulmonary vascular resistance and secretion of atrial natriuretic peptide, a potent diuretic.
  - Medications: Poorly timed/dosed diuretics that exert maximal effect during sleeping hours.
  - Excessive fluid intake prior to bedtime, resulting in a physiologic large volume excretion.
- Reduced bladder capacity
  - Nonneurogenic or Neurogenic OAB (over active bladder)
  - Inflammatory: UTI, radiation cystitis, bladder calculi, interstitial cystitis
  - Neoplastic: Bladder cancer, prostate cancer, extrinsic compression from pelvic masses
  - Traumatic: Spinal cord injury, urethral stricture, injury to pelvic nerves or bladder, foreign body within bladder
  - Obstructive; BPH, urethral stricture

ASSOCIATED CONDITIONS

- Bladder outlet obstruction
- OAB: Idiopathic and neurogenic
- Detrusor hyperactivity with impaired contractility
- Radiation cystitis
- Diabetes mellitus
- Psychogenic polydipsia
- Depression
- Obesity
- See also “Pathophysiology”

GENERAL PREVENTION

- Avoid excessive evening fluid intake, alcohol, and caffeine
- Closely monitor and control the underlying conditions that cause nocturia

DIAGNOSIS

HISTORY

- Number of times getting up at night to urinate from time of going to bed until time of waking in the morning
- Degree of bother assessment
- Differentiate between awakening due to the urge to void vs. awakening due to other sleep disturbances
- Fluid intake habits
- Timing, volume
- Caffeine and alcohol consumption
- Previous pelvic surgery or radiation
- Daytime fatigue and depression
- Review of medications known to contribute to nocturia: such as diuretics, excessive calcium supplementation, antacids, or lithium.
- Swelling of lower extremities

PHYSICAL EXAM

- Global or focal neurologic deficits
- Digital rectal: Assess anal tone, prostate exam in men
- Pelvic exam in women: Anterior prolapse causing retention, urethral diverticulum, atrophic vaginitis causing irritative urinary symptoms
- Lung auscultation for rales, crackles
- Dependent edema, pedal edema
- Suprapubic distension consistent with urinary retention
- Obesity and a wide neck circumference raises the possibility of sleep apnea

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis: Low specific gravity (polyuria), RBCs (rule out stones, bladder cancer, foreign body, etc.), proteinuria (nephrotic syndrome), glucosuria (diabetes mellitus), pyuria (UTI)
- Urine culture: UTI
- Urine osmolality: Dilute low values suggest inappropriate excretion of ADH or excess intake of water
- PSA if indicated
- Serum electrolytes: Hypokalemia with diuretic use, CHF, or hyperaldosteronemia

Imaging

- Bladder US with PVR volume for suspected urinary retention, especially if considering antimuscarinics
- Renal US may demonstrate hydronephrosis in cases of urinary retention or poorly compliant bladders

Diagnostic Procedures/Surgery

- Voiding diaries
  - All voiding episodes and volumes should be recorded for a 24-hr period; the time the patient actually goes to sleep and awakens for the day should also be noted.

- Nocturnal urine volume (NUV) is the total volume of urine voided during the night (the 1st morning void is included in this sum since it represents urine excreted during sleep hours).
- Nocturnal polyuria index (NPi): NUV divided by the total volume voided over the 24-hr period:
  - NPi > 33% = nocturnal polyuria
- Nocturnal Bladder Capacity index (NBCi)
- NBCi = (NUV/Maximal volume per void)–1
  - NBCi > 0 suggests that the nocturnal bladder capacity cannot store the amount of urine made at night.

• Urodynamics
- Helpful when empiric treatment for overactive bladder (OAB) or bladder outlet obstruction has failed to improve nocturia

• Polysomnographic sleep studies: Differentiate between sleep disorder and true nocturia

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

• Sleep disorders:
- Most patients awaken due to the sleep disturbance, but recall this as an awakening to void.
- May need polysomnography

• Urologic
- Bladder outlet obstruction, OAB, incomplete bladder emptying.

• Nonurologic:
- Renal failure, idiopathic nocturnal polyuria, diabetes mellitus, central diabetes insipidus, nephrogenic diabetes insipidus, primary polydipsia, hypercalcemia, drugs, autonomic failure, obstructive sleep apnea.

TREATMENT

GENERAL MEASURES

• Nocturnal polyuria secondary to diuretics
- Change to afternoon dosing to induce an early evening diuresis rather than a nocturnal diuresis

• Treatment of underlying condition associated with nocturia

MEDICATION

First Line

• Antimuscarinics are appropriate for reduced voided volumes.

• Men only: α-blocker alone or combined with a 5-α-reductase inhibitor (only modest benefit) (2)[A].

Second Line

• DDAVP for nocturia associated with nocturnal polyuria (3)[B]:
- Dosing: 0.01 mg PO; titrate up to 0.04 mg.

– DDAVP has a high risk of hyponatremia.
– Greatest risk seen in men >65 yr old.

SURGERY/OTHER PROCEDURES

Sacral neuromodulation for nocturia secondary to reduced voided volumes is associated with refractory daytime frequency and urgency (4)[B].

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Behavioral training:
  - Pelvic floor muscle exercises, +/– biofeedback: More effective than both drug therapy and placebo in treatment of nocturia associated with daytime urgency and urge incontinence (5)[A]
- CPAP for obstructive sleep apnea

Complementary & Alternative Therapies

None

ONGOING CARE

PROGNOSIS

Although it is often difficult to completely eliminate episodes of nocturia, characterizing nocturia according to cause-specific etiologies allows for cause-specific treatment.

COMPLICATIONS

- Traumatic falling accidents, including hip fractures, from rising from sleep to urinate
- DDAVP can lead to hyponatremia
- Urinary retention secondary to antimuscarinics

FOLLOW-UP

Patient Monitoring

- Bladder sonography with PVR as needed, particularly when treating men with antimuscarinics
- Repeat 24-hr voiding diaries
- Regular monitoring of serum electrolytes with DDAVP, starting 3 days after initiation of treatment

Patient Resources

- Medline Plus — Excessive Urination at Night

CODES

ICD9

- 596.59 Other functional disorder of bladder
- 788.42 Polyuria
- 788.43 Nocturia

ICD10

- N31.9 Neuromuscular dysfunction of bladder, unspecified
- R35.1 Nocturia
- R35.8 Other polyuria

CLINICAL/SURGICAL PEARLS

- The etiology of nocturia is not prostate or bladder related in the majority of men. Poor sleep

pattern and fluid consumption/mobilization need to be considered.

- A voiding diary is extremely helpful to determine the cause of nocturia.

ORCHITIS, GENERAL CONSIDERATIONS

James B. Angel, MD
Stephen E. Strup, MD, FACS

BASICS

DESCRIPTION

- Inflammatory reaction of the testes secondary to infectious or noninfectious etiology
  - Infectious (viral, bacterial, fungal)
  - Noninfectious (idiopathic, trauma, autoimmune)
- Can be acute or chronic if present for >6 weeks
- Untreated epididymitis can progress to epididymo-orchitis

EPIDEMIOLOGY

Incidence

- Dramatic decline in incidence following the development MMR vaccine (Measles-Mumps-Rubella)
- 4 out of 5 cases occur in prepubertal males (<10 years old) prior to widespread use of MMR vaccine
- Recent increase in incidence in postpubertal males corresponding to mumps outbreaks following national shortages of MMR vaccine as well as controversy related to MMR vaccine itself[1]
- Bacterial orchitis even more rare and usually associated with concurrent epididymitis

Prevalence

- ~20% prepubertal males with mumps develop orchitis
- Recent case reports of postpubertal vaccinated males with mumps developing orchitis in outbreaks[2]

RISK FACTORS

- Not being vaccinated against mumps virus
- Sexually transmitted diseases (STD) leading to epididmo-orchitis (i.e., *Neisseria*, *Chlamydia*, *Treponema*)
- Epididymitis or benign prostatic hypertrophy, BPH (ie, *Escherichia*, *Klebsiella*, *Pseudomonas*, *Staphylococcus*, and *Streptococcus*)
- Fungal infections occasionally (i.e., candidiasis, aspergillosis, histoplasmosis, coccidioidomycosis, blastomycosis, actinomycosis)
- History of intravesical Bacillus Calmette Guerin (BCG) for bladder cancer
- Immunocompromised patients (i.e., *Mycobacterium*, *Tuberculosis*, *Cryptococcus*, *Toxoplasma*, *Haemophilus*, *Candida*)
- Case reports of mumps orchitis after immunization with MMR vaccine

Genetics

- There is no clearly defined genetic predisposition toward or familial disorders commonly associated with most cases of orchitis

- Autoimmune states have been implicated in truly noninfectious orchitis

PATHOPHYSIOLOGY

- Most commonly caused by hematogenous spread of mumps virus directly attacking testicular tissue resulting in parenchymal edema, congestion of seminiferous tubules, and perivascular infiltration of lymphocytes
  - Rare case reports of other viruses causing orchitis (mononucleosis, coxsackie virus, others)
- Cases of bacterial orchitis usually result from local spread from the ipsilateral epididymitis
- Truly noninfectious orchitis is usually idiopathic, trauma-related, or possibly autoimmune
- Orchitis is unilateral in 70% of cases
- Contralateral testis involvement can follow in 1–9 days
- Seminiferous tubules can experience necrosis from increased pressure and edema

ASSOCIATED CONDITIONS

- Mumps
- Epididymitis
- STD in sexually active men
- Urinary Tract Infections (UTI) in boys or elderly men
- BPH particularly in men >50
- Bladder cancer and history of intravesical BCG
- Immunocompromised states

GENERAL PREVENTION

- Vaccination against mumps virus limits mumps orchitis
- Protection from STD
- Treatment of epididymitis prior to progression to epididymo-orchitis

DIAGNOSIS

HISTORY

- Testicular pain and swelling
  - Mild discomfort to severe pain
  - Onset of scrotal pain and edema is acute
- History of recent scrotal trauma
- Systemic symptoms
  - Fatigue
  - Malaise
  - Myalgias
  - Fever and chills
  - Nausea, emesis
  - Headache
- Obtain vaccination history
- Mumps orchitis follows development of parotitis by 4–7 days
- Obtain sexual history as appropriate
- Evidence or history of immunocompromise
- History of BPH
- History of recent instrumentation (ie, catheterization, prostate biopsy, cystoscopy) increases

likelihood of epididymo-orchitis
- History of intravesical BCG therapy, may result in granulomatous orchitis

PHYSICAL EXAM
- Testicular exam:
  - Unilateral or bilateral involvement
  - Enlargement, induration, tenderness common
  - Erythema and edema of overlying scrotal skin
  - An enlarged epididymis is associated with epididymitis, typically unilateral
  - May find concurrent reactive hydrocele which transilluminates
- Rectal exam:
  - A soft, boggy prostate, which signifies prostatitis, can be associated with epididymitis
- Other:
  - Fever and/or chills
  - Urethral discharge
  - Abdominal masses or tenderness
  - Parotitis
  - Urethritis

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urinalysis and urine culture
- Urethral cultures if concern for urethritis
- Mumps: serum immunofluorescence antibody assay

Imaging
- Trans-scrotal color Doppler Ultrasound is considered required by many clinicians:
  - Can rule out testicular torsion or malignancy
- Additional imaging is unnecessary (i.e., CT Scan or MRI)

Diagnostic Procedures/Surgery

Usually not necessary

Pathologic Findings
- With viral infection, destruction of germ cells, edema and extensive inflammatory cell infiltrate is noted
- Later seminiferous tubules can experience necrosis from increased pressure and edema, with subsequent interstitial fibrosis.

DIFFERENTIAL DIAGNOSIS
- Epididymitis
- Granulomatous orchitis, infectious and noninfectious
- Reactive hydrocele
- Scrotal pyocele
- Testicular malakoplakia
- Testicular torsion
- Torsion of testicular appendage
- Testicular tumor

TREATMENT

GENERAL MEASURES

- Supportive in nature
  - Bed rest
  - Hot or cold packs for analgesia
    - Applied for 10–15 mins q.i.d or until pain subsides
  - Scrotal elevation and support with tight fitting underwear or athletic support Analgesics
  - Nonsteroidal anti-inflammatory drugs (NSAID)
  - Antiemetics
  - Counsel patient on safe sex practices if STD suspected

MEDICATION

First Line

- There are no targeted medications indicated the treatment of viral orchitis. Supportive care is essential.
- Bacterial orchitis requires coverage with appropriate antibiotic for suspected pathogen(1)[C]
  - < 35 years old, suspected STD as causative agent:
    - Ceftriaxone 125-250 mg IM once and either doxycycline 100 mg PO b.i.d. for 7 days or azithromycin 1-2 g PO once
  - > 35 years old, or epididymo-orchitis secondary to UTI:
    - Additional gram-negative coverage with a fluoroquinolone or trimethoprim-sulfamethoxazole (TMP-SMX)
- Tailor antibiotic prescription to local resistance patterns of most common UTI pathogens

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Surgical intervention is generally not indicated in the treatment of acute or chronic orchitis
- Associated scrotal pyocele or symptomatic hydrocele may require surgery
- Orchidectomy for chronic orchitis refractory to supportive measures is an option, but patients must be counseled surgery may not alleviate pain (2)[B]
- Consider microsurgical denervation of cord for chronic refractory orchitis/orchalgia following favorable response to spermatic cord block (3)[A]
  - 10 mL of 0.5% bupivacaine injected to cord for block

ADDITIONAL TREATMENT

Radiation Therapy

There is no role for radiation therapy

Additional Therapies

Interferon-α2B has been investigated in bilateral mumps orchitis, given that the mumps virus replicates with a virion-associated transcriptase

Complementary & Alternative Therapies

Patient specific referral for psychologic evaluation and support for chronic refractory orchitis

ONGOING CARE

PROGNOSIS

- Most cases of mumps orchitis are self-limited, resolving within 3-10 days
- With appropriate antibacterial coverage, most cases of bacterial orchitis resolve without complication

COMPLICATIONS

- Unilateral testicular atrophy in up to 60% with mumps orchitis
- Sterility is rarely a sequel of unilateral orchitis
- Impaired fertility reported rates of 7–13%
- No definitive evidence for increased risk of testicular tumor with history of orchitis

FOLLOW-UP

Patient Monitoring

- Most patients can be safely monitored in an outpatient setting
- A patient with a STD as the cause of orchitis should be tested for other STDs including Human immune deficiency virus (HIV)

Patient Resources

- http://www.mayoclinic.com/health/orchitis

CODES

ICD9

- 604.90 Orchitis and epididymitis, unspecified
- 604.91 Orchitis and epididymitis in diseases classified elsewhere
- 604.99 Other orchitis, epididymitis, and epididymo-orchitis, without mention of abscess

ICD10

- N45.1 Epididymitis
- N45.2 Orchitis
- N45.3 Epididymo-orchitis

CLINICAL/SURGICAL PEARLS

- Most cases of orchitis are viral in nature and self-limited, other cases are bacterial and most commonly associated with epididymitis.
- Physical exam findings include tender, swollen testes with associated erythema of the scrotum with or without fever.
- Testicular ultrasonography is important to rule out torsion and malignancy.
- Medical therapy for orchitis is largely supportive; antibiotic coverage should be targeted to cover STDs in the young and sexually active and UTIs in the elderly.
- The role for surgical management of orchitis is limited.

OSTEITIS PUBIS, UROLOGIC CONSIDERATIONS

Patrick T. Gomella, MD, MPH
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION

- Osteitis pubis is a painful sterile inflammatory condition affecting the pubic symphysis
  - Most commonly seen in athletes
- First described with suprapubic surgery and remains a potential complication of pelvic procedures

EPIDEMIOLOGY

Incidence

- Overall incidence in nonathlete populations unknown
  - 0.16% in procedures using bone anchors

Prevalence

Overall prevalence in nonathlete populations unknown

RISK FACTORS

- Invasive pelvic procedures
  - Several urologic procedures implicated
    - Radical prostatectomy
    - Prostate cryotherapy
    - TRUS Bx of prostate
    - TURP
    - Retropubic urethropexy: Specifically Marshall–Marchetti–Krantz procedure
    - Sling procedures
    - Pelvic radiation
- Trauma
- Rheumatic disorders
- Pregnancy/parturition
- Overuse syndrome in athletes

Genetics

No known genetic predisposition

PATHOPHYSIOLOGY

- Symphysis pubis is a nonsynovial amphiarthrodial joint at the confluence of the two pubic bones, consisting of an intrapubic fibrocartilaginous disc between thin layers of hyaline cartilage
- Etiology unknown but may be related to periosteal trauma

ASSOCIATED CONDITIONS

- Ankylosing spondylitis

- Rheumatoid arthritis

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Inciting event such as a pelvic procedure or trauma
- Insidious onset of suprapubic pain
- Pain radiating to thigh adductors, lower abdomen, perineum
- Pain worse when walking or when rising from a seated position (1)[C]

PHYSICAL EXAM
- Point tenderness over pubic symphysis
- Waddling gait
- Low-grade fever
- Increased pain with coughing or Valsalva
- Painful hip abduction

DIAGNOSTIC TESTS & INTERPRETATION

ALERT
Must rule out osteomyletis, especially in postoperative patients.

Lab
- Not generally required to make diagnosis
- May see moderate leukocytosis and an increased erythrocyte sedimentation rate (2)[C]
  Raised levels of acute phase proteins (fibrinogen, C-reactive protein), and increased erythrocyte sedimentation rate are more suggestive of osteomyelitis

Imaging
- Pelvic radiograph
  – Typically normal in acute phase
  – Articular surface erosion, sclerosis, osteophyte formation
- Scintigraphy
  – Increased uptake around pubic symphysis
- Symphysogram of joint
  – Extravasation of contrast material
  – Diagnostic and therapeutic
- Magnetic resonance imaging (MRI) most sensitive and considered gold standard
  – Acute (<6 mo): Bone marrow edema, fluid in joint, periarticular edema
  – Chronic (>6 mo): Subchondral sclerosis/resorption, bony margin irregularities, osteophytes (3)[C]

Diagnostic Procedures/Surgery
- Symphysogram of joint
  – Pain on injection of contrast diagnostic (4)[C]
  – Generally replaced by MRI

- Aerobic/anaerobic culture of joint aspirate to rule out infection if clinically indicated

Pathologic Findings

Sclerotic changes in bony architecture and degeneration of hyaline cartilage with normal periosteum (5)[C]

DIFFERENTIAL DIAGNOSIS

- Osteomyelitis (the most critical)
- Neoplasia of pelvic rami
- Bony metastases
- Pubic osteolysis
- Sports hernia (athletic pubalgia, sportsman's hernia)
- Adductor strain
- Muscle tears
- Avulsion injuries
- Stress fractures
- Tears of acetabular labrum

TREATMENT

GENERAL MEASURES

- Rest, heat, or ice
- Physical therapy to strengthen pelvic girdle can be considered

MEDICATION

First Line

- Nonsteroidal anti-inflammatory
  - Ibuprofen 200–800 mg 2–4×/d (max dose 2.4 g/d)
  - Naproxen 250–500 mg 2×/d (max dose 1.5 g/d for limited time)
- Cyclooxygenase-2 (COX-2) inhibitor
  - Celecoxib 100–200 mg 1–2×/d
  - Adverse CV events noted with COX-2 inhibitors, use lowest effective dose for shortest duration possible

Second Line

- Oral glucocorticoids such as prednisone if local glucocorticoid injections fail
  - Typical short course (ie, 60 mg for 5 days)
  - Can use a taper dose

SURGERY/OTHER PROCEDURES

- Glucocorticoid injection in joint may be useful for cases refractory to rest and NSAIDs (4)[C]
  - Any steroid preparation can be used based on provider preference
    - Include an adjuvant anesthetic
- Various surgical techniques can be used for cases refractory to medical management
  - Curettage
  - Wedge resection
  - Wide resection
  - Arthrodesis

- If bone anchors are in place, their removal may be necessary

ADDITIONAL TREATMENT

Radiation Therapy

Has been attempted in the past with mixed results, but not recommended due to risk of neoplasia

Additional Therapies

- Cryotherapy, ultrasound therapy, laser therapy, and electric stimulation have been used with variable success in athletic osteitis pubis
  - No data on success of these modalities for nonathlete populations
- Anticoagulant therapy with heparin has been suggested as a possible treatment in a postoperative setting with some minimal success

Complementary & Alternative Therapies

Physical therapy

ONGOING CARE

PROGNOSIS

- Typically a drawn out and variable clinical course
  - Symptoms can last several months to several years
  - Operative procedures may be needed in 5–10% of cases

COMPLICATIONS

- Wedge or wide resection of pubic symphysis—risk of posterior instability of pelvic girdle leading to damage to sacroiliac joints
- Arthrodesis—risk of nonunion or death of bone graft site requiring additional surgery

FOLLOW-UP

Patient Monitoring

Follow-up depends on patient symptomatology and procedures obtained

Patient Resources

N/A

- Osteitis Pubic Images ☼

CODES

ICD9
733.5 Osteitis condensans

ICD10
M85.38 Osteitis condensans, other site

CLINICAL/SURGICAL PEARLS
- Osteitis pubis pain and osteomyelitis pain worse when walking or when rising from a seated position.
- Essential to rule out osteomyelitis as a more significant cause.
- Rarely osteitis pubis and osteomyelitis of the pubis can coexist.
- To distinguish between osteomyelitis and osteitis pubis, a biopsy and culture of the affected area are necessary.
- Suspect the condition in a urologic patient where the pubic symphysis has been involved in urologic surgical intervention such as bone anchors or sling procedures.

OVERACTIVE BLADDER (OAB)

Nima Baradaran, MD
Samuel Walker Nickles
Eric S. Rovner, MD, FACS

BASICS

DESCRIPTION

- OAB is defined as a symptom syndrome consisting of urinary urgency, with or without incontinence usually with urinary frequency and nocturia in the absence of causative factors or other identified pathologic conditions causing such symptoms.
- Urinary urgency is the key symptom.

ALERT
OAB is not synonymous with detrusor overactivity (DO, strictly a urodynamic term) and should be distinguished from bladder pain syndrome.

EPIDEMIOLOGY

Incidence

Overall 10.2–17.4% in adult males and 7.7–31.3% in adult females.

Prevalence

~16% of men and women over 40 suffer from OAB and the prevalence increases to 31% and 42%, respectively in patients >75 yr. OAB wet is more common in females.

RISK FACTORS

- Neurogenic: Stroke, Parkinson disease, multiple sclerosis, spinal injury, etc.
- Nonneurogenic: Caucasian, Insulin-dependent diabetes mellitus, Female gender, Depression, Aging associated with estrogen deficiency, Outflow obstruction, Arthritis, Increased BMI.

Genetics

For OAB a definite genetic link is not well established.

PATHOPHYSIOLOGY

- Not well established or understood.
- DO is found in some but not all patients with OAB.
- Urothelial afferent and efferent innervation, connective tissue, smooth muscle, pharmacologic (receptors, neurotransmitters, peptides, etc.), hormones, and other factors may contribute to OAB in individual patients.
- Ultimately, OAB results from either an afferent mechanism (underlying urgency), or a neurogenic or myogenic source or a combination of these.

ASSOCIATED CONDITIONS

- Pelvic floor disorders
- IBS
- High caffeine intake
- Depression/anxiety

- DM
- Smoking
- ADHD
- Obesity

GENERAL PREVENTION

Currently there are no known preventative measures to reduce the potential for development of OAB.

DIAGNOSIS

HISTORY

- Duration of symptoms
- Quantitative assessment of urinary frequency, nocturia, and incontinence (pad use)
- Documentation of urgency
- Quantitation of daily fluid intake
- Aggravating factors (caffeine, stress, etc.)
- Presence of dysuria, hematuria
- Response to prior therapy
- GU history including childhood voiding dysfunction, prior surgery (BPH, urethral stricture, dilation, etc.)
- History should include assessment of the impact of the disorder on daily life (I-QOL (1) and ICIQ (2) for urinary incontinence and OAB-q (3) for men and women with OAB specifically)
- Medical/surgical/OB-GYN history (especially if associated with the initial symptom onset):
  - Prior pelvic surgery: Prolapse, hysterectomy, anti-incontinence surgery, history of radiation therapy, etc.
  - Pregnancy especially vaginal delivery/episiotomy
  - UTI (frequency, urgency, dysuria)
  - Bowel function: Constipation
  - Neurologic history or events (eg, CVA/TIA, MS, Parkinson disease, trauma, back surgery, etc.)
  - Sexual function: Dyspareunia
  - Medical comorbidities: Congestive heart failure (CHF), diabetes, obesity, venous insufficiency, BPH, sleep apnea, etc.
  - Medications (diuretics, prescription, OTC)
  - Menopausal status and hormonal replacement: Contributes to atrophic vaginitis/urethritis
- Use of tobacco, alcohol, fluid intake, caffeine, etc.

PHYSICAL EXAM

- General exam:
  - Abdominal masses, bladder distention
  - Mental status/cognitive function
  - Neurologic exam including perineal sensation, anal wink, resting, and volitional sphincter tone, bulbocavernous reflex
  - Knee/ankle deep tendon reflexes: Sacral nerve compromise/injury
- Pelvic exam:

- Condition of vaginal mucosa: Atrophy (thinning, pallor), narrowing of introitus, inflammation
- Pelvic organ prolapse
- Pelvic floor tone
- Bimanual exam for mass or tenderness
- Cough stress test: Stress incontinence
- Rectal exam: Constipation and prostate evaluation for men

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis, urine cultures:
  - Infection, Glycosuria: Possible diabetes, Hematuria: Possible kidney/bladder pathology, Proteinuria: Kidney/chronic disease, Cytology: Atypia, urothelial carcinoma
  - The diagnosis and initial management of OAB does not require more than a history, physical exam, and urine analysis. Other diagnostic studies should be utilized selectively

Imaging

- These are optional studies usually reserved for complex patients or patients who have failed initial therapy
  - VCUG/Cystography/video urodynamic
  - Renal/bladder US

Diagnostic Procedures/Surgery

- 1–3-day frequency–volume chart (FVC) and/or bladder diary are helpful in documenting presence and severity of OAB
- Post-void residual volume (PVR) (catheterized or ultrasound)
  - PVR >100 is found in 10–19% women with OAB, 15.9% women with SUI, and 5% of asymptomatic women
  - Elevated PVR may be associated with urgency/frequency and nocturia
- Pressure flow urodynamics:
  - Provides functional information about bladder and urethral function
  - Assesses bladder filling and urinary storage as well as bladder emptying, contractility, voiding efficacy, and outlet obstruction
  - Can document presence of DO which is associated with OAB but is NOT required for the diagnosis
- Cystoscopy identifies lesions, tumors, trabeculation, and foreign bodies

ALERT
OAB is a clinical diagnosis and does not require UDS confirmation.

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Bladder calculi
- Bladder cancer/carcinoma in situ
- Bladder outlet obstruction/prostatic hypertrophy
- Congestive heart failure

- Detrusor-external sphincter dyssynergia
- Diabetes
- Interstitial cystitis/painful bladder syndrome
- Pelvic pain syndrome
- Medications
- Neurogenic bladder
- Pelvic organ prolapse
- Polyuria/polydipsia
- Sexually transmitted infection
- Stress incontinence
- Urethral diverticulum
- Urinary tract infection

TREATMENT

GENERAL MEASURES

- Lifestyle modifications and bladder/pelvic floor training in conjunction with pharmacotherapy are 1st-line therapy and are mainstays of treatment.
- Behavioral therapy:
  - Dietary and lifestyle modification (weight loss, reduce caffeine intake, EtOH, and nicotine cessation)
  - Bladder retraining (education, diaries, self-monitoring)
- Pelvic floor physiotherapy: To reestablish inhibitory control over bladder storage
  - Pelvic floor exercises (Kegel)
  - Adjunctive measures include biofeedback, electrical stimulation, vaginal weights/cones, magnetic therapy, etc.

MEDICATION

First Line

- Antimuscarinics: Inhibits the effect of acetylcholine at postjunctional muscarinic receptors on detrusor muscle cells. All used to treat OAB and all have level 1 evidence.
  - Tolterodine (2–4 mg/d)
  - Trospium XR (60 mg/d)
  - Darifenacin (7.5–15 mg/d)
  - Solifenacin (5–10 mg/d)
  - Oxybutynin (IR 7.5–20 mg/d, XL 5–30 mg/d, patch twice weekly)
  - Fesoterodine (4–8 mg/d)
- β_3-adrenergic agonist agent: Promotes detrusor muscle relaxation
  - Mirabegron (25–50 mg/d)

Second Line

- Urgent PC (PTNS): Tibial nerve stimulation: Office-based therapy requiring repetitive weekly therapy sessions over 3–4 mo and then periodic treatments thereafter
- InterStim (sacral neuromodulation): Implanted neurostimulation of sacral nerves: Modulates activities of bladder, sphincter, and pelvic floor muscles
- Intravesical botulinum toxin (onabotulinumtoxinA) injection:

– Addresses both motor efferent innervation and sensory afferent nerves that contribute to OAB. It is a transient effect requiring periodic retreatment at intervals of 4–12 mo.

surgery/other procedures (4)

- Augmentation enterocystoplasty: Using a portion of GI tract to increase bladder capacity. Usually involves use of ileum or colon
  – Auto-augmentation: Incision of detrusor muscle creating a pseudodiverticulum (most commonly performed in pediatric age group)
- Urinary diversion such as Bricker bilateral ureteroileostomy, rarely needed
- Clinical use of endoscopic bladder transection, bladder overdistension, or transvesical phenol injection is no longer recommended for nonneurogenic OAB

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Non-FDA approved:
  – Estrogens for females (topical or oral)
  – Tricyclic antidepressants (imipramine, etc.)
- For intractable OAB, options are appliances, catheters (urethral), and pads with careful attention to skin care

Complementary & Alternative Therapies

- Acupuncture
- Cognitive therapy

ONGOING CARE

PROGNOSIS

- Varies according to severity of disorder and compliance of the patient
- 50–80% of patients respond to combination of behavioral modification, pelvic floor therapy, and pharmacotherapy

COMPLICATIONS

- Antimuscarinic agents are contraindicated in narrow angle glaucoma and patients should be aware of side effects (dry mouth, constipation, etc.)
- Augmentation cystoplasty may lead to metabolic abnormalities and short bowel syndrome.
- SNS implant site complications include infection and pain.
- Botulinum toxin is associated with UTI, and urinary retention.

FOLLOW-UP

Patient Monitoring

Depending on treatment modality close follow-up with urologist or primary care physician is necessary

Patient Resources

- National Association for Continence 1-800-BLADDER (www.nafc.org)
- Simon Foundation (www.simonfoundation.org)

- National Institute of Diabetes and Digestive and Kidney Diseases (http://kidney.niddk.nih.gov/kudiseases/pubs/uiwomen/)

- Incontinence, Urinary, Adult Male
- Nocturia
- Overactive Bladder (OAB) Image
- Posterior Tibial Nerve Stimulation (PTNS)
- Sacral Neuromodulation
- Urgency, Urinary (Frequency and Urgency)

CODES

ICD9

- 596.51 Hypertonicity of bladder
- 788.41 Urinary frequency
- 788.63 Urgency of urination

ICD10

- N32.81 Overactive bladder
- R35.0 Frequency of micturition
- R39.15 Urgency of urination

CLINICAL/SURGICAL PEARLS

- OAB is NOT synonymous with detrusor overactivity.
- The key symptom of OAB is urinary urgency.
- The diagnosis and initial management of OAB require only a history, physical exam, and normal urinalysis.

PAPILLARY NECROSIS, RENAL

Demetrius H. Bagley, MD, FACS
Kelly A. Healy, MD

BASICS

DESCRIPTION

- Renal papillary necrosis is ischemic necrosis of the papillae and occasionally the medullary pyramids.
- The clinical course may be acute and rapidly progressive or chronic
  - Acute forms are symptomatic and may present with hydronephrosis, pyelonephritis, and hematuria
  - Typically chronic forms are asymptomatic and discovered incidentally on radiographic studies
- Acute presenting symptoms include hematuria, flank or abdominal pain, and fever and chills

EPIDEMIOLOGY

Incidence

- Most cases occur after the 6th decade of life and papillary necrosis is uncommon in patients <40 yr
- Female > Male (1.1:1.0) (1)[B]

Prevalence

N/A

RISK FACTORS

- Include any condition causing ischemia that can predispose to the development of renal papillary necrosis. Many have >2 risk factors
- Diabetes mellitus
- Sickle cell trait or disease
- Analgesic abuse:
  - Most commonly phenacetin and NSAIDs
- Antiretroviral treatment:
  - Indinavir
- Urinary tract obstruction of any cause
- Pyelonephritis
- Systemic vasculitis
- Lupus nephritis
- Wegener granulomatosis
- Renal artery stenosis
- Systemic vasculitis
- Global ischemia:
  - Shock, hypoxia, dehydration

Genetics

N/A

PATHOPHYSIOLOGY

- The renal papilla normally exists in the state of hypoxia because of the blood flow in the vasa recta which can be affected further with conditions that reduce blood flow
  - Perfusion compromise in diabetes mellitus
  - Diminution in blood flow because of sickling of blood cells (sickle cell disease)
  - Infection that causes inflammation of the interstitium can lead to compression of the medullary vasculature
- Analgesic use causes COX inhibition and decreased prostaglandin production. This leads to decreased vascular perfusion, vasoconstriction and can cause ischemic necrosis
- Some medications can cause direct interstitial cell necrosis and decrease in prostaglandin production
- The necrotic, soft tissue can cause unilateral or bilateral ureteral obstruction

ASSOCIATED CONDITIONS

- Analgesic abuse
- Diabetes mellitus
- Pyelonephritis
- Sickle cell disease
- Urinary tract obstruction

GENERAL PREVENTION

- Treatment of underlying disorders including diabetes or sickle disease
- Avoidance of analgesic use

DIAGNOSIS

HISTORY

- May present with hematuria or obstruction with flank pain (2)
- With infection, fever, chills, dysuria, frequency, urgency, flank pain, and renal colic can occur
- Rarely, bilateral ureteral obstruction with necrotic tissue can present as acute oliguric renal failure

PHYSICAL EXAM

- Costovertebral angle tenderness
- Fever

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis and urine culture:
  - Proteinuria, pyuria, bacteriuria, and low urine-specific gravity
  - Epithelial cells and casts may be present
- CBC may demonstrate leukocytosis
- Metabolic panel can demonstrate azotemia and elevated creatinine

Imaging

- CT has become the imaging modality of choice

- Contrast images show:
  - Ring shadows in the medullae
  - Contrast-filled clefts in the renal parenchyma
  - Renal pelvic filling defects
- Excretory urography has historically been the gold standard for diagnosis
  - Findings include shrinkage and irregularity of papilla defined by contrast materials as a ring shadow often in a triangular shape
  - A calix without a papilla
  - Filling defect in the renal pelvis or ureter
  - Contrast containing rice-grain–sized cavities in the papilla
- Retrograde pyelogram:
  - Useful in patients with azotemia, contrast sensitivity, or other situations where intravenous contrast is contraindicated
  - Findings may reveal a club-shaped calyx or a filling defect in the ureter

Diagnostic Procedures/Surgery

Patient presenting with hematuria needs a full urologic workup even if papillary necrosis is confirmed.

Pathologic Findings

- The cortex features depressed areas of cortical atrophy (3)
- Papilla shows various stages of necrosis, desquamation, and sloughing
  - Focal necrosis: Involves only the tip of the papilla
  - Diffuse necrosis: The entire papilla and portions of the medulla are involved
- Microscopically, changes of papilla may be a patchy appearance or complete coagulative necrosis. Glomeruli are typically unchanged

DIFFERENTIAL DIAGNOSIS

- Acute tubular necrosis
- Nephrolithiasis
- Carcinoma of the ureter or bladder
- NSAID abuse and/or overuse
- Pyelonephritis
- Renal trauma
- TB
- Ureteral stricture disease

TREATMENT

GENERAL MEASURES

- Hydration, oral or intravenous
- Glycemic control, if diabetic
- Definition and treatment of sickle disease

MEDICATION

First Line

- Cessation of any associated/causative medications including analgesics

- Treatment of underlying cause of ischemia
- Broad-spectrum antibiotics, if associated with pyelonephritis

Second Line
N/A

SURGERY/OTHER PROCEDURES
- When a patient presents with acute urinary obstruction, drainage is indicated with percutaneous nephrostomy, ureteral stent placement, or endoscopic/ureteroscopic removal of obstructing sloughed tissue
- In the nonacute case, renal pelvic or ureteral filling defect can be electively evaluated with ureteroscopy
- Nephrectomy is rarely warranted

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE
PROGNOSIS
Depends on the basis for the ischemia, the compounding factors, and the amount of necrosis

COMPLICATIONS
- Infection may develop in the desquamated necrotic papilla
- Calculi can develop on the base of the sloughed papilla
- Obstruction can develop along the ureter from multiple sloughed papilla

FOLLOW-UP
Patient Monitoring
- Monitoring includes the kidney itself for further necrosis and for changes in function
- Causes of ischemia should be closely monitored

Patient Resources

CLINICAL/SURGICAL PEARLS

Gross hematuria in a patient with sickle cell disease suggests papillary necrosis.

PARATESTICULAR TUMORS

Mohamed T. Ismail, MD
Sallyanne M. Fisher, MSN, FNP-C, CUNP

BASICS

DESCRIPTION

- Intrascrotal tumors involving the testicular tunic, epididymis, or cord structures. Can be benign (~70%) or malignant (~30%)
- The paratesticular region includes the contents of the spermatic cord, testicular tunics, epididymis, and vestigial remnants (appendices testis and epididymis)
- 90% of extratesticular tumors are found within the spermatic cord:
  - Of these, 30% are malignant
  - The majority represent benign lipomas
  - Mesenchymal tumors of the spermatic cord include rhabdomyosarcoma, leiomyosarcoma, liposarcoma, lipoma, fibrosarcoma, and myxochondrosarcoma
- The most common paratesticular tumor in children is rhabdomyosarcoma, which accounts for ~24–40% of all paratesticular tumors
- Adenomatoid tumor accounts for 30% of epididymis tumors and are benign:
  - Typically seen in 3rd and 4th decades of life
  - Rarely arise in testicular tunicae or spermatic cord (1)[C]
- Leiomyosarcoma is the most common type of paratesticular sarcoma in adults:
  - Incidence peaks in the 6th and 7th decades
  - Can be bilateral
  - May accompany a hydrocele or hernia
- Cystadenoma is a benign tumor that involves the epididymis in young adults:
  - Two-thirds associated with von Hippel–Lindau syndrome (2)[C]
  - Frequently bilateral
- Malignant mesothelioma presents in older patients (55–75 yr) and usually presents in association with a hydrocele
- Malignant lymphoma: Cord structures are frequently invaded by testicular lymphoma, but primary lymphomas do occur rarely
- Epididymal cysts occur in up to 40% of men
  - 75% of these are true cysts and contain lymphatic fluid (1)[C]

EPIDEMIOLOGY

Incidence

- The exact incidence of paratesticular soft tissue neoplasms is difficult to estimate
- Rhabdomyosarcoma
  - Occurs primarily in children and adolescents during the 1st 2 decades of life
- Racial differential: White > Black (3:1)
- Leiomyosarcoma: Exceedingly rare, ~110 reported cases in the literature

Prevalence

- Primary malignancies of the epididymis or paratesticular structures in adults extremely rare
- Rhabdomyosarcoma accounts for a large proportion of the paratesticular tumors in the pediatric population.

RISK FACTORS
- Marijuana and cocaine use in the parents is associated with rhabdomyosarcoma.
- Von Hippel–Lindau syndrome is associated with epididymal cystadenomas.
- Equestrians are prone to scrotal injury with up to 77% evidence of scrotal pathology (1)[C].

Genetics
- Partial monosomy of chromosome 11 often leads to embryonal rhabdomyosarcoma.
- Alveolar rhabdomyosarcoma is characterized by translocations t(2;13)(q35;q14) or t(1;13)(p36;q14); this subtype carries a poor prognosis.

PATHOPHYSIOLOGY
- Electron microscopy is very helpful in differentiating the type of sarcoma.
- Subtypes of sarcoma include rhabdomyosarcoma, leiomyosarcoma, liposarcoma, fibrosarcoma, malignant fibrous histiocytoma, and desmoplastic round cell tumor.
- Soft tissue sarcomas tend to infiltrate local tissues widely and have a tendency for local recurrence.
- Rhabdomyosarcoma:
  – 97% belong to the favorable histology group of embryonal cell tumors.

ASSOCIATED CONDITIONS
Renal cell carcinoma with von Hippel–Lindau

GENERAL PREVENTION
Testicular self-exam should be performed monthly.

DIAGNOSIS
HISTORY
- Patient complains of mass within his scrotum, distinct from the testicle
  – Typically painless
  – Delays in presentation due to embarrassment
- Obtain complete history to include accompanying symptoms, duration, and constitutional changes (2)[C]

PHYSICAL EXAM
- Palpation of the testes, epididymis, and cord structures bilaterally including the inguinal region:
  – Rhabdomyosarcoma reveals a firm mass that is usually distinct from the testis.
  – Adenomatoid tumor appears clinically as small solid lumps and is most commonly found at the head of the epididymis, testicular tunics, or spermatic cord.
  – Cystadenoma presents as asymptomatic cystic lumps and are bilateral in up to 1/3 of cases.
  – Leiomyosarcoma normally presents as a discrete nodular mass, frequently near the spermatic cord and entirely separate from the testicle.
  – Liposarcoma usually presents in an older patient as a large fatty-appearing mass.

  - Lymphoma presents as a hard, nontender mass, separate from the testis; seen in young adults. Transillumination suggests a fluid-filled lesion such as a hydrocele.
- Careful exam of the groin is necessary to rule out hernia and to evaluate for lymphadenopathy.
- Masses are occasionally accompanied by hydrocele.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis (midstream) and culture if epididymitis is suspected (1)[C].
- Tumor markers to include β-human chorionic gonadotropin (β-hCG), α-fetoprotein (AFP), or lactic dehydrogenase (LDH) should be sent if the origin of the tumor is in question.

Imaging

- Gold standard: Scrotal ultrasound (US) (1)[C]
  - To evaluate location and characteristics of the lesion within the scrotum
  - Testicular vs. paratesticular
  - Solid vs. cystic (2)[C]
    - Solid lesions almost always require exploration
    - Simple cystic lesions are mostly benign
- Computed tomography (CT) of the abdomen and pelvis with and without contrast for staging
  - Paratesticular tumors may spread to retroperitoneal lymph nodes or hematogenously depending on the histology of the primary tumor
- Chest radiograph
- Chest CT
  - If abdominal or pelvic metastases are seen
- Clinical staging of retroperitoneal lymph nodes
- Radioisotope bone scan:
  - Especially for elevated alkaline phosphatase or symptoms with rhabdomyosarcoma

Diagnostic Procedures/Surgery

Surgery is often diagnostic and therapeutic

ALERT
Percutaneous biopsies are contraindicated due to the documented risk of seeding in the scrotal wall with malignancy.

- Bone marrow aspirate:
  - Routine part of staging at a time of diagnosis for rhabdomyosarcoma

Pathologic Findings

- Electron microscopy can help differentiate between the different types of sarcoma; these differences can be quite subtle.
- Leiomyosarcoma spreads 1st by lymphatics, then hematogenously, and last by local extension.

DIFFERENTIAL DIAGNOSIS

- Adenomatoid tumors

  – Most common benign paratesticular tumor
- Angiomyofibroblastoma
- Cystadenoma of the epididymis
- Epididymal cyst
- Epididymitis
- Fibrous pseudotumor of testicular tunic
- Fibrosarcoma
- Leiomyosarcoma
- Lipoma of the spermatic cord
- Liposarcoma
- Malignant fibrous histiocytoma
- Mesothelioma, benign, testicular tunic
- Mesothelioma, malignant, tunica vaginalis
  – Associated with asbestos exposure
- Postoperative changes
  – Sperm granuloma after vasectomy
- Spermatocele
- Testicular torsion
- Traumatic injury
- Tunica albuginea lesions
  – Cysts, fibrous pseudotumor
- Varicocele
- Hydrocele
- Hydrocele of the spermatic cord
- Inguinal hernia

TREATMENT

GENERAL MEASURES

- US suggests initial management.
- Lesions suggestive of a benign process can be observed with serial exams.
- Remove malignant or potentially malignant structures while minimizing effects on fertility, function, esthetics (2)[C].
- Benign lesions only require intervention if they become massive or cause pain (1)[C].
- Any concern about malignancy and the scrotum should be explored through a high inguinal incision.
- Transscrotal manipulation or biopsy is contraindicated.
- Rhabdomyosarcoma always requires primary surgical excision via inguinal orchiectomy.
- Leiomyosarcoma should also be treated with radical orchiectomy to be followed with adjuvant radiation therapy to reduce local recurrence.
  – No survival benefit has been demonstrated from the addition of radical pelvic lymph node dissection (RPLND) to radical orchiectomy.

MEDICATION

First Line

- Chemotherapy for malignant rhabdomyosarcoma
  - Vincristine, cyclophosphamide, and dactinomycin, and actinomycin D-based chemotherapy in patients with gross or microscopic residual disease

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Testicular or paratesticular lesions suspected to be malignant should be removed by radical inguinal orchiectomy with high ligation of the spermatic cord.
  - Early clamping of the cord limits hematogenous spread in leiomyosarcoma.
- Rhabdomyosarcoma:
  - Consider hemiscrotectomy for any degree of scrotal wall involvement.
  - The Intergroup rhabdomyosarcoma study group (IRS) recommended radical inguinal orchiectomy and routine RPLND in all males >10 yr and in boys <10 with metastasis noted on imaging.
- Complete surgical excision with a negative margin has significant impact on local recurrence and overall survival in soft tissue sarcomas.

ADDITIONAL TREATMENT

Radiation Therapy

- Rhabdomyosarcoma:
  - 4,000–6,000 centigray units of radiation (cGy) over 5 wk
  - Dose and port size determined by the tumor's primary site, patient age, and tumor burden

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Benign lesions—recurrence is rare
- Rhabdomyosarcoma—75% 5-yr survival when multimodal therapy is administered
- Leiomyosarcoma—50–80% survival with microscopic residual disease in 27% of cases
  - Adjuvant treatment via radiation is warranted.
- Malignant mesothelioma—high recurrence and mortality
- Larger tumor size, metastasis, higher-grade tumor, and incomplete primary resection lead to poorer overall prognosis.

COMPLICATIONS

- Disease associated death in ~10% of malignant cases
- Treatment-associated:
  - Retrograde ejaculation and intestinal obstruction if RPLND is performed
  - Hypogonadism and/or infertility secondary to chemotherapy
  - Hemorrhagic cystitis secondary to chemotherapy

– Growth abnormalities secondary to radiation therapy (spinal and renal) in children

FOLLOW-UP

Patient Monitoring

- Serial US for equivocal lesions, especially in the epididymis
- Benign lesions need patient-performed monthly testicular self-exams
- Rhabdomyosarcoma monitoring is provider dependent
  – Should be followed closely by a urologist

Patient Resources

CODES

ICD9

- 187.8 Malignant neoplasm of other specified sites of male genital organs
- 222.8 Benign neoplasm of other specified sites of male genital organs
- 239.5 Neoplasm of unspecified nature of other genitourinary organs

ICD10

- C63.7 Malignant neoplasm of other specified male genital organs
- D29.8 Benign neoplasm of other specified male genital organs
- D49.5 Neoplasm of unspecified behavior of other genitourinary organs

CLINICAL/SURGICAL PEARLS

- It is impossible to distinguish a benign from a malignant tumor based on physical exam.
- Can be indistinguishable from testicular masses.
- Percutaneous biopsies contraindicated due to documented seeding in scrotal wall with malignancy.

PARKINSON DISEASE, UROLOGIC CONSIDERATIONS

Robert C. Flanigan, MD, FACS
Sam J. Brancato, MD

BASICS

DESCRIPTION

- Parkinson disease (PD), also called paralysis agitans is a neurodegenerative disorder associated with loss of dopaminergic neurons.
- Three cardinal features are rest tremor, rigidity, and bradykinesia.
- Postural instability, sometimes deemed a cardinal feature, is nonspecific and usually absent in early disease.
- Autonomic dysfunction is manifested by urinary urgency and frequency, constipation, and orthostatic hypotension. Retention can also be seen.

EPIDEMIOLOGY

Incidence

- PD incidence increases with age, from 17.4 cases per 100,000 persons per year between 50–59 yr of age to 93.1 in 100,000 persons per year between 70–79 yr of age.
- Life risk of developing PD is 1.5%
- Voiding dysfunction occurs in 40–70% of patients with PD.

Prevalence

N/A

RISK FACTORS

- Men are about 1.5 times more likely than women to develop PD
- The median age of onset is 60 yr and the mean duration of the disease from diagnosis to death is 15 yr.
- Young-onset PD affects 5–10% of patients with the initial symptom arising before the age of 50 yr.

Genetics

- About 15% of patients with PD have a 1st-degree relative with the disease, typically without a clear mode of inheritance
- Mutations in two genes cause autosomal dominant forms of PD
  – α-Syn gene (*SNCA*): Located on chromosome 4q
  – Leucine-rich repeat kinase 2 (*LRRK2*): located on chromosome 12q
- To date, approximately 16 risk loci have been identified, some of which overlap with the genes known to contain disease-causing mutations

PATHOPHYSIOLOGY (1)

- Selective loss of dopaminergic projections from the substantia nigra pars compacta (a component of the basal ganglia) to the caudate nucleus and putamen
- Dopamine deficiency in the nigrostriatal pathways accounts for most of the clinical motor features of the disease

- The net effect of the basal ganglia on micturition is inhibitory, which is abolished due to cell loss in the substantia nigra
  - The bladder detrusor can thus become unstable and result in urgency and frequency with urge incontinence
- The smooth sphincter is synergic, however pseudodyssynergia, as well as delay in striated sphincter relaxation (bradykinesia) leading to urinary retention (2)
  - Impaired detrusor contractility may also occur
- PD can also be associated with bowel dysfunction (constipation) and sexual dysfunction
- Urinary symptoms tend to become worse in the course of the disease. Early on other correctable causes such as benign prostatic enlargement in men can cause similar symptoms
- Centrally acting anticholinergic drugs such as trihexyphenidyl and benztropine have been used to treat PD and can cause urinary retention

ASSOCIATED CONDITIONS

- Autonomic dysfunction
  - Constipation
  - Orthostatic hypotension
  - Urinary urgency/frequency/urge incontinence
- BPH
- Dementia
- Depression
- Sleep disturbance
- Erectile dysfunction
- Hyposmia
- Visual hallucination

GENERAL PREVENTION

N/A

DIAGNOSIS

HISTORY

- Urinary symptoms usually appear after the onset of neurologic symptoms
- Assess for LUTS:
  - Storage symptoms: Most common, include nocturia, urgency, frequency, and incontinence
  - Voiding symptoms: Difficulty initiating stream, weak FOS/prolonged urination, and straining
- Elevated PVRs are uncommon in PD patients
- Assess for concurrent urologic conditions:
  - BPH in men and SUI in women
- Assess for polypharmacy
  - Central acting anticholinergics listed below can be used in younger patients in whom tremor is the major symptom but may exacerbate incomplete emptying and urinary retention
  - Benztropine mesylate (Cogentin), trihexyphenidyl (Artane), biperiden (Akineton), orphenadrine (Norflex, Flexon)

PHYSICAL EXAM

- Cardinal features are rest tremor, rigidity, and bradykinesia.
- Slow, pill-rolling tremor of the hands (4–6 cycles/s) seen primarily at rest
  - Abolished by use of the affected hand
  - Aggravated by stress and cold weather
- Facial expressions can be immobile or rigid and speech slowed
- Slow, shuffling gait with loss of normal arm swing (rarely prominent early in the course of PD)
- Assessment of pelvic floor reflexes, motor and sensory
- Digital rectal exam

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- No diagnostic test exists for PD as the diagnosis is clinical.
- Standard urologic evaluation (U/A, C&S) based on initial symptoms

Imaging

- Brain MRI is reserved for patients suspected of having PD who fail to respond to therapeutic doses of L-dopa administered for 12 wk, to exclude rare secondary causes and subcortical vascular pathology.
- Routine urologic imaging is not required.

Diagnostic Procedures/Surgery

- PD is a clinical diagnosis, although the definition of PD is a postmortem finding based on the neuropathologic examination.
- Urodynamics:
  - Detrusor overactivity is the most common cystometric abnormality.
  - Sporadic involuntary activity in the striated sphincter during involuntary bladder contraction is common, however, this does not cause obstruction.
  - Pseudodyssynergia may occur, as well as delay in striated sphincter (bradykinesia) relaxation at the onset of voluntary micturition, both of which can be misinterpreted as true dyskinesia.
  - Detrusor areflexia relatively rare in PD and when present may often be due to anticholinergic medications.
- Urodynamics is a useful tool for investigating concomitant obstruction secondary to BPH.

Pathologic Findings

Intraneuronal Lewy bodies and Lewy neurites are the pathologic hallmarks of PD.

DIFFERENTIAL DIAGNOSIS

- Parkinson
  - Multiple system atrophy
  - Normal aging
  - Vascular parkinsonism (multiple infarcts within the basal ganglia and subcortical white matter)
  - Parkinson plus syndromes
- Voiding dysfunction

TREATMENT

GENERAL MEASURES

- PD is a progressive neurodegenerative disorder despite treatment.
- Levodopa is the mainstay of therapy for PD and the gold standard against which new therapies are compared.
  - In the United States, levodopa is combined with the decarboxylase inhibitor carbidopa (Sinemet).
  - Levodopa has been shown to have unpredictable effects on bladder function.
- Clinicians should offer behavioral therapies (eg, fluid management, clean intermittent catherization) as 1st-line therapy.
- Evaluate medications that may result in urinary symptoms (such as retention/hesitancy) with anticholinergic drugs such as trihexyphenidyl and benztropine used to treat some patients with PD.

MEDICATION

First Line

- For urologic symptoms of frequency, urgency, and urge incontinence, anticholinergics are commonly used but should be monitored closely in elderly as they may contribute to cognitive decline (3):
  - Oxybutynin 5 mg PO TID
  - Tolterodine LA 4 mg PO daily
  - Others (solifenacin, fesoterodine, darifenacin, trospium)
- β3-Adrenergic agonist agent: Promotes detrusor muscle relaxation and can also be considered for overactive bladder symptoms
  - Mirabegron (25–50 mg)

Second Line

- OnabotulinumtoxinA
  - While not specifically approved for PD, it is approved for the treatment of urinary incontinence due to detrusor overactivity associated with a neurologic condition in adults who have an inadequate response to or are intolerant of an anticholinergic medication
- The following are used but currently not FDA approved for urinary incontinence
  - Tricyclic antidepressants (TCA): Imipramine 10–25 mg PO BID–TID
  - Selective serotonin norepinephrine reuptake inhibitors (SSNRIs): Duloxetine 20–40 mg PO BID
- Nocturnal polyuria can be treated with desmopressin

SURGERY/OTHER PROCEDURES

Bladder outlet procedure: Consider if coexisting obstruction is found on urodynamic testing

ADDITIONAL TREATMENT

- PDE5 inhibitors for treatment of erectile dysfunction:
  - Sildenafil, tadalafil, vardenafil
- Deep brain stimulation of the subthalamic nucleus may decrease urinary symptoms

Additional Therapies

Incontinence aids may be necessary and are primarily chosen by the degree of absorbency

required and the ease of use. During the night, high absorbency pads are usually required.

Complementary & Alternative Therapies

Dietary fiber, laxatives, and prokinetic drugs (such as serotonergic agonists) are used to treat PD-related bowel dysfunction.

ONGOING CARE

PROGNOSIS

- PD is a progressive neurodegenerative disorder.
- Despite a variable disease course, the overall prognosis is poor with a mean duration of the disease from diagnosis to death of 15 yr.

COMPLICATIONS

- Urinary incontinence
  - Skin breakdown secondary to incontinence
- Urinary retention (often related to anticholinergics)

FOLLOW-UP

Patient Monitoring

Assess for elevated PVRs, specifically if taking anticholinergics

- 788.63 Urgency of urination

ICD10
- G20 Parkinson's disease
- N39.41 Urge incontinence
- R35.0 Frequency of micturition

CLINICAL/SURGICAL PEARLS
- Cardinal features are rest tremor, rigidity, and bradykinesia.
- Urinary incontinence is a common feature of PD due to symptoms of overactive bladder.

PELVIC ORGAN PROLAPSE (CYSTOCELE AND ENTEROCELE)

W. Stuart Reynolds, MD, MPH
Roger R. Dmochowski, MD, MMHC, FACS

BASICS

DESCRIPTION

- Pelvic organ prolapse (POP): The descent of one or more of the anterior vaginal wall, posterior vaginal wall, uterus/cervix, or apex of vagina (vaginal vault or cuff after hysterectomy)
- Cystocele: Anatomic defect of the anterior vaginal wall in which bladder prolapses into the vagina
- Enterocele: Anatomic defect of the vaginal apex typically; small intestine prolapses into the vagina
- Rectocele: Anatomic defect of the posterior vagina; the rectum prolapses into the vagina
- Defects in many or all vaginal compartments (anterior, posterior, apex) may occur together

EPIDEMIOLOGY

Incidence

Insufficient data to conclusively establish incidence rates

Prevalence

- Estimates vary, based on definitions, symptoms, and/or physical exam findings
  - 3% of US women report symptoms of vaginal bulging
  - 40% of US women have POP on exam
- Women have an 11% lifetime risk of undergoing surgery for POP and/or UI by age 80

RISK FACTORS

- Age
- Race/ethnicity (Hispanic > White > African American)
- Parity
- Obesity
- Hysterectomy
- Prior POP surgery
- Menopause
- Pelvic strain (high impact activity or work)

Genetics

- Increased familial risk (sisters and mothers)
  - 2.5 times more common if positive family history for POP
- Inheritable collagen disorders (eg, Ehlers–Danlos syndrome)
- Genome-wide studies ongoing with several potential candidate genes identified, most related to elastin and collagen metabolism (eg, *LAMC-1*)

PATHOPHYSIOLOGY

- Integrated support to the bony pelvis through the endopelvic fascial structures, suspensory

ligaments, levator ani muscles, and pelvic organs help maintain the pelvic organs in the proper anatomic position in the pelvis.
- Classically, three levels of vaginal support are described:
  - Level I: Uterosacral and cardinal ligaments support upper 1/3 of vagina, cervix, and uterus.
  - Level II: Pubocervical and rectovaginal fascia attach laterally to the arcus tendineus fascia pelvis to support midportion of vagina
  - Level III: Direct attachment of vagina to urethra, perineal body, and levator ani muscles
- Damage or weakness to the muscular and connective tissue supporting mechanisms, including innervation, contribute to POP

ASSOCIATED CONDITIONS
- Urinary incontinence
  - Stress urinary incontinence (SUI)
    - Present in 65% of POP
  - Occult SUI ("masked" or "latent" SUI)
    - SUI only observed after reduction of POP
    - Present in 25–80% of women with POP, especially with advanced stages
- Lower urinary tract symptoms
  - Overactive bladder
  - Voiding dysfunction
    - Advanced POP (stage III or greater) may result in urethral "kinking" resulting in bladder outlet obstruction
- Upper urinary tract obstruction
  - Advanced POP may result in bilateral ureteral obstruction with hydronephrosis
- Bowel dysfunction
  - Constipation
  - Fecal/anal incontinence
- Sexual dysfunction
  - Dyspareunia

GENERAL PREVENTION
- Weight management
- Protective role of elective cesarean section debatable

DIAGNOSIS

HISTORY
- Assess for prolapse symptoms
  - Vaginal bulging, including visualization or palpation of a "bulge" in the vagina
  - Pelvic pressure, heaviness, or dragging sensation
  - Vaginal mucosal irritation, bleeding, discharge, and/or infection
  - Splinting/digitation: Applying manual pressure to vagina or rectum to assist with voiding or defecation
  - Low backache, temporally associated with POP
- Assess for other pelvic floor symptoms

- Urinary incontinence and voiding dysfunction
- Constipation/anal incontinence
- Dyspareunia

PHYSICAL EXAM

- Useful to employ POP staging
  - POP quantification system (POPQ)
    - Stage 0: No prolapse is demonstrated
    - Stage I: Most distal portion of the prolapse is >1 cm above the level of the hymen
    - Stage II: Most distal portion of the prolapse is 1 cm or less proximal to or distal to the plane of the hymen
    - Stage III: The most distal portion of the prolapse is >1 cm below the plane of the hymen
    - Stage IV: Complete eversion of the total length of the lower genital tract is demonstrated
- Assessment of urinary incontinence
  - Provocative maneuvers (cough and Valsalva) to demonstrate urethral leakage; repeated with prolapse reduced to detect occult SUI

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis and urine culture, as indicated
- Serum creatinine, BUN: May be abnormal in advanced POP with bladder outlet or ureteral obstruction

Imaging

- Routine imaging is not indicated; imaging may supplement exam with complex cases
- Defecography
  - Assesses defecatory dysfunction, including degree of rectocele and rectal emptying
- Voiding cystourethrogram
  - Assesses degree bladder prolapse and bladder neck function; may detect fistula, vesicoureteral reflux, or urethral diverticulum
- Pelvic ultrasound
  - Allows dynamic assessment of pelvic organs and bladder volume
- Magnetic resonance imaging (MRI)
  - Allows dynamic imaging of functional relationships among the pelvic floor viscera and supporting structures, and assesses pelvic pathology
  - Expensive; clinical utility over exam alone not established

Diagnostic Procedures/Surgery

- Postvoid residual (PVR) urine volume
- Urodynamic testing
  - Routine use not indicated; clinical utility not established
  - May detect voiding dysfunction or occult incontinence with POP reduction
  - Urethral function tests (leak point pressure, urethral pressure profilometry) assess urethral function and degree of SUI, if any

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS
- Uterovaginal prolapse
- Cystocele
- Enterocele
- Rectocele
- Soft tissue vaginal mass
- Urethral diverticulum

TREATMENT

GENERAL MEASURES
- Management is primarily surgical
- Bowel regimen for constipation
- Hormone replacement, topical vaginal, for atrophic vaginitis
  - Estrogen alone in postmenopausal with after hysterectomy; estrogen and progesterone if uterus present, even if postmenopausal

MEDICATION
First Line
N/A

Second Line
N/A

SURGERY/OTHER PROCEDURES

ALERT
The FDA has identified safety concerns with use of synthetic mesh materials for POP repair, specifically for transvaginal placement of synthetic mesh/prosthetics (See "Additional Reading").

- Transvaginal approach
  - Allows for concomitant repair of anterior, posterior, and apical compartment defects and anti-incontinence procedures
  - Augmentation of native tissue repairs with biologic or synthetic materials/grafts
    - Outcomes improved with augmented materials, but graft materials may pose safety concerns (1)[A]
    - Transvaginal "mesh kits": Prepackaged medical devices for transvaginal placement of mesh material
  - Anterior colporrhaphy or paravaginal repair
  - Posterior colporrhaphy, perineorrhaphy
  - Vaginal apical/vault suspension
    - Sacrospinous ligament fixation
    - Uterosacral ligament fixation
- Abdominal approach
  - Abdominal sacrocolpopexy (ASC)
    - Open, laparoscopic, or robotic approaches

- Vaginal apex fixation to the presacral fascia at S3–S4 using biologic or synthetic material
- Hysterectomy
  - Transvaginal or transabdominal approach
  - Complete vs. supracervical
    - Potential increased risk of vaginal mesh exposure after ASC in setting of hysterectomy; supracervical hysterectomy may be protective (2)[B]
- Colpocleisis
  - Closure or removal of the entire vagina
    - Reserved for those who are not candidates for more extensive surgery or do not plan future vaginal intercourse
    - Partial colpocleisis (Le Fort colpocleisis)
    - Total colpocleisis
- Concomitant anti-incontinence procedure
  - Retropubic colposuspension (Burch)
    - Prophylactic Burch procedure with ASC can decrease subsequent SUI by 50% (3)[A]
  - Suburethral sling, including midurethral (MUS) and pubovaginal, synthetic or biologic graft materials
    - Prophylactic, synthetic MUS at time of vaginal POP surgery reduces need for additional surgery in women at 12 mo (OR 0.48, 95% CI 0.30–0.77) (4)[A]
    - Number of slings needed to prevent 1 case of SUI at 12 mo is 6 (4)[A]

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Vaginal pessary: Supportive and space-occupying devices for nonsurgical management of POP
  - Requires routine maintenance and care (removal, cleaning, vaginal inspection)

Complementary & Alternative Therapies

- Pelvic floor muscle training
  - Pelvic muscle strengthening can improve stage and symptoms, best with supervision of a physical therapist

ONGOING CARE

PROGNOSIS

- Recurrent POP
  - Historically 30% recurrence rate after surgery

COMPLICATIONS

- Mesh material complications occur in 10% of women (1)[B]
- Perioperative complications of bleeding, pelvic organ injury, bladder dysfunction, infection
- Postoperative complications include vaginal and pelvic pain, vaginal shortening or narrowing, dyspareunia

FOLLOW-UP

Patient Monitoring

- Evaluation for recurrent or de novo POP through history and exam
- Evaluation for urinary incontinence after POP surgery, if anti-incontinence procedure not performed
- Routine evaluation for complications related to synthetic mesh materials, if used in POP surgery
  - Patient history for vaginal symptoms, discharge, bleeding, dyspareunia
  - Physical exam for vaginal exposures
  - Cystoscopy for lower urinary tract perforations, as indicated

Patient Resources

ICD10

- N81.5 Vaginal enterocele
- N81.9 Female genital prolapse, unspecified
- N81.10 Cystocele, unspecified

CLINICAL/SURGICAL PEARLS

- Complete assessment of all vaginal compartments for POP staging is essential, including occult SUI.
- Nonsurgical treatments with pelvic floor muscle exercises and vaginal pessary should be offered prior to surgical intervention.
- Surgical repair with augmentation materials improves outcomes, but may pose serious safety risks.
- Patients must be informed of ongoing FDA concerns regarding safety of synthetic mesh materials used in POP surgery.
- Patient monitoring for recurrence and delayed mesh-related complications is imperative.

PELVIC PAIN, FEMALE

Kai-Wen Chuang, MD
Robert M. Moldwin, MD, FACS

BASICS

DESCRIPTION
- Chronic pelvic pain (CPP) is defined as discomfort below the umbilicus lasting ≥6 mo
- Etiology often unclear and symptom severity often out of proportion to objective findings
- Bears impact on physical, mental, emotional, and sexual well-being

EPIDEMIOLOGY
Incidence
N/A

Prevalence
- Difficult to ascertain due to varied definition
  - Affects ~1 in 7 women
  - 39% prevalence rate in primary care setting
  - Accounts for 10% of all gynecologic referrals

RISK FACTORS
- Depression, anxiety
- Personal history of abuse
- Prior sexually transmitted infections (STIs)
- Prior pelvic inflammatory disease (PID) increases risk 4-fold, prior STI/STD
- Substance dependence
- 1st-degree family with CPP

Genetics
- Twin studies and familial clustering do suggest genetic basis for increased nociception
- No established inheritance pattern

PATHOPHYSIOLOGY
- Exact mechanism unknown
- Complex and multifactorial, combining, biologic, psychological, and social factors

ASSOCIATED CONDITIONS
- Endometriosis, ectopic pregnancy, ovarian cysts, adhesions
- Urinary tract infections (UTIs), STIs, and PID
- Irritable bowel syndrome (IBS)
- Interstitial cystitis (IC)

GENERAL PREVENTION
- Prompt recognition
- Safe sex practices

DIAGNOSIS

HISTORY

- History of present illness
  - Onset/pallaition or provocation quality/radiation/severity/timing (OPQRST) of pain
  - Alleviating or aggravating factors
  - Ask if symptomatic during sexual intercourse
  - Menstrual history
- Past medical and surgical history
  - Check history of PID, STIs, ectopic pregnancy
  - Obtain history of trauma
  - Abdominal and pelvic surgeries contribute to adhesions
  - Check trigger points from incisional scars
- Family and social history
  - 1st-degree family with CPP
  - Inquire about physical and/or sexual abuse
  - Number of sex partners, method of contraception
  - Substance dependence, exposure to analgesics

PHYSICAL EXAM

- Vital signs
  - Fever, hypotension, and tachycardia suggest infectious etiology
- Abdominal exam
  - Search for trigger points
  - Assess peritoneal signs
  - Sensory evaluation of dermatomes
- Back and musculoskelet al exam
  - Evaluate posture and gait
  - Rule out scoliosis or lordosis
- Pelvic exam
  - Inspect vulva for skin lesions, signs of trauma, and irritation
  - Speculum exam to assess vaginal mucopurulent discharge and erythema
  - One-hand pelvic exam to identify muscular trigger points, cervical motion tenderness, urethral tenderness, and to delineate bladder base and vaginal fornix
  - Bimanual exam to assess uterine shape, direction, tenderness and mobility; assess adnexal masses and tenderness
- Rectal exam
  - Check rectal tone, rectovaginal septum, *cul-de-sac*, and uterosacral ligaments

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum
  - Complete blood count: Leukocytosis and left shift suggest infection
  - Erythrocyte sedimentation rate: Nonspecific markers of subacute or chronic inflammation
  - Cancer antigen-125: Marker for endometriosis, PID, and certain cancers
  - β-Human chorionic gonadotropin: Becomes positive 7 days after conception, a negative

test excludes ectopic pregnancy
- Urine
  - Urine pregnancy test
  - Urine analysis
  - Urine culture
  - Nucleic acid amplification test for gonorrhea and Chlamydia
  - Cytology, if hematuria to evaluate for bladder cancer
- Others
  - Cervical culture
  - Vaginal wet mount
  - PAP smear
  - Fecal occult blood test

Imaging
- Ultrasound
  - Transvaginal and/or pelvic ultrasound: Modality of choice in the initial evaluation of pelvic pain
  - Renal and bladder ultrasound: Assess hydronephrosis, renal stone disease, and bladder distension
- Plain films
  - Kidney, ureter, bladder x-ray (KUB): Assess urinary stone burden or dermoid cyst
  - Spinal and bony x-ray: Indicated when osseous and skelet al etiologies of pelvic pain are suspected
- Hysterosalpingography: Allow anatomic evaluation of the uterus and fallopian tubes
- Pelvic venogram: Assess pelvic vascular anatomy and venous congestion
- Axial imaging (CT, MRI)
  - Indicated when ultrasound negative or inconclusive
  - With intravenous and/or oral contrast
  - More sensitive evaluation of the gastrointestinal and genitourinary systems

Diagnostic Procedures/Surgery
- Diagnostic laparoscopy
  - Endometriosis most common (33%)
  - Adhesions (24%)
  - Negative 35–66% of the time
  - Negative findings do not exclude somatic cause and positive findings do not necessarily represent true etiology of CPP
- Barium enema or colonoscopy
- Urodynamics
- Cystoscopy, bladder biopsy, hydrodistension

Pathologic Findings
Based on diagnosis

DIFFERENTIAL DIAGNOSIS
- Gynecologic: Accounts for 20% of CPP
  - Cervical stenosis

  – Chronic PID (occurs after 30% of acute PID)
  – Endometriosis/chronic endometriosis
  – Gynecologic cancers
  – Pelvic congestion syndrome
  – Uterine fibroids
- Gastrointestinal
  – Colorectal cancers
  – Diverticulitis
  – IBS
  – Inflammatory bowel disease (IBD)
- Genitourinary
  – Bladder cancer
  – Cystitis, urinary retention
  – IC/painful bladder syndrome (PBS)
  – Kidney stones
  – Urethral diverticulum, urethritis
  – Urethral syndrome
- Others
  – Abdominal myofascial pain
  – Fibromyalgia
  – Pelvic floor muscular pain
  – Physical and/or sexual abuse
  – Psychiatric disorders
  – Radiculopathy
  – Surgical adhesions

TREATMENT

GENERAL MEASURES

- Goals of care for managing CPP
  – Symptomatic control
  – Patient education
  – Patient empowerment
- Multidisciplinary and individualized approach
  – Psychosocial counseling
  – Chronic pain management
  – Biofeedback
  – Physical therapy
  – Medications and surgery when needed
- Validated questionnaires and fluid diaries can help monitor progress

MEDICATION

First Line

- Target underlying condition, nerve block
- Nonsteroidal antiinflammatory drug (1)[B]

  – Superior to placebo
  – Can be given with acetaminophen
- Opioids (2)[A]
  – Oral, intramuscular, or transdermal
- Tricyclic antidepressants
  – More effective in neuropathic pain

ALERT
Common contraindications to antidepressants include recent infarction, arrhythmias, and severe hepatic/renal disease.

Second Line
- Selective serotonin reuptake inhibitors
- Anticonvulsants
  – Gabapentin (3)[A]
    - More effective in neuropathic pain
    - No place in acute pain

SURGERY/OTHER PROCEDURES
- Local injection of anesthetics
- Sacral neuromodulation (4)
- Surgical removal of endometriosis
- Hysterectomy
  – May be beneficial in women who have completed reproduction and whose CPP is believed to be due to uterine disorders such as adenomyosis or fibroids
- Presacral neurectomy

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
- Pelvic floor physical therapy
- Biofeedback and relaxation therapies
- Transcutaneous electrical nerve stimulation (TENS)
- Intravesical instillations or injections

Complementary & Alternative Therapies
- Acupuncture
- Massage and manipulations

ONGOING CARE

PROGNOSIS
Variable and dependent on underlying etiology and treatment modalities

COMPLICATIONS
- Risk of pharmacologic dependence, tolerance, and abuse associated with long-term

analgesia
- Surgical complications such as bleeding and infections are procedure specific

FOLLOW-UP

Patient Monitoring

- CPP is typically managed in outpatient setting
- Monitor serum hepatic/renal function and electrocardiogram when using antidepressants

Patient Resources

- The International Pelvic Pain Society
  – www.pelvicpain.org

- Prostatitis, Chronic, Nonbacterial, Inflammatory and Noninflammatory (NIH CP/CPPS III A and B)

CODES

ICD9

- 338.29 Other chronic pain
- 617.9 Endometriosis, site unspecified
- 625.9 Unspecified symptom associated with female genital organs

ICD10

- G89.29 Other chronic pain
- N80.9 Endometriosis, unspecified
- R10.2 Pelvic and perineal pain

CLINICAL/SURGICAL PEARLS

- The pathophysiology of CPP is multifactorial, and the treatment for it is multidisciplinary.
- Initial evaluation for CPP aims to identify life- or organ-threatening conditions and rule out anatomic or structural abnormalities.
- Subsequent management of CPP focuses on symptomatic control and patient education.
- Treatment takes time, and cure may not be possible. Therefore, it is important to set patient-centered yet realistic goals of care.

PENILE PROSTHESIS PROBLEMS (INFECTION/EXTRUSION/MALFUNCTION)

Nelson Bennett Jr., MD

BASICS

DESCRIPTION

- While generally very reliable, penile prostesis can become infected, undergo extrusion and suffer form mechanical failure.
- 2 types of penile prosthesis, malleable (semirigid, noninflatable, nonhydraulic) and inflatable. Inflatables consist of 2-piece (pump and cylinders) and 3-piece (pump, cylinders, and reservoir).
- Implanted via suprapubic or penoscrotal approach.
- Meticulous sterility is required.
- Infections of any or all parts of the device components require removal of the entire device.
- Extrusion/erosion of the device may occur into or through the urethra, penile glans, proximal crura, bladder or bowel, or adjacent vascular structures.
- Mechanical breakdown may manifest as inability to inflate/deflate device, abnormal erectile morphology, or auto inflation.

EPIDEMIOLOGY

Incidence

N/A

Prevalence

- Overall infection rate: 1–8%
- Prosthesis revision infection rate: 10–13%
- Prosthesis revision through infected field infection rate: 18%
- Mechanical failure rate 2-piece: 5% @ 5 yr
- Mechanical failure rate 3-piece: 18% @ 15 yr

RISK FACTORS

- Infection: Diabetes, spinal cord injury, previous penile prosthesis, immunocompromised state, h/o UTI, obesity
- Extrusion/erosion: Previous surgery, previous pelvic radiation, penile fibrosis, aggressive dilation, lack of surgical experience, Peyronie disease, previous penile prosthesis, upsizing of cylinders
- Mechanical failure: Inadequate dilation of reservoir space

Genetics

N/A

PATHOPHYSIOLOGY

- Infection
  - 1–8% this percentage increases with number of revision surgeries

  - Most common bacteria – *Staphylococcus epidermidis*
  - Other bacteria: MRSA, Pseudomonas, Enterococcus, Prevotella, Morganella
  - Gram-negative bacteria may be associated with rapid infection
  - Biofilm plays important role in bacterial adherence and infection
- Extrusion/erosion
  - Erosion through skin is inherently infected
  - Pre-existing infection may hasten erosion
  - Iatrogenic-facilitated erosion may result from overaggressive dilation
- Malfunction
  - Mechanical failure rates are 15% at 5 yr and 30% at 10 yr
  - Common reasons include aneurysm, tubing breakage, reservoir leakage, and connector failure
  - Auto inflation is usually due to improperly positioned reservoir

ASSOCIATED CONDITIONS

- Conditions associated with erectile dysfunction
  - Adrenal disorders
  - AIDS-associated neuropathy
  - Alzheimer's
  - Cardiac arterial disease
  - CNS infections
  - CNS tumors
  - Diabetes mellitus (Type I and II)
  - History of kidney or liver transplant
  - History of myocardial infarction
  - History of prostatectomy, cystectomy, or colectomy
  - Hyperprolactinemia
  - Hypertension
  - Hyperthyroidism
  - Hypogonadism
  - Hypothyroidism
  - Liver failure
  - Multiple sclerosis
  - Peripheral vascular disease
  - Renal failure

GENERAL PREVENTION

- The preoperative assessment should include issues such as the patients' needs and expectations of the device (1,2)
  - Issues such as complications and the irreversibility of the procedure should be exhaustively discussed and documented through informed consent
- Infection
  - Ensure UTI or infectious skin rash is absent
  - Tight control of serum glucose and HbA1C
  - Preoperative parenteral antibiotic of vancomycin + aminoglycoside or imipenem
  - Meticulous adherence to sterile technique

  - Limit OR traffic
  - 10-min scrub of operative area
  - 10-min scrub for OR staff
  - Use of alcohol-based solution for final prep
  - Avoid having prosthesis contact skin
  - Use antibiotic-coated/antibiotic dripped prosthesis (3)
    - Postoperative oral antibiotics 7–10 days postoperatively
- Extrusion/erosion
  - Avoid aggressive corporal dilation
  - Avoid upsizing of cylinders
  - Avoid early/premature inflation of device
- Malfunction
  - Place corporotomy closing sutures before device insertion to avoid iatrogenic puncture
  - Demonstrate proper function and placement of the device prior to conclusion of surgery

DIAGNOSIS

HISTORY

Assess for fever, chills, pain, lethargy, fatigue, change in bowel or bladder function, dysuria, frequency, urethral discharge.

PHYSICAL EXAM

- Assess penis/scrotum for erythema, edema, induration, pain in palpation of penis/scrotum, presence of wound drainage, adherence of prosthesis components to skin.
- Erosion/extrusion of device through glans, urethral meatus, scrotal skin, or perineum.
- Assess functionality of device by inflation/deflation—if suboptimally rigid or deflated pump, consider fluid leak.
- Assess penile contour/morphology upon inflation:
  - Buckling of cylinder or S-shaped deformity suggests oversizing of cylinders.
  - Floppy glans (SST deformity) suggests undersized cylinders or inadequate corporal dilation.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis
- Urine culture and sensitivity
- CBC with differential
- Metabolic profile
- Erythrocyte sedimentation rate

Imaging

- Usually not necessary
- Ultrasound scrotum—may reveal abscess
- MRI (with device inflated)—useful in assessment of corporal abnormalities.

Diagnostic Procedures/Surgery

Cystourethroscopy may reveal urethral erosion of cylinders or erosion of device component

into bladder.

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Intraoperative complications (4)
  - During corporal body dilation: Urethral perforation, cross over perforation of opposite crura during dilation
  - Reservoir position: Bladder perforation or improper positioning during the implant procedure
  - Component failure: Check device function before implantation; careful technique to avoid cylinder injury during corporal body closure
- Postoperative complications:
  - Infection
  - Erosion (oversized cylinder): Often associated with pain and buckling
  - Undersized cylinder ("concorde deformity" or "floppy glans") whereby there is excess mobility of the glans
  - Cylinder aneurysm
  - Fluid leak
  - Auto inflation/inability to deflate or inflate

TREATMENT

GENERAL MEASURES
- Broad-spectrum antibiotic should be started if infection is suspected.
- If sepsis is present, resuscitation is indicated prior to explanation of prosthesis.

MEDICATION
First Line
- AUA guidelines recommend the following antibiotic prophylaxis at the time of implantation (See Additional Reading)
  - Aminoglycoside (or aztreonam with renal insufficiency) plus
  - 1st/2nd-generation cephalosporin or vancomycin
  - Alternative regimens include:
    - Ampicillin/Sulbactam
    - Ticarcillin/Clavulanate
    - Piperacillin/Tazobactam

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Infection
  - Removal of prosthesis may be completed on a semiurgent basis (within 24 hr)
  - Immediate prosthesis salvage (replacement) may be possible in absence of frank purulence, erosion, necrotic tissue, poorly controlled diabetes, immunosuppression
  - Mulcahy protocol for prosthesis salvage (4):

- 1. Antibiotic solution (1 g vancomycin and 80 mg gentamicin in 1 L of normal saline)
- 2. ½ strength hydrogen peroxide
- 3. ½ strength betadine
- 4. Pressure washing with 1 g vancomycin and 80 mg gentamicin in 5-L irrigation
- 5. ½ strength betadine
- 6. ½ strength hydrogen peroxide
- 7. Antibiotic solution
- 8. Change instruments, gowns, drapes, and gloves immediately before prosthesis insertion

- Extrusion/erosion
  - Proximal erosion/extrusion managed by affixing RTE to the interior, proximal corpora with permanent suture
  - Alternatively, placing a purse-string suture in the corpora at tubing exit site
  - Distal extrusion/erosion (urethral) is best managed by immediately removing offending cylinder and prolonged Foley drainage. If contralateral cylinder has been placed, it may remain in place
- Malfunction
  - Floppy glans: Perform corporoplasty to reposition glans or dilate distal corpora
  - Cylinder aneurysm: Replace device
  - Fluid leak: Replace device
  - Auto inflation: Reposition, incise fibrotic capsule, or replace reservoir

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Prosthesis satisfaction rates approach 95% for patients and partners
- Satisfaction rates for revision surgery is ~80%
- Infection rates have decreased with antibiotic coated or antibiotic dipped prosthetics

COMPLICATIONS

- Revision surgery may result in infection, extrusion/erosion, or malfunction
- Delay replacement of device may result in corporal fibrosis

FOLLOW-UP

Patient Monitoring

- In case of revision surgery, prolonged antibiotic treatment may be required.
- Biweekly follow-up is indicated until patient is cleared to use the device.

Patient Resources

CODES

ICD9

- 996.39 Other mechanical complication of genitourinary device, implant, and graft
- 996.69 Infection and inflammatory reaction due to other internal prosthetic device, implant, and graft
- 996.76 Other complications due to genitourinary device, implant, and graft

ICD10

- T83.6XXA Infect/inflm react d/t prosth dev/grft in genitl trct, init
- T83.89XA Other specified complication of genitourinary prosthetic devices, implants and grafts, initial encounter
- T83.420A Displacement of penile (implanted) prosthesis, initial encounter

CLINICAL/SURGICAL PEARLS

- Meticulous sterility is required during the implant in the operating room.
- Infections of any or all parts of the device components require removal of the entire device.
- Extrusion/erosion of the device may occur into or through the urethra, penile glans,

proximal crura, bladder or bowel, or adjacent vascular structures.

- Mechanical breakdown may manifest as inability to inflate/deflate device, abnormal erectile morphology, or auto inflation.

PENIS, CANCER, GENERAL CONSIDERATIONS

Igor I. Kislinger, MD
Fernando J. Bianco, Jr., MD

BASICS

DESCRIPTION

- Most common: Squamous cell carcinomas (SCCs)
  - SCC in situ or CIS: Erythroplasia of Queyrat (glans or prepuce), Bowen disease (shaft)
  - Low-grade noninvasive (eg, verrucous carcinoma)
  - Progression risk 5–33% if untreated
- Other penile cancer histology: Adeno- and adenosquamous carcinoma, basal cell carcinoma, melanoma, sarcomas, Kaposi sarcoma, neuroendocrine (small cell) undifferentiated carcinoma, sebaceous gland carcinoma, and rarely, metastases from other sites (prostate, bladder, colon, kidney, leukemia most common)

EPIDEMIOLOGY

Incidence

- In 2014 in the United States the American Cancer Society estimates that about 1,640 new cases of penile cancer will be diagnosed and 320 men will die of penile cancer
- In the United States
  - Hispanics (6.6 per million)
  - Blacks (4.0 per million)
  - Whites (3.9 per million)

Prevalence

- Rare in developed countries
- Most common genitourinary malignancy in Uganda
  - In Brazil 6–14/100,000 males (1)

RISK FACTORS

- Poor hygiene (2)
- Presence of foreskin and/or phimosis
- STD: HPV types 16, 18, and 33 or HIV
- Genital ultraviolet radiation, alone or combined with 8-methoxypsoralen
- Multiple partners, smoking
- Premalignant conditions:
  - Leukoplakia, Lichen sclerosus
  - Balanitis xerotica obliterans (BXO)
  - Giant condylomata

Genetics

Viral genes E6 & E7 expressed on high-risk HPV, E-cadherin (16q22) immunoreactivity correlates with increased risk of nodal metastases

PATHOPHYSIOLOGY

- Invasive SCC is thought to be preceded by superficial CIS (Bowen disease or erythroplasia of Queyrat). Invasive SCC grows into the skin locally before invading the corporal bodies and extending locally.
- Penile SCC spreads by a relatively reliable pattern: Form superficial pelvic lymph nodes to deep pelvic lymph nodes.
- SCC is found on the glans in 48%, prepuce in 21%, glans and prepuce in 9%, coronal sulcus in 6%, and shaft $<2\%$.

ASSOCIATED CONDITIONS
- Phimosis
- Balanitis
- Sexually transmitted infections (STIs)/STDs

GENERAL PREVENTION
- Good hygiene, avoid smegma accumulation
- Newborn circumcision more protective than circumcision later in life
- HPV vaccines may reduce the risk of HPV and, consequently, penile cancer (unproven)

ALERT
Presentation at advanced stage is not uncommon due to denial and poor hygiene.

DIAGNOSIS

HISTORY
- Persistent induration, erythema, nodularity of prepuce and/or glans. Usually has been treated with several agents, lotions
- Growth or sore on the penis that doesn't heal within 4 wk
- Patients often denies or ignores lesions and present at later stages
- Bleeding ulcer
- Penile pain—infection
  - New onset of priapism with a mass suggests metastatic corporeal body lesion (eg, melanoma)

PHYSICAL EXAM
- Induration, erythema, nodularity of prepuce and/or glans
- Bleeding ulcer
- Foul smell with purulence
- Phimosis
- Inguinal adenopathy

DIAGNOSTIC TESTS & INTERPRETATION
Lab
CBC, urinalysis, urine culture

Imaging
- Penile ultrasound
- CT pelvis—evaluate pelvic adenopathy
- Penile MRI—surgical planning

Diagnostic Procedures/Surgery

- Superficial lesion
  - Biopsy, preferably excisional
  - Circumcision
- Large or extensive
  - Partial penectomy

Pathologic Findings

- Most malignancies involve the epithelial surface of the penis
- CIS (erythroplasia of Queyrat, Bowen disease of the penis, bowenoid papulosis)
- Verrucous carcinoma, warty carcinoma, Buschke–Löwenstein tumor, and giant condyloma are terms used to describe infrequently seen rare tumors that may invade locally but do not metastasize. Mostly considered to be benign, but malignant degeneration has been reported
- Invasive cancer:
  - 95% are SCCs
  - Tongues of invasive atypical keratinocytes with multiple mitosis invade the lamina propria or deeper. Sites with foci of aberrant and ectopic keratinization called squamous pearls
  - SCCs are graded using the Broders System:
    - Grade I: Well-differentiated, keratin pearls, prominent intercellular bridges
    - Grade II–III: Greater nuclear atypia, increased mitotic activity, decreased keratin pearls
    - Grade IV: Cells deeply invasive, marked nuclear pleomorphism, nuclear mitoses, necrosis, lymphatic and perineural invasion, no keratin pearls

DIFFERENTIAL DIAGNOSIS

- BXO
- Erythroplasia of Queyrat; shiny red patches on mucosal surfaces (glans and prepuce if uncircumcised)
- Bowen disease (red, scaly patches on the keratinized skin of the penis typically penile shaft)
- Bowenoid papulosis (multiple flat, warty lesions, sometimes pigmented)
- Condyloma acuminatum, lata
- Giant condylomata
- Extramammary Paget disease: Adenocarcinoma of apocrine gland bearing skin, often pruritic
- Kaposi sarcoma: Friable nodular lesions of varying size and varying color (purplish, red, blue, dark brown black) often ulcerate/ bleed
- Lichen sclerosis
- Psoriasis
- Seborrheic keratosis
- Ulcer from STD
- Zoon balanitis

TREATMENT

GENERAL MEASURES

- 1st line is surgical excision of lesion on penis.
- Wound care issues are paramount after excision of the primary and after inguinal node

dissections.
- Surgical care should be taken to minimize the complications of penile deformity and/or meatal stenosis after excising the primary and diligent attention to avoiding infection, hematoma, and lymphocele after inguinal node dissection is necessary.
- Treatment based on extent of disease and specific tumor type. Recommendations below are for invasive SCC (3). For other tumor types, see specific sections.

MEDICATION

First Line

- Topical 5-fluorouracil for cases of CIS
- For invasive SCC of the penis, after resection of the primary tumor, inguinal adenopathy should be treated with 6 wk of broad-spectrum antibiotics (augmentin or cephalosporin such as keflex) to determine if the enlarged nodes resolve
  – Consideration to early fine-needle aspiration biopsy of enlarged nodes can be considered
- Some authors recommend immediate fine-needle aspiration of enlarged inguinal nodes

Second Line

- There is no established chemotherapeutic regimen for metastatic disease.
  – Potential active agents include 5-FU, bleomycin, methotrexate, and cisplatin.

SURGERY/OTHER PROCEDURES

- Initial dorsal slit may be necessary to assess the lesion in phimosis
- Circumcision, if preputial and noninvasive
- Laser ablation, if small and noninvasive
- Mohs micrographic surgery, if small and noninvasive or minimally invasive (4)
- Wide local excision for small lesions. A 2-cm margin considered necessary
- Partial or total penectomy should be considered in patients exhibiting adverse features for cure by organ preservation strategies, including tumors 4 cm or more, grade III lesions and tumors invading deeply into the glans urethra or corpora cavernosa
  – Partial penectomy must achieve a 2-cm safety surgical margin
- Inguinal lymphadenectomy is mandatory for persistent lymphadenopathy after antibiotics and control of the primary lesion
- Inguinal lymphadenectomy is controversial if inguinal nodes are palpably normal before and after eradication of the primary
- Lymph node sampling (either sentinel node biopsy or modified inguinal dissection) may be offered for patients with palpable normal inguinal nodes and T2 or above lesion:
  – Usually, bilateral dissections are recommended
  – A total inguinal and pelvic lymphadenectomy is necessary if metastases are noted on sentinel or modified dissection

ADDITIONAL TREATMENT

Radiation Therapy

- External radiation to primary lesion if patient refuses surgical excision
- Some advocate this as primary therapy with salvage surgery with recurrences
- Typical doses are 50–60 Gy over 4–6 wk
- Overall local control provided by interstitial brachytherapy appears superior to that provided by external beam radiation therapy with 5-yr local control rates of 70%–87%

Additional Therapies
Chemotherapy-based clinical trails

Complementary & Alternative Therapies
- Ketogenic diet
- Holistic approaches

ONGOING CARE

PROGNOSIS
- Depends on T-stage and nodal status
- AJCC staging
  - Stage I: Cancer is moderately or well-differentiated and only affects the subepithelial connective tissue
  - Stage II: Cancer is poorly differentiated, affects lymphatics, or invades the corpora or urethra
  - Stage IIIa: Deep invasion into the penis and metastasis in one lymph node.
  - Stage IIIb: Deep invasion into the penis and metastasis into multiple inguinal lymph nodes
  - Stage IV: The cancer has invaded into structures adjacent to the penis, metastasized to pelvic nodes, or distant metastasis is present
- 5-yr overall survival for men with node-negative disease is 80–90%.
- 5-yr survival for N+ men 30–40%
- Married or previously married men have better prognosis
- African Americans tend to present with more advanced disease and have a poorer prognosis

COMPLICATIONS
- Infections
- Erosion of lymphadenopathy into femoral artery
- After radiation or brachytherapy urethral fistula, stricture, or stenosis with or without penile necrosis, pain, and edema. Radical penectomy may be required

FOLLOW-UP
Patient Monitoring
- Close inspection for local recurrence usually every 3 mo for 5 yr
- Consider imaging for ambiguous findings on physical exam

Patient Resources
- http://www.cancer.gov/cancertopics/types/penile. Accessed 1/3/2014.

CODES

ICD9

- 187.2 Malignant neoplasm of glans penis
- 187.3 Malignant neoplasm of body of penis
- 187.4 Malignant neoplasm of penis, part unspecified

ICD10

- C60.1 Malignant neoplasm of glans penis
- C60.2 Malignant neoplasm of body of penis
- C60.9 Malignant neoplasm of penis, unspecified

CLINICAL/SURGICAL PEARLS

- A painless lesion on the penis is the most common presentation.
- 40% of cases of penile cancer in the United States derive from HPV infections.
- 2-cm surgical margin is critical for a successful partial penectomy.
- Historically 6 wk of antibiotics are required to appropriate assessment of inguinal region adenopathy; consideration can also be given to early fine-needle biopsy.

PENIS, CANCER, LYMPHADENOPATHY

Jonathan H. Huang, MD
Viraj A. Master, MD, PhD, FACS

BASICS

DESCRIPTION

- Penile cancer spreads systematically to inguinal lymph nodes (LNs) before spreading to the common iliac and para-aortic LNs and becoming metastatic disease
  - Drainage is bilateral in 81% of cases
- The inguinal LNs are classified as either superficial or deep
  - Superficial inguinal LNs (up to 25 nodes) are located under dermis and above the fascia lata in Scarpa's triangle
  - Deep inguinal LNs are located in the region of the fossa ovalis, medial to the femoral vein
- Extent of LN metastasis determines survival
- Lymphadenectomy (LAD) for penile cancer is associated with significant morbidity, but can improve long-term survival
- LAD is the primary form of treatment for localized lymphatic spread
  - Extent of LAD (radical vs. modified) remains controversial

EPIDEMIOLOGY

Incidence

1 in 100,000 men in the United States and Europe develop penile cancer

Prevalence

- LN spread occurs in 10–15% of patients with nonpalpable inguinal LNs
- LN spread occurs in 50% of patients with palpable inguinal LNs
  - Palpable inguinal LNs are present in 60% of presenting patients

RISK FACTORS

- Inguinal LN spread is correlated with an increase in clinical grade of primary tumor (0–29% in grade 1 vs. 33–50% in grade 3)
- Inguinal LN spread is correlated with an increase in local stage of primary tumor (<10% in pT1/pTis, 50–70% in pT2 disease, and 50–100% in pT3/pT4)

Genetics

HPV contributes to the development of penile cancer through interactions with tumor protein 53 (p53) and retinoblastoma (RB) tumor suppressor proteins

PATHOPHYSIOLOGY

- Inguinal LNs serve at the primary lymphatic drainage for the penis, scrotum, urethra, vulva, vagina, perineum, gluteal region, lower abdominal wall, lower anus, and lower extremities
- Inguinal LNs lie within the femoral triangle (inguinal ligament, sartorius, and adductor longus) and are separated into superficial and deep groups by the fascia lata of thigh

ASSOCIATED CONDITIONS

- Balanitis
- Phimosis
- STDs

GENERAL PREVENTION
- Prepubertal circumcision is protective against penile cancer
- Good genital hygiene
- STD education and safe sexual practices
- Sun protection against melanoma
- HPV vaccination may reduce risk (unproven)

DIAGNOSIS
HISTORY
- Circumcision
- Phimosis
- HPV infection
- Penile condylomata
- Penile cancer
- Sexual history (multiple partners, early age of initial intercourse)
- Smoking history
- Balanitis xerotica obliterans
- Treatment with sporalene and ultraviolet A phototherapy

PHYSICAL EXAM
Palpable inguinal LNs

DIAGNOSTIC TESTS & INTERPRETATION
Lab
No tissue parameters, including HPV and p53 status, are predictive of LN involvement

Imaging
- No imaging studies are currently utilized extensively in the diagnosis of LN involvement
- Ultrasound and PET-CT can be used to detect recurrences
- Chest x-ray and CT abdomen/pelvis can be used for staging

Diagnostic Procedures/Surgery
- Ultrasound-guided fine-needle aspiration cytology (FNAC)
  - Palpable LNs: Sensitivity of 93% and specificity of 91%
  - Nonpalpable LNs: Sensitivity of 39% and specificity of 100%
- Dynamic sentinel node biopsy (DSNB): Lymphoscintigraphy and blue dye staining for identification of positive LNs
  - False-negative rate of 5%
  - Should only be offered in experienced centers

Pathologic Findings
Squamous cell carcinoma accounts for 95% of penile cancers

DIFFERENTIAL DIAGNOSIS

- Reactive LNs
- Infections: Syphilis, herpes, chancroid, lymphogranuloma venereum, pedal fungal disease
- Malignant diseases: Metastatic melanoma, lymphoma
- Systemic diseases: Mononucleosis, rubella, human immunodeficiency virus, cytomegalovirus
- Autoimmune diseases: Sarcoidosis, lupus

TREATMENT

GENERAL MEASURES

- Tis, Ta primary tumors (1)
  - Nonpalpable inguinal LNs
    - Surveillance
  - Palpable inguinal LNs
    - Antibiotics for 1 mo to rule out infection vs. immediate fine-needle aspiration biopsy
    - If persistent LNs and either FNAC or excisional biopsy are positive, ipsilateral inguinal and pelvic LAD and contralateral superficial or modified inguinal LAD
- T1 grade 1 and grade 2 primary tumors
  - Nonpalpable inguinal LNs
    - Surveillance
  - Palpable inguinal LNs
    - If FNAC is negative and no resolution with antibiotics, excisional biopsy or inguinal LAD
    - If FNAC is positive, ipsilateral inguinal and pelvic LAD and contralateral superficial or modified LAD
- T2–T4 primary tumors
  - Nonpalpable inguinal LNs should undergo bilateral superficial inguinal LAD or DSNB
    - If frozen section is negative, surveillance
    - If frozen section is positive, that side should undergo ipsilateral inguinal and pelvic LAD
  - Palpable unilateral LNs should undergo ipsilateral inguinal and pelvic LAD and contralateral superficial or modified inguinal LAD
    - If contralateral frozen section is negative, surveillance
    - If contralateral frozen section is positive, deep inguinal or pelvic LAD
  - Palpable bilateral LNs should undergo FNAC to determine the extent of LAD
    - If FNAC is negative, at least bilateral superficial inguinal LAD or DSNB
    - If FNAC is positive, bilateral inguinal and pelvic LAD and chemotherapy is warranted
- Fixed or LNs >4 cm
  - Neoadjuvant chemotherapy potentially followed by surgery
- Pelvic LNs spread is more likely if (1) 2 or more inguinal node involvement, (2) extranodal metastasis, (3) Cloquet node involvement
- LAD should involve at least 8 LNs, as this improves 5-yr survival

MEDICATION

First Line

- Antibiotics
  - Use of antibiotics has become controversial for enlarged LNs
  - Historically, a 4–6-wk course of antibiotics (such as a cephalosporin or augmentin) was

recommended to rule out infection in Tis and Ta tumors with palpable LNs
  - Delay in LAD, a potentially curative treatment, has brought the use of antibiotics into question
  - FNAC can help determine if LNs are due to metastasis or infection

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Radical LAD (2,3)
  - Superior margin: Superior margin of the external ring to the anterior superior iliac spine (ASIS)
  - Lateral margin: ASIS to 20 cm inferiorly
  - Medial margin: Pubic tubercle to 15 cm inferiorly
  - Inferior margin: 20 cm inferior from the ASIS to 15 cm inferior from the pubic tubercle
- Modified LAD (after Catalona)
  - Excludes area lateral to the femoral artery and caudal to the fossa ovalis
  - Preservation of the saphenous vein
  - No transposition of the sartorius muscles
  - Conversion to radical LAD if there are positive LNs
- Techniques to minimize complications of LAD
  - Careful skin-flap management
  - Meticulous LN dissection
  - Prophylactic antibiotics: Cephalosporins for 2 mo
  - Vacuum drains
  - Elastic and/or pneumatic stocking
  - Early ambulation
- Endoscopic LAD (4)
  - Complete radical LAD can be completed through 3 endoscopic ports
  - Node yield is equivalent to open surgery
  - Decreased complications
- The viability of the skin flaps developed during an inguinal LN dissection are based on the anastomotic vessels within the superficial fatty layer of Camper's fascia which course lateral to medial along the skin lines. This is a key anatomic dissection plane as the lymphatic drainage of the penis lies beneath Camper's fascia allowing this superficial fatty layer to remain attached to the skin flaps during a groin dissection
- When performing an inguinal LN dissection for a clinically negative groin, a modified technique should be used to decrease morbidity. The key components of this technique include the following: Shorter incision (~10 cm), preservation of the saphenous vein, minimizing dissection lateral to the femoral artery, and avoiding transposition of the Sartorious muscle

ADDITIONAL TREATMENT

Radiation Therapy

- Adjuvant radiotherapy may improve locoregional control in patients with extensive metastases and/or extranodal disease

  – Side effects include edema and pain
• Radiotherapy in clinical N0 patients is not recommended

Additional Therapies
• Adjuvant chemotherapy
  – 3 courses of cisplatin and 5-fluorouracil for pN2–3
  – No adjuvant chemotherapy for pN1

Complementary & Alternative Therapies
None are effective

ONGOING CARE

PROGNOSIS
• 5-yr cancer-specific survivals:
  – 90–100% in pN0 disease
  – 70–80% in pN1 disease
  – <30% in pN2–pN3 disease
  – 15% in patients with positive pelvic LNs who had inguinal and pelvic LAD
• Predictors of cancer-specific survival: Pathologic stage of LNs, vascular and/or lymphatic involvement, primary tumor thickness

COMPLICATIONS
• LAD complications
  – Wound infection
  – Skin necrosis
  – Wound dehiscence
  – Thigh numbness
  – Lymphedema
  – Lymphorrhea
  – Scrotal swelling
  – Suprapubic swelling
  – Pulmonary embolism

FOLLOW-UP
Patient Monitoring
• Recurrences occur most often within 2 yr after inguinal LAD
• Nomograms available (5)
• Evaluation should include an exam and ultrasound-guided FNAC
• Maximum follow-up length of 5 yr
• Surveillance (patient did not have LAD)
  – Every 3 mo for yr 1 and 2
  – Every 6 mo for yr 3, 4, and 5
• LAD and pN0 disease
  – Every 6 mo for yr 1 and 2
  – Every 6 mo for yr 3, 4, and 5
• LAD and pN+ disease

– Every 3 mo for yr 1 and 2
– Every 6 mo for yr 3, 4, and 5

CODES

ICD9
- 187.4 Malignant neoplasm of penis, part unspecified
- 196.5 Secondary and unspecified malignant neoplasm of lymph nodes of inguinal region and lower limb
- 785.6 Enlargement of lymph nodes

ICD10
- C60.9 Malignant neoplasm of penis, unspecified
- C77.4 Sec and unsp malig neoplasm of inguinal and lower limb nodes

- R59.0 Localized enlarged lymph nodes

CLINICAL/SURGICAL PEARLS

- Penile cancer metastasizes to regional LNs before disseminating systemically.
- Treatment is dependent on the clinical presence of LNs, tumor stage, and tumor grade.
- Inguinal LAD is potentially curative and can improve long-term outcomes in penile cancer with nodal metastases.
- Careful tissue management, antibiotics, vacuum drains, and compression stockings can minimize the morbidities associated with LAD.

PENIS, CURVATURE, AND/OR PAIN

Abhinav Sidana, MD
Anish K. Shah, MD

BASICS

DESCRIPTION

- Penile pain could be a result of multiple etiologies and present in both a flaccid and erect penis
  - Penile pain: Flaccid penis
    - Usually secondary to inflammation of bladder and urethra with referred pain localized to meatus
    - Potentially secondary to paraphimosis
  - Penile pain: Erect penis
    - May be secondary to priapism or Peyronie disease (PD)
- Acquired penile curvature in men, known as PD, is an inflammatory condition of the tunica albuginea usually associated with painful erection with curvature. If severe, it can cause dyspareunia
  - Can be a result of complications of penile prosthesis implantation
  - Congenital chordee may present as penile curvature in infants due to a deficiency in formation of the urethra or the Buck fascia ventrally
  - Iatrogenic chordee secondary to circumcision or other penile skin procedures

EPIDEMIOLOGY

Incidence

- Common at all ages, but mean age: 53
- Mostly affects males 40–70 yr old, with 0.4–3.2% incidence

Prevalence

In general 5% of men have evidence of PD

RISK FACTORS

- Buckling erectile trauma
- Fracture of the tunica albuginea during sexual activity
- Intracavernous injection of vasoactive agents
- Priapism
- Urethral and penile surgery
- See also “Commonly Associated Conditions”

Genetics

- Associated with HLA (histocompatability B7) cross-reactive antigens
- PD less frequent in patients with Asian or African ancestry

PATHOPHYSIOLOGY

- Mechanical tunical stress forces causing microvascular hemorrhage and inflammation in the tunical wall or septum. The result is hypertrophic scar formation (plaque).

- Autoimmune components have been demonstrated in 38–75% of men with PD.
- Altered cell-mediated immunity and antielastin antibodies support an immunologic component.
- In the setting of erectile trauma, an altered immunologic response to wound healing may predispose a subpopulation to PD.

ASSOCIATED CONDITIONS
- Chronic intracavernous injection therapy
- Dupuytren contracture
- ED (venoocclusive dysfunction)
- Ledderhose disease (Plantar fasciitis)
- Paget disease
- Tympanic sclerosis
- Urethral stricture
- Hypospadias

GENERAL PREVENTION
Avoidance of penile trauma during intercourse

DIAGNOSIS
HISTORY
- Obtain a thorough medical, surgical, and sexual history (1)[A]
- It is critical to differentiate penile pain from urethral pain: History of voiding symptoms and/or recurrent UTIs
- Establish duration, degree, and location of curvature and pain
- Dyspareunia
- Painful erection (suggests PD)
- Painful ejaculation
- Nature of deformity: Curvature, indentation or instability (hinge effect)
- Condition causes distress to patient or partner
- Coexisting ED
- Palpable nodule
- History of penile prosthesis
- History of penile trauma
- History of penile surgery as a child
- Sickle cell disease suggests predisposition to priapism
- Insect bites

PHYSICAL EXAM
- Circumcised/uncircumcised; retractable foreskin
- Measurement of stretched penile length
- Palpation of stretched shaft to amplify plaque and determine its location and size
- Plaque tenderness
- Location of meatus for evidence of hypospadias
- Evidence of hematoma that suggests acute trauma
- Solitary or multiple plaques

- Erythema and crepitus with Fournier gangrene
- Eggplant sign with penile fracture

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Usually not useful unless for workup of infections
- Urinalysis with or without culture in cases of referred pain from other GU cause
- Serum-free testosterone (morning) and prolactin levels if erectile dysfunction coexists
- Corporal blood gas for priapism

Imaging

- Radiograph of penile shaft if calcification is suspected.
- Duplex Doppler US with intracavernous pharmacologic injection to assess cavernous arterial function, presence of venoocclusive dysfunction, and degree of erectile curvature, lateral indentation or circumferential wasting.
- Private self-photography of erect penis using instant (Polaroid) or digital film imaging is useful to classify the extent of the curvature.

Diagnostic Procedures/Surgery

- Uroflowmetry to rule out associated urethral stricture
- Bladder US for postvoid residual
- Retrograde urethrogram (if history and exam suggest urethral injury, such as blood at meatus. May be seen with penile fracture.)
- Urethroscopy for urethral pathology

Pathologic Findings

- PD is characterized by a fibrous noncompliant plaque within the tunica albuginea, which may calcify, preventing uniform expansion of the corpora cavernosa during erection.
  - Microscopy: Affected tunica albuginea demonstrates nonpolarized arrangement of collagen fibers and disordered arrangement of elastin fibers in PD.

DIFFERENTIAL DIAGNOSIS

- Balanitis, balanoposthitis, paraphimosis
- Cellulitis
- Chordee
- Congenital penile curvature
- Epispadius
- Erectile dysfunction
- Fournier gangrene
- Hypospadias
- Idiopathic urethralgia
- Insect bite
- Penile ischemia (embolic, atherosclerosis)
- Leukemic infiltration of the penile shaft
- Penile cancer
- Penile fracture, trauma, or contusion
- Penile pain syndrome

- Penile prosthesis problem: S-shaped or sigmoid curvature with buckling of prosthesis cylinders that are too long; pain also suggests infected prosthesis components
- Priapism
- Psychiatric causes of pain
- Pudendal neuralgia
- Referred pain, GI (rectum, hemorrhoids, fistula, fissures)
- Referred pain, GU (cystitis, urethritis, prostatitis, retention, urolithiasis, urethral calculus)
- Reiter syndrome
- STD (herpes, chancroid)
- Torn frenulum
- Trauma (GSW, penile fracture)
- Urethral foreign bodies
- Urethral shortening following urethroplasty
- Urethral stricture

TREATMENT

GENERAL MEASURES

Identify the specific cause of the penile pain and/or curvature and treat accordingly

MEDICATION

First Line

- PD
  - All oral agents yield insignificant therapeutic benefit:
    - Vitamin E (antioxidant), potaba (antifibrotic), colchicine (antifibrotic), tamoxifen (antifibrotic), L-carnitine (antioxidant), pentoxifylline
- Paraphimosis
  - Urgent manual reduction with firm pressure ± local anesthetic (see section on paraphimosis for details)
- Priapism
  - Irrigation and aspiration
  - Intracavernosal phenylephrine injection (100–500 mcg/mL)
- Referred pain to penis or urethra should be aimed at treating primary problem
- Treat infectious causes (cellulitis, STD) with antimicrobials

Second Line

- PD intralesional therapy
  - Collagenase clostridium histolyticum (CCH) (Xiaflex) (3)[A]
    - FDA approved curvature deformity of the penis due to the presence of a plaque in PD. Restricted distribution through Risk Evaluation and Mitigation Strategy (REMS) due to the risks of serious adverse reactions, including penile fracture and other serious penile injury
    - Maximum 4 treatment cycles. Each treatment cycle consists of 2 Xiaflex injection procedures (in which Xiaflex is injected directly into the collagen-containing structure of the penis) and 1 penile modeling procedure performed by the healthcare professional.
    - Breaks down collagen, promotes remodeling

- Other intralesional agents (off-label) Verapamil (antifibrotic), collagenase (antifibrotic), interferon-α (antifibrotic)
- Steroid therapy
  - Subcutaneous, nonintralesional injections of triamcinolone (50 mg) (2)[C]

SURGERY/OTHER PROCEDURES

- PD
  - Plication of the corporal body
  - Plaque incision with graft interposition
    - Synthetic (Dacron)
    - Autologous (buccal mucosa, dermis, tunica albuginea, tunica vaginalis)
    - Prepackaged biologic (porcine small intestine submucosa)
  - Penile prosthesis with manual molding, if necessary (4)[A]
- Paraphimosis
  - Dorsal slit or incision of constricting band
  - Circumcision may be necessary
- Chordee and epispadias
  - See specific topic for surgical correction
- Penile Fracture
  - See specific topic for surgical correction
- Priapism
  - Distal and/or proximal shunting procedures
  - See specific topic for surgical correction
- Penile reconstruction of scars, contractures, or other deformities
  - Z-plasty or other plastic operation

ADDITIONAL TREATMENT

Radiation Therapy

Ineffective in PD

Additional Therapies

N/A

Complementary & Alternative Therapies

- None have been shown to have convincing benefit
  - Vitamin E (α-tocopherol)
  - Potaba (potassium aminobenzoate)
  - L-carnitine
- Acupuncture

ONGOING CARE

PROGNOSIS

- Prognosis dependent on primary etiology of penile curvature and/or pain.
  - Surgical straightening of erection is predictably successful (>85%).
  - Shortened penile length and sensory loss may be noted postoperatively.

COMPLICATIONS

- Residual pain and curvature
- Dyspareunia
- Erectile dysfunction and loss of penile length due to PD or surgical repair

FOLLOW-UP

Patient Monitoring

Periodic monitoring of erectile function, penile length, and sensory function

Patient Resources

- The Peyronie Disease Society (www.peyroniessociety.org)
- Urology Care Foundation (http://www.urologyhealth.org/urology/index.cfm?article=115)

CODES

ICD9

- 605 Redundant prepuce and phimosis
- 608.89 Other specified disorders of male genital organs
- 752.63 Congenital chordee

ICD10

- N47.2 Paraphimosis
- N48.89 Other specified disorders of penis
- Q54.4 Congenital chordee

CLINICAL/SURGICAL PEARLS

- Focused history and physical exam allows for prompt diagnosis and effective treatment.
- High index of suspicion for emergent etiologies (Fournier gangrene, penile fracture, priapism, paraphimosis).
- New data suggests that CCH can significantly reduce the symptoms of Peyronie disease.

PENIS, CUTANEOUS LESION

Kiranpreet K. Khurana, MD
Edmund S. Sabanegh, Jr., MD

BASICS

DESCRIPTION
- 3 categories: Benign, premalignant, malignant
- May be male genitalia-specific (primary) or associated with other cutaneous lesions or systemic disease (secondary)
- May occur at any age

EPIDEMIOLOGY
Incidence
Varies widely by etiology

Prevalence
- Depends on etiology
  - Pearly penile papule found in 14–48% of postpubertal males
  - Genital warts found in 0.1–1% of men

RISK FACTORS
Systemic disease, irritant or allergen, sexual contact, trauma, uncircumcised penis, family history, inflammation, infections, medications, local skin hygiene, obesity, age, smoking

Genetics
- Reiter syndrome: Associated with HLA-B27 haplotype
- Hailey–Hailey disease: Autosomal dominant
- Penile cancer: Associated with altered expression of P53, P21, c-ras, myc, Ki-67 genes

PATHOPHYSIOLOGY
- Idiopathic, allergic, infectious, autoimmune, inflammatory, systemic, sexual transmission, genetic
- Lesions appear similar; biopsy often needed for diagnosis

ASSOCIATED CONDITIONS
- Lesler–Trélat syndrome: Increase in size and number of seborrheic keratosis lesions sometimes signaling internal malignancy
- Stevens–Johnson syndrome and toxic epidermal necrolysis: Prodromal upper respiratory illness followed by life-threatening desquamating lesions due to medications, infections, or cancers
- Psoriasis: Lesions under preputial skin, glans, or prepuce
- Reiter syndrome (reactive arthritis): Urethritis, arthritis, conjunctivitis. Circinate balanitis
- Behçet disease: Painful ulcers found in 57–93% of patients, mostly scrotum (90%), but glans and shaft also affected
- Inflammatory bowel disease: Arterial thrombosis of penis, penile swelling, and noncaseating

granulomas on biopsy; also pyoderma gangrenosum
- Hailey–Hailey disease: Vesiculobullous rash
- Diabetes: Phimosis
- HIV: Kaposi sarcoma, seborrheic dermatitis

GENERAL PREVENTION
- Circumcision helpful in some cases
- Proper hygiene
- Safe sex practices
- Avoid contact with allergens or irritants

DIAGNOSIS
HISTORY
- Age
- Symptoms: Pain, pruritus, burning, discharge
- Location: Scrotum, glans, shaft, preputial skin, urethral/bladder lining, other sites
- Duration
- Rate of onset: Acute or chronic
- Exposures: New bath/laundry soap, lotions, oils, travel (exotic plants, animals, insects, people), shared towels/clothes, new medications, industrial, chemical
- Sexual history: Sexual partner with lesions
- Trauma
- History of systemic diseases or cancers
- Allergies
- Family history
- Previous treatment

PHYSICAL EXAM
- Examine and describe lesion(s):
  - Elevated, nonelevated
  - Color of lesion
  - Morphology of lesion
  - Configuration of lesion (linear vs. serpiginous)
  - Degree of margination
  - Degree of firmness
  - Examine genitalia: Circumcised, uncircumcised, proper placement of foreskin
  - Describe primary lesion(s) (1)[A]:
    - Papule: ≤0.5 cm, solid, elevated
    - Plaque: >0.5 cm, solid, elevated
    - Nodule: >0.5 cm, solid, dome-shaped
    - Vesicle: ≤0.5 cm, fluid-filled, well-circumscribed
    - Bulla: >0.5 cm, fluid-filled, well-circumscribed
    - Pustule: Vesicle with purulent fluid, well-circumscribed
    - Wheal: Hive, edematous plaque
  - Describe secondary lesion(s) (1)[A]:

- Scale: Flakes on lesion surface
- Crust/scab: Collected cellular debris
- Atrophy: Thinning of skin causing depression
- Scar: Connective tissue collection
- Cyst: Lesion with wall and lumen
- Erosion: Defect with red/moist base
- Fissure: Thin linear defect
- Ulcer: Deep defect

• Full dermatologic exam:
  – Single or multiple lesions
  – Organ-specific or generalized
• Lymph node exam

DIAGNOSTIC TESTS & INTERPRETATION

Lab

• Urinalysis, Gram stain, culture
• Complete blood count
• Serum chemistry profile
• STD screening if suspected

Imaging

• If locally advanced lesion or internal lesions/tumors/malignancies suspected
• Workup for associated abnormalities

Diagnostic Procedures/Surgery

• Cytologic smears: Potassium hydroxide or periodic acid-Schiff staining for fungal infections
• Tzanck smear: Herpes, varicella, Molluscum contagiosum
• Microscopic exam: Scabies, pubic lice, pinworm, and other infections
• Gram stain, bacterial, and fungal cultures of lesion: Infections
• Excisional or incisional biopsy

Pathologic Findings

• Depth of lesion
• Exam of epidermis, dermis, and subcutaneous tissue and any changes noted
  – Infiltration with other cells or infectious agents

DIFFERENTIAL DIAGNOSIS

• Common benign lesions (1)[A]
  – Acrochordon: “Skin tag”
  – Angiokeratoma of Fordyce: Red papules on penis, scrotum; ectasia of dermal blood vessels
  – Epidermoid cysts: Most common cysts of genital area. Filled with keratin. Postsurgical after circumcision or hypospadias repair
  – Fordyce spots: Sebaceous glands on genitalia
  – Pearly penile papule: Small, white/flesh colored, multiple, on glans or corona
  – Seborrheic keratoses: “Stuck on” appearance
  – Vitiligo: Patchy depigmentation of skin
  – Zoon balanitis: Nonelevated, erythematous, glistening plaques on glans in uncircumcised

men. Biopsy to distinguish from SCC in situ
  - Sclerosing lymphangitis: Cordlike lesion of coronal sulcus; after vigorous sexual activity
- Allergic dermatitis, eczematous lesion with erythema, discharge, excoriations (1)[A]
  - Atopic dermatitis: Also known as lichen simplex chronicus, pruritic, red/scaly lesion on posterior scrotum. "Atopic triad" of eczema, allergic rhinitis, asthma
  - Contact dermatitis: Irritant or allergic. Scaly with crust. Direct cytotoxic effect of irritant or local type IV hypersensitivity reaction
  - Erythema multiforme: Red papules and target lesions, blisters. Minor or major. Major: Stevens–Johnson syndrome, toxic epidermal necrolysis
- Papulosquamous disorders, scaly lesion on erythematous base (2)[C]
  - Psoriasis: Thick plaque with silver scales. Corona and glans lesions in circumcised, underneath preputial skin in uncircumcised
  - Reiter syndrome: Circinate balanitis, urethritis, arthritis, ocular, oral, and skin lesions. History of infection with Chlamydia, Gonococcus, Ureaplasma, or GI bacteria
  - Lichen planus: Idiopathic autoimmune reaction against basal keratinocytes; small, flat, shiny, violaceous papules on glans
  - Lichen sclerosis: Pruritic pearly white papules and plaques on glans and inner prepuce that scar. Late stage called balanitis xerotica obliterans. Biopsy to exclude SCC
  - Fixed drug eruption: Hypersensitivity reaction to medication 1–2 wk after starting. Lesions occur in same location after challenge
- Vesicobullous disorders, autoimmune blisters and erosions (1)[A]
  - Pemphigus vulgaris: Extensive painful blisters and erosions. Difficult to treat and may be fatal
  - Bullous pemphigoid: LgG mediated, typically in patients older than 70 yr
  - Dermatitis herpetiformis: Associated with celiac disease; IgA mediated
  - Hailey–Hailey disease: Familial, seen in 20–30s, blisters in axilla, inguinal, perianal areas
- Noninfectious ulcers, lesions extending to dermis (1)[A]
  - Behçet disease: Painful oral and genital ulcers, uveitis and other systemic involvement
  - Pyoderma gangrenosum: Chronic painful ulcer associated with Crohn's, ulcerative colitis, collagen vascular disease
  - Traumatic ulcers: Direct impact, sexual activity, body piercings, cleansing techniques
- Infections and infestations (1)[A]
  - STDs: Herpes simplex, syphilis, chancroid, genital warts, granuloma inguinale, lymphogranuloma venereum, molluscum contagiosum, Chlamydia, gonorrhea, trichomoniasis
  - Genital warts: HPV 6 and 11.4 variants: Condylomata acuminate, common warts, flat-topped papules/plaques, Buschke–Löwenstein tumor (giant condyloma). Biopsy for flat-topped and giant condylomas to rule out SCC
  - Balanoposthitis: Inflammation of glans and foreskin in uncircumcised males. Can be due to bacteria, yeast, irritants, trauma
  - Cellulitis: Infection of deep dermis and subcutaneous tissues due to *Staphylococcus aureus* and *Streptococcus pyogenes*
  - Folliculitis: Infection of hair-bearing follicles
  - Furunculosis: "Boil"

- Hidradenitis suppurativa: Painful, firm, red nodules with draining sinuses; chronic inflammation of gland-bearing skin, superinfection possible
- Fournier's gangrene: Necrotizing fasciitis; progresses from cellulitis to blisters to foul-smelling necrotic lesions. Surgical emergency
- Infestation: Pubic lice (*Pediculosis pubis)* or scabies (*Sarcoptes Scabiei* mite); very pruritic

• Neoplastic lesions, see Section I "Bowen disease and Erythroplasia of Queyrat," "Penis, cancer, general considerations," "Penis, squamous cell carcinoma"

TREATMENT

GENERAL MEASURES

• Common benign lesions (1)[A]:
- No treatment if asymptomatic
- If inflamed or infected, treat with antibiotics
- Topical corticosteroids or emollient for symptomatic relief
- Recurrent infections or cosmetic reasons: Excise, remove with laser or cryotherapy
  - Zoon balanitis: Topical steroids for symptoms, circumcision for cure
  - Contact dermatitis: Remove offending agent
  - Psoriasis: Topical corticosteroids, clobetasol, or systemic treatment
  - Lichen sclerosis: Biopsy to exclude SCC. Long-term follow-up required. Circumcision curative.
  - Pemphigus vulgaris: Oral corticosteroids, immunosuppressive therapy
  - Behçet disease: Oral corticosteroids, immunosuppressive therapy
  - Genital warts: Topical 0.5% podofilox, 5% imiquimod, green tea polyphenol extract, 25% podophyllin or trichloroacetic acid, cryotherapy, electrosurgery, laser ablation, surgical excision
  - Balanoposthitis: Circumcision curative
  - Hidradenitis suppurativa: Skin care, topical clindamycin or oral clindamycin and rifampin. Surgical excision for recurrent lesions
  - Fournier's gangrene: Broad-spectrum intravenous antibiotic coverage and emergent surgical debridement
  - Infestation with scabies or pubic lice: 5% permethrin cream overnight and repeated a week later

MEDICATION

First Line

• Varies with etiology (see above) (3)[B]
- Low-potency topical corticosteroids for symptoms, eg, Hydrocortisone 1%, 2.5%
- Specific antibiotics aimed at pathogen

Second Line

• Varies with etiology (3)[B]
- High-potency or oral corticosteroids
- Immunosuppressive mediations
- Intravenous antibiotics

SURGERY/OTHER PROCEDURES
- Excision of lesion(s) and surrounding tissue
- Laser ablation, electrocautery, cryotherapy
- Circumcision
- More extensive surgeries if neoplastic lesion

ADDITIONAL TREATMENT
Radiation Therapy
Limited role in nonneoplastic lesions

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE
PROGNOSIS
- Most cutaneous lesions have a good prognosis but should be addressed promptly
- Widespread lesions difficult to control

COMPLICATIONS
- See "Differential Diagnosis" section
- If left untreated, lesions may progress locally or distally and cause symptoms

FOLLOW-UP
Patient Monitoring
Follow patients to monitor response to intervention and any change in lesion

Patient Resources
- http://www.cdc.gov/std/general/default.htm
- http://www.aad.org/skin-conditions/dermatology-a-to-z

CODES

ICD9

- 078.11 Condyloma acuminatum
- 608.89 Other specified disorders of male genital organs
- 709.8 Other specified disorders of skin

ICD10

- A63.0 Anogenital (venereal) warts
- N48.89 Other specified disorders of penis
- R23.8 Other skin changes

CLINICAL/SURGICAL PEARLS

- Do a complete skin exam when genital cutaneous lesion found.
- Skin lesions appear similar and excisional or incisional biopsies are often necessary for diagnosis and to rule out cancer.
- Stevens–Johnson syndrome, toxic epidermal necrolysis, Fournier gangrene, pemphigus vulgaris can be life-threatening.

PENIS, SQUAMOUS CELL CARCINOMA

Michael A. Poch, MD
Philippe E. Spiess, MD

BASICS

DESCRIPTION

- The majority of penile carcinomas are squamous cell carcinoma (SCC) histology
- Can be SCC in situ (erythroplasia of Queyrat, Bowen disease of the penis, bowenoid papulosis), low-grade noninvasive (eg, verrucous carcinoma), or invasive carcinoma
- Other rare types of penile cancer histologies include adeno- and adenosquamous carcinoma, basal cell carcinoma, melanoma, sarcomas, Kaposi sarcoma, neuroendocrine (small cell) undifferentiated carcinoma, sebaceous gland carcinoma, and rarely, metastases from other sites (prostate, bladder, colon, kidney)
- Inguinal and pelvic lymph nodes are common sites of metastases

EPIDEMIOLOGY

Incidence

- Rare in developed countries. Approximately 1,640 new cases annually in US with approximately 320 deaths in 2014.
- Hispanics are more commonly affected than whites.
- Circumcision is protective.
- Accounts for up to 10% of cancers in men in South America.

Prevalence

Accounts for 0.4–0.6% of cancers in men

RISK FACTORS

- Human papilloma virus (HPV) types 16, 18, 31, and 33 (associated with 45–80%)
- Presence of foreskin and/or phimosis
- Poor hygiene
- Sexually transmitted disease (STD)
- HIV infection
- Chronic inflammation
- Lichen sclerosis
- Smoking

Genetics

N/A

PATHOPHYSIOLOGY

- HPV-associated DNA and chromosomal changes
- Smegma that forms from desquamated epithelial cells is thought to be a primary instigating factor in penile cancer; good hygiene and circumcision limit smegma accumulation
- Penile SCC spreads by a reliable pattern: Superficial inguinal lymph nodes to deep inguinal lymph nodes to pelvic lymph nodes

ASSOCIATED CONDITIONS
- Balanitis xerotica obliterans (BXO)
- Bowen disease
- Chronic inflammation
- Erythroplasia of Queyrat
- Giant condylomata
- Leukoplakia
- Phimosis
- Premalignant lesions that predispose to the development of invasive SCC of the penis and penile cancer
- STIs

GENERAL PREVENTION
- Good penile hygiene
- Newborn circumcision more protective than circumcision later in life

DIAGNOSIS
HISTORY
- Induration, erythema, nodularity of prepuce, glans, and/or shaft
- Bleeding ulcer on glans and/or penile shaft
- Inguinal adenopathy
- Penile pain if lesion infected
- Patients often deny or ignore symptoms resulting in presentation at advanced stage
- New onset priapism with a mass suggests a metastatic corporal body lesion
- Constitutional symptoms may suggest metastatic disease

PHYSICAL EXAM
- Induration, erythema, nodularity of prepuce and/or glans
- Fungating mass emanating from glans or shaft
- Bleeding ulcer on glans
- Purulence suggests concomitant infection
- Inguinal adenopathy
  - Location, number, unilateral, bilateral, mobility or fixation

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum CBC, electrolytes (including calcium), and liver function studies
- Urinalysis, urine culture

Imaging
- US or MRI of penis for local tumor (T) staging
- CT/MRI of pelvis and inguinal regional to evaluate for lymphadenopathy and metastatic disease

Diagnostic Procedures/Surgery
- Biopsy; punch, excisional, or incision
- Shave biopsy will not give adequate local tumor (T) staging

Pathologic Findings

- Most malignancies involve the epithelial surface of the penis
- Subtypes of SCC
  - Usual, papillary, verrucous, warty, basaloid, sarcomatoid
- CIS (erythroplasia of Queyrat, Bowen disease of the penis, bowenoid papulosis)
- Verrucous carcinoma, warty carcinoma, Buschke–Löwenstein tumor, and giant condyloma are terms used to describe infrequently seen rare tumors that may invade locally but do not metastasize. Mostly considered to be benign, but malignant degeneration has been reported
- Grade:
  - Broder's classification used
    - Keratinization, nuclear pleomorphism, number of mitosis
  - SCC grade classification: Grade strong predictor for metastatic nodal involvement
    - Grade I: Well differentiated, no evidence of anaplasia
    - Grade II: Moderately differentiated (<50% anaplastic cells)
    - Grade III: Poorly differentiated (>50% anaplastic cells)
    - Grade IV: Undifferentiated
- Vascular invasion is associated with prognosis

DIFFERENTIAL DIAGNOSIS

- BXO
- Bowen disease (red, scaly patches on the keratinized skin of the penis typically penile shaft)
- Erythroplasia of Queyrat; shiny red patches on mucosal surfaces (glans and prepuce if uncircumcised)
- Bowenoid papulosis (multiple flat, warty lesion sometimes pigmented)
- Condyloma acuminatum
- Condyloma lata
- Extramammary Paget disease
- Giant condylomata
- Kaposi sarcoma
- Lichen sclerosis
- Psoriasis
- Seborrheic keratosis
- Ulcer from STI
- Balanitis of Zoon

TREATMENT

GENERAL MEASURES

- Treatment typically based on grade and stage of primary tumor (1)
- Palpable lymphadenopathy
  - Fine-needle aspiration (FNA)
  - 6-wk course of oral antibiotics followed by repeat physical exam

MEDICATION

First Line

- Tis/Ta lesions

- Topical: Imiquimod 5% cream applied for 5 d/wk for 4–6 wk or 5-FU 5% cream every other day for 4–6 wk

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Primary lesions
  - Tis/Ta lesions
    - Laser ablation: CO_2 or neodymium
    - Circumcision (preputial lesions)
    - Wide local excision, Mohs surgery, glansectomy, glans resurfacing
  - T1 grade 1–2
    - Mohs, wide local excision
    - External beam radiation therapy
    - Brachytherapy (with interstitial placement)
    - Laser ablation
  - T1 grade 3–4 or ≥T2
    - Partial penectomy (with intraoperative frozen section)
    - Traditionally 2-cm margin is required
    - Total penectomy with perineal urethrostomy
- Regional nodes (2)
  - Sentinel node biopsy
    - High false-negative rate (25%)
  - Nonpalpable nodes
    - High-risk T2 or G3 and intermediate-risk cancer with lymphovascular invasion—inguinal node dissection (ILND)
  - Unilateral palpable nodes <4 cm
    - FNA or ILND if high risk
    - 6 wk of oral antibiotics less recommended
  - Palpable nodes ≥4 cm
    - Standard or modified ILND
    - Possible preoperative EBRTchemotherapy
- Pelvic lymph nodes
  - Pelvic Lymph node dissection if >2 inguinal nodes positive on frozen section at the time of ILND

ADDITIONAL TREATMENT

Radiation Therapy

- External radiation to primary lesion or inguinal lymph nodes
- Typical doses are 50–60 Gy over 4–6 wk
- Interstitial brachytherapy for clinically indicated lesions

Additional Therapies

- Neoadjuvant chemotherapy
  - TIP: Ifosfamide, paclitaxel, cisplatin
- Adjuvant for high-risk disease

  - Bilateral inguinal nodal disease
  - Pelvic lymph node involvement
  - Extranodal extension
  - >4 cm nodes
- Metastatic disease
  - TIP
  - Clinical trial
  - Supportive/palliative care

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Depends on T-stage and nodal status
- Overall survival for men with node-negative disease is 80–90%.
- 20–30% of men with inguinal lymph node metastasis will have pelvic lymph node metastasis
  - Pelvic nodal metastasis have a 10% 5-yr survival
- When applicable, ILND associated with improved disease-specific survival

COMPLICATIONS

- Infections
- Erosion of lymphadenopathy into femoral vessels
- Partial penectomy and total penectomy
  - Urethral stenosis
  - Loss of erective function
- ILND
  - Infection (43%)
  - Seroma (24%)
  - Wound breakdown (16%)
  - Lymphedema
  - Vascular injury

FOLLOW-UP

Patient Monitoring

- Close inspection for local recurrence usually every 3 mo for 5 yr (frequency depends on grade and stage)
- Consider imaging for ambiguous findings on physical exam

CODES

ICD9

- 176.0 Kaposi's sarcoma, skin
- 187.4 Malignant neoplasm of penis, part unspecified
- 233.5 Carcinoma in situ of penis

ICD10

- C46.0 Kaposi's sarcoma of skin
- C60.9 Malignant neoplasm of penis, unspecified
- D07.4 Carcinoma in situ of penis

CLINICAL/SURGICAL PEARLS

- Grade and stage associated with prognosis FNA of palpable nodes is preferred over 6-wk course of oral antibiotics.

- Modified ILND is associated with improved morbidity.
- Bulky inguinal lymph node metastases should be managed by multimodal therapy consisting of neoadjuvant systemic chemotherapy followed by surgical resection (± radiotherapy).

PENIS, TRAUMA

Hunter Wessells, MD, FACS
Brad Figler, MD

BASICS

DESCRIPTION

Acute traumatic injury to the penis may be due to blunt trauma (penile fracture to the erect penis), penetrating injury (stab wound, firearm, improvised explosive device [IED], or amputation), degloving (MVC, power takeoff injury), burns, human and animal bites, or constriction with reduced blood flow

EPIDEMIOLOGY

Incidence

- Penetrating trauma to genitals is relatively rare in civilian setting
- Gunshot wounds and penetrating injuries make up 40–60% of battlefield urologic injuries during times of war; likely due to lack of protection to external genitalia
- In the battlefield, use of fragmentation devices (mines, IED) and high-velocity missiles cause a significantly greater percentage of genitourinary injuries to involve the penis and genitalia
- Penile fracture infrequently seen in US, with incidence of 1 in 175,000 hospital admissions
- Penile fractures are common in Iran where it is a social practice (Taghaandan)

Prevalence

N/A

RISK FACTORS

- Occupational (military, farming, heavy machinery)
- Bicycling is leading sport associated with injury to the external genitalia

Genetics

N/A

PATHOPHYSIOLOGY

- Transfer of kinetic energy to the penis is most devastating due to penetrating mechanisms
- Blunt injuries to the flaccid phallus are much less likely to cause any damage
- Penis is very resistant to injury in flaccid state; in erect state, bending injury can lead to rupture of tunica albuginea (“penile fracture”)
  – Typically results from impact with partner’s pubic symphysis or perineum
- Redundant blood supply to the penis (dorsal, cavernosal, and bulbourethral arteries and superficial skin vasculature) all protect from ischemic loss of the penis
- Penile strangulation
  – Constricts blood flow, leading to edema, ischemia, constricted micturition
  – Pediatric patients: Hair or string causes constriction
  – Adult patients: Penile constricting devices designed for sexual enhancement
- Pelvic fracture can lead to avulsion of the crura of the corpora cavernosa with subsequent dysfunction

- Associated injuries are common due to the proximity to other pelvic organs
- Degloving injuries: Loss of superficial penile tissue (skin and Dartos fascia)

ASSOCIATED CONDITIONS

- Injury to scrotum, testicle, urethra, or rectum may accompany penile trauma
- Pelvic fracture

GENERAL PREVENTION

- Military services are developing devices for ballistic protection of the external genitalia
- Protective equipment during contact sports
- Proper safety training for industrial machinery
- Proper instruction in patients prescribed penile constriction devices for the management of erectile dysfunction
- Cautious sexual intercourse

DIAGNOSIS

HISTORY

- Type of injury
- Magnitude of force transmitted
- Type of object in penetrating injury
- Determine species of animal in bite injuries
- In cases of amputation history of method of preservation of amputated portion if available
  - Method of penile preservation
  - Self-inflicted amputation may occur in psychotic states
- Timing, severity, progression of pain, swelling, discoloration of penis, scrotum, and genitalia
- Circumstances and timing of penile constriction device
- Intercourse-related trauma to the penis may be reported as a “pop” or “snap” associated with swelling and immediate penile detumescence
- Intercourse-related trauma with “pop,” swelling but no immediate penile detumescence is suspicious for rupture of superficial dorsal vein
- Associated abdominal pain, nausea, emesis

PHYSICAL EXAM

- Pattern of erythema, ecchymosis
- Assess for injuries of adjacent organs
- Blood at meatus concerning for urethral injury
- Size of laceration, if present
- Transilluminate any palpable scrotal mass
  - Hydrocele will transilluminate
  - Hematocele or tumor will not transilluminate
- Penile fracture:
  - Penile swelling, ecchymosis with possible palpable defect in corpora cavernosa
  - “Eggplant sign”: Hematoma deep to Buck’s fascia
- “Butterfly hematoma”: Hematoma deep to Colles’ fascia
- Penile strangulation:
  - Penile edema, ischemic changes, gangrene

– Suprapubic fullness secondary to urethral constriction
• Gunshot wounds: Search for associated injuries especially injured femoral vessels, urethral injury, or rectal injury.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

• Urinalysis
• Urine culture if infection suspected
• CBC
• For delayed presentation with abscess formation, culture abscess

Imaging

• Suspicion of urethral injury warrants evaluation with retrograde urethrography to evaluate for the presence of injury and injury location.
• Penile fracture:
– MRI or US useful if rupture of superficial dorsal vein suspected
– Cavernosography historically described
• Scrotal ultrasound or CT scan may be useful if suspicious for associated injuries

Diagnostic Procedures/Surgery

Cystoscopy: Used to assess for urethral injury

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

• Burn
• Constriction injury (band or other device placed around base of penis) can include medically approved devices
• Fournier gangrene
• Human or animal bite
• Laceration
• Penetrating injury
• Penile “fracture”
• Rupture of superficial dorsal vein
• Penile amputation

TREATMENT

GENERAL MEASURES

• Ensure the overall stability of the patient (1)
• Recognize and appropriately manage injuries to the external genitalia
• Maintain high index of suspicion for urethral injury and assess with retrograde urethrogram or cystoscopy
• Association for the Surgery of Trauma (AAST) organ injury scale classification (2):
– I: Cutaneous laceration/contusion
– II: Buck’s fascia (cavernosum) laceration without tissue loss
– III: Cutaneous avulsion; laceration through glans/meatus; cavernosal/urethral defect < 2

cm
  - IV: Partial penectomy; cavernosal or urethral defect >2 cm
  - V Total penectomy
- For burns see section on “Burns, External Genitalia, and Perineum”

MEDICATION

First Line

- Appropriate fluid resuscitation based on severity of injury
- Broad-spectrum antibiotic prophylaxis for all penetrating genital injuries
- See section on Bites to penis (animal and human) for appropriate antibiotic coverage
- Tetanus prophylaxis for all penetrating injuries

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Surgical exploration is required in almost all cases of penile injury (3 – 5)
  - Exploration typically performed through a circumferential skin incision at coronal margin
  - Deeper injuries require penoscrotal or perineal incisions
- Hemostasis is achieved by closure of corporal defects due to fracture, gunshot, or stab wound
- The urethra should be directly inspected for appropriate identification of any urethral injuries which need to be identified and repaired
- Glans injuries are repaired by debridement and reduction in the size of the glans while maintaining its overall configuration
- Primary skin closure is appropriate unless significant contamination of wound is noted
- Penile amputation
  - Preservation of the amputated phallus
  - “2-bag method” (penis wrapped in saline gauze in inner bag; ice in the outer bag)
  - Cold ischemia >24 hr is acceptable if it allows transfer to a specialized center for microvascular replantation
  - Even at normal temperatures, replantation 16 hr after injury has been successful
  - Technique for microvascular replantation:
    - Single-layer urethral repair over catheter
    - Tunica albuginea reanastomosis (5-0 PDS)
    - Dorsal vein and dorsal artery microvascular reanastomosis (to preserve skin perfusion and venous drainage; 0-0 nylon)
    - Dorsal nerve reanastomosis for sensation, 10-0 nylon
  - If amputated segment cannot be reattached:
    - Close corporal bodies with 4-0 PDS
    - Spatulate urethral meatus to tunica
    - Can gain penile length later by cutting suspensory ligament, defatting pubis, or considering reconstruction with free flap
- Penile fracture:
  - Circumcising incision via subcoronal approach with evacuation of hematoma
  - Close cavernosal injuries with absorbable suture (5-0 PDS)

  – Explore for urethral injuries and, if present, repair (5-0 PDS)
- Penile strangulation:
  – Incision of offending agent if possible (cut hair, string, bands, soft rings with scissors)
  – Solid constricting devices: Attempt removal with lubrication; distal penile compression with manual pressure may decrease tissue edema long enough to remove foreign body
  – Some devices may require ring cutters, operative drills, industrial drills, various saws; protect phallus with tongue depressors, malleable retractors
  – Suprapubic tube may be needed for bladder decompression
- Avulsions (degloving injury):
  – Exposed surface should be immediately covered with sterile saline-soaked gauze and area re-examined in 24 hr to assess extent of injury
  – Penile shaft can be covered with split-thickness skin graft
  – Scrotum can be covered with meshed split-thickness skin graft
- Gunshot wounds:
  – If wound contaminated, then conservatively débride and allow healing by secondary intention
  – If wound clean, tunical margins can be reapproximated with absorbable suture; urethral injuries should be identified and repaired
- Human bites:
  – Should not be closed; antibiotic therapy includes oral dicloxacillin or cephalexin

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Most penile injuries can be successfully repaired with low rate of erectile dysfunction when immediate reconstruction is performed.
- Delayed repair or nonoperative approach to penile injuries may lead to penile curvature and erectile dysfunction.
- Even after penile amputation, with successful replantation patients can have sensation with erectile function.

COMPLICATIONS

- Decreased sensation
- Impotence
- Penile curvature
- Skin loss (particularly with nonmicrovascular penile replantation)
- Urethral stricture

- Urethral stricture or fistula
- Wound infections

FOLLOW-UP

Patient Monitoring

- Patient monitoring is required for detection for complications.
- Traumatic injury may result in erectile dysfunction requiring additional therapy.

CODES

ICD9

- 878.0 Open wound of penis, without mention of complication
- 959.13 Fracture of corpus cavernosum penis
- 959.14 Other injury of external genitals

ICD10
- S31.20XA Unspecified open wound of penis, initial encounter
- S39.840A Fracture of corpus cavernosum penis, initial encounter
- S39.94XA Unspecified injury of external genitals, initial encounter

CLINICAL/SURGICAL PEARLS
- Penile injuries have high likelihood of associated injuries to the external and internal pelvic organs.
- Urethral injury must be excluded.
- With penile fracture there is 10–22% associated urethral injury; surgical repair is associated with lower rates of erectile dysfunction or curvature.
- Early surgical exploration and repair allows excellent preservation of function and cosmesis.
- Penile fracture characteristically causes ecchymosis, swelling, an associated popping or cracking sound during intercourse followed by immediate detumescence.

PEYRONIE DISEASE

Irvin H. Hirsch, MD

BASICS

DESCRIPTION

- An idiopathic, localized connective tissue disorder with increased collagen deposition in the tunica albuginea, resulting in a fibrous plaque that leads to pain and penile angulation (1)[C]
- Plaque (2)[C]:
  - Most commonly dorsal plaque on side of penis to which curvature directed
- Penile angulation may cause dyspareunia and even preclude sexual intercourse
- First described by French surgeon François Gigot de Peyronie
- Synonym(s): Acquired penile curvature, chronic inflammation of the tunica albuginea (CITA), penile induration, *Induratio penis plastica*

EPIDEMIOLOGY

Incidence

- Affects males 40–70 yr old, with 0.4–3.2% incidence (1)[C]
- 3–7% men 40–70 yr old have PD (3)[C]
- Mean age: 53

Prevalence

Estimated 388 in 100,000 men (1,2)[C]

RISK FACTORS

- Inherent tendency to produce abnormal fibrous tissue
- Erectile trauma or injury to the tunica albuginea of the penis may incite fibrotic reaction from repetitive microvascular injury and healing
- Intracorporal injection therapy and oral pharmacotherapy for ED not implicated as risk (2)[C]

Genetics

Association with Dupuytren contracture (in 9–39%) and HLA-B7 antigens (1)[C]

PATHOPHYSIOLOGY

- Idiopathic (1,2)[C]
- Origin of initial inflammatory process that leads to fibrosis, calcification, elastic fiber alterations, and plaque formation in tunica albuginea unknown, but likely predisposing genetic alteration with inciting trauma
- Acute phase:
  - Occurs in 1st 6–18 mo
  - Proliferation of fibroblasts, myofibroblasts, and collagen deposition
  - Pain with erections, slight penile curvature, and nodule formation
  - Medical therapy most effective in acute phase
- Chronic phase:

– Remodeling of connective tissue into a dense fibrotic plaque
– Stable plaque size, penile curvature possibly causing ED, erections less painful
• Natural history: Minority of patients (10%) will have spontaneous regression, yet most patients will not develop disease significant enough to require surgery

ASSOCIATED CONDITIONS
• ED: Occurs in 20% men with PD (1)[C]
– Comorbidities: Diabetes, hypertension, dyslipidemia, smoking, coronary disease
• PD is found in 10% men with ED
– Urethral stricture may coexist

GENERAL PREVENTION
Avoidance of penile trauma during intercourse

DIAGNOSIS
HISTORY
• Distress and depression resulting from Peyronie disease
• Duration and onset of symptoms, history of erectile trauma. Severe pain or snap or popping during intercourse
• Pain: With or without erection; during intercourse
• Penis: Induration; degree and direction of penile angulation; hourglass deformity; lateral indentation; shortening; sensory loss, partner's perception
• Erections: Quantify rigidity; sufficient for intercourse
• History of Dupuytren contractures or hand surgery for deformity

PHYSICAL EXAM
• Penile exam noting plaque size, tenderness and location
• Autophotography may be helpful in assessing degree of angulation
– Examine the palmar fascia for associated Dupuytren contracture

DIAGNOSTIC TESTS & INTERPRETATION
Lab
N/A

Imaging
No imaging necessary for diagnosis/medical therapy

Diagnostic Procedures/Surgery
• Preoperative assessment of stretched penile length and sensory threshold (Biothesiometry)
• Preoperative Doppler US with intracavernous vasoactive challenge: Assess plaque size, calcification, vascular hemodynamics of penis and erectile curvature
• Preoperative intracavernous injection of vasoactive agent and genital sexual stimulation with measurement of erectile curvature
• Photographic confirmation by the patient of degree of curvature is often helpful

Pathologic Findings
Excess collagen deposition and inflammatory infiltrate is found in the tunica albuginea

DIFFERENTIAL DIAGNOSIS

- Cancer: Primary or metastatic to corpora
- Chordee: Usually associated with hypospadias
- Kelami syndrome: Fibrosis of the corpus spongiosum that limits expansion of the ventral corpora cavernosa
- Penile fracture (hematoma)

TREATMENT

GENERAL MEASURES

- A small percent of men will undergo spontaneous remission.
- Surgery is not a common 1st-line option but ultimately offers definitive resolution of curvature and deformity.
- The lack of randomized, placebo-controlled trials makes evaluation of efficacy and comparison between any medical therapies for PD difficult.
- Patients most likely to respond to medical therapy: Young patients in acute phase. (1,2)[C]
- All medical therapies provide varying decrease in pain, curvature, or plaque size; complete resolution of curvature is uncommon.

MEDICATION

First Line

- Oral therapy (2):
  - No therapy has proven more or less effective than another
  - Vitamin E (tocopherol):
    - 800–1,000 U/d PO in divided doses
    - Antioxidant effects; may cause bleeding
  - Potassium aminobenzoate (Potaba):
    - 3 g PO q6h
    - May increase monoamine oxidase, decrease serotonin, or increase utilization of oxygen by tissues; Expensive, GI side effects
  - Colchicine:
    - 0.6 mg PO q8h
    - May decrease collagen synthesis and increase collagenase activity
  - Pentoxifylline:
    - Growth factor blocker and anti-inflammatory
    - 400 mg PO BID
  - Other reported oral therapy: Tamoxifen, acetyl-L-carnitine,
- Intralesional therapy (2):
  - Collagenase clostridium histolyticum (CCH (4)[C]:
    - Breaks down collagen, promotes remodeling
    - FDA approved for curvature deformity of the penis due to the presence of a plaque in PD. Restricted distribution through Risk Evaluation and Mitigation Strategy (REMS) due to the risks of serious adverse reactions, including penile fracture and other serious penile injury
    - A cycle consists of 2 CCH injection procedures and a penile modeling procedure
    - Induce a penile erection (eg, intracavernosal injection of 10–20 mcg of alprostadil)

- With the erection, identify and mark the target area in the Peyronie plaque
- The penis should be in a flaccid state before injecting CCH. Inject 0.58 mg CCH into the target plaque of a flaccid penis once on each of 2 days, 1–3 days apart
- Perform a manual penile modeling procedure 1–3 days after the 2nd injection of each treatment cycle. For each plaque causing the curvature deformity, up to 4 treatment cycles may be administered. Each treatment cycle may be repeated at approximately 6-wk intervals. If the curvature deformity is <15 degrees after the 1st, 2nd, or 3rd treatment cycle, or if further treatment is not indicated, then subsequent treatment cycles should not be administered
- 10,000 U in 0.25 cm^3 per injection

– No other intralesional therapy has proven more or less effective than another
– Verapamil (5)[C]:
- 12 injections (10 mg/10 mL) given once every 2–4 wk
- Calcium blockage inhibits extracellular transport of collagen; increases collagenase activity in vitro; must commit to full course
- Applicable for young patients in acute phase

– Interferon α2a or 2b (6)[C]:
- 5×10^6 U biweekly for 3–6 mo
- Inhibits fibroblast proliferation, diminishes collagen production, increases collagenase
- Applicable for young patients in acute phase
- Flu-like side effects

– Intralesional corticosteroids no longer recommended due to local side effects

Second Line
N/A

SURGERY/OTHER PROCEDURES
• Indications: Curvature or erectile dysfunction that precludes intercourse (2)[C]
• Patient must be in chronic phase with stable painless plaques
• Preoperative US with intracavernous vasoactive challenge is useful to evaluate vasculature and anatomy of penis, as described above
• Plication procedures:
– Candidates: Longer penis, mild, distal curvature, good erectile function
– Relative to corporal plaque, plication of opposite aspect of corpora cavernosa with a 12–24-point plication. A relaxing incision of plaque is rarely required
– Complications/side effects: Hematoma, stitch erosion/granuloma, penile shortening
• Plaque excision with grafting:
– Candidates: Shorter penis, proximal plaque, severe curvature, hourglass deformity, lateral indentation and good erectile function
– Plaque incised/excised and corporotomy defects grafted with small intestine submucosal graft (Surgisis, Cook Biotech)
– Complications: Loss of sensitivity, infection, hematoma, shortening, de novo venoocclusive erectile dysfunction
• Inflatable penile prosthesis placement:
– Candidates: Significant erectile dysfunction, severe curvature

- Modeling:
  - When prosthesis placement alone fails to straighten penis, manual modeling is recommended, with good outcomes
  - Forcible manual manipulation of penis ("modeling" over inflated prosthesis)
- Complications: Infection (1–3%), erosion (<5%), mechanical malfunction (5–10%), urethral injury

ADDITIONAL TREATMENT

Radiation Therapy

Mixed results reported; not recommended

Additional Therapies

Extracorporeal shockwave therapy: No good placebo-controlled studies to document efficacy; studies report decreased pain after ESWL therapy (2)

Complementary & Alternative Therapies

- Penile traction therapy may have utility when combined with other therapies
- Carnitine supplementation: Mixed results

ONGOING CARE

PROGNOSIS

See "Pathophysiology–Natural History"

COMPLICATIONS

- PD can impact quality of life and cause relationship difficulties
- Depression can be associated

FOLLOW-UP

Patient Monitoring

- Patients should be re-examined frequently to assess disease status and response to therapy.
- Recent studies suggest up to 48% of men with PD have clinically relevant signs of depression and should be considered for mental health screening. (7)

CODES

ICD9

- 607.84 Impotence of organic origin
- 607.85 Peyronie's disease
- 608.89 Other specified disorders of male genital organs

ICD10

- N48.6 Induration penis plastica
- N52.9 Male erectile dysfunction, unspecified
- N53.12 Painful ejaculation

CLINICAL/SURGICAL PEARLS

- Diagnosis of Peyronie disease is exclusively based on history and physical exam.
- Patients with mild curvature and no evidence of erectile dysfunction should be observed.
- New data suggests that CCH can significantly reduce the symptoms of Peyronie disease.
- The ideal candidate for CCH is having Peyronie disease for at least 12 mo, has stable disease, and a curvature of 30 degrees or greater.

PHEOCHROMOCYTOMA

Shaun G.S. Grewal, MD
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION

- Pheochromocytoma is a rare catecholamine-producing tumor arising chromaffin cells in the adrenal medulla
- Paragangliomas refer to lesions found in extra-adrenal sites arising from the sympathetic nervous system

ALERT
Hypertensive crisis and life-threatening complications can be seen with pheochromocytoma.

EPIDEMIOLOGY

Incidence

- 3–4 cases per million population yearly in US (1)
  - Average age in sporadic cases: 40–50 yr
  - Average age in hereditary cases: < 40 yr

Prevalence

- 0.005–0.1% of the general population
  - 01–0.2% of adult hypertensive patients
- > 50% of catecholamine-producing tumors undiagnosed until death

RISK FACTORS

- Familial tumors associated with MEN multiple endocrine neoplasia (MEN) syndromes:
  - MEN IIA (Sipple syndrome): Pheochromocytoma (50%), medullary carcinoma of the thyroid (50%), and parathyroid adenoma (25%):
  - MEN IIB (MEN III): Pheochromocytoma (50%), medullary carcinoma of the thyroid (100%), ganglioneuromatosis, multiple mucosal neuromas of eyelids, lips, tongue
- Neurofibromatosis Type I (von Recklinghausen syndrome): 1% has pheochromocytoma; 5% of patients with pheochromocytoma have neurofibromatosis.
- Von Hippel–Lindau disease (retinal cerebellar hemangioblastomatosis): 10% with pheochromocytoma

Genetics

- Germ-line mutations specific to each syndrome
- Syndromes are all autosomal dominant
  - Men IIA: Codon 634 of RET protein
  - Men IIB: Mutation in intracellular domain of RET protein
  - Von Hippel–Lindau: VHL tumor suppressor gene on chromosome 3p35
  - Von Recklinghausen syndrome: Neurofibromatosis type 1 gene
  - Familial nonsyndromic paraganglioma: Succinate dehydrogenase gene (1)

PATHOPHYSIOLOGY

- Tumors arise from chromaffin cells of neural crest origin in the sympathetic nervous system
- Rule of 10 (10% bilateral, 10% extra-adrenal, 10% familial, 10% malignant) no longer accurate:
  - 10% of sporadic tumors bilateral, 50% of familial tumors bilateral
  - Extra-adrenal up to 20%
  - Hereditary 20–30%
  - Malignant up to 5% in adrenal pheochromocytoma, 33% for extra-adrenal pheo
- Histologic determination of malignancy is not possible; diagnosed based on metastases
- Tumors contain enzymes necessary to convert tyrosine to catecholamines
- Clinical manifestations secondary to the release of these catecholamines, NE, and EPI
- Bladder pheochromocytomas account for $<1\%$ of bladder tumors and $<1\%$ of pheochromocytomas:
  - Can present with micturition syncope
  - Partial cystectomy is the treatment of choice. Transurethral excision is contraindicated because it may precipitate a hypertensive crisis

ASSOCIATED CONDITIONS

- MEN IIA
- MEN IIB
- Von Recklinghausen syndrome
- Von Hippel–Lindau disease

GENERAL PREVENTION

- No specific preventive measures exist.
- Screening of patients with familial pheochromocytomas allows earlier diagnosis and treatment.

DIAGNOSIS

HISTORY

- Most patients symptomatic
  - Paroxysmal HTN with severe headache, drenching, perspiration, and palpitations
  - Additional symptoms include nervousness, tremor, pallor, panic, pain in the chest and abdomen, nausea, fever, and flushing

PHYSICAL EXAM

- Hypertension: Most common sign
  - Sustained HTN: Children and MEN II
  - Paroxysmal HTNL dramatic attacks, 3–4 times a week
  - Sustained hypertension with superimposed paroxysms: 50% incidence
- Fine tremors, pallor, perspiration
- Palpable tumor (rare)
- Accelerated hypertensive retinopathy: Papilledema, exudate, A-V knicking
- Raynaud phenomenon
- Hyperhidrosis

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Plasma or urinary-fractionated metanephrines are the best screening tests:
  - Chromaffin cells metabolize NE to NMN and EPI to MN
  - Fractionated metanephrines refers to MN and NMN
  - Both plasma metanephrines and urine metanephrines are acceptable options; current recommendations do not recommend either test over the other
  - Plasma metanephrines have a high sensitivity (96–100%) but poor specificity, particularly in older patients (77–89%) (2)
- Urine test: 24-hr urine for NE, EPI, MN, NMN, and VMA:
  - VMA highly specific (95%) but not sensitive (64%)
  - If urinary values are >3 times normal, then proceed to localize the tumor
  - If urinary values are <3 times normal and suspicious, then repeat the test and proceed to pharmacologic testing
- Plasma metanephrine testing
  - No caffeine prior
  - No acetaminophen for 5 days prior
  - Rest supine for 20 min prior to draw
  - MN >96 pg/mL, NMN >130 pg/mL, or total metanephrines >200 abnormal (2)
- Pharmacologic testing:
  - Stimulation and suppression tests are generally not utilized
  - Provocative tests dangerous, with several reported deaths
- Clonidine suppression test:
  - Centrally acting α_2-agonist that suppresses sympathetic outflow
  - Normally results in decreased BP and lower levels of plasma catecholamines
  - Draw blood for NE/EPI before and 3 hr after administering clonidine (0.3 mg/70 kg)
  - Plasma catecholamines remain the same or elevated in patients with pheochromocytoma

Imaging

- Localization studies should be started only if clinical evidence for the tumor's existence is strong (hereditary predisposition or signs and symptoms with very high MN/NMN)
- CT or MRI for initial localization:
  - Neither CT nor MRI is recommended above the other
  - Pheochromocytoma characteristically hyperintense of T2-weighted images
  - Scan abdomen and pelvis 1st
  - If no tumor found, scan chest and neck
  - Metastases in long bones may be missed
  - Cannot reliably differentiate between types of adrenal tumors
- Iodine^{123}-labeled MIBG scintigraphy is more specific for localization of pheo:
  - Provides both anatomic and functional characterization of the tumor
  - Concentrated in sympathomedullary tissue through the catecholamine pump
  - Useful to evaluate for residual or multiple tumors, and MEN syndromes

Diagnostic Procedures/Surgery

ALERT

Biopsy of adrenal mass should not be performed until pheochromocytoma has been ruled out.

Pathologic Findings

- Sporadic tumors are solitary, well-circumscribed, and encapsulated.
- Malignant pheo cannot be differentiated from benign pheo by exam of primary tumor. Malignant pheo is defined by metastases.

DIFFERENTIAL DIAGNOSIS

- Essential HTN
- Renovascular disease
- Anxiety, tension states, psychoneurosis
- Hyperthyroidism
- Paroxysmal tachycardia
- Menopause
- Vasodilating headaches (migraine and cluster)
- Acute hypertensive encephalopathy
- Nephrologic diseases
- Cocaine, amphetamines

TREATMENT

GENERAL MEASURES

Surgical removal of the tumor is the only definitive method of treatment.

MEDICATION

First Line

- Appropriate antihypertensive drugs to manage HTN, control symptoms, and prepare for surgery
- α-Adrenergic blocking agents essential before surgery:
  - Phenoxybenzamine 0–40 mg BID or TID
  - Prazosin 1–10 mg BID
- β-Blocking agents contraindicated in the absence of established α-blockade:
  - Use only for concomitant cardiac arrhythmias or persistent tachycardia
  - Blockade of peripheral vasodilatory β-adrenergic receptors results in unopposed α-adrenergic stimulation with resultant hypertension
  - Can precipitate cardiomyopathy and pulmonary edema due to chronic catecholamine excess

Second Line

See “Additional Therapies”

SURGERY/OTHER PROCEDURES

- Preoperative adrenergic blockade is mandatory
- Volume expansion with high sodium diet (>5,000 mg/daily) recommended on day 2 or 3 of α-blockade due to catecholamine-induced volume contraction
- Laparoscopic surgical removal of the tumor is the preferred treatment for tumors <10 cm

(3):
  – Initial dissection aimed at early ligation and division of the adrenal vein before manipulation of the tumor
  – Malignant pheochromocytoma is slow growing
    ◦ Resection should be attempted
    ◦ Large masses can be debulked for palliation

ADDITIONAL TREATMENT

Radiation Therapy

An option for malignant pheochromocytoma

Additional Therapies

• Malignant pheochromocytoma
  – Iodine^{131}-MIBG radiation is the most effective treatment after surgery
  – Combination chemotherapy with cyclophosphamide, vincristine, and dacarbazine: 50–60% partial response
  – Local radiation or chronic blockade with metyrosine for symptomatic disease

Complementary & Alternative Therapies

No recommended complementary or alternative therapies exist.

ONGOING CARE

PROGNOSIS

• 10-yr survival for nonmalignant tumors: >80%
• 5-yr survival for malignant pheo: 34–60%:
  – Currently no cure for malignant pheo

COMPLICATIONS

• Retinopathy and nephropathy from persistent HTN
• Catecholamine-nduced cardiomyopathy
  – Cardiomyopathy reversible with α-blockade and β-methylparatyrosine
  – All patients should have preop cardiac evaluation including echocardiogram
• Cerebral vascular accident
• Hypertensive encephalopathy
• Renal insufficiency
• Hemorrhagic necrosis
• Dissecting aneurysm
• Ischemic enterocolitis
• Neurogenic pulmonary edema

FOLLOW-UP

Patient Monitoring

• Because of uncertainties about which tumors are malignant, measure urinary or plasma catecholamines 1–2 wk postoperatively and annually for 5 yr.
• BP should be monitored every month for the 1st 6 mo, then every 6 mo thereafter.
• 25% of patients have persistent HTN after surgery.

CODES

ICD9

227.0 Benign neoplasm of adrenal gland

ICD10

- D35.00 Benign neoplasm of unspecified adrenal gland
- D35.01 Benign neoplasm of right adrenal gland
- D35.02 Benign neoplasm of left adrenal gland

CLINICAL/SURGICAL PEARLS

- Hydration and adequate α-adrenergic blockade preop is mandatory.
- Laparoscopic adrenalectomy treatment of choice with early control and ligation of adrenal vein.

PHIMOSIS AND PARAPHIMOSIS

Michael A. Poch, MD
Philippe E. Spiess, MD

BASICS

DESCRIPTION

- Phimosis (preputial stenosis) is the inability to retract the foreskin.
- Can be seen in children and adults
  - Physiologic (congenital) phimosis: Foreskin (prepuce) is usually not retractile in a newborn. The majority can be retracted by 3–5 yr of age
  - Pathologic (acquired) phimosis: The prepuce cannot be retracted when previously possible or it has never been retractile and is associated with symptoms and/or complications
- Paraphimosis
  - The prepuce is retracted, left in position causing vascular engorgement of the glans preventing reduction.

EPIDEMIOLOGY

Incidence

- Phimosis
  - 10% nonretractile at age 3–5
  - <1% nonretractile at puberty
- Paraphimosis
  - 0.7% of uncircumcised boys

Prevalence

N/A

RISK FACTORS

- Poor hygiene
- Forced or traumatic retraction of foreskin
- Indwelling catheter
- Chronic balanitis
- Genital piercings

Genetics

N/A

PATHOPHYSIOLOGY

- Physiologic phimosis:
  - The foreskin is naturally adherent to the glans in infants.
  - Glandular secretions and keratin debris (smegma) and intermittent erections facilitates separation of preputial skin from glans
  - This is best simply observed; the newborn foreskin does not require manipulation or retraction.
- Pathologic phimosis:

  - Chronic irritation, often due to poor hygiene, leads to sclerosis of the preputial opening
    - Premature manipulation and trauma leads to scarring of the delicate prepuce.
    - Inadequate circumcision or postcircumcision care allows constriction of the circumcision line
- Paraphimosis
  - Retraction of the prepuce and leaving it in place behind the glans leads to vascular engorgement of the glans and subsequent inability to reduce the prepuce

ASSOCIATED CONDITIONS

- Penile cancer
- Balanitis (inflammation of the glans)
- Posthitis (inflammation of the prepuce)
- Balanoposthitis
- Balanitis xerotica obliterans (BXO)
- Diabetes mellitus

GENERAL PREVENTION

- Good hygiene
- Don’t prematurely manipulate the foreskin
- Circumcision

DIAGNOSIS

HISTORY

- Was foreskin previously retractile?
- Recent urethral manipulation (Foley catheter placement, cystoscopy)
- Circumcision status
- Dysuria and/or other voiding symptoms
- Penile discharge
- Cracking or bleeding from the foreskin
- Ballooning of the foreskin with voiding
- Postvoid dribbling
- Penile pain

PHYSICAL EXAM

- Evaluate for penile abnormalities such as hypospadias, chordee, webbed penis
- Local irritation and redness
- Appearance of foreskin:
  - Normal skin color
  - Erythema and inguinal adenopathy
  - Penile discharge
  - Circumferential white discoloration
  - Urethral meatus cannot be visualized
  - Crack in skin with attempted retraction
  - Severe scarring or BXO
  - Smegma (normal finding)
- Paraphimosis:

– Marked edema of inner prepuce distal to the constricting band
– Ulcerations if chronic
– Evaluate glans for ischemia/necrosis
– Glans tenderness
– Glans firm with flaccid penile shaft
– Rule out hair or foreign body in a circumcised male

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Usually not necessary unless symptoms of urinary tract infection (UTI) or sexually transmitted infection (STI) are present.

Imaging

Not usually performed

Diagnostic Procedures/Surgery

Physical exam is usually all that is necessary

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Phimosis:
  – Physiologic vs. pathologic
  – Trapped penis occurs when a dense cicatricial scar traps the penis under the prepubic or scrotal skin after neonatal circumcision.
  – BXO
- Paraphimosis:
  – Penile edema
  – Postcircumcision cicatrix
  – Hair/thread tourniquet:
    ○ Hair or thread wraps around a child's penis and causes penile edema or strangulation
- Balanitis

TREATMENT

GENERAL MEASURES

- In the elderly male undergoing bladder catheterization, failure to replace the foreskin to its normal reduced position may result in paraphimosis (1,2).
- Paraphimosis
  – Manual reduction should be attempted 1st prior to medication or surgical procedure
  – 1st attempt manual compression for 5 min to reduce edema and reposition foreskin
  – Manual reduction technique:
    ○ Place thumbs on the glans while stabilizing the foreskin in between the 2nd and 3rd fingers.
    ○ Apply pressure on the thumbs while attempting to pull the foreskin over the glans
- Physiologic phimosis:
  – Observation and reassurance

MEDICATION

First Line

- Physiologic phimosis:
  - Topical steroids (0.05% betamethasone) may allow atraumatic retraction (3)
  - Parents should be taught to never force back the foreskin but gradually retract it over time.
- Pathologic phimosis
  - Topical steroid
  - Aggressive retraction can cause worsening of preputial scarring
- Paraphimosis:
  - Immediate manual reduction should be attempted
  - Pain medication (eg, morphine, Demerol) or local anesthesia (lidocaine without epinephrine, infiltration, or penile block) may be necessary

Second Line

- Paraphimosis
  - Hyaluronidase injection
  - If manual reduction fails, a dorsal slit or incision of constricting band is indicated
  - Recurrent paraphimosis may need definitive circumcision to prevent recurrence.

SURGERY/OTHER PROCEDURES

- Phimosis:
  - Preputioplasty (dorsal slit with transverse closure) for patients wanting to maintain foreskin
  - Circumcision is curative; should be generally avoided in children unless for indications such as recurrent UTI, vesicoureteral reflux, or superficial infections
  - Circumcision is contraindicated in newborns with penile deformities (hypospadias, chordee, webbed penis, etc.) as foreskin may be needed for possible reconstructive surgery
- Paraphimosis
  - Dorsal or ventral slit urgently treats narrowing and preserves the foreskin
  - Immediate circumcision is occasionally necessary

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

- Paraphimosis
  - Compression wraps
  - Topical osmotic agents

ONGOING CARE

PROGNOSIS

- 95% of physiologic phimosis resolves by puberty, with the majority retractile by the age of 5

- Circumcision is curative.

COMPLICATIONS

- Complications of phimosis:
  - UTI
  - Postvoid dribbling
  - Chronic inflammation with recurrent balanitis or balanoposthitis
  - Calculi or pearls from smegma
  - Penile carcinoma (rarely)
- Complications of paraphimosis
  - Glans necrosis
- Complications of circumcision:
  - Hemorrhage
  - Persistent adhesions
  - Skin bridges
  - Inadequate skin removal
  - Insufficient skin removal
  - Inclusion cyst
  - Cicatrix/concealed penis
  - Meatal stenosis

FOLLOW-UP

Patient Monitoring

- Proper hygiene of uncircumcised males
- Foreskin reduction after procedures

Patient Resources

N/A

CODES

ICD9

- 605 Redundant prepuce and phimosis
- 607.1 Balanoposthitis

ICD10

- N47.1 Phimosis
- N47.2 Paraphimosis
- N48.1 Balanitis

CLINICAL/SURGICAL PEARLS

- In most cases physiologic phimosis will resolve.
- Aggressive retraction of phimosis can cause preputial scarring.
- Manual reduction of paraphimosis should be attempted 1st prior to surgical intervention.

PNEUMATURIA (GAS IN URINE)

Michael Perrotti, MD

BASICS

DESCRIPTION

Passage of gas in the urine

EPIDEMIOLOGY

Incidence

This is a rare disorder.

RISK FACTORS

- Diverticular disease
- Other disease of the colon
- Crohn disease
- Advanced age
- Diabetes

PATHOPHYSIOLOGY

- Most commonly there is an abnormal connection between the enteric and urinary system secondary to inflammation
- Much less common in gas-producing bacterial urinary tract infection (UTI) (*Escherichia coli*, *Klebsiella pneumoniae*) seen most frequently in elderly diabetic females

ASSOCIATED CONDITIONS

- Diverticulitis of sigmoid colon
- Colon cancer
- Crohn disease
- Diabetes
- Iatrogenic (radical prostatectomy, radiation)

GENERAL PREVENTION

- Colon health
- Prompt treatment of UTI

DIAGNOSIS

HISTORY

- Pneumaturia
- Dysuria
- Irritative urinary symptoms
- Fecaluria

PHYSICAL EXAM

- Depends upon etiology
- May have no significant findings if acute diverticular abscess has resolved

- In emphysematous cystitis there is frequently fever and abdominal tenderness

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine analysis
- Urine culture
- Complete blood count
- Comprehensive metabolic profile

Imaging

- Computerized tomography scan identifies air or orally administered contrast in the bladder, colonic and bladder wall thickening, abscess (1)[A]
- Barium enema (definitive: 25%; suggestive: 100%)

Diagnostic Procedures/Surgery

- Colonoscopy may directly visualize the fistula, and is essential to inspect the remainder of the colon
- Cystoscopy may visualize the actual fistula, or identify suggestive localized inflammation and edema

Pathologic Findings

- Diverticular disease with abscess
- Colon malignancy
- Crohn disease
- Bladder malignancy
- Radiation or surgical induced fistula
- UTI

DIFFERENTIAL DIAGNOSIS

- Emphysematous cystitis
- Emphysematous pyelonephritis
- Urethral rectal fistula
- Vesical enteric fistula

TREATMENT

GENERAL MEASURES

- Antibiotic therapy
- Percutaneous drainage of gas and purulent material
- Relief of urinary obstruction

MEDICATION

First Line

- Parenteral antibiotic therapy for all patients with gas-producing UTI [A]
  - Ampicillin sulbactam 1.5 g IV q6h
  - Ticarcillin clavulanate 3.1 g IV q6h
  - Piperacillin tazobactam 3.375 g IV q6h
  - Meropenem 500 mg IV q8h

- Imipenem 500 mg IV q6h
- Doripenem 500 mg IV q8h

• Antibiotic therapy for acute diverticulitis
- Ciprofloxacin 500 mg PO BID with metronidazole 500 mg PO TID [A]
- Amoxicillin clavulanate 875 mg/125 mg PO BID
- Ampicillin sulbactam 3 g IV q6h
- Piperacillin tazobactam 3.375 g IV q6h
- Ticarcillin clavulanate 3.1 g IV q6h
- Ceftriaxone 1 g IV q24h with metronidazole 500 mg IV q8h

SURGERY/OTHER PROCEDURES
• Emphysematous UTI
- Percutaneous management of purulent material and gas
- Percutaneous nephrostomy placement for emphysematous pyelonephritis
- Emergent nephrectomy is associated with very high mortality

• Enterovesical fistula
- Enterovesical fistulae typically do not close spontaneously
- The portion of bowel responsible for the fistula is excised in a 1-stage procedure with resection and primary anastomosis
- Ureteral stent placement may be performed preoperatively to allow identification of the ureter intraoperatively
- Resection of the bladder is rarely necessary
- A small defect in the bladder can be managed with suture repair, indwelling Foley catheter, and closed suction drain in the pelvis

ONGOING CARE
PROGNOSIS
• Gas-producing UTI (2)[A]
- Parenteral antibiotic therapy is successful in the majority of patients with gas limited to bladder
- Patients with gas in the upper urinary tract are at increased risk of mortality and require percutaneous drainage with parenteral antibiotics
- Gas in the perinephric space and pararenal tissues are at increased risk of mortality

• Diverticular abscess and enteric vesical fistula
- Patients have an excellent prognosis after elective resection of the disease bowel segment
- In many cases this can be performed laparoscopically (3)[B]

COMPLICATIONS
• Patients with inflammatory disorders such as Crohn may have complex and recurrent fistulae
• Patients with fistulae following radiation therapy may have impaired healing and experience recurrence

FOLLOW-UP
Patient Monitoring

- Management of associated illness
- Prompt treatment of disease flare

Patient Resources
NA

- Fistula, Enterovesical
- Inflammatory Bowel Disease (Ulcerative Colitis and Crohn disease), Urologic Considerations
- Pneumaturia (Gas in Urine) Image
- Urinary Tract Infection (UTI), Adult Female
- Urinary Tract Infection (UTI), Adult Male

CODES

ICD9
- 596.1 Intestinovesical fistula
- 599.0 Urinary tract infection, site not specified
- 599.84 Other specified disorders of urethra

ICD10
- N32.1 Vesicointestinal fistula
- N39.0 Urinary tract infection, site not specified
- R39.89 Other symptoms and signs involving the genitourinary system

CLINICAL/SURGICAL PEARLS
- Pneumaturia is the distinct sensation by the patient of passage of air from the urinary tract.
- Pneumaturia should be considered secondary to an enteric vesical fistula until proven otherwise.
- The CT scan finding of air in the bladder is abnormal and of high diagnostic value in the evaluation of the patient with suspected pneumaturia and is likely to reveal associated pathology.
- The most common cause of pneumaturia is diverticular disease.

POLYCYSTIC KIDNEY DISEASE, AUTOSOMAL DOMINANT

Megan T. Bing, MD
James A. Brown, MD, FACS

BASICS

DESCRIPTION

- Inherited disease characterized by bilateral development of renal and extrarenal cysts with variable progression to ESRD, requiring either dialysis or transplantation
- Autosomal dominant polycystic kidney disease (ADPKD) is the most common form of genetic kidney disease leading to chronic kidney disease

EPIDEMIOLOGY

Incidence

- 1–2:1,000 live births
  - Occurs worldwide and in all races
  - 4.4% of patients with renal replacement therapy have ADPKD

Prevalence

- 1:400 to 1:1,000
  - Renal volume increases 5.27% per year as cysts grow

RISK FACTORS

- Having a family member with ADPKD
  - Inherited in autosomal dominant fashion
  - Ages range from infant to elder

Genetics

- 1:1,000 carry mutant gene
- Autosomal dominant with 100% penetrance
- Genetically heterogenous: 2 genes
  - PKD1 (16p13.3) (Type 1 ADPKD)
    - Accounts for 85% of cases
    - More severe disease
    - Encodes polycystin-1 (PC1)
  - PKD2 (4q21) (Type 2 ADPKD)
    - Accounts for 15%
    - Less severe disease
    - Encodes polycystin-2 (PC2)

PATHOPHYSIOLOGY

- Loss of PC1 or PC2 results in inability of tubular cells to maintain polarity, increased rate of proliferation and apoptosis, increased cellular secretion and remodeling of extracellular matrix (ECM)
  - Epithelial cell growth
  - ECM remodeling

– Na^+-K^+ ATPase found apically which leads to abnormal flow of fluid

ASSOCIATED CONDITIONS
- Abdominal wall hernia
- Cardiac valvular abnormalities
- Colon diverticula
- Hepatic cysts from 29–73%
- Splenic and pancreatics in a small percentage
- Intracranial aneurysms
  – Only screen if patient has previous rupture
  – Saccular "berry" aneurysm of cerebral arteries in 3–13%
- Pancreatic cysts
- Polycystic liver disease

GENERAL PREVENTION
Genetic and prenatal counseling

DIAGNOSIS

HISTORY
- Typical presentation is 30- to 50-yr-old patient with HTN, hematuria, flank pain
- Calculi may also be present
- Family history: 3 generations with cystic renal disease

PHYSICAL EXAM
- HTN, hypertensive retinopathy
- Heart murmur
- Enlarged kidneys on abdominal exam

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum Cr may be elevated
- BUN may be elevated
- Hematuria on UA
  – In up to 50% and often the initial presenting symptom

Imaging
- Imaging is the main diagnostic tool
- Plain abdominal radiographs: Limited in early-stage disease; later may indicate displacement of organs with or without calcifications
- US
  – With unknown genotype, the presence of 3 or more (unilateral or bilateral) renal cysts establishes the diagnosis in 15–39 yo, 2 or more cysts in each kidney is sufficient if aged 40–59 yr, and 4 or more cysts in each kidney is required for individuals ≥ 60 yr
  – Conversely, < 2 renal cysts in at-risk individuals aged ≥ 40 yr are sufficient to exclude the disease
- CT and MRI methods have greater sensitivity compared to US for detecting cysts < 1 cm and in evaluating individual cysts for hemorrhage or malignancy

- Hemorrhagic renal cysts are fairly common
- On MRI uncomplicated cysts resemble simple cortical cysts
  - Homogeneous low signal intensity on T1 and high signal intensity on T2

• Echocardiography
- Evaluate for mitral prolapse

Diagnostic Procedures/Surgery

Cytogenetic analysis: May be needed when FH or imaging is equivocal

Pathologic Findings

• Gross pathology
- Bilaterally enlarged kidneys with multiple colored and fluid-filled cysts

• Histopathology
- Multicystic renal dysplasia in cortex and medulla
- Sclerosis

DIFFERENTIAL DIAGNOSIS

• Patients >10 yr old
- Simple cysts
  - Simple cyst not common <30 yr of age
  - >4 simple cysts in each kidney is rare
- Localized renal cystic disease
- Medullary sponge kidney
- Bilateral parapelvic cysts
- Autosomal recessive polycystic kidney disease (ARPKD)
- Tuberous sclerosis complex
- Von Hippel–Lindau disease
- Medullary cystic disease
- Orofaciodigital syndrome type I
- Autosomal dominant polycystic liver disease: Liver lesions predominate but also have renal cysts; genetic testing may be needed to differentiate

• Patients <10 yr of age
- Contiguous PKD1–TSC2 deletion syndrome
- ARPKD
- Meckel–Gruber syndrome

TREATMENT

GENERAL MEASURES

• Increase fluid intake
• Coordinated care with nephrology
• Protein-restricted diet is controversial
• Neurosurgery consult if intracranial aneurysm is present (1)

MEDICATION

First Line

• Hypertension:

  - Angiotensin-converting enzyme (ACE) inhibitors (ie, captopril, enalapril, lisinopril) or
  - Angiotensin II receptor blockers (ARBs) such as telmisartan, losartan, irbesartan, and candesartan
- Hyperlipidemia: Statin

Second Line
- Somatostatin (2)
- Inhibitors of mTOR

SURGERY/OTHER PROCEDURES
- Renal replacement therapy (2,4)
  - Renal transplantation
  - Hemodialysis/peritoneal dialysis
- Percutaneous cyst aspiration
  - < 200 mL
  - Sclerosing agent should be used
- Cyst decortication—typically for pain with large dominant cysts(s)
  - 95–100% success rate for relieving pain
  - Initial improvement in lowering HTN, but not sustained
- Nephrectomy
  - Disabling symptoms due to massively enlarged kidneys
  - Worsening or development of ventral (abdominal wall) hernias
  - Nephrectomy may be considered before renal transplant
    - Suspected malignancy
    - Recurrent infection
    - Extension of the polycystic kidney into the potential pelvic surgical transplant location

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies
- Infection: Lipid soluble antibiotic (sulfamethoxazole and trimethoprim or ciprofloxacin)
- Chronic pain: Avoid NSAIDs
- A small, randomized, placebo-controlled trial found that intramuscular octreotide slowed progression of renal cystic disease

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS
- Renal function usually normal until the 4th decade of life
- Disease diagnosed in utero carries a poor prognosis
- Patients on RRT carry the same or better prognosis than non-ADPKD patients on RRT
- Risk factors for progression:
  - Genetic factors (PKD1 vs. PKD2)

  – Hypertension
  – Early onset of symptoms including proteinuria and hematuria
  – Male gender
  – Increased kidney size (kidney size is greater with PKD1 mutations)
  – Increased left ventricular mass index
  – Dipstick detectable proteinuria
  – Low birth weight
  – Decreased renal blood flow
  – Increased urinary sodium excretion
  – Increased LDL cholesterol
  – Increased plasma copeptin (surrogate marker for vasopressin)
- With more advanced renal disease, ACE inhibitors and ARBs can cause hyperkalemia or worsen renal failure. Monitoring of serum chemistries is essential
- When screening family members with a family history of ADPKD data suggests that individuals >40 yr with a family history but without renal cysts are unlikely to develop ADPKD

COMPLICATIONS

- Cerebral hemorrhage
- Chronic kidney disease
- Renal cell carcinoma risk is not elevated; but when present is often bilateral and multicentric
  – Often present with fever
- Proteinuria
- Chronic pain
  – Nephrolithiasis in 25% of patients
- Pyelonephritis
- Cyst rupture
- Rarely portal HTN, cholangiocarcinoma

FOLLOW-UP

Patient Monitoring

- Follow BUN and Cr
- Prenatal testing for ADPKD is clinically available if the mutation has been identified in an affected family member or if linkage has been established in the family

Patient Resources

- www.pkdcure.org
- www.pkdinternational.org

CODES

ICD9

• 585.9 Chronic kidney disease, unspecified
• 753.13 Polycystic kidney, autosomal dominant

ICD10

• N18.9 Chronic kidney disease, unspecified
• Q61.2 Polycystic kidney, adult type

CLINICAL/SURGICAL PEARLS

• Lipid soluble antibiotics are needed for treatment of renal cyst infection.
• Abdominal pain and flank pain is common and may be due to infection, nephrolithiasis, or cyst hemorrhage.
• Cyst decortication is useful for large painful cysts.
• Patients with a personal or family history of cranial bleed need surveillance by neurosurgery.
• Acute cyst rupture usually best treated with pain control and observation.

POLYCYSTIC KIDNEY DISEASE, AUTOSOMAL RECESSIVE

Kymora Scotland, MD, PhD
T. Ernesto Figueroa, MD, FAAP, FACS

BASICS

DESCRIPTION

- A group of inherited disorders involving cystic dilatation of the renal collecting ducts and varying degrees of biliary dysgenesis and periportal fibrosis
- Formerly known as infantile polycystic kidney disease
- An overlap in the spectrum of renal and liver involvement precludes use of the Blyth and Orkenden classification (perinatal, neonatal, infantile, and juvenile subtypes)
- Best grouped as polycystic disease of newborn and young infant, polycystic disease of childhood, and congenital hepatic fibrosis

EPIDEMIOLOGY

Incidence

- Most common inherited cystic renal disease in infancy and childhood
- Incidence: 1–2 in 10,000 live births
- Males = females
- Severely affected neonates usually die hours after birth; overall survival is much improved if they live beyond the neonatal period

Prevalence

- Commonly discovered in perinatal period; can present early in childhood or adolescence
- Survival: For patients living to 1 mo: 86% alive at 1 yr, 67% alive at 15 yr

RISK FACTORS

- Definite risk factor: Heterozygous parents
- The cause of ARPKD remains poorly understood
- Genetic and/or epigenetic factors may promote aberrant epithelial hyperplasia that causes cystic expansion of the collecting ducts and fluid accumulation
- Less is known about hepatobiliary changes; however, epithelial hyperplasia may have role

Genetics

- Associated with mutations of the PKHD1 gene (1 – 3)
- Autosomal recessive, heterozygotes unaffected, gene locus at chromosome 6p21
- Gene located at 6p21 produces a protein called fibrocystin which has been identified at the renal collecting ducts and the hepatic bile duct; possible involvement in renal cilia function
- Multiple allelism is likely responsible for variable phenotypic presentation
- Offspring of heterozygotes: 25% risk of disease, 50% carriers

PATHOPHYSIOLOGY

- Clinical course (renal):
  - Severely affected neonates commonly die of pulmonary complications hours after birth
  - Patients surviving the neonatal period have a better prognosis; they can have some renal

maturation
  – Progressive renal cyst enlargement, fibrosis, and renal insufficiency
  – Eventually, most develop renal failure
  – Later presentation: Less severe renal component
• Clinical course (hepatobiliary):
  – Development of hepatosplenomegaly, portal HTN, extrahepatic bile duct dilation, gall bladder enlargement, occasional choledochal cyst formation, and hepatic dysfunction
  – Liver failure ultimately develops later in childhood

ASSOCIATED CONDITIONS
• Ehlers–Danlos syndrome
• Potter syndrome

GENERAL PREVENTION
Genetic counseling for families with proven ARPKD (linkage studies with polymorphic DNA markers)

DIAGNOSIS
HISTORY
• Age of the patient:
  – Other cystic renal disorders rarely present in the pediatric population:
    ○ Younger, more respiratory and renal issues;
    ○ Older, more hepatobiliary issues
  – ~1/3 are diagnosed before age 1; 1/3 between ages 1 and 20 yr; and 1/3 beyond 20 yr
• Prenatal care
  – Characteristic changes on prenatal US after week 30, abnormal uterine growth measurements, maternal α-fetoprotein levels, amniocentesis results, history of stillbirth
• Birth history:
  – Difficult delivery suggests possible flank or abdominal mass
• Family history:
  – Normal parents with a normal renal US suggests recessive disease
• Medical history:
  – For older patient, may suggest evolution of disease
• Present illness:
  – Polydipsia, polyuria, fatigue, unexplained fever, hematuria, pyuria, edema, difficult feeding, recent GI bleed or vague GI symptoms

PHYSICAL EXAM
• HTN, respiratory rate, temperature
• General appearance:
  – Potter phenotype, pallor
• Palpable kidneys: Hepatosplenomegaly
• Extremities: Joint contractures, edema

DIAGNOSTIC TESTS & INTERPRETATION
Lab

- Electrolytes, blood chemistry, urine analysis, urine culture
- CBC (exclude anemia, hypersplenism)
- Coagulation profile
- Liver function tests (usually normal)
- High maternal α-fetoprotein (associated with ARPKD), high amniotic fluid release (possible correlation)

Imaging

- Renal ultrasound is best initial test (4):
  - Prenatal: Enlarged kidneys, oligohydramnios, normal liver, no bladder filling (more reliable after 30-wk gestation)
  - Infancy: Enlarged reniform kidneys, cortical echogenicity
  - Older children: Macrocysts (< 2-cm diameter), decreased size, medullary echogenicity, hepatosplenomegaly
  - Loss of corticomedullary differentiation: The kidneys typically have a homogeneous appearance
- CT may be used in confusing cases: More sensitive to inhomogeneity of cysts

Diagnostic Procedures/Surgery

- Renal biopsy
- Liver biopsy

Pathologic Findings

- Renal
  - Bilateral enlarged kidneys with reniform shape
  - Pinpoint opalescent dots on capsule (cortical collecting duct cysts)
  - Cut surface with sponge-like quality due to linear distention of nephrons in radial pattern
  - Normal pelvicaliceal system and renal vessels
  - In neonates, kidneys at least 10% of body weight
  - Microscopic pathology: Fusiform cysts (< 2 mm + diameter) lined by low columnar or cuboidal epithelium
  - No normal parenchyma
- Hepatobiliary
  - All children with ARPKD have lesions in the periportal areas of the liver
  - Can have hepatosplenomegaly at presentation; frequently normal
  - Elongated, hyperplastic biliary ducts with ectasia
  - Periportal fibrosis with normal hepatocellular histology

DIFFERENTIAL DIAGNOSIS

- Autosomal dominant polycystic kidney disease (ADPKD)
- Bardet–Biedl syndrome
- Caroli disease
- Chondrodysplasia syndrome
- Congenital hypernephronia nephromegaly with tubular dysgenesis
- Glutaric aciduria type II
- Ivemark syndrome
- Jeune syndrome

- Juvenile nephronophthisis
- Meckel–Gruber syndrome
- Renal dysplasia
- Trisomy 9 and 13
- Zellweger syndrome

TREATMENT

GENERAL MEASURES

- No specific therapy for ARPKD. Treatments are supportive
- Pulmonary issues 1st priority initially; survival better with advances in perinatology
- Goals: Delay progression to renal failure, liver failure, and portal HTN
- Avoid nephrotoxic mediations
- Social support and respite care

MEDICATION

First Line

- Thiazides to help urine-concentrating defect
- Treatment of renal osteodystrophy with vitamin D and phosphate binders
- Recombinant human erythropoietin
- Growth hormone treatment

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Preemptive bilateral nephrectomy and peritoneal dialysis catheter (significant pulmonary distress)
- Unilateral nephrectomy (improve feedings, help with breathing)
- Gastrostomy tube placement (improve feedings)
- Splenorenal shunt or portocaval shunt procedures (portal HTN)
- Renal transplantation (ESRD)
- Liver transplantation (hepatic failure)
- Progressive liver fibrosis with portal hypertension may require combined liver and kidney transplantation

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Adequate hydration
- Correct acid–base and electrolyte abnormalities
- Aggressive HTN control
- Peritoneal dialysis
- Enteral feedings
- Advanced pulmonary support as required

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS

- Prenatal: Abnormal prenatal US (oligohydramnios, enlarged reniform kidneys, absent urine in bladder, seen after 30-wk gestation) (5)
- Neonates: If present at birth, the usual clinical course is death. Patients have feeding intolerance, respiratory distress
- Infants: Palpable flank masses, abdominal mass, respiratory distress, HTN, polydipsia, polyuria, edema, feeding intolerance, Potter phenotype, nonspecific GI complaints, failure to thrive, growth retardation, infection
- Older children: Palpable flank mass, abdominal mass, Potter phenotype, GI bleed, hematuria, pyuria, polydipsia, polyuria, HTN, nonspecific GI complaints, edema, growth retardation, fatigue, infection. Will eventually develop renal failure and HTN
- All patients with ARPKD have liver involvement. Those with severe ARPKD have mild congenital hepatic fibrosis and those with severe congenital hepatic fibrosis have milder ARPKD

COMPLICATIONS

- Renal: Renal failure (concentrating defect with polydipsia and polyuria), HTN, anemia, occasional metabolic acidosis, hyponatremia, osteodystrophy, growth failure, UTI
- Hepatobiliary: Hepatosplenomegaly, bleeding esophageal varices, portal thrombosis, hypersplenism, choledochal cysts, bacterial cholangitis
- Pulmonary: Respiratory failure, pulmonary hypoplasia, pneumothorax, atelectasis, poor diaphragmatic excursion
- GI: Feeding intolerance, failure to thrive

FOLLOW-UP

Patient Monitoring

- Progressive renal failure in most patients requiring ongoing renal assessments
- Blood pressure
- Liver functions and ultrasound at least annually
- Overall assessment of growth and nutritional status
- Parental counselling is critical as there is a 1 in 4 chance of another child having the disease

- 753.14 Polycystic kidney, autosomal recessive
- 777.8 Other specified perinatal disorders of digestive system

ICD10

- P78.89 Other specified perinatal digestive system disorders
- Q44.5 Other congenital malformations of bile ducts
- Q61.19 Other polycystic kidney, infantile type

CLINICAL/SURGICAL PEARLS

- Renal and liver involvement is typical.
- Often fatal if present at birth.
- Treatments are supportive; no specific therapy.

POLYHYDRAMNIOS/OLIGOHYDRAMNIOS

Bruce J. Schlomer, MD
Laurence S. Baskin, MD, FACS, FAAP

BASICS

DESCRIPTION

- Oligohydramnios is defined as an abnormally low amniotic fluid (AF) volume:
  - Associated with increased fet al morbidity and mortality
- Polyhydramnios is defined as an abnormally high AF volume:
  - Up to 20% of neonates will have a congenital anomaly
  - Associated with increase in aneuploidy, congenital malformations, preterm delivery, and perinatal death
- These conditions are diagnosed using prenatal US with strict criterion described below

EPIDEMIOLOGY

Incidence

- Oligohydramnios in 3–5% of pregnancies (1)
- Polyhydramnios in 1–3% of pregnancies (1)
- Usually discovered in 2nd trimester with 40% normal by term

Prevalence

N/A

RISK FACTORS

- Oligohydramnios:
  - Rupture of membranes
  - Some medications (eg, NSAIDs)
  - Maternal HTN
  - Maternal autoimmune disorders
- Polyhydramnios:
  - Maternal diabetes
  - Drug abuse

Genetics

Several genetic syndromes are associated with oligohydramnios or polyhydramnios

PATHOPHYSIOLOGY

- After 22–23 wk, most of AF is fet al urine
- Late in gestation AF averages ~700–800 mL
- Oligo- and polyhydramnios are due to an imbalance in the production and removal of amniotic fluid
- Production of amniotic fluid (2)
  - 600–1,200 mL/d fet al urine
  - 60–100 mL/kg/d tracheal secretions
- Removal of amniotic fluid (2)

- 200–1,500 mL/d fet al swallowing
- 200–500 mL/d removed across fet al placenta into fet al blood stream (intramembranous pathway)

• Oligohydramnios causes
- PROMs
  - Iatrogenic: Amniocentesis
  - Spontaneous/idiopathic
- Decreased fet al urine production
  - Prerenal: Placental insufficiency, umbilical cord compression, fet al demise, maternal hypotension or severe dehydration, chronic maternal HTN, autoimmune disorders, drugs (NSAIDs, ACE inhibitors)
  - Intrarenal: Renal dysplasia, renal agenesis
  - Obstructive: Posterior urethral valves (PUVs), prune belly syndrome, urethral atresia, bilateral ureteropelvic junction obstruction (UPJO), bilateral ureteral obstruction, bilateral ectopic ureters

• Effects of oligohydramnios
- Pulmonary hypoplasia: Correlated with fet al outcome and main cause of fet al death
- Intrauterine growth restriction
- Potter facies with severe oligohydramnios
- Better outcome if presents in 3rd trimester vs. 2nd trimester (3)
- Better outcome if cause is PROM vs. congenital anomaly (3)

• Causes of polyhydramnios
- Idiopathic: ~60%
  - Better outcomes
- Maternal causes: ~15%
  - Maternal diabetes
  - Infections: Syphilis, rubella, MV, toxoplasmosis, parvovirus, Rh isoimmunization
  - Drug abuse: Polyhydramnios in ~25–30% of drug-addicted women. Leads to decreased neurologic function of fetus and decreased swallowing
- Fet al causes:
  - Reduced fet al swallowing: Maternal drug use, fet al neurologic anomalies, aneuploidy
  - GI anomalies: T-E fistula, choanal atresia, facial cleft, esophageal atresia, imperforate anus
  - Cardiac failure with diuresis
  - Karyotype anomalies

ASSOCIATED CONDITIONS

• Oligohydramnios:
- Rupture of membranes
- Placental insufficiency
- Chronic maternal HTN
- Postdate gestation
- Multicystic dysplastic kidney or prune-belly syndrome
- Severe cardiac disease
- Pulmonary hypoplasia, limb abnormalities

  - Potter syndrome:
    - Characteristic appearance usually due to bilateral renal agenesis, obstructive uropathy, renal hypoplasia, autosomal recessive polycystic kidney disease
    - Less severe form referred to as Potter sequence
- Polyhydramnios
  - Anencephaly
  - Neural tube defects
  - GI obstruction (esophageal atresia, duodenal atresia)
  - Multiple gestation
  - Nonimmune hydrops fet alis
  - Maternal diabetes

GENERAL PREVENTION

- Oligohydramnios
  - Avoid known medications (NSAIDs, etc.)
  - Avoid unneeded amniocentesis
  - Avoid maternal dehydration
- Polyhydramnios
  - Control of maternal diabetes
  - Prevention of infections transmittable from mother to fetus
  - Avoid drug abuse

DIAGNOSIS

HISTORY

- Polyhydramnios:
  - Increased maternal weight
  - Maternal drug use
  - Maternal infectious exposure
- Oligohydramnios:
  - Poor weight gain
  - Medication history

PHYSICAL EXAM

- Polyhydramnios: Increased maternal fundal height
- Oligohydramnios: Decreased maternal fundal height
- Enlarged newborn urinary bladder due to obstruction
- Potters facies:
  - Characteristic of bilateral renal agenesis and other severe renal malformations
  - Ocular hypertelorism, low-set ears, receding chin, flattening of the nose

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Polyhydramnios:
  - Maternal testing for glucose, autoantibodies, TORCH screen, parvovirus, fet al karyotype
- Oligohydramnios:
  - General: Fet al karyotype, pulmonary maturity, maternal autoantibodies (lupus,

anticardiolipin, antinuclear)
  – Renal: Fet al urinary electrolytes
  – Better outcome associated with Na <100 mmol/L, Cl <90 mmol/L, and osm <210 mmol/L
  – Serial measurements may have better prognostic value
  – May also measure β2-microglobulin, α-microglobulin, and retinal-binding protein

Imaging

- US measurements of AF volumes are very operator-dependent and very variable (4)
- No perfect means to determine actual volume, but several surrogate markers are used:
  – Maximum vertical pocket: Polyhydramnios >8 cm, oligohydramnios <1 cm
  – AFI: Sum of largest volumes from each of 4 placental quadrants:
    ○ Oligohydramnios: <5 cm, polyhydramnios >25 cm
- Fet al MRI increasingly used for better anatomic detail

Diagnostic Procedures/Surgery

- Polyhydramnios
  – Remove excess fluid
- Oligohydramnios:
  – Amnioinfusion: Especially for premature PROM

Pathologic Findings

- Depends on cause (see pathophysiology)
- Renal dysplasia common finding in oligohydramnios

DIFFERENTIAL DIAGNOSIS

- Oligohydramnios
  – Premature rupture of membranes (PROM)
    ○ Iatrogenic: Amniocentesis
    ○ Spontaneous/idiopathic
  – Decreased fet al urine production
    ○ Prerenal: Placental insufficiency, umbilical cord compression, fet al demise, maternal hypotension or severe dehydration, chronic maternal HTN, autoimmune disorders, drugs (NSAIDs, ACE inhibitors)
    ○ Intrarenal: Renal dysplasia, renal agenesis
    ○ Obstructive: PUVs, prune belly syndrome, urethral atresia, bilateral UPJO, bilateral ureteral obstruction, bilateral ectopic ureters
  – Prolonged gestation can lead to oligohydramnios late in the pregnancy
- Polyhydramnios
  – Idiopathic: ~60%
    ○ Better outcomes
  – Maternal causes: ~15%
    ○ Maternal diabetes
    ○ Infections: Syphilis, rubella, MV, toxoplasmosis, parvovirus, Rh isoimmunization
    ○ Drug abuse: Polyhydramnios in ~25–30% of drug-addicted women. Leads to decreased neurologic function of fetus and decreased swallowing
    ○ Placental chorioangioma or arteriovenous fistula

– Fet al causes:
  - Reduced fet al swallowing: Maternal drug use, anencephaly, neural tube defects, muscular dystrophy syndromes, aneuploidy
  - GI anomalies: T-E fistula, choanal atresia, facial cleft, esophageal atresia, imperforate anus, gastroschisis, duodenal atresia/stenosis, diaphragmatic hernia
  - Cardiac failure: Congestive heart failure, severe anemia
  - Karyotype anomalies: Trisomy 21, etc.
  - Hydrops fet alis: Rh disease, severe anemia, infections in mother (eg, parvovirus, CMV), twin–twin transfusion syndrome, maternal hyperparathyroidism, disorders of glycosylation
  - Other: Sacrococcygeal teratoma, skelet al dysplasias, thoracic/mediastinal masses

TREATMENT

GENERAL MEASURES

- Polyhydramnios:
  – US every 3–4 wk
  – Follow pregnancy to 38 wk
  – Monitor for uterine hemorrhage
- Oligohydramnios:
  – US every 3–4 wk for fet al viability and BPP
  – Consider early delivery with steroids for pulmonary development
  – Newborn needs intensive care and urologic assessment

MEDICATION

First Line

- Maternal indomethacin has been used in cases of polyhydramnios
- Surfactant for the neonate with severe oligohydramnios and pulmonary hypoplasia

Second Line

None

SURGERY/OTHER PROCEDURES

In utero vesicoamniotic shunt in select cases of oligohydramnios due to bladder outlet obstruction

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Amnioinfusion of isotonic sodium chloride solution in the 2nd trimester may benefit some patients with oligohydramnios

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Polyhydramnios:
  - If idiopathic, the prognosis is usually good
- Oligohydramnios:
  - With renal agenesis, mortality rate is 100%
  - Fet al outcomes correlated to degree of pulmonary hypoplasia
  - Mild forms of obstructive uropathy may cause renal insufficiency
  - Better prognosis with presentation in 3rd vs. 2nd trimester (3)
  - Better prognosis with PROM as cause vs. congenital anomalies (3)

COMPLICATIONS

- Polyhydramnios can cause increased preterm labor
- Oligohydramnios can cause fet al distress before or during labor and severe respiratory distress and pneumothorax due to pulmonary hypoplasia

FOLLOW-UP

Patient Monitoring

Close monitoring by prenatal sonography

See Also (Topic, Algorithm, Media)

- Polyhydramnios/Oligohydramnios Image
- Posterior Urethral Valves
- Potter Syndrome/Potter Facies

CODES

ICD9

- 657.00 Polyhydramnios, unspecified as to episode of care or not applicable
- 658.00 Oligohydramnios, unspecified as to episode of care or not applicable
- 761.2 Oligohydramnios affecting fetus or newborn

ICD10

- O40.9XX0 Polyhydramnios, unspecified trimester, not applicable or unspecified
- O41.00X0 Oligohydramnios, unspecified trimester, not applicable or unspecified
- P01.2 Newborn (suspected to be) affected by oligohydramnios

CLINICAL/SURGICAL PEARLS

- If anmiotic fluid (AF) levels are normal, the fetus is very likely to have adequate urine production even with bilateral hydronephrosis.
- In utero intervention with vesicoamniotic shunt is controversial.
- Idiopathic polyhydramnios has good outcomes.

POLYOMA VIRUS (BK, JC), UROLOGIC CONSIDERATIONS

Nathan Roberts, MD
Patrick J. Shenot, MD, FACS

BASICS

DESCRIPTION

- JC and BK viruses are 2 of 10 different human polyoma viruses
  - Small DNA viruses in the papovaridae family
  - JC and BK viruses named after 1st patients the viruses were isolated from in 1971
  - These viruses typically manifest clinical sequelae only in immunocompromised hosts
  - BK virus has a tropism for genitourinary epithelium
    - Clinical manifestations: Hemorrhagic cystitis (HC), ureteral stenosis, nephropathy, and rare GU-associated malignancies

EPIDEMIOLOGY

Incidence

N/A

Prevalence

- BK virus has an 82–99% seroprevalence in adults of the United States, Italy, and Australia
  - 50% @ 2 yr of age; 90% @ 10 yr of age
- JC virus has a 39–81% seroprevalence in same regions
  - Clinically manifest only in immunocompromised subjects
- Ureteral stenosis due to BK virus infection among allograft recipients is approximately 3%
- BK-induced nephropathy:1–10% of transplants
- Hemorrhagic cystitis
  - Reported to cause hemorrhagic cystitis in 5.7–7.7% of bone marrow transplant recipients

RISK FACTORS

- Immunocompromised host
  - Degree of immunosupression
  - Transplant recipients
    - Solid organ (especially kidney), stem cell transplants
  - HIV/AIDS
    - Predilection toward hemorrhagic cystitis
  - Autoimmune disorders requiring immunosuppression
  - Multiple sclerosis
  - Systemic lupus erythematous

Genetics

- Small nonenveloped icosahedral particles of 40–45-nm diameter, with a nonenveloped, circular double-stranded DNA genome
- Polyoma viruses encode 6 proteins
- 3 structural capsid proteins

- 3 noncapsid regulatory proteins
  - Large and small T antigen (cell immortalization and latency), and agnoprotein (assembly of viral particles)
    - Proteins interact with cellular target proteins and impair pathways involved with cell cycle and DNA repair

PATHOPHYSIOLOGY

- Route of transmission is unknown but seems to occur early in life most likely oral/respiratory exposure (1,2)
- Hypothesized that subclinical infection leads to viremia that seeds the kidneys
- Pathology is postulated to occur from reactivation of latent infection and not reinfection
- Immuno-reconstitution inflammatory syndrome
  - Dominant inflammatory response to abundant polyoma virus antigen followed by brisk recovery of the cellular immune response
    - Seen in BKV-associated hemorrhagic cystitis after allogeneic stem cell transplantation
- Cytopathic-inflammatory polyomavirus pathology
  - High-level virus replication and a significant inflammatory response due to cytopathic lysis, necrosis, with infiltration of granulocytes and lymphocytes. Dominant inflammatory response to abundant polyoma virus antigen followed by brisk recovery of the cellular immune response
    - Seen in BKV-associated nephropathy in kidney allografts
- Oncogenic polyoma virus pathology
  - Early viral gene expression activating host cells but without sufficient late gene expression to cause rapid host cell lysis
    - Seen in rare BKV-associated urothelial and renal tubular cancers
    - There is conflicting evidence of BK virus involvement in these tumors
- Hemorrhagic cystitis
  - Another theory suggests 3 phases
    - Conditioning regimen for stem cell transplant damages the bladder mucosa providing environment for virus replication
    - Viral replication unchecked in the absence of functional immunity
    - Further damage to the bladder mucosa with immune reconstitution and return of anti-BK immunity

ASSOCIATED CONDITIONS

- BK virus has a tropism for genitourinary epithelium
  - Kidney transplant recipients
    - Tubulointerstitial nephritis
    - Ureteral stenosis
  - Stem cell transplant recipients
    - Hemorrhagic cystitis
- JC virus has a tropism for neural tissue
  - Causes progressive multifocal leukoencephalopathy
  - Not as common, but JC can also be related to genitourinary manifestations like BK virus and vice versa

GENERAL PREVENTION
- Route of transmission is unknown so difficult to prevent
- Competent immune system will prevent clinical sequelae

DIAGNOSIS
HISTORY
- Hemorrhagic cystitis
  - From pink colored urine to clot retention
  - Pt can also have bladder pain
  - Pt may have LUTS
- BK virus nephropathy
  - Typically occurs 10–13 mo after transplant
  - Often asymptomatic
  - May have hematuria
  - May have decreased urine output
- Transplanted ureteral stenosis (3)
  - Typically occurs 2–4 mo after transplant
  - Often asymptomatic
  - May have decreased urine output

PHYSICAL EXAM
- Hemorrhagic cystitis
  - May present with palpable bladder if in clot retention
- BK virus nephropathy
  - No significant findings on exam
- Ureteral stenosis of kidney transplant
  - May have no significant findings
  - Pelvic mass bulge from transplant hydronephrosis
  - Due to denervation of transplanted kidney, patient may not present with pain

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Virus culture mostly used in research setting
  - Takes weeks to months to grow
- Urine cytology
  - Detects virus shedding
  - Characteristic finding is an enlarged nucleus with a single large basophilic intranuclear inclusion (“decoy cells”)
    - Does not distinguish between various types of polyoma virus
- Urine quantitative PCR
  - Correlates with BK virus associated nephropathy
  - Can be positive in normal controls, elderly patients and HIV-infected patients without clinical manifestations
    - Difficult to assess clinical significance
- Plasma quantitative PCR

- Hemorrhagic cystitis
  - Urinalysis positive for blood/RBCs
- BK virus nephropathy
  - Elevated creatinine
  - Urinalysis
    - Pyuria, hematuria, and/or cellular casts of renal tubular cells and inflammatory cells
- Transplanted ureteral stenosis
  - Can have elevated creatinine

Imaging

- Hemorrhagic cystitis
  - Ultrasound or CT can show bladder thickening and possibly clot if present
- Transplanted ureteral stenosis
  - Hydronephrosis seen on renal ultrasound, CT or MRI
  - Obstruction seen on renogram

Diagnostic Procedures/Surgery

- Hemorrhagic cystitis
  - Cystoscopy can show evidence of clots/active bleeding
- BK virus Nephropathy
  - Renal Biopsy
    - Most often percutaneous approach
    - Histopathology results listed below
    - Can also use Immunohistologic or in situ hybridization evidence of virally infected cells to make diagnosis
    - Strongly positive using an SV40 immunohistochemical stain

Pathologic Findings

- BK Virus nephropathy
  - Usually infects tubular epithelial cells
  - Anisonucleosis, hyperchrmoasia, and chromatin clumping of infected cells
  - Interstitial mononuclear or polymorphonuclear cell infiltrates in the areas of tubular damage
  - Tubular injury with tubular cell apoptosis
  - Intranuclear basophilic viral inclusions with a surrounding halo
  - Not pathognomonic for BK virus
    - CMV has cytoplasmic inclusion
    - HHSV has both intranuclear and cytoplasmic inclusions

DIFFERENTIAL DIAGNOSIS

- Hemorrhagic cystitis
  - Medication related (high-dose cyclophosphamide)
    - Often occurs within 72 hr
  - Adenovirus related
  - Radiation induced
  - Infectious source
  - Trauma

    - Possibly from urethral catheter placement
  - BPH related
- BK virus nephropathy
  - Cellular rejection
- Transplanted ureteral stenosis
  - Surgical technique; ischemia of distal ureter
  - Typically occurs in 7–10 days

TREATMENT

GENERAL MEASURES

- Reduction of immunosuppression if possible (4)
  - Often most effective strategy

MEDICATION

First Line

- Quinolone antibiotic (ciprofloxacin, etc.)
  - Suggested for prophylactic role
- Intravenous immunoglobulin
  - Can be used in hypogammaglobulinemic patients
  - Leflunomide: Antiviral activity
- Hemorrhagic cystitis
  - Increased hydration
  - Catheter placement with clot evacuation
  - Continuous bladder irrigation (CBI)

Second Line

- Intravesical vs. intravenous cidofovir
  - Nucleotide analog of cytosine
  - Active against DNA viruses
  - Anecdotal evidence for use against polyoma viruses
  - Highly nephrotoxic
- Hemorrhagic cystitis
  - Cystoscopic fulguration (electro cautery or laser)
  - Conjugated estrogens: Act by stabilization of microvasculature
  - Intravesical instillation of alum
    - An astringent precipitates protein over bleeding surface
    - 1% Alum solution in CBI
    - Can be used in presence of VUR
  - Intravesical instillation of silver nitrate
    - Chemical coagulation and eschar at bleeding sites
    - 0.5–1% instilled for 10–20 min
    - VUR may lead to renal failure due to precipitation and obstruction of upper tracts
  - E-aminocaproic acid
    - Inhibits fibrinolysis preventing activation of plasminogen to plasmin
    - Given orally, parenterally, or intravesically

- Patients can form hard clots that are difficult to flush from the bladder
- Intravesical instillation of prostaglandin
  - PGE2: May encourage platelet aggregation and induce vasoconstriction
  - PGE2: 0.75 mg in 200 mL of normal saline and left indwelling
  - May cause bladder spasms
- Intravesical instillation of formalin (40% formaldehyde)
  - Hydrolyzes proteins and coagulates tissue on superficial level
  - Painful and needs to be done with general anesthesia
  - Should not be done with VUR. Can fibrose the ureters, cause obstruction, hydronephrosis and also papillary necrosis
  - Can result in small contracted bladder

SURGERY/OTHER PROCEDURES

- Hemorrhagic cystitis (5)
  - Cystectomy if refractory life-threatening cases
  - Selective embolization
    - Vesical or internal iliac artery
- BK virus Nephropathy
  - Kidney re-transplant
    - Limited information for outcomes
    - Recommend patients have absence of BK replication prior to re-transplantation
- Transplant ureteral stenosis
  - Decompression of the transplanted kidney
    - Percutaneous nephrostomy tube
    - Ureteral stent placement
  - Surgical excision of stenotic segment

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Hemorrhagic cystitis
  - Hyperbaric oxygen: Promotes healing of hypoxic tissues and aid in angiogenesis

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Hemorrhagic cystitis: Dramatic in presentation but usually resolves spontaneously within 2 wk with supportive care
- BK virus nephropathy: Graft failure in 15–50%

FOLLOW-UP

Patient Monitoring

BK virus nephropathy: After transplant some recommend periodic monitoring for viremia

Patient Resources

CODES

ICD9

- 079.89 Other specified viral infection
- 593.3 Stricture or kinking of ureter
- 595.9 Cystitis, unspecified

ICD10

- B33.8 Other specified viral diseases
- N13.5 Crossing vessel and stricture of ureter w/o hydronephrosis
- N30.90 Cystitis, unspecified without hematuria

CLINICAL/SURGICAL PEARLS

Polyoma virus will only have clinical sequelae in immunocompromised patients.

POSTERIOR URETHRAL VALVES

Steve J. Hodges, MD
Anthony Atala, MD

BASICS

DESCRIPTION

- Congenital obstruction of the posterior urethra that can cause variable degrees of dysfunction of all segments of the urinary tract, including the bladder, ureters, and kidneys
- Urinary tract dysfunction can include
  - Functional bladder disorders including increased bladder wall thickness, fibrosis, and hyperactivity that may progress to myopathy and poor function
  - The bladder changes may affect the upper tracts by transmitting high pressure to the renal parenchyma, causing deterioration of renal function
  - Patients may have congenital renal dysplasia

EPIDEMIOLOGY

Incidence/Prevalence

- Congenital disorder
- 1 in 4,000–7,500 live male births
- No racial predilection
- Most common cause of lower urinary tract obstruction in males
- Accounts for 16.8% of children with ESRD
- The prevalence is 1:2,400–1:8,000

RISK FACTORS

- No racial predilection
- Only affects males

Genetics

- This disorder is usually sporadic.
- Cases have been seen in twins and siblings suggesting a poorly understood genetic component.

PATHOPHYSIOLOGY

- Congenital mucosal membrane (fold/valve) in the posterior urethra
- Hugh H. Young Classification (1919)
  - Type I: Folds that extend distally from the verumontanum to divide into 2 membranes that attach to the anterolateral wall, most common variant (95%)
  - Type II: Folds extending from the verumontanum to the bladder neck superiorly, not clinically obstructing, only of historical significance
  - Type III: Transverse membrane in the posterior urethra, has a central aperture, located distal to verumontanum, rare (5%)

ASSOCIATED CONDITIONS

- Renal dysplasia

- Bladder diverticula
- Ascites
- Urine extravasation
- Vesicoureteral reflux
- Azotemia
- Hydroureteronephrosis
- VURD

GENERAL PREVENTION

No known methods of prevention

ALERT

High risk of end-stage renal disease in urethral valve patients.

DIAGNOSIS

HISTORY

- Antenatally
  - No specific questions in the maternal or family history aid in diagnosis
  - Prenatal US usually demonstrates bilateral hydroureteronephrosis and thick walled bladder in males (+/– oligohydramnios)
- Postnatally
  - Nature or strength of urinary stream is a poor predictor of valves, or severity of obstruction
  - Failure to thrive may be seen
  - Straining or grunting while voiding
  - May present with symptoms indicative of sepsis in a neonate due to UTI
  - Delayed presentation considered in any male with a chronic history of day and night urinary incontinence, UTI, and/or chronic polydipsia/polyuria

PHYSICAL EXAM

- Common neonatal presentation
  - General: Palpably enlarged bladder, possible abdominal distention due to ascites
  - Pulmonary: Pulmonary distress syndrome, pulmonary hypoplasia
  - Musculoskelet al: Potter's facies, limb deformities (in patients with severe oligohydramnios)
  - Genitalia: Bulge in the penoscrotal junction during urination is a sign of anterior urethral valves

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis and urine culture
- Serum electrolytes, BUN, and Cr
- Cr has early prognostic value
- Elevated Cr in 1st few days of life (after the 1st 5 days) indicates renal dysfunction and poor prognosis
- Cr >1 at the end of the 1st yr of life predictive of eventual ESRD

Imaging

- Renal/Bladder US
  - Assesses for hydroureteronephrosis, corticomedullary differentiation, echogenicity, signs of renal dysplasia, thickness of renal parenchyma and bladder wall
- VCUG
  - Diagnoses urethral valves, detects vesicoureteral reflux and bladder trabeculation diverticula
  - Shows dilated posterior urethra, trabeculated bladder, vesicoureteral reflux, perhaps ascites
  - Hydroureteronephrosis
- DMSA Renogram
  - After 6 wk of life may be used to evaluate renal function, dysplasia

Diagnostic Procedures/Surgery

- Prenatal
  - Antenatal US: Bilateral hydroureteronephrosis (+/– oligohydramnios, the earlier the diagnosis the worse the prognosis)
- Postnatal
  - US, VCUG, laboratory evaluation
  - Cystoscopy: Confirms the diagnosis of PUV by direct visualization of the obstructing valves

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Anterior urethral valves
- Bilateral UPJ obstruction
- Congenital urethral polyp
- Congenital urethral stricture (Cobb collar)
- Megacystis-megaureter
- Megalourethra
- Multicystic dysplastic kidney
- Neuropathic bladder
- Nonneurogenic neurogenic bladder (Hinman syndrome)
- Plicae colliculi
  - Normal anatomic finding
  - Represents this folds of mucosa that extend from the verumontanum in the prostatic urethra to the membranous urethra
- Prune belly syndrome
- Urethral atresia

TREATMENT

GENERAL MEASURES

- Place urethral catheter immediately after birth to drain the bladder (1)

- Measure daily weights, I/O's (fluid balance), routine vital signs
- Fluid and electrolytes as needed

MEDICATION

First Line

- Prophylactic antibiotics
  - < 2 mo age: Amoxicillin 20 mg/kg/d
  - ≥ 2 mo of age: Trimethoprim-sulfamethoxazole 2 mg/kg/d (concentrates in urine); nitrofurantoin is an alternative
- Anticholinergics for bladder dysfunction

SURGERY/OTHER PROCEDURES

- Transurethral ablation of urethral valves is possible in 80% of neonates
- Cutaneous vesicostomy in children too small for endoscopy (usually < 2,000 g)
- Bilateral cutaneous pyelostomies of mostly historical significance, but may be used in extreme cases

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Prenatal surgical intervention remains investigational
  - Associated with risk of fet al and maternal morbidity; long-term renal benefit proven
- In children with persistent worsening renal function and hydroureteronephrosis following valve ablation may require upper tract diversion if possible to salvage renal function
- Persistent vesicoureteral reflux following valve ablation may require vesicoureteral reflux
- Low compliance fibrotic bladder or myogenic failure (valve bladder) may require enterocystoplasty and/or clean intermittent catheterization (CIC)

Complementary & Alternative Therapies

- Behavioral measures
  - Timed voiding, constipation therapy
- Biofeedback
  - Physical therapy to relax external sphincter
- Diet
  - Avoid bladder irritant, caffeine
- Perineal hygiene
  - Voiding positioning

ONGOING CARE

PROGNOSIS

- Depends on the amount of congenital renal dysplasia, vesicoureteral reflux, bladder function
- Incontinence and later ESRD correlated
- Cr > 1 mg/dL at the end of the 1st yr of life correlated with ESRD
- Long-term bladder dysfunction may progress to overactive/fibrotic bladder or possibly eventual myogenic failure

• Sexual function and fertility seems to be normal in most patients

COMPLICATIONS
• End-stage renal disease
• Voiding dysfunction
• Incontinence

FOLLOW-UP
Patient Monitoring
• Follow-up for observation of progress of renal function, as high risk of ESRD
  – Usual late or difficulty toilet training; treat voiding dysfunction, incontinence
  – Patients need serial electrolyte and Cr measurements, US evaluations, VCUG following ablation to monitor success of surgery, resolution of reflux
  – UDS for bladder function
  – Prophylactic antibiotics as needed

  Incontinence, Pediatric
• Hydronephrosis/Hydroureteronephrosis, (Dilated Ureter/Renal Pelvis), Prenatal
• Posterior Urethral Valves Image
• Urethra, Obstruction
• VURD Syndrome

CODES

ICD9
• 599.69 Urinary obstruction, not elsewhere classified
• 753.8 Other specified anomalies of bladder and urethra
• 753.15 Renal dysplasia

ICD10
• N13.8 Other obstructive and reflux uropathy

- Q61.4 Renal dysplasia
- Q64.79 Other congenital malformations of bladder and urethra

CLINICAL/SURGICAL PEARLS

- No benefit to early delivery as children with pulmonary hypoplasia also have severe renal dysplasia.
- Select centers offer prenatal interventions with dubious efficacy.
- Poor kidney function at presentation is associated with worse renal prognosis.

POSTOBSTRUCTIVE DIURESIS

John J. Pahira, MD

BASICS

DESCRIPTION

- Postobstructive diuresis is excessive polyuria resulting from the relief of bilateral ureteral obstruction or obstruction of a solitary kidney, bladder outlet obstruction
- More likely with chronic rather than acute obstruction
- After relief of obstruction, >3 L over 24 hr or >200 mL/hr over each of 2 consecutive hr is diagnostic of polyuria found with POD

EPIDEMIOLOGY

Incidence

- Peak incidence in men 70–90, due to increased obstruction from BPH and prostatic cancer
- Peak incidence in women 40–60, due to obstruction from pregnancy and carcinoma of the cervix and uterus

Prevalence

N/A

RISK FACTORS

- Urinary tract obstruction is caused by a number of processes, grouped into extrinsic and intrinsic causes:
  - Intrinsic: Nephrolithiasis, blood clot, ureteral strictures, urethral strictures, neurogenic bladder, anticholinergic agents, levodopa
  - Extrinsic: BPH, prostate cancer, tubo-ovarian abscess, ovarian tumor or cyst, endometriosis, arterial aneurysms, tumors of the kidney, ureter, bladder, and urethra and their corresponding lymphatic and metastatic spread
- Obstructed patients most likely to have POD
  - Chronic obstruction
  - Edema
  - Congestive heart failure
  - HTN
  - Weight gain
  - Azotemia
  - Uremic encephalopathy

Genetics

N/A

PATHOPHYSIOLOGY

- Retained urea, sodium, and water; impaired sodium reabsorption and concentrating ability of the renal tubule; and circulating hormones all contribute:
  - Increased sodium, potassium, and magnesium losses result in increased water excretion
  - Accumulated urea acts as an osmotic agent, bringing fluid with it as it is cleared, thereby

increasing diuresis
  – Impaired concentrating ability of the renal tubule leads to continuing fluid losses and hypovolemia
- ANP, which causes vasodilation, natriuresis, and diuresis, has been found to be elevated in patients with ureteral obstruction (1)[B]

ASSOCIATED CONDITIONS
- BPH
- Malignancies (bladder or prostate cancer)
- Urolithiasis
- Any cause of chronic obstruction with hydronephrosis

GENERAL PREVENTION
Treat and repair the cause of obstruction to prevent recurrence

DIAGNOSIS
HISTORY
- Obstruction:
  – Asymptomatic but often associated with flank pain radiating to groin and/or ipsilateral thigh, nausea, vomiting, fevers, chills
  – Resulting uremia may cause mental status changes, tremors, and GI bleeding (2)[A]
- Diuresis:
  – Increase in urine output out of proportion to fluid intake, usually >200 mL/hr
- Chronic obstruction:
  – Weight gain, malaise, fatigue, shortness of breath
- Acute obstruction
  – Flank pain associated with forced diuresis (consumption of coffee, tea, or alcohol), nausea, vomiting, hematuria, anuria

PHYSICAL EXAM
- Chronic obstruction:
  – Pulmonary congestion, pitting edema of lower extremities, HTN
- Acute obstruction:
  – Abdominal mass, suprapubic tenderness, flank tenderness

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CBC, urine culture and sensitivity:
  – Infection in the setting of obstruction requires emergent evaluation and treatment
- SMA-7
  – BUN and creatinine are typically elevated and are monitored after relief of obstruction
  – POD may cause profound hypokalemia
- Magnesium and calcium may need preplacement
- Urine osmolality:
  – Evaluate the kidney's ability to concentrate urine; typically impaired concentrating ability

Imaging

- US is the screening test of choice to evaluate obstruction:
  - Avoid risk of contrast agents
  - Without hydronephrosis, diagnosis of POD should be questioned

Diagnostic Procedures/Surgery

Monitor urine output

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Causes of polyuria:
  - Medications:
    - Lithium carbonate, methoxyflurane, demethylchlortetracycline, amphotericin B, mannitol, glycerol, diuretics, ethanol, opiate antagonist, phenytoin
  - Diabetes insipidus, diabetes mellitus
  - Renal disease: Diuretic phase of ATN
  - Physiologic diuresis from fluid excess

TREATMENT

GENERAL MEASURES

- After the obstruction is relieved, admit the patient to the hospital to closely monitor hemodynamic status and electrolytes, I/O's and daily weights
- Monitor urine output q2h and replace with oral fluids or if oral intake is not keeping up then with IV fluids (0.5–1.0 mL of 1/2 NS/mL of urine output) in addition to PO fluids
  - If urine output decreases to <250 mL/hr replace fluids volume <50 mL of the urine output per hour. Adjust accordingly as the diuresis resolves
- If patient at risk of congestive heart failure or has pulmonary edema, replace at a slower rate
- Check serum sodium and potassium q6–12h and replace as needed
- Follow BUN and creatinine values until normal:
- Replace sodium, potassium, magnesium, and bicarbonate as needed
- Diuresis is usually self-limiting and typically lasts <48 hr
- If diuresis lasts >48 hr, usually due to impaired proximal tubular reabsorption of sodium causing a salt diuresis
  - If outputs remain elevated, obtain a follow-up renal US to rule out hydronephrosis

ALERT

If there is persistent hydronephrosis, consider persistent obstruction of ureter(s) above the level of the bladder or a nonfunctioning stent/percutaneous tube (3)[A].

MEDICATION

First Line

None needed beyond replacement of fluid and electrolyte losses as noted above

Second Line

N/A

SURGERY/OTHER PROCEDURES
N/A

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
Management of any renal insufficiency

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- The rate of recovery is largely determined by the duration and severity of obstructive disease.
- Extent of recovery can be estimated by the improvement in renal function within 7–14 days after the obstruction has been relieved:
  – Some patients may require short-term treatment with dialysis, until their renal function recovers.

COMPLICATIONS
- Uremic death
- Hypovolemic circulatory collapse
- Bladder mucosal bleeding secondary to vein rupture resulting from rapid bladder decompression
- Arrhythmia secondary to electrolyte abnormalities

FOLLOW-UP
Patient Monitoring
Serial (weekly to monthly) renal function testing (creatinine, BUN), renal US imaging if lab values do not return to normal range

Patient Resources
N/A

CODES

ICD9

- 592.0 Calculus of kidney
- 599.60 Urinary obstruction, unspecified
- 788.42 Polyuria

ICD10

- N13.9 Obstructive and reflux uropathy, unspecified
- N20.0 Calculus of kidney
- R35.8 Other polyuria

CLINICAL/SURGICAL PEARLS

- Maintain a high degree of suspicion for the potential for postobstructive diuresis when relieving chronic obstruction of the urinary tract.
- Diuresis is usually self-limiting and typically lasts <48 hr.

PREGNANCY, UROLITHIASIS

Demetrius H. Bagley, MD, FACS
Kelly A. Healy, MD

BASICS

DESCRIPTION

- The presence of calculi in the urinary tract during pregnancy can lead to severe risks and problems in management
- Urolithiasis is the most common cause of nonobstetric abdominal pain that requires hospitalization among pregnant patients
- Symptoms in urolithiasis can result in premature labor and fet al loss
- Stones with obstruction may lead to urosepsis requiring appropriate treatment
- Calcium phosphate most common followed by calcium oxylate

EPIDEMIOLOGY

Incidence

- Calculi in pregnant women occur at a rate of 1/1,500 pregnant patients; a rate similar to that of nonpregnant females (0.03–0.53%)
- Ureteral stones occur twice as often as kidney stones in pregnant patients
- Usually present in the 2nd or 3rd trimester
- Incidence—right vs. left side is similar
- Hispanics and whites more likely than blacks to develop stones during pregnancy
- Multiparous women are more commonly affected than are primiparous women

Prevalence

N/A

RISK FACTORS

- Dehydration
- Relative immobility
- Voluntary dietary modification (increased calcium)

Genetics

- Increased stone formation is likely with a positive family history
- Factors related to stone formation tend to group in families
- Women with known cystinuria should obtain genetic counseling and management of the stone disease before becoming pregnant

PATHOPHYSIOLOGY

- Several factors occur in pregnancy may enhance formation of stones:
  - Pregnancy-induced urinary stasis
  - Hypercalcemia and hypercalciuria
  - Decreased ureteral peristalsis
  - Physiologic hydronephrosis
    - Starts 6–20 wk, in 90% by 3rd trimester

- Right side > left; may persist postdelivery

– Infection

- Associated higher incidence of maternal UTI (10–20%)
- Stone passage can precipitate premature labor and/or interfere with normal labor
- Controversial considerations may cause a higher rate of spontaneous abortions
- Physiologic dilation of calyces, ureters, and renal pelves begins in the 1st trimester and continues into the postpartum period
- Dilation is greater on the right than the left
- Decreased ureteral peristaltic activity because of hormonal and mechanical factors
- Dilation and decreased peristalsis allowed relative urinary stasis
- Increased urinary calcium excretion in pregnancy (↑2–3 times)

– Increased levels of 1, 25-dihydroxy vitamin D

– GFR increases 25–50% in pregnancy

- Urine is more alkaline in pregnancy and thus protective against uric acid stones
- Increase in excretion of stone inhibitors including citrate and magnesium

ASSOCIATED CONDITIONS

- Hydroureteronephrosis is the most significant renal alteration during pregnancy
- Physiologic dilatation of the collecting system begins in the 1st trimester and persists until 4–6 wk following delivery. This factor may also allow the passage of relatively larger calculi
- Increased urinary calcium excretion during pregnancy may present the major problem with indwelling stents and catheters

GENERAL PREVENTION

- Prophylactic measures to prevent the difficulties of treating urolithiasis during pregnancy should be considered
- Metabolic evaluation should be performed for known stone formers at a time when they are not pregnant and not lactating
- There should be consideration of treatment of asymptomatic stones prior to pregnancy
- As noted above, cystinurics have good management of the disease before becoming pregnant

DIAGNOSIS

HISTORY

- Pregnancy history
- History of previous calculi
- Flank and back pain and changes in symptoms
- Dietary modifications
- Medications
- Voiding symptoms—urgency and frequency with urination

PHYSICAL EXAM

- Abdominal tenderness
- Tenderness at costovertebral angle
- Fever/chills
- Nausea/vomiting

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis:
  - Hematuria/pyuria
- Urine culture:
  - UTIs are more common in pregnancy associated with stone disease (10–20%)
  - A UTI can induce premature labor
- Serum creatinine:
  - May be lower if the increased GFR (25–50%) in pregnancy
- CBC

Imaging

- Renal ultrasound (Standard initial imaging study in evaluation of pregnant patients) (1)
  - Hydronephrosis
  - Renal stones/proximal ureteral stones
  - Extravasation/perirenal urinoma
  - Abscess
  - Resistive index (RI) >0.70 in intrarenal arteries supportive of acute obstruction
  - No radiation exposure to fetus
- Transvaginal ultrasound
  - Can demonstrate distal ureteral stones
  - Can demonstrate ureteral jets, confirming urinary flow
  - Document the diameters of distal ureter
- Noncontrast helical/spiral CT
  - Although utilized increasingly in nonpregnant patients, delivers a relatively high radiation exposure
  - Recent techniques have been decreased the radiation exposure
- Other imaging including standard excretory urogram and computerized tomographic scan are discouraged during the 1st and 2nd trimesters
  - Abdominal radiographic and one excretory urogram has been widely used in pregnancy
  - There has been no adverse effect of contrast material reported on the fetus
  - Radiation exposure is the major concern
    - Typical urogram gives <1.5 rads of exposure
    - 5–15 rads to the maternal pelvis in the 1st trimester increases the risk of congenital anomalies by 1–3%
    - As little as 0.4–1.0 rads of fet al exposure can increase the risk of childhood malignancy 2.4 times
- MRI urography:
  - Effect on fet al development poorly defined
  - May be able to distinguish acute obstruction from the dilation of pregnancy

Diagnostic Procedures/Surgery

- The presence of ureteral calculi with obstruction is generally defined before interventional procedures
  - Occasionally, the diagnosis is not certain and the presence of an obstructing calculus is defined only at the time of ureteroscopy

Pathologic Findings
N/A

DIFFERENTIAL DIAGNOSIS
- Acute pyelonephritis
- Appendicitis
- Cholecystitis
- Gastroenteritis
- Hydronephrosis of pregnancy
- Neurologic/musculoskelet al pathology
- Obstetric etiology of pain
- Other intra-abdominal conditions
- Renal vein thrombosis

TREATMENT

GENERAL MEASURES
- Often misdiagnosed initially (appendicitis/diverticulitis/placental abruption)
- Conservative measures are taken initially to manage pain and infection so that the stone may pass (2)
- Hydration and analgesia, antiemetics and antibiotics are used
- Approximately 60–80% of renal calculi pass spontaneously. Among pregnant patients with dilated ureter, the passage rate is not defined
- Ureteral calculi associated with obstruction and upper tract infection demand immediate treatment with drainage and antibiotics

MEDICATION
First Line
- Narcotics including morphine, hydromorphone, butorphanol, meperidine, and acetaminophen can provide short-term pain relief without fet al harm
- Avoid codeine during pregnancy because of its association with fet al defects
- Nonsteroidal anti-inflammatory drugs are contraindicated because of the increased risk of miscarriage in the 1st trimester and other risks including fet al renal anomalies, fet al pulmonary hypertension and premature closure of the ductus arteriosus when used near term
- Medical management for the prevention of calcium stones should be delayed until after delivery

Second Line
N/A

SURGERY/OTHER PROCEDURES
- Intervention may be required in 20–30% of cases (3)
- Drainage may be necessary
- Cystoscopy/stent placement can be done with or without ultrasound guidance (4)
  - Stents must be changed every 6 to 8 wk because of rapid encrustation in the pregnant women's urine

- Percutaneous nephrostomy placement can be done under ultrasound:
  - To minimize radiation exposure
  - The stone or obstruction can be addressed postpartum
  - The tube should be changed every 6–8 wk
  - Clearly tube drainage alone must consider the duration of pregnancy
- Ureteroscopy with laser lithotripsy or impact lithotripsy has been very successful in treating stones in the upper urinary tract in the pregnant patient
- Shock wave lithotripsy has generally not been employed because of concerns of safety and the readily available alternatives

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

- Dietary changes including:
  - Limiting high oxalate foods and purines
  - Increase in fluid intake
  - Limiting salt and sodium intake
  - May be best preserved until metabolic evaluation postpartum

ONGOING CARE

PROGNOSIS

Pregnancy outcome is not appreciably worsened because of symptomatic urolithiasis with appropriate management (5)

COMPLICATIONS

- Premature labor, fet al loss
- Urosepsis, renal insufficiency

FOLLOW-UP

Patient Monitoring

- During gestation:
  - Conservative management with hydration
  - Indications for intervention:
    - Worsening renal function associated with persistent obstruction
    - Intractable pain
    - Obstruction of a solitary kidney
    - Persistent infection associated with an obstruction
    - Renal colic, precipitation premature labor that is refractory to treatment
  - Preventive medications for stone disease have unacceptable side effects during pregnancy
    - Thiazides: Can cause fet al thrombocytopenia, hypoglycemia, and hyponatremia
    - Xanthanine oxidase inhibitors: No adverse effects on fet al animals but effects on human fetus known

- Penicillamine: Teratogenic in rats; fet al defects have been found in infants of mothers who took this during gestation

- Postpartum:
  - Metabolic screening should be undertaken postpartum and should be delayed until completion of lactation period

CODES

ICD9

- 592.1 Calculus of ureter
- 592.9 Urinary calculus, unspecified
- 646.80 Other specified complications of pregnancy, unspecified as to episode of care or not applicable

ICD10

- N20.1 Calculus of ureter

- N20.9 Urinary calculus, unspecified
- O99.89 Oth diseases and conditions compl preg/chldbrth

CLINICAL/SURGICAL PEARLS

- Most urinary stones pass.
- Intractable pain or infection with obstruction may necessitate drainage.
- Catheters, ureteral stent, or percutaneous nephrostomy (must be changed frequently at 4 to 6 wk because of the risks of encrustation).
- Ureteroscopic treatment with endoscopic lithotripsy appears to be the most efficacious and possibly safest treatment.

PRIAPISM

Hunter Wessells, MD, FACS
Brad Figler, MD

BASICS

DESCRIPTION

- Prolonged, usually painful erection, occurring in the absence of sexual stimulation
  - Named for Priapus, the Greek god of fertility who had an oversized, eternally erect penis
- Ischemic priapism (low-flow, veno-occlusive) is most common: Compartment syndrome of the erectile bodies causing ischemia, and ultimate necrosis of the cavernosal smooth muscle
- Nonischemic priapism (high flow, arterial) is less common: Uncontrolled arterial inflow into the cavernosal sinusoids without ischemia or necrosis of cavernosal smooth muscle
- Recurrent (Stuttering) priapism: Episodes are recurrent but of limited duration
- Refractory priapism: Persistent after surgical therapy
- Clitoral priapism (Clitorism): Described in case reports and usually presents as severe vulvar pain; associated with the use of antipsychotics:
  - Management is conservative with removal of the inciting agent
- Priapism in children usually associated with leukemia or sickle cell disease

ALERT
A low-flow ischemic priapism is considered an emergency since early intervention improves the chances for proper erectile function after.

EPIDEMIOLOGY

Incidence

- It is suggested that 10% of patients with sickle cell disease experience priapism, either recurrent short episodes (stuttering priapism) or single prolonged episodes. A higher percentage of men with sickle cell disease may report past attacks, although not all of them requiring medical care
- Priapism is most common between ages 5 and 10 in boys and ages 20 and 50 in men
- Alprostadil intracavernosal injection for the treatment of erectile dysfunction associated with a 1% rate of priapism in clinical trials
- FDA data (2007): 93 cases due to PDE5 inhibitors (likely higher due to unreported cases)

Prevalence

N/A

RISK FACTORS

- Ischemic priapism
  - Sickle cell, other hematologic disorders
    - Neonatal polycythemia, thalassemia
  - Intracavernosal injection therapy (papaverine, phentolamine, prostaglandin E1)
  - Prescription drugs
    - PDE5 inhibitors (sildenafil, others in class)

    - Hydralazine, guanethidine, α-adrenergics [eg, tamsulosin], psychotropics (risperidone, olanzapine, trazodone, SSRIs (fluoxetine bupropion), heparin, coumadin, erythropoietin, methylphenidate
  - Illegal drugs: Cocaine, marijuana
  - Poisonous venom, spinal cord injury
  - Malignancy: Metastatic cancers (GU tumors most common), melanoma, leukemia
  - Dialysis, TPN
- Nonischemic priapism: Straddle injury to the perineum or direct blow to the cavernosal bodies anywhere along the length

Genetics

Associated with genetic blood dyscrasias (sickle cell anemia, sickle cell trait, thalassemia) and Fabry disease

PATHOPHYSIOLOGY

- Ischemic priapism comprises the great majority of cases of prolonged erection
  - Ischemic priapism is caused by a veno-occlusive phenomenon in which a variety of environmental factors lead to hypoxia, acidosis, and dysregulation of cavernosal smooth muscle relaxation leading to persistent veno-occlusion, a compartment syndrome, with absent further arterial inflow
  - A feature of ischemic priapism is the ischemia reperfusion injury and oxidative stress that occurs after release of the ischemic insult
  - Hematologic abnormalities generally cause a low-flow state with red blood cells sludging and veno-occlusion (sickle cell disease, thrombophilia, thalassemia, leukemic infiltration, splenism, erythropoietin, hemodialysis with heparin, total parental nutrition)
  - Pharmacologic (α-adrenergic antagonist, intracavernosal injection, intraurethral alprostadil, antihypertensive medications, psychotropic medications)
  - Neurologic (spinal cord injury, brain tumor, neurosyphilis)
  - Neoplastic (local vs. metastatic, infiltration)
  - Idiopathic
- Nonischemic priapism
  - Unregulated arterial inflow due to traumatic injury to cavernosal artery or one of its branches with unimpeded arterial inflow to the corporal sinusoids
  - Persisting fluid shear stress due to increased inflow leads to further vasorelaxation due to endothelial NO synthase activation

ASSOCIATED CONDITIONS

- Alcohol abuse, psychiatric disorders
- Attention deficit hyperactivity disorder (ADHD): Methylphenidate use
- Blood dyscrasias
- Cocaine abuse
- Epidural anesthesia and analgesia
- Hemoglobinopathies
- Hypercoagulable states
- Intracavernous or intraurethral ED therapy
- Oral PDE5 inhibitors (sildenafil, etc.)

- Pelvic/perineal trauma
- Prostate or bladder cancer
- Renal failure and dialysis

GENERAL PREVENTION

Oral pseudoephedrine (60 mg) if high-risk for recurrence has been suggested

DIAGNOSIS

HISTORY

- Pain, duration of priapism, precipitating factors, and prior episodes
- Medical, drug, and social history. Include intracorporal injection of PDE5 inhibitors
- Determine current level of sexual function
- Prior episodes; successful treatments
- History of perineal straddle injury, malignancy

PHYSICAL EXAM

- Palpation of penis will demonstrate nontender tumescence (nonischemic priapism) or tender rigidity (ischemic priapism).
- The hallmark of a priapism is that the corpora are involved but the glans penis and corpora spongiosum are flaccid and soft
- Abdominal, perineal, and digital rectal exam to search for traumatic or malignant etiology

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- CBC with differential and platelet count
  - Reticulocyte count (may be increased in sickle cell disease)
- Sickle cell prep for "S" hemoglobin
- Hemoglobin electrophoresis
- Urine toxicology for prohibited drugs
- Psychoactive drug screen
- "Penile blood gas" (see below)

Imaging

- Color Doppler US imaging of the cavernous arteries can distinguish ischemic priapism (minimal arterial flow) from nonischemic priapism (high peak systolic arterial flow velocity)
  - Color Doppler imaging may reveal cavernous arterial fistula or perineal arterial extravasation
- Pudendal arteriography (with the potential for therapeutic super-selective embolization) if nonischemic priapism is suspected

Diagnostic Procedures/Surgery

- Aspiration of cavernosal blood with a "butterfly needle" and blood gas syringe for "penile blood gas" allows differentiation between ischemic priapism (low pH, low PO_2, high PCO_2, blood is very dark) vs. nonischemic priapism (normal penile blood gas, blood bright red). Typical values:
  - Ischemic priapism (pO_2 <30 mm Hg, pCO_2 >60 mm Hg, pH <7.25)

– Nonischemic priapism (pO_2 >90 mm Hg, pCO_2 <40 mm Hg, pH >7.4)

Pathologic Findings

Initially liquefactive necrosis of the corporal tissue; later corporal smooth muscle fibrosis

DIFFERENTIAL DIAGNOSIS

- Ischemic vs. nonischemic priapism
- "Pseudo priapism" in men with penile prosthesis, vacuum constriction device with band, intraurethral foreign body causing penile rigidity

TREATMENT

GENERAL MEASURES

- Appropriate differentiation between ischemic and nonischemic priapism is critical (1)
- Ischemic priapism of longer than 4-hr duration is a urologic emergency that requires prompt penile decompression. This is usually a bedside corporal aspiration with or without irrigation
- Aspirate cavernosal blood for "penile blood gas"
  - Duplex color ultrasound has been suggested in lieu of penile blood gas to differentiate ischemic and nonischemic priapism
- All patients should undergo monitoring of blood pressure and pulse, peripheral IV placement, appropriate use of pain medication and sedation

MEDICATION

First Line (3)

- Ischemic priapism
  - Use local anesthesia (lidocaine without epinephrine) and choose technique (local injection site, dorsal nerve block, etc.)
  - Corporal body aspiration +/− irrigation with dilute adrenergic agent
    - Phenylephrine 100–500 mcg/mL (1 mL/1 mg) in 9 mL of injectable normal saline
    - A 27–29G needle is used to inject about 0.5 mL directly into the corpora every 3–5 min until a response. Can be repeated to a max of 1.5 mg phenylephrine has been administered or a total of 1 hr (if no response after 1 hr should be considered initial treatment failure)
    - Use lower volumes in children or with significant cardio vascular disease
    - Corporal compression helps facilitate the process
  - This technique has best results for priapism <24 hr in duration:
    - Aspirate with a large needle (16–18G) connected to a 50-mL syringe and a 3-way stopcock. Insert the needle perpendicular into the skin into the lateral aspect of the corpora and aspirate 20–30 mL at a time (the glans is a less desirable site). Continue until the dark ischemic blood turns bright red
    - If not successful, aspirate and irrigate the corpora with dilute solution of phenylephrine (10 mg in 500 mL saline) using 10–20 mL each time
    - When aspirations and irrigations are completed, apply pressure for 5–10 min to limit hematoma and refilling of corpora
- Ischemic priapism in sickle cell disease:

  - Opioid, analgesics, aggressive hydration, and supplemental oxygen if <4 hr duration
  - Standard treatment if >4 hr, as for ischemic priapism above
  - Terbutaline or other oral agents not recommended per AUA guidelines
- Nonischemic priapism
  - No role for pharmacologic therapy
- Stuttering priapism
  - Treat as for ischemic priapism
  - LHRH agonists/antiandrogens may be considered (but not for children/adolescents)
  - Intracavernous self-injection who fail or reject systemic treatment

Second Line

Injection of epinephrine (1 mg in 1,000 mL saline) has been used in place of phenylephrine; however, phenylephrine is more of a pure α-agonist with a lower systemic side-effect profile

SURGERY/OTHER PROCEDURES

- Surgical intervention is considered 2nd line after corporal injection/aspiration attempts fail
- Ischemic priapism
  - If aspiration/irrigation fails, cavernosal glanular shunting is recommended; creating a fistula between the corpora cavernosa and the glans. Unilateral usually sufficient; if not successful perform bilateral procedure
  - Distal cavernosal glanular shunt is 1st line
    - Winter shunt: 16G core biopsy needle passed from glans into 1 or both of the corporal bodies. Biopsy needle removes tissue core
    - Ebbehoj shunt using a pointed scalpel blade
    - Al-Ghorab shunt is an open excision of tunical tip and usually next if Winter shunt fails
    - T-shunt #11 scalpel blade inserted dorsolaterally to the meatus on both sides, and rotated (blade-edge) 90 degrees laterally
  - Consider proximal shunting if distal shunting fails (cavernosal–spongiosal shunt [Quackles])
- Nonischemic priapism
  - No role for shunting in nonischemic priapism
  - Conservative measures are appropriate in the short term as nonischemic cases of priapism do not lead to underlying cavernosal tissue damage
  - Duplex Doppler Ultrasonography with color flow to localize potential abnormal vascular accumulation (arteriovenous fistula, see image)
  - Internal pudendal arteriography with selective embolization (clot or gel foam)
  - Surgical exploration of the cavernosal body and ligation in cases refractory to embolization

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Immediate placement of penile prosthesis if priapism is of significantly prolonged duration and ED is highly likely is advocated by some

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- Based on duration/severity of ischemia. Priapism associated with sickle cell disease may resolve in 35% of patients treated systemically.
- Risk of permanent erectile dysfunction increases substantially after 24 hr of ischemic priapism (92% potency preserved with <1 day of priapism vs. 69% or less if more prolonged) (2).
- Monitoring of ischemic priapism may be clinical (complete flaccidity of the penis) or radiologic (color duplex Doppler ultrasonography showing persistent flow in cavernosal artery)

COMPLICATIONS
- Erectile dysfunction, particularly with cases of prolonged ischemic priapism
- Cavernosal urethral fistula (after cavernosal spongiosal shunt)
- Cavernositis and corporal fibrosis
- Penile deformity

FOLLOW-UP
Patient Monitoring
- Patient should be monitored for development of erectile dysfunction
- Patient should undergo appropriate testing to complete workup for any hematologic abnormalities or other potential underlying causes

CODES

ICD9
607.3 Priapism

ICD10
- N48.30 Priapism, unspecified
- N48.33 Priapism, drug-induced
- N48.39 Other priapism

CLINICAL/SURGICAL PEARLS
- The hallmark of a priapism: Corpora are involved but the glans is flaccid and soft.
- Penile blood gas allows appropriate diagnosis.
- Ischemic priapism is an emergency and intervention should start within 4–6 hr, including decompression of the corpora cavernosa by aspiration and intracavernous injection of sympathomimetic drugs (eg, phenylephrine).
- Nonischemic priapism can be managed in a semielective manner once diagnosis confirmed.

PROSTATE BIOPSY, INFECTIONS AND COMPLICATIONS

Christopher L. Starks MD
Edmund S. Sabanegh Jr., MD

BASICS

DESCRIPTION

- The current standard for the diagnosis of prostate cancer is transrectal ultrasound (TRUS) guided biopsy of the prostate
- A 12-core biopsy scheme is optimal for 1st time prostate biopsy strategy using local anesthesia
- Active surveillance programs incorporate serial prostate biopsy and may result in a potential for increased risk for biopsy-related complications
- Bleeding is the most common complication observed after prostate biopsy. However, the use of aspirin or nonsteroidal anti-inflammatory drugs is not an absolute contraindication to prostate biopsy

EPIDEMIOLOGY

Incidence

- Prostate biopsy is integral to the workup of elevated prostate-specific antigen (PSA) as well as abnormal prostate exams
- An estimated 800,000–1 million prostate biopsies are performed each year in the United States
- In 1 recent series of repeat biopsies in men on active surveillance 3.5% experienced infectious complications with most requiring hospitalization (1)
- The Rotterdam center of the ERSPC trial noted (0.5%) men required hospitalization for signs of prostatitis or urosepsis (2)

Prevalence

Due to a variety of factors including an aging population widespread use of PSA testing, the number of TRUS and prostate biopsies has increased significantly over the last decade

RISK FACTORS

- For the diagnosis of prostate cancer:
  - 1st-degree relatives with prostate cancer
  - Older age
  - African American race
  - Family history of breast cancer
- For infectious complications the following have been suggested as risk factors:
  - Number of previous prostate biopsies was significantly associated with an increased risk of infectious complications
  - Long-term fluoroquinolone use (3)
  - Healthcare workers

Genetics

- HPC-1 gene on chromosome 1 associated with familial CaP
- Many polymorphisms in genes, such as ELAC2 (locus HPC2), RNase L (locus hereditary prostate cancer 1 gene [HPC1]), and MSR1 may confer an increased risk of developing prostate cancer in many populations (4)

PATHOPHYSIOLOGY
- Normal adult prostate is approximately 20 g
- The majority of prostate cancer is adenocarcinoma and located in the peripheral zone of the prostate
- In the absence of antibiotic prophylaxis, bacteremia and bacteruria occur in 16% and 44% respectively of transrectal ultrasound-guided prostate biopsy

ASSOCIATED CONDITIONS
Benign prostate hypertrophy

GENERAL PREVENTION
- Consider urine culture before prostate biopsy if there is any concern over subclinical UTI
- Preprocedure enema does not appear to have any impact on complication rates
- Rectal swab with culture and sensitivity has been suggested as a method to identify potentially resistant pathogens and is not considered standard of care
- Transperineal biopsy may have a lower rate of infection than the transrectal approach
- Continuing or cessation of antiplatelet or anticoagulant medications prior to biopsy is based upon risk/benefit for each patient. Consider discussion with the patient's cardiologist or primary care physician as needed

DIAGNOSIS
HISTORY
- Prostate cancer most commonly presents without any symptoms
- Family history of prostate cancer
- Specific review of any recent urinary tract infections, catheterization, or acute prostatitis
- Further review of the patient's medication list, with special attention to anticoagulation or antiplatelet medication (ie, aspirin)
- Determine any symptoms of urinary tract infection
- History of anorectal surgery

PHYSICAL EXAM
- Digital rectal exam may reveal nodularity, induration, or an asymmetric gland
- Other anorectal pathology (anal stenosis, significant hemorrhoids) may be detected that might impact on the prostate biopsy procedure

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- PSA
- Screening UA with culture if indicated

Imaging
- TRUS provides images of the prostate
  – Nodules may be hypoechoic on ultrasound

Diagnostic Procedures/Surgery

- A rectal probe should be gently placed with the patient in a lateral decubitus position (5)
- A periprostatic nerve block injecting approximately 5 cc of local anesthetic via a spinal needle can decrease discomfort and pain
- Full visualization of the prostate in transverse and sagittal views should be performed for an overview of the prostate and any abnormalities identified
- The prostate volume should be calculated
- Using a spring-loaded biopsy needle, a minimum of 12 cores, and additional biopsies as needed to obtain representative samples
- The peripheral zone in the posterolateral aspect of the prostate account for the majority of prostate cancers
- Additional biopsy of palpable nodule or hypoechoic areas may be performed at the discretion of provider

Pathologic Findings

- Prostate adenocarcinoma
- Prostatic intraepithelial neoplasia (PIN)
- Atypical small acinar proliferation (ASAP)
- Benign prostate tissue

DIFFERENTIAL DIAGNOSIS

- ASAP
- Benign prostatic hypertrophy
- No evidence of malignancy
- PIN

TREATMENT

GENERAL MEASURES

Although many clinicians have patients perform a self-administered enema, this is not needed. There is little evidence to support their use.

MEDICATION

First Line

- At our institution (Cleveland Clinic), patients receive an oral single dose of fluoroquinolone as well as a single dose of intramuscular aminoglycoside (80 mg gentamicin)
- AUA guidelines (see “Complications” below)

Second Line

N/A

SURGERY/OTHER PROCEDURES

- For patients with anorectal malformations or previous colorectal operations preventing TRUS, a transperineal biopsy can be performed.
- The increasing incidence of antimicrobial resistance with increasing concerns of the risk of sepsis is favoring renewed interest in transperineal biopsy as a relatively sterile alternative to standard TRUS-guided biopsy.

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- A retrospective analysis from Israel suggests that a single injection of 240 mg gentamicin along with a quinolone for 3 days significantly reduces infectious complications (6)
- Another case series demonstrated that 500 mg intravenous amikacin 30 min before the biopsy along with several days of ciprofloxacin reduced the incidence of urosepsis/septicemia following prostate biopsy (7)

Complementary & Alternative Therapies

Topical rectal cleansing with povidone-iodine resulted in a 42% reduction in infectious complications in 1 prospective clinical trial but was not statistically significant

ONGOING CARE

PROGNOSIS

Although prostate biopsy is usually generally safe and well tolerated, it is an invasive procedure that is not without risk and required a clear understanding through informed consent of the patient.

COMPLICATIONS

- Bleeding is the most common complication and includes hematuria, hematospermia, and rectal bleeding
  - Bleeding is usually minor, self-limiting, and resolves with conservative measures. More significant bleeding has been reported and may require transfusion or colorectal intervention
- The 2nd most common complication is infection
  - The incidence of infectious complications, including sepsis, is increasing
  - Compared to controls, men undergoing biopsy have a significant risk for serious infection as requiring hospitalization (approximately 2.26 risk increase and 2.65 risk increase, respectively)
  - Updated AUA Best Practice Policy Panel (8): Antibiotic prophylaxis should be given for all prostate biopsy procedures, duration of therapy is <24 hr. Recommended 1/1/2014 drug of choice regimens and are:
    - Fluoroquinolones or
    - 1st/2nd/3rd-generation cephalosporin
    - Alternative regiments: Trimethoprim Sulfamethoxazole (TMP-SMX) or Aminoglycoside (Aztreonam can be substituted for aminoglycosides in patients with renal insufficiency)
    - Familiarity with local resistance patterns including fluoroquinolone-resistant bacteria is important

FOLLOW-UP

Patient Monitoring

- Prompt medical evaluation for patient with signs and symptoms of infection or significant bleeding

- Counseling regarding transient hematuria and the potential for hematospermia that may last for several weeks
- Follow-up of prostate biopsy results

Patient Resources

CODES

ICD9

- 602.9 Unspecified disorder of prostate
- 998.59 Other postoperative infection
- 998.9 Unspecified complication of procedure, not elsewhere classified

ICD10

- N42.9 Disorder of prostate, unspecified
- T81.4XXA Infection following a procedure, initial encounter
- T81.9XXA Unspecified complication of procedure, initial encounter

CLINICAL/SURGICAL PEARLS

- A minimum of 12 cores is considered standard of care in the United States.
- Additional biopsy of nodules and hypoechoic areas may be needed.
- Be familiar with local resistance patterns when selecting antibiotic prophylaxis.
- In men with prostate cancer on active surveillance the number of previous prostate biopsies may be associated with a significant risk of infectious complications and every previous biopsy increases the risk of infectious complication.

PROSTATE CANCER, BIOCHEMICAL RECURRENCE (ELEVATED PSA) FOLLOWING CRYOTHERAPY

Michael C. Large, MD

BASICS

DESCRIPTION

- Primary cryotherapy is an option for patients with clinically localized prostate cancer of low-, intermediate- or high-grade (1)[B]
- Especially suited for comorbid patients who cannot tolerate alternative therapy (extensive previous surgery, inflammatory bowel disease) (1)[B]

EPIDEMIOLOGY

Incidence

- Nearly 7,000 cryoablations for prostate cancer were performed in US in 2005 (2)[C]
  - Usage projected to increase

RISK FACTORS

- For recurrence after primary cryotherapy:
  - Larger glands make uniform freezing more difficult
  - PSA >10 ng/mL
- For complications after primary cryotherapy:
  - Prior TURP increases risk of urethral necrosis

PATHOPHYSIOLOGY

- Tissue destruction from cryotherapy multifactorial
  - Induces apoptosis
  - Intracellular ice formation and local hypoxia cause necrosis
  - Maximum cell death with: Nadir temperature $< -20^{\circ}C$, rapid freezing rate, slow thawing rate, multiple freeze/thaw cycles
  - Urethral warming catheter protects urothelium but increases potential for preserving PSA-producing tissue

DIAGNOSIS

HISTORY

- History of prostate cancer treated by primary cryotherapy
  - Recommend ≥3 mo elapse from primary treatment before testing for recurrence

PHYSICAL EXAM

- Digital rectal exam
  - Findings may be difficult to interpret given previous therapy

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- PSA spikes initially from necrosis of the prostate tissue

- Following cryotherapy PSA rechecked every 3 mo × 1 yr, then every 6 mo thereafter
- PSA may not decrease to undetectable
- PSA-based definition for biochemical recurrence is not standardized. Various parameters used:
  - PSA >0.4 ng/mL, >0.5 ng/mL, >1.0 ng/mL,
  - 3 consecutive increases ("ASTRO" definition)
  - Nadir + 2 ng/mL ("Phoenix" definition)

Imaging

- Complete metastatic workup may include:
  - CXR
  - CT abdomen/pelvis
  - Bone scan
  - Endorectal MRI

Diagnostic Procedures/Surgery

- Transrectal biopsy
  - Commonly performed post-cryotherapy
  - Recommend waiting 6 mo for inflammation to resolve
  - Negative biopsy reported in 75–95% (1)[B],(2)[C]
  - Lower PSA nadir and lower clinical stage predict negative re-biopsy

DIFFERENTIAL DIAGNOSIS

- Necrosis, especially if within 3 mo of procedure
- Residual benign prostatic tissue
- Treatment failure
- Recurrent disease (local or metastatic)

TREATMENT

GENERAL MEASURES

Confirmation of recurrence via transrectal biopsy

MEDICATION

First Line

- No first-line medication therapy
  - Consider androgen-deprivation therapy or clinical trial if metastatic disease
  - No significant data on the use of androgen-deprivation after local cryotherapy failure

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Salvage prostatectomy feasible but large series are lacking
- Reported techniques include:
  - Open retropubic or perineal
  - Laparoscopic or robotically assisted
- Salvage cystoprostatectomy with urinary diversion

- Option for extensive local recurrence with severe, treatment-refractory lower urinary tract symptoms

ADDITIONAL TREATMENT

Radiation Therapy

- Conformal or Intensity-modulated radiotherapy
  - Largest series 49 patients, received conformal RT (3)[C]
  - Mean preradiation PSA 2.4 ng/mL
  - Mean RT dose 62.9 Gy
  - At median follow-up 32 mo, biochemical-free survival rate 61%

Additional Therapies

- Repeat cryotherapy
  - Largest series 32 patients (4)[C]
  - Median follow-up 63 mo
    - 22, 23, and 29 were biochemical disease free by definitions of 0.5 ng/mL, 1.0 ng/mL, and ASTRO definition

Complementary & Alternative Therapies

None widely studied

ONGOING CARE

PROGNOSIS

- Biochemical recurrence-free survival after primary cryotherapy (Phoenix definition)
  - 5-yr estimates based on D'Amico risk category: (1)[B],(2)[C]
    - Low risk: 85–90%
    - Intermediate risk: 80%
    - High risk: 60–70%
  - 10-yr estimates based on D'Amico risk category:
    - Low risk: 80%
    - Intermediate risk: 75%
    - High risk: 45%

COMPLICATIONS

- No large series following postcryotherapy salvage treatment
- Surgery:
  - Intraoperative rectal injury
    - Small injury: 2-layer primary repair and omental interposition
    - Large injury, gross spillage, poor tissue viability: Primary repair and diverting colostomy
  - Urinary incontinence, impotency
- Radiation
  - Rectourethral fistula, urethral stricture, urinary incontinence, impotency, and bladder and rectal toxicities
- Repeat cryotherapy
  - Rectourethral fistula, urethro-cutaneous fistula, urethral stricture, urinary incontinence, impotency, and bladder and rectal toxicities

FOLLOW-UP

Patient Monitoring

- No standards exist for postcryotherapy recurrence follow-up
- If biochemical disease untreated, may treat patient according to algorithms for (1) localized or (2) advanced prostate cancer outlined in prior chapters
- If patient has undergone salvage treatment after cryotherapy, no standards exist
  - PSA often performed every 3 mo after salvage therapy
  - Re-biopsy may be offered 6 mo after treatment, or if clinically indicated

- Prostate Cancer, Biochemical Recurrence (elevated PSA) Following Radiation Therapy
- Prostate Cancer, Biochemical Recurrence (elevated PSA) Following Radical Prostatectomy
- Prostate Cancer, General
- PSA Elevation, General Considerations
- Reference Tables: TNM: Prostate Cancer

CODES

ICD9

- 185 Malignant neoplasm of prostate
- 790.93 Elevated prostate specific antigen [PSA]
- V10.46 Personal history of malignant neoplasm of prostate

ICD10

- C61 Malignant neoplasm of prostate
- R97.2 Elevated prostate specific antigen [PSA]
- Z85.46 Personal history of malignant neoplasm of prostate

CLINICAL/SURGICAL PEARLS

- An early rise in PSA after cryotherapy is normal, and further testing should be deferred until at least 3 mo following treatment.
- Various definitions of PSA failure after cryotherapy exist: >0.4 ng/mL, >0.5 ng/mL, >1.0 ng/mL, 3 consecutive rises, and nadir $+$ 2 ng/mL.
- Prostate biopsy is useful in the workup of postcryotherapy biochemical recurrence.
- Postcryotherapy treatment of recurrent disease should be reserved for highly experienced surgeons and radiation oncologists.

PROSTATE CANCER, BIOCHEMICAL RECURRENCE (ELEVATED PSA) FOLLOWING RADIATION THERAPY

Robert B. Den, MD
Mark Hurwitz, MD

BASICS

DESCRIPTION

- Rising PSA after treatment, referred to as biochemical recurrence, is nearly always the first indication of recurrent prostate cancer. The site of recurrence—local, regional, distant, or a combination of sites, however, cannot be discerned by PSA level alone
- Definitions of biochemical recurrence following radiation:
  – ASTRO definition: 3 consecutive rises in PSA (backdating)
  – Phoenix definition: PSA nadir + 2 ng/mL

EPIDEMIOLOGY

Incidence

- Most men with clinically localized disease will not experience recurrence. However, given the widespread use of radiation therapy for treatment of prostate cancer, biochemical recurrence is not an uncommon problem in routine clinical practice.
- 5-yr rates of biochemical recurrence ~5–40% depending on risk stratification criteria

Prevalence

The time from biochemical recurrence to clinical recurrence is typically measured in years. Therefore prevalence is relatively high as compared to incidence.

RISK FACTORS

- Risk of recurrence is associated with original risk stratification including clinical stage, PSA, and Gleason score.
- A rise in PSA of >2 points in the year preceding diagnosis is associated with increased risk for both recurrence and prostate cancer–specific mortality
- Gleason score 4 + 3 = 7 vs. 3 + 4 = 7 and/or ≥50% positive biopsies in intermediate-risk patients
- Lower doses of radiation
- Lack of use of androgen deprivation therapy in high-risk patients

Genetics

New tests linking tumor-specific genetic profiles to adverse risk in prostate cancer including risk of recurrence after prostatectomy have recently become clinically available. Their ultimate clinical value remains to be fully defined. In regard to biochemical recurrence following radiation therapy, the utility of such tests to guide further therapy is not yet known.

PATHOPHYSIOLOGY

- >95% of prostate cancers are adenocarcinoma
- Rare variants such as TCC, small cell carcinoma, and sarcomas are not associated with

elevation of PSA

ASSOCIATED CONDITIONS

Symptoms of urinary outlet obstruction can occur but are uncommon during the initial period of biochemical recurrence.

GENERAL PREVENTION

- Optimized radiation therapy including dose escalation with daily image guidance to ensure proper targeting with external beam radiation and use of proper brachytherapy techniques
- Use of androgen deprivation in combination with radiation for high risk and selected intermediate risk patients

DIAGNOSIS

HISTORY

- Prior radiation treatment information should be obtained including type of radiation, technique, and dose prescribed. For prostate brachytherapy postimplant dosimetry analysis should be reviewed to determine if there were underdosed regions.
- Thorough assessment of general health with emphasis on urinary and bowel function is important in guiding the advisability of potential salvage therapies.

PHYSICAL EXAM

General physical exam including rectal exam

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- PSA.
  - In addition to total PSA, PSA kinetics may be helpful in identifying patients at greater risk of development of distant vs. local recurrence.
  - Patients with short time to PSA nadir after treatment and short doubling times (PSADT) are at greater risk of subsequent diagnosis of metastatic disease (PSDAT < 3–6 mo)
- Testosterone establishes baseline for future hormonal intervention
- Basic metabolic panel
- CBC

Imaging

- Bone scan
- CT of abdomen and pelvis
- Pelvic/prostatic MR. Magnetic resonance spectroscopic imaging may improve results over MR alone
- New techniques for PET/CT including use of ^{18}F-NaF may be useful in select cases
- Other imaging as clinically indicated

Diagnostic Procedures/Surgery

- Prostate biopsy should be considered if more than 2 yr have elapsed since completion of radiation therapy and additional local therapy is being contemplated.
  - As the full effects of radiation are not manifested for 24–30 mo, biopsy before this time is not indicated.

- Approximately 20% of patients who have postradiation biopsies will have no clinical evidence of disease with additional long-term follow-up. Conversely, given the limitations of sampling, local recurrence may be present despite negative biopsy.
- Biopsy to assess findings concerning for distant metastases as clinically indicated.

Pathologic Findings

- Discerning posttreatment change from residual disease in irradiated prostate tissue can be difficult.
  - Immunohistochemical analysis with basal cell-specific keratin monoclonal antibodies can aid in differentiating benign and malignant glands since only benign glands display basal cell immunoreactivity.

DIFFERENTIAL DIAGNOSIS

- PSA bounce phenomenon
  - 35% incidence after brachytherapy
  - Less common with external beam radiation
- Testosterone rebound after completion of androgen deprivation with associated rise in PSA

TREATMENT

GENERAL MEASURES

- Efforts should be made to discern if biochemical recurrence is due to presence of local vs. distant disease or a combination of both.
- In the presence of metastatic disease androgen ablation is the standard choice.
- In cases of only localized disease there are many more options including observation, androgen ablation or salvage therapies including radical prostatectomy or cryotherapy.
  - In general candidates for local salvage therapy should have original clinical stage tumor T-1, T2 NX/N), life expectancy of >10 yr, and a PSA <10 ng/mL (1)
  - Patient who are not ideal candidates for salvage therapy should be treated by androgen deprivation or observation

MEDICATION

First Line

- Hormonal therapy (androgen deprivation):
  - LHRH agonists: Leuprolide, goserelin, triptorelin
    - Suppress LH and FSH release by the pituitary
  - LHRH antagonists: Degarelix (only 1 FDA approved in US;
    - Suppress LH and FSH release by the pituitary
  - Antiandrogens: Flutamide, bicalutamide, nilutamide, directly block the activity of androgens on the androgen receptor
  - LHRH agonists can be used alone or in combination with oral antiandrogens
  - When LHRH agonist therapy is initiated, a release of testosterone is induced (androgen flare) that may exacerbate symptoms from metastatic lesions. In particular, patients with spinal metastasis may be in jeopardy of cord compression
    - Flare avoided by initiating antiandrogen therapy 2 wk prior to 1st LHRH agonist injection

– Orchiectomy remains an infrequently utilized option for androgen ablation

Second Line

Alternate androgen deprivation therapy or clinical trial

SURGERY/OTHER PROCEDURES

- Radical prostatectomy is rarely performed following prostate radiation due to high rates of morbidity (2)
  – However, surgery can be considered in carefully selected cases for relatively young healthy patients with established local recurrence
  – 5- and 10-yr rates of freedom from biochemical recurrence with salvage radical prostatectomy range up to 59% and 37% respectively with disease-specific survival as high as 83% at 10 yr
  – Common toxicities include bladder neck contracture (17–47%), rectal fistula (7–20%), and erectile dysfunction in nearly all patients

ADDITIONAL TREATMENT

Radiation Therapy

- Administration of additional radiation therapy in most instances should be limited to research protocols.
  – The most commonly investigated approach is salvage brachytherapy following external beam radiation failures.
  – 5-yr freedom from biochemical recurrence has been reported between 25–75% and disease-specific survival between 74–100%. Wide variation in reported outcomes is likely due to variation in risk criteria across studies.
  – Crude rates of grade ≥3 GU and GI complications average 13% and 5%, respectively. Rates may be higher in elderly patients.

Additional Therapies

- Thermal ablative therapies including cryoablation and high-intensity focused ultrasound remain investigational.
- Cryotherapy in particular has shown promise in selected series.
  – 5–10-yr freedom from biochemical recurrence with cryotherapy ranges between 34–59%.
  – Rates of ≥3 GU and GI complications average approximately 10% and 3% across reported series.
- Focal ablative therapies that attempt to identify the site of recurrence and ablate the site are investigational (3).

Complementary & Alternative Therapies

Low-fat diets and diets high in polyphenols as found in broccoli, turmeric, pomegranate, and green tea may be beneficial

ONGOING CARE

PROGNOSIS

PSA doubling time of less than approximately 6 mo and in particular 3 mo has been linked to increased risk of prostate cancer–specific mortality

COMPLICATIONS

- Urinary outlet obstructive symptoms
- Proctalgia due to rectal invasion is typically seen only with advanced stages of recurrence

FOLLOW-UP

Patient Monitoring

- Dependent in part on subsequent treatment
- Every 3–6 mo including general and prostate exam and PSA

Patient Resources

American Cancer Society.

CODES

ICD9

- 185 Malignant neoplasm of prostate
- 790.93 Elevated prostate specific antigen [PSA]
- V15.3 Personal history of irradiation, presenting hazards to health

ICD10

- C61 Malignant neoplasm of prostate
- R97.2 Elevated prostate specific antigen [PSA]

- Z92.3 Personal history of irradiation

CLINICAL/SURGICAL PEARLS

- Risk stratification, morbidities associated with the primary course of radiation, and PSA kinetics posttreatment are important to consider in selecting the best management option.
- Participation in clinical trials should be encouraged in areas such as this where no consensus exists.

PROSTATE CANCER, BIOCHEMICAL RECURRENCE (ELEVATED PSA) FOLLOWING RADICAL PROSTATECTOMY

Gurdarshan S. Sandhu, MD
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION

- Biochemical recurrence following radical prostatectomy is a clinical state characterized by a detectable and increasing serum prostate specific antigen (PSA) after radical prostatectomy in the absence of detectable disease based on current imaging modalities
- Men with a biochemical recurrence fall into 3 groups
  - Those with a PSA that fails to fall to undetectable after surgery (persistent disease)
  - Those with an initially undetectable PSA after surgery that subsequently increases on 2 or more tests (recurrent disease)
  - Those with stable but low PSA levels (rare)
    - Attributed generally to residual benign disease
- Generally defined as detectable or rising PSA value after surgery that is ≥ 0.2 ng/mL with a 2nd confirmatory level ≥ 0.2 ng/mL

EPIDEMIOLOGY

Incidence

Up to 30% of men will develop a biochemical recurrence after radical prostatectomy in large, institutional, long-term follow-up series (1)

Prevalence

Based on the estimated probability of relapse after surgery OR radiation therapy, more than 50,000 American men have biochemical recurrence without other detectable disease (2)

RISK FACTORS

- Biochemical recurrence is predicted by several factors:
  - Advanced pathologic tumor stage (3)
    - Adverse features include positive surgical margins, non-organ confined disease, seminal vesicle invasion, and lymph node metastases
  - High Gleason score
  - High preoperative PSA
- In addition to the risk factors above, risk factors for the development of clinical metastases and prostate cancer related mortality include:
  - Time to biochemical recurrence
  - PSA doubling time (PSADT) after recurrence

Genetics

See “Prostate cancer, general considerations”

PATHOPHYSIOLOGY

- In a patient with biochemical recurrence, it is important to try to distinguish local from systemic
  - In general, low preoperative PSA, lower Gleason grade, lower tumor stage, prolonged time from surgery to biochemical recurrence and long PSADT are more suggestive of local recurrence
  - Conversely, higher stage, higher Gleason score, shorter (< 2 yr) time to biochemical recurrence and shorter (< 3–6 mo) doubling time suggest distant disease

ASSOCIATED CONDITIONS

- Biochemical recurrence of PSA after surgery when the PSA after surgery was initially undetectable generally precedes metastatic progression and prostate cancer specific mortality by a median of 8 and 13 yr, respectively (4)
  - Importantly, not **all** men with biochemical recurrence will develop metastases or die of prostate cancer (1)
  - PSADT after recurrence is an important factor in assessing the risk of subsequent metastases and prostate cancer mortality

GENERAL PREVENTION

Although proper surgical technique can limit the risk of PSA recurrence it cannot be guaranteed to do so due to varying tumor biology

DIAGNOSIS

HISTORY

- Preoperative PSA
- Time since surgery
- Pathologic information from the radical prostatectomy
- Postoperative continence and erectile function
  - Timing of adjuvant/salvage therapy after surgery may be affected by the patient's functional recovery

PHYSICAL EXAM

Digital rectal exam to palpate for local recurrence in the prostate bed

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serial surveillance of PSA after biochemical recurrence is necessary to monitor disease progression and response to additional treatment if offered
  - PSADT assessment (can be calculated using widely available online calculators)
  - PSA level can vary depending on the lab assay used so use of the same laboratory recommended for serial follow-up
- Baseline testosterone to guide future therapy

Imaging

- Imaging evaluation is necessary to determine if distant metastases are present under some circumstances (eg, short time to recurrence, short PSADT, rapid rise in PSA)
  - Computed tomography (CT) or magnetic resonance imaging (MRI) of the abdomen/pelvis
    - Identify local recurrence or lymphadenopathy

- Multiparametric MRI has an emerging role in this setting and appears to be more sensitive than CT in detecting local recurrence
- Bone scintigraphy to evaluate for bony metastases
  - Unlikely to be positive unless the PSA is generally >20 ng/mL
- ProstaScint is approved by the US Food and Drug Administration (FDA) to detect occult metastatic disease in patients with early prostate cancer
  - Is associated with a significant number of false positive and false-negative results
- Positron emission tomography/computed tomography (PET-CT), with choline
  - Approved by the FDA in September 2012
  - Falsely positive PET scans can be observed in 15–47% so confirmatory tissue sampling of abnormalities detected with PET-CT is required

Diagnostic Procedures/Surgery

Transrectal ultrasound guided biopsy of the prostate bed may be helpful only if imaging or digital rectal exam suggest local recurrence

ALERT

"Blind biopsies" of the prostate bed in the absence of evidence to suggest locally recurrent disease have a low yield, often do not affect decision making, poorly predict the efficacy of salvage radiation and should not be a standard of care.

Pathologic Findings

Dictated by pathology from the radical prostatectomy. Often positive surgical margins or seminal vesicle invasion is noted

DIFFERENTIAL DIAGNOSIS

- PSA elevation due to residual benign epithelium after prostatectomy
- Local recurrence of adenocarcinoma
- Systemic recurrence of adenocarcinoma
- Local and systemic recurrence of adenocarcinoma

TREATMENT

GENERAL MEASURES

- Close monitoring of the serum PSA postoperatively. NCCN Guidelines recommend PSA every 3 mo if high risk or 6–12 mo up to 5 yr, then annually thereafter; annual DRE
- Follow up treatment decision primarily based on pathology, imaging, and PSA dynamics
- Can include observation, androgen ablation, or pelvic radiation
- Careful observation can be considered with slow PSADT, in older patients with other comorbidities

MEDICATION

First Line

- Androgen deprivation therapy (ADT)
  - ADT drug classes include Gonadotropin-Releasing Hormone(GnRH) agonists (eg, goserelin, histrelin, leuprolide, and triptorelin) and antagonists (Degarelix)
  - Depot injections of the GnRH agonists allow dosing to extend from 28 days up to 1 yr

- GnRH antagonist dosing is every 28 days
- See “Prostate Cancer, metastatic” for more information on drug classes

• No data are available on the optimal PSA value at which to initiate treatment
- ADT is potentially detrimental to cognitive function, quality of life, sexual health, cardiovascular risk, and bone integrity
- Timing of initiation of ADT should be based on a patient’s risk of metastatic progression and risk of death from disease as opposed to absolute PSA levels
- When ADT is initiated, in the absence of metastases, intermittent ADT is preferred to continuous ADT given the side effects of this treatment and the non-inferior overall survival of intermittent ADT (6)
- With the benefits that have been observed with adjuvant/salvage radiation, the role of ADT as monotherapy may be somewhat limited

Second Line

See “Prostate Cancer, metastatic” and “Prostate Cancer, rising PSA following androgen ablation” for more information on additional drug classes

SURGERY/OTHER PROCEDURES

• Scrotal orchiectomy
- Can be used instead of ADT
  - Is more cost effective than ADT
  - Does not allow for intermittent androgen deprivation
- Quickly achieves castrate levels of testosterone (< 50 ng/mL) within 24 hr
- Subcapsular scrotal orchiectomy can also be offered in lieu of ADT
  - May help avoid the psychological consequences of an empty scrotum

ADDITIONAL TREATMENT

Radiation Therapy

• Patients with demonstrable disease in the prostate bed or those with suspected local recurrence may be considered for adjuvant/salvage radiation
- Favorable responses to adjuvant/salvage radiation are associated with low PSA levels prior to radiation(< 1 ng/mL), long PSADTs, lower Gleason scores, longer time to biochemical recurrence and positive surgical margins
- Adjuvant or early salvage radiation (based on a lower PSA trigger value) should be considered for patients with positive margins, extraprostatic extension, and seminal vesicle invasion (3)
  - Such therapy, compared to radical prostatectomy only, reduces the risk of biochemical recurrence, local recurrence, and clinical progression of cancer (3,7)
  - The impact on subsequent metastases, prostate-cancer specific mortality, and overall survival is less clear (3,7). The survival benefit was established in one randomized trial but was refuted in another randomized trial, which was not powered to look at this outcome (3,7)
  - Adjuvant/early salvage radiation is well supported by randomized trials for patients with adverse pathology at the time of prostatectomy and is endorsed by AUA/ASTRO Guidelines

Additional Therapies

Clinical trials should be available and offered

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Prognosis is dictated by several variables including:
  - Preoperative PSA
  - Pathologic Gleason score
  - Pathologic tumor stage
  - Time to biochemical recurrence
  - PSADT: <3–6 mo associated with the development of metastatic disease
- For those patients that progress after biochemical recurrence, in general, metastatic progression and prostate cancer specific mortality occur at a median of 8 and 13 yr after biochemical recurrence (4)

COMPLICATIONS

- Patient anxiety
- Complications are dictated by adjuvant and salvage therapy offered
  - Either radiation or ADT

FOLLOW-UP

Patient Monitoring

- Monitoring of serum PSA is necessary to diagnose biochemical recurrence and the response to treatment when/if it is offered
- For patients on ADT, baseline and periodic assessment of bone density is recommended
  - If PSA begins to rise on ADT, serum testosterone should be assessed to ensure a castrate level

CLINICAL/SURGICAL PEARLS

- Distinguishing local from systemic disease recurrence dictates adjuvant/salvage therapy options.
- Adjuvant/early salvage radiation is supported by randomized trials for patients with adverse pathology at the time of prostatectomy and is endorsed by AUA/ASTRO Guidelines.

PROSTATE CANCER, GENERAL

Robert B. Den, MD
Mark Hurwitz, MD

BASICS

DESCRIPTION

Prostate cancer (CaP) usually refers to adenocarcinoma as other types are rare

EPIDEMIOLOGY

Incidence/Prevalence

- Most common solid tumor in US males
- 2014: 233,000 new cases; 29,480 deaths
- Advent of PSA blood test led to a sharp increase of CaP incidence from 1989 to 1992
- Highest worldwide incidence is in African Americans, with a relative incidence of ~2 compared to US whites
- Lowest worldwide incidence is in Asian men (1.9/100,000/yr in China); however, Asians who immigrate to US increase risk to that of US men
- Mortality rate decreased sharply since 1991; now lower than before PSA era
- 5-yr relative survival rates ~100%
- Lifetime CaP risk is 16.15%

RISK FACTORS

- Genetic and environmental factors are important in CaP development
- Family history: Risk is increased by number of affected family members, degree of relation, and age at diagnosis.
- Infection/inflammation: Prostatitis and STD
- Oxidant stress: Several genetic determinant of CaP code for proteins that repair oxidant stress
- Western diet (high levels of meat, dairy, and saturated fat); folate supplements
- Androgens: Essential for development and maturation of prostate gland
  - Lack of androgen associated with decreased risk of CaP, although no dose-dependent relationship has been established
  - Shortened CAG repeat length in the AR gene associated with increased risk
  - Estrogen: Mixed effects on CaP
  - IGF-1
  - Vitamin D may protect against CaP

Genetics

- HPC-1 gene on chromosome 1 associated with familial CaP; HPC-1 mutation leads to defective RNase L, accumulation of genetic defects, and eventually cancer
- CaP susceptibility genes: P53 tumor suppressor, ELAC2/HPC2, SR-A/MSR1, CHEK2, BRCA2, PON1, OGG1, and MIC1.
  - Multifocal and heterogeneous nature of CaP makes clinical genetic studies difficult
- Familial CaP tends to follow a similar clinical course to sporadic CaP

PATHOPHYSIOLOGY
- Normal adult prostate 20–25 g; secretes fluid comprising about 30% of ejaculate
- Most CaP arise in peripheral zone of gland
- High-grade prostatic intraepithelial neoplasia (HGPIN) may be a premalignant lesion:
  - Risk of CaP on subsequent biopsy 16–44%; repeat biopsy within a year not necessary unless other signs of cancer
- Atypical small acinar proliferation (ASAP) considered premalignant; 42–49% risk of cancer, biopsy should be repeated

ASSOCIATED CONDITIONS
ED and urinary incontinence are associated with all local CaP therapies.

GENERAL PREVENTION
- Randomized trials have been conducted
  - Prostate Cancer Prevention Trial (PCPT) finasteride vs. placebo; REDUCE (dutasteride vs. placebo); while there was 23–25% reduction in CaP risk, concern over slight increase in diagnosis of high-grade cancers prevented these from being FDA-approved agents
  - SELECT: Examined antioxidants Vit E and selenium terminated in 2008 due to lack of benefit; increased risk of CaP and diabetes

DIAGNOSIS
HISTORY
- Rarely presents with symptoms; most cases are detected by PSA screening and/or DRE
- Occasionally local tumor symptoms: Urinary obstruction, irritative voiding symptoms, rarely impotence, hematuria, hematospermia
- Metastatic symptoms: Bone pain, weight loss, malaise; spinal cord compression with paralysis

PHYSICAL EXAM
DRE may reveal induration, nodularity, or asymmetry in the gland (uncommon in most men)

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- PSA, is typically elevated in serum of patients with CaP (See Section I: PSA Elevation, General)
- PSA is the most widely used and controversial screening test (sensitivity/specificity suboptimal)
- Recent guidelines have called PSA screening into question
- PSA velocity of >2.0 ng/mL/yr: Poorer prognosis after prostatectomy or radiation therapy
- Free PSA: Lower % free PSA indicates higher risk of CaP
- Prostatic acid phosphatase: Limited utility
- Alkaline phosphatase: Elevated in bone mets

Imaging
- Transrectal ultrasound (TRUS) primarily used to guide biopsy; CaP classically a hypoechoic nodule on TRUS, but can be iso- and hyperechoic
- Multiparametric MRI w/ or w/o endorectal coil may identify some cancers, used to assess

local extent of disease; utility of multiparametric MRI growing
- Bone scan: Usually ordered in intermediate- and high-risk patients; blastic bone lesions w/mets
- CT abdomen/pelvis: Used to assess for visceral or lymph node metastasis; indicated for intermediate- and high-risk patients
- ProstaScint: Nuclear scan using a PSMA monoclonal antibody to detect occult metastases. FDA-approved post prostatectomy; limited use

Diagnostic Procedures/Surgery
- TRUS-guided needle biopsy extended template now standard (10–12 cores)
- Effort should be made to sample all hypoechoic lesions and palpable nodules
- Transperineal w/ or w/o MRI image fusion increasing

Pathologic Findings
- >95% CaP adenocarcinoma, with <5% transitional cell (next most common), small cell carcinoma, and sarcoma
- Gleason Grade (1–5) determined by architectural features observed at low magnification. The 2 most prominent grades are added together for Gleason score (2–10):
  - Main criterion of CaP: Loss of basal cell layer
  - Small, crowded acini with irregular contours, nuclear, and nucleolar enlargement
  - Hormonal Rx artifactual grade increase
  - Score <6 rare today; 6, 7, 8–10 are low-, intermediate-, and high-grade disease, respectively
- Staging:
  - TNM staging, see Section VII
  - 75% of newly diagnosed cases are T1c
  - PSA >10, Gleason score ≥7, or T2b or higher should undergo imaging (CT/bone scan)
  - CaP spreads from the prostate directly to adjacent tissues, usually via the perineural and lymphovascular spaces
  - Can also directly invade the seminal vesicle
  - Early metastasis to the pelvic lymph nodes
  - Distant metastasis: To bone, less common lung, and in advanced stages, the liver and CNS

DIFFERENTIAL DIAGNOSIS
- Localized: BPH, prostatitis (granulomatous, acute, chronic), recent instrumentation, nonadenocarcinoma prostate malignancy (sarcoma, urothelial carcinoma)
- Metastatic: Paget disease, other causes of pelvic/retroperitoneal lymphadenopathy (lymphoma, TB, etc.)

TREATMENT

GENERAL MEASURES
- Localized disease, best treatment controversial and must be individualized; includes active surveillance, radical prostatectomy, radiation therapy, cryotherapy
- Consider age, overall health, life expectancy, patient and physician preferences
- Metastatic disease less controversial and relies primarily on reduction of testosterone

- Risk groups (localized disease, per NCCN)
  - Low risk: T1-2a/Gleason 2–6/PSA <10 ng/mL
  - Intermediate: T2b–T2c/Gleason 7/PSA 10–20 ng/mL
  - High:T3a or greater or Gleason score 8–10 or PSA >20 ng/mL

MEDICATION

First Line

- Metastatic disease: Androgen deprivation
  - LHRH agonists: Leuprolide, goserelin, triptorelin; histrelin; transient flare then suppression of pituitary LH and FSH
  - LHRH antagonists: Degarelix; suppress LH and FSH release by the pituitary
  - Antiandrogens: Flutamide, bicalutamide, nilutamide, directly block the activity of androgens on the androgen receptor
  - LHRH agonists can be used alone or in combination with oral antiandrogens
  - LHRH agonist 1st dose, a release of testosterone is induced (androgen flare) that may exacerbate symptoms from metastatic lesions. In particular, patients with spinal metastasis may be in jeopardy of cord compression. Minimize flare by antiandrogen therapy 2 wk prior to 1st LHRH agonist injection

Second Line

- Metastatic castrate–resistant CaP: W/rising PSA and "castrate" testosterone (<50 ng/dL)
  - Secondary hormonal manipulations
    - Ketoconazole: Inhibits adrenal and gonadal androgen synthesis; castration hormone levels in <8 hr, historically used w/ spinal compression
    - Add/stop nonsteroidal antiandrogens
  - Sipuleucel-T: Autologous immunotherapy; minimally symptomatic or asymptomatic disease
  - Abiraterone: Androgen biosynthesis inhibitor; approved in men with metastatic castrate–resistant prostate cancer previously treated with docetaxel and pre-docetaxel
  - Enzalutamide: 2nd gen oral antiandrogen, previously treated with docetaxel and pre-docetaxel
  - Radium 223 chloride; systemic α-emitter for symptomatic bone mets, no visceral disease
  - Cabazitaxel and prednisone: Systemic microtubule inhibitor failing docetaxel
  - Docetaxel and prednisone: Systemic microtubule inhibitor

SURGERY/OTHER PROCEDURES

- For low-risk (T1 and T2a) cancer, 5-yr biochemical disease-free rates are equivalent for prostatectomy, radiation therapy, and brachytherapy. Thus, therapy should be driven by the preferences of the well-informed patient
- Radical prostatectomy:
  - Resection of prostate and seminal vesicles and reanastomosis of bladder to urethra
  - Nerve-sparing technique if possible
  - Open (retropubic, perineal), laparoscopic, or robot-assisted laparoscopic; Laparoscopic approaches may offer quicker discharge, lower blood loss; equivalent functional/oncologic results between techniques; robot higher cost
- Bilateral orchiectomy provides permanent androgen ablation in men with advanced disease

- Cryotherapy uses multiple probes to ablate prostate tissue by freezing and thawing, using TRUS to monitor the extent of the ice ball

ADDITIONAL TREATMENT

Radiation Therapy

- External beam RT:
  - IMRT with IGRT: Provides high doses of radiation to prostate, minimal dose to surrounding tissues
  - Wide-field pelvic XRT with neoadjuvant androgen deprivation may be considered in men at high risk for nodal metastases
  - Proton beam gaining support
  - Hypofractionation approaches in clinical trials
- Brachytherapy:
  - RT is delivered locally by permanent radioactive (low dose rate I125 or Pd103) seeds or temporary (high dose rate with Ir192) placed percutaneously through the perineum:
  - Low-dose monotherapy appropriate for low-risk disease and gland <60 g
  - Gleason ≥ 7, PSA ≥ 10, and $\geq$T2b use EBRT in lieu of or in addition to brachytherapy
- Neoadjuvant/concurrent androgen deprivation for 6 mo–3 yr with XRT increases survival vs. XRT alone or hormonal therapy alone (select intermediate and all high-risk patients)

Additional Therapies

- Active surveillance: Option for many patients due to the slow progression of CaP, especially in men >70 who may be likely to die of other causes
  - Ideal patient: PSA <10 ng/mL, T1c, Gleason ≤ 6; <3 biopsy cores positive ($<50\%$ cancer in any core); PSA density <0.15 ng/mL/g
- HIFU: Investigational focal ablative therapy in use outside of US

Complementary & Alternative Therapies

Consider dietary changes: Reduced meat and saturated fat; increased vitamin D (see "Risk Factors"); increased lycopenes (cooked tomato products, red fruits; increased fiber and exercise

ONGOING CARE

PROGNOSIS

- Determining prognosis is multimodal
- Increased recurrence risk with:
  - High PSA (≥ 10), high Gleason score (≥ 7), advanced clinical stage ($\geq$T3)
  - Pathologic features: Positive surgical margins, seminal vesicle invasion, capsular penetration, lymph node involvement
  - New genomic markers available for prognosis (See Section II: "Prostate Cancer, Genomic markers.")

COMPLICATIONS

- Disease related:
  - Bladder outlet obstruction, bone pain, pathologic fractures, spinal cord compression, ureteral obstruction usually due to metastasis

- Treatment related:
  - Local therapy (surgery, radiation): Impotence, incontinence, rectal injury
  - Androgen deprivation: Hot flashes, loss of libido, impotence, fatigue, osteoporosis
  - Chemotherapy: Neutropenia, sepsis

FOLLOW-UP

Patient Monitoring

- PSA every 6–12 mo × 5 yr; yearly after:
  - Should be undetectable (< 0.1 ng/mL) after prostatectomy
  - Should drop to < 0.5 ng/mL after radiation for best prognosis
- DRE every other year
- CT of abdomen/pelvis and/or bone scan if patient has new bone pain, rapid PSA rise, short doubling time

CODES

ICD9

- 185 Malignant neoplasm of prostate
- 601.9 Prostatitis, unspecified
- V16.42 Family history of malignant neoplasm of prostate

ICD10

- C61 Malignant neoplasm of prostate
- N41.9 Inflammatory disease of prostate, unspecified
- Z80.42 Family history of malignant neoplasm of prostate

CLINICAL/SURGICAL PEARLS

Prostate cancer requires informed decision making and a risk based approach; consider active surveillance if low risk and $<$10-yr life expectancy.

PROSTATE CANCER, LOCALIZED (T1, T2)

Nicholas J. Kuntz, MD
Judd W. Moul, MD, FACS

BASICS

DESCRIPTION

- Biopsy-proven adenocarcinoma of the prostate, clinically confined to the prostate gland
- Clinical T1 or T2, N0, M0

EPIDEMIOLOGY

Incidence

- Prostate cancer (CaP) (American Cancer Society Data)
  - Estimated 233,000 new cases and 29,480 deaths in 2014 in US
- Localized prostate cancer (LCaP)
  - 81% of newly diagnosed CaP

Prevalence

- Age dependent
  - CaP cumulative prevalence in US men
    - Age 50–60: 44%; Age 70–80: 83%
- 20–35% worldwide

RISK FACTORS

- Age
- Family history of CaP with highest risk in 1st-degree relative
  - Suggestion that familial breast cancer increasies prostate cancer risk
- African American race
  - 40% increased risk of disease
  - 2.4 times risk of mortality

Genetics

See “Prostate cancer, general considerations”

PATHOPHYSIOLOGY

- Genetic predisposition
- Chronic inflammatory states
- Oxidative stress

ASSOCIATED CONDITIONS

- Benign prostatic hypertrophy (BPH)
- Lower urinary tract symptoms (LUTS) (unrelated to cancer)
- Obesity

GENERAL PREVENTION

- See also “Prostate Cancer, prevention”
- There are unfortunately no approved agents for the chemoprevention of CaP. Major clinical

trials include:
- 5α-reductase inhibitors
  - Finasteride (PCPT trial, 2003)
    - 25% CaP risk reduction
  - Dutasteride (REDUCE trial, 2009)
    - 27% CaP risk reduction
- Vitamin E and selenium (SELECT trial, 2011)
  - Increases the risk of CaP by 17%

DIAGNOSIS

HISTORY
- LCaP is rarely symptomatic
- Unintentional weight loss or new-onset skelet al pain suggests nonlocalized disease
- LUTS
  - More commonly attributed to BPH

PHYSICAL EXAM
- Digital rectal exam (DRE)
  - No palpable nodule (cT1)
  - Nodule confined to prostate gland (cT2)
  - Ablation of lateral sulcus or palpable seminal vesicles suggests more advanced disease than T2

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Prostate-specific antigen (PSA)
  - Produced by prostatic epithelium
  - Half-life of 2–3 days; Not specific to CaP
  - A continuous parameter
    - The higher the value, the more likely the existence of CaP (1)[A]
- Routine PSA screening is controversial
  - 2013 AUA Guidelines (2):
    - Under age 40 yr: Do not screen [C]
    - 40–54 yr, average risk: Do not screen [C]
    - <55 yr at higher risk: Individualized decision [C]
    - 55–69 yr: Shared decision-making if considering PSA screening [B]
    - Greatest benefit of screening in men ages 55–69 yr
    - Routine screening interval: 2 yr [C]
    - >70 yr and <10–15-yr life expectancy: Do not screen [C]
- Other PSA parameters
  - PSA velocity/doubling time
    - Limited use in diagnosis (1)[A]
    - Velocity >2 ng/mL: Increased risk for death from CaP
  - % free PSA <10

- Increased (56%) risk of cancer (1)[A]
  - PSA density
    - ≥0.15 mg/mL/g suggests CaP
- CaP antigen 3 (PCA3) (see "PCA3 Prostate Cancer Gene 3 urine assay")
  - Limited clinical use in diagnosis
  - May help in decision to a repeat biopsy in men with a negative 1st biopsy (1)[A]

Imaging

- 2014 NCCN Guidelines for LCaP:
  - No imaging if low risk
  - Bone scan: PSA >10 ng/mL or Gleason ≥8
  - Pelvic CT or MRI
    - Lymph node involvement risk >10%
- ProstaScint imaging: Not indicated for LCaP
- No imaging modality can accurately estimate the extent of tumor and location within or surrounding the prostate

Diagnostic Procedures/Surgery

- Prostate biopsy (3)[C]
  - Diagnosis is based on histologic exam
  - Transrectal ultrasound guided (TRUS) transrectal or transperineal needle biopsy
    - Laterally directed, 18G, 10–12 cores
    - Increases detection rate
  - Periprostatic local anesthetic injection
  - Antibiotic prophylaxis is always recommended
  - Infection rate: 0.5–1% (see "Prostate biopsy, Infections and Complications")

Pathologic Findings

- Gleason score (See "Gleason Grading/Scoring System")
- Proportion of biopsies positive for carcinoma
- Presence of extraprostatic extension
- High-grade PIN and perineural invasion is usually reported

DIFFERENTIAL DIAGNOSIS

- Abnormal DRE: Granulomatous prostatitis prostatic cyst, calcifications, cancer
- Elevated PSA: UTI, BPH, acute or chronic prostatitis, recent prostatic instrumentation

TREATMENT

GENERAL MEASURES

- Assess life expectancy, overall health status, and tumor characteristics prior to treatment decisions (4)[A]
- Review risk and benefits of all treatments and engage patient in informed decision making process.
- Treatment recommendations based on cancer biology, patient overall health, life expectancy, and preferences

- Gleason score and tumor stage are predictive of cancer outcomes
- Risk strata are used to develop treatment recommendations (4)[A]
  - Low risk: PSA 10 and a Gleason score of 6 or less and clinical stage T1c or T2a
  - Intermediate risk: PSA >10–20 or a Gleason score of 7 or clinical stage T2b
  - High risk: PSA >20 or a Gleason score of 8 to 10 or clinical stage T2c

MEDICATION

First Line

- Primary androgen deprivation therapy (ADT)
  - Rarely indicated for LCaP (4)[C]
    - Palliation of symptomatic patients
    - Extensive or poorly differentiated tumors
    - Short life expectancy
  - Not recommended by 2014 NCCN Guidelines
- Neoadjuvant ADT for surgical treatment
  - Not recommended (1)[A]
- Neoadjuvant/concurrent androgen deprivation for 6 mo–3 yr with XRT increases survival vs. XRT alone or hormonal therapy alone (select intermediate and all high-risk patients)

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Radical prostatectomy (RP)
  - Removal of prostate gland, seminal vesicles, and ampulla of the vas; pelvic lymph node dissection for elevated risk of positive nodes
  - Cancer "cure" in truly localized disease
  - Option for low, intermediate risk with ≥10-yr life expectancy and selected high-risk patients (1)[B]
  - Similar survival between RP and watchful waiting in low-risk CaP, <65 yr (4)[B]
  - Technique:
    - Open (perineal or retropubic)
    - Laparoscopic (LRP), Robotic assisted laparoscopic prostatectomy (RALP): Lower blood loss and transfusion rates; oncologic and long-term outcome similar
    - Pelvic lymphadenotomy (PLND) if predicted nodal mets is ≥2%
    - Nerve-sparing surgery: Preoperatively potent patients, T1c, Gleason <7, and PSA <10 (1)[B]
    - Non–nerve-sparing for high risk (high erectile dysfunction rates)
- Salvage RP
  - Highly selected patients with local recurrence
  - Absence of metastatic disease
  - High morbidity

ADDITIONAL TREATMENT

Radiation Therapy

- External beam RT (EBRT)

- Intensity-modulated RT (IMRT) is preferred
- Image-guided RT (IGRT) if dose >78 Gy
- Dose: Low risk: 75–79 Gy, 8–9-wk fractionation; intermediate/high risk: Up to 81 Gy
- Combined with ADT
  - Neoadjuvant, concomitant, or adjuvant ADT
  - Increased survival in high-risk patients if given before and during EBRT (1)[B]
  - 4–6 mo or 2–3 yr for high risk (high Gleason or high volume based on biopsy)
- Irradiation to the pelvic lymph nodes; no general indication; ongoing trials (1)[B]

• Brachytherapy
- Delivered via interstitial seeds
  - Temporary: High-dose rate (HDR): Ir^{192}
  - Permanent: Low-dose rate (LDR): I^{125} or Pd^{103}
- Monotherapy: Low-risk disease
  - Dose: I^{125} 145 Gy and Pd^{103} 125 Gy
- Combined with EBRT: Intermediate/high risk
  - 40–50 Gy of EBRT
  - ± 4–6 mo of ADT
- Higher risk of side effects:
  - Previous TURP
  - Large (60–80 g) or small (<20 g) gland
  - Bladder outlet obstruction

• Stereotactic body RT (SBRT), ie, CyberKnife
- Highly conformal, high dose
- Hypofractionation (as little as 5 fractions)
- May be equivalent to EBRT; under trial

• Proton therapy
- Not recommended for routine use currently

Additional Therapies

• Active Surveillance
- See “Prostate Cancer, Very Low Risk and Active Surveillance”

• Cryosurgical ablation of the prostate (CSAP)
- Patients not suitable for RP or life expectancy <10 yr, gland <40 mL
- Freezing techniques to induce cell death
  - Placement of 12–15 17G cryoneedles under TRUS guidance
  - Thermosensors at external sphincter and bladder neck
  - Insertion of urethral warmer
  - 2 freeze–thaw cycles: –40°C at midgland and at the neurovascular bundle
- NCCN: Currently not recommended as routine primary therapy for LCaP

• High-intensity focused ultrasound (HIFU) and vascular-targeted photodynamic (VTP) therapies
- Currently not considered valid treatment options

Complementary & Alternative Therapies

Not applicable

ONGOING CARE

PROGNOSIS

- Dependent on risk strata
  - Low, intermediate, and high risk
  - Indicate probability of biochemical failure after definitive local therapy
- See on line prediction tools such as http://www.mskcc.org/cancer-care/adult/prostate/prediction-tools orPartin tables: http://urology.jhu.edu/prostate/partintables.php (Accessed August 23, 2014)

COMPLICATIONS

- RP
  - Significantly reduced if performed in a high-volume hospital and experienced surgeon
  - Intraoperative: Rectal injury (0–5%), major bleeding (1–12%), death (0–2%)
  - Postoperative: Deep vein thrombosis (0–8%), pulmonary embolus (1–8%), lymphocele (1–3%)
  - Long term: Incontinence (0–50%), stricture (2–9%), impotence (30–100%)
- RT
  - Short term: Bowel symptoms (bleeding, diarrhea, fecal incontinence), irritative voiding symptoms
  - Long term:
    - Genitourinary (16%): Strictures, hematuria, cystitis, incontinence
    - Gastrointestinal (10%) Proctitis, chronic diarrhea, small bowel obstruction
    - Increased risk of secondary cancers

FOLLOW-UP

Patient Monitoring

- No consensus for follow-up after definitive treatment of LCaP
- Usually followed for at least 10 yr
- NCCN: PSA every 6–12 for 5 yr, then every year, DRE every year (omitted if PSA undetectable)
- Palpable nodule on DRE and rising PSA can indicate local disease recurrence (1)[B]
- See “Prostate cancer, biochemical recurrence (elevated PSA)”

- V16.42 Family history of malignant neoplasm of prostate

ICD10

- C61 Malignant neoplasm of prostate
- Z80.42 Family history of malignant neoplasm of prostate

CLINICAL/SURGICAL PEARLS

- Represents majority of newly diagnosed men with CaP; minority of men will die from their disease.
- Nerve-sparing RP technique is standard of care.
- Surgical outcomes are highly dependent on surgeon experience.
- Radiation techniques, improving disease control, and reducing side effects.
- Consider active surveillance if low risk and <10-yr life expectancy.

PROSTATE CANCER, LOCALLY ADVANCED (CLINICAL T3, T4)

Erin M. Burns, MD
James S. Rosoff, MD

BASICS

DESCRIPTION

- Clinical stage T3 prostate cancer (CaP) refers to disease that is thought to extend outside the prostate and may be palpable or seen on imaging
- Pathologic stage T3 CaP refers to extracapsular extension (T3a), or tumor invading seminal vesicles (SVs) (T3b) based on final surgical pathology
- Clinical stage T4 CaP refers to palpable tumor that is fixed and/or invading adjacent structures
- Pathologic stage T4 CaP refers to tumor that is invading the bladder neck, external sphincter, rectum, or levator muscle, and/or is fixed to the pelvic sidewall based on final surgical pathology
- Transrectal ultrasound (TRUS) of the prostate, magnetic resonance imaging (MRI), and computed tomography (CT) can supplement physical exam findings to assist with diagnosing clinical stage T3 and T4 disease

EPIDEMIOLOGY

Incidence

Declining incidence of locally advanced CaP: 10–15% in 1989–1990, 1–5% in 2001–2003 (1,2)

Prevalence

N/A

RISK FACTORS

- Higher Gleason score, elevated prostate-specific antigen (PSA), and increased tumor volume on biopsy predict increased likelihood of locally advanced disease
- Older males (≥75) are more likely to present with high-risk prostate cancer (3)
- African Americans and men with diabetes tend to have more aggressive disease and higher stage at presentation (4)

Genetics

Research is ongoing to determine genetic markers that differentiate organ confined from locally advanced CaP

PATHOPHYSIOLOGY

- Extension beyond prostatic capsule occurs when tumor develops biologic ability to degrade physical barriers to cancer cell movement, such as the prostatic capsule and/or fascial investments of the prostate and SVs
  - Intermediate-grade (Gleason 7) and high-grade (Gleason 8–10) CaPs more commonly extend outside the prostate than low-grade (Gleason 6) CaP.

ASSOCIATED CONDITIONS
Locally invasive prostate cancer can present with resulting symptoms such as hematuria, obstructive voiding symptoms and changes in bowel habits

GENERAL PREVENTION
- 5α-Reductase inhibitors (5-ARIs): Finasteride and dutasteride
  - Discuss with patient risks/benefits of 5-ARI use for CaP prevention (5)[A]
- Vitamin E, selenium, vitamin C:
  - No beneficial effect; should not be used
- Statins, green tea, lycopene
  - Insufficient evidence to advocate these supplements for CaP prevention (6)

DIAGNOSIS
HISTORY
- Family history of CaP
- Voiding symptoms: Obstructive/irritative, hematuria

PHYSICAL EXAM
Digital rectal exam (DRE): Note palpable abnormalities, unilateral vs. bilateral, whether prostate is fixed, any extension of mass into adjacent structures

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- PSA
  - Positive predictive value (PPV): 12–32% for PSA levels 4–10, 60–80% for PSA levels >10, higher PSA increases risk for capsular penetration and SV invasion
  - Value is decreased by 5-ARIs, elevated with instrumentation, infection, larger prostate volume
  - Lab variability: 20–25% (7)[A]
- PSA density: Serum PSA/prostate volume
  - >0.15 is associated with CaP, >0.35 is associated with 66% risk of extraprostatic extension
- PSA velocity
  - Rate of rise of >0.75/yr is a specific marker for CaP
  - Should be calculated over 18 mo with 3 PSA measurements
- Free PSA (fPSA)
  - Lower fPSA is found in CaP; <10% free correlates with 56% probability of CaP
    - PSA velocity, density, and fPSA do not correlate with Gleason score or CaP stage
- PCA3
  - RNA overexpressed in CaP, higher values indicate higher risk of CaP
  - Collected via post-DRE urine sample
  - Sensitivity 48%, specificity 79%, not currently used for routine screening
  - May correlate with Gleason score (8)

Imaging
- TRUS

  - Low sensitivity (23–66%), specificity (46–86%), and PPV (50–62%) for predicting extracapsular extension (9)[A]
  - Useful in guiding widespread sampling of prostate tissue during biopsy
- MRI
  - May delineate T2 from T3 disease
  - Specificity for T3 disease is 95% when PSA >10, abnormal DRE and >3 cores positive on TRUS biopsy (10)[A]
- CT
  - Consider for staging when PSA >20 or Gleason score ≥8
- Bone scan
  - Indicated when PSA ≥20 to evaluate for skelet al metastases
- ProstaScint
  - May be useful in ruling out metastatic disease in patients with locally advanced CaP

Diagnostic Procedures/Surgery
- TRUS-guided prostate biopsy
  - Should be performed for abnormal DRE or PSA elevation

Pathologic Findings
TRUS biopsy can confirm T3 disease with biopsy of the capsule or SVs

DIFFERENTIAL DIAGNOSIS
- PSA can be elevated in the setting of prostatic and/or urethral instrumentation, infection, or benign prostatic hypertrophy (BPH)
- Lesions of the prostate seen on imaging can be areas of infarct, prostatitis, or tumor
- No single diagnostic modality can accurately predict pathologic stage of CaP; incorporating multiple clinical parameters helps to best determine disease extent

TREATMENT

GENERAL MEASURES
- Currently no consensus regarding optimal management of locally advanced CaP
- Compared to clinically localized, low-grade CaP, locally advanced CaP has a higher risk of recurrence after any single treatment modality (up to 30%), and should be treated unless life expectancy is ≤5 yr

MEDICATION
First Line
- Androgen deprivation therapy (ADT): Option for patients unable or unwilling to undergo surgery or radiation therapy (RT)
  - Orchiectomy, luteinizing hormone-releasing hormone (LHRH) agonist or antagonist
  - Can be administered continuously or intermittently; optimal timing of administration with respect to quality of life and survival benefit is debated
  - More effective when combined in neoadjuvant or adjuvant fashion with RT

Second Line
Antiandrogen monotherapy is less effective and not usually recommended; however, side

effects are more tolerable overall

SURGERY/OTHER PROCEDURES

- Radical prostatectomy (RP) with pelvic lymph node dissection (PLND)
  - Select patients can benefit from local control
  - Complete excision/cure is possible
  - Clinical overstaging of T3 disease can occur in up to 7–27% of patients, thus exclusion from surgery on the basis of clinical staging may be inappropriate
- Neoadjuvant ADT does not confer cancer specific or overall survival (OS) benefit
- Adjuvant RT 55–70 Gy improves local control and reduces the risk of biochemical recurrence for T3 disease; it may also confer OS benefit (11)[A]
  - Indications include T3 disease, positive surgical margins, Gleason score of 8–10
  - Should be administered within 1 yr of surgery and after operative side effects (eg, urinary continence) have improved/stabilized

ADDITIONAL TREATMENT

Radiation Therapy

- 75–80 Gy to prostate, SVs, and pelvic lymph nodes, or 40–50 Gy and brachytherapy for cT3/T4 disease
  - NCCN guidelines recommend 2–3 yr neoadjuvant/concomitant/adjuvant ADT for higher disease free and OS in men with T3 and T4 disease (12)[A]
- Advances in 3D conformal, intensity-modulated and image-guided RT are designed to deliver higher doses directly to prostate, avoiding adjacent structures and thus limiting side effects

Additional Therapies

- Cryoablation of the prostate
  - Higher rates of biochemical failure than RT (87% vs. 53%) for T2c–T3 CaP (13)[A]
- High-intensity focused ultrasound (HIFU)
  - Currently investigational, may prove to be an option in combination with ADT for intermediate- and high-risk CaP

Complementary & Alternative Therapies

Clinical trials should be considered

ONGOING CARE

PROGNOSIS

- Significant risk of progression and disease-specific death if locally advanced prostate cancer is left untreated
  - OS without intervention ranges from 10 to 92% at 5 yr and 14–78% at 10 yr for high-grade/stage CaP
- RP for T3 CaP: OS 64–96% at 5 yr, 13–72% at 10 yr
  - Cancer-specific survival (CSS): 85–92% at 5 yr, 79–82% at 10 yr
- RT monotherapy: OS 60–70% at 5 yr and $<50\%$ at 10 yr
  - RT with ADT: OS 72–87% at 5 yr

COMPLICATIONS

- Therapy complications are similar to those for localized CaP
- Untreated T3–T4 CaP may lead to hematuria, obstruction at the level of the prostate requiring indwelling catheter or transurethral resection of the prostate, or ureterovesical junction obstruction requiring ureteral stents or percutaneous nephrostomy

FOLLOW-UP

Patient Monitoring

- Periodic PSA measurements, initially at 3-mo intervals posttherapy and then gradually increasing to annually
- Failure of PSA to nadir or consecutive rises in PSA should prompt further evaluation with bone scan and/or CT
  - Risk of biochemical recurrence increased in: Gleason score 8–10, PSA doubling time <10 mo (14)
  - ProstaScint scan may be helpful in identifying local recurrence if bone scan and CT scan are negative
  - Consider additional treatment options such as ADT, adjuvant RT, and/or chemotherapy and participation in clinical trials

CODES

ICD9

- 185 Malignant neoplasm of prostate
- 198.1 Secondary malignant neoplasm of other urinary organs
- 198.82 Secondary malignant neoplasm of genital organs

ICD10

- C61 Malignant neoplasm of prostate
- C79.11 Secondary malignant neoplasm of bladder
- C79.82 Secondary malignant neoplasm of genital organs

CLINICAL/SURGICAL PEARLS

- Risk assessment requires incorporating serum PSA, clinical stage, Gleason score, tumor volume, and patient age and comorbidities to best provide counseling and treatment recommendations.
- RP should include PLND for locally advanced CaP, and adjuvant RT should be offered for T3–T4 disease, particularly if surgical pathology demonstrates positive margins.

- RT should be administered in conjunction with ADT for locally advanced CaP to maximize survival benefit with support from randomized clinical trials.

PROSTATE CANCER, LOCALLY ADVANCED (PATHOLOGIC T3, T4)

Divya Ajay, MD
Judd W. Moul, MD, FACS

BASICS

DESCRIPTION

- Pathologic T3/T4 (pT3/T4) is prostate cancer that extends beyond the confines of the prostatic gland without evidence of lymph node or distant metastases after radical prostatectomy (RP) based on pathology
- Pathologic stage is determined by histologic analysis of the prostate, SVs, and lymph nodes
- Per the TNM system, this is considered locally advanced prostate cancer defined by the categories T3a, T3b, T4, if combined with an absence of regional lymph node metastasis (N0) and distant metastasis (M0). Where:
  - T3a: Extracapsular extension
  - T3b: Tumor invades seminal vesicle(s)
  - T4: Tumor is fixed or invades adjacent structures other than seminal vesicles (bladder neck, external sphincter, rectum, levator muscles, or pelvic wall)
- Tumor volume, grade, pelvic lymph node involvement, extracapsular and SV extension, and surgical margin status predict biochemical recurrence-free survival and cancer-specific survival

EPIDEMIOLOGY

Incidence

PSA screening has led to downward pathologic stage migration. Since 2001, rates of extracapsular extension had remained stable at 25%. In 2012 and 2013, USPSTF and AUA revised guidelines against PSA screening; this may increase rates of T3–T4 disease.

RISK FACTORS

- Poor health literacy, use of multivitamins more than 7 times a week, obesity, and lack of screening increase the risk of locally advanced disease at presentation
- Partin tables use DRE-based primary T stage, serum PSA, and Gleason grade to predict cancer extent and long-term outcomes
- D'Amico has also suggested a risk stratification into low, intermediate, and high risk based on DRE, PSA, and Gleason grade
- While these predictive models are helpful in counseling patients, studies show that status post prostatectomy up to 3% of men were down-T-staged and 35% of men were up-T-staged (1)

Genetics

- Abnormal p53 expression, low levels of p16 and deregulation of the RB pathway and aneuploidy of Chr 9 have been associated with locally advanced prostate cancer
- In 2013, 2 commercial genetic biomarker assays (Prolaris, Oncotype Dx-prostate) became

available. Based on RNA expression profiles, these assays may help to predict more advanced stage/grade

PATHOPHYSIOLOGY

- Peripheral zone tumors tend to invade the capsule more often than transition zone tumors
- Tumor spread:
  - T3a (extracapsular invasion) occurs posteriorly and posterolaterally by vascular invasion and increases risk of recurrence after RP
- Tumor volume:
  - Extraprostatic invasion is more common in tumors >0.5 cm^3 and seminal vesicle invasion is more common in tumors >4 cm^3
  - Tumor volume does not independently predict postsurgical progression once grade, pathologic stage, and margins are accounted for

ASSOCIATED CONDITIONS

Locally invasive prostate cancer can present with resulting symptoms such as hematuria, obstructive voiding symptoms, and changes in bowel habits

GENERAL PREVENTION

- 5-Alpha Reductase Inhibitors (5-ARIs): Finasteride and dutasteride; discuss with patient risks/benefits of 5-ARI use for CaP prevention; not FDA approved
- Vitamin E, Selenium, Vitamin C: No beneficial effect; should not be used
- Statins, Green Tea, Lycopene: Insufficient evidence to advocate these supplements for CaP prevention

DIAGNOSIS

HISTORY

- Family history of CaP; race
- Voiding symptoms: Obstructive/irritative, hematuria
- Any bone/back/hip pain or hematuria?

PHYSICAL EXAM

Digital rectal exam (DRE): Note palpable abnormalities, unilateral vs. bilateral, whether prostate is fixed, any extension of mass into adjacent structures

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- PSA
  - Positive predictive value (PPV): 12–32% for PSA levels 4–10, 60–80% for PSA levels >10, higher PSA increases risk for capsular penetration and SV invasion
  - Value is decreased by 5-ARIs, elevated with instrumentation, infection, larger prostate volume
  - Laboratory variability: 20–25%
- PSA density: Serum PSA/Prostate volume
  - >0.15 is associated with CaP, >0.35 is associated with 66% risk extra-prostatic extension
- PSA velocity
  - Rate of rise of >0.75/yr is a specific marker for CaP

  – Should be calculated over 18 mo with 3 PSA measurements
- Free PSA (fPSA)
  – Lower fPSA is found in CaP; <10% free correlates with 56% probability of CaP
- PSA velocity, density, and fPSA do not correlate with Gleason score or CaP stage
- PCA3
  – RNA overexpressed in CaP, higher values indicate higher risk of CaP
  – Collected via post-DRE urine sample
  – Sensitivity 48%, Specificity 79%, not currently used for routine screening
  – May correlate with Gleason score

Imaging
- Preoperative imaging for locally advanced cancer:
  – Pelvic CT or MRI is indicated for locally advanced disease (PSA >20 ng/mL, Gleason score 8 or greater, or a T3/T4 tumor) to evaluate for pelvic lymph node involvement
  – Distal metastasis may be ruled out using Technetium 99 bone scan, axial MRI, PET, and immunoscintigraphy
  – Multiparametric prostate MRI using a 3T magnet and/or an endorectal coil is being touted to improve accuracy
  – Repeat or 1st time staging with bone scan and/or CT may be needed in selected patients who are significantly upstaged and/or upgraded after RP

Diagnostic Procedures/Surgery
Prostate biopsy rarely indicates the presence of pathologic T3 disease; seminal vesical biopsy may confirm T3

Pathologic Findings
- Clinically localized disease is upstaged if pathologic tissue from a prostatectomy indicate T3 or T4 disease
- The risk of cancer recurrence after prostatectomy is based on extracapsular extension, seminal vesicle involvement, lymph node involvement, and corresponds most strongly with a positive surgical margin
- A gross PSMs carry worse 5-r progression survivals vs. microscopic margins 65% vs. 40%
- PSM at the bladder neck, vas deferens, and posterolateral surface of the prostate have been shown to have a particularly poor progression-free outcomes in comparison to PSM at the apex, posterior, anterior, or lateral prostate
- With respect to the nerve-sparing technique, when patients are selected appropriately, no statistical difference has been shown in PSM in comparison to the nonnerve sparing technique

TREATMENT

GENERAL MEASURES
- The American Society of Therapeutic Radiation Oncology (ASTRO) and the American Urologic Association (AUA) have a joint guideline on the use of adjuvant and salvage radiotherapy after prostatectomy
  – They note clinical benefit of adjuvant radiotherapy in reducing clinical progression in

high-risk patients (seminal vesicle involvement, positive surgical margins, extra prostatic extension) while the impact on future development of metastasis and survival remains less clear
  - It also emphasizes the value of early intervention with a threshold PSA $\geq$ 0.2 ng/mL with a 2nd confirmatory after surgery to confirm relapse (2)
- Therapy is considered adjuvant if the postoperative PSA level is undetectable ($<$0.2 ng/mL)
- Therapy is considered salvage if there is a biochemical/PSA recurrence
- Lymph node metastasis is an indication for ADT, pelvic RT, or observation

MEDICATION

First Line

- Androgen deprivation therapy (ADT) using an LHRH agonist or GNRH antagonist with or without an oral antiandrogen is sometimes added to adjuvant or salvage EBRT although there is not yet level I evidence from RCTs in the adjuvant/salvage setting for pathologic T3/T4 disease
- Potential benefits of ADT must be balanced against the side-effect profile

Second Line

Newer generation oral hormonal therapies (abiraterone acetate, enzalutamide) may have future role in adjuvant and salvage therapy

SURGERY/OTHER PROCEDURES

- In the setting of clinical T3/T4 disease, extended lymph node dissection is gaining support in these patients (obturator, external iliac, internal iliac, and presacral nodes)
- Neoadjuvant ADT with leuprolide and flutamide for 3 mo prior to RP has shown to reduce positive margins, but has no impact on lymph node metastasis or 5-yr biochemical recurrence rate. It may be used in selected cases for technical downsizing
- Chemo hormonal downstaging trials are ongoing before RP for clinical T3/T4 disease

ADDITIONAL TREATMENT

Radiation Therapy

- 3 randomized trials have been completed demons-trating a benefit to early adjuvant radiation therapy
- Treatment is optimally offered after continence is restored, to allow healing to take place after surgery
- With a median follow-up of 12 yr, (Southwest Oncology Group [SWOG] 8794), confirmed a significant improvement in the risk of metastasis (43% vs. 54%) and overall survival (41% vs. 52%) among patients randomized to adjuvant radiation (3)
- The largest trial included 1,000 patients with T3 disease randomly assigned to 60 Gy of radiation vs. observation. At 5-yr, progression-free survival was significantly improved (74% vs. 53%), with no demonstration of an overall survival benefit (4)
  - A subsequent update suggested that the benefit might be limited to patients with positive surgical margins
- A German trial of 395 patients demonstrated a biochemical progression-free survival benefit (72% vs. 54%) to early radiation therapy in this pT3 group. The benefit of therapy was observed with or without positive margins (5)
- Genomic assays may allow more rationale decision making for post operative radiation

following radical prostatectomy (7)

Additional Therapies

Proton beam external radiotherapy is offered at selected major US centers. However, there is no Level I evidence that it is superior to photon-based radiotherapy using an intensity modulated method.

Complementary & Alternative Therapies

No level I evidence of benefit

ONGOING CARE

PROGNOSIS

- With salvage EBRT and persistent or increasing PSA levels after surgery 45% of patients were free of disease at 4 yr after salvage EBRT
  - Patients with no adverse risk features achieved a 4-yr progression-free probability of 77%. A nomogram based on established risk factors to more accurately identify patient-specific risks to assist in clinical decision-making is available (6)

COMPLICATIONS

- Morbidity from pelvic RT include radiation proctitis, cystitis, incontinence, ED, lymphedema, and stricture disease
- Morbidity from hormone therapy include hot flushes, breast tenderness, osteoporosis, diabetes mellitus, depression, and cardiac disease

FOLLOW-UP

Patient Monitoring

For pT3/T4 after RP; patients are generally followed every 3 mo for the 1st yr, every 6 mo for the next 2–5 yr and yearly thereafter depending on risk.

CODES

ICD9

- 185 Malignant neoplasm of prostate
- 198.1 Secondary malignant neoplasm of other urinary organs
- 198.82 Secondary malignant neoplasm of genital organs

ICD10

- C61 Malignant neoplasm of prostate
- C79.11 Secondary malignant neoplasm of bladder
- C79.82 Secondary malignant neoplasm of genital organs

CLINICAL/SURGICAL PEARLS

- Pathologic T3/T4 prostate cancer includes extracapsular cancer than extends beyond the gland, without distant metastasis.
- High clinical stage, PSA levels, and Gleason score (from biopsy cores) predict more advanced pathologic staging.
- Level I evidence from 3 RCTs support adjuvant EBRT for high-risk pT3/T4 prostate cancer after RP.
- For patients who do not receive adjuvant EBRT, close follow-up with early salvage EBRT is very commonly practiced.
- There is no level I evidence for adding ADT to EBRT as part of adjuvant or salvage EBRT, but selected high-risk patients may benefit.

PROSTATE CANCER, METASTATIC (CLINICAL AND PATHOLOGIC N+, M+)

Debasish Sundi, MD
Misop Han, MD

BASICS

DESCRIPTION

- Metastatic prostate cancer (CaP) can be nodal disease discovered at prostatectomy or on imaging (N+), or can be distant spread (M+). Most commonly, it affects distant lymph nodes and bone.
- Can be the initial presentation or develop after previous local therapy for CaP, such as radiation therapy or RP.

EPIDEMIOLOGY

Incidence

With PSA screening, the number of men with metastatic disease at 1st presentation has declined over the last 20 yr (~4%, 2003–2009, SEER data).

Prevalence

Nearly 28,800 men die annually (US) from metastatic disease.

RISK FACTORS

- African American ancestry
- High-fat diet
- Family history

Genetics

None

PATHOPHYSIOLOGY

- CaP arises in prostate glandular epithelium and can spread through the lymphatics or hematogenously.
- Batson plexus are paravertebral veins that extend up from the pelvis to the dural sinuses. This plexus is likely responsible for the high rate of spread of CaP to the vertebral column.
- Testosterone and dihydrotestosterone are the primary regulators of prostate growth.
- 2 sources of androgens in men; testes (95% of total androgens); adrenal glands (remaining 5%).

ASSOCIATED CONDITIONS

Osteoporosis secondary to hormonal therapy

GENERAL PREVENTION

Early androgen blockade for high-risk patients with localized cancer may delay the development of detectable metastatic disease.

DIAGNOSIS

HISTORY

- Urinary symptoms can be indistinguishable from those of BPH and include increased urinary frequency, nocturia, difficulty initiating and maintaining a steady stream of urine, dysuria, and hematuria, and sexual dysfunction.
- The most common symptom of metastatic disease is bone pain, often in vertebrae, pelvis, or ribs.

PHYSICAL EXAM

- DRE may reveal a nodular or enlarged prostate, but the exam may be unremarkable.
- After RP the fossa may be empty or contain palpable recurrent cancer.
- Adenopathy may be detected in the supraclavicular and inguinal lymph nodes.
- Point tenderness elicited on vertebral bodies or rib cage may be indicative of spinal or epidural metastasis.
- CaP metastatic to the spine may result in neurologic symptoms, either from vertebral instability or epidural extension of tumor. Note any leg weakness or urinary and fecal incontinence.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Serum PSA should be obtained on all patients prior to the start of therapy and is a useful marker of response to therapy.
- Prostatic acid phosphatase is elevated in up to 67% of men with metastatic disease
- Monitor serum testosterone to verify that androgen ablation has testosterone <50 ng/dL

Imaging

- CT of the abdomen and pelvis and bone scan should be performed after initial diagnosis. Bone metastases are typically osteoblastic.
- Evaluate for hydronephrosis secondary to ureteral obstruction.

Diagnostic Procedures/Surgery

Biopsy of prostate or metastatic lesions is required to establish a diagnosis. Identification of visceral metastasis with neuroendocrine features may alter initial management to include initial chemotherapy.

Pathologic Findings

- Adenocarcinoma most common.
- Neuroendocrine carcinoma of the prostate is associated with high Gleason score (9–10), low or undetectable PSA levels, and visceral and lytic bone metastases.

DIFFERENTIAL DIAGNOSIS

- Paget disease; bone metastases from other malignancies
- Adenopathy can be due to lymphoma or other advanced malignancy.

TREATMENT

GENERAL MEASURES

- Androgen blockade for metastatic disease, which is usually considered noncurative.

- Androgen deprivation therapy (ADT) can be administered continuously as well as intermittently (intermittent hormonal therapy or IHT); studies suggest similar survivals when continuous combined androgen blockade (CAB) is compared to intermittent CAB, especially with lower disease burdens.

MEDICATION

First Line

- ADT (1)[B]
  - ADT to achieve castrate levels of testosterone, generally considered <50 ng/mL, with some advocating <20 ng/mL (similar to orchiectomy levels)
  - Testicular androgen secretion is regulated by the hypothalamus, and the pulsatile secretion of luteinizing hormone releasing hormone (LHRH)
  - LHRH agonists (leuprolide, goserelin, triptorelin) interfere with this pulsatile secretion, and after initial flare (testosterone increase) at 7–10 days, achieve medical castration at about 30 days.
  - LHRH antagonists (degarelix) rapidly decrease testosterone levels with 44% testosterone castration (<50 ng/dL) at day 1, 96% by day 3. No flare, so useful in situations such as spinal cord compression.
  - Antiandrogens (bicalutamide, flutamide, nilutamide) block the LHRH flare reaction initially caused by LHRH agonists and should be used for 7–10 days. Long-term use of antiandrogens + LHRH agonists past the flare period, or CAB is controversial.
  - ADT using high-dose bicalutamide (150 mg/d), called antiandrogen monotherapy, is associated with less side effects but may also be a less effective form of ADT and should not be routinely used (not FDA approved in US).
  - Initial chemohormonal therapy has recently been reported to extend survival in men presenting with newly diagnosed metastatic prostate cancer (4)
    - ECOG3805 clinical trial demonstrated a 12 month survival advantage when docetaxel was initially combined with androgen deptivation therapy

Second Line

- Most patients initially benefit from ADT, but the disease usually progresses after 1–4 yr
  - Castration-resistant CaP (CRPC): Progression on primary hormonal with a testosterone level of <50 ng/mL, and a rising PSA
  - With measurable disease on bone or CT scan of the abdomen and pelvis, the disease is classified as metastatic castration-resistant prostate cancer (mCRPC)
- Secondary hormonal therapy is often utilized for CRPC without metastasis
  - If on antiandrogen, the antiandrogen should be discontinued; this will result in a PSA decline in 5–20% of patients
  - Addition of an antiandrogen will result in PSA declines of 50% in 15–54% of patients, with median duration of response 4–6 mo
  - Ketoconazole blocks testicular and adrenal androgen synthesis; associated with $>50\%$ PSA decline in over 50% of patients
  - LHRH agonists are continued during therapy to prevent escape from androgen blockade
- Several systemic therapies have demonstrated improved overall survival for metastatic castrate-resistant disease and are discussed in detail in the section on Prostate cancer, rising

PSA following androgen ablation (Castratration Resistant Prostate Cancer (CRPC, and mCRPC), Section I.
  - Docetaxel, sipuleucel-T, cabazitaxel, abiraterone, enzalutamide, and radium 223
  - Mitoxantrone is also an FDA-approved agent for palliation of symptomatic CRPC
  - For asymptomatic or minimally symptomatic patients, sipuleucel-T immunotherapy can be used; other agents can be used with more significant symptoms
  - In patients with neuroendocrine features, androgen blockade should be initiated along with an immediate chemotherapy regimen incorporating cisplatin/etoposide, carboplatin/etoposide, or a docetaxel-based regimen

SURGERY/OTHER PROCEDURES

- Resection of solitary metastases is not generally performed with curative intent.
- Decompression of epidural metastatic CaP can result in stabilization of the spinal cord and neurologic symptoms. Best results are obtained if the procedure is performed within 24 hr of the onset of symptoms.
- Stabilization of weight-bearing bones (femur and hip) by internal fixation or replacement of the joint prophylactically may prevent fracture.
- In one randomized trial, immediate ADT was associated with improved overall and disease-specific survival among men who had pathologically positive lymph nodes after RP (2)[A]. However, this study was limited by sample size and lack of central pathologic review. In a randomized EORTC study with clinically node-positive disease, early ADT did not have any survival benefit. Because of the gradual natural history of CaP (median survival after development of metastasis after RP = 5 yr (3)[C]) and because the oncologic benefit of early ADT is uncertain, many consider it reasonable to delay ADT until symptoms or measurable disease on imaging are present, to minimize systemic adverse effects of ADT.

ADDITIONAL TREATMENT

Radiation Therapy

- Radiation can be used to palliate solitary painful bony metastases.
- Strontium^{89} and samarium^{153} (β-emitters) can palliate bone pain and are most useful for diffuse metastasis.
- Radium-223 (α-emitter) can also be used in the setting of symptomatic bone metastasis

Additional Therapies

- Bone health
  - Patients should receive calcium (1,200 mg/d) and vitamin D (800–1,000 IU/d) supplements.
  - With ADT, consider zoledronate 4 mg IV yearly, alendronate 70 mg PO weekly, denosumab (RANK ligand inhibitors Prolia 60 mg q6mo SQ for men on ADT or Xgeva with bone mets 120 mg SQ q4wk).
- Metastatic CRPC: Zoledronate 4 mg adjusted to renal function every 3–4 wk IV or denosumab (Xgeva) 120 mg SQ q4wk to prevent skelet al-related events.

Complementary & Alternative Therapies

Weight-bearing exercise and stopping smoking benefits osteoporosis.

ONGOING CARE

PROGNOSIS

- The estimated 5-yr survival of metastatic CaP is 28% (3)[C].
- For patients with lymph node–positive disease post-RP, adjuvant hormone ablation following RP increases overall survival by 2.6 yr vs. RP alone (13.9 vs. 11.3 yr) and reduces mortality risk by ~46%.
- With metastatic CaP starting androgen blockade, the median time to progression is 18–24 mo. The median survival once patients progress on androgen blockade is 12–19 mo.

COMPLICATIONS

- ADT: Hot flashes, loss of sexual function and libido, loss of muscle mass, decreased in bone mineral density, weight gain, diabetes, lipid profile changes, and neurocognitive dysfunction.
- In a metaanalysis of 8 randomized controlled trials, long-term ADT was not associated with an increased risk of death from cardiovascular causes, however.
- Antiandrogens: Increased liver function test.
- Skelet al-related events: Defined by pathologic fracture, spinal compression/vertebral body collapse, osteonecrosis of the jaw, radiation or surgery to bone, or change in antineoplastic therapy. Androgen blockade can cause osteopenia/osteoporosis; bisphosphonate/RANK ligand therapy can limit reductions in bone mineral density.
  - Zoledronic acid: Renal insufficiency, adjust based on creatinine.
  - Osteonecrosis of the jaw can result from bisphosphonates and RANK ligand inhibitors; avoid major dental work (extractions) on therapy; perform oral exam before starting.

FOLLOW-UP

Patient Monitoring

- Monitoring patients is controversial. With start of androgen blockade: Check PSA every 3 mo. Confirm castrate testosterone (<50 ng/dL) periodically and upon demonstration of rising PSA while on LHRH therapy.
- At PSA progression, antiandrogen should be withdrawn, and if the patient continues to progress, a CT scan of the abdomen and pelvis should be obtained.
- Timing of PSA testing during chemotherapy is controversial; usually every 3 wk.
- Serum creatinine should be monitored for patients on bisphosphonates. Zoledronic acid should not be given with a Cr >2 mg/dL.
- Monitoring for osteoporosis, obesity, insulin resistance, lipid alteration, and the concern of increased risk of diabetes and cardiovascular diseases in men on ADT should be considered.

CODES

ICD9

- 185 Malignant neoplasm of prostate
- 196.5 Secondary and unspecified malignant neoplasm of lymph nodes of inguinal region and lower limb
- 198.5 Secondary malignant neoplasm of bone and bone marrow

ICD10

- C61 Malignant neoplasm of prostate
- C77.4 Sec and unsp malig neoplasm of inguinal and lower limb nodes
- C79.51 Secondary malignant neoplasm of bone

CLINICAL/SURGICAL PEARLS

- ADT is the 1st-line treatment for metastatic CaP.
- There are several antiandrogen and chemo-immunotherapeutic options for men with ADT-refractory metastatic CaP.

- Bone-related issues should be considered in this population.

PROSTATE CANCER, POSITIVE MARGIN FOLLOWING RADICAL PROSTATECTOMY

Kiranpreet K. Khurana, MD
Eric A. Klein, MD, FACS

BASICS

DESCRIPTION

- Prostate cancer that extends to the margin of resection upon pathologic analysis of radical prostatectomy specimen
- May be reported as: Focal or extensive, solitary or multiple

EPIDEMIOLOGY

Incidence

- 5–27% for organ-confined prostate cancer (1)
- 17–65% for nonorgan-confined prostate cancer (1)

Prevalence

N/A

RISK FACTORS

- Higher preoperative prostate-specific antigen (PSA)
- Higher clinical stage
- Higher Gleason score
- Higher pathologic stage
- Surgeon experience

Genetics

None directly correlate with positive surgical margin (PSM)

PATHOPHYSIOLOGY

- 3 causes of PSM:
  - Tumor extends beyond prostate to margin of resection
  - Disruption of prostate capsule exposed cancerous glands
  - Artifact from intraoperative manipulation of prostate or pathologic processing

ASSOCIATED CONDITIONS

Nonorgan-confined prostate cancer: Higher likelihood of PSM compared to organ confined

GENERAL PREVENTION

- Do not dissect too closely at prostatic apex or posterolaterally since PSM frequently seen there
- For radical prostatectomy, choose surgical approach with most familiarity to surgeon

DIAGNOSIS

HISTORY

History of risk factors (higher PSA, clinical stage, and Gleason grade) may increase chance of PSM

PHYSICAL EXAM

Digital rectal exam has been shown to be unnecessary if PSA is undetectable

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Monitor PSA at follow-up visits
- In patients with PSM, there is 25–40% chance of subsequent biochemical recurrence (1)[B]

Imaging

- No additional imaging needed after radical prostatectomy for PSM unless there is suspicion of locoregional recurrence or metastatic disease
- Bone scan, pelvic MRI, and/or computer tomography scan may be considered if above suspected (2)[C]
- Indium In 111 ProstaScint is also indicated as a diagnostic imaging agent in postprostatectomy patients with a rising PSA and a negative or equivocal standard metastatic evaluation in whom there is a high clinical suspicion of occult metastatic disease. Limited utility for use in this setting

Diagnostic Procedures/Surgery

None indicated

Pathologic Findings

- PSM is a pathologic diagnosis
  - Most common site is prostatic apex
  - Posterolateral margin and bladder neck also commonly involved
  - Note that capsule is missing at the apex, so PSM at the apex may be artifactual
- Often classified as: Focal or extensive, solitary or multiple
  - Extensive and/or multiple PSM increase chance of biochemical recurrence, but these subclassifications of PSM do not have greater predictive usefulness than comparing positive vs. negative surgical margin alone (1)[B]

DIFFERENTIAL DIAGNOSIS

- Nonorgan-confined disease with extraprostatic extension or locally advanced disease
- Iatrogenic capsular incision

TREATMENT

GENERAL MEASURES

- Surgical approach (open, laparoscopic, robotic) does not appear to influence rate of PSM (3)[B]
  - Use good surgical principles to avoid PSM
  - PSM vary by different pathologic sectioning
  - Surgical experience decreases rate of PSM

MEDICATION

First Line
N/A

Second Line
N/A

SURGERY/OTHER PROCEDURES
N/A

ADDITIONAL TREATMENT
Radiation Therapy
- External beam, delivered as 3D-conformal or intensity modulated
  – 64–65 Gy usual dose
- Adjuvant radiotherapy shown to decrease biochemical and local recurrence, and clinical progression (2)[A]
- Effect on subsequent metastasis and overall survival not as clear
- Treatment with adjuvant radiotherapy results in lower use of salvage treatment
- Since majority of patients with PSM do not develop clinical recurrence, immediate adjuvant radiotherapy may lead to overtreatment
- However, salvage radiotherapy may not be as effective for high-risk disease
- Controversy over use of immediate vs. salvage adjuvant therapy

Additional Therapies
- ·Radiation Therapy Oncology Group trial 9601 is investigating radiotherapy with or without long-term androgen deprivation in postprostatectomy men with pT3N0 disease or pT2N0 disease with a positive margin with PSA $\geq$0.2–4 ng/mL
  – Preliminary results show that 24 mo of antiandrogen therapy (bicalutamide) and radiotherapy improve biochemical-free survival and incidence of metastatic disease
  – Full results awaited
- Radiotherapy and androgen deprivation in combination after local surgery (RADICALS) trial is evaluating immediate adjuvant radiotherapy vs. salvage radiotherapy
  – Also addresses role of androgen deprivation
  – Results awaited

Complementary & Alternative Therapies
See “Additional Therapies” above

ONGOING CARE

PROGNOSIS
- Not all PSM result in biochemical recurrence, nor higher risk of metastatic disease and death, but those with PSM are at higher risk of both than those with negative margins; these risks are associated with other pathologic features as well
- Prediction tools such as http://nomograms.mskcc.org/Prostate/PostRadicalProstatectomy.aspx are used at some centers for decision making concerning postradical prostatectomy management
- Preliminary results with new genomic classifers may indicate which patients might benefit form adjuvant radiaion therap (4)

COMPLICATIONS

- Complications related to radiotherapy (2):
  - Grade 1 or 2 acute toxicities: Common, up to 45%
  - Grade 3 or 4 acute toxicities: Up to 20%
  - Up to 28% may develop late toxicities
    - Urinary incontinence, stricture more common than gastrointestinal toxicities (proctitis)

FOLLOW-UP

Patient Monitoring

- PSA every 3–6 mo for 1st 3–5 yr, then annually thereafter
  - Value $\geq$0.2 ng/dL after surgery with confirmatory value of $\geq$0.2 ng/dL defines biochemical recurrence

Patient Resources

American Cancer Society.

- Prostate Cancer, Locally Advanced (Pathologic T3, T4)
- Prostate Cancer, Positive Margin Following Radical Prostatectomy Image ☼
- PSA Elevation, General
- Reference Tables: TNM: Prostate Cancer

CODES

ICD9

- 185 Malignant neoplasm of prostate
- V45.77 Acquired absence of organ, genital organs

ICD10

- C61 Malignant neoplasm of prostate
- Z90.79 Acquired absence of other genital organ(s)

CLINICAL/SURGICAL PEARLS

- PSM most commonly found at prostatic apex, posterolaterally, and bladder neck.
- Avoid overzealous dissection at these locations during radical prostatectomy in patients suspected of being high-risk for PSM.
- PSM are diagnosed pathologically and may be real or artifactual.
- Subset of men with PSM develop biochemical recurrence.
- Adjuvant radiotherapy decreases chance of biochemical and local recurrence but effect on metastatic disease and overall survival not clear.

PROSTATE CANCER, RISING PSA FOLLOWING ANDROGEN ABLATION (CASTRATION-RESISTANT PROSTATE CANCER, CRPC AND mCRPC)

Jianqing Lin, MD
Wm. Kevin Kelly, DO

BASICS

DESCRIPTION

- Castration-resistant prostate cancer (CRPC) is defined as prostate cancer with disease progression despite effective androgen deprivation (serum total testosterone <50 ng/dL)
- CRPC patients are classified as having metastatic disease (bone or soft tissue visible on imaging) (mCRPC) or nonmetastatic disease (CRPC rising PSA without any radiographic evidence of metastasis)
- CRPC survival is improved significantly with more effective treatment options
- Synonym(s): The preferred term is castrate-resistant prostate cancer but sometimes called castrate refractory prostate cancer. Older terms such as hormone refractory or androgen-independent prostate cancer are not considered accurate
  - Latest data shows that in CRPC prostate cells are still sensitive to low levels of androgens

EPIDEMIOLOGY

Incidence

- 233,000 cases of prostate cancer will be diagnosed in the United States in 2014
- There will be 29,480 deaths due to prostate cancer in 2014
- The vast majority of patients who die with prostate cancer will die from progressive metastatic CRPC
- Historically the median survival with mCRPC is <2 yr; newer agents, most introduced since 2010, have improved overall survival by several months

Prevalence

N/A

RISK FACTORS

- No definitive tool is available to determine the risk of developing CRPC
  - Molecular biomarkers and genomic profiles are being explored for prognosis and treatment
- CRPC risk features for poor survival
  - Low hemoglobin
  - Elevated lactate dehydrogenase
  - Elevated alkaline phosphatase
  - Poor performance status
  - Visceral metastasis particularly liver metastasis
  - Narcotic use for pain
  - Nomogram based on these clinical features can predict overall prognosis for CRPC (1)

Genetics
Common chromosomal translocations found in CRPC include the TMPRSS2-ERG fusions. Epigenetic abnormalities are common in CRPC

PATHOPHYSIOLOGY
Restored androgen receptor (AR) activity is a major driver of therapeutic failure and CRPC development. This may occur through intracrine (intracellular) androgen synthesis, AR deregulation; AR mutation and alternative splicing; and posttranslational modifications and cofactor alterations.

ASSOCIATED CONDITIONS
- Fatigue, muscle wasting, metabolic syndrome
- Bone pain/fracture
- Hematuria, urinary retention
- Edema
- Spinal cord compression
- Anemia
- Renal failure, usually due to hydronephrosis
- Cognitive dysfunction

GENERAL PREVENTION
N/A

DIAGNOSIS

HISTORY
- Prostate cancer history including Gleason score, disease stage at diagnosis, initial treatment for localized prostate cancer
- Time of 1st diagnosis of metastatic disease
- Past hormonal treatments including time when treatments were started
- PSA history
- Extent of disease at the time of diagnosis and also current extent of disease on the bone and CT/MRI scan
- Recent changes in bowel and urinary habits
- Potency
- New neurologic symptoms
- Past medical history including any specific cardiac, renal, or gastrointestinal disease
- Performance status
- Mental status evaluation
- Current medications and allergies
- Caregiver
- Family history of prostate cancer or other cancers
- Smoking, alcohol, and drug history

PHYSICAL EXAM
- Examine for adenopathy
- Gynecomastia

- GU and rectal exam
- Extremity edema and swelling
- Neurologic exam with focus on lower extremity weakness and sensation

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Complete blood count
- Renal, electrolyte, and liver function panel
- Testosterone: Confirm <50 ng/dL
- Prostate-specific antigen (PSA)

Imaging

- Determine presence of radiographic metastasis as a guide to treatment
- Bone scan, CT, or MRI of the abdomen and pelvis at baseline and then every 6–12 mo or based on clinical setting
- Bone density as needed

Diagnostic Procedures/Surgery

- Postvoid residue (PVR) to evaluate for urinary retention
- Cystoscopy and other tests as needed

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Bone pain may also be due to degenerative joint disease, osteoarthritis, Paget disease, or secondary malignancy
- Weight loss due to depression, other malignancies, or failure to thrive
- Anemia related to iron and vitamin deficiency, second malignancy (ie, multiple myeloma), or prior therapies

TREATMENT

GENERAL MEASURES

- Initial strategies for nonmetastatic CRPC are unclear as no randomized clinical trial has shown survival advantage in the setting of no radiographically measurable metastatic disease
- Continuing medical castration recommended
- Verify castrate levels of testosterone. If not <50 ng/dL, consider alternative LHRH agonist/antagonist administration or orchiectomy if not castrate
- Define the treatment objectives for patients: Palliative vs. prolonging survival
- Disease progression based on a rapidly rising PSA, objective changes on bone scan or CT/MRI scan or symptoms from the metastatic CRPC
- Sequencing of newer agents in the setting of disease progression remains under study
- AUA, ASCO, NCCN, and other groups have issued guidelines for the management of CRPC

MEDICATION

First Line

- There are multiple treatment options based on disease acuity and prior treatment history such as before or after docetaxel-based chemotherapy; clinical trials always need to be considered.
- Often secondary or tertiary hormonal manipulation is the initial therapy in asymptomatic mCRPC. These include
  - Antiandrogen withdrawal (ie, stopping bicalutamide, etc.)
    - Paradoxical decrease in PSA after stopping
  - 2nd-line hormonal therapy with nonsteroidal antiandrogen: bicalutamide, flutamide, nilutamide
    - Rarely results in a durable response
- Immunotherapy with sipuleucel-T: Autologous immunotherapy for minimally symptomatic or asymptomatic mCRPC; improved survival (2)
- Androgen biosynthesis inhibitors:
  - Ketoconazole/hydrocortisone (not FDA approved for CRPC); a high-dose ketoconazole with steroid supplementation
  - Abiraterone acetate/prednisone
    - 1,000 mg (four 250 mg tabs) with 5-mg prednisone BID
    - Specific CYP17 inhibitor; approved both pre- and postchemotherapy
    - Improved overall survival (3,4)
- Pure AR antagonist:
  - Enzalutamide (160 mg PO daily)
  - Blocks AR translocation to nucleus; approved for both pre and post docetaxel chemotherapy in mCRPC (5,6)
- First-line chemotherapy: Docetaxel 75 mg/m^2 IV every 3 wks w/prednisone (5 mg PO twice daily) (7)
- Radium 223 (Alpharadin)
  - mCRPC with symptomatic bone metastases (not for visceral disease as only site)
  - 6 injections at 4-wk intervals
  - Delays time to disease progression and improves survival; low rate of adverse events (8)

Second Line

- Consider abiraterone or enzalutamide with mCRPC progression if either was not used previously
- Chemotherapy: Cabazitaxel (20–25 mg/m^2 IV every 3 wk) with 10-mg prednisone daily (9)
  - Approved postdocetaxel
- Mitoxantrone; chemotherapy FDA approved for palliation; limited utility
- Consider clinical trials

SURGERY/OTHER PROCEDURES

- Urinary diversion (stents or percutaneous nephrostomy) in cases of hydronephrosis and renal insufficiency
- Bladder outlet procedures such as TURP for obstruction
- Decompressive laminectomy for spinal cord compromise

ADDITIONAL TREATMENT

Radiation Therapy

- Samarium-153 or Strontium-89
  – For palliation painful bony mets; no survival benefit; cause bone marrow suppression
- Palliative radiotherapy
  – Focal painful bone lesion
  – Epidural disease associated with neurologic symptoms or pain, or spinal cord compression
- Radium 223 (alpharadin) see “First Line" above

Additional Therapies
- Daily calcium (≥1,200 mg daily)/vitamin D (800–1,000 IU daily)
- Bisphosphonate (zoledronic acid) or denosumab for bone health for mCRPC to reduce skeletal-related events (fractures, etc.)
- High dose of steroids (dexamethasone 2–10 mg) useful in acute pain syndromes or neurologic compromise
- Adding nonsteroidal anti-inflammatory drugs or narcotics for pain
- Palliative care or pain specialist referral for refractory pain

Complementary & Alternative Therapies
May be helpful but randomized clinical trials needed to establish clinical benefit

ONGOING CARE

PROGNOSIS
Median survival of patients with CRPC range from 18 to 27 mo depending on the extent of disease

COMPLICATIONS
- Altered mental status
- Anemia
- Bone marrow failure
- Cord compression with loss of motor or sensory function
- Cranial nerve deficits from prostate cancer in the base of the skull
- Depression
- Disseminated intravascular coagulation (DIC)
- Fatigue
- Hematuria
- Muscle wasting/weakness
- Pain
- Pathologic fractures (vertebral, hip, and long bone)
- Rectal bleeding
- Renal failure (acute and chronic)
- Urinary retention

FOLLOW-UP
Patient Monitoring
Frequency of visits, exams, blood work, and radiographs will be dependent upon the patient’s acuity and prostate cancer symptoms

Patient Resources

CODES

ICD9

- 185 Malignant neoplasm of prostate
- 790.93 Elevated prostate specific antigen [PSA]
- V45.77 Acquired absence of organ, genital organs

ICD10

- C61 Malignant neoplasm of prostate
- R97.2 Elevated prostate specific antigen [PSA]
- Z90.79 Acquired absence of other genital organ(s)

CLINICAL/SURGICAL PEARLS

- Castration resistant prostate cancer must be classified as with (mCRPC) or without (CRPC) radiographic metastasis.
- Bone or visceral metastasis will evolve if not initially present.
- Androgen–androgen receptor axis remains the key survival factor and treatment target for CRPC.
- Androgen receptor targeted therapy, immunotherapy, chemotherapy, and bone-targeted therapy are all effective to improve survival.

PROSTATE CANCER, UROTHELIAL

Eric A. Klein, MD, FACS
Samuel Haywood, MD

BASICS

DESCRIPTION

- 1st described in 1952 by Melicow and Hollowell—originally noted as Bowen's disease of the prostatic urethra (1)
- Can occur in 1 of the 3 forms
  - Primary urothelial carcinoma (UC) of the prostate
  - Direct extension of bladder UC
  - Nondirect extension of bladder UC
- Multiple prior staging systems
- Primary UC of the prostate—TNM staging 2001
  - Tis pu—carcinoma in situ (CIS) affecting prostatic urethra
  - Tis pd—CIS affecting prostatic ducts
  - T1—tumor invading subepithelial connective tissue
  - T2—tumor invading prostatic stroma, spongiosum body, periurethral muscle
  - T3—tumor invading cavernous body prostatic capsule or bladder neck (extraprostatic extension)
  - T4—tumor that invades surrounding organs
- Prostatic UC concurrent with bladder UC
  - Prior TNM staging defined prostatic invasion of bladder UC as T4a disease
  - However, given the heterogeneity of this classification, did not accurately predict survival
  - Most recent TNM classification (2010) clarifies T4a as prostatic invasion from direct transmural or extravesical spread
  - Stromal invasion from subepithelial invasion of prostatic urethra classified as organ confined disease
- Synonyms: Transitional cell carcinoma (TCC)

EPIDEMIOLOGY

Incidence

- Of all patients with bladder UC undergoing cystoprostatectomy, 12–48% will have prostatic involvement (1).
- However, underreporting of prostatic involvement likely present in radical cystectomy specimens.
- Prostatic involvement of UC is a predictor of understaging in recurrent nonmuscle invasive bladder UC (2).
- Stromal invasion of the prostate is present in 7–17% of cystectomy specimens (1).
- Primary UC of the prostate is rare malignancy—~1–4% of all primary prostatic tumors (1).

Prevalence

N/A

RISK FACTORS

- Risk factors for prostatic involvement
  - CIS of the bladder
  - Multifocal disease in bladder
  - High-stage bladder UC
  - Previous involvement of prostate
  - Tumors involving trigone or bladder neck
- Risk factors for stromal invasion—presence of CIS (odds ratio 3.2) and location of tumor at or below trigone (odds ratio 3.3) (2)

Genetics

- Genetics:
  - No specific genes associated with prostatic UC

PATHOPHYSIOLOGY

- May involve any part of the prostatic urethra, prostatic duct system, or prostate stroma
- Arises from extension of bladder primary tumor, implantation of malignant cells, or transformation secondary to carcinogenic field effect
- Metastases commonly to bone, lung, liver

ASSOCIATED CONDITIONS

Almost all cases (>95%) associated with bladder UC

GENERAL PREVENTION

General Prevention: Prevention strategies similar as to bladder UC

DIAGNOSIS

HISTORY

- Risk factors similar to bladder UC—tobacco exposure, chemical/workplace exposures
- Hematuria is the most common complaint
- Other symptoms include obstructive voiding symptoms, hematospermia, or systemic symptoms (bone pain, fatigue, weight loss)

PHYSICAL EXAM

- Hematuria or bloody urethral discharge
- Lymphadenopathy
- Abnormal digital rectal exam

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- PSA: Elevations rare in UC
- Urine studies: Urinalysis, urine cytology

Imaging

- Staging workup involves abdominal and chest imaging (CT vs. MRI) to identify local, regional, and distant spread
- Bone scan: UC lesions osteolytic vs. adenocarcinoma (ADC) lesions osteoblastic

Diagnostic Procedures/Surgery

- Cystoscopy—sensitivity 83.3%, specificity 95.1% (2)[C]
  - Focus on macroscopic disease and concurrent bladder lesions
  - Unlikely to find microscopic disease or CIS
- Transurethral biopsy (3)[C]
  - No clear consensus on timing or methods
  - Spectrum of sampling recommended in literature from few resectoscope swipes to complete TURP
  - Pathologic analysis shows involvement most frequently observed around verumontanum
  - Biopsies recommended if positive cytology and/or macroscopic lesions
- Methods of biopsy have varying accuracy (1)[C]
  - Transurethral resection (TUR) biopsy is most accurate: 90% accuracy
  - Fine needle aspirate (FNA) biopsies: 40% accuracy
  - Transrectal needle biopsy: 20% accuracy
- Biopsies poor at accurately detecting stromal invasion—sensitivity 53%, specificity 77%, positive predictive value (PPV) 45%
- Diagnosis of primary UC of prostate requires both transrectal prostate biopsy and random biopsies of bladder to exclude concurrent UC in the bladder (4)[C].

Pathologic Findings

- Urothelial cancer in situ (CIS) of the prostate:
  - Can involve the prostatic urethra, the prostatic ducts, and the prostatic acini.
  - Most prostate urothelial CIS arises along with bladder urothelial neoplasia or from pagetoid spread from the bladder into the prostate.
  - Partial or complete replacement of urethra or duct by atypical urothelial cells with pleomorphic nuclei, coarse chromatin, and frequent mitoses. Fibrosis and chronic inflammation may be seen.
- Invasive UC into prostatic stroma consists of irregular nests, clusters, or single atypical cells that infiltrate prostatic tissue. There are 2 distinct pathways that invade the prostate:
  - Invasive carcinoma arising from the prostatic urethra and duct, which is often associated with CIS within the prostatic duct or acini.
  - Prostatic stroma invasion, in which bladder cancer penetrates from posterior periprostatic soft tissue or the bladder neck.
- Immunohistochemistry (IHC) of prostatic urethral carcinoma is identical to bladder UC: Positive for cytokeratin (CK) 7 (90%), and high–molecular-weight CK (HMWCK) 34βE12 (59%), and do not stain positive for PSA or PAP.

DIFFERENTIAL DIAGNOSIS

- High-grade prostatic intraepithelial neoplasia (HGPIN)
- Prostatic adenocarcinoma
- Other uncommon prostatic tumors

TREATMENT

GENERAL MEASURES

- Risk reduction
- Assessment of the degree of invasion is imperative—management decision strongly

dependent on this

MEDICATION

First Line

- Bacille Calmette–Guerin (BCG)
  - – As with primary bladder UC, BCG efficacious for prostatic urethra CIS
  - – Evidence regarding depth of penetration of BCG into prostatic stroma is unclear
  - – CIS of prostatic urethra has response rates to BCG of ~70–100%. Response rate when combined with bladder primary decreases to 47–72% (1)[C].
  - – Response rate of bladder CIS of prostatic urethra to BCG immunotherapy is ~70–100%.
  - – Some propose TUR prior to BCG therapy to increase exposure—improved prevention of recurrence compared to TUR alone (5)[C].
  - – Absolute contraindications to BCG: Active urinary infection, gross hematuria, traumatic catheterization.

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Options include TUR alone, TUR with BCG (as in “First line" above), and radical cystoprostatectomy
- Radical cystoprostatectomy is the treatment of choice for stromal-invasive prostatic UC. It should also be recommended for patients with progression or recurrence after nonsurgical therapies. (1,2,5)[C]
- Cystoprostatectomy may also be considered as treatment for prostatic UC involving the prostatic ducts.
- Pelvic lymphadenectomy should be performed as with primary bladder UC.
- Options for diversion similar to bladder UC. While debated, prostatic urethral involvement of UC is not an absolute contraindication to orthotopic diversion (1).

ADDITIONAL TREATMENT

Radiation Therapy

Radiotherapy has insufficient data to make recommendations (1)[C]

Additional Therapies

- Chemotherapy
- Data not sufficient to evaluate use of neoadjuvant/adjuvant chemotherapy with respect to prostatic UC (1)[C]. Data from bladder UC shows ~5% survival advantage with neoadjuvant chemotherapy

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Degree of prostatic invasion has prognostic implications with respect to 5-yr survival rates (1)

  – Involvement of the urethral mucosa: 100%
  – Ductal/acinar involvement: 50%
  – Stromal invasion: 40%
- In addition, the path of invasion from concurrent bladder UC also has significant prognostic role on 5-yr survival rate (1)
  – Contiguous from bladder: 7% survival
  – Noncontiguous from bladder: 46%
- Prostatic stromal invasion is associated with higher rates of node-positive disease as well as decreased survival (3)[C]
- Decreased survival associated with prostatic stromal invasion persists regardless of concurrent bladder UC stage (4) or surgical resection (3)[C]

COMPLICATIONS

- Adverse reactions to BCG therapy
  – Local reactions include hematuria, fever, dysuria
  – BCG infectious complications include fevers and/or sepsis, and are managed with hospitalization and antibiotics (eg, isoniazid, rifampin, ethambutol, and fluoroquinolones)
- Erectile dysfunction may occur after cystoprostatectomy
- Bowel diversion risks include electrolyte abnormalities, nutritional deficiencies, bowel obstruction, and ureteral strictures

FOLLOW-UP

Patient Monitoring

- Detection of prostatic relapse can be difficult, requiring frequent and/or lifelong biopsies of bladder, neck, and prostate.
- Surveillance of prostatic urethra recommended with high-risk bladder UC or prior prostatic involvement.
- Monitor with urine cytology, cystoscopy, and transurethral prostate biopsies.
- Biopsy is surveillance of choice with positive cytology and no identifiable bladder lesion. (1)
- Random biopsies occasionally recommended given frequent microscopic disease.

CODES

ICD9

- 185 Malignant neoplasm of prostate
- 198.1 Secondary malignant neoplasm of other urinary organs
- 233.6 Carcinoma in situ of other and unspecified male genital organs

ICD10

- C61 Malignant neoplasm of prostate
- C79.11 Secondary malignant neoplasm of bladder
- D09.19 Carcinoma in situ of other urinary organs

CLINICAL/SURGICAL PEARLS

- Incidental prostatic involvement frequently found at cystoprostatectomy.
- Detecting stromal invasion important for determination of appropriate therapy.
- Involvement of prostatic urethra only may be treated with BCG therapy.
- Stromal invasion of prostate necessitates radical cystoprostatectomy.
- Prognosis highly dependent on degree of prostatic invasion.

PROSTATE CANCER, VERY LOW RISK AND ACTIVE SURVEILLANCE

Michael A. Gorin, MD
Trinity J. Bivalacqua, MD, PhD

BASICS

DESCRIPTION

- The National Comprehensive Cancer Network (NCCN) (1) defines very–low-risk prostate cancer (PCa) with the following criteria: Clinical stage T1c, prostate-specific antigen (PSA) <10 ng/mL, PSA density <0.15 ng/mL/g, biopsy Gleason score ≤6, ≤2 positive biopsy cores, and ≤50% cancer in any 1 core.
  - This definition is based on the work of Epstein et al. (2) which identified parameters associated with low-volume organ-confined (ie, insignificant) PCa at the time of radical prostatectomy.
- Active surveillance (AS) aims to spare men with insignificant tumors the side effects of treatment while maintaining the ability to intervene with curative intent upon the detection of disease progression.
  - The goals of AS are accomplished by carefully following men with serial PSA measurements, digital rectal exams (DREs), and prostate biopsies.
- AS is most appropriate for men with very–low-risk PCa and a life expectancy of <20 yr, or for those with low-risk PCa (defined by the NCCN as clinical stage T1 to T2a, biopsy Gleason score ≤6, and PSA <10 ng/mL) and a life expectancy of <10 yr (1).
- The exact criteria for AS enrollment vary by institution.
  - Triggers for intervention while on AS also vary by center, but typically include violation of the enrollment criteria or a rapid rise in PSA.
    - Dahabreh et al. (3) have reviewed the enrollment and progression criteria used at number of different institutions.

EPIDEMIOLOGY

Incidence

- ~240,000 new cases of PCa are diagnosed annually in the United States.
- >90% of new cases will be clinically localized.
- Up to 40% cases would have remained clinically insignificant had they not been detected on routine screening.

Prevalence

An estimated 2.6 million men in the United States carry a diagnosis of PCa.

RISK FACTORS

- Age
- Family history/genetics
- African American race
- Possibly obesity and a Western diet

Genetics

Mutations in a number of genes have been linked to PCa including BRCA1, BRCA2, HOXB13, and HPC1.

PATHOPHYSIOLOGY

- A combination of genetic, hormonal, and environmental factors underlies the development of PCa.
- >95% of all tumors are adenocarcinoma.
  - Other histologic types include transitional cell, small cell, and sarcoma.
    - NCCN risk categories and AS only pertain to adenocarcinoma.
- High-grade prostate intraepithelial neoplasia is felt to be a precursor to adenocarcinoma.
- Early-stage adenocarcinoma is androgen dependent. As PCa becomes more advanced, tumors dedifferentiate and lose this dependency.
- ~70% of PCa arise from the peripheral zone of the prostate.
- Tumors are often multifocal.

ASSOCIATED CONDITIONS

- Many men with PCa also have benign prostatic hyperplasia (BPH)/lower urinary tract symptoms.
  - BPH is not a precursor to PCa.

GENERAL PREVENTION

- The 5α-reductase inhibitors (5-ARIs) finasteride and dutasteride have been shown in 2 randomized clinical trials (PCPT and REDUCE) to decrease the incidence of PCa.
  - These medications, however, failed to receive FDA approval for PCa prevention due to their suggested association with increased risk of high-grade tumors (controversial).
- The SELECT trial showed that daily selenium and/or vitamin in E do not prevent PCa and should not be recommended to patients.

DIAGNOSIS

HISTORY

- Uniformly asymptomatic.
  - Typically detected on prostate biopsy performed for an elevated PSA and/or finding of a prostate nodule on DRE.
  - Occasionally detected at the time of transurethral resection of the prostate for BPH.

PHYSICAL EXAM

Very–low-risk PCa has no findings on DRE (clinical stage T1c).

DIAGNOSTIC TESTS & INTERPRETATION

Lab

PSA <10 ng/mL and PSA density <0.15 ng/mL/g are required for the definition of very–low-risk PCa.

Imaging

- Transrectal ultrasound is used to guide template-based prostate biopsies.
- A bone scan and/or cross-sectional imaging are unnecessary due to the exceedingly low risk of metastatic disease.

- Magnetic resonance imaging (MRI) of the prostate is currently under investigation for its utility in evaluating tumor extent and the presence of high-grade disease.

Diagnostic Procedures/Surgery

- PCa is definitively diagnosed with prostate biopsy.
  - Most commonly performed in the office setting using transrectal ultrasound.
    - A 10–12-core biopsy should be performed to ensure adequate sampling of the prostate.
    - Requires only local lidocaine for analgesia.
    - A hypoechoic lesion may represent an area of cancer but is not a sensitive finding.
  - Transperineal biopsy is typically reserved for men with several negative biopsies in whom PCa is still suspected.
    - Allows for systematic saturation biopsies using a grid-based approach.
    - Requires general anesthesia.
  - Image fusion biopsy combining ultrasound/MRI images are being explored.

Pathologic Findings

- Biopsy Gleason score ≤ 6 and ≤ 2 positive cores with $\leq 50\%$ cancer in each core are required for the definition of very–low-risk PCa.
- Evolving use of genomic assays based on the prostate biopsy to determine risk of progression on AS (Oncotype DX and Prolaris).

DIFFERENTIAL DIAGNOSIS

- Localized PCa:
  - BPH, prostatitis (granulomatous, acute, or chronic), recent instrumentation, nonadenocarcinoma prostate malignancy (sarcoma, urothelial carcinoma)

TREATMENT

GENERAL MEASURES

- Adequate patient evaluation and review of all treatment options is essential
- Identification of patients who may be an appropriate candidate for AS

MEDICATION

First Line

- No role for chemotherapy or androgen deprivation for men who are candidates for AS.
- 5-ARIs do not appear to prevent disease progression of men on AS.

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Radical prostatectomy may be offered to men who desire treatment.
  - A pelvic lymph node dissection may be omitted given the low risk of lymph node metastases in this population.
  - Comparing open to robotic or laparoscopic surgery, outcomes appear to be equivalent between surgical approaches (4).
  - Major side effects of surgery include urinary incontinence and erectile dysfunction.

ADDITIONAL TREATMENT

Radiation Therapy

- External beam radiation therapy or brachytherapy are acceptable alternatives to AS and surgery.
  - Adjuvant hormonal therapy is not indicated with either approach in this group of men.
  - When external beam radiation therapy is performed, treatment with either intensity-modulated or 3-dimensional conformal radiation therapy should be utilized to limit toxicity to surrounding organs.
  - Brachytherapy should be avoided in men with symptoms of bladder outlet obstruction (high International Prostate Symptom Score) due to the risk of worsening lower urinary tract symptoms.
  - Major side effects of radiation include urinary incontinence, irritative voiding symptoms, erectile dysfunction, radiation induced proctitis, hemorrhagic cystits and secondary malignancies most commonly of the bladder and rectum.

Additional Therapies

- Technologies for focal and hemi- ablation are currently in the early phases of investigation.
  - Modalities include cryotherapy, high intensity focused ultrasound, interstitial laser and electroporation.

Complementary & Alternative Therapies

Low fat diet appropriate recommendation

ONGOING CARE

PROGNOSIS

- Up to 30% of men enrolled in AS will be reclassified and go onto require some form of treatment.
  - It remains unknown if these men would have had a superior oncologic outcome had they undergone immediate treatment.

COMPLICATIONS

- AS spares men with insignificant tumors the side effects of unnecessary treatment.
- The major risk of AS is missing the opportunity to intervene when cure is still possible.
- A small percentage of men will experience an infectious or bleeding complication related to a prostate biopsy.

FOLLOW-UP

Patient Monitoring

- The optimal protocol for monitoring men on AS is unknown.
  - Most advocate for biannual PSA measurements with DRE and annual 12–14-core prostate biopsy.
    - PSA kinetics do not appear to be helpful in predicting disease progression (5).
- Monitoring for disease progression is not indicated after age 75 of when life expectancy is <10 yr.

- Prostate Cancer, General Considerations
- Prostate Cancer, Genomic Markers
- Prostate Cancer, Localized (T1, T2)
- PSA Elevation, General Considerations

CODES

ICD9

- 185 Malignant neoplasm of prostate
- 790.93 Elevated prostate specific antigen [PSA]
- V76.44 Screening for malignant neoplasms of prostate

ICD10

- C61 Malignant neoplasm of prostate
- R97.2 Elevated prostate specific antigen [PSA]
- Z12.5 Encounter for screening for malignant neoplasm of prostate

CLINICAL/SURGICAL PEARLS

- A large percentage of older men with screen-detected PCa will have insignificant tumors and, therefore, not benefit from intervention.
- To avoid the potential morbidity associated with treatment, AS should be offered to men

with very–low-risk PCa and a life expectancy of <20 yr.

- The optimal follow-up protocol is not well defined but typically includes biannual PSA measurements with DRE and annual 12–14-core prostate biopsy.
- PSA kinetics are less useful than biopsy findings for accurately reclassifying men while on AS.
- It is unknown if men reclassified on AS would have been better served with immediate treatment; however, long-term data from a number of centers suggest good oncologic outcomes with this management strategy.

PROSTATE, ABSCESS

Garjae D. Lavien, MD
Michael J. Naslund, MD

BASICS

DESCRIPTION

- Prostate abscess is an infection of the prostate with focal accumulation of pus within the prostate gland
- Difficult to initially clinically distinguish from acute bacterial prostatitis
- Usually as a result of ineffective antibiotic therapy for acute prostatitis
  – Rare in nonhospitalized patients

EPIDEMIOLOGY

Incidence

Decreasing with widespread use of antibiotics

Prevalence

Diagnosed in 0.2% of patients with urologic symptoms, 0.5–2.5% of patients hospitalized for prostatic symptoms (1)

RISK FACTORS

- Bladder outlet obstruction, history of bacterial prostatitis
- Chronic hemodialysis
- Compromised immune system (eg, HIV/AIDS, diabetes, etc.)
- Indwelling catheters
- Lower urinary tract instrumentation
- Sexually transmitted infections

Genetics

N/A

PATHOPHYSIOLOGY

- Usually an ascending infection in association with poor bladder emptying.
- Urethral infection combined with intraprostatic reflux of infected urine causes acute prostatitis.
- Acute prostatitis can, in patients with immunosuppression or other risk factors, progress to abscess.
- Hematogenous dissemination, especially with *Staphylococcus* sp. seen in immunocompromised patients/IV drug users.
- Most common etiologic agent is *Escherichia coli* (2)[B].
- With the advent of antibiotics, the incidence of *Neisseria gonorrhea* as causative agent has decreased significantly.
- Most common etiologic agent seen in emphysematous prostate abscess (EPA) is *Klebsiella pneumoniae* (3)[B].

- With severe immunocompromise, such as HIV; more unusual organisms such as TB, *Cryptococcus*, histoplasmosis, and *Candida* should be considered.
- Melioidosis is an infection (usually abscesses in many sites including the prostate).
  - Caused by the gram-negative *Burkholderia pseudomallei.*
  - Usually associated with diabetes.
  - Very high prevalence in East Asia and Northern Australia.

ASSOCIATED CONDITIONS

- Any disease process that causes immunocompromise:
  - Cancer
  - Chronic renal failure, hemodialysis
  - Cirrhosis
  - Diabetes
  - HIV/AIDS

GENERAL PREVENTION

- Aimed at preventing and treating sexually transmitted infections
- Relieving/improving signs/symptoms of bladder outlet obstruction
- Diabetic glycemic control
- Appropriate treatment of patients with acute prostatitis

DIAGNOSIS

HISTORY

- Fevers, chills
- Urinary symptoms with attention paid to voiding patterns prior to acute presentation
  - Dysuria, urinary urgency and frequency are almost universal symptoms
  - Suprapubic or subpubic pain,
  - Severe perineal pain
  - Rectal tenesmus
- Acute urinary retention
- Sexual history/social history (IV drug use, etc.)
- Associated medical comorbidities

ALERT
Where prostate abscess or acute prostatitis is suspected, rectal exam may be contraindicated.

PHYSICAL EXAM

- Perineal pain, tenderness
- Urethral discharge
- Digital rectal exam can reveal exquisitely tender and warm prostate with fluctuance or simply an enlarged prostate
- Signs of other medical comorbidities (ie, new cardiac murmur, ascites, cough, track marks, etc.)

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Complete blood count with differential

- Urinalysis, urine/blood cultures
- Gram stain/culture of prostatic fluid once drained
- AFB or mycobacterium-specific PCR if TB suspected
- Prostate-specific antigen should not be obtained in this setting as it will usually be elevated due to the inflammatory process

Imaging

- Transrectal ultrasound (TRUS)
  - Will reveal hypoechoic zones with irregular internal echoes, septations, and indirect borders with the surrounding prostate;
  - Must be performed cautiously.
  - May guide drainage and aspiration
  - The presence of gas suggests EPA
- Color Doppler sonography
  - Will show an increase in vascularity around the abscess, due to hyperemia stemming from the surrounding inflammation
- Computed tomography (CT)
  - Can determine penetration of the abscess into the periprostatic tissues and identify gas within the prostate
  - CT findings include nonenhancing fluid-density collections that can be multiseptated or rim-enhancing lesions.
- MRI
  - MRI may not be feasible in patients who are critically ill and require acute management

Diagnostic Procedures/Surgery

- TRUS with aspiration
- Transperineal ultrasound with aspiration
- Transurethral unroofing of prostate abscess

Pathologic Findings

- Purulent material will be expressed from prostate during surgical drainage procedure:
  - Gram stain and culture of material will give causative agent, most commonly bacterial

DIFFERENTIAL DIAGNOSIS

- Clinically can be hard to distinguish from urinary tract infection (UTI), acute prostatitis, or any other lower UTI.
- Should have clinical suspicion, which can be confirmed with imaging.

TREATMENT

GENERAL MEASURES

- Initial treatment should focus on broad-spectrum antibiotics, IV hydration, and pain control.
- In the setting of acute urinary retention, a Foley catheter placement can be attempted.
  - Occasionally the transurethral catheter may block drainage of an acutely inflamed prostate or cause bacteremia.
  - In the setting of extreme discomfort or if the catheter is difficult to pass, a suprapubic punch cystostomy is preferred.

MEDICATION

First Line

- Broad-spectrum IV antibiotic therapy followed by directed therapy after causative organism determined by urine culture or Gram stain/culture of abscess fluid:
  - 2nd-generation cephalosporins (cefoxitin, zinacef) or 3rd-generation cephalosporins (ceftriaxone, cefotaxime, ceftazidime)
  - IV fluoroquinolones
  - Clindamycin for additional anaerobic coverage is recommended initially
    - 600–900 mg IV every 8 hr (q8h)
  - After acute phase, continue oral antibiotic regimen based on cultures for up to 4 wk

Second Line

- Vancomycin for coverage of MRSA is suspected.
  - Dose based on renal function
- Fungal infections may require 4–6 wk of systemic therapy in addition to drainage.

SURGERY/OTHER PROCEDURES

- Transurethral unroofing of prostate abscess
- Transperineal or transrectal needle aspiration with US guidance followed by urethral catheter drainage
  - Can be performed using local anesthesia or sedation
  - Higher risk of recurrence of abscess
- Open incision and drainage through a perineal approach
  - Utilized in patients with penetration of the abscess through the capsule of the prostate or through the levator ani
  - Allows placement of a drain
  - Increased morbidity compared to open percutaneous or transurethral approaches
- Suprapubic cystotomy can be used as an adjunct for urinary diversion in patients with urinary retention

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Relates to predisposing conditions
- For patients with bladder outlet obstruction, therapy should be started to relieve obstruction, (ie, α-blockers or 5α-reductase inhibitors)

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Should recover fully once definitive therapy undertaken
- Although EPA is rare, a 25% mortality rate has been reported

COMPLICATIONS

- May progress to spontaneous fistulization into the urinary bladder, prostatic urethra, rectum, or perineum.
- Urosepsis, and possibly death if diagnosis not made in timely manner.

FOLLOW-UP

Patient Monitoring

- Supportive once definitive therapy performed
- Once acute events resolves, monitoring focuses on optimizing medical comorbidities and improving voiding symptoms.
- Author recommendation: CT or TRUS 4–6 wk after definitive therapy to confirm that no residual abscess remains
- Follow-up urine culture recommended

Patient Resources

CODES

ICD9

- 596.0 Bladder neck obstruction
- 601.0 Acute prostatitis
- 601.2 Abscess of prostate

ICD10

- N32.0 Bladder-neck obstruction
- N41.0 Acute prostatitis

- N41.2 Abscess of prostate

CLINICAL/SURGICAL PEARLS

- Prostate abscess is uncommon and thus often overlooked in the differential diagnosis.
- Suspect prostatic abscess in patients presenting with fever and persistent lower urinary tract symptoms that do not respond to antibiotics.
- A pelvic CT scan is generally the best test to evaluate for the possibility of a prostate abscess.
- A delay of antimicrobial therapy in the management of acute bacterial prostatitis can increase the risk of prostatic abscess.

PROSTATE, BENIGN HYPERPLASIA/HYPERTROPHY (BPH)

Shaun G.S. Grewal, MD
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION

- Benign prostatic hypertrophy (BPH) refers to histologic changes within the prostate gland.
  - May not imply the presence of an enlarged prostate or symptoms.
  - LUTS are 1 manifestation of BPH.
  - Synonym(s): Nodular hyperplasia
- Definitions from the International Continence Society (ICS):
  - Benign prostatic hyperplasia is a term used (and reserved for) the typical histologic pattern which defines the disease.
  - Benign prostatic obstruction is a form of bladder outlet obstruction (BOO) and may be diagnosed when the cause of outlet obstruction is known to be benign prostatic enlargement, due to histologic benign prostatic hyperplasia.
  - Benign prostatic enlargement (BPE) is defined as prostatic enlargement due to histologic benign prostatic hyperplasia. The term "prostatic enlargement" should be used in the absence of prostatic histology.

EPIDEMIOLOGY

Incidence

- 50% of men >40 yr will develop histologic evidence of BPH
  - 30–50% of these men will develop bothersome LUTS (1)

Prevalence

- Histologic prevalence of BPH increases with age:
  - 10% for men in their 30s
  - 20% for men in their 40s
  - 50–60% for men in their 60s
  - 80–90% for men in their 70s and 80s
- Men with significant prostate enlargement (>50 cc) 3.5 times more likely to have moderate-to-severe LUTS (2)
  - BPH is a histologic diagnosis that does not always result in clinical LUTS

RISK FACTORS

- Although family history and advancing age are risk factors for BPH, evidence for comorbidity, environmental, dietary, or lifestyle-related risk factors are generally weak.
- Massachusetts Male Aging Study: Cigarette smoking and increased physical activity protective against BPH, heart disease correlated with development of BPH. Possible association between obesity and prostate volume/LUTS.

Genetics

Some men with younger age of onset and larger glands have a family history of BPH.

PATHOPHYSIOLOGY

- BPH/LUTS begins with abnormal microscopic hyperplasia and macroscopic growth. Causes outflow obstruction and obstructive voiding symptoms (decreased force of stream, intermittent stream, and hesitancy).
- Detrusor response to increased resistance is to generate higher pressures to overcome the outlet resistance. Leads to a variety of cellular and morphologic changes in the bladder. Causes the common storage symptoms of frequency, urgency, and nocturia.
- May lead to bladder decompensation, in which the bladder is no longer able to generate sufficient pressures to empty.
- Primary androgen-dependent growth process involves periurethral and transition zones of the prostate.

ASSOCIATED CONDITIONS

- OAB (overactive bladder defined as urinary frequency, urgency, nocturia, urge incontinence)
- Sexual dysfunction (erectile and/or ejaculatory dysfunction)

GENERAL PREVENTION

- Randomized clinical trials (MTOPS) suggested that the combination of an α-blocker with a 5α-reductase inhibitor (5-ARI) can reduce the lifetime risk of acute urinary retention and may prevent symptomatic disease progression in men with enlarged prostate volume (>25 cc) (3).
- Bladder decompensation may be prevented by treatment of BOO.

DIAGNOSIS

HISTORY

- Focus on identifying the presence of LUTS
  - Voiding symptoms (previously called obstructive symptoms): Hesitancy, intermittency, weak stream, abdominal straining to void, postvoid dribbling, incomplete emptying, double voiding)
  - Storage symptoms (previously called irritative symptoms): Daytime frequency, nocturia, urgency, urge incontinence, enuresis, dysuria)
- Identify other contributing factors to LUTS
  - Medications (ie, diuretics, cold medications)
  - Comorbidities (ie, diabetes, multiple sclerosis, Parkinson)
- Previous interventions/therapies
- Family history
- IPSS is a reproducible, validated index designed to determine disease severity and response to therapy:
  - Scores of 0–7, 8–19, and 20–35 signify mild, moderate, and severe symptoms, respectively.
  - Equivalent to AUASS with the addition of a quality of life (QOL) score

PHYSICAL EXAM

- Evaluation of the abdomen, pelvis, perineum
- Examine external genitalia
- DRE to estimate prostate size and detect any nodularity suggestive of prostate cancer:

  – Anal sphincter tone and sensation should be noted
- Focused neurologic exam on the anus and lower extremity motor and sensory function. A more extensive neurologic exam is indicated for patients with possible neurogenic lower urinary tract dysfunction

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis to exclude hematuria or evidence of infection
- PSA:
  – May be a proxy for prostate size
    ◦ PSA of 1.5 ng/dL correlates with prostate volume >30 mL in most men (4)
  – Informed discussion of risks/benefits of PSA screening warranted
- Urine cytology: Not considered standard; only if there is a predominance of irritative symptoms, hematuria, and/or risk factors for bladder cancer such as smoking

Imaging

- Not indicated unless there is evidence of upper tract deterioration or a need to further evaluate hematuria
- TRUS may be beneficial in determining accurate size prior to surgical intervention

Diagnostic Procedures/Surgery

- Uroflowmetry is a simple noninvasive urodynamic measurement in which a patient voids into a device that measures the volume/time of urine accumulation:
  – Combined with a measurement of PVR (post void residual) volume (see next heading below), it is an excellent screening tool for BOO in men with LUTS.
  – Uroflowmetry measures voided volume, voiding time, average flow rate, and maximum flow rate (Qmax), also called the PFR.
  – Qmax: The single best measurement obtained by this study to assess voiding dysfunction. While formal definitions vary, in general with a voided volume of >125–150 mL, a Qmax of >15 mL/s is often considered normal, whereas a value of <7 mL/s is suggestive of significant obstruction.
  – May need urodynamics to differentiate BOO from hypocontractile bladder (pressure flow study).
    ◦ Obstruction confirmed with low flow (Qmax <15 mL/s) and high voiding pressure >60 cm water.
- PVR: Although generally used, PVR does not convincingly correlate with the severity of LUTS, the presence of BOO, or treatment outcomes:
- Voiding diary to evaluate for occult polyuria or polydipsia.
- Cystoscopy not essential unless there is concern for malignancy, obstruction due to foreign body, or stricture. May be useful to evaluate for most appropriate surgical or minimally invasive treatments.

Pathologic Findings

- Varying degrees of glandular and stromal nodular hyperplasia (as such, hypertrophy is a misnomer). The glandular component is made up of small and large acini lined by basal and secretory cells. The stromal component is rich in smooth muscles. Nodular growth is a major histologic component of BPH.

- Diffuse stromal infiltration of plasma cells and lymphocytes can be seen, but no infectious agent nor clinical diagnosis of prostatitis is typically present.

DIFFERENTIAL DIAGNOSIS

- Obstructive symptoms: Detrusor sphincter dyssynergia, foreign body, meatal stenosis, neurogenic bladder, pelvic floor dysfunction, prostate cancer, prostatic abscess, prostatitis syndrome, urethral obstruction (stricture, condyloma)
- Irritative/storage symptoms: Bladder cancer, detrusor hyperreflexia/OAB, interstitial cystitis, polyuria/polydipsia, prostatitis syndromes

TREATMENT

GENERAL MEASURES

- Directed at QOL unless evidence of significant damage to urinary tract from obstruction (hydronephrosis, bladder calculi, recurrent infections)
- Guidelines suggest watchful waiting for men with mild symptoms IPSS ≤ 7 or for more severe symptoms if they are not bothersome to the patient. Simple behavior modification (fluid restriction, decreased alcohol/caffeine) may help
- Medical therapy considered 1st-line by most, but usually requires continuous therapy to maintain benefit
- α-Blocker and 5-ARIs often prescribed together

MEDICATION

First Line

- α-Blockers (reduce muscle tone in prostate/bladder neck):
  - Terazosin (start 1 mg/d to max 20 mg)
  - Doxazosin (start 1 mg/d to max 8 mg; XL form 2–8 g/d)
  - Tamsulosin (start 0.4 mg to max 0.8 mg)
  - Alfuzosin (10 mg/d)
  - Silodosin (8 mg/d)
    - Dizziness, orthostatic hypotension, and ejaculatory dysfunction are most common side effects
- 5-ARIs (block intracellular DHT conversion; generally best for larger glands, may take 6–12 mo for improvement):
  - Finasteride (5 mg/d)
  - Dutasteride (0.5 mg/d)
- α-Blocker (tamsulosin 0.4 mg) combined with 5-ARI (dutasteride 0.5 mg)

Second Line

- Antimuscarinic agents may help with bladder overactivity:
  - Various agents including oxybutynin (5 mg TID), tolterodine (2–4 mg/d), solifenacin (5–10 mg/d), others
- Phosphodiesterase-5 inhibitor
  - Tadalafil (2.5–5 mg/d)
    - FDA approved for LUTS secondary to BPH
    - Contraindicated in patients on nitrates, nonselective α-blockers, and CYP 450 inhibitors

- Side effects include back pain, dizziness, headache, and dyspepsia (5)

SURGERY/OTHER PROCEDURES

- Often considered 2nd-line after failure of medical therapy; may be 1st-line in retention or if very large prostate.
- TURP represents gold standard against which all other therapies are compared.
- Open simple prostatectomy usually for glands >100 g:
  - Suprapubic prostatectomy: Enucleation of adenoma through bladder; useful with coexisting problems such as very large bladder calculi or to repair diverticulum
  - Retropubic simple prostatectomy: Enucleation of adenoma through incision in anterior prostate commissure
- Many minimally invasive alternative surgical procedures: Microwave- and water-induced hyper thermia, transurethral needle ablation, laser vaporization (contact, noncontact, interstitial, diode), laser prostatectomy (holmium, KTP)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Prostatic stents; best if need TURP but poor surgical risk
- Prostatic urethral lift (UroLift TM) mechanically opens the prostatic urethra with UroLift implants that are placed transurethrally under cystoscopic visualization, thereby separating the encroaching prostatic lobes (6)

Complementary & Alternative Therapies

Phytotherapy (plant extracts) includes saw palmetto, *Pygeum africanum*; β-sitosterols have limited support in the literature

ONGOING CARE

PROGNOSIS

- Symptoms usually well managed by medications
- Progression of disease, when risk factors identified, can be well managed

COMPLICATIONS

- Generally accepted sequelae of untreated, undertreated, or progressive BPH
- Historically, many men typically had complications of BPH including UTIs, hematuria, bladder calculi, bladder decompensation, incontinence, and upper tract deterioration. With modern awareness and management techniques, this is less common.
- The most commonly used endpoints in medical trials are symptom deterioration, BPH-related surgery, and AUR. AUR continues to be the most widely accepted and most scientific endpoint, although the exact pathophysiologic mechanism is not completely understood.

FOLLOW-UP

Patient Monitoring

- Periodic monitoring depending on severity of symptoms
  - Monitor response to therapy with history, AUA SS, PVR, flow rate

– Upper tract imaging and measure of renal function if elevated PVR (>300 cc)

CODES

ICD9

- 600.00 Hypertrophy (benign) of prostate without urinary obstruction and other lower urinary tract symptom (LUTS)
- 600.01 Hypertrophy (benign) of prostate with urinary obstruction and other lower urinary tract symptoms (LUTS)
- 600.10 Nodular prostate without urinary obstruction

ICD10

- N40.0 Enlarged prostate without lower urinary tract symptoms

- N40.1 Enlarged prostate with lower urinary tract symptoms
- N40.2 Nodular prostate without lower urinary tract symptoms

CLINICAL/SURGICAL PEARLS

- 5-ARIs (such as finasteride and dutasteride) contraindicated if prostate enlargement absent (< 25 g).
- Goal of treatment is improving symptoms/QOL.

PROSTATE, CALCULI

Christopher Amling, MD, FACS
Nicholas Cowan, MD

BASICS

DESCRIPTION
- Prostatic calculi are extremely common and rarely symptomatic
- Most stones are discovered incidentally
- Treatment typically reserved for severely symptomatic men
- Stones within the prostatic urethra rare and likely due to bladder or upper tract stones that become trapped in the prostatic urethra
- Reports of calculi in the prostatic urethra following transurethral resection of the prostate

EPIDEMIOLOGY
Incidence
- 7% in pathologic specimens
- 20% in autopsies
- 30% in radiologic studies, with higher percentages in ultrasound scan exams

Prevalence
- Small areas of microcalcification can be seen in 2nd and 3rd decades of life
- Almost all men (99%) have some degree of prostatic calcification noted at autopsy
  - Stone burden and size typically increase as a man ages

RISK FACTORS (1)
- Intraprostatic calculi:
  - Recurrent urinary tract infections (UTIs)
  - Pelvic radiation (for prostate cancer)
  - Studies are mixed on role of inflammation in stone development
- Prostatic urethral calculi
  - Urolithiasis
  - Enlarged prostatic utricle
  - History of transurethral resection of the prostate

Genetics
N/A

PATHOPHYSIOLOGY
- Urinary intraprostatic reflux implicated in stone formation
- Intraprostatic calculi presumed to form by the precipitation of prostatic secretions and calcification of the corpora amylacea under inflammatory conditions
  - Inspissation of prostatic secretions within the prostatic ducts
  - Concentric layering of calcium phosphate and calcium carbonate on inspissated core result in growth
  - Stone elements may contain constituents found only in urine and not in prostatic

secretions
- Stones may harbor bacteria and serve as source for relapsing UTI
- For prostatic utricle stones, prostatic utricle distends during voiding and then passively drains.
  - Impaired emptying results in urinary stasis stone formation. Patients present clinically with chronic UTI, hematuria, urethral discharge, epididymitis, and voiding dysfunction.

ASSOCIATED CONDITIONS
- Chronic pelvic pain syndrome
- Prostatitis
- No association between prostate calculi and risk of prostate cancer
- Hypospadias (enlargement of the prostatic utricle, a Müllerian duct remnant)

GENERAL PREVENTION
No known preventative strategies

DIAGNOSIS
HISTORY
- Typically stones are asymptomatic
- Evaluate for history of lower urinary tract symptoms (LUTS) (2)
  - Patients should complete the international prostate symptom score (IPSS)
  - Presence of large calculi associated with moderate LUTS
- 25–47% of men with chronic pelvic pain have significant prostatic calcifications
  - Correlation seen with stone size, not number
- Prostatitis history
- With prostatic utricle stones patients typically present with chronic UTI, hematuria, urethral discharge, epididymitis, and voiding dysfunction. Often a history of hypospadias is present

PHYSICAL EXAM
- Genitourinary exam including DRE
  - DRE unlikely to localize stones
- Presence of hypospadias

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Urine culture
  - *Escherichia Coli,* enterococci, and *Klebsiella* spp. more common
- Expressed prostatic secretions
  - May see increased leukocytes
- PSA optional
  - PSA levels not influenced by presence or volume of prostatic calculi, but infection related to chronic nidus may falsely elevate PSA (3)

Imaging
- Stones often identified incidentally
- Transrectal ultrasound (TRUS)
  - Highly sensitive for large calculi

• Sometimes seen on plain film

Diagnostic Procedures/Surgery
• Postvoid residual (PVR)
• Uroflow if significant obstructive voiding symptoms present
• If intraurethral stones are suspected, cystoscopy is diagnostic

Pathologic Findings
• Majority of calculi are found in the posterior and posterolateral zones of the prostate
  – Rare to find large stones obstructing the urethra

DIFFERENTIAL DIAGNOSIS
• Benign prostatic enlargement (BPE)
• Calcified prostatic utricle cyst or utricle stone
• False prostatic calculi: Calculi trapped in dilated prostatic urethra or in dilated prostatic utricle
• Prostate cancer
• Prostatitis
• Seminal vesical calculi
• UTI

TREATMENT

GENERAL MEASURES
Evaluate and treat coexisting conditions such as UTI, prostatitis, and BPO

MEDICATION
First Line
Culture-directed antibiotic therapy if urine culture positive

Second Line
N/A

SURGERY/OTHER PROCEDURES
• Surgery rarely indicated and is typically for severely symptomatic patients
• Transurethral resection of the prostate
  – Unroof stone containing cavities where nidus of infection is thought to exist
  – Stone burned usually visible on TRUS
• Open prostatolithotomy for large stones
• Cystoscopy with lithotripsy for stones within the prostatic urethra or prostatic utricle

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
N/A

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS

Excellent, as majority of stones are asymptomatic

COMPLICATIONS

- Rarely results in urinary obstruction
- May predispose to chronic UTI.

FOLLOW-UP

Patient Monitoring

- No follow-up necessary for asymptomatic incidentally identified stones
- Consider postoperative PVR or uroflow if surgical intervention undertaken

Patient Resources

N/A

CLINICAL/SURGICAL PEARLS

Prostate calculi are very common and rarely require treatment.

PROSTATE, NODULE

Gurdarshan S. Sandhu, MD
Gerald L. Andriole, MD, FACS

BASICS

DESCRIPTION

- A prostatenadule is usually described as a palpable lesion detected on digital rectal exam (DRE) raise concern for prostate cancer (CaP)
- Nodules can be described as soft, rubbery, firm, hard, or rock hard
- Nodules can be well circumscribed or irregular and diffuse
- A normal prostate is about the size of a chestnut and has a consistency similar to that of the contracted thenar eminence of the thumb.
  - This can be simulated by opposing the thumb to the little finger and palpating the contracted muscle
- Consistency of nodule can denote underlying pathology.
- Rapidity of appearance and changes in size and consistency can infer malignant potential.
- Nodule detection by DRE is recommended as part of prostate cancer detection programs.
  - Current recommendations from the American Cancer Society are, if men decides to be tested for prostate cancer, they should have the PSA blood test with or without a rectal exam.

EPIDEMIOLOGY

Incidence

- Prostate nodule as an isolated finding with normal PSA is found in $<10\%$ of cases of prostate cancer in the US
- Increasingly men are being diagnosed with prostate cancer based on an elevated serum prostate-specific antigen (PSA) and not an abnormal DRE (50% of diagnoses in 2002) (1)
- 94% of men diagnosed with prostate cancer in 2004–2005 have localized disease (cT1 or cT2) (2)

Prevalence

5–10% of men in screening programs have abnormal/suspicious DRE

RISK FACTORS

- Prostate cancer
  - Nodule that changes in consistency and size over time
  - Elevated serum PSA (>2.5–4 ng/mL)
  - Positive family history
- Benign nodule
  - No significant change over time
  - Nodule may be softer
  - Prior episodes of prostatitis, biopsy, or prostate surgery (transurethral resection)
  - Prior therapy with intravesical Bacillus Calmette–Guérin (BCG)
  - Granulomatous nodules can be due to infectious causes (eg, tuberculosis [TB]) or systemic

granulomatous diseases

Genetics

See “Prostate Cancer, General Considerations”

PATHOPHYSIOLOGY

- Normal prostate has a soft, uniform consistency.
- Prostate enlarges with age.
- Microscopically, nodular prostatic hyperplasia consists of nodules of glands and intervening stroma. May occasionally form benign palpable nodules.
- Nodule can be subjectively graded by degree of firmness/hardness (grades 1–3)
- CaP has to have a volume of 0.2 mL or larger to be detected by DRE.

ASSOCIATED CONDITIONS

- Prostate adenocarcinoma
- Benign prostatic hyperplasia (BPH)
- History of intravesical BCG for bladder cancer

GENERAL PREVENTION

None

DIAGNOSIS

HISTORY

- History of lower urinary tract symptoms
  - Irritative voiding symptoms
  - Obstructive voiding symptoms
  - Fever
  - Previous prostate biopsy or surgery such as TURP
  - Previous pelvic external beam radiation or prostate brachytherapy
  - History of prostatitis, abscess, or exposure to TB
  - Systemic granulomatous disease (Wegner’s, etc.)
  - Family history of genitourinary malignancies

ALERT

Where prostate abscess or acute prostatitis is suspected, rectal exam may be contraindicated.

PHYSICAL EXAM

- DRE
  - Carcinoma (prostatic or urothelial cell carcinoma)
    - Firm, indurated nodules within the prostate gland
    - Prostate cancer most often arises in the posterior peripheral region of the prostate
    - Advanced prostate cancer can make the entire gland firm and cause obliteration of the medial and lateral sulci
    - Advanced cancer can also extend into the seminal vesicles or toward the side wall laterally
- BPH
  - Prostate gland can be variably enlarged (size does not correlate with extent of voiding

symptoms)
  – Rubbery consistency
- Infectious lesions
  – Prostatitis
    - Warm, tender prostate
    - Can be fluctuant or feel “boggy”
  – Prostate abscess
    - Localized, fluctuant tender region in prostate
- Calculus can present as hard, small nodule

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- PSA
  – Serum levels vary with age, race, and prostate volume
  – Improves the positive predictive value of DRE for cancer
  – No cut-off value below which the absence of prostate cancer can be guaranteed
    - Risk of prostate cancer is continuous as PSA increases (3)
  – See “PSA Elevation, General Considerations” for further specifics on PSA
- Urinalysis
  – Variable findings in men with abnormal DRE; sterile pyuria in granulomatous prostatitis
  – Generally normal in men with prostate cancer without urinary tract infection
  – Urine culture can be positive for gram-negative bacteria in acute and chronic bacterial prostatitis
  – Urine cytology can be positive in urothelial cancer

Imaging

- Transrectal ultrasound (TRUS)
  – Classic appearance of prostate adenocarcinoma is a round or oval hypoechoic lesion located in the peripheral zone
    - Not very sensitive as 39% of tumors can be isoechoic
    - Also nonspecific as granulomatous lesions can be hypoechoic
  – BPH can have variable appearance
    - Distinguishable from prostate cancer only by biopsy
- Abdominal computed tomography (CT) or magnetic resonance imaging (MRI)
  – Primarily used for staging purposes in patients with high-risk prostate cancer
- Bone scan to detect bone metastases
  – Also primarily used for staging purposes in patients with high-risk prostate cancer

Diagnostic Procedures/Surgery

- TRUS-guided biopsy (4)
  – Used to widely sample the prostate during biopsy in men with an elevated PSA and/or abnormal DRE
  – Modern biopsy schemes have modified the standard sextant biopsy scheme to focus on laterally directed cores
    - Generally 12 cores
- Cystoscopy

– Used to evaluate bladder outlet obstruction and hematuria when present

Pathologic Findings

See “Prostate Cancer, General Considerations”

DIFFERENTIAL DIAGNOSIS

- Neoplasm, malignant
  - Lymphoma, primary and secondary
  - Prostate adenocarcinoma
  - Other prostate malignancies
    - Sarcoma
    - Small cell carcinoma
    - Other more rare tumors and metastasis
  - Urothelial carcinoma
- Benign
  - BPH
  - Calculus
  - Ejaculatory duct cyst
  - Granulomatous prostatitis
    - BCG related or other cause
  - Scarring from prior radiation, surgery, or infection (TURP, etc.)
  - Rectal wall lesions (thrombosed hemorrhoid, carcinoma, etc.)

TREATMENT

GENERAL MEASURES

- Abnormal DRE is an indication for TRUS-guided biopsy of the prostate
  - Workup includes assessment of PSA
  - Staging investigations including bone scan, CT, and/or MRI are reserved for high-risk cases as dictated by PSA, Gleason score, and DRE

MEDICATION

First Line

Antibiotics may be required for infectious causes of nodules such as bacterial prostatitis or TB

Second Line

N/A

SURGERY/OTHER PROCEDURES

See “Diagnostic Procedures/Surgery" above

ADDITIONAL TREATMENT

This is dictated by the results of the TRUS biopsy and presence/extent of prostate cancer

Radiation Therapy

While not a specific treatment of the nodule, it can be used as primary therapy or as additional adjuvant/salvage therapy after prostatectomy in patients with prostate cancer

Additional Therapies

May be required in cases with metastatic disease or disease that recurs after definitive local therapy

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
Depends on diagnosis after TRUS-guided biopsy

COMPLICATIONS
- TRUS-guided biopsy
  - Hematuria
  - Hematochezia
  - Hematospermia
  - Urinary tract infection or sepsis
  - Urinary retention

Other complications are dictated by the treatment received for prostate cancer

FOLLOW-UP
Patient Monitoring
Negative biopsy in a patient with an abnormal DRE or elevated PSA requires follow-up with serial PSA and DRE

Patient Resources

CODES

ICD9

- 600.10 Nodular prostate without urinary obstruction
- 600.11 Nodular prostate with urinary obstruction
- 790.93 Elevated prostate specific antigen [PSA]

ICD10

- N40.2 Nodular prostate without lower urinary tract symptoms
- N40.3 Nodular prostate with lower urinary tract symptoms
- R97.2 Elevated prostate specific antigen [PSA]

CLINICAL/SURGICAL PEARLS

- A firm prostate nodule generally deserves further workup with a serum PSA and prostate biopsy.
- Up to 40% of patients may develop granulomatous prostatitis after intravesical BCG that may present as a prostate nodule.

PROSTATIC INTRAEPITHELIAL NEOPLASIA (PIN)

Joseph C. Klink, MD
Eric A. Klein, MD, FACS

BASICS

DESCRIPTION

- Prostatic intraepithelial neoplasia (PIN) describes cytologically atypical cells confined within architecturally benign prostatic glands and acini
- Historically subclassified
  - Low-grade PIN (LGPIN) and high-grade PIN (HGPIN)
  - PIN 1, 2, or 3
- LGPIN no longer reported because
  - Not reliably distinguished from benign prostate by pathologists
  - LGPIN carries no increased risk of prostate cancer (PCa) on future biopsies
- HGPIN, and atypical small acinar proliferation (ASAP) are both considered by most to be premalignant and the terms should not be used interchangeably.
- Antiquated names for PIN include intraductal hyperplasia, hyperplasia with malignant change, large acinar atypical hyperplasia, marked atypia, ductal-acinar dysplasia
- Remainder of this chapter will focus on HGPIN

EPIDEMIOLOGY

Incidence

- Parallels PCa incidence
- Increases with age
- In PSA screened men, incidence ranges 0–25%
  - Mean incidence 7.7%

Prevalence

- Parallels PCa prevalence
- 7% of men in their 30s
- 91% of elderly African American men
- 67% of elderly Caucasian men
- 21% of Korean men undergoing cystoprostatectomy

RISK FACTORS

- Age
- PCa
  - HGPIN often found close to PCa, but does not carry independent prognostic significance once PCa is diagnosed

Genetics

- Many genetic abnormalities shared by HGPIN and PCa
  - Leads to conclusion that HGPIN is a precursor of PCa
- TMPRSS2-ERG gene fusion in 16–19% of HGPIN lesions in patients with PCa

- Overexpression of PTOV1 in HGPIN is an independent predictor of PCa on repeat biopsy
- mTOR pathway upregulation
- Chromosomal anomalies in >50% of HGPIN
- Gains of chromosomes (decreasing order of frequency) 8, 10, 7, 12, and Y
- Loss of heterozygosity on 8p12–21
- Telomerase activation
- Epigenetic changes including hypermethylation

PATHOPHYSIOLOGY

- HGPIN may be precursor of PCa (1)
  - PCa can develop without HGPIN
- HGPIN extent and frequency greater when PCa present
- Usually in peripheral zone
- Often multifocal

ASSOCIATED CONDITIONS

ALERT
Multifocal HGPIN Predicts Increased Risk of PCa on subsequent biopsy.

- Historically, HGPIN on prostate biopsy often represented failure to sample a nearby PCa (2)
  - As the number of cores routinely sampled at prostate biopsy increased, the predictive value of HGPIN for PCa decreased
- With modern 12-core biopsies, a single focus of HGPIN does NOT increase the risk of PCa diagnosis on subsequent biopsies
  - Decision for repeat prostate biopsy should be made on other clinical factors (elevated PSA, high PSA velocity, new nodule on DRE), not influenced by the presence of 1 focus of HGPIN
- Multifocal HGPIN indicates higher risk of PCa on repeat biopsy (3)
  - Multivariate odds ratio 3.2 for increased cancer detection with multifocal HGPIN
  - 16–75% (usually around 30%) PCa rate on repeat biopsy for multifocal HGPIN
- Repeat biopsy usually done 1 yr after initial biopsy

GENERAL PREVENTION

- 5α-reductase inhibitors can reduce the incidence of PIN but are not FDA approved for this use
  - Finasteride daily for 7 yr decreased the incidence of HGPIN from 7.1–6% in the Prostate Cancer Prevention Trial
  - Dutasteride reduced the incidence of HGPIN from 6–3.7% in the REDUCE trial
- The risk posed by unifocal HGPIN to a patient's health and life in the absence of PCa is so low that prevention is not indicated

DIAGNOSIS

HISTORY

HGPIN produces no symptoms

PHYSICAL EXAM

- Digital rectal exam (DRE) is usually normal, but may reveal a prostate nodule or induration

• No other physical exam findings

DIAGNOSTIC TESTS & INTERPRETATION

Lab

Elevated PSA may be present but not caused by the HGPIN

Imaging

Not reliably seen on any imaging

Diagnostic Procedures/Surgery

• Transrectal ultrasound-guided biopsy of the prostate taking at least 12 cores
  – Indicated to look for PCa. HGPIN is an incidental finding

Pathologic Findings

• Characterized by proliferation of secretory cells with significant cytologic atypia within prostate glands and acini
• Secretory cells are enlarged with increased nuclear/cytoplasmic ratio and prominent nucleoli
• Cytoplasm of the HGPIN cells tends to stain positively for α-methylacyl-CoA
• Most of these features are shared by PCa
• In PCa, basal cells are absent. In HGPIN the basal cell layer is retained although is often discontinuous on H&E stain (Figure 2)
  – Basal cells can be demonstrated by immunohistochemical staining with antibodies to high–molecular-weight cytokeratins or nuclear p63
• 4 main architectural patterns of HGPIN have been described (tufting, micropapillary, cribriform, and flat), but these do not make a difference clinically
• HGPIN usually found in the peripheral zone

DIFFERENTIAL DIAGNOSIS

• Prostate Cancer (PCa)
• ASAP
  – Confers an increased risk of subsequent PCa diagnosis
  – Requires repeat prostate biopsy in a few months to rule out PCa
• Normal anatomic structures and embryonic rests
• Atypia induced by inflammation, infarction, or radiation
• Lobular atrophy and postatrophic hyperplasia
• Transitional cell metaplasia
• Typical and atypical basal cell metaplasia
• Cribriform hyperplasia
• Cribriform, ductal endometrioid, and urothelial carcinoma

TREATMENT

GENERAL MEASURES

• If HGPIN was found on initial prostate biopsy of <10 cores, the biopsy should be repeated with an extended scheme
• If multifocal HGPIN is found on initial prostate biopsy, the biopsy should be repeated within 1 yr

- Repeat biopsy should sample the entire prostate, not just the HGPIN area

MEDICATION

First Line

- Not necessary to treat HGPIN
- HGPIN often used to identify patients at "high risk" of developing PCa to enroll them in clinical trials of medications to prevent PCa

Second Line

N/A

SURGERY/OTHER PROCEDURES

Radical prostatectomy not indicated for HGPIN in the absence of PCa

ADDITIONAL TREATMENT

Radiation Therapy

Not indicated for HGPIN in the absence of PCa

Additional Therapies

N/A

Complementary & Alternative Therapies

- Green tea catechins for 1 yr in men with HGPIN reduced the incidence of PCa from 30 to 3%
- Soy, vitamin E, and selenium did not slow the rate of progression of HGPIN to PCa in a randomized double-blind trial (SELECT Trial)
- None of these therapies routinely recommend to men with HGPIN

ONGOING CARE

PROGNOSIS

- Excellent prognosis in the absence of PCa
- Must monitor for the development of PCa as outlined above

COMPLICATIONS

None other than the risks of biopsy

FOLLOW-UP

Patient Monitoring

- In certain situations as noted, HGPIN may indicate an increased risk of PCa and, therefore, may require repeat biopsy at 1 yr
- LGPIN should not be diagnosed on pathology and, therefore, does not require any follow-up

CLINICAL/SURGICAL PEARLS

- If HGPIN was found on initial prostate biopsy of <10 cores, the biopsy should be repeated with an extended scheme.
- If multifocal HGPIN is found on initial prostate biopsy, the biopsy should be repeated within 1 yr.
- With modern 12-core biopsies, a single focus of HGPIN does NOT increase the risk of PCa diagnosis on subsequent biopsies.
- Decision for repeat prostate biopsy should be made on other clinical factors (elevated PSA, high PSA velocity, new nodule on DRE), not influenced by the presence of 1 focus of HGPIN.

PROSTATITIS, ACUTE, BACTERIAL (NIH I)

Nicholas J. Kuntz, MD
Judd W. Moul, MD, FACS

BASICS

DESCRIPTION

- Acute bacterial prostatitis is cute, potentially life-threatening bacterial infection of the prostate
- The symptoms are typically severe and sudden and usually cause the patient to seek emergency care
- The NIH prostatitis classification system it is referred to as NIH:I

EPIDEMIOLOGY

Incidence

- Least common form of prostatitis
  - 1–5%
- Incidence peaks at 20–40 yr (1)[B]
- Not affected by race and ethnicity (1)[B]

Prevalence

Estimated to be ~10% for all types of prostatitis worldwide (1)[B]

RISK FACTORS

- Bladder outlet obstruction
  - Benign prostatic hyperplasia (BPH)
  - Stricture disease
- Previous episodes of prostatitis
- Lower urinary tract procedures
  - Prostate biopsy or urethral catheterization
- Phimosis
- Immunocompromised
  - Human immunodeficiency virus (HIV)
- Immunosuppression
  - Diabetes
- Indwelling urethral catheter
- Urinary tract infection (UTI)
- History of sexually transmitted disease

Genetics

Not applicable

PATHOPHYSIOLOGY

- Intraprostatic reflux of infected urine
- Ascending urethral infection:

- Unprotected sexual intercourse
- Urologic instrumentation
- Prolonged catheterization

• Direct invasion or lymphogenous spread from the rectum
- Following biopsy, BPH procedures

• Hematogenous seeding
- *Staphylococcus aureus* most common, including methicillin-resistant strands (MRSA)

• Usually a single bacterial uropathogen
- *Escherichia coli* 87% (2)[B]
- Pseudomonas, Proteus, Klebsiella
- Enterococci 5–10%

• Sexually active and < 35 yr
- *Neisseria gonorrhoeae*

• Severe immunocompromise (HIV/AIDS)
- Mycobacterium tuberculosis, Serratia, Salmonella, and fungi (Candida, Histoplasma, Aspergillus, Cryptococcus) (1)[B]

• NIH classification: (3)[A]
- I: Acute bacterial prostatitis
- II: Chronic bacterial prostatitis: Recurrent infection
- III: Chronic abacterial prostatitis/chronic pelvic pain syndrome (CPPS): No demonstrable infection:
  - IIIA: Inflammatory CPPS: White blood cells (WBCs) present in semen/expressed prostatic secretions or voided bladder urine (VB3)
  - IIIB: Noninflammatory CPPS: WBCs not present in semen/expressed prostatic secretions or voided bladder urine (VB3)
- IV: Asymptomatic inflammatory prostatitis: Detected by prostate biopsy or presence of WBCs in prostatic secretions during evaluation for other disorders

ASSOCIATED CONDITIONS
• BPH
• Urethral stricture disease
• Diabetes
• HIV
• UTI

GENERAL PREVENTION
• Safe sex practices may prevent some cases.
• Management of underlying BPH, DM, etc.

DIAGNOSIS
HISTORY
• Systemic symptoms
- Fever, chills, malaise, arthralgia, myalgia

• Irritative or obstructive voiding symptoms
- Dysuria, urgency, frequency

- Acute urinary retention (20%)
  - Due to bladder neck spasm
- Perineal/rectal pain, lower back pain

PHYSICAL EXAM

ALERT
Avoid vigorous prostatic exam or massage in a patient with suspected acute bacterial prostatitis. This may cause bacteremia and sepsis. Likewise urethral instrumentation should be avoided if possible (4)[C].

- Vital signs:
  - Signs of sepsis including fever, tachycardia, and hypotension
- Abdominal exam:
  - Palpable bladder or abdominal fullness suggesting acute urinary retention
- Digital rectal exam (DRE):
  - Perform cautiously
  - Exquisitely tender, warm, boggy, swollen prostate gland

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Complete blood count
  - Leukocytosis with left shift
- Urinalysis
  - Proteinuria, pyuria, and hematuria
  - Positive leukocyte esterase and nitrite has a sensitivity of 68–88% (1)[B]
- Urine culture
- Blood cultures
  - Particularly for immunosuppressed patients
- Prostate-specific antigen (PSA)
  - Little clinical value in the acute setting
  - Will be elevated in the majority of cases
  - Should be repeated 1–2 mo following treatment

Imaging

- Not routinely required
- Indicated if fever persists despite appropriate treatment to evaluate for prostatic abscess
  - CT scan
    - Area of low attenuation
    - Rim enhancing with IV contrast
  - Ultrasound
    - Hypoechoic lesion
  - MRI
    - High intensity on T2-weighted images
    - Rim enhancing with gadolinium

Diagnostic Procedures/Surgery

None: Clinical diagnosis

Pathologic Findings

Prostate biopsy is contraindicated in the presence of acute bacterial prostatitis

DIFFERENTIAL DIAGNOSIS

- UTI
- Pyelonephritis
- Chronic bacterial prostatitis
- Granulomatous prostatitis
- Perirectal abscess
- Prostate cancer
- Prostatic abscess
- Prostatodynia

TREATMENT

GENERAL MEASURES

- Indications for admission and IV antibiotics:
  - High fever
  - Significant leukocytosis
  - Sepsis
- Analgesics/antipyretics
- Stool softeners
- Bladder drainage if there is evidence of urinary retention:
  - A urethral catheter should be placed cautiously
  - With any difficulty or if the patient is too uncomfortable, percutaneous suprapubic tube should be placed
- If no clinical response in 48 hr despite appropriate treatment consider prostatic abscess
- Postprostate biopsy prostatitis suspect resistance to fluoroquinolones

MEDICATION

First Line (4)[C]

- Antibiotics with high lipid solubility and concentrated in prostatic tissue
  - Fluoroquinolones
    - Levofloxacin, 250–750 mg daily IV or by mouth (PO)
    - Ciprofloxacin, 250–750 mg PO twice daily (BID), 400 mg IV BID
    - Ampicillin with gentamicin (ampicillin 1–2 g IV every 4–6 hr, 500 mg PO every 6 hr; gentamicin 1–2 mg/kg IV every 8–12 hr or daily dosing 4–7 mg/kg every 24 hr IV)
    - Ceftriaxone 1–2 g IV or IM daily
  - Afebrile 24–48 hr may change to oral antibiotics
- Adjust antibiotic regimen based on urine and/or blood culture results
- Transition to oral antibiotic following resolution of acute toxicity
- Total antibiotic duration: 2–4 wk

Second Line

- Oral antibiotics are a reasonable 1st option in nontoxic patients.
  - Fluoroquinolones (see above oral dose) for 10 days (4)[C]

– Trimethoprim–sulfamethoxazole 160/800 mg PO every 12 hr
- If STD is suspected (sexually active male younger than 35 yr) empiric treatment with ceftriaxone 250 mg IM and doxycycline 100 mg BID for 7 days may be warranted, but this is controversial (5)[C]

SURGERY/OTHER PROCEDURES
- Suprapubic tube placement
  – If Foley catheter cannot be passed easily in setting of acute urinary retention
- If prostatic abscess develops, surgical drainage of prostatic abscess is usually required (4)[B]
  – Transrectal or perineal needle aspiration
    - Ultrasound guided
    - Local anesthetic
  – Transurethral drainage
    - Incision or unroofing
    - Resection may be associated with higher rates of sepsis
  – Open drainage
    - If less invasive methods fail
    - Abscess extends beyond prostate

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

Limited, if any role in the acute setting

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS
- If initial response to therapy is favorable then patient prognosis is excellent.
- Studies using quinolone antibiotics suggest that a negative culture after 7 days of therapy is predictive of a long-term response.
- If the patient with suspected bacterial prostatitis is not responding to initial empiric therapy, consider prostatic abscess.

COMPLICATIONS
- Prostatic abscess
- Decreased fertility
- Epididymitis
- Chronic prostatitis
- Emphysematous prostatitis
- Pyelonephritis
- Sepsis
- Urinary retention

FOLLOW-UP

Patient Monitoring

- Follow-up urine cultures to verify that the infection has cleared and that chronic bacterial prostatitis is not present.
- If PSA was obtained during the acute episode, and was elevated, repeat in 1–2 mo to resolution.

• Urinary Tract Infection (UTI), Adult Male

CODES

ICD9

• 041.49 Other and unspecified *Escherichia coli* [*E. coli*]
• 098.12 Gonococcal prostatitis (acute)
• 601.0 Acute prostatitis

ICD10

• A54.22 Gonococcal prostatitis
• B96.20 Unsp Escherichia coli as the cause of diseases classd elswhr
• N41.0 Acute prostatitis

CLINICAL/SURGICAL PEARLS

• *E. coli* is most common organism in acute bacterial prostatitis.
• Avoid vigorous prostatic exam or massage during an episode of acute bacterial prostatitis.
• It is not advisable to measure serum PSA during an episode of acute bacterial prostatitis as it will most likely be falsely elevated.
• Urinary retention requires bladder drainage.
• May require hospital admission and IV antibiotics.
• Consider prostatic abscess if no clinical response in 48 hr.

PROSTATITIS, CHRONIC NONBACTERIAL, INFLAMMATORY AND NONINFLAMMATORY (NIH CP/CPPS III A AND B)

Amin S. Herati, MD
Robert M. Moldwin, MD, FACS

BASICS

DESCRIPTION

- Chronic prostatitis/chronic pelvic pain syndrome (CP/CPPS), NIH categories IIIA and IIIB are characterized by pelvic, perineal, and/or testicular pain ± LUTS in the absence of other well-defined pathology.
  - IIIA: Inflammatory CPPS: WBCs present in prostatic secretions
  - IIIB: Noninflammatory CPPS: WBCs not present in prostatic secretions

EPIDEMIOLOGY

Incidence

N/A

Prevalence

Estimated prevalence of CP/CPPS is 1.8%, equating to approximately 2,000,000 US men (1).

RISK FACTORS

- Urethral catheterization or instrumentation
- Inadequately treated urinary tract infections
- Pelvic trauma
- Urethral strictures
- Psychological stress or depression

Genetics

- A large proportion of patients with CP/CPPS express the IL-10 AA genotype with low IL-10 expression
- Category IIIA patients are more likely to have a low TNFα genotype

PATHOPHYSIOLOGY

- 90% of cases of CP/CPPS have an unclear etiology, the remainder of cases can be attributed to bacterial in origin (Category II)
- Although the exact cause is not known, it is thought to be multifactorial with a combination of factors contributing to the pathophysiology (image)
- Current theories include:
  - Nanobacterial colonization
  - Atypical bacterial infection
  - Voiding dysfunction causing intraprostatic urinary reflux and elevated intraprostatic pressure
  - Pelvic floor muscle dysfunction
  - Endocrine

  - Neuropathic
  - Autoimmune
- Stratification of each patient into a 6-point clinical phenotyping system, termed UPOINT, based on likely etiologic mechanisms has been proposed to improve outcomes by tailoring therapies to target the involved mechanisms (2).

ASSOCIATED CONDITIONS
- Allergies
- Sinusitis
- Erectile dysfunction
- Irritable bowel syndrome
- Depression
- Fibromyalgia
- Fatigue
- Neurologic disorders

GENERAL PREVENTION
N/A

DIAGNOSIS
HISTORY
- Determine duration of symptoms (of at least >3-mo duration)
- Pain in the suprapubic region, lower back, penis, testes, and/or scrotum
- Painful ejaculation: One of the most discriminatory symptoms associated with CP/CPPS III and a strong predictor of QOL and severity of pain (3)
- Sexual dysfunction
- Pelvic floor muscle spasms
- Irritative and obstructive voiding symptoms
  - Urgency
  - Frequency
  - Hesitancy
  - Poor interrupted flow
- History should also cover neurologic disease, hematologic, cardiovascular, and infectious diseases
- NIH-CPSI is a validated questionnaire assessing pain, urinary function, and QOL. Can be used to measure symptoms upon initial presentation and follow-up

PHYSICAL EXAM
- Careful exam of the genitalia, groin, perineum, coccyx, external anal sphincter, and internal pelvic floor and side walls
- Exam is usually unremarkable except for pain: Degree of pain not helpful in differentiating between various categories of CP/CPPS
- Digital rectal exam should not be performed until urine from preprostatic massage has been collected

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urinalysis and urine culture
- Stamey test (Meares–Stamey 4-glass test)—considered to be "gold standard" in diagnosis
- Limitations: EPS cannot be obtained in all patients, variable interpretation of WBC counts, difficult-to-culture organisms not routinely identified
- 2-glass test (premassage and postmassage test)
  - Difficulties encountered with interpretation of bacterial localization studies as asymptomatic individuals often harbor uropathogens

Imaging
- Pelvic imaging with ultrasonography, CT, or MRI is considered optional and can be obtained if clinically indicated to rule out other causes of pelvic pain
- TRUS has poor specificity in differentiating among the subtypes of CP/CPPS

Diagnostic Procedures/Surgery
- Stamey test (Meares–Stamey 4-glass test)
- Video-urodynamics: Should be considered in patients with significant lower urinary tract symptoms in addition to pain. Findings often include decreased peak and mean urinary flow rates, elevated maximal urethral closing pressure, incomplete funneling of the bladder neck, and urethral narrowing at the level of the external urethral sphincter (4)
- Cystoscopy is not indicated in the majority of cases: Can be performed if history indicates other etiology
- Prostate biopsy: Tissue for culture not helpful in diagnosis and not recommended

Pathologic Findings
Not formally reported for Category III, therefore N/A

DIFFERENTIAL DIAGNOSIS
- Acute or chronic bacterial prostatitis
- Benign prostatic hyperplasia
- Bladder calculus
- Bladder cancer
- Bladder neck contracture
- Interstitial cystitis
- Primary voiding dysfunction
- Prostate abscess
- Prostate cancer
- Prostate cyst
- Radiation cystitis
- Tuberculosis of the prostate
- Urethral stricture
- Urethritis

TREATMENT

GENERAL MEASURES
- As the pathogenesis of CP/CPPS category III is considered multifactorial, effective treatment

for CP/CPPS III often requires multimodal therapy
- A meta-analysis comparing α-Blockers, antibiotics and anti-inflammatory/immune modulating therapies found a combination of α-blockers and antibiotics to be superior to α-blockers, antibiotics, or anti-inflammatory/immune modulating therapies alone in the reduction of NIH-CPSI scores (5)
- Treatment should also be targeted to the etiologic mechanisms using the UPOINT system
- Focus of therapy should be on symptom relief
- Conservative measures such as diet modification, myofascial physical therapy, phytotherapies, acupuncture should be considered as part of the 1st-line therapy
- Symptoms should be followed with NIH-CPSI questionnaires and voiding diaries

MEDICATION

First Line

- The choice of agents in the 1st- or 2nd-line setting is practitioner dependent with no specific agent approved specifically for this condition
- α-Blockers: Multiple randomized, placebo-controlled trials have demonstrated a duration of at least 3 mo or longer may be needed before assessment can be made of treatment failure or success.
  - Side effects of α-blockers include hypotension, dizziness, fatigue, and retrograde ejaculation
    - Alfuzosin 10 mg BID for 12 wk; contraindicated with moderate hepatic insufficiency or with cytochrome P450 3A4 inhibitors
    - Doxazosin 1–4 mg daily for 12 wk; escalate dose until symptom relief obtained
    - Tamsulosin 0.4 mg daily for 12 wk
    - Terazosin 1–5 mg daily; escalate dose until symptom relief obtained
    - Silodosin (8 mg/d)
- Antibiotic therapy: Data conflicting on the benefit and therapeutic benefit should be reassessed after 2 to 4 wk of initiating therapy
  - Can be considered in antibiotic-naïve patients
  - Fluoroquinolones: Side effects include dizziness, restlessness, headache, nausea, rash
    - Ciprofloxacin, levofloxacin 500 mg daily for 4 wk (some concern over growing resistance to this class of drugs)
    - Trimethoprim–sulfamethoxazole 160/80 mg BID for 4 wk: Side effects include anorexia, nausea, vomiting, rash, urticaria
- 5α-Reductase inhibitor:
  - Finasteride 5 mg daily or
  - Dutasteride 0.5 mg daily
- Anti-inflammatory agents
  - Rofecoxib 25–50 mg daily: Symptom relief at higher doses, but not recommended because of cardiovascular risk
  - Oral prednisolone
- Pentosan polysulfate 100 mg TID
- Gabapentanoids
  - Pregabalin 150–600 mg daily
- Muscle relaxants

– Baclofen
– Diazepam

Second Line
See above

SURGERY/OTHER PROCEDURES
• Not recommended. Last resort unless other indications are discovered during the workup
– Transurethral microwave thermotherapy

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
See below

Complementary & Alternative Therapies
• Dietary and lifestyle modification
• Phytotherapy
– Pollen extract
– Quercetin
– Saw palmetto
• Acupuncture
• Myofascial physical therapy
• Stress management/cognitive-behavioral therapy
• Frequent ejaculation

ONGOING CARE

PROGNOSIS
Remissions and flare-ups common over the long term

COMPLICATIONS
None known

FOLLOW-UP
Patient Monitoring
Long-term supportive care

Patient Resources

CLINICAL/SURGICAL PEARLS

Multimodal therapy is oftentimes required because of the varied pathologies associated with this condition.

PROSTATITIS, CHRONIC, BACTERIAL (NIH II)

John J. Pahira, MD

BASICS

DESCRIPTION

- Chronic bacterial prostatitis (NIH II) includes symptoms of prostatitis with positive urine culture and no signs of systemic infection
- Occasionally, without local symptoms
- Recurrent UTI with a single organism that persists is the classic hallmark
- Overlap of symptoms makes it difficult to distinguish clinically from chronic nonbacterial prostatitis (NIH Type III, CP/CPPS); about 10% of these patients with type III prostatitis will have positive cultures
- NIH classification and current definitions of prostatitis (1):
  - Type I: Acute bacterial prostatitis
  - Type II: Chronic bacterial prostatitis; recurrent infection
  - Type III: Chronic abacterial prostatitis/CPPS; no demonstrable infection:
    - IIIA: Inflammatory CPPS: WBCs present in semen/expressed prostatic secretions or voided bladder urine (VB3)
    - IIIB: Noninflammatory CPPS: WBCs not present in semen/expressed prostatic secretions or voided bladder urine (VB3)
  - Type IV: Asymptomatic inflammatory prostatitis: Detected by prostate exam or presence of WBCs in prostatic secretions during evaluation for other disorders

EPIDEMIOLOGY

- Prostatitis in general is the most common urologic diagnosis in men <50 yr old, and the 3rd most common diagnosis in men >50 yr old.
- Affects 10–14% of men of all ages and accounts for 2 million office visits annually.
- Chronic bacterial prostatitis is the most common cause of recurrent UTI in the adult male population.

RISK FACTORS

- Inadequately treated episodes of acute bacterial prostatitis may increase risk for developing chronic prostatitis syndromes
- Older men with BPH/bladder outlet obstruction
- Urethral strictures
- Urethral catheterization
- Possibly reduced sexual activity with resulting prostatic congestion

Genetics

N/A

PATHOPHYSIOLOGY

- With progressive benign prostatic enlargement, obstruction causes reflux into prostatic ducts (2).

- Obstructive, turbulent, and/or high-pressure voiding combined with intraprostatic ductal reflux, leads to acute intraductal inflammation.
- Progresses to chronic intraductal inflammation.
- Bacteria are present in inflamed ducts in protected bacterial aggregates or bacterial biofilms.
- Increased incidence of prostatic calculi may serve as a nidus of infection.
- Prostatic zinc levels (zinc is thought to be antibacterial) are lower in patients with chronic bacterial prostatitis; however, it is not clear if this is a cause of or due to the infection.
- pH of prostatic fluid may increase from a normal of ~6.5 to >8.0 with infection.
- Common pathogens: *Escherichia coli* (most common), *Enterococcus faecalis*, *Klebsiella pneumoniae, Pseudomonas aeruginosa, Proteus spp.*
- Others: *Staphylococcus epidermatitis, S. saprophyticus, Corynebacterium,* and *Ureaplasma urealyticum*, *Chlamydia trachomatis, Candida*, *trichomonas*, *Mycobacterium hominis*, and *Tuberculosis*:
  - *Chlamydia, Ureaplasma, Mycoplasma spp.* can cause prostatitis but do not grow in routine culture.

ASSOCIATED CONDITIONS
- BPH
- Detrusor/sphincter dyssynergia
- Sexual dysfunction
- STDs
- Subfertility/infertility
- Urethral stricture

GENERAL PREVENTION
- Adequate treatment of acute bacterial prostatitis
- Protected intercourse
- Voiding after all sexual experiences may help

DIAGNOSIS

HISTORY
- Fever and chills are not usual and suggest acute bacterial prostatitis.
- Dysuria, urgency, nocturia, weak stream
- Perineal, penile, scrotal, suprapubic, or groin pain; pain with or after ejaculation
- ED, decreased libido
- Prior UTIs, STDs
- Unprotected intercourse, new partners, sexual orientation
- Urethral catheterization or other lower genitourinary surgery
- NIH-CPSI, a self-administered validated symptom index, may be useful.

PHYSICAL EXAM
- Exam of the genitalia may reveal vague widespread pelvic discomfort.
- Perineal tenderness may be present.
- DRE may reveal a minimally tender or boggy prostate.
- Prostatic calculi may be palpable.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urine analysis and culture (2):
  - Routine urine culture may be negative. A positive culture may be obtained as part of the Meares–Stamey 4-glass test (see below):
  - Pyuria and bacteruria may be present.
  - Hematuria should prompt workup for other causes.
- PSA may be elevated in the setting of prostate infection and should not be obtained until the infection clears.

Imaging

Imaging has low yield and is performed only to exclude the presence of other more definable and treatable causes of the patient's symptoms.

- Transrectal US performed in patients with pain on ejaculation may reveal enlargement of the prostate or seminal vesicle. Prostatic calculi may be visualized.

ALERT
In the setting of possible acute bacterial prostatitis or prostatic abscess, prostatic massage should not be performed.

Diagnostic Procedures/Surgery

- Meares–Stamey 4-glass test considered gold standard for the diagnosis of chronic bacterial prostatitis and involves isolated cultures of different portions of the lower urinary tract:
  - Make sure that the patient has a full bladder
  - Clean the glans thoroughly with antimicrobial solution. Retract foreskin as necessary
  - Void 10 mL into sterile container (VB1). Represents urethral flora sample
  - After voiding 100 mL, collect 10 mL midstream urine in another sterile container (VB2). Represents bladder flora sample
  - Perform prostatic massage to collect EPS from the urethra; submit for culture and examine on a glass slide under 40×. Represents prostate flora
  - Collect the next voided 10 mL in a sterile container. Represents a combination of prostate and bladder flora
- Normal:
  - Negative urethral, prostatic, and bladder cultures (VB1, VP2, EPS, and VB3 negative)
  - Normal prostatic secretions show no evidence of excess WBCs (<10 WBC cells per high-power field)
- Positive:
  - If EPS or VB3 colony counts are 10× higher than VB1 or VB2, bacterial prostatitis is present
  - If all cultures are positive, then bacterial cystitis is likely present and the test should be repeated after 5 days of antibiotics (prostatitis and cystitis can coexist, and cystitis in men is often secondary to prostatitis)
  - EPS result is >10–20 WBC per high-power field or clumping of WBC. It is not diagnostic for bacterial infection as it can also be seen with NIH Class IIIA prostatitis
- A modified Meares–Stamey test (2-glass test) can also be performed that is considered more convenient and practical

  - After cleansing the glans, obtain 10 mL of a midstream urine for culture (preprostate massage). Represents bladder flora. Should also be dipped for white cells
  - Perform prostate massage and obtain 10 mL of urine (postprostate massage) for culture and microscopic exam. Represents prostate and bladder flora. If white cells are present, they may represent bacterial prostatitis or NIH type IIIA
  - If postmassage colony counts are 10× higher than premassage sample, bacterial prostatitis is present. If both cultures have similar counts, cystitis is present
- Semen culture is of limited use, demonstrating low sensitivity but high specificity compared to Stamey test
- Uroflowmetry may demonstrate diminished flow with intermittency
- Elevated PVR may be present

Pathologic Findings

N/A

DIFFERENTIAL DIAGNOSIS

- Acute bacterial prostatitis/prostatic abscess
- Bladder outlet obstruction/BPH
- Chronic nonbacterial prostatitis (NIH IIIA/B)
- Cystitis
- Interstitial cystitis
- Prostatic cyst
- Seminal vesiculitis
- STDs
- Tuberculous/granulomatous prostatitis
- Urethritis or urethral pathology (stricture)

TREATMENT

GENERAL MEASURES

- Antibiotic course normally extends for 6–8 wk and sometimes longer with refractory infections. Goal is to eradicate the nidus of infection in the prostate. Follow culture results (3,4).
- Avoid alcohol, spicy foods, perineal pressure for extended times (sitting or bicycle riding), acidic beverages.
- Continue to engage in safe protected sexual activity, as this is thought to reduce prostatic congestion.

MEDICATION

First Line

- Current sensitivity patterns are showing increased resistance to quinolones, TMX/SULFA, ampicillin. In choosing antibiotic coverage prior to culture sensitivity reports, know local resistance patterns based on your hospital antibiogram
- Fluoroquinolones still preferred
  - No difference in bacterial eradication between levofloxacin and ciprofloxacin, although prostatic fluid concentration of levofloxacin is higher than ciprofloxacin. Levofloxacin has

daily dosing and may have better prostatic penetration
  - Ciprofloxacin 500 mg PO BID for 4–6 w;
  - Levofloxacin 500 mg/d for at least 6–8 wk
- Trimethoprim 60 mg–sulfamethoxazole 80 mg BID for at least 6–8 wk
- Tetracycline derivatives (eg, doxycycline) only if *Chlamydia* or *Mycoplasma* suspected

Second Line
- Anti-inflammatories (ibuprofen) for symptoms
- α-Blockers (doxazosin, tamsulosin, alfuzosin, silodosin) may help with LUTS

SURGERY/OTHER PROCEDURES
- Not generally recommended
- TURP
  - Can be considered in select cases of refractory prostatitis with infected calculi and/or obstruction

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
- Frequent ejaculation (in patients with enlarged, symptomatically congested glands)
- Dietary modifications of common comestibles found to irritate the lower urinary tract
- Moist heat with Sitz baths or heating pad for symptomatic relief

Complementary & Alternative Therapies
- Prostate massage (very controversial):
  - May work by stimulating hibernating bacterial biofilms (making them more susceptible to antimicrobials), draining the obstructed inflamed ducts (allowing for better antimicrobial penetration), and stimulating blood supply to the area.
- Avoid bicycling or other activities that cause perineal pressure
- Zinc supplements: Unproven benefit
- Phytotherapy: Plant extracts and herbal medications (ie, saw palmetto) popular but may only be as effective as placebo (5)

ONGOING CARE

PROGNOSIS
- Fluoroquinolones have improved the ability to clear the infection (60–90% cure reported).
- Variable course with flare-ups possible. If culture-positive infection persists, consider longer course of therapy (3–6 mo) with a lower daily dose.
- Treating underlying obstruction or prostatic calculi if necessary may prevent further infections.

COMPLICATIONS
- Recurrent cystitis, epididymitis, urethritis
- CPPS
- Infertility (effect on semen quality debatable)

- Primarily affects QOL
- Unknown if predisposes to prostate cancer

FOLLOW-UP

Patient Monitoring

- Document clearing of positive culture
- Following prostate cancer screening guidelines is recommended. Do not obtain PSA for at least 6 wk after culture clears.

CLINICAL/SURGICAL PEARLS

Inadequately treated acute bacterial prostatitis may increase risk for developing chronic prostatitis syndromes including chronic bacterial prostatitis.

PROSTATITIS, GENERAL

Ryan S. Levey, MD
Justin D. Ellett, MD, PhD

BASICS

DESCRIPTION

- Prostatitis is a general term that refers to inflammation of the prostate.
- Traditionally classified as acute bacterial prostatitis, chronic bacterial prostatitis, nonbacterial prostatitis, and prostatodynia today the definitions used are much more precise and based on the NIH system (1).
- Revised 1995 NIH classification of prostatitis is standard nomenclature:
  - NIH Class I: Acute bacterial prostatitis; infection of prostate, sudden onset, often associated with UTI
    - >10 WBC/HPF in 1st 10 mL voided urine and midstream catch
    - Positive culture in 1st 10 mL voided urine and midstream catch
  - NIH Class II: Chronic bacterial prostatitis; insidious onset, relapsing, recurrent UTI
    - >10 WBC/HPF
    - Positive culture in expressed prostatic secretions (EPS) and 1st 10 mL of voided urine after EPS
  - NIH Class III: Chronic prostatitis (CP)/Chronic pelvic pain syndrome (CPPS):
  - NIH Class IIIA: Inflammatory: Inflammatory cells in prostatic secretion, seminal fluid, postprostatic massage urine
    - >10 WBC/HPF in EPS, 1st 10 mL of voided urine after EPS, or semen
  - NIH Class IIIB: Noninflammatory: Insignificant inflammatory cells
    - <10 WBC/HPF in EPS, 1st 10 mL voided urine after EPS, or semen
  - NIH Class IV: Asymptomatic inflammatory prostatitis, incidental biopsy finding
    - >10 WBC/HPF and/or bacteria in EPS, 1st 10 mL voided urine after EPS, semen, or histologic specimens in asymptomatic patients

EPIDEMIOLOGY

Incidence

- 2 million cases annually
- 9–16% men have had diagnosis of prostatitis
- 3–12% male outpatient urology visits
- Most common urologic diagnosis in men <50 yr, 3rd most common >50 yr (2)
  - Overall incidence of acute prostatitis or prostatitis NOS 2.8/1,000 person-years (PY) over 70,166 PY of follow-up (3)
    - 3.2/1,000 PY in patients aged 20–29 yr
    - 3.6/1,000 PY in patients aged 30–39 yr
    - 5.4/1,000 PY in patients aged 70–79 yr

Prevalence

N/A

RISK FACTORS

- Acute epididymitis
- Chronic catheterization (indwelling or condom)
- Dysfunctional voiding
- Immunocompromised states
- Intraprostatic ductal reflux
- Phimosis
- Urethral stricture, distal
- BPH
- Prostatic calculi
- Transurethral surgery/instrumentation
- Transrectal prostate biopsy
- Unprotected anal sex
- UTI

Genetics

N/A

PATHOPHYSIOLOGY

- Extension of UTI
- Manipulation of urinary tract or prostate
- Bacterial:
  - Ascending infection through urethra
  - Refluxing urine into prostate ducts
  - Direct extension or lymphatic spread from rectum
  - Hematogenous spread
  - Calculi serve as a nidus for infection
  - Aerobic gram-negative bacteria (Enterobacteriaceae [most common cause], *Escherichia coli* [most common organism], Pseudomonas, Klebsiella, Proteus, Serratia), *Neisseria gonorrhoeae*, *Burkholderia pseudomallei*
  - Miscellaneous: *Chlamydia trachomatis*
  - Gram-positive bacteria (Enterococcus, *Streptococcus faecalis*, *Staphylococcus aureus*)
- Organisms suspected, but unproven: *Staphylococcus epidermidis*, micrococci, nongroup D Streptococcus, diphtheroids, *Ureaplasma urealyticum*, *Trichomonas vaginalis*
- Nonbacterial:
  - Leading theory: Nonrelaxation of internal urinary sphincter and pelvic floor muscles leading to increased prostatic urethral pressure and intraprostatic urinary reflux
- Uncommon: *Mycobacterium tuberculosis*, parasitic, mycoses (blastomycosis, coccidioidomycosis, Cryptococcus, histoplasmosis, candidiasis paracoccidiomycosis)

ASSOCIATED CONDITIONS

- Cystitis (secondary to bacterial prostatitis)
- Epididymitis
- Prostatic hypertrophy
- STD
- Urethritis/urethral stricture

- UTI

GENERAL PREVENTION

- Proper treatment of acute bacterial prostatitis may reduce chronic bacterial prostatitis (NIH II)
- Safe sex practices

DIAGNOSIS

HISTORY

- Acute bacterial prostatitis (NIH I)
  - Fever, chills, malaise
  - Perineal, suprapubic pain
  - Irritative voiding symptoms: Urgency, frequency, dysuria
  - Obstructive voiding symptoms: Hesitancy, intermittent stream, acute urinary retention
  - Rare sepsis
  - 5% will develop CP
- Chronic bacterial prostatitis (NIH II)
  - Recurrent UTIs
  - Asymptomatic or CPPS (see below)
- CP/CPPS (NIH IIIA/B)
  - Pain in perineum, suprapubic region, penis, testicles, groin, low back
  - Pain especially after or during ejaculation
  - Irritative/obstructive voiding symptoms lasting >3 mo
  - ED, sexual disturbances, severe effect on quality of life
- NIH Class IV: None; usually only elevated PSA or nodule that prompts biopsy

PHYSICAL EXAM

- Acute bacterial prostatitis (NIH I):
  - Suprapubic tenderness
  - Assess for acute urinary retention
  - DRE: Hot, boggy, exquisite tenderness
  - Sepsis: Febrile, tachycardia
- Chronic bacterial prostatitis/CPPS (NIH II/IIIA/IIIB)
  - Suprapubic tenderness
  - DRE: May be normal or soft/boggy, variable amounts of pain, prostatic calculi

ALERT
Do not perform massage or aggressive rectal exam in the face of acute prostatitis or prostatic abscess.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- PSA may be elevated with prostatitis PSA should not be checked in cases of acute bacterial prostatitis.
- Suspected acute bacterial prostatitis:
  - Urinalysis, urine culture, CBC, blood culture

- Suspected CPB/CP/CPPS (NIH II/III)
  - Urinalysis, urine culture
  - Meares–Stamey 4-glass test (gold standard)
  - 2-glass test more convenient: Pre/postprostatic massage:
    - Urine microscopy and culture of midstream urine specimen prior to prostate massage (Pre-M)
    - Urine microscopy and culture of 10-mL urine postprostate massage (Post-M)
    - With NIH II (chronic bacterial):
  - Pre-M: ± Urine WBC, ± culture
  - Post-M: + Urine WBC, + culture
    - NIH IIIA inflammatory CP/CPPS:
  - Pre-M: − Urine WBC, − culture
  - Post-M: + Urine WBC, − culture
    - NIH IIIB noninflammatory CP/CPPS
  - Pre-M: − Urine WBC, − culture
  - Post-M: − urine WBC, − culture

Imaging
- CT: If suspicion of abscess/malignancy or failure appropriate antimicrobial treatment
- Transrectal US: If suspicion of abscess or fail antibiotic therapy (rule out abscess, calculi)

Diagnostic Procedures/Surgery
- PVR if sensation of incomplete emptying
- Urodynamics: CPPS patients; debatable utility
- Cystoscopy: CPPS patients with hematuria; rules out bladder neck pathology, lower tract malignancy

Pathologic Findings
- Sheets, clusters, nodules of lymphocytes, plasma cells in fibromuscular stroma
- No relationship to the ducts and acini
- Infiltrates of inflammatory cells restricted to the glandular epithelium and lumen found in prostate and BPH
- Inflammatory changes noted in up to 44% of asymptomatic males at autopsy

DIFFERENTIAL DIAGNOSIS
- Acute urinary retention
- Cystitis (bacteria, interstitial)/urethritis
- Obstructive bladder calculus
- Prostate cancer
- Prostatic abscess
- Pyelonephritis

TREATMENT

GENERAL MEASURES
- NIH I acute prostatitis:
  - IV antibiotics, then switch to oral agents

- Acute retention may be treated with in-and-out catheter or small-caliber Foley for <12 hr or suprapubic drainage with acute prostatitis
- Acute bacterial prostatitis that does not resolve with conventional measures; must rule out prostate abscess

- NIH II: Long-term antibiotic therapy
- NIH IIIA/B: Similar management; empiric antibiotics often used with variable success, focus on symptomatic and supportive therapy; α-adrenergic blockers and NSAIDs may be useful adjuncts in this population
- NIH IV is only a histologic diagnosis and no specific therapy necessary

MEDICATION

First Line

- Antibiotics: For acute bacterial prostatitis (inpatient)
  - Ampicillin with gentamicin (ampicillin 1–2 g IV every 4–6 hr, 500 mg PO every 6 hr; gentamicin 1–2 mg/kg IV every 8–12 hr or daily dosing 4–7 mg/kg every 24 hr IV)
  - Fluoroquinolones
    - Levofloxacin, 250–750 mg daily IV or by mouth (PO)
    - Ciprofloxacin, 250–750 mg PO twice daily (BID), 400 mg IV BID
  - Ceftriaxone 1–2 g IV or IM daily
  - Afebrile 24–48 hr may change to oral antibiotics
- Acute bacterial prostatitis (outpatient)
  - Trimethoprim–sulfamethoxazole DS PO BID for 2–4 wk
  - Ciprofloxacin 500 mg PO BID for 2–4 wk
- Chronic bacterial prostatitis:
  - Ciprofloxacin 500 mg PO BID for 4–6 wk; levofloxacin has daily dosing and may have better prostatic penetration
  - Fluoroquinolones more cost effective and may be superior to TMP/SMX
- CP/CPPS:
  - NIH IIIA: Antibiotics may reduce symptoms but should work within 4–6 wk
  - Previously treated men do not benefit from further antibiotics
- α-Adrenergic blockers:
  - Chronic bacterial prostatitis (NIH II): In combination with antibiotics, will reduce symptoms
  - CP/CPPS (NIH III): Benefit men with recent onset of symptoms, not heavily treated, and on medication for >6 mo
- Anti-inflammatory agents:
  - NSAIDs/analgesics/antipyretics
- Stool softeners

Second Line

- Antibiotics: Erythromycin, azithromycin, clarithromycin if *Chlamydia trachomatis* implicated
- Finasteride or dutasteride: Only if associated BPH in patients with CP/CPPS

SURGERY/OTHER PROCEDURES

- Transurethral resection: If concern for prostatic abscess or in the setting of intractable chronic bacterial disease

- Transurethral microwave therapy: Refractory CP

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

- Numerous unproven therapies have been suggested with little to no evidence for treatment of CP or CPPS, including: Allopurinol, balloon dilation, TUNA, acupuncture, neuromodulation
- Frequent ejaculation (in patients with enlarged, symptomatically congested glands), prostatic massage (not in acute prostatitis)
- Dietary modification
- Sitz baths for symptomatic relief

Complementary & Alternative Therapies

- Phytotherapy provides modest benefit in CP/CPPS
- Neuromodulation (CP/CPPS): Amitriptyline, gabapentin, acupuncture, biofeedback, massage, neurostimulation

ONGOING CARE

PROGNOSIS

- Prolonged course, often difficult to cure
- 50–97% cure rate, depending on category
- 20% with recurrent or persistent infection

COMPLICATIONS

- Acute urinary retention
- Chronic bacterial prostatitis with incomplete treatment of acute bacterial prostatitis
- Epididymitis, orchitis, seminal vesiculitis (rare)
- Gram-negative sepsis, bacteremia
- Prostatic abscess

FOLLOW-UP

Patient Monitoring

- Most improve with antibiotics in 3–4 wk
- Long-term management of CP/CPPS requires multimodal therapy and supportive care

Patient Resources

- Stamey Test (3-Glass Test, 4-Glass Tests, Meares–Stamey Test)

CODES

ICD9

- 601.0 Acute prostatitis
- 601.1 Chronic prostatitis
- 601.9 Prostatitis, unspecified

ICD10

- N41.0 Acute prostatitis
- N41.1 Chronic prostatitis
- N41.9 Inflammatory disease of prostate, unspecified

CLINICAL/SURGICAL PEARLS

- Prostatitis is considered the most common urologic diagnosis in men <50.
- If suspected CBP/CP/CPPS, perform 2-glass test to help establish the diagnosis.
- Most chronic bacterial prostatitis cases improve after 3–4 wk of antibiotics.

PROSTATITIS, GRANULOMATOUS

Brian Cox, MD
Christopher Amling, MD, FACS

BASICS

DESCRIPTION

- Granulomatous prostatitis is inflammation of the prostate associated with granuloma formation
- Often confused with carcinoma of the prostate
  - Similar findings on digital rectal exam (DRE); has the findings of a “prostate nodule"
  - Similar elevations in prostate-specific antigen (PSA)
  - Similar findings on transrectal ultrasound (TRUS) and magnetic resonance imaging (MRI) images
  - Can be due to infectious and noninfectious etiologies

EPIDEMIOLOGY

Incidence

N/A

Prevalence

- 0.8–1% of benign inflammatory prostatic specimens
- Reported up to 4–10% of prostatitis cases
- Reported in 1.3–40% of post-Bacillus Calmette–Guérin (post-BCG) patients

RISK FACTORS

- Age: Mean age 62 yr (range 18–86 yr) (1)
  - Typically 50–70 yr of age
- Infections:
  - Bacterial, viral, fungal, parasitic, Mycobacterium, and sexually transmitted diseases (STDs)
  - Human immunodeficiency virus (HIV) infection may increase risk for tuberculosis (TB) prostatitis
  - Infectious etiologies make up ~15–20% of granulomatous prostatitis cases
- Iatrogenic causes:
  - Transurethral resection of prostate (TURP)
  - BCG instillation for bladder cancer—up to 40% may develop granulomatous prostatitis after BCG.
  - Iatrogenic etiologies make up ~75% of granulomatous prostatitis cases
- Systemic granulomatous diseases:
  - Wegener granulomatosis, Churg–Strauss syndrome, sarcoidosis, rheumatoid arthritis, polyarteritis nodosa, malakoplakia
  - These make up a minority of granulomatous prostatitis cases
- Idiopathic: No specific cause identified
  - Theory: Ductal/acinar obstruction causes prostatic secretions to leak into the stroma and cause granulomatous reaction

– Idiopathic etiologies make up a significant proportion of granulomatous prostatitis cases

Genetics
N/A

PATHOPHYSIOLOGY
- Specific subtype:
  – Caused by identifiable infectious agent (mycobacterium, fungi, syphilis, brucellosis, virus, parasites)
    - It is often associated with systemic TB
    - With HIV, TB may cause prostatic abscess
- Nonspecific subtype:
  – Usually an incidental finding on biopsy
    - Reported 0.3–3.0%
- Iatrogenic:
  – After TURP- or TRUS-guided biopsy, necrotizing lesions may resemble lesions associated with rheumatoid diseases
- Eosinophilic subtype:
  – Very rare, may suggest allergic etiology
  – Associated with systemic condition (asthma, Wegener granulomatosis, Churg–Strauss syndrome
- Autoimmune based:
  – HLA-DR15–linked T-cell–mediated response against PSA

ASSOCIATED CONDITIONS
- Prostate cancer can be coincident with granulomatous prostatitis in 10–14% of biopsy specimens (2)
- May be associated with systemic conditions
  – Asthma, Wegener granulomatosis, Churg–Strauss syndrome, sarcoidosis, rheumatoid arthritis, polyarteritis nodosa, malakoplakia

GENERAL PREVENTION
N/A

DIAGNOSIS

HISTORY
- Often asymptomatic
- Previous urinary tract infection (UTI) or STD:
  – Syphilis, TB, or other infectious etiology
  – Often associated with UTI 2–3 m prior to onset of symptoms
- History of lower urinary tract symptoms (LUTS)
  – Voiding symptoms including urgency, frequency, dysuria
  – Obstructive voiding symptoms, including acute urinary retention
- Systemic granulomatous disease:
  – If associated with systemic vasculitis or granulomatous disease, may have constitutional signs/symptoms

- History of prostate surgery or bladder cancer:
  - BCG or TURP can cause granulomatous prostatitis
- Fever, chills, or other constitutional signs:
  - Suggest infectious, systemic etiology

PHYSICAL EXAM

- DRE may be normal or abnormal
- Abnormal DRE:
  - Indurated gland with/without nodule
  - Tender or nontender
- TB prostatitis should be suspected if a draining perineal fistula is present

ALERT

- Digital Rectal Exam (DRE) cannot differentiate between prostate nodules due to granulomatous prostatitis and prostate cancer.
- Biopsy is required to differentiate these 2 etiologies.

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Urinalysis may be unremarkable
- Urine cultures
  - Are often sterile
- Elevated erythrocyte sedimentation rate (ESR), acid phosphatase, serum eosinophils may be present
- PSA may rise transiently
- If evidence of TB/mycotic disease, appropriate testing includes:
  - AFB stain of urine and semen
  - TB cultures (may take up to 10 wk)
  - Polymerase chain reaction (PCR): Genomic amplification of *Mycobacterium Tuberculosis* DNA
    - High sensitivity/specificity
    - Rapid: Takes 48 hr

Imaging

- TRUS
  - Limited utility except to direct biopsy
  - Appears as focal hypoechoic area
  - Difficult to discern granulomatous prostatitis and prostate cancer
- MRI
  - Limited utility
  - Difficult to discern granulomatous prostatitis from prostate cancer on MRI

Diagnostic Procedures/Surgery

TRUS-guided prostate biopsy is needed for pathologic diagnosis

Pathologic Findings

- Histologically granulomatous prostatitis appears as noncaseating granulomas, prominent macrophage infiltrates with occasional multinucleated giant cells (Langerhan cells) which

are characteristic of granulomas
  – Immunohistochemistry for cytokeratin (CAM 5.2) may stain glands positive but not the macrophage infiltrate
  – Macrophage infiltrate stains for macrophage marker CD68
- Fibrosis replaces parenchyma
- BCG therapy related
  – Caseating or noncaseating granulomas located next to benign prostatic glands (not engulfing them)
  – Usually AFB negative

DIFFERENTIAL DIAGNOSIS
- Nodular DRE (neoplasm/malignant):
  – Lymphoma, primary, and secondary
  – Prostatic adenocarcinoma
  – Sarcoma, small-cell carcinoma, and other rare tumors and metastases
  – Urothelial carcinoma
  – Granulomatous prostatitis
    - Infectious, iatrogenic, etc. (See Risk Factors)
- Nodular DRE (benign):
  – Prostatic calculus/calcification
  – Ejaculatory duct cyst
  – Scarring/fibrosis from prior surgery or infection
    - TURP, prostate biopsy
  – Granulomatous prostatitis
- Rectal wall lesions (thrombosed hemorrhoid, carcinoma, etc.)

TREATMENT

GENERAL MEASURES
- Majority of granulomatous prostatitis symptoms resolve spontaneously including those that are BCG related (3 – 5)
- DRE changes and PSA elevation may persist
- Use antibiotics as indicated for UTI
- Symptom control:
  – Sitz baths, fluids, anti-inflammatory α-blockers, and other symptomatic medications
- Temporary transurethral urinary catheterization if acute urinary retention or severe symptoms are present
- TRUS biopsy is indicated for:
  – Differentiating granulomatous prostatitis from prostate carcinoma
  – Consider rebiopsy if PSA remains elevated or DRE remains abnormal several months after treating symptomatic granulomatous prostatitis

MEDICATION
First Line
- Antibiotics as indicated for documented UTI
- Anti-TB medications for TB prostatitis:

– Use only if documented TB cause
– Isoniazid, rifampin, pyrazinamide, and either ethambutol or streptomycin for initial regimen, then change based on TB isolate sensitivities
– Pyridoxine (Vitamin B6) 25–50 mg/d to prevent isoniazid neuropathy

Second Line
N/A

SURGERY/OTHER PROCEDURES
• Majority of symptomatic cases of granulomatous prostatitis resolve spontaneously
• Reserve TURP or prostatectomy for refractory cases
– Reported in up to 10% of cases in some series

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
Corticosteroids and antihistamines have been recommended in idiopathic cases

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
• Majority of symptomatic cases of granulomatous prostatitis resolve spontaneously
• DRE findings may persist for months/years
• PSA elevation may last up to 3 mo

COMPLICATIONS
• Acute urinary retention
• Possible transmission of infectious etiology to sexual partner
• Possible infertility
• Possible undetected prostate cancer

FOLLOW-UP
Patient Monitoring
Rebiopsy may be indicated if DRE remains abnormal or PSA remains elevated after treatment to avoid missing coincident prostate cancer (reported in 10–14% of cases)

• 135 Sarcoidosis
• 446.4 Wegener's granulomatosis
• 601.8 Other specified inflammatory diseases of prostate

ICD10

• D86.9 Sarcoidosis, unspecified
• M31.30 Wegener's granulomatosis without renal involvement
• N41.4 Granulomatous prostatitis

CLINICAL/SURGICAL PEARLS

• Majority of symptomatic cases of granulomatous prostatitis resolve spontaneously.
• Up to 40% of patients may develop granulomatous prostatitis after intravesical BCG.
• DRE changes and PSA elevation may persist for months.
• TRUS-guided prostate biopsy is needed for pathologic diagnosis.
• Rebiopsy may be indicated if DRE remains abnormal or PSA remains elevated after treatment to avoid missing coincident prostate cancer (reported in 10–14% of cases).

PROTEINURIA

Anthony J. Tracey, MD, MPH
Raju Thomas, MD, MHA, FACS

BASICS

DESCRIPTION

- Persistent abnormal amounts or types of protein in the urine:
  - May be 1st indication of renal disorders either primary (eg, proliferative glomerulonephritis) or secondary (eg, hypertension [HTN], lupus nephritis, diabetes [DM])
  - Marker of overall cardiovascular health
- Healthy adult excretes 80–150 mg of protein per day in urine, consisting of 30% albumin, 30% serum globulins, and 40% tissue proteins.
- Dipstick urinalysis detects proteinuria only when protein excretion >300 mg/d:
  - Microalbuminuria: 30 and 300 mg/d:
    - Earliest sign of diabetic nephropathy
    - Identifies those at risk of cardiovascular disease in both diabetic and nondiabetic populations (1)[2]
- Important to distinguish between benign (no long-term renal significance) and pathologic causes of proteinuria. Can often differentiate based on:
  - Associated clinical findings (eg, known diabetes or HTN; edema and lipiduria in nephrotic syndromes)
  - *Persistency* of proteinuria:
    - Transient or intermittent proteinuria is unlikely to be associated with significant renal pathology
    - Example etiologies: Exercise, emotional stress, fever, orthostatic proteinuria
    - Document proteinuria on >1 visit
  - Degree of proteinuria:
    - 500 mg/24 hr usually heralds significant glomerular disease
    - Proceed to quantitative measurement when dipstick is persistently positive

EPIDEMIOLOGY

Incidence

- In diabetic patients, progression to microalbuminuria 2% per year; from microalbuminuria to proteinuria 2.8% per year
- 1.7% of males and 0.9% of females
- Increases with age
- Higher in patients with DM:
  - Microalbuminuria 24.9%; proteinuria 5.3%

Prevalence

- African Americans afflicted with higher levels of proteinuria due to increased risk of associated diseases

- Orthostatic proteinuria in 2–5% of adolescents:
  - Uncommon in age >30 yr:
    - Increased protein excretion in the upright position. Resolves in supine position (2)[2]
    - No therapy required, often resolves with time

RISK FACTORS
- DM
- HTN
- Obesity (BMI >35 kg/m^2), but progression to renal disease not proven

Genetics
Disease specific

PATHOPHYSIOLOGY
- Glomerular proteinuria:
  - Results from increased glomerular capillary permeability to albumin
  - Usually >1 g/24 hr
  - When total protein >3 g/24 hr: Nephrotic syndrome (look for hypoalbuminemia, lipiduria, edema, ascites)
- Tubular proteinuria:
  - Inability of proximal convoluted tubule to absorb low–molecular-weight proteins such as immunoglobulin light chains, β2-microglobulin, amino acids, and retinol-binding protein
  - Proteinuria usually 2–3 g/24 hr
- Overflow proteinuria:
  - No underlying renal disease
  - Absorptive capacity of PCT is overwhelmed by overproduction and accumulation of immunoglobulins and low–molecular-weight proteins.
- Tissue proteinuria:
  - Associated with acute inflammation of urinary tract due to cystitis, acute prostatitis, and urinary tract tumors
- Transient proteinuria:
  - Glomerular permeability and decreased tubular reabsorption have both been proposed as possible mechanisms (2)

ASSOCIATED CONDITIONS
- See “Differential Diagnosis”
- Hypercoagulability, lipiduria, edema, and hypoalbuminemia (nephrotic syndrome)

DIAGNOSIS

HISTORY
- Presence of underlying systemic disease:
  - DM, HTN, autoimmune disorders, cardiac disease, multiple myeloma
- Transient proteinuria triggered by:
  - Exercise, emotional stress, fever, recent illness
- Medication-induced glomerular injury
- Associated symptoms that would suggest clinically significant proteinuria:

  - Hematuria, bone pain (myeloma)
- Age <30 and healthy (orthostatic proteinuria) (1,2)

PHYSICAL EXAM
- BP measurement to rule out HTN
- Edema with nephrotic syndrome, heart failure
- Papilledema: Uncontrolled HTN
- Jugular venous pressure elevation, heart sounds (heart failure, HTN)
- Abdominal bruits: Renal artery stenosis

DIAGNOSTIC TESTS & INTERPRETATION

Lab
- Urine dipstick:
  - Qualitative test only (1+ to 4+); detects protein concentration >20–30 mg/dL
  - Cannot detect microalbuminuria; if persistently positive proceed to quantitative test (spot or 24-hr protein)
  - False positive: Alkaline urine; concentrated urine; contamination with blood; recent IV contrast dye
  - False negative: Dilute urine; dipstick only detects albumin and will miss other plasma proteins (eg, Bence Jones proteinuria in multiple myeloma)
- Urinalysis for associated hematuria, casts (glomerulonephritis)
- Serum creatinine to rule out renal insufficiency
- Blood glucose: DM
- Albumin-to-creatinine ratio or total protein-to-creatinine ratio in a random urinary sample:
  - Quantitative test that is reliable and not dependent on concentration. Less cumbersome than 24-hr collection
  - Corresponds to 24-hr albumin excretion in a linear manner (eg, ratio of 3 = 3 g/24 hr)
  - Serial measurements monitor therapeutic response
  - Preferred screening strategy for diabetic patients
  - 2 out of 3 positive tests separated by 3–6 mo considered persistent proteinuria
- Albumin, cholesterol: Nephrotic syndrome
- 3% sulfosalicylic acid test:
  - Detects all types of proteinuria
  - Strongly consider in patients with acute renal failure and negative or trace protein on dipstick to rule out myeloma
- Split urine collection: Daytime (7 AM to 11 PM) and overnight (11 PM to 7 AM) to rule out orthostatic proteinuria
- Urine protein electrophoresis: To assess for light chain immunoglobulins/Bence Jones proteins associated with multiple myeloma
- Others as indicated: Hepatitis and/or HIV testing, autoantibodies (ANA, etc.) (2)

Imaging
- Renal US in cases of persistent proteinuria to rule out anatomic abnormality
- 3-phase CT if renal function sufficient and associated hematuria
- MRI urogram

Diagnostic Procedures/Surgery

- Tissue analysis:
  - Renal biopsy strongly considered for:
    - Proteinuria with hematuria
    - Prolonged ARF of unknown etiology
    - Nephrotic proteinuria
    - Transplanted kidney (3)
- Cystoscopy if concurrent hematuria
- Cystoscopy with retrograde pyelogram if upper tract imaging indicated (hematuria, hydronephrosis) and unable to evaluate upper tracts with excretory phase imaging

Pathologic Findings

Depends on underlying etiology

DIFFERENTIAL DIAGNOSIS

- Glomerular proteinuria:
  - IgA nephropathy
  - Diabetic nephropathy
  - Medications (eg, NSAIDs, captopril, lithium)
  - Minimal change
  - Primary glomerulonephritides
  - Autoimmune (eg, SLE, amyloidosis)
- Tubular proteinuria:
  - Obstructive uropathy
  - Toxins and drugs
  - Fanconi syndrome
- Overflow proteinuria:
  - Multiple myeloma
  - Monoclonal gammopathy of unknown significance
  - Rhabdomyolysis causing myoglobinuria
  - Any hemolytic state causing hemoglobinuria
- Transient proteinuria:
  - Fever
  - Strenuous exercise
  - Emotional stress
  - Pregnancy
  - Cold exposure
  - Orthostatic proteinuria

TREATMENT

GENERAL MEASURES

- Treat specific underlying etiology.
- All patients with persistent proteinuria should be referred to a nephrologist.
- Hematology–oncology evaluation for patients with Bence Jones protein for treatment of multiple myeloma
- Mild dietary protein restriction may prevent progression of chronic kidney disease.

- Strict glycemic and BP control in diabetics
- Salt/fluid restriction for edema associated with nephrotic syndrome

MEDICATION

First Line

- ACE inhibitors reduce proteinuria and can both prevent and slow deterioration of renal function in patients with diabetes or nondiabetic renal disease, independent of their antihypertensive effects (3)[A]:
  - Can reduce protein excretion by 35–45%
  - Lisinopril 2.5 mg/d PO; increase as tolerated
  - Ramipril 2.5–5 mg/d PO, 20 mg/d max
  - Captopril 12.5–25 mg PO BID/TID, 50 mg TID max

Second Line

- Angiotensin II receptor antagonists:
  - Use if side effects such as cough and angioedema develop from ACE inhibitors
  - Candesartan, eprosartan, irbesartan, losartan, valsartan
  - Calcium channel blockers: May be better for HTN with less renal effect in the relatively ischemic kidney

SURGERY/OTHER PROCEDURES

N/A

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

N/A

ONGOING CARE

PROGNOSIS

- Isolated proteinuria; degree dependent:
  - Nonnephrotic proteinuria has low risk of progressive kidney disease (3)[2]
  - Nephrotic proteinuria (>3 g/d) associated with glomerular disease and high risk of progression to chronic kidney disease
  - Japanese study of screened healthy patients; cumulative incidence of ESRD over 17 yr:
    - 1.4% with 1+ proteinuria
    - 7.1% with 2+ proteinuria

COMPLICATIONS

- Progression to renal failure
- Proteinuria is a marker for overall cardiovascular health (3)[2]

FOLLOW-UP

Patient Monitoring

- Transient proteinuria: Active monitoring unnecessary
- Nephrologist for any patient with large quantity of proteinuria and high-risk patients with microalbuminuria:
  - Monitor urine albumin-to-creatinine ratio
  - Monitor serum creatinine

Patient Resources

National Kidney and Urologic Diseases Information Clearinghouse (NKUDIC).

CODES

ICD9

791.0 Proteinuria

ICD10

- R80.0 Isolated proteinuria
- R80.2 Orthostatic proteinuria, unspecified
- R80.9 Proteinuria, unspecified

CLINICAL/SURGICAL PEARLS

Proteinuria in excess of 500 mg/d likely represents significant glomerular disease.

PRUNE BELLY (EAGLE–BARRETT OR TRIAD) SYNDROME

Bruce J. Schlomer, MD
Laurence S. Baskin, MD, FACS, FAAP

BASICS

DESCRIPTION

- Prune belly refers to the classic appearance of abdominal wall wrinkling and budging flanks caused by varying degrees of abdominal wall deficiency, found almost exclusively in males (image) (1)
- Prune belly syndrome (PBS) triad:
  - Deficient abdominal musculature
  - Bilateral cryptorchidism
  - Urinary tract anomalies (eg, dilated prostatic urethra, renal dysplasia, hydroureteronephrosis)
- Incomplete variants lack abdominal wall features; females lack gonadal anomalies
- Woodard classification:
  - Type I: Usually fatal; marked oligohydramnios due to severe renal dysplasia or bladder outlet obstruction with pulmonary hypoplasia and skelet al anomalies (Potter sequence)
  - Type II: Full spectrum of disease with no immediate threat to life; renal dysplasia; hydroureteronephrosis; possible mild pulmonary hypoplasia
  - Type III: Mild external features of triad or incomplete variant; no evidence of pulmonary hypoplasia, mild uropathy
- Synonyms: Eagle–Barrett or Triad syndrome

EPIDEMIOLOGY

Incidence

- 3.8/100,000 live births
- 95% males
- Higher incidence in African Americans
- Lower incidence in Hispanic population
- Increased incidence in younger mothers

Prevalence

N/A

RISK FACTORS

Slightly increased risk in African Americans and younger mothers

Genetics

- Most cases are sporadic, with normal karyotype.
- Potential inheritance patterns in rare familial cases (influenced autosomal recessive; X-linked)
- Monozygotic twins reported concordant and discordant for PBR suggests some nongenetic basis

PATHOPHYSIOLOGY

- Exact mechanism unknown:
  - Early in utero transient urethral obstruction
  - Mesodermal developmental defect
- Abdominal defects due to deficient musculature medially and inferiorly:
  May be partial hypoplasia of the abdominal wall to complete absence of musculature
- Testes:
  - Usually intra-abdominal (over iliac vessels)
  - Epididymis poorly attached
  - Descent in part affected by mechanical forces (eg, large bladder, low intra-abdominal pressures)
- Kidneys:
  - Dysplasia in 50%, to varying degrees
  - Nonobstructive hydronephrosis is common; does not correlate to degree of dysplasia
- Ureters:
  - Dilated, tortuous, and redundant; distal >proximal
  - Increased ratio of collagen to smooth muscle
  - Poor peristalsis and ureteral coaptation lead to stasis and reflux
  - ~75% with reflux
- Bladder:
  - Enlarged with no significant hypertrophy
  - May have urachal pseudodiverticulum
  - Urachus patent in up to 30%
  - Increased ratio of collagen to smooth muscle
  - Urodynamics commonly show normal compliance, delayed sensation, large capacity; 50% void with normal pressures and flow, and have low postvoid residual
- Prostatic urethra:
  - Dilated due to prostatic hypoplasia
  - 20% can have distal obstructive lesions (eg, valves, atresia, stenosis)
- Anterior urethra:
  - Usually normal
  - Most common abnormalities: Megalourethra and urethral atresia (latter can be fatal unless patent urachus)
  - Megalourethra can be caused by transient obstruction
  - Fusiform: Defect in corpus cavernosum and spongiosum; entire phallus dilates on voiding
  - Scaphoid: Defect in corpus spongiosum; only ventral urethra dilates
- Fertility:
  - Usually infertile (rare cases of paternity with sperm retrieval) due to azoospermia
  - Histologic defect in testes
  - Atretic vas deferens and seminal vesicles
  - Retrograde ejaculation from incompetent bladder neck

ASSOCIATED CONDITIONS

- Genetic:
  - Turner syndrome; trisomy 13, 18, and 21; Beckwith–Wiedemann syndrome

- Gastrointestinal:
  - Malrotation of gut (~40%); bowel atresia, gastroschisis, omphalocele, imperforate anus (rare)
- Pulmonary:
  - >50% with pulmonary hypoplasia
- Cardiac:
  - Atrial and ventricular septal defects, tetralogy of Fallot, valvular anomalies, patent ductus arteriosus
- Musculoskelet al:
  - Scoliosis; vertebral anomalies, congenital hip dislocation, club feet

GENERAL PREVENTION
None known

DIAGNOSIS
HISTORY
- Gestational history (eg, oligohydramnios, prenatal hydronephrosis)
- Rarely positive family history

PHYSICAL EXAM
- 75% will have nonurologic manifestations
- General: Observe for Potter facies (eg, wide set eyes, flattened nasal bridge)
- Heart: Auscultate for murmurs due to atrial or ventricular septal defects, patent ductus arteriosus
- Lungs/chest: Auscultate for pneumothorax; evaluate for pectus excavatum/carinatum
- GI: Associated with gastroschisis or omphalocele; imperforate anus; intestinal malrotation, atresia, or stenosis
- Urologic: Evaluate meatus, observe urinary stream, attempt to palpate testes
- Abdomen: Wrinkled, redundant skin over lower abdomen with bulging flanks
- Extremities: Observe for dimpling on lateral aspect of knees, knock knees, clubfoot, hip dislocation, scoliosis

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Serum electrolytes, urea nitrogen, and creatinine:
- Nadir creatinine <0.7 ng/dL is predictive of adequate renal function through childhood.
- Urinalysis and urine culture as indicated

Imaging
- Prenatal US: Bilateral hydroureteronephrosis, thin-walled distended bladder, possible oligohydramnios
- Chest x-ray (pneumothorax)
- Postnatal renal/bladder US (degree of renal dysplasia and hydroureteronephrosis)
- Radioisotope studies (technetium-99m/99Tc):
  - DMSA at 4–6 wk to assess renal parenchymal function
  - MAG3 scan to assess presence/degree of obstruction

Diagnostic Procedures/Surgery

- VCUG:
  - Perform while on antibiotic prophylaxis
  - Reflux in up to 75% of cases
  - Large bladder and dilated prostatic urethra tapering to membranous urethra

Pathologic Findings

- Renal dysplasia on biopsy
- Ureter and bladder with increased collagen and fibrous tissue

DIFFERENTIAL DIAGNOSIS

- Megacystis microcolon
- Intestinal hypoperistalsis syndrome (marked female predominance
- Posterior urethral valves (prenatal appearance can be similar)

TREATMENT

GENERAL MEASURES

- Primary goal is to preserve renal function and prevent UTI
- Early aggressive surgery for dilated urinary tract without evidence of progressive renal dysfunction or UTIs should be avoided
  - High complication rate
- Demonstrate proper bladder emptying
  - Double voiding
  - Timed voiding
  - Clean intermittent catheterization (CIC)
- UTI prophylaxis
- Avoid instrumentation early to reduce UTI risk

MEDICATION

First Line

- UTI prophylaxis:
  - Ampicillin 25 mg/kg/d as neonates
  - Trimethoprim–sulfamethoxazole 2 mg/kg once daily or nitrofurantoin 1–2 mg/kg once daily beyond 2 mo of age

Second Line

None

SURGERY/OTHER PROCEDURES

- Prenatal: Vesicoamniotic shunting for oligohydramnios in 2nd trimester (controversial)
- Consider circumcision to reduce incidence of UTI
- Urinary tract reconstruction (eg, reimplant) is controversial due to potential for improvement or resolution, stabilization of function, and high complication rates (2)
- Early intervention may be warranted with progressive/severe hydronephrosis, progressive renal failure, or recurrent UTIs (2)
  - Temporary cutaneous vesicostomy or bilateral cutaneous pyelostomies (avoid proximal ureterostomies)

– Ureteral reimplantation with/without tapering
- Reduction cystoplasty reserved for large urachal diverticulum or as part of extensive reconstruction, since large bladder tends to recur
- Orchidopexy:
– Transabdominal, preferably done by 1 yr of age or in combination with other procedures:
- Abdominal wall reconstruction for cosmesis, may enhance Valsalva voiding and improve bladder emptying (3)
- Renal transplantation
– 1/3 will eventually need renal transplant
– Achieve adequate bladder emptying prior to transplant

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

Use of corsets for abdominal wall laxity have been reported

ONGOING CARE

PROGNOSIS

- Degree of renal dysplasia most important determinant of long-term survival
- Up to 1/3 develop renal failure and will require dialysis/renal transplantation

COMPLICATIONS

- Renal failure
- Respiratory failure (early)
- Recurrent UTIs
- Urosepsis

FOLLOW-UP

Patient Monitoring

- Serial evaluation of renal function, bladder function and emptying, and for UTIs
- Imaging is individualized

Patient Resources

- http://www.urology.ucsf.edu/patient-care/children/urinary-tract-obstruction/prune-belly-syndrome
- Prune belly syndrome network: www.prunebelly.org

- Q79.4 Prune belly syndrome

CLINICAL/SURGICAL PEARLS

- Antireflux surgery with high complication rates; avoid if possible.
- Prenatally can be difficult to distinguish from posterior urethral valves.
- Goal is to avoid renal damage, UTIs.

PSA ELEVATION FOLLOWING NEGATIVE PROSTATE BIOPSY

Michael J. Amirian, MD
Leonard G. Gomella, MD, FACS

BASICS

DESCRIPTION

- Transrectal ultrasound-guided (TRUS) prostate biopsy (PB) is the gold standard for diagnosis of prostate cancer (CaP)
- While CaP screening is controversial, a subset of men have a negative TRUS PB with persistent or increasing elevation in PSA. This can be a challenge for urologist and the patient
- Repeat PB performed after negative PB suggests up to 30% of patients have cancers not previously identified (1)

EPIDEMIOLOGY

Incidence

800,000–1.2 million prostate biopsies are performed in the United States annually

Prevalence

- 24.1% of men in a screening population undergoing TRUS diagnosed with PCa
- False-negative rate for TRUS PB as high as 35%
  - Cancer detection rate as high as 14% after 3rd repeat biopsy

RISK FACTORS

- Both technical and anatomical considerations contribute to a false-negative PB
- Advances in biopsy techniques have improved positive sampling rates
  - Digital-direct biopsy without ultrasound guidance provides inadequate sampling
  - TRUS guided is gold standard
    - <10 cores are considered inadequate for cancer detection
    - "Double sextant" or 12-core with inclusion of laterally directed cores have lower false-negative rates
- Anatomical
  - Large gland size (>50 cc) may limit detection of CaP on standard core biopsy
  - End-fire ultrasound probe allows better sampling anterior and apical prostate gland
    - These areas likely to harbor unrecognized malignancy in larger glands
- High-grade cancers (Gleason 9–10) may not have PSA elevation

Genetics

- CaP has both familial and genetic component
  - Relative risk increases with number of 1st-degree relatives affected
    - Higher index of suspicion if 1st-degree relatives have diagnosis of prostate malignancy

PATHOPHYSIOLOGY

- 12 biopsy cores from a standard 18G needle enables only 0.04% of prostate gland to be evaluated for pathology (2)

- PSA elevations can be from non-PCa causes
- Series reporting follow-up biopsy results (Mo)
  - In 2012 Ca detection rates on follow-up biopsies 1, 2, 3, and 4 were 22%, 10%, 5%, and 4%, respectively; 58%, 60.9%, 86.3%, and 100% of patients who had RP had organ-confined disease on biopsies 1, 2, 3, and 4.
  - A 2008 series with extended biopsies found CaP 18%, 7%, and 14% of patients had PCa in 2nd, 3rd, and 4th biopsies, respectively; significant CaP in 85% of cases (3).

ASSOCIATED CONDITIONS

The following can cause elevated PSA: infection, recent instrumentation, benign prostatic hypertrophy (BPH)

GENERAL PREVENTION

- Obtain serial PSA at same lab; avoid sexual activity for 24 hr before
- Preventing a false-negative PB is greatly dependent on technique
  - 12-core template is now standard
    - 6 parasagittal plus 6 lateral cores
  - Sextant (6-core) biopsy can miss up to 50% of small tumors
  - No evidence of increased complication rate of 12-core compared to sextant biopsy

DIAGNOSIS

HISTORY

- Prior history of negative prostate biopsies
- Evaluate for nonmalignant causes of elevated PSA
  - Prostatitis
  - Recent instrumentation of genitourinary tract
  - Rarely sexual activity, bicycling can briefly elevate
- Increase risk of PCa
  - 1st-degree relative with PCa and recent data suggestion increased risk with a relative with breast cancer
    - Increase risk by 120–150%
  - Ethnicity: Black race highest risk
  - History of exposure to exogenous androgen or anabolic steroid use
- Percent-free PSA
  - With negative prior biopsy and low percent-free PSA (<12%) have higher risk of malignancy
- PSA velocity
  - Rate of change of PSA over 1-yr period
  - Recommend biopsy if PSA velocity exceeds 0.35 ng/mL/yr
  - PSA velocity independent predictor of overall PCa, intermediate- and high-grade cancer.

PHYSICAL EXAM

- Digital rectal exam (DRE)
  - Induration or nodularity
    - Concerning for malignancy
  - Symmetric and enlarged gland

- BPH more likely with elevated PSA and negative biopsy
  - Tenderness or bogginess on exam
    - Likely acute prostatitis
- Decreased testicular volume
  - Consider exogenous androgen exposure

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Free/total PSA (4)
- Prostate cancer antigen 3 (PCA3)
  - Gene that is overexpressed in PCa; measured in 1st voided urine after attentive digital rectal exam
  - FDA approved for men >50 yr who have had 1 or more previous negative biopsies
  - Cutoff debatable 25–35
  - Compared to PSA
    - Lower sensitivity (67%); higher specificity (83%)
    - Some studies suggest superior to F/T PSA
    - Patient stratified into lower risk or higher risk of having a positive biopsy

Imaging

- MRI may identify anterior tumor not reached by biopsy needle
  - T2-weighted MRI
    - Identify focal lesions within gland
    - Need to wait 6–8 wk after negative biopsy as recent biopsy sites cause distortion
  - Multiparametric (mp) MRI
    - Combination of dynamic contrast-enhanced MRI, MR spectroscopic imaging, and diffusion-weighted imaging; need access to experienced center
  - Contrast-enhanced TRUS
    - Neovascularity of tumor enhances with microbubble contrast agent (not FDA approved)
    - Targeted biopsy show increase sensitivity from 38–65% vs. unenhanced imaging
  - Color Doppler of limited utility w/o contrast
  - Elastography ultrasound: Tumors allow less displacement with compression than normal tissue; color coded map allows targeted biopsy; not widely available
- MRI TRUS fusion biopsy may help identify specific lesions for directed biopsy

Diagnostic Procedures/Surgery

- Mapping/saturation biopsy
  - Obtaining 20 or more cores with standard biopsy technique; can be transrectal but more likely to be done transperineally using a brachytherapy-like template guide
  - Studies vary in yield of detection with increased cores; increased morbidity
  - Usually require additional anesthesia
- Transitional zone targeted biopsy
  - 15% increased detection in gland >50 cc
- Template transperineal PB
  - May allow better sampling of peripheral zone
  - Controversial if better cancer detection

- MRI and ultrasound fusion targeted biopsy
  - Stored MRI is fused with real-time ultrasound using a digital overlay
  - Series report 41% vs. 18% compared to conventional ultrasound in detection of CaP in men with prior negative biopsies
  - Requires specialized training and equipment

Pathologic Findings

- Quality assurance in the initial biopsy is critical. Data suggests a core length of >10 mm and the presence of glandular elements suggest an adequate sample
- High-grade prostatic intraepithelial neoplasia (HGPIN) 0–24.6% on initial biopsy (median 4%)
  - Considered by some to be premalignant lesion: 23–35% risk of diagnosis cancer on subsequent biopsy; however, EAU does not recommend repeat biopsy with HGPIN
- Atypical small acinar proliferation (ASAP)
  - Incidence 0.7–23.4%, median 4.4%
  - Increased CaP risk on subsequent biopsy (up to 40%)

DIFFERENTIAL DIAGNOSIS

- ASAP
- BPH
- HGPIN
- Prostatitis

TREATMENT

GENERAL MEASURES

- Most recommendations are for repeat biopsy for patients with either ASAP or multifocal HGPIN within 3–6 mo regardless of PSA (5)
- For others with negative biopsy and persistently elevated or rising PSA, consider the use of supplementary lab tests such as PCA3, free/total PSA Confirm MDx to guide decision
- Repeat PB appears justified in:
  - An initial negative biopsy and persistent suspicion of PCa based on age, comorbidities, DRE findings, repeated PSA, PSA derivatives, (% free PSA, complexed PSA, PSAD, PSA velocity, or urinary PCA3 score) and patient and physician preferences
- With concerns over the interpretation of the earlier biopsy, consider a 2nd opinion

MEDICATION

First Line

- Limited utility in managing elevated PSA
- Antibiotics if presumed prostatitis cause of elevation
  - 2–3-wk course of oral antibiotics
  - Sulfamethoxazole and trimethoprim (Bactrim DS) BID or ciprofloxacin 500 mg BID
    - Repeat PSA after termination of treatment
  - Studies have not shown routine antibiotics decreased need for future biopsy
- 5-α reductase inhibitors
  - Finasteride 5 mg or dutasteride 0.5 mg PO QD for 6 mo

- Should lower PSA by 50% after 6 mo but not proven useful in determining repeat biopsy, but any PSA rise after 6 mo raises CaP risk

Second Line
N/A

SURGERY/OTHER PROCEDURES
- The number of cores on repeat biopsy is debatable. NCCN guidelines suggest performing a 2nd extended biopsy and consider saturation biopsies only in with high risk of cancer after multiple negative biopsies
- Transurethral resection prostate biopsy
  – Once advocated for diagnosis of transition zone cancers
  – Less than 5% CaP are transitional zone CaP without concomitant peripheral zone tumors
  – Improved TRUS technique in sampling transitional zone; no definite value in performing transurethral resection PB

ADDITIONAL TREATMENT
Radiation Therapy
N/A

Additional Therapies
- The European Randomized Study of Screening for PCa (ERSPC)-based model has several calculators to determine outcome after negative biopsy (http://www.prostatecancer-riskcalculator.com/)
- Genomic testing may help determine risk after negative biopsy
  – Confirm MDx™: Epigenetic assay to distinguish men who have a true-negative biopsy from those with occult cancer
  – Identifies methylation signature in area near PCa location using recent prostate biopsy material

Complementary & Alternative Therapies
N/A

ONGOING CARE

PROGNOSIS
- There is no PSA threshold that can rule out PCa in any age range
  – Regardless of initial PSA value, a PSA velocity greater than 0.75 ng/mL/yr warrants repeat biopsy
- Lowering PSA threshold for initial biopsy
  – Many urologists recommend PB to men younger than 60 yr of age once PSA >2.5 ng/mL; enables earlier CaP detection

COMPLICATIONS
See Section I: “Prostate biopsy, Infections and Complications”

FOLLOW-UP
Patient Monitoring
If low risk with negative biopsy can be followed with routine surveillance protocol

Patient Resources

CODES

ICD9

- 185 Malignant neoplasm of prostate
- 601.9 Prostatitis, unspecified
- 790.93 Elevated prostate specific antigen [PSA]

ICD10

- C61 Malignant neoplasm of prostate
- N41.9 Inflammatory disease of prostate, unspecified
- R97.2 Elevated prostate specific antigen [PSA]

CLINICAL/SURGICAL PEARLS

- Threshold for repeat biopsy should be low if atypia seen on initial biopsy.
- PCA3 can elucidate the need for further biopsy in those with prior negative biopsy and persistently elevated PSA.
- Emerging imaging modalities are promising in detecting CaP not found on initial PB.

PSA ELEVATION, GENERAL CONSIDERATIONS

Leonard G. Gomella, MD, FACS
Adam P. Dicker, MD, PhD

BASICS

DESCRIPTION

- PSA is used for diagnosis and treatment of prostate cancer (CaP). This section reviews the use of PSA in the diagnosis of CaP recognizing that screening is an area of controversy
- CaP is only diagnosed through tissue biopsy and not by PSA alone
- Normal PSA level is controversial, and can be elevated due to malignant or benign causes.
  - Elevated PSA traditionally >4.0 ng/mL based on the Baltimore Longitudinal Study of Aging
    - Specificity 91%, sensitivity 21% (51% for Gleason ≥8), PPV 30%
  - Elevated PSA >2.5 ng/mL has support
- Age/race-specific proposed, but controversial:

Range (yr)	Asian	Black	White
40–49	0–2.0	0–2.0	0–2.5
50–59	0–3.0	0–4.0	0–3.5
60–69	0–4.0	0–4.5	0–4.5
70–79	0–5.0	0–5.5	0–6.5

- Based on Prostate Cancer Prevention Trial (biopsy regardless of PSA), can have CaP with "low" PSA. No lower cutoff or normal PSA to indicate absence of cancer. PCPT data:

PSA	CaP Rate	PSA	CaP Rate
0–0.5	6.6%	3.1–4.0	26.9
0.6–1.0	10.1%	4.0–10.0	25%
1.1–2.0	17%	>10.0	>50%
2.1–3.0	23.9%		

- The challenge: Lower normal PSA to recommend biopsy where life-threatening cancer is present, but not to point where "overdetection" of incidental (autopsy/insignificant CaP) occurs
- PSA derivatives may overcome problem, but not absolute: Used in PSA range of 4.0–10 ng/mL: PSA density (PSAD), PSA velocity (PSAV), newer PSA assays (free, molecular forms)
- PSA changes over time more useful than a single PSA in screening for CaP
- A single PSA of >1.3 ng/mL before age 50 predicts increased lifetime CaP risk (1)
- PSA >10: More risk of advanced disease.
- PSA proportional to prostate volume; prostate volume/mean PSA were as follows: 14 cm^3/1; 25 cm^3/1.13/52 cm^3 1.45 in 1 study

ALERT
PSA should not be done with acute prostatitis or within 3–4 wk of prostate instrumentation: false-positive risk.

EPIDEMIOLOGY

Incidence

- Across all races, age >50, only 7.9% of men randomly screened have PSA >4.0 ng/mL
- Median PSA: 4th decade, 0.7 ng/mL; 5th decade, 0.9 ng/mL 6th decade, 1.3 ng/mL; 7th decade, 1.7 ng/mL

Prevalence

US CaP approximately 2,106,499 men, or 1.5% all ages and races

RISK FACTORS

- For elevated PSA
  - Advancing age
  - Benign prostatic hypertrophy (BPH)
  - CaP
  - Infection, infarction
  - Recent instrumentation (TURP, cystoscopy, catheterization, prostate biopsy)
- CaP (See chapter "Prostate Cancer, General")

Genetics

- PSA associated with kallikrein genes family (long arm of chromosome 19 region q13.2–q13.4).
- PSA is also called human kallikrein 3 (hKLK3)

PATHOPHYSIOLOGY

- PSA: A serine protease produced by the prostatic epithelium and periurethral glands that liquefies seminal coagulum
- Seminal fluid has high PSA concentrations (mg/mL); PSA is much lower (ng/mL) in serum
- Many forms of serum PSA: Free PSAs (nicked, intact, several forms of proPSA) and complexed PSA (bound to protease inhibitors α1-antichymotrypsin [ACT], α2-macroglobulin [MG], α1-protease inhibitors [API]); bound PSA forms stable complex (no serum enzymatic activity) (2)
  - 60–90% complexed to ACT; free portion is also detected by assay, while that bound to MG is not detected by routine assay
  - Complexed PSA: Hepatic clearance (1/2-life 2.2 days); FPSA cleared by glomerular filtration (1/2-life 2–3 hr)
- CaP PSA elevation is due to disrupted prostatic architecture and compromised integrity of the basal layer or basement membrane
  - CaP makes less PSA/g than benign tissue
- Androgens influence PSA levels
- Sources of fluctuation in PSA:
  - No PSA analytic standard; can vary by lab and use same lab to compare serial values
  - 15% coefficient of variation in PSA assay
  - Physiologic variation in PSA 15–30% in the short term; BPH can vary up to 30%
  - 26–37% with elevated PSA return to normal 1 yr later, and 45–55% normal within 4 yr
  - Seasonal variation: PSA is higher in summer
  - Infection, infarction, trauma, ejaculation within 24 hr, or prostate instrumentation or massage can produce elevations (not routine DRE)

– Finasteride (5 mg BPH; 1 mg alopecia) and dutasteride are 5α-reductase inhibitors; lower PSA by 50% over 6 mo; "correct" PSA by doubling to maintain PSA utility

ASSOCIATED CONDITIONS
- BPH
- Acute and chronic bacterial prostatitis
- Urinary retention

GENERAL PREVENTION
- None for CaP
- Avoid PSA measurement when false-positive elevation likely (See "Risk Factors" above)
- Use same lab/assay for serial measurements

DIAGNOSIS
HISTORY
- Difficulty with urination, such as hesitancy, straining, weak stream, or intermittency
- Dysuria, frequency, or urgency
- Previous PSA levels or prostate biopsies
- Family history of prostate carcinoma
- Medications, including herbals
- Markedly elevated PSA >20 ng/mL with bone, back, or hip pain suggests metastatic CaP

PHYSICAL EXAM
- DRE: Nodules, induration, asymmetry, bogginess, tenderness (Note: American Cancer Society recommends PSA screening with or without DRE)
- Adenopathy, supraclavicular
- Bony pain, point tenderness with metastasis
- Neurologic: Lower extremity strength/sensation

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- Routine UA to rule out UTI/prostatitis (1 – 3)
- Consider evaluation for prostatitis by modified Stamey–Meares test or exam of EPS (See Section I: Prostatitis, Chronic, Bacterial [NIH II])
- Consider %FPSA (FPSA/TPSA or F/T PSA)
  – With CaP lower FPSA; postulated that CaP produces more ACT
  – FPSA best with TPSA 4.0–10.0 ng/mL and prostates <50 g; not useful if TPSA >10 ng/mL
  – FPSA stratifies CaP risk on biopsy (table) (3)

PSA ng/mL	CaP Rate	%FPSA	CaP Prob
0–2	1%	0–10	56%
2–4	15%	10–15	28%
4–10	25%	15–20	20%
>10	>50%	20–25	16%
		>25	8%

- Consider PSAD: PSA ÷ TRUS volume:

– Correlates PSA to TRUS prostatic size to distinguish BPH from CaP:

- $\text{PSAD} = \frac{\text{PSA ng/mL}}{\text{Prostate Volume (cc)}}$

– Useful with PSA 4–10 ng/mL and a previous negative biopsy
– Cutoff of 0.15 ng/mL/cm^3 improves specificity by 50%, missed 27–48% CaP
– Cutoff 0.1 avoids 31% of biopsies, misses 10% cancers; cutoff of 0.8 avoids 12% of biopsies, misses 5% of cancers

• Consider PSAV:
– Rate of PSA increase; PSA rises more rapidly if clinically significant CaP present:
– Minimum 18-mo interval with ≥3 repeat PSAs for most accurate PSAV determination.

- $\text{PSAV} = 0.5\left(\frac{\text{PSA}_2 - \text{PSA}_1}{\text{Time}_1} + \frac{\text{PSA}_3 - \text{PSA}_2}{\text{Time}_2}\right)$

  - PSA_1 = 1st PSA (ng/mL)
  - PSA_2 = 2nd PSA (ng/mL)
  - PSA_3 = 3rd PSA (ng/mL)
  - Time_1 = time between PSA_1 & PSA_2 (yr)
  - Time_2 = time between PSA_2 & PSA_3 (yr)

– Baltimore Longitudinal Study: 72% CaP had PSA rise >0.75 ng/mL/yr vs.10% with BPH
– PSAV > 0.35 predicts PCa death w/ PSA <4
– PSAV >0.75 90–100% PCa sensitivity w/ PSA >4
– PSA velocity >02 in year before dx predicts PCa mortality

• "Prostate Health Index" or phi assay
– CaP low FPSA, increased % proPSA
– Calculation ([–2]proPSA/FPSA) × √TPSA
– phi 27–55, CaP 9.8–50%, Gl ≥7 3.9–28.9%; phi 27: 18.8% could be spared biopsy (low risk)

Imaging

• TRUS: Determine prostatic size; PSAD; most useful to guide systematic needle biopsy
• Multiparametric MRI with/without endorectal coil: Useful if CaP suspicion and negative biopsy. Anterior tumors and other sites can be identified
• CT or bone scan: No role in CaP screening

Diagnostic Procedures/Surgery

• TRUS-guided prostate biopsy with 18G biopsy needle and local anesthesia:
– Systematic biopsy (12 cores) with laterally directed samples is now standard for CaP.

Pathologic Findings

See Section I: "Prostate Cancer, General."

DIFFERENTIAL DIAGNOSIS

• Adenocarcinoma of the prostate (CaP)
• BPH
• Prostatitis (usually bacterial infection)

- Prostatic infarction: Idiopathic or after shock
- Iatrogenic: Recent cystourethroscopy, Foley catheter placement, prostate biopsy
- Prostatic massage (but not routine DRE)
- Trauma (cycling, extensive)
- Ejaculation within 24 hr of PSA test (rare)

TREATMENT

GENERAL MEASURES

- Shared decision making before PSA based CaP screening in asymptomatic patients
- Due to PSA fluctuations, confirm an elevated PSA with a 2nd reading before biopsy. Patient should not ejaculate for 48 hr before test.
- Review serial PSA determinations for PSAV
- CaP screening recommendations:
  - See Appendix for ACS, ACP, EAU, NCCN, USPSTF
- AUA 2013 CaP Early Detection Guideline (4):
  - No PSA screening in men under age 40 yr
  - Does not recommend routine screening between ages 40 and 54 yr at average risk
  - Shared decision-making for men 55–69 yr considering PSA screening due to risks/benefits; proceed based on a man's values and preferences
  - To reduce harms, screening intervals of 2 yr preserves the benefits and reduces overdiagnosis and false-positives
  - No routine PSA screening in men age 70+ yr or <10–15-yr life expectancy; but some 70+ yr in excellent health may benefit from screening
- Some published prostate biopsy indications:
  - Prostate nodule, regardless of PSA
  - PSA >10 ng/mL in the absence of prostatitis
  - PSA >4.0 ng/mL and PSAV >0.75 ng/mL/yr
  - PSA <4.0 ng/mL and PSAV >0.3–0.5 ng/mL/yr
  - PSA >2.5 ng/mL and PSAV >0.60 ng/mL/yr
  - PSA 4–10 and F/T PSA<10%
  - F/T PSA <20% and PSAV >0.75 ng/mL/yr
- Numerous assays under study to help differentiate benign form malignant PA elevation (See Section II: "PSA, General Considerations.")

MEDICATION

First Line

- Empiric antibiotics for elevated PSA is no longer recommended by most sources
- With bacterial prostatitis, treat and repeat PSA 4 wk after: Fluoroquinolone (eg, ciprofloxacin 500 mg BID.) or TMP-SMX (180/800 mg BID)

Second Line

N/A

SURGERY/OTHER PROCEDURES

If patient has anorectal pathology, consider transperineal prostate biopsy for CaP diagnosis

ADDITIONAL TREATMENT

- CaP risk calculators are available on the Internet to predict outcome of biopsy.
- PCA3 urine testing after attentive DRE; FDA approved only after initial negative biopsy; PCA3/TMPRSS2-ERG urine test investigational

Additional Therapies

Any PSA rise while on finasteride/dutasteride baseline raises CaP risk

Complementary & Alternative Therapies

No evidence for herbals effect on PSA

ONGOING CARE

PROGNOSIS

- With elevated PSA, positive biopsy rate is about 25–30%; elevated PSA and nodule 18–60%
- Overall, if 2nd biopsy is performed after initial negative, detection rate is 10–35%.

COMPLICATIONS

Failure to diagnose cancer; patient anxiety over repeat testing; risk of biopsy and drugs

FOLLOW-UP

Patient Monitoring

- There is no single threshold PSA which should prompt prostate biopsy. Biopsy decision based on PSA, DRE, and multiple factors (F/T PSA, age, PSA velocity, PSA density, family history, ethnicity, prior biopsy history, comorbidities, patient preferences) (5).
- PSA <2.5 ng/mL, low PSAV: Annual DRE/PSA
- PSA 2.6–10 ng/mL, low PSAV:
  - Consider biopsy or obtain FPSA
  - F/T PSA $>25\%$: Repeat PSA/DRE in 6 mo
- Based on TRUS biopsy results:
  - Negative: Repeat DRE/PSA in 6 mo; consider F/T PSA as guide for another biopsy
  - HGPIN or ASAP:
    - Repeat biopsy (3–6 mo); consider transition zone sampling with any repeat biopsy.
  - Positive biopsy (CaP): Staging studies, discuss treatment options
- Persistent PSA elevation (PSA >10 ng/mL)
  - Repeat biopsy; transition zone sampling; multiparametric MRI of TRUS/MRI fusion biopsy

CODES

ICD9

- 185 Malignant neoplasm of prostate
- 600.00 Hypertrophy (benign) of prostate without urinary obstruction and other lower urinary tract symptom (LUTS)
- 790.93 Elevated prostate specific antigen [PSA]

ICD10

- C61 Malignant neoplasm of prostate
- N40.0 Enlarged prostate without lower urinary tract symptoms
- R97.2 Elevated prostate specific antigen [PSA]

CLINICAL/SURGICAL PEARLS

- Routine DRE will not clinically significantly elevate PSA.
- PSA 1/2-life is 2.2 days; may remain elevated for up to 4 wk after instrumentation.

PSEUDOHERMAPHRODITISM, MALE (XY DSD) AND FEMALE (XX DSD)

Luigi Avolio, MD

BASICS

DESCRIPTION

- Pseudohermaphroditism is an obsolete term that referred to pathologic conditions in which chromosomal sex is inconsistent with phenotypical sex
- Disorders of sexual development (DSDs) is the preferred term which indicates a congenital condition in which development of chromosomal, gonadal or anatomic sex is atypical (1)
- Female pseudohermaphroditism is now defined as XX DSD
  - Karyotype 46XX
  - Gonads: Normal ovaries
  - External genitalia: Varying degree of virilization
- Male pseudohermaphroditism is now defined as XY DSD
  - Karyotype 46XY
  - Gonads: Normal testes
  - External genitalia: Incomplete virilization

EPIDEMIOLOGY

Incidence

- 1 in 5,000 live births
  - 21-hydroxylase deficiency is the most common cause of 46XX DSD; 90% of congenital adrenal hyperplasia (CAH); 1:15,000 live births

Prevalence

N/A

RISK FACTORS

- Family history
- In utero exposure to androgens

Genetics

See “Disorders of Sex Development” chapter

PATHOPHYSIOLOGY

- XX DSD (Female pseudohermaphroditism) Disorders of androgen excess
  - 21-hydroxylase deficiency (21-OHD) is the most common cause for CAH, a family recessive disorders involving impaired synthesis of cortisol from cholesterol by the adrenal cortex
  - Impaired cortisol biosynthesis relieves feedback inhibition and thus increases ACTH secretion, which leads to hyperplasia of the adrenals and to disordered steroidogenesis; as a consequence cortisol precursors are shunted to androgen synthesis

ALERT

Newborns with salt-wasting 21-OHD CAH are at risk for life-threatening salt-wasting crises.

- β-Hydroxysteroid dehydrogenase (HSD3B2) deficiency: Deficiency of this enzyme results in adrenal insufficiency due to lack of conversion of δ5 steroids to δ-4 and consequent accumulation of pregnenolone, dehydroepiandrosterone (DHEA) and androstenediol. Phenotypically girls with mild virilization
- 11b-Hydroxylase (CYP11B1) deficiency: Characterized by accumulation of 11-deoxycorticosterone. This is the 2nd most common causes of virilizing CAH (5% of all cases)
- P450 oxidoreductase (POR) deficiency: Combined deficiencies of 21α-hydroxylase, 17α-hydroxylase and aromatase enzymes.
  - Familial glucocorticoid resistance: Rare condition with mutation in the glucocorticoid receptor determining high ACTH, cortisol, mineralocorticoids and androgens levels.
  - Aromatase (CYP19) deficiency: High serum androgens and low estrogen concentrations with progressive virilization.
- Maternal androgen excess:
  - Ovarian tumors (luteoma, arrhenoblastoma)
  - Ingestion of androgens, progestogens
- XY DSD (male pseudohermaphroditism)
  - Disorders of androgen synthesis
    - Cholesterol synthesis defects: Deficiency of 7-dehydrocholesterol reductase (DHCR7) results in a failure of cholesterol synthesis and elevated levels of its precursor 7-dehydrocholesterol. Causative factor of Smith–Lemli–Opitz syndrome (multiple congenital malformation and mental retardation syndrome)
    - Leydig cell hypoplasia: A defect of LH receptors leads to Leydig cells hypoplasia or agenesia. Genital anomalies range from hypospadias to completely normal female external genitalia
    - Lipoid CAH: Severe disorder of steroid hormone biosynthesis, caused by a defect in the conversion of cholesterol to pregnenolone, the 1st step in adrenal and gonadal steroidogenesis. All affected individuals are phenotypic females with a severe salt-losing syndrome, fatal if not promptly treated in early infancy
    - P450 side-chain cleavage deficiency: Rare disorder with ACTH and plasma renin activity grossly elevated and adrenal steroids inappropriately low or absent; patients have female external genitalia, sometimes with clitoromegaly
    - β-Hydroxysteroid dehydrogenase (HSD3B2) deficiency: (see XX DSD). 46 XY patients phenotype ranges from isolated hypospadias or micropenis to more severe undermasculinization
    - 17α-Hydroxylase/17,20-lyase deficiency: Production of excessive corticosterone and deoxycorticosterone with hypertension and hypokalemic alkalosis; aldosterone synthesis almost totally absent. Variable degree of undermasculinization
    - P450 oxidoreductase (POR) deficiency: (see XX DSD). The genitalia in 46 XY patients range from isolated hypospadias or micropenis to more severe undermasculinization
    - 17β-Hydroxysteroid dehydrogenase (17βHSD) type 3 deficiency: The HSD17B3 isozyme catalyzes the conversion of androstenedione to testosterone in the testis. Deleterious mutations in the HSD17B3 gene cause undermasculinization in genetic males attributable to impaired testosterone biosynthesis

- Steroid 5α-reductase type 2 deficiency: Reduced activity of 5α-RD type 2 with defective conversion of testosterone to DHT. Patients show ambiguous genitalia at birth, including perineal hypospadias

– Disorders of the androgen receptor (AR): Patients with partial or complete androgen insensitivity syndrome (PAIS/CAIS) have normal testosterone level and DHT response to hCG stimulation; usually normal anti-müllerian hormone (AMH) level
  - PAIS: Phenotype ranges from normal male with infertility (mild form) or isolated hypospadias to ambiguous genitalia with blind vaginal pouch
  - CAIS: Patients have female external genitalia, female breast development, blind vagina, absent uterus and female adnexa, and abdominal or inguinal testes

• Persistent müllerian duct syndrome (PMDS): Phenotype produced by a mutation in the gene encoding AMH or by a mutation in the AMH receptor; it results from failure of müllerian duct regression in otherwise normal males. Patients usually present bilateral cryptorchidism and inguinal hernias: A uterus and fallopian tubes are found in the inguinal canal; gonads are testes (2)

ASSOCIATED CONDITIONS

• Hypospadias
• Cryptorchidism
• Inguinal hernia

GENERAL PREVENTION

See “Disorders of Sex Development” chapter

DIAGNOSIS

HISTORY

• Family history:
  – Genital abnormalities
  – Amenorrhea
  – Sterility
  – Hirsutism
  – Early infant deaths (possible unrecognized CAH with salt-wasting crisis)
• Maternal exposure to androgens
• History of maternal virilization (androgen-producing tumor)

PHYSICAL EXAM

• External genitalia
  – Phallic structure (length, breadth, and amount of erectile tissue)
  – Position of urethral meatus
  – Number of orifices in the perineum and their characteristics
  – Labioscrotal folds (separated or fused)
• Gonads
  – Palpable gonads (testis, very rarely ovotestis)
• Abdomen
  – Mass referable to enlarged uterus

DIAGNOSTIC TESTS & INTERPRETATION

Lab

- Karyotype
- Serum levels of sodium, potassium, and 17-hydroxyprogesterone
- Androgens (testosterone, dihydrotesterone, androstenedione)
- Cortisol, gonadotrophins, and AMH levels
- Stimulation test with human chorionic gonadotropin (suspected defect of androgen production)

Imaging

- Abdominal/pelvic ultrasound (utero presence)
- Cystogram/genitogram (visualization of vagina, sinus)
- MRI

Diagnostic Procedures/Surgery

- Laparoscopy to define internal anatomy
- Cysto/vaginoscopy to confirm anatomy and level of confluence of urogenital sinus
- Gonadal biopsy to analyze presence of ovarian and/or testicular tissue
- Skin biopsy to obtain cellular lines

Pathologic Findings

See “Disorders of Sex Development” chapter

DIFFERENTIAL DIAGNOSIS

- Cryptorchidism
- Inguinal hernia, hydrocele
- Hypospadias
- Microphallus
- Gonadoblastoma
- Menstruation disorders

TREATMENT

GENERAL MEASURES

- Multidisciplinary team for evaluation of the patient
- Gender assignment early

MEDICATION

First Line

- Salt-wasting CAH
  - Fluid and electrolytes replacement
  - Glucocorticoid and mineralocorticoid replacement
    - Hydrocortisone 10 mg/m^2/d
    - Fludrocortisone 0.1–0.2 mg/d
  - Oral sodium chloride, 1–2 g/d added to formula or breast milk

Second Line

N/A

SURGERY/OTHER PROCEDURES

- Masculinizing genitoplasty (between the ages of 6 and 18 mo) (See "Disorders of Sex Development" chapter)
- Feminizing genitoplasty (during the 1st 6 mo of life) (3)[A] (See "Disorders of Sex Development" chapter)
- Müllerian remnants (See "Disorders of Sex Development" chapter)

ADDITIONAL TREATMENT

Radiation Therapy

N/A

Additional Therapies

N/A

Complementary & Alternative Therapies

Actually some patient groups strongly advocate to delay any surgical procedures until patients are competent to provide informed consent

ONGOING CARE

PROGNOSIS

- Generally good with appropriate care
- Many patients have a good quality of life
- Many patients remain fertile

COMPLICATIONS

See "Disorders of Sex Development" chapter

FOLLOW-UP

Patient Monitoring

- Lifelong psychosocial support mandatory
- Monitoring for increased risk for developing malignancies
- Evaluation of sexual function

CODES

ICD9

752.7 Indeterminate sex and pseudohermaphroditism

ICD10

- Q56.1 Male pseudohermaphroditism, not elsewhere classified
- Q56.2 Female pseudohermaphroditism, not elsewhere classified
- Q56.3 Pseudohermaphroditism, unspecified

CLINICAL/SURGICAL PEARLS

- Infants with a DSD presenting with truly ambiguous genitalia are a rare occurrence.
- DSD should be regarded as a heterogeneous group of conditions with substantially different prognoses and treatment prospects.
- DSDs represent a broad complex field that requires the interaction of multiple disciplines with a diverse knowledge base.

PYELONEPHRITIS, ACUTE, ADULT

Sanjay S. Kasturi, MD

BASICS

DESCRIPTION

- An infectious process that involves the renal pelvis and parenchyma.
  - Most often ascending infection from the lower urinary tract.
  - It is most often a result of bacterial infection, but fungi, parasites, and viruses may be involved.
- Classified as uncomplicated or complicated (ie, associated with obstruction, anatomic anomaly, or stones) making treatment more difficult.

EPIDEMIOLOGY

Incidence

- Estimated at 15–17 cases per 10,000 females and 3–4 cases per 10,000 males (1).
- At least 250,000 cases of pyelonephritis are diagnosed annually in the United States.
- Highest among young women, then infants, then the elderly.

RISK FACTORS

- Anatomic or functional abnormalities: Incomplete emptying of the bladder→urine is more prone to infection
  - Vesicoureteral reflux, neurogenic bladder, BOO
- Foreign body: Acts as a nidus for bacterial colonization and infection
  - Calculous disease, medullary sponge kidney
  - Indwelling catheters
- Medical conditions: Diabetes mellitus, immunosuppression, alcohol abuse
- Social: Poor perineal hygiene (soiling)
  - Variables in sexual behavior (new or multiple partners) and use of spermicide
  - Previous episodes of pyelonephritis

Genetics

Related to vesicoureteral reflux

PATHOPHYSIOLOGY

- Women are at increased risk because the female urethra is shorter and in close proximity to the anus, allowing enteric organisms to more easily colonize the urinary tract
- Most common organism are gram-negative rods:
  - *Escherichia coli* accounts for the majority of cases (80% in women, 70% in men)
  - *Klebsiella pneumoniae* is the 2nd most common organism (5–10%)
- Bacteria enter urinary tract:
  - Ascending infection: Urethra and bladder
  - Results from colonization of the vaginal introitus with fecal flora in females
  - Lymphatic and hematogenous dissemination to the kidneys is uncommon
- Bacteria adhere to the urothelium, with subsequent invasion and inflammatory response

- Adhesins and fimbriae: Allow bacteria to adhere to urothelium
- Lipopolysaccharides: Have toxic and inflammatory effects
- Hemolysins: Allow for bacterial invasion by damaging cells
- Aerobacter: Enables bacteria to compete for iron, necessary for aerobic metabolism and reproduction

ASSOCIATED CONDITIONS
See “Risk Factors”

GENERAL PREVENTION
- Eliminate anatomic/functional abnormalities
- Patients with recurrent infections may require low-dose prophylactic antibiotics
- Proper indwelling catheter management

DIAGNOSIS
HISTORY
- Fevers, chills, malaise, nausea, vomiting (2)
- Flank or abdominal pain
- Dysuria, urgency or frequency, gross hematuria
- Prior episodes of UTIs
- History of renal calculi or urinary tract abnormalities
- History of vaginal discharge and irritation makes a urinary source less likely
- History of diabetes, immunosuppression, or alcoholism; recent instrumentation
- Children may present with failure to thrive

PHYSICAL EXAM
- Vital signs for signs of sepsis
- CVA tenderness
- Abdominal distention with decreased bowel sounds may be present
- Pelvic exam in women may help differentiate from gynecologic disease

DIAGNOSTIC TESTS & INTERPRETATION
Lab
- CBC: Leukocytosis with neutrophil predominance (90%)
- Serum chemistry: Renal failure uncommon unless obstruction or sepsis present
- Blood culture: 12% of hospitalized pyelonephritis patients will have bacteremia
- Pregnancy test in women
- Urinalysis: Pyuria >5–10 WBCs/HPF:
  - WBC casts indicate renal source of infection
  - Hematuria and bacteria may be present
  - Leukocyte esterase often positive, but nitrite may not be positive with staph or enterococci
- Gram stain urine may rapidly identify organism
- Urine culture: Positive with >100,000 bacteria/mL and identifies causative organism; 10,000 bacteria/mL suggests acute pyelonephritis in patients with catheterized urine samples
- Newer data suggests that urinary cultures may be negative especially if patients were started

on antibiotics prior to presentation

Imaging

- In uncomplicated acute pyelonephritis, imaging studies are unnecessary; however, the combination of fever and flank pain especially with elevated WBC count requires imaging to rule out ureteral obstruction, which, with fever and infection, is a surgical emergency (3)
- Failure to respond to appropriate therapy within 72 hr requires radiographic evaluation to rule out obstruction, abscess, or other abnormalities
- Pediatric patients are at risk of scarring and should undergo imaging
- Abdominal x-ray (KUB): Evaluate for renal or ureteral calculi
  - Intraparenchymal gas: Emphysematous pyelonephritis
  - Renal shadow may be enlarged and poorly defined secondary to parenchymal edema
- IVP/ExU: 75% of patients with uncomplicated acute pyelonephritis will have a normal ExU
  - ExU shows an enlarged kidney (>15 cm in length or 1.5 cm greater than the unaffected side with decreased nephrogram and delayed excretion)
  - Cortical striations may be seen
  - Focal enlargement of the kidney is consistent with focal bacterial nephritis, or acute lobar nephronia may be confused with tumor or abscess
  - Nonobstructive dilation of the renal pelvis and ureter may be present (endotoxins impair ureteral peristalsis)
- US: Renal enlargement with hypoechoic parenchyma and loss or corticomedullary differentiation
  - Noninvasive; no ionizing radiation
- CT: Noncontrast CT of the abdomen reveals an enlarged kidney with decreased attenuation of parenchyma, and perinephric fat stranding
