DESCRIPTION One of the least common genitourinary anomalies, this mass of renal tissue has no parenchymatous connection with the definitive kidney (unlike a horseshoe kidney).

The supernumerary kidney is usually in a caudal position relative to the normal kidney and rarely is in a more cephalad position. The kidney is usually smaller or hypoplastic than a normal kidney and can function normally or not function at all. The ureter can insert into a normal ureter or bladder. It is usually associated with other GU anomalies, such as duplicated renal pelvis, vaginal atresia, and duplicated female urethra. Treatment is unnecessary unless disease is present. (See also Section I: "Renal Ectopia and Renal Fusion Anomalies.")

KLINEFELTER SYNDROME

DESCRIPTION A syndrome characterized by small, firm testes, gynecomastia, and elevated urinary gonadotropins; it is present in 1 out of 600 male births. Usually presents as incomplete virilization, infertility, or rarely as male pseudohermaphroditism. Mental retardation and low bone mineral density (BMD) are associated. A testicular biopsy usually shows sclerosis of tubules. The condition is caused by a nondisjunction of the meiotic chromosome, resulting in XXY karyotype and its variants. FSH is markedly elevated. Azoospermia is traditionally described on semen analysis, but recent series indicate that sperm can be found in over 50% of men with Klinefelter syndrome; thus, these men are not always sterile. Recent evidence suggests that children with Klinefelter syndrome are born with spermatogonia and lose large numbers of germ cells during puberty. No treatment can improve spermatogenesis. (See also Section II: "XXY Syndrome.")

REFERENCE

Paduch DA, Fine RG, Bolyakov A, et al. New concepts in Klinefelter syndrome. *Curr Opin Urol.* 2008;18(6):621–627. Review.

KLIPPEL–TRENAUNAY–WEBER SYNDROME

DESCRIPTION Klippel–Trenaunay–Weber syndrome was 1st described by French physicians in 1900. It consists of cutaneous vascular malformations in combination with soft tissue and bone hypertrophy. The defects are present at birth and most commonly involve the lower extremities. The vascular lesions have a propensity for hemorrhage. In a study of 214 patients by Husmann et al., 30% had genital cutaneous involvement. Of these patients, 36% developed intractable bleeding. Surgical excision of these vascular malformations was associated with significant blood loss.

KOCK POUCH AND HEMI-KOCK NEOBLADDER

DESCRIPTION A Kock continent catheterizable urinary reservoir (pouch) is created from 70–80 cm of small bowel. The mid 45-cm portion is folded into a U-shaped configuration and

opened along its antimesenteric border, and the adjoining edges of the U are sutured together. The resulting U patch is folded again from top to bottom to form a reservoir. The 17-cm end limbs are intussuscepted and stapled to create nipple valves at each end. The ureters are anastomosed in the proximal afferent limb, where the nipple prevents reflux and the efferent limb is used to create a continent stoma, which is catheterized to empty the pouch.

The hemi-Kock neobladder is an orthotopic neobladder constructed based on the theme of the Kock pouch. In this diversion, a single intussuscepted ileal nipple valve is used to create a nonrefluxing ureteroileal anastomosis. The remainder of the pouch is made from a detubularized ileum, which is configured into a pouch and anastomosed to the urethra. It is not currently a recommended form of urinary diversion due to complications related to intussuscepted nipple valves.

KOYLE STENT

DESCRIPTION The Koyle diaper stent (Cook Medical Inc., Bloomington, IN, USA) is used for stenting the urethra after hypospadias repair. It has an 8-Fr circumference in the fossa navicularis to minimize distal meatal or urethral stenosis while providing excess tubing externally to allow drainage into a 2nd or outside diaper while keeping the inside diaper dry to allow healing.

REFERENCE

Koyle MA. Hypospadias: A 30 year personal journey. *Scand J Surg*. 2011;100(4):250–255.

KRUGER STRICT SPERM MORPHOLOGY

DESCRIPTION Some fertility experts use the test to decide between intrauterine insemination (IUI) and in vitro fertilization (IVF) although the test is controversial. This test examines sperm morphology more in-depth than the standard WHO method. Freshly ejaculated sperm are smeared on a slide and stained. Sperm are judged as normal based on the following criteria:

- Head must be oval in shape with smooth contours, 5–6 μm in length and 2.5–3.5 μm wide with the acrosome taking up 40–70% of the head.
- Neck and mid-piece must have no abnormalities and a cytoplasmic droplet (a remnant from sperm production) if present must not be larger than 1/2 the size of the head.
- Tail must not be coiled or bent and should not have a droplet at the end.

After 200 individual sperm are counted at 1,000 X, the percent normal forms are calculated. The IUI prognosis is based on the following scale:

≥15% normal	Normal range: Good prognosis
5–14% normal	Sub optimal range: Prognosis is fair to good, however, the lower the percent normal, the lower the chance of successful fertilization
0–4% normal	Poor prognosis: Will usually need IVF with intracytoplasmic sperm injection (ICSI)

REFERENCE

LABIAL ADHESIONS AND FUSION

DESCRIPTION Complete (fusion) or partial adherence of labia minora. Low estrogen levels contribute to a thin atrophic lining, which is easily denuded and later heals with adhesions. The condition is acquired, not found at birth, and occurs in prepubescent girls and postmenopausal women. Fecal soiling as an infant, vulvovaginitis, eczema, dermatitis, and sexual abuse may be inciting factors. It may cause voiding dysfunction in severe cases, with resulting hydroureteronephrosis.

SYNONYMS

- Acquired postinflammatory cohesion of the labia minora
- Vulvar fusion
- Synechiae of the vulva

TREATMENT

- Conjugated estrogen cream locally applied
- Surgical treatment for severe cases

REFERENCE

Tebruegge M, Misra I, Nerminathan V. Is the topical application of oestrogen cream an effective intervention in girls suffering from labial adhesions? *Arch Dis Child.* 2007;92(3):268–271.

LACTATE DEHYDROGENASE (LDH), UROLOGIC CONSIDERATIONS

DESCRIPTION LDH is a cellular enzyme useful in monitoring the treatment of GCT. It tends to have a low specificity (further impaired in smokers), and therefore must be correlated with other clinical findings and lab markers (ie, α-fetoprotein and β-hCG). Some correlation has been made between LDH and tumor bulk. LDH can also be elevated in cases of liver involvement by other tumors such as RCC.

REFERENCE

Barlow LJ, Badalato GM, McKiernan JM. Serum tumor markers in the evaluation of male germ cell tumors. *Nat Rev Urol.* 2010;7(11):610–617.

LAPIDES CLASSIFICATION OF VOIDING DYSFUNCTION

DESCRIPTION A historic system for categorizing neurogenic voiding dysfunction into 5 areas:

- Sensory neurogenic bladder: Interrupted afferent bladder sensation can lead to chronic bladder distension and deterioration. Common processes include diabetes mellitus, tabes dorsalis, and pernicious anemia.
- Motor paralytic bladder: Destruction of parasympathetic motor innervation to the bladder results in painful overdistension initially and inability to initiate and maintain micturition. Common processes include pelvic surgery or trauma and possibly herpes zoster.
- Uninhibited neurogenic bladder: Injury to the corticoregulatory tract of the sacral spinal cord (micturition reflex center) leads to frequency, urgency, and urge incontinence.

Common processes include cerebrovascular accident, brain or spinal cord tumor, Parkinson disease, and demyelinating disease.

- Reflex neurogenic bladder: Complete interruption of sensory and motor pathways between the sacral spinal cord and brainstem leads to lack of bladder sensation and inability to voluntarily micturate. Common processes include trauma and transverse myelitis.
- Autonomous neurogenic bladder: Complete motor and sensory separation from the sacral spinal cord leads to inability to voluntarily micturate and lack of reflex bladder activity and bladder sensation.

LASER TECHNOLOGIES AND UROLOGIC APPLICATIONS

DESCRIPTION The use of laser (short for "light amplification by stimulated emission of radiation") systems in urologic surgical practice has gained widespread acceptance. The primary mechanism of laser operating systems is based on the process of stimulated emission of radiation where excited electrons rapidly decay and emit photon energy, which leave a resonator cavity as a coherent laser beam.

Lasers impart 4 different effects: Thermal, mechanical, photochemical, and tissue-welding effects. The thermal effect is most commonly employed. The laser light energy is absorbed and transformed into heat. The heat denatures proteins at 42–65°C, shrinks arteries and veins at 70°C, and cellular dehydration at 100°C. After water has evaporated from the tissue, the temperature rapidly rises, with carbonization at 250°C, and vaporization occurs at 300°C. Mechanical effects are used to create a plasma bubble that expands rapidly to disrupt stones. Photochemical effects involve laser activation of specific drugs or compounds taken up by the tissue and tissue welding relies upon collagen cross-linking using materials activated by a lasers specific wavelength.

Conditions such as nephrolithiasis, benign prostatic obstruction (BPO), bladder cancer, kidney cancer, urothelial cancer, and stricture disease have all been treated by laser therapy. Some modern laser systems include potassium titanyl phosphate (KTP), neodymium:yttrium-aluminum-garnet (Nd:YAG), holmium:yttrium-aluminum-garnet (Ho:YAG), and semiconductor diode lasers. The frequency-doubled, double-pulse Nd:YAG (FREDDY) laser is a short-pulsed, double-frequency solid-state laser with wavelengths of 532 and 1064 nm. It is a low-power, low-cost laser developed for intracorporeal lithotripsy. CO_2 lasers are used for ablation of skin lesions such as condylomata. The thulium:YAG laser has been developed improve on some of the shortcomings of the Ho:YAG laser. This new laser more closely matches the water absorption peak in soft tissue to minimize collateral tissue damage. The methods of laser delivery can include end firing, side firing, and interstitial technologies with many fibers designed to fit trough endoscopes. Specific clinical applications:

- Soft tissue incisions (eg, strictures, posterior urethral valves, endopyelotomy, bladder neck contractures): Ho:YAG, Nd:YAG, or KTP.
- Resection and tissue ablation (eg, BPH, bladder cancer, condylomata, penile cancer, hemangiomata), use Nd:YAG, Ho:YAG, KTP:YAG, semiconductor diode, or CO_2.

- Lithotripsy (renal pelvis, ureter, bladder stones): Ho:YAG, FREDDY, pulsed dye, or alexandrite.
- Tissue welding (eg, vasovasotomy; urethral reconstruction for hypospadias): Diode, KTP, Nd:YAG, or CO_2.
- Laser hair removal (eg, perineal skin used for local urethral grafts): Alexandrite, semiconductor diode, or Nd:YAG.

LAURENCE–MOON–BARDET–BIEDL SYNDROME

DESCRIPTION This autosomal recessive disease was initially described in 1860 by Laurence–Moon and received a more exact description in 1920 by Bardet–Biedl. A wide variety of manifestations include retinal pigmentary dystrophy (previously termed *retinitis pigmentosa*), postaxial polydactyly, central obesity, mental retardation, and hypogenitalism. More recently, renal abnormalities have been described, including chronic glomerulonephritis, characteristic cystic tubular disease, lower urinary tract malformations, and defects of tubular concentrating ability. Renal failure is the major cause of morbidity and early mortality. Undescended or maldescended testes can be present neonatally in up to 25% of males.

SYNONYMS

- Bardet–Biedl syndrome: More general, including all of the above description
- Laurence–Moon syndrome: Much rarer; differs with the above description, including progressive spastic paraparesis and distal muscle weakness but without polydactyly

REFERENCES

Beales PL, Warner AM, Hitman GA, et al. Bardet-Biedl syndrome: A molecular and phenotypic study of 18 families. *J Med Genet.* 1997;34(2):92–98.

LAZY BLADDER SYNDROME (NURSE'S BLADDER)

DESCRIPTION 1st described by Swenson in 1962, this condition occurs when children exhibit holding behavior and void infrequently. Thought to be caused by the continuous voluntary suppression of the normal desire to void, it is more common in girls. Patients are prone to develop UTIs due to urinary stasis and often have problems with constipation. Some patients have overflow or stress incontinence. The VCUG shows a large smooth-walled bladder, and US of the upper tract is usually normal. Urodynamic studies show large bladders with decreased sensation during bladder filling, low pressures, and large postvoid residuals. Timed voiding schedules, antibiotic suppression, biofeedback bladder training, and intermittent catheterization are all options for treatment.

LEADBETTER–CLARKE URETERAL ANASTOMOSIS

DESCRIPTION A nonrefluxing anastomosis is created by making a longitudinal incision through the taenia, just outside the mucosa. The ureter is laid over the mucosa and a small buttonhole is made through the mucosa to anastomose the spatulated end of the ureter. The taenia is closed over the ureter.

REFERENCE
Porena M, Mearini L, Zucchi A, et al. Ureterointestinal anastomosis in orthotopic neobladders. *Urol Int.* 2000;64(4):181–184.

LEADBETTER–POLITANO URETERONEOCYSTOSTOMY

DESCRIPTION Through a transvesical exposure, the ureter is mobilized from the bladder wall and surrounding peritoneum. A new ureteral hiatus is created 2–3 cm above the old hiatus. The ureter is then delivered behind the entire bladder, through the new hiatus and tunneled submucosally toward the old hiatus, where it is reimplanted.

REFERENCE
Kay R. Reimplantation of the ureter. In: Novick AC, Streem SB, Pontes JE, et al., eds. *Stewart's Operative Urology*. Baltimore, MD: Williams & Wilkins; 1989:526–538.

LEAK POINT PRESSURE (LPP)/ABDOMINAL LEAK POINT PRESSURE (ALPP)

DESCRIPTION LPP is a urodynamic variable. Abdominal leak point pressure (ALPP), related to stress urinary incontinence (SUI), is the lowest abdominal pressure required to cause urinary leakage during either a Valsalva maneuver or a cough in the absence of a detrusor contraction. An ALPP of <60 cm H_2O suggests significant intrinsic sphincter deficiency (ISD). If the ALPP is –90, it suggests mild sphincter deficiency. Sphincter deficiency is minimal with an ALPP >90 cm H_2O. Detrusor leak point pressure (DLPP) is the lowest detrusor pressure required to cause urinary leakage in the absence of a detrusor contraction or increased abdominal pressure. High DLPP (>40 cm H_2O) may put patients at a higher risk for upper urinary tract deterioration.

REFERENCE

LeBAG NEOBLADDER

DESCRIPTION This is a modification of the Mainz I orthotopic neobladder, which uses only 1 ileal limb instead of 2. The detubularized colon and a single segment of ileum can be joined using met al staplers to create a broad intestinal plate, which is then converted into a pouch with a ureterocolonic and urethral anastomosis.

REFERENCE

Pannek J, Senge T. History of urinary diversion. *Urol Int.* 1998;60(1):1–10.

LeDUC URETERAL ANASTOMOSIS

DESCRIPTION The end of the small bowel segment is opened 4–5 cm and a longitudinal incision is made in the mucosa, which is then raised. At the distal end of this incision, a hole is made through the wall. The ureter is pulled through this opening and laid in the mucosal incision. The mucosa is then sutured to the side of the ureter.

REFERENCE

LEIOMYOMATOSIS, HEREDITARY

DESCRIPTION Familial cancer syndrome of a triad of cutaneous leiomyomas, uterine leiomyomas, and type 2 papillary RCC. Renal tumors tend to be solitary and unilateral and are likely to be aggressive; collecting duct RCCs have also been observed. The lesions are usually seen in women 20–35 yo. Given their aggressive nature, the prompt surgical resection of renal tumors is recommended. (See also Section II: “Reed Syndrome.”)

REFERENCE

Coleman JA. Familial and hereditary renal cancer syndromes. *Urol Clin N Am.* 2008;35(4):563–572.

LEOPARD SYNDROME

DESCRIPTION An autosomal dominant condition similar to Noonan syndrome, except for multiple lentigines (macule pigment accumulation within the dermis and epidermis). LEOPARD syndrome is the mnemonic for lentigines, ECG abnormalities, ocular hypertelorism/obstructive cardiomyopathy, pulmonary valve stenosis, abnormalities of genitalia in males, retardation of growth, and deafness. Cardiomyopathy is an important feature because it is associated with significant mortality. Genital hypoplasia in males, including a small penis and small, often undescended testicles, is the most common association. Hypospadias and delayed puberty may also be found.

SYNONYMS

- Multiple lentigines syndrome
- Progressive cardiomyopathic lentiginosis

TREATMENT
Orchiopexy, repair of hypospadias

REFERENCE
Coppin BD, Temple IK. Multiple lentigines syndrome (LEOPARD syndrome or progressive cardiomyopathic lentiginosis). *J Med Genet.* 1997;34(7):582–586.

LERICHE SYNDROME

DESCRIPTION Described in 1923 as symptoms characteristic of thrombotic occlusion of the terminal aorta, this syndrome is caused by atherosclerosis of the arterial wall, with thrombus and gradual occlusion. Symptoms include fatigue of both lower limbs, symmetrical atrophy of lower extremities, pallor of legs/feet, and an inability to maintain a stable erection due to inadequate arterial flow to the penis (hypogastric arterial obstruction). Gradual occlusion allows for collateral circulation; therefore, acute symptoms are unlikely.

SYNONYM
Gradual thrombotic obliteration of the abdominal aorta and iliac arteries

TREATMENT
Bypass graft from the aorta to iliac or common femoral arteries

REFERENCE
Setacci C, Galzerano G, Setacci F, et al. Endovascular approach to Leriche syndrome. *J Cardiovasc Surg (Torino)*. 2012;53(3):301–306.

LESCH–NYHAN SYNDROME

DESCRIPTION 1st described in 1964 as an X-linked recessive disorder associated with failure to form hypoxanthine phosphoribosyltransferase, this disorder is caused by loss of function of the enzyme hypoxanthine guanine posphoribosyltransferase. Manifestations are hyperuricemia and uric acid lithiasis, choreoathetosis, mental retardation, spastic cerebral palsy, and self-mutilation of fingers and lips by biting. Allopurinol is the main urologic intervention to reduce hyperuricemia.

REFERENCE
Ngo TC, Assimos DG. Uric acid nephrolithiasis: recent progress and future directions. *Rev Urol.* 2007;9(1):17–27.

LEUKEMIA, UROLOGIC CONSIDERATIONS

DESCRIPTION Leukemic infiltration of the testicle can be seen in children with acute lymphoblastic leukemia (ALL). The typical presentation is testicular enlargement, typically bilateral. Open testicular biopsy, bilaterally, should be performed along with bone marrow and CSF analysis for tumor recurrence. Orchiectomy is not indicated for leukemic infiltration. Testes were once a common site of relapse, but with current intensive chemotherapy regimens, the testicular relapse rate is $<5\%$. No strong evidence suggests an increase in birth defects in the children of leukemia survivors. Patients treated with cyclophosphamide-

containing regimens are at risk for hemorrhagic cystitis and long-term urothelial tumors. (See also Section I: "Cystitis, Hemorrhagic [Infectious, Noninfectious].")

TREATMENT

- If the testicle is the isolated site of relapse, local irradiation (up to 20 Gy) to both testes and reinstitution of systemic chemotherapy can be curative.
- Therapy can cause irreversible damage to seminiferous tubules and Leydig cells.

Patients can develop hypogonadotropic hypogonadism and low testosterone with azoospermia.

REFERENCES

LEUKOPLAKIA, PENIS

DESCRIPTION Solitary or whitish plaques with hyperkeratosis, parakeratosis, and hypertrophy of the squamous rete pegs, with edema and lymphocytic infiltration. The condition often involves the penile meatus and has been associated with in situ squamous cell carcinoma (SCC) and verrucous carcinoma.

TREATMENT

- Eliminate chronic irritation
- Circumcision
- Surgical excision with periodic biopsy of incompletely excised lesions

REFERENCE

Bissada NK. Conservative extirpative treatment of cancer of the penis. *Urol Clin N Am.* 1992;19(2):283–290.

LEUKORRHEA

DESCRIPTION Generally refers to nonmalodorous, mucous like, white, or yellowish vaginal discharge in the absence of any pathologic cause. The quantity and quality vary among individuals, and mild irritative symptoms can be normal. Leukorrhea is also seen during infancy secondary to maternal estrogens, as well as during puberty secondary to estrogen surges. Reassurance is all that is necessary if the cervical and vaginal exam is normal, vaginal pH is normal (<4.5), and there are normal findings on microscopy and a negative amine test. (See also Section II: "Vaginosis"; Section III: "Vaginal Discharge Algorithm.")

REFERENCE

Anderson AU, Karasz A, Friedland S. Are vaginal symptoms ever normal? A review of the literature. *MedGenMed.* 2004;22:49.

LICHEN NITIDUS, PENIS

DESCRIPTION An uncommon chronic inflammation appearing as flesh-colored papules with sharp demarcations and flat, shiny, and slightly elevated surfaces. The etiology is unknown, but it is believed to be a variant of lichen planus. Histologically, lymphocytes, histiocytes, and melanophages form a ball-like structure covered by epidermis with a characteristic claw-like projection of the rete ridges. The condition is usually asymptomatic.

TREATMENT

- Spontaneous healing is common
- Oral histamines
- Topical antipruritics and topical corticosteroids may be helpful

REFERENCE

Davis DA, Skidmore RA, Woosley JT. Lichen nitidus. *Urology*. 1996;47(4):573.

LICHEN PLANUS, PENIS

DESCRIPTION An uncommon pruritic inflammation of the skin, which typically occurs on the penile glans. Benign, it is characterized by pruritic, violaceous, and flat-topped papules. Histologically, there can be degeneration of the basal cell-layer keratinocytes and dense infiltration of lymphocytes in the upper dermis hugging the epidermis. Multiple lesions occur and can ulcerate. Differential diagnoses include secondary syphilis, bowel disease, psoriasis, Zoon balanitis, and squamous cell carcinoma (SCC). There is no specific treatment; symptomatic relief is obtained through antihistamines, ataractics, and topical lotions.

REFERENCE

Hoshi A, Usui Y, Terachi T. Penile carcinoma originating from lichen planus on glans penis. *Urology*. 2008;71(5):816–817.

LICHEN SCLEROSIS ET ATROPHICUS

DESCRIPTION An uncommon cutaneous disorder with a female predominance. Early lesions are characterized as either white macules, which may coalesce into patches, or flat, white, or pink-depressed papules and plaques. Confluence of the papules and marked hyperkeratosis and atrophy may develop. Extra-genital areas (eg, arms, shoulders, trunk, neck, and face) are less commonly affected in men. Dysuria, pruritus, and pain are associated with the disease process. Squamous cell carcinoma (SCC) has been reported to occur.

SYNONYMS

- Lichen sclerosis
- The late stage evolves into balanitis xerotica obliterans

TREATMENT

- Circumcision
- Topical treatments for nongenital areas

REFERENCE

West DS, Papalas JA, Selim MA, Vollmer RT. Dermatopathology of the foreskin: An institutional experience of over 400 cases. *J Cutan Pathol.* 2013;40(1):11–18.

LICHEN SIMPLEX CHRONICUS (LICHEN SIMPLEX COMPLEX)

DESCRIPTION Localized chronic pruritus with patches of dermatitis, resulting from chronic scratching/rubbing. Common sites are the perineum, thigh, scrotum, and vulva. The lesions appear as multiple oval plaques that become thickened and scaly. There is a whitish gray discoloration caused by lichenification and maceration. The skin may become more susceptible to secondary infection and allergic contact dermatitis. Etiologies include contactants (irritant and allergic), infection, and underlying dermatoses. Microscopically, the lesions resemble chronic dermatitis with hyperkeratosis and parakeratosis. Diagnosis is usually clinical, but biopsy may be necessary.

SYNONYM
Circumscribed neurodermatitis

TREATMENT
- Break the scratch-itch cycle
- Stop all irritants
- Sitz baths or soaks
- Open wet compresses to affected areas
- Systemic antipruritics and/or sedating medications may be necessary to lessen the itching
- Topical and occasionally systemic steroids are necessary

REFERENCE
Margesson LJ. Vulvar disease pearls. *Dermatol Clin.* 2006;24(2):145–155.

LICH–GREGOIR URETERAL REIMPLANTATION

DESCRIPTION This extravesical, less invasive repair does not disrupt the ureteral trigonal continuity. A 4–5-cm trough is created by dissecting the detrusor of the mucosa, and the mobilized ureter is placed in the trough with the detrusor closed over it.

REFERENCE
Kay R. Reimplantation of the ureter. In: Novick AC, Streem SB, Pontes JE, eds. *Stewart's Operative Urology*. Baltimore: Williams & Wilkins; 1989:526–538.

LIDDLE'S SYNDROME

DESCRIPTION Liddle's syndrome is an autosomal dominant disorder of the sodium channels of the collecting duct. Mutations in the epithelial sodium channels in the kidney result in increased activity and severe hypertension is typically the result. Features of hypokalemia and metabolic alkalosis can also occur mimicking primary hyperaldosteronism. Treatment generally focuses on a low salt diet in conjunction with a potassium-sparing diuretic.

tract. In: Goldman L, Schafer A, eds. *Goldman's Cecil Medicine.* Philadelphia, PA: Elsevier Saunders; 2011:802.

LIFE EXPECTANCY, UROLOGIC CONSIDERATIONS

DESCRIPTION Life expectancy is commonly used by urologists when determining therapy for localized prostate cancer, as age may influences choice of treatment.

Current Age	Life Expectancy (yr) Male	Life Expectancy (yr) Female
65	17.19	19.89
66	16.48	19.10
67	15.77	18.32
68	15.08	17.55
69	14.40	16.79
70	13.73	16.05
71	13.08	15.32
72	12.44	14.61
73	11.82	13.91
74	11.21	13.22
75	10.62	12.55
76	10.04	11.90
77	9.48	11.26
78	8.94	10.63
79	8.41	10.03
80	7.90	9.43
81	7.41	8.86
82	6.94	8.31
83	6.49	7.77
84	6.06	7.26
85	5.65	6.77
86	5.26	6.31
87	4.89	5.87
88	4.55	5.45
89	4.22	5.06
90	3.92	4.69

LIPOMA, BLADDER

DESCRIPTION Bladder lipoma is a rare entity. It can be associated with a pelvic lipoma, and has been reported to cause bladder outlet obstruction. A capsule circumscribes the homogeneous, sharply marginated fat. It is benign and must be distinguished from liposarcoma, angiolipoma, and cystic teratoma, usually by CT. Treatment is by surveillance, unless symptomatic. (See also Section II: "Bladder Mass.")

REFERENCE

Kunkle DA, Mydlo JH. Bladder wall lipoma in patient with irritative voiding symptoms. *Urology*. 2005;66(3):653–654.

LIPOMA, SPERMATIC CORD

DESCRIPTION Benign lobulated preperitoneal fat that can project down the cord. Accounts for up to 90% of spermatic cord tumors and is most commonly seen in adults. Histologic variants include angiolipoma, fibrolipoma, fibromyxolipoma, myxolipoma, and myxoid

myolipoma. The lesion can present as a mass, and must be distinguished from adenomatoid tumor, leiomyoma, fibroma, liposarcoma, leiomyosarcoma, and fibrosarcoma. (See also Section I: "Spermatic Cord Mass.") Complete excision at time of surgery is recommended.

REFERENCE

Cavazzola LT, Lieberknecht M, Machado AS, et al. Giant lipoma of the spermatic cord. *Am J Surg.* 2009;198(5):e54–e55.

LIPOMATOSIS, PELVIC

DESCRIPTION Pelvic lipomatosis was 1st described in 1959 as an overgrowth of fat in the perirectal and perivesical regions that can cause compression of the lower urinary tract and lead to uremia. Rare disease found primarily in men in the 3rd–6th decades of life. Approximately 2/3 of patients are African American, with an 18:1 male-to-female ratio. Lipomatous tissue is composed of mature adipose and may be associated with inflammation. Histopathologically, it is found to be dense, vascular, unencapsulated lipomatous tissue that commonly envelops the pelvic viscera. It differs from a simple lipoma by the fact that it does not arise from a single focus, is not encapsulated, and does not expand centrifugally. Clinical features vary from urinary frequency to constipation. Pelvic lipomatosis has been associated with a higher incidence of hypertension. On a plain abdominal x-ray, it presents with radiolucency of the perivesical areas. Other radiographic signs include an elongation and elevation of the bladder, and the rectum and sigmoid colon. There is widening of the retrorectal space with increased lucency of the pelvic sidewalls. On cystography, a full bladder has an abnormal shape (banana shape) and position (superiorly as well as anteriorly). Cystoscopy should be performed, as there are reports of associated cystitis glandularis. Surgical removal of the fat (difficult and feasible in selected few patients) may be possible. For those patients with obstructive uropathy, treatment options include ureteral stenting, nephrostomy tubes, ureteral reimplantation, or urinary diversion. Pelvic exploration is done with caution as the normal anatomic planes are disrupted by the infiltrating fat.

LIPOMENINGOCELE, UROLOGIC CONSIDERATIONS

DESCRIPTION A meningocele associated with an overlying lipoma. This condition belongs to the family of occult spinal dysraphisms in which the formation of the spinal column is affected but does not result in an open vertebral canal. Outward signs and symptoms may be subtle, and the neurologic exam may be normal. As children get older, they may present with absent perineal sensation, back pain, secondary incontinence (incontinence after initial period of dryness), recurrent UTIs, or fecal soiling. In children <3 yo, urodynamic testing may be normal but it is usually abnormal in children >3 yr.

Address urinary symptoms as appropriate after urodynamic testing, and refer to a neurosurgeon for evaluation of tether release to prevent further injury and growth.

REFERENCE

Rendeli C, Ausili E, Tabacco F, et al. Urodynamic evaluation in children with lipomeningocele: Timing for neurosurgery, spinal cord tethering and follow-up. *J Urol.* 2007;177(6):2319–2324.

LIVER METASTASIS, UROLOGIC CONSIDERATIONS

DESCRIPTION The liver is a primary site for many malignant neoplasms, including those arising in the GU tract. Urothelial carcinoma (TCC), renal cell carcinoma (RCC) and testicular carcinoma may spread to the liver, but metastasis is most commonly seen in prostate cancer. In addition to bone pain and spinal cord compression, liver metastasis can be very painful. A liver lesion itself should not affect the urinary tract, but extensive disease may be reflected in increased bilirubin and urobilinogen levels on urine analysis.

TREATMENT

- Evaluate and treat primary tumor.
- Segmental resection or locally ablative therapies may be appropriate (Image ☼).

REFERENCE

Campbell SC, Lane BR. Malignant renal tumors. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2012:1413–1474.

LOBAR NEPHRONIA

DESCRIPTION A renal mass caused by acute focal infection without liquefaction. Clinical characteristics most frequently encountered are fever, flank pain, or back pain. Uroradiographic findings in this condition can mimic a renal abscess or neoplasm. Bacterial infection (*E. coli, Klebsiella, Aerobacter aerogenes, Proteus, Pseudomonas*) and *Candida albicans* are common causes. Appropriate medical treatment will cause the infected mass to disappear, but scarring may occur. (See also Section I: “Pyelonephritis, Acute, Adult.”)

SYNONYMS

- Acute lobar nephronia
- Acute focal bacterial nephritis

TREATMENT

- IV antibiotics
- Radiologic surveillance: CT or US

REFERENCE

Papanicolaou N, Pfister RC. Acute renal infections. *Radiol Clin North Am.* 1996;34(5):965–995.

LORD PROCEDURE (HYDROCELECTOMY)

DESCRIPTION During the Lord procedure for hydrocelectomy, radial sutures are used to gather the sac around the posterior aspect of the testis and epididymis. It was initially developed in 1964 to reduce the rate of postoperative hematoma formation after

hydrocelectomy. This technique does not require dissection of the hydrocele sac and therefore can be relatively bloodless. Generally this technique is recommended for thin-walled hydroceles.

REFERENCE

Singh DR, Gupta SK, Gupta S. Lord's procedure: a curative outpatient operation for primary hydrocele. *J Indian Med Assoc*. 1996;94(4):141–142.

LOWE SYNDROME

DESCRIPTION Also called *oculocerebrorenal syndrome*, it was 1st described in 1952 as an X-linked recessive disorder manifested by congenital cataracts, hypotonia, developmental delay, poor growth, and renal tubular dysfunction. Proteinuria and aminoaciduria are present by 1 yr of age, with gradual progression of Fanconi syndrome (typically failure to reabsorb water, electrolytes, bicarbonate, glucose, calcium, phosphorus, and small molecules). Polyuria, metabolic acidosis, hypophosphatemia with rickets, hypercalciuria, and sodium and potassium wasting can occur, leading eventually to end stage renal disease (ESRD). Nephrolithiasis has been reported due to the hypercalciuria. Vitamin D supplements and surveillance for nephrolithiasis are recommended.

REFERENCE

Sliman GA, Winters WD, Shaw DW, et al. Hypercalciuria and nephrocalcinosis in the oculocerebrorenal syndrome. *J Urol.* 1995;153(4):1244–1246.

LUB SYNDROME

DESCRIPTION Very rare, incomplete androgen insensitivity of karyotype XY with testes but ambiguous genitalia. Nonfertile, with elevated testosterone and LH levels, these children are usually raised as female and early gonadectomy and feminizing genitoplasty is performed in infancy. (See Section I: "Disorders of Sexual Development [DSD].")

REFERENCE

Snyder HM. Management of ambiguous genitalia in the neonate. In: Snyder NM, ed. *Urologlic Surgery in Neonates and Young Infants*. 19th ed. Philadelphia, PA: Saunders; 1988:346–348.

LYME DISEASE, UROLOGIC CONSIDERATIONS

DESCRIPTION Lyme disease is caused by the spirochete *Borrelia burgdorferi* and is a multisystem inflammatory disorder. Urinary dysfunction is rarely reported but has been linked to detrusor hyperreflexia or, less commonly, hyporeflexia. Detrusor external sphincter dyssynergia has not been described. The urinary tract may be part of the neuroborreliosis phase or the spirochete may directly invade the urinary tract.

SYNONYMS

- Neuroborreliosis
- Bannwarth syndrome
- Acrodermatitis chronica atrophicans

TREATMENT

- Therapy is aimed at stage of dissemination and symptomatology; 1st-line therapy is doxycycline 100 mg BID or amoxicillin 500 mg QID for 10–15 days; a longer course or IV antibiotics are required for more severe disease.
- Conservative bladder management including clean intermittent catheterization (CIC) guided by urodynamic evaluation.

REFERENCE

Puri BK, Shah M, Julu PO, et al. Urinary bladder detrusor dysfunction symptoms in lyme disease. *Int Neurourol J.* 2013;17(3):127–129.

LYMPHANGIOGRAM, PEDAL

DESCRIPTION Contrast injection into lymphatic channels on the dorsum of foot to visualize retroperitoneal lymph nodes. This technique has been largely replaced by CT, but it can be used to assess the retroperitoneal lymph nodes in patients with testicular and prostatic cancer. Its major advantage over CT scan is the detection of architectural changes in nonenlarged lymph nodes. It is time-consuming, invasive, does not opacify sentinel nodes, cannot differentiate between malignant and nonmalignant changes, and may cause fibrosis of lymph nodes due to reaction to the contrast medium (Image ☼).

REFERENCE

Pollack H. Tumors of the testis and testicular adnexa. In: Pollack H, ed. *Clinical Urography*. Philadelphia, PA: Saunders; 1990:1424–1428.

LYMPHANGIOMA, BLADDER

DESCRIPTION This rare bladder lesion presents with hematuria, and several cases are reported in children. Treatment is by partial cystectomy. The lesion is composed of multiple small cystic cavities filled with proteinaceous material, typical of cavernous lymphangiomas.

REFERENCE

Bolkier M, Ginesin Y, Lichtig C, et al. Lymphangioma of bladder. *J Urol.* 1983;129(5):1049–1050.

LYMPHANGIOMA, RENAL

DESCRIPTION A rare tumor, with 1/3 occurring in children and 2/3 in adults. The lesion appears as a solitary encapsulated mass with multiple cysts. Microscopy reveals benign endothelial cells with septa, which may contain smooth muscle. If within the renal sinus, the mass may cause obstruction.

REFERENCE

Chaabouni A, Rebai N, Fourati M, et al. Cystic lymphangioma of the kidney: diagnosis and management. *Int J Surg Case Rep.* 2012;3(12):587–589.

LYMPHANGIOMA, RETROPERITONEAL

DESCRIPTION Lymphangiomas are benign cystic tumors of the lymphatic system. They are rare tumors and retroperitoneal lesions account for only 1% of all lymphangioma lesions. <200 cases have been reported in the literature. They typically present clinically with a palpable abdominal mass, abdominal pain or distention, anorexia, nausea/vomiting, or diarrhea. These lesions can easily be confused with other retroperitoneal cystic tumors, including those arising from the liver, kidney, or pancreas. Surgical excision is generally required for definitive diagnosis and treatment. (See also Section I: "Retroperitoneal Masses and Cysts.")

REFERENCE

Bhavsar T, Saeed-Vafa D, Harbison S, et al. Retroperitoneal cystic lymphangioma in an adult: A case report and review of the literature. *World J Gastrointest Pathophysiol*. 2010;1(5):171–176.

LYMPHANGIOMA, SCROTAL

DESCRIPTION Congenital malformations of the intrascrotal lymphatic system, which may form cystic masses. These lymphangiomas are benign tumors, occurring mostly in children. They are found relatively infrequently in the scrotum. Treatment consists of surgical excision; unless completely removed, recurrences are common.

REFERENCE

MacMillan RW, MacDonald BR, Alpern HD. Scrotal lymphangioma. *Urology*. 1984;23(1):79–80.

LYMPHATIC ASCITES

DESCRIPTION Nonmalignant ascites is the most common form (80–90%) and can be the result of cardiac, liver, or renal failure. Malignant ascites accounts for 10–20% . Lymphatic ascites can be the result of obstruction of lymphatic vessels or, less frequently, a surgical complication following retroperitoneal surgery or trauma. Persistent lymphatic fluid leakage with ascites has been described following both nephrectomy and retroperitoneal lymph node dissections and other surgical procedures (colorectal, gynecologic). The cisterna chyli (enlarged lymphatic vessel within the lumbar region) is the transition point between chylomicron rich or poor lymphatic fluid. When lymphatic fluid is encountered superior to the cisterna chyli, it is termed "chylous" (milky white appearance due to high cholesterol) and in urology is most often seen associated with retroperitoneal lymph node dissection for testicular cancer. When the fluid is distal to this transition point, the condition is classified as lymphatic (minimal cholesterol, straw-colored or clear fluid) (See Section I: "Chylous Ascites.") (Image ☼)

REFERENCE

Micha JP, Mendivila AA, Cupp JS, et al. Recurrent lymphatic ascites in a patient cured of cervical carcinoma. *Gynecologic Oncology Case Reports*. 2012;2(3):105–106.

LYMPHOGRANULOMA VENEREUM

DESCRIPTION Lymphogranuloma venereum (LGV) is a relatively uncommon STI/STD caused by *Chlamydia trachomatis* (L1, L2, and L3 serovariants). While uncommon in the United States, it is endemic in parts of Africa, India, Southeast Asia, South America, and the Caribbean and is diagnosed more often in men than women. It is also known as lymphogranuloma inguinale, tropical bubo, and Nicolas–Favre disease. Initial infection (after 3 d) is a painless herpetiform lesion on the penis or scrotum in males and rarely presents initial symptoms in females. This is followed by a secondary stage (2–4 wk later) of tender groin lymphadenitis (buboes) and malaise in heterosexual males. Suppurative granulomatous lymphadenitis and matted draining nodes are seen. Genital swelling is common due to obstructed lymphatics. Females and anal receptive homosexual males are more likely to develop pelvic and perianal abscesses with proctocolitis in tertiary disease. Potentially fatal bowel obstruction with perforation if rectal stenosis is severe. The main differential is between syphilis and chancroid. Nucleic acid amplification testing is the diagnostic test of choice; screening for other STI/STD including HIV should be considered. Fluctuant buboes can be aspirated to reduce morbidity.

TREATMENT

Doxycycline is the treatment of choice and erythromycin, sulfisoxazole, and azithromycin are alternatives and should be used for at least 3 wk. Treat contacts within the last 30 d as well.

LYMPHOMA, UROLOGIC CONSIDERATIONS

DESCRIPTION Lymphoma can involve any part of the urinary tract, but is more commonly seen in the testicle and kidney:

- Lymphoma represents a common cause of testicular cancer in older men. It may be a local tumor growth or a late manifestation of widespread disease. >50% of testicular tumors in men >60 are lymphomas; these must be differentiated from seminoma. In adults, most are diffuse, large B-cell lymphomas; children can have Burkitt lymphoma involving the testicle.
- Bladder involvement is usually secondary to systemic disease and is present in 13% of patients dying of non-Hodgkin lymphoma. Primary bladder lymphoma occurs almost exclusively in females. Lesions may be sessile or polypoid and should be differentiated from chronic inflammatory bladder involvement, small cell carcinoma, and a rare entity called *lymphoma-like carcinoma.*
- Prostate lymphoma typically presents in older men, with symptoms of bladder outlet obstruction. PSA is rarely elevated. This is usually a manifestation of systemic disease, with primary prostate disease rare. The differential diagnosis includes chronic prostatitis with follicular hyperplasia, neuroendocrine prostate cancer, and granulomatous prostatitis.
- Adrenal involvement is present in up to 25% dying of systemic disease. The adrenals are a rare primary site of disease, with bilateral, clinical, adrenal involvement in 18% of non-Hodgkin lymphoma and 9% of Hodgkin lymphoma. (See also Section II: “Hodgkin

Lymphoma, Urologic Considerations.")

TREATMENT

- Testicular lymphomas: radical orchiectomy followed by systemic chemotherapy, depending on the extent of the disease. For stage I disease, 5-yr survival is >60%; if advanced, survival at 5 yr is <20%.
- Bladder lymphoma: Treated with radiation. If the bladder site is part of systemic disease, use systemic therapy.
- Prostatic lymphoma: Systemic therapy with TUR is used for obstructive symptoms. A poor prognosis, regardless of primary site; most die in <24 mo.

REFERENCE

Wang Y, Li ZM, Huang JJ, et al. Three prognostic factors influence clinical outcomes of primary testicular lymphoma. *Tumour Biol.* 2013;34(1):55–63.

LYMPHORETICULAR MALIGNANT NEOPLASM, PENIS

DESCRIPTION Rarely, lymphoreticular malignancies (eg, leukemia) may infiltrate the penis. Primary disease is rare, and a search for systemic disease is mandatory. The most common presentation is priapism, a painful prolonged erection. Treatment involves chemotherapy for primary lesions combined with local low-dose radiation.

REFERENCE

Begun FP, Derus J, Toorkey B, et al. Leukemia of the penis. *J Urol.* 1989;142(1):123–124.

LYMPHOVASCULAR INVASION (LVI), UROLOGIC CONSIDERATIONS

DESCRIPTION LVI describes an important feature for many aspects of urologic oncology, because it is an adverse prognostic indicator in urothelial carcinoma of the bladder and upper tracts, prostate cancer, and testicular cancer. In upper tract TCC, it has been found to be an independent prognostic factor for disease-specific survival. In noninvasive bladder cancer, it is a relative indication for early cystectomy. In testicular cancer, it is a risk factor for retroperitoneal and/or systemic failure.

REFERENCE

Sheinfeld J, Bosl GJ. Surgery of testicular tumors. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2012:871–892.

LYNCH SYNDROME

DESCRIPTION An autosomal dominant genetic syndrome caused by mutations in mismatch-repair enzymes, most commonly MSH2 and MLH1. This creates DNA MSI (Microsatellite instability) and increases the risk of colon and endometrial malignancy. An increased risk of upper tract urothelial carcinoma (TCC) is also observed and these cases can be successfully managed with ureteroscopic treatment/surveillance. In addition, these patients are at increased risk of developing bladder lesions as well.

SYNONYMS

- Hereditary nonpolyposis colorectal cancers
- Hereditary site-specific colon cancer

TREATMENT

- Screening for mutation can be performed via genetic testing.
- If screening is positive, surveillance colonoscopy is recommended.
- Netherlands Surveillance Protocol for specific individuals (includes regimented colonoscopies, urine cytologies, upper endoscopy, and US of the endometrium).

REFERENCE

Hubosky SG, Boman BM, Charles S, et al. Ureteroscopic management of upper tract urothelial carcinoma (UTUC) in patients with Lynch Syndrome (hereditary nonpolyposis colorectal cancer syndrome). *BJU Int.* 2013;112(6):813–819.

MACE (MALONE ANTEGRADE CONTINENCE ENEMA)

DESCRIPTION The Malone antegrade continence enema (MACE) procedure is performed mostly in children with complex constipation or fecal incontinence secondary to neurogenic dysfunction. Using the appendix, a continent catheterizable colonic stoma is made. Antegrade enemas delivered by this route produce complete colonic emptying and minimize fecal soiling.

REFERENCE

Hoy NY, Metcalfe P, Kiddoo DA, et al. Outcomes following fecal continence procedures in patients with neurogenic bowel dysfunction. *J Urol.* 2013;189(6):2293–2297.

MACRO-ORCHIDISM (MO)

DESCRIPTION Macro-orchidism (MO) is an increase of testicular volume, up to 25 mL, seen in the adult male. It is frequently associated with mental retardation with fragile X-chromosome. MO has also been described in association with bilateral testicular tumors, idiopathic precocious puberty, juvenile hypothyroidism, and, more rarely, with congenital testicular cysts (cystic testicular dysplasia). Management of MO must be conservative in all cases, and testicular biopsy must only be performed to diagnose leukemic infiltration, carcinoma in situ, or as part of a fertility workup. MO may be related pathogenically to some hormonal regulation mechanism or to higher seminiferous tubule sensitivity to FSH.

MAG 3 RENAL SCAN

DESCRIPTION A nuclear medicine study is used to evaluate renal function and the presence of obstruction. MAG3 (technetium^{99m}-mercaptoacetyltriglycine) is a nuclear isotope secreted by the renal tubules. Multiple images are taken over time to give anatomic details, including scarring and function of the kidney. A split differential function between the 2 kidneys is obtained. Commonly, furosemide is administered to induce diuresis, and the time for the kidney to clear 1/2 of the tracer is calculated ($t_{1/2}$). A $t_{1/2}$ of 0–10 min indicates nonobstructive drainage, 10–20 min is indeterminate, and >20 min is consistent with obstruction.

REFERENCE

MAGPI HYPOSPADIAS REPAIR

DESCRIPTION The meatal advancement and glanuloplasty procedure (MAGPI) was 1st described by Duckett in 1981. After a circumferential subcoronal incision, the bridge of tissue

immediately distal and dorsal to the meatus is split in a vertical fashion and closed in a horizontal orientation (Heineke–Mikulicz closure). The ventral edge of the new meatal opening is pulled up, and the glans is reapproximated ventrally, which, in effect, advances the meatus.

REFERENCE

Duckett JW. MAGPI (meatoplasty and glanuloplasty) a procedure for subcoronal hypospadias. 1981. *J Urol.* 2002;167(5):2153–2158.

MAINZ I, II, III POUCH URINARY DIVERSION

DESCRIPTION The Mainz I (ileocecal pouch) is an orthotopic pouch created by opening the cecum and 2 limbs of distal ileum; the limbs are then sutured to create a broad intestinal plate. After a tunneled ureterocolonic anastomosis is made, the cecal portion of the plate is anastomosed to the male urethral stump and the plate is closed into a sphere. The Mainz II (sigma rectum pouch) is an augmented valved rectum created by making a 10–12-cm rectosigmoid opening. The sigmoid colon is configured into a U shape, and the medial plate is closed. Ureters are implanted through submucosal tunnels. After securing the apex of the pouch to the sacral promontory, the remaining plate is closed. The Mainz III is a continent cutaneous pouch made exclusively of colon (transverse-ascending colon pouch or transverse-descending colon pouch) with the efferent segment created from a tapered bowel segment embedded in the pouch wall.

REFERENCE

MALACOPLAKIA, GENITOURINARY

DESCRIPTION Malacoplakia, derived from the Greek term for soft plaque, is a chronic inflammatory disease, the etiology of which remains obscure. It appears related to an underlying infectious process. It has a very low incidence and affects primarily the GU tract. The diagnosis is made by biopsy. The pathologic specimens typical of malacoplakia consist of large histiocytes known as *von Hansemann cells* and intracytoplasmic inclusions known as *Michaelis–Gutmann bodies*. The goal of treatment is to stabilize the disease process by controlling UTI (Image ☼).

MALARIA (BLACK WATER FEVER), UROLOGIC CONSIDERATIONS

DESCRIPTION The protozoan *Plasmodium falciparum* is the parasite responsible for malaria. From a urologic perspective, malaria can cause hemoglobinuria. Treatment includes full dose

antimalarials with supportive care. Acute renal tubular necrosis can occur if the infection is left untreated and some patients with chronic malaria develop nephrotic syndrome. (See Section II: “Black-Water Fever.”)

REFERENCE

Kehinde EO, Anim JT, Hira PR. Parasites of urological importance. *Urol Int.* 2008;81:1–13.

MALE SEXUAL FUNCTION SCALE

DESCRIPTION An 8-question sexual health inventory completed by the patient, which assesses core components of male sexual function including desire, erection, ejaculation, and satisfaction. The scale is meant to screen for sexual health in both the primary care and urologic practice settings.

REFERENCE

Lue TF, Broderick GA. Evaluation and nonsurgical management of erectile dysfunction and premature ejaculation. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 9th ed. Philadelphia, PA: Saunders Elsevier; 2007.

MALE SEXUAL HEALTH QUESTIONNAIRE (MSHQ) AND THE MSHQ SHORT FORM

DESCRIPTION A patient self-administered test developed in 2004, the MSHQ is a 25-question questionnaire that evaluates sexual function and satisfaction in older men with LUTS. It provides more in-depth assessment of ejaculatory function than previous measures of sexual dysfunction, mainly the International Index of Erectile Function (IIEF). A 4-item version is called the MSHQ short form, and both forms can be used in research settings as well as in clinical practice to assess ejaculatory dysfunction. (See Section VII: “Reference Tables: Male sexual health questionnaire, Short Form".)

REFERENCE

Rosen RC, Catania JA, Althof SE, et al. Development and validation of four-item version of Male Sexual Health Questionnaire to assess ejaculatory dysfunction. *Urology*. 2007;69(5):805–809.

MALROTATED KIDNEY/RENAL MALROTATION

DESCRIPTION Malrotated kidney occurs when the kidney does not rotate 90° medially during fet al development. As a result, the renal pelvis, which normally lies medial to the parenchyma, is located anterior to the parenchyma. Often a malrotated kidney is an incidental finding. Malrotation makes the kidney more susceptible to trauma, and is also commonly observed in ectopic kidneys. (See also Seection I: “Renal Ectopia.”) (Image ☼)

REFERENCE

MARSHALL–MARCHETTI–KRANTZ (MMK) CYSTOURETHROPEXY

DESCRIPTION A historical procedure for the treatment of stress incontinence in women performed through a Pfannenstiel incision. The retropubic space is exposed and the urethra, vaginal wall, bladder neck, and bladder are identified. The original description reports placement of interrupted sutures to attach the paraurethral tissue to the back of the symphysis pubis, with the most proximal suture being at the bladder neck.

REFERENCE

Parnell JP 2nd, Marshall VF, Vaughan ED Jr. Primary management of urinary stress incontinence by the Marshall-Marchetti-Krantz vesicourethropexy. *J Urol.* 1982;127(4):679–682.

MARTIUS GRAFT

DESCRIPTION A surgical technique used to repair urinary-vaginal fistulae. The flap is a well-vascularized fat pad from the labia majora and receives its blood supply from the branches of the pudendal artery. It is tunneled beneath the labia minora into the vaginal lumen, where it is used an interposition graft at the site of the fistula repair. It serves as a well-vascularized barrier between suture layers to prevent recurrent fistula formation.

SYNONYMS

- Martius labial pedicle graft
- Martius labial fat pad
- Martius flap

REFERENCE

Rangnekar NP, Imdad Ali N, Kaul SA, et al. Role of the Martius procedure in the management of urinary-vaginal fistulas. *J Am Coll Surg.* 2003;191(3):259–263.

MATHIEU HYPOSPADIAS REPAIR

DESCRIPTION A ventral flap is mobilized based on the dartos blood supply, and it is transposed over the urethral plate to advance the meatus. The lateral wings of the glans are reapproximated over the repair.

REFERENCE

Minevich E, Pecha BR, Wacksman J, et al. Mathieu hypospadias repair: Experience in 202 patients. *J Urol.* 1999;162(6):2141–2142.

MATURATION ARREST

DESCRIPTION The term *maturation arrest* has been used to describe testicular biopsies in cases of infertility. 2 forms of maturation arrest have been described: Spermatogenic arrest and spermatocytic (meiotic) arrest. The arrest is most frequently observed at the primary spermatocyte level. Reversible arrest at that level can be due to heat, infections, and hormonal and nutritional factors. Irreversible arrest at the primary spermatocyte or spermatid level has a genetic origin due to chromosomal anomalies. The dysfunction occurs in somatic

and germ cells.

REFERENCE

MAXIMUM ANDROGEN BLOCKADE (MAB)/COMBINED HORMONAL THERAPY (CHT)

DESCRIPTION The main concept behind maximum androgen blockade (MAB), sometimes referred to as combined hormonal therapy (CHT) or total androgen blockade is that by adding an antiandrogen in conjunction with surgical castration or LHRH agonist therapy, urologists can minimize the effects of any extragonadal sources of androgen production in patients with prostate cancer. This source was traditionally noted to be the adrenal gland. Studies have been conflicting with some showing prolonged survival in patients treated with MAB with advanced prostate cancer and others demonstrating no significant difference. In a large meta-analysis published by the Prostate Cancer Trialists' Collaborative group, a nonsignificant 1.8% 5-yr survival was found in the MAB group. This study included 27 randomized trials and over 8,200 patients.

Short-term MAB (1–2 wk) is generally agreed to in men with newly diagnosed metastatic disease when starting androgen deprivation with an LHRH analog to block the so-called "flare" reaction. Most RTOG trials that combine radiation therapy and external beam radiation therapy for intermediate and high-risk disease are performed using MAB (6 mo to 2–3 yr based on the risk and protocol).

MAYER–ROKITANSKY–KUSTER–HAUSER SYNDROME (ROKITANSKY—KUSTER–HAUSER SYNDROME)

DESCRIPTION A congenital absence of the vagina. The uterus is either abnormal or absent. The diagnosis is usually made when amenorrhea is noted in a normal pubertal XX person with a female phenotype. Renal and skelet al anomalies are a common association. The defect involves mesodermal development and the mesonephric kidney, the latter resulting in abnormalities in the paramesonephros (uterus and vagina) and in the metanephric kidney.

REFERENCE

MAYO CLINIC GRADING SYSTEM FOR PROSTATE CANCER

DESCRIPTION A grading system for prostate cancer that uses not only assessment of glandular architecture similar to Gleason's grading system, but also histologic criteria. Grading is done on a scale of 1–4, with 4 having the worst prognosis. Cellular features, such as cytoplasmic-nuclear-nucleolar morphology, mitotic activity, and tumor invasiveness, are all used to assign grade.

McCUNE–ALBRIGHT SYNDROME

DESCRIPTION A syndrome characterized by a classic triad of fibrous dysplasia (cystic bone lesions), gonadotropin-independent precocious puberty, and cutaneous pigmentation with cafe-au-lait spots. It is caused by a mutation of chromosome 20q13, coding for the α-subunit of G-proteins that are involved with many hormone receptor signaling pathways.

SYNONYMS

- Polyostotic fibrous dysplasia
- Osteitis fibroso cystica

TREATMENT

Treatment is targeted at the specific endocrinopathy and may include:

- Hyperthyroidism surgery
- Adrenalectomy
- Aromatase inhibitors, anti-estrogens, and ant-iandrogens

REFERENCE

Collins MT, Singer FR, Eugster E. McCune-Albright syndrome and the extraskelet al manifestations of fibrous dysplasia. *Orphanet J Rare Dis*. 2012;7:S4. Published online May 24, 2012.

McGUIRE URINAL

DESCRIPTION An external male urine collection device consisting of a reusable latex urinal sheath that is either self-contained or attached directly to a leg bag. It is often supported by fabric suspensions in a jock-strap type fashion.

REFERENCE

MEATAL STENOSIS, URETHRAL, FEMALE

DESCRIPTION Distal urethral (meatal) stenosis is a recognized entity. Females with this condition present clinically with complaints ranging from UTI to enuresis. Distal urethral

stenosis may be associated with the radiographic appearance of a prominent, collar-like bladder neck, which reflects generalized detrusor hypertrophy. When treatment is deemed necessary, the distal urethra is calibrated with bougies or female urethral sounds. (See also Section III: "Urethra, Meatus, Normal Caliber.")

REFERENCE

Perlmutter AD, Colodny A, Harris PD, et al. Urethral meatal stenosis in female children simulating bladder-neck obstruction. *J Pediatr.* 1966;69(5):739–743.

MEATAL STENOSIS, URETHRAL, MALE

DESCRIPTION Most commonly seen after neonatal circumcision, this acquired condition is theorized to follow a postsurgical inflammatory reaction at the glans, resulting in an extremely narrow meatus. Meatal stenosis is usually not apparent until the child is toilet trained. Strength and/or direction of stream can be affected. Dysuria, frequency, incontinence, and hematuria are symptoms that have been associated with this condition. Meatal stenosis rarely causes obstructive changes in the urinary tract. Meatoplasty is the corrective procedure for those requiring surgical correction. (See also Section II: "Calibration, Meatus and Urethra.")

REFERENCE

Brem J, Jaffee SR. Hidden meatal stenosis in male infants and children. *Am Fam Physician (GP).* 1970;2(2):72–73.

MECKEL–GRUBER SYNDROME (MECKEL SYNDROME)

DESCRIPTION Meckel–Gruber syndrome is a rare, lethal, autosomal recessive disorder with major characteristic features consisting of the triad of occipital encephalocele, polydactyly, and bilateral polycystic kidneys. Prenatal sonographic exam has been demonstrated to be of reliable diagnostic accuracy. For this reason, appropriate prenatal counseling is advocated for those at high risk.

REFERENCE

Sepulveda W, Sebire NJ, Souka A, et al. Diagnosis of the Meckel-Gruber syndrome at eleven to fourteen weeks' gestation. *Am J Obstet Gynecol.* 1997;176(2):316–319.

MEDIAN BAR

DESCRIPTION Median bar refers to prostatic posterior commissural hyperplasia, an acinar hyperplasia involving the posterior bladder lip that produces a wide bar. Patients suffering enlargement of the middle lobe or posterior commissure are more likely to develop obstructive symptoms due to the tissue location, which easily obstructs the bladder neck. This explains the correlation between the size of the gland and the degree of obstruction.

REFERENCE

Randall A. *Surgical Pathology of Prostatic Obstruction.* Baltimore, MD: Williams & Wilkins; 1931.

MEDIAN RAPHE CYST

DESCRIPTION Median raphe cysts are uncommon congenital lesions of the male genitalia. Theories proposing its origin include the development of embryologic outgrows of epithelium after primary closure of urethral folds, or that they arise from epithelial remains caused by incomplete closure of the folds. Cysts can be found anywhere from the distal penis to anus at the midline. They are usually asymptomatic until adulthood, when they can be traumatized or secondarily infected, producing swelling, tenderness, and purulent discharge. Treatment is simple excision followed by primary closure.

REFERENCE

Krauel L. Median raphe cysts of the perineum in children. *Urology*. 2008;71(5):830–831.

MEDICATIONS THAT CAN IMPACT VOIDING FUNCTION

DESCRIPTION A variety of agents can impact on urinary function. Some can worsen incontinence, others can cause retention and difficulty voiding.

Medications That Can Impact Voiding Function

Medication	Effect on Voiding Function
Alcohol	Frequency, urgency, sedation, delirium, immobility
Angiotensin-converting enzyme inhibitors	Associated cough worsens stress and possibly urge leakage in persons with impaired sphincter function
Anticholinergics	Impaired emptying, retention, delirium, sedation, constipation, fecal impaction
Antipsychotics	Anticholinergic effects plus rigidity and immobility
β-Blockers	Urge incontinence
Calcium channel blockers	Impaired detrusor contractility and retention; the dihydropyridine agents can cause pedal edema, leading to nocturnal polyuria
Cholinesterase inhibitors	Alone may increase incontinence; increased functional impairment when combined with anti-incontinence antimuscarinic agents
Estrogen	Worsens stress and mixed leakage in women
GABAergic agents (gabapentin, pregablin)	Pedal edema causing nocturia and nighttime incontinence
Histamine 1 receptor antagonists	Confusion
Latanoprost	Urge incontinence
Lithium	Polyuria
Loop diuretics	Polyuria, frequency, urgency
Narcotic analgesics	Urinary retention, fecal impaction, sedation, delirium
Nonsteroidal anti-inflammatory drugs	Pedal edema causing nocturnal polyuria
Opioid analgesics	Sedation, anticholinergic effects
Oral contraceptives	Stress, urge, and mixed incontinence
Sedative hypnotics	Sedation, delirium, immobility
Thiazolidinediones	Pedal edema causing nocturnal polyuria
Tricylic antidepressants	Anticholinergic effects, sedation
α-Adrenergic agonists	Outlet obstruction (men)
α-Adrenergic blockers	Stress leakage (women)

MEDULLARY CYSTIC KIDNEY

DESCRIPTION A form of progressive renal disease with up to 75% of cases having

medullary cysts, although it is primarily a tubulointerstitial disease. Juvenile nephronophthisis and medullary cystic disease are similar anatomically and clinically, but they have different modes of transmission and different clinical presentations. Juvenile nephronophthisis usually is inherited as an autosomal recessive trait (onset age: 6–20 yr), and medullary cystic disease typically is inherited as an autosomal dominant trait that presents after the 3rd decade. Patients present with polyuria and polydipsia due to salt wasting, a concentrating defect, anemia, and profound growth retardation. Juvenile nephronophthisis often is associated with disorders of the retina (ie, retinitis pigmentosa), skelet al abnormalities, hepatic fibrosis, and Bardet–Biedl syndrome (obesity, mental retardation, polydactyly, retinitis pigmentosa, and hypogenitalism). On US or CT, the medullary cysts can be seen with parenchyma and may appear hyperechogenic due to tubulointerstitial fibrosis.

SYNONYMS
- Juvenile nephronophthisis
- Uremic medullary cystic disease
- Salt-losing enteropathy
- Uremic sponge kidney

TREATMENT
Sodium replacement initially, with dialysis and transplantation later. The transplant graft appears to be resistant to the disease.

REFERENCE
Bernstein J, Gardner KD Jr. Familial juvenile nephronophthisis: Medullary cystic disease. In: Edelman CM Jr., ed. *Pediatric Kidney Disease*. Boston: Little, Brown; 1979:580.

MEGAPREPUCE (CONGENITAL MEGA PREPUCE)

DESCRIPTION Also known as *megameatus intact-prepuce variant*, this is a variant of hypospadias in which the ventral prepuce is intact and characterized by intermittent ballooning of the genital area. It may only be discovered following a dorsal slit at the time of circumcision. Associated anomalies include chordee, penoscrotal inversion, bifid scrotum, and cryptorchidism. One surgical repair consists of limited preputial resection of the phimotic ring, wide dissection of the outer prepuce to the base of the penis, fixation of the proximal outer prepuce to Buck's fascia to create a new penoscrotal junction. Next step is unfurling and wide tailoring of the inner prepuce in the ventral midline to resurface the whole elongated penile shaft. A catheter is left in place for 5 or 6 days.

MEGACALYCOSIS

DESCRIPTION A nonobstructive enlargement of the calyces due to a congenital

malformation of the renal papillae. There is no dilation of the renal pelvis, and no evidence of UPJ obstruction. Found almost exclusively in males (6:1), it often presents in children due to a UTI workup or in adults with hematuria and renal calculi. The clinician must differentiate between hydronephrosis and UPJ obstruction.

TREATMENT
Not necessary. A diuretic renogram should fail to demonstrate any obstruction.

REFERENCE
Redman JF, Neeb AD. Congenital megacalycosis: a forgotten diagnosis? *Urology*. 2005;65(2):384–385.

MEGACYSTIS, CONGENITAL

DESCRIPTION A dilated, thin-walled bladder with a wide and poorly developed trigone. Because of the laterally displaced ureters, vesicoureteral reflux is commonly seen. Bladder contractility is normal, but most urine refluxes retrograde into the collecting system. Correction of the reflux often restores normal bladder dynamics. It is most often diagnosed on prenatal US. It is associated with *megacystis-microcolon-intestinal hypoperistalsis syndrome,* a rare congenital disorder characterized by a dilated, nonobstructive urinary bladder and hypoperistalsis of the GI tract.

TREATMENT
Correction of vesicoureteral reflux after 6 mo of age.

REFERENCE
Frimberger D, Kropp BP. Bladder anomalies in children. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 9th ed. Philadelphia, PA: Saunders Elsevier; 2007.

MEGACYSTIS-MEGAURETER SYNDROME

DESCRIPTION The term *megacystis-megaureter* describes the radiologic appearance of a large-capacity, thin-walled bladder, and massive primary vesicoureteral reflux. The pathophysiology of these massively dilated ureters and the large-capacity bladder is the constant recycling of large volumes of refluxed urine. Bladder contractility is normal, even with a poorly developed trigone. Surgical correction of the reflux usually leads to a normal voiding pattern. (See also Section I: “Vesicoureteral Reflux, Pediatric.”)

TREATMENT
Correction of the reflux surgically should lead to a normal voiding pattern.

REFERENCE
Burbige KA, Lebowitz RL, Colodny AH, et al. The megacystis-megaureter syndrome. *J Urol.* 1984;131(6):1133–1136.

MEGALOURETHRA

DESCRIPTION Megalourethra is an extremely rare congenital deficiency of the mesodermal

tissues of the phallus. It can best be described as a urethral diverticulum that affects the entire penile urethra. 2 types have been described, scaphoid and fusiform. Scaphoid megalourethras are more common and have an absence of corpus spongiosum, whereas fusiform megalourethras lack both spongiosum and corpora cavernosa. Often associated with lethal congenital anomalies, fusiform megalourethras are present in some stillborns. Transient obstruction during early development may be responsible for the fusiform type. With the scaphoid type, a failure of development of erectile tissue is present, a mesenchymal defect similar to the pathophysiology of prune belly syndrome (PBS). Many other conditions are associated, such as PBS, renal agenesis, hypospadias, cryptorchidism, and others. For PBS, urethrostomy may be needed secondary to bladder outlet obstruction and renal failure. In surgical repair of the scaphoid type, longitudinal reduction urethroplasty over a catheter to decrease urethral caliber or plication techniques can be used.

For the fusiform variant, each case is managed based on the amount of tissue present and the severity of disease (Image ☼).

MELANOMA, ADRENAL

DESCRIPTION Primary malignant melanoma of the adrenal gland is an established entity. It originates in the adrenal medulla from cells derived from the neural crest. Because of the high frequency of metastatic involvement of the adrenal by cutaneous and ocular melanomas, diagnosis can be difficult. Primary adrenal melanoma is a highly malignant tumor of middle age that often manifests as a painful flank mass. Distant lymph node metastases can be seen as a presenting sign. Treatment is not effective, with a mortality rate approaching 100% within 2 yr.

REFERENCE

Dao AH, Page DL, Reynolds VH, et al. Primary malignant melanoma of the adrenal gland. A report of two cases and review of the literature. *Am Surgeon.* 1990;56(4):199–203.

MELANOMA, GENITOURINARY

DESCRIPTION Malignant melanoma of the GU tract is rarely a primary disease. However, lesions of the penis, scrotum, and urethra can present as primary sites of disease. Secondary melanoma metastatic to the GU tract is a common autopsy finding. The majority of patients whose secondary melanoma is discovered clinically die of metastatic disease within 2 yr.

REFERENCE

Stein BS, Kendall AR. Malignant melanoma of the genitourinary tract. *J Urol.* 1984;132(5):859–868.

MELANOMA, URETHRAL

DESCRIPTION A malignant degeneration of melanocytes and nevus cells, primary

malignant melanomas are rare. The urethra is the preferred site of the urinary tract and accounts for ~4% of urethral cancers. A urethral melanoma is more likely to be primary compared with cases in the bladder or kidney. It is 3 times more common in women, more frequent in the white population, and most commonly affects the distal urethra. Presentation is similar to that of other urethral tumors, but melanuria is sometimes seen. It may be confused with urethral polyps, caruncles, mucosal prolapse, chancre, or more common malignant urethral tumors. It is most commonly unifocal. These are usually deeply invasive; local extension is common and inguinal lymph node metastases are present at diagnosis in 1/2 of the cases. Most patients do not survive >3 yr. (See also Section I: "Urethra, Carcinoma, General Considerations.")

TREATMENT

- Limited data are available; most are treated with radical surgery and frequently bilateral lymph node dissection.
- Chemotherapy, immunotherapy, radiotherapy, or a combination of all 3 is experimental.

REFERENCE

Oliva E, Quinn TR, Amin MB, et al. Primary malignant melanoma of the urethra: A clinicopathologic analysis of 15 cases. *Am J Surg Pathol.* 2000;24(6):785–796.

MENKES SYNDROME (MENKES KINKY HAIR DISEASE)

DESCRIPTION A rare congenital disorder of copper metabolism with an X-linked recessive inheritance. Symptoms appear in the neonatal period and include hypothermia, poor feeding, and impaired weight gain. Neurogenic function progressively deteriorates. A colorless and friable hair is characteristically found. There tends to be a high incidence of GU conditions, including bladder diverticula, UTI, UPJ obstruction, vesicoureteral reflux, and cryptorchidism.

TREATMENT

- Parenteral copper therapy
- Bladder diverticula generally are treated with clean intermitent catheterization (CIC), as well as open cutaneous vesicostomy. Excision of the bladder diverticula is usually hazardous because of the generally poor health of these patients.

REFERENCE

Oshio T, Hino M, Kirino A, et al. Urologic abnormalities in Menkes' kinky hair disease: Report of three cases. *J Pediatr Surg.* 1997;32(5):782–784.

MENOPAUSE, UROLOGIC CONSIDERATIONS

DESCRIPTION Menopause is the cessation of the menstrual cycle and is caused by reduced secretion of the ovarian hormones estrogen and progesterone. This causes a variety of symptoms, including those that affect the GU tract. Vaginal side effects such as dyspareunia (~40%), itching, and vaginal dryness (~55%) occur secondary to reduced estrogen and androgen secretions. A change in the pH of vaginal fluid from acidic to neutral occurs that increases urinary infections. Decreased estrogen contributes to collagen loss and subsequent

pelvic organ prolapse and urinary symptoms. Urinary incontinence and irritative bladder symptoms occur in 20–40% of perimenopausal and postmenopausal women.

TREATMENT

- Topical estrogen therapy has been shown to decrease the incidence of urinary infections, increase bladder control with reduction in urge and irritative symptoms, and improve vaginal dryness and atrophy. It has no effect on stress urinary incontinence (SUI).
- The use of hormone therapy is generally on a short-term basis and only for symptomatic individuals. Although it has been shown to possibly have cardioprotective effects, an increase in breast cancer risk is also seen.

REFERENCE

Lobo RA. Menopause: Endocrinology, consequences of estrogen deficiency, effects of hormone replacement therapy, treatment regimens. In: Katz VL, et al. *Comprehensive Gynecology*. 5th ed. Philadelphia, PA: Mosby Elsevier; 2007.

MESOTHELIOMA, BENIGN, TESTICULAR TUNIC

DESCRIPTION Both a benign papillary, nonpapillary (adenomatoid tumor), and benign multicystic varieties exist. The nonpapillary tumor is the most common tumor of the epididymis and cord. All arise from the tunica vaginalis and are usually seen in young men 20–50 yr of age. The most common clinical presentation is associated with a painless scrotal mass or hydrocele. Benign multicystic mesothelioma has a recurrence rate of 27–75% in 3 mo–19 yr. (See also Section I: “Paratesticular Tumors.”)

REFERENCE

Aber A, Tahir A, Arumuham V, et al. Benign cystic mesothelioma: A rare cause for scrotal swelling. *Case Rep Med.* 2012;2012:572186.

MESOTHELIOMA, MALIGNANT, TESTICULAR TUNIC

DESCRIPTION Mesothelioma is a rare tumor (<100 cases reported), affecting the serosal surface of pleura, pericardium, peritoneum, and tunica vaginalis (an extension of the peritoneum). It usually presents as an incidental finding at the time of hydrocele surgery. It most commonly presents in the 5th–7th decades, although it has been reported in a patient 10 yo. Patients typically present with a hydrocele, but the initial physical exam rarely suggests malignancy. Metastatic spread occurs early via the lymphatic system to the paraaortic, inguinal, and supraclavicular nodes. The tumor spreads less commonly via the bloodstream to the lungs and liver. In the absence of metastatic spread, aggressive local surgery seems to yield the best results. The role of adjuvant chemotherapy and radiotherapy is less clear. (See also Section I: “Paratesticular Tumors.”) (Image ☼)

REFERENCE

Brimo F, Illei PB, Epstein JI. Mesothelioma of the tunica vaginalis: A series of eight cases with uncertain malignant potential. *Modern Pathology*. 2010;21:1165–1172.

METABOLIC STONE EVALUATION (24-HR URINE STUDIES)

DESCRIPTION Patients with urolithiasis should be encouraged to retrieve stones or stones removed surgically should be submitted for stone analysis. The extent of further evaluation is somewhat controversial. It is generally agreed that all patients who present with nephrolithiasis undergo a basic evaluation to rule out a systemic disease. This limited evaluation include history, physical exam, imaging for any residual stones, electrolytes, creatinine, calcium, uric acid, phosphorus, stone analysis and urinalysis, including urine pH. This may diagnose uncommon, but potentially serious, systemic conditions (eg, primary hyperparathyroidism or distal renal tubular acidosis). Patients with complex anatomy should undergo a comprehensive evaluation with their first episode of urolithiasis. In contrast, a comprehensive metabolic stone evaluation goes beyond the limited evaluation. The results of the metabolic stone evaluation can provide information on the best strategy to reduce future stone formation and allow monitoring of therapeutic interventions.

- Two 24-hr urine collections on a random diet with components noted below with initial quantitative cystine determination (optional)
- Serum calcium, phosphorus, uric acid, HCO_3, BUN, creatinine, albumin, alkaline phosphate, intact PTH (optional), 1,25-di-OH-vitamin D2 (optional)

Metabolic Stone Evaluation

Urine	Normal (24-hr collection)	Clinical Implications
Urine volume	0.5–4 L/d	Increase daily urine output to at least 2L. Low urine output as an isolated condition can result in urolithiasis. Consider diarrheal disease, very poor fluid intake or occupational causes
pH	5.8–6.2	If <5.8 consider K or Na citrate 25–30 mEq BID; > 6.5, RTA if citrate is low; >8, consider urea splitting infection
Urine ammonium	15–60 mmol/d	High level with pH >7, urea splitting infection; low level with pH <5.5 consider: Renal disease, uric acid stones, gout
Urine calcium	male <250, female <200 mg/dL	Idiopathic hypercalciuria, consider hydrochlorothiazide 25 mg BID or chlorthalidone 12.5–25 mg QAM. Keep urine Na <100 by sodium restriction
Urine chloride	70–250 mmol/d	Varies with sodium and potassium intake
Urine citrate	male >450, female >550 mg/d	Consider K citrate 20–30 mEq BID; if due to RTA (urine pH >6.5) also use K citrate
Urine creatinine	mg/d; varies with body weight	Used as a check for day to day consistency of urine collection (see urine creatinine/kg)
Urine creatinine/kg	male 18– 24, female 15–20 mg/kg/d	Low in obesity, incomplete urine collection.
Urine magnesium	30–120 mg/d	Low with poor nutrition, some laxatives, malabsorption syndrome
Urine oxalate	20–40 mg/d	If elevated, usually dietary; if enteric, consider cholestyramine, oral calcium 1–2 g with meals; if >80 mg/d, may be primary hyperoxaluria
Urine phosphorus	0.6–1.2 g/d	Low in bowel disease, malnutrition, high with large food intake
Urine potassium	20–100 mmol /d	If <20, consider bowel disease, diuretics, laxatives
Urine sodium	50–150 mmol/d	When high raises urine Ca, and K loss from thiazide; ideal is <100
Urine sulfate	20–80 mmol /d	When high indicates a high protein diet
Urine urea nitrogen	6–17 g/d	Measures urea production from diet protein
Urine uric acid	male <0.800 g/d, female <0.750 g/d	Often due to diet; if stones are severe and low protein diet fails try allopurinol 200 mg/d

Cystine screening is performed on an optional basis and is not part of standard metabolic stone evaluation unless following patients with cystinuria.		
Qualitative cystinuria screen	Negative	Sodium cyanide–nitroprusside test detects urinary cystine >75 mg/g of creatinine
Urine cysteine	<75 mg/d	Most stone formers are >300 mg/d. Heterozygotes excrete 200–400 mg/d; Homozygotes excrete 600–1,400 mg/d. Basic treatments are high fluids to achieve a urine volume >3.5 L daily, and increased urine pH to 7–7.5 using potassium alkali; K or Na citrate 25–30 mEq BID; to keep pH above 7.0 in cystinuria patients. Sulfhydryl drugs (tiopronin, penicillamine, and captopril) may interfere with assay results.

d = day.
Values and recommended clinical implications based on data from Litholink; https://www.litholink.com/en/OurReports0, (Accessed April 5, 2014.

REFERENCE

Paterson RF. Arguments for a comprehensive metabolic evaluation of the first-time stone former. *Can Urol Assoc J*. 2010;4(3):209–210.

METABOLIC SYNDROME, UROLOGIC CONSIDERATIONS

DESCRIPTION An increasingly more prevalent disease affecting ~22% of American adults, metabolic syndrome is characterized by having any 3 of the following: Abnormal waist circumference, hypertriglyceridemia, low HDL, hypertension, or abnormal fasting glucose parameters. Sexual dysfunction can occur, including hypogonadism and erectile dysfunction (ED). Many patients have a low urinary pH, thus increasing the risk of uric acid stones. Subclinical Cushing syndrome accounts for 3–5% of metabolic syndrome and should be in the differential diagnosis. ADT can contribute to metabolic syndrome.

SYNONYMS

- Syndrome X
- Insulin resistance syndrome
- Obesity dyslipidemia syndrome

TREATMENT

- Lifestyle modifications with dietary changes, increased physical activity, and smoking cessation
- Obesity: Goal of gradual 5–10% weight reduction. Consider bariatric surgery in extreme cases if conservative management fails.
- Pharmacologic therapy: aimed at hypertension, hyperlipidemia/dyslipidemia, other
- Impaired glucose tolerance: initial management with diet and exercise
  - Prothrombotic states: Consider low-dose aspirin in high coronary artery disease risk
  - Testosterone for hypogonadism may have protective cardiovascular effects (controversial)
- Oral hydration and urine alkalinization can be considered for uric acid stone formers.

METANEPHRIC ADENOFIBROMA, KIDNEY (NEPHROGENIC

ADENOFIBROMA)

DESCRIPTION A pediatric benign renal tumor with stromal features resembling congenital mesoblastic nephroma. The epithelial component has varying levels of activity ranging from inactive metanephric adenoma to Wilms tumor. Some masses contain areas identical to papillary RCC. Lesions with a Wilms tumor component occur at a young age (mean of 12 mo). No tumors have recurred after nephrectomy, but all have been treated with Wilms tumor chemotherapy. There has been 1 case described with nodal metastasis of the papillary RCC component of their tumor.

REFERENCE

Argani P. Metanephric neoplasms: The hyperdifferentiated, benign end of the Wilms Tumor spectrum? *Clin Lab Med.* 2005;25(2):379–392.

METANEPHRIC ADENOMA

DESCRIPTION A recently recognized renal tumor originally described in 1980; it bears a cytologic resemblance to early metanephric tubular differentiation and to the metanephric hamartomatous element of nephroblastomatosis. Fewer than 100 cases have been reported, with a 2:1 female-to-male predominance. Most cases present in the 5th–6th decades of life, and the lesion is often discovered incidentally. An association with polycythemia has been reported in 12% of the cases that resolves after surgical resection. These adenomas are typically unilateral and rarely multifocal. The majority are either unencapsulated or have only a limited and discontinuous pseudocapsule. It is largely regarded as a benign neoplasm but in 1 case lymph node metastases were reported. It cannot be differentiated from RCC on imaging studies. WT1 and CD57 immunohistochemical staining aids in the diagnosis of metanephric adenoma (Image ☼).

REFERENCE

Hartman DJ, MacLennan GT. Renal metanephric adenoma. *J Urol.* 2007:178(3):1058.

METAPYRONE TEST

DESCRIPTION Cushing syndrome describes the symptom complex caused by excess circulating glucocorticoids. Metapyrone is a blocking agent used to reduce the secretion of functional steroids, thereby lessening the severity of symptoms. Metapyrone blocks the conversion of 11-deoxycortisol to cortisone. It is a diagnostic test for hypothalamic–pituitary ACTH function:

- Day 1: Control period: Collect 24-hr urine to measure 17-hydroxycorticosteriods or 17-ketogenic steroids.
- Day 2: ACTH test: 50 units ACTH infused over 8 hr and measure 24-hr urinary steroids.
- Days 3–4: Rest period.
- Day 5: Administer metyrapone with milk or snack. (Adult: 750 mg PO q4h for 6 doses; Pediatric: 15 mg/kg q4h for 6 doses [min 250 mg dose]).
- Day 6: Determine 24-hr urinary steroids.
- Normal 24-hr urine 17-OHCS is 3–12 mg; following ACTH, it increases to 15–45 mg/24 hr; normal response to metyrapone is a 2–4-fold increase in 17-OHCS excretion; drug

interactions with phenytoin, cyproheptadine, and estrogens may lead to subnormal response.

MEYER–WEIGERT LAW

DESCRIPTION In cases in which separate ureteric buds on the same mesonephric duct form a completely duplicated collecting system, separate investigators (Weigert and then Meyer) noted that there exists a consistent relationship between the upper and lower pole orifices as they relate to 1 another on the trigone. The caudad, or distally placed, orifice actually drains the upper pole moiety; whereas the cranial, or superior, orifice drains the lower pole moiety. The distal orifice is more medial on the trigone, as opposed to the laterally placed cranial orifice. This is a reliable rule for cases of ureteral duplication.

REFERENCE

MIBG SCAN

DESCRIPTION A form of molecular imaging using metaiodobenzylguanidine (MIBG), an analog of guanethidine. MIBG accumulates into cells via norepinephrine transporters and is collected into secretory granules. It is useful in identifying primary and metastatic pheochromocytoma, paraganglioma, and neuroblastoma.

MICHAELIS–GUTMANN BODIES

DESCRIPTION Michaelis–Gutmann bodies are the pathognomonic finding in the benign inflammatory process known as ***malakoplakia***. Light microscopy demonstrates a granulomatous inflammatory process, characterized by the accumulation of large mononuclear cells with abundant granular cytoplasm and PAS-positive calcific intracytoplasmic inclusions (so-called Michaelis–Gutmann bodies). On electron microscopy, such inclusions appear as concentric lamellated structures with a mineralized core (Image ☼).

REFERENCE

MICROCYSTIC/NESTED VARIANT UROTHELIAL CARCINOMA

DESCRIPTION Microcystic and nested variant urothelial carcinoma are rare histologic subtypes of bladder cancer that appear similar to benign conditions of the bladder, however demonstrate aggressive behavior. Microcystic urothelial cancer has an inverted growth pattern that resembles cystitis cystica. It has been identified in bladder, upper tract, and prostatic urethra. Nested variant urothelial carcinoma is easily mistaken for reactive von Brunn nests. Lesions have a low-grade appearing cytology even when invasive. Lymphovascular invasion (LVI) is usually present at the time of diagnosis (Image ☼).

REFERENCE

Shanks JH, Iczkowski KA. Divergent differentiation in urothelial carcinoma and bladder cancer subtypes with selected mimics. *Histopathology*. 2009;54:885–900.

MICROLITHIASIS, TESTIS

DESCRIPTION Testicular microlithiasis is an uncommon condition characterized by the presence of calcifications within degenerating seminiferous tubules. There is a reported incidence of between 2 and 6% of males. Microlithiasis is often found in conjunction with other testicular pathologies, with testicular malignancy being the most concerning, however, there are conflicting reports. Currently, no guidelines exist for follow-up of patients diagnosed with microlithiasis of the testis. Recommendations range from no follow-up to a staging workup for testicular carcinoma. At a minimum, testicular self-exams are important and annual physical exam by a physician is recommended. Some authors suggest annual exam by a urologist in conjunction with annual ultrasound for patients with risk factors for testicular cancer (Image ☼).

REFERENCE

Rashid HH, Cos LR, Weinberg E, et al. Testicular microlithiasis: A review and its association with testicular cancer. *Urol Oncol.* 2004; 22(4):285–289.

MICROPAPILLARY BLADDER CANCER

DESCRIPTION A variant of bladder cancer 1st described in 1994. The histologic features closely resemble papillary serous carcinoma of the ovary. It accounts for 0.7–2.2% of all urothelial tumors and is nearly always associated with an advanced stage of disease and aggressive clinical course. A recent review of 100 consecutive patients at MD Anderson Cancer Center indicated an average age of 64.7 yr, with a male-to-female ratio of 10:1. 5 and 10-yr survivals of 51% and 24%, respectively. Intravesical therapy appears to be ineffective. Radical cystectomy provides a chance of cure in these patients. (See also Section I: “Bladder Cancer, General.”) (Image ☼)

TREATMENT

Expeditious radical cystectomy in patients with surgically resectable disease

REFERENCE

Kamat AM, Dinney CP, Gee JR, et al. Micropapillary bladder cancer: A review of the

University of Texas MD Anderson Cancer Center experience with 100 consecutive patients. *Cancer.* 2007;110(1):62–67.

MICTURITION SYNCOPE

DESCRIPTION Syncopal episodes occurring during voiding are known as micturition syncope. This was originally though to be a disorder of young healthy men, however additional studies have found micturition syncope to span ages and gender. Several mechanisms have been suggested in the literature. 1 is that decompression of the bladder results in a decreased intra-abdominal pressure therefore decreasing blood return and causing a sudden decrease in cerebral blood flow. Another is that increased vagal tone during voiding results in a syncopal episode. Finally, micturition syncope could be an orthostatic event as a result of waking from sleep that occurs during the 1st void of the day immediately after wakening. Rarely, micturition syncope can be a symptom of a pheochromocytoma/paraganglioma of the bladder. Further investigation with urinalysis and cystoscopy are warranted in addition to workup of a cardiovascular source of syncope.

REFERENCE

Kapoor WN, Peterson JR, Karpf M. Micturition syncope. *JAMA*. 1985;253:796–798.

MILK OF CALCIUM, URINARY TRACT

DESCRIPTION The crystallization of calcium salts without actual stone formation. These usually accumulate in simple renal cysts or calyceal diverticula. On ultrasound, it is an echogenic focus or layer within the cyst. On IVP, it appears as a crescent-shaped density whose meniscus may adjust relative to patient positioning.

TREATMENT

Endoscopic, percutaneous, or ablative procedures may be performed if clinically indicated (ie, pain, infection).

REFERENCE

Sidhu R, Bhatt S, Dogra V, et al. Renal colic. *Ultrasound Clin.* 2008;3:159–170.

MILK–ALKALI SYNDROME

DESCRIPTION Hypercalcemia and alkalosis associated with the ingestion of large amounts of milk and antacids containing calcium and absorbable alkali. Patients can develop nephrocalcinosis and renal insufficiency, but typically do not have hypercalciuria. The associated vomiting and dehydration can produce further volume contraction and alkalosis. (See also Section I: “Nephrocalcinosis, Adult.”)

TREATMENT

- Withdrawal of milk and alkali, with gentle hydration to lower serum calcium
- Vigorous hydration can result in rebound hypocalcemia due to the chronic suppression of the parathyroid glands

REFERENCE

Smith SG. Milk-alkali syndrome. In: Domino FJ M, ed. *The 5-Minute Clinical Consult 2014*. Philadelphia, PA: Wolters Kluwer/Lippincott Williams & Wilkins; 2014.

MITROFANOFF PRINCIPLE

DESCRIPTION A surgical procedure, originally described by Mitrofanoff, in which the appendix is excised with a button of cecum, reversed, and tunneled to create a catheterizable channel with a reported continence rate of 93–100%. Stomal stenosis is an early complication affecting 7–24% within 3 yr in published series.

REFERENCE

Harris CF, Cooper CS, Hutcheson JC, et. al. Appendicovesicostomy: The mitrofanoff procedure – A 15 year perspective. *J Urol.* 2000;163(6):1922–1926.

MIXED EPITHELIAL STROMAL TUMOR OF THE KIDNEY (MESTK)

DESCRIPTION MESTK is a subset of benign renal tumors composed mainly of smooth muscle cells in which epithelial structures are embedded. It is usually found in middle-aged and perimenopausal women. Grossly, MESTK is well-circumscribed but unencapsulated, and cystic on a cut surface. Microscopically, it is composed both of epithelial structures similar to renal tubules and stroma comprising nonspecific spindle cells. The differential diagnosis for these tumors includes cystic nephroma and cystic partially differentiated nephroblastoma.

REFERENCE

Michal M, Hes O, Bisceglia M, et al. Mixed epithelial and stromal tumors of the kidney. A report of 22 cases. *Virchows Arch.* 2004;445(4):359–67.

MOLLUSCUM CONTAGIOSUM

DESCRIPTION A benign, self-limited skin tumor or papular eruption caused by a virus. Infection occurs after breakage of the skin and characteristically begins as a small papule. When mature, it is a discrete 2–5 mm smooth, dome-shaped, pearly or flesh-colored nodule that is often umbilicated. Single to hundreds of lesions may track alone the line of a scratch. In adults, they occur on the trunk, thighs, and pubic areas. Lesions usually disappear by themselves within 6–12 mo, although this may take up to 4 yr with impaired cell-mediated immunity. Diagnosis is usually clinical, but brick-shaped virions can sometimes be seen under negative-stain electron microscopy. Henderson–Paterson bodies are characteristically seen on pathology. (See also Section I: “Sexually Transmitted Diseases [STDs], General.”)

TREATMENT

- Observation is reasonable for nongenital lesions.
- Curettage is useful for treating a few lesions; scarring may develop.
- Liquid nitrogen therapy, cantharidin 0.7%, tretinoin 0.025% gel, or 0.1% cream; laser therapies are also common.

REFERENCE

tanapox. In: Mandell GL, et al., eds. *Mandell, Douglas, & Bennett's Principles and Practice of Infectious Diseases.* 6th ed. Philadelphia, PA: Elsevier; 2005.

MONDOR DISEASE

DESCRIPTION Mondor disease is superficial thrombophlebitis of the dorsal vein of the penis. It is typically diagnosed in young males after excessive sexual activity and can be diagnosed in older males due to venous obstruction secondary to bladder distention. Physical exam typically reveals a tender palpable cord on the dorsal surface of the penis as well as distal penile edema. Treatment is conservative with abstinence of sexual activity until completely resolved. Anticoagulation and antiplatelet medications have not been shown to be of benefit. Vein stripping surgery is indicated for patients with associated cellulitis.

REFERENCE

MONFORT TECHNIQUE

DESCRIPTION A type of abdominal wall reconstruction in patients with prune belly syndrome. This technique utilizes an elliptical incision that preserves the umbilicus and thickens and strengthens the anterior abdominal wall. Full-thickness resection of skin from the central abdomen is performed, and the anterior wall is sutured in a double-breasted fashion preserving vascularity and the umbilicus. This technique offers excellent exposure for concomitant intra-abdominal surgery.

REFERENCE

Monfort G, Guys JM, Bocciardi A, et al. A novel technique for reconstruction of the abdominal wall in the prune belly syndrome. *J Urol.* 1991;146(2):639–640.

MONTI PROCEDURE

DESCRIPTION Also known as the *Monti ileovesicostomy,* a technique most often used in children to create a continent catheterizable stoma. A short segment of bowel (2–3 cm of ileum) is incised along the antimesenteric border and then closed transversely to create a uniform tube that can be tunneled into the bladder and out through the abdominal wall. This allows preservation of the appendix for the Malone antegrade continent enema (MACE) procedure. A review of 199 patients undergoing Monti ileovesicostomy at a single institution reported a revision rate of 8.5% and a continence rate of 96.5% with mean follow-up of 28 mo.

REFERENCE

Rink RC, Dussinger AM, Gitlin J, et al. Updated Experience with the Monti catheterizable channel. *Urology*. 2008;72(4):782–785.

MORRIS SYNDROME

DESCRIPTION An intersex disorder that affects 1 in 20,000 live male births; it is caused by a mutation in the androgen receptor gene located on the long arm of the X chromosome. This prevents appropriate androgen binding and/or function. If complete androgen insensitivity occurs, the child will appear to have a normal female phenotype and the testes are located internally. Many children are diagnosed at the time of hernia repair as infants or not diagnosed until puberty during an evaluation for primary amenorrhea.

SYNONYMS
- Testicular feminization syndrome
- In class of male pseudohermaphroditism

REFERENCE
Hyun G, Kolon TF. A practical approach to intersex in the newborn period. *Urol Clin N Am.* 2004;31(3):435–443.

MOSKOWITZ VAGINAL PROLAPSE REPAIR

DESCRIPTION Through a transabdominal exposure, the procedure entails closing the cul-de-sac through placement of a series of purse-string sutures. The procedure was initially described to treat rectal prolapse by securing the rectum to the fixed vagina, and the same logic has been used to correct vaginal prolapse by fixing it to the rectum. Unfortunately, the rectum is not well anchored. (See also Section I: “Pelvic Prolapse [Cystocele and Enterocele].”)

REFERENCE
Raz S, et al. Vaginal reconstructive surgery for incontinence and prolapse. In: Walsh PC, Retik AB, Vaughan ED, et al., eds. *Campbell’s Urology*. 7th ed. Philadelphia, PA: Saunders; 1998:1066–1094.

MOSTOFI (WHO) GRADING SYSTEM, PROSTATE CANCER

DESCRIPTION Traditional prostate cancer grading system, generally replaced by the Gleason grading system:
- Grade I: Well differentiated, with slight nuclear anaplasia
- Grade II: Moderately to poorly differentiated, with moderate nuclear anaplasia
- Grade III: Poorly differentiated, with marked nuclear anaplasia, or undifferentiated carcinoma

SYNONYM
World Health Organization Grading System

REFERENCE
Mostofi FK. Grading of prostatic carcinoma. *Cancer Chemother Rep.* 1975;59(Pt I):111–117.

MOWAT–WILSON SYNDROME

DESCRIPTION A syndrome of multiple congenital anomalies due to a heterozygous mutations or deletions in *ZEB2*, or Zinc finger E-box-biding homeobox 2 gene. It is generally

discovered on genetic workup for Hirschsprung disease. Patients present with a distinct facial phenotype, mental retardation, epilepsy, agenesis of corpus callosum, and congenital heart defects. Roughly 50% of patients have genitourinary anomalies with hypospadias being the most prominent (52%). Another common anomaly is cryptorchidism (36%). Bifid scrotum, vesicoureteral reflux and micropenis are rare but have been reported.

REFERENCE

Garavelli L, Mainardi PC. Mowat- Wilson syndrome. *Orphanet J Rare Dis.* 2007;2:42.

MUCORMYCOSIS, GENITOURINARY

DESCRIPTION A fungal infection that usually affects immunocompromised patients. Patients receiving hemodialysis and deferoxamine are at particular risk for disseminated disease. The kidneys are the organs most often involved in the GU system, but penile involvement has also been reported. The course is usually fatal. (See also Section I: "Fungal Infections, Genitourinary.")

TREATMENT

Amphotericin B systemically; nephrectomy for involved kidney

REFERENCE

Wise GJ, Freyle J. Changing patterns in genitourinary fungal infections. *AUA Update Series.* Vol. XVI, Lesson 1; 1997.

MUCOSURIA (MUCINURIA)

DESCRIPTION Passage of mucous during urination. This is a normal finding in patients who have undergone bladder replacement surgery using bowel segments. Mucosuria can be a symptom of mucinous adenocarcinoma of the urinary tract, most commonly of the urachus however mucin producing tumors of the prostate and renal pelvis have been reported. Other sources of mucin production in the bladder include invasive colorectal cancer and colovesical fistulas. (See also Section I: "Bladder Cancer, Adenocarcinoma.")

REFERENCE

Bohman KD, Osunkoya AO. Mucin-producing tumors and tumor-like lesions involving the prostate: A comprehensive review. *Adv Anat Pathol.* 2012;19(6):374–387.

MUIR–TORRE SYNDROME

DESCRIPTION An autosomal dominant skin condition characterized by tumors of the sebaceous gland or keratoacanthoma associated with ≥ 1 visceral malignancies including colorectal, endometrial, urologic, and upper GI. Usually considered a subtype of hereditary nonpolyposis colorectal cancer syndrome; $\sim 25\%$ of the visceral cancers are associated with the urogenital tract, the most common of which are urothelial carcinoma.

REFERENCE

Ponti G, Ponz de Leon M. Muir-Torre syndrome. *Lancet Oncol.* 2005;6:980–987.

MULBERRY STONES

DESCRIPTION A term that refers to the surface appearance of irregular calcium oxylate dihydrate stones often seen in the bladder. Based on their less well-developed spikes than seen on jackstones; the spikes possess more of a mamillated appearance.

REFERENCE

Amis ES, Newhouse JH, eds. *Essentials of Uroradiology*. 1st ed. Boston: Little-Brown; 1991:224.

MULCAHY PROTOCOL

DESCRIPTION Infection of a penile prosthesis is suspected when there is local pain and erythema, fever and cutaneous fixation of the prosthesis components. In this situation there are 2 main options. The 1st is to remove the prosthesis and reinsert it at least 6–8 mo later. This repeat surgery can be difficult due to formation of scar tissue in the corpora. Another option is to remove the prosthesis, perform a copious antibiotic washout of the corpora cavernosa with an antibiotic solution, then place a "tutor" cylinder inside the corpora to prevent shortening and scarring. Another approach to the management of an infected penile prosthesis is the Mulcahy protocol. This involves complete removal of the infected part of the prosthesis and all other components followed by the use of the specific Mulcahy salvage procedure outlined below with reinsertion of a new penile prosthesis in the same sitting with a reported success rate of 85%. (See also Section I "Penile Prosthesis Problems [Infection/Extrusion/Malfunction]".)

- Remove all prosthetic parts and foreign material
- Irrigate wounds using 5 antiseptic solutions:
  - Antibiotic solution (1 g vancomycin and 80 mg gentamicin in 1 L of normal saline)
  - 1/2 strength hydrogen peroxide
  - Pressure washing with 1 g vancomycin and 80 mg gentamicin in 5 L irrigation
  - 1/2 strength Povidone-iodine (Betadine or similar)
  - Antibiotic solution rinse
- Change gowns, gloves, surgical drapes, and instruments immediately before prosthesis insertion
- Insert new prosthesis
- Close wounds with no drains or catheters
- Administer oral antibiotics for 1 month

MÜLLERIAN DUCT REMNANTS AND SYNDROME (PMDS)

DESCRIPTION Refers to the persistence of the müllerian duct structures (uterus, fallopian tubes) in the genotypically and phenotypically normal male. The remnants persist due to the

absence of müllerian inhibiting substance. It is an autosomal recessive inherited disorder. Patients present with cryptorchidism and hernia, and the persistent müllerian structures are found within the hernia sac. Increasing evidence is mounting that persistent müllerian structures are at risk for malignant transformation. 11 cases of malignancy have been reported in the literature out of 200 reported cases of persistent Müllerian dcut syndrome (PMDS).

SYNONYMS
- Prostatic utricular cyst
- Müllerian duct cyst (Image ☼)

REFERENCE
Farikullah J, Ehtisham S, Nappo S, et al. Persistent Müllerian duct syndrome: lessons learned from managing a series of eight patients over a 10-year period and review of literature regarding malignant risk from the Müllerian remnants. *BJU Int.* 2012;110(11 Pt C):E1084–E1089.

MULTILOCULAR CYSTIC NEPHROMA (CYSTIC NEPHROMA, MULTILOCULAR CYST)

DESCRIPTION A round, well-encapsulated multilocular cystic mass whose septa are composed of well-differentiated tissues, without blastemal elements. The current thinking is that multilocular cystic nephroma is at the benign end of a spectrum that includes cystic partially differentiated nephroblastoma (CPDN) and Wilms tumor on the malignant end. Grossly, multilocular cystic nephroma and CPDN look identical. The contents of the cysts consist of either clear to yellow fluid or thick myxomatous gel. The lesion is usually solitary but rarely can be multiple. Cystic nephroma presents in a bimodal age distribution of 3 mo–2 yr (2:1 male-to-female) and in adulthood (8:1 female-to-male). Children usually present with a palpable mass and adults with pain, hematuria, or infection. Imaging cannot distinguish between cystic nephroma and CPDN. The lesion often is close to the renal pelvis, and herniation of the renal pelvis is a pathognomonic finding on IV urography, CT, or MRI. The nephromas contain noncommunicating cysts with thin septa separating the cysts. On US, multiple anechoic spaces are seen, separated by hyperechoic septa. CT reveals a well-marginated, rounded, or polycyclic cortical mass that extends beyond the normal renal outline. Enhancement of the septa may be seen due to the presence of thin vessels. Imaging cannot reliably predict malignant potential.

SYNONYMS
- Cystic kidney, cystic nephroma
- Focal polycystic kidney
- Multicystic or cystic adenoma

TREATMENT
- Partial nephrectomy or radical nephrectomy is indicated.
- Follow-up is required because of local recurrence (Image ☼).

REFERENCE

Stamatiou K, Polizois K, Kollaitis G, et al. Cystic nephroma: A case report and review of the literature. *Cases J.* 2008;1(1):267.

MULTIPLE ENDOCRINE NEOPLASIA (MEN I, MEN II)

DESCRIPTION A group of inherited syndromes primarily consisting of endocrine tumors of both benign and malignant nature. MEN syndrome lesions are of urologic interest because of the possibility of adrenal involvement, hyperparathyroidism, renal stones, and hyperlactatemia:

- MEN I (Wermer syndrome): Autosomal dominant condition with neuroendocrine parathyroid, pancreas, duodenal, and pituitary lesions. Cutaneous tumors may also be seen (angiofibromas, others). Hyperparathyroidism is the most common presentation of this syndrome, but overall this is a rare cause of hyperparathyroidism in the general population. Pituitary lesions may cause hyperprolactinemia and ACTH-producing lesions.
- MEN II (Sipple syndrome): Autosomal dominant:
  - Type IIA triad: Pheochromocytoma, medullary carcinoma of the thyroid, parathyroid adenoma
  - Type IIB: Pheochromocytoma, medullary carcinoma of the thyroid (but not parathyroid hyperplasia) with mucosal neuromas, intestinal ganglioneuromas, and occasionally marfanoid habitus. Some literature refers to this as MEN III (mucosal neuroma syndrome).

REFERENCE

Callender GG, Rich TA, Perrier ND. Multiple endocrine neoplasia syndromes. *Surg Clin N Am.* 2008;88(4):863–895.

MULTIPLE MYELOMA, UROLOGIC CONSIDERATIONS

DESCRIPTION A malignant proliferation of plasma cells derived from a single clone. The classic triad involves marrow plasmacytosis, lytic bone lesions, and a serum and/or urine M component. Renal failure occurs in 25% of patients. Hypercalcemia is the most common cause, but hyperuricemia is also present and a likely cause. Tumor lysis syndrome is uncommon with multiple myeloma. There may be tubular precipitation of light-chain proteins (myeloma kidney), urinary obstruction due to uric acid or calcium-containing stones, or recurrent pyelonephritis. Glomerular, tubular, and interstitial involvement can cause renal insufficiency. The development of a myeloma kidney can lead to adult Fanconi syndrome, which is a type II proximal renal tubular acidosis. NSAIDs are to be avoided. Renal failure is rare but has been reported after the use of contrast agents in patients with multiple myeloma.

REFERENCE

Sakhuja V, Jha V, Varma S, et al. Renal involvement in multiple myeloma: A 10-year study. *Ren Fail.* 2000;22(4):465–477.

MUMPS ORCHITIS

DESCRIPTION Mumps is a single-stranded RNA (paramyxo) virus. After the prodromal period, 1 or both parotid glands begin to enlarge. Mumps orchitis follows the development of

parotitis by 4–7 days, with about 20% of males developing orchitis (10% bilateral and 80–90% unilateral). It has been reported following mumps vaccination. The presentation is high fever, testicular pain, and swelling. The management of mumps orchitis is supportive (bedrest, scrotal support, analgesics) with resolution in about 7 days. Unilateral testicular atrophy occurs in 60%. Impaired fertility can affect up to 13%, but sterility is rare. (See also Section I: "Orchitis, General.")

REFERENCE

Masarani M, Wazait H, Dinneen M. Mumps orchitis. *J R Soc Med.* 2006;99(11):573–575.

MURCS ASSOCIATION (MüLLERIAN DUCT, RENAL, AND CERVICAL VERTEBRAL DEFECTS)

DESCRIPTION MURCS association consists of a nonrandom association of müllerian duct aplasia, renal aplasia/agenesis, and cervicothoracic somite dysplasia. The incidence of cervicothoracic vertebral defects, especially from C5–T1, is 80%. Other abnormalities may include Sprengel deformity, upper limb defects, and moderately frequent rib anomalies. It is the 2nd most frequent cause of primary amenorrhoea after Turner syndrome.

REFERENCE

Braun-Quentin C, Billes C, Böwing B, et al. MURCS association: Case report and review. *J Med Genet.* 1996;33(7):618–620.

MUSCLE FLAP TYPES, UROLOGIC CONSIDERATIONS

DESCRIPTION Muscle flaps are a reconstructive technique using local or distant muscle donor sites to provide tissue coverage in complex reconstructive procedures. The most simple muscle flaps are local and regional flaps where blood supply of the muscle is not interrupted when the flap is repositioned to its new location. Pedicle and micro vascular free flaps are more complicated forms of tissue transfer that are finding new indications in reconstructive urologic procedures. Tissue transfer has become increasingly used in centers for complex repair of fistula disease following radiation. In addition, clinical study has shown latissimus dorsi transferred to acontractile detrusor tissue with microsurgical coaptation of the thoracodorsal nerve to low intercostal nerves innervating the rectus abdominus has restored voluntary voiding in patients with detrusor areflexia.

REFERENCE

Ninkovic M, Dabernig W. Flap technology for reconstructions of urogenital organs. *Curr Opin Urol.* 2003;13:483–488.

MUSTARDé HYPOSPADIAS REPAIR

DESCRIPTION A more extensive Mathieu technique in which the ventral flap is tubularized to form a neourethra and then transposed distally. The glans wings are again approximated over the neourethra.

REFERENCE

Belman AB. The modified Mustardé hypospadias repair. *J Urol.* 1982;127(1):88–90.

MYCOPLASMA GENITALIUM INFECTION

DESCRIPTION *Mycoplasma genitalium* is a common organism that resides within the genital tracts of both men and women. However, it may be a cause of chronic prostatitis in men or urgency and frequency in women. Identifying and culturing this organism is difficult. Initial treatment includes doxycycline 100 mg BID for 2 wk or azithromycin 1 g in a single dose.

REFERENCE

Moi H, Reinton N, Moghaddam A. Mycoplasma genitalium is associated with symptomatic and asymptomatic nongonococcal urethritis in men. *Sex Transm Infect.* 2009;85(1):15–18.

MYCOPLASMA HOMINIS, URINARY TRACT INFECTION

DESCRIPTION *Mycoplasma hominis* commonly resides in the genital tracts of both men and women. This organism is often found in women with bacterial vaginosis and can be a cause of PID and dyspareunia. It is generally susceptible to tetracycline and quinolones.

REFERENCE

Kenny GE. Genital mycoplasmas: *Mycoplasma genitalium, Mycoplasma hominis,* and *Ureaplasma* species. In: Mandell GL, Bennett JE, Dolin R, eds. *Mandell, Bennett, & Dolin: Principles and Practice of Infectious Diseases.* 6th ed. Philadelphia, PA: Elsevier, 2005:2280–2282.

MYOCUTANEOUS FLAPS

DESCRIPTION Myocutaneous flaps, such as rectus flap, gracilis flap, or tensor fascia flap, can be utilized during urologic reconstructive surgery. Common applications are for skin coverage during ilioinguinal node dissections for penile cancer, closure of urinary fistulae, and reconstruction after Fournier gangrene:

- Rectus abdominis flap: The blood supply of the rectus abdominis is the superior and deep inferior epigastric vessels. The deep superior epigastric vessels are not utilized as a vascular pedicle for the free flap because of their smaller caliber and a greater amount of skin can be transferred by relying on the interior epigastric pedicle.
- Gracilis flap: The origin of the gracilis muscle is the ischium and inferior ramus of the pubis and the insertion is the medial tibia. The gracilis muscle is 4–8 cm wide and is harvested from the inner thigh. It can be utilized either as a muscle flap or myocutaneous flap and leaves the patient without any functional deficit. The nerve supply to the gracilis muscle is a branch of the obturator nerve, and its blood supply is a single artery from the profunda femoral system.
- Tensor fascia lata flap: The tensor fascia lata can be harvested from the lateral aspect of the upper leg. The vascular pedicle is comprised of the transverse branch of the lateral circumflex femoral artery, and the sensory supply is the lateral femoral cutaneous nerve of the thigh, which originates from T12. A skin island of up to 15 cm can be harvested and leaves the patient without any functional deficit.

REFERENCE

Smith HO, Genesen MC, Runowicz CD, et al. The rectus abdominis myocutaneous flap: Modifications, complications, and sexual function. *Cancer.* 1998;83(3):510–520.

MYOFASCIAL PAIN, UROLOGIC CONSIDERATIONS

DESCRIPTION Myofascial sources of pain have been defined in women with myofascial pelvic pain syndrome (MPPS) (see below) and new evidence is mounting that myofascial pain may be a contributing factor in a constellation of chronic male pelvic pain syndromes previously diagnosed as prostatitis or orchitis. Trigger points, defined as hyperirritable, sensitive, or tender spots usually associated with a taut band of skelet al muscle or fascia, have been identified in women with MPPS. A recent study has identified several reproducible trigger points in males with chronic pelvic pain (CPP) on external and internal pelvic exam and an initial investigation has shown improved response to internal and external myofascial physical therapy compared to external massage (57–28%).

REFERENCE

Anderson RU, Sawyer T, Wise D, et al. Painful myofascial trigger points and pain sites in men with chronic prostatitis/chronic pelvic pain syndrome. *J Urol.* 2009;182:2753–2758.

MYOFASCIAL PELVIC PAIN SYNDROME (MPPS)

DESCRIPTION MPPS is a disorder in which pelvic pain is attributed to short, tight, tender pelvic floor muscles, usually with hypersensitive trigger points. Pelvic floor trigger points refer pain to the vagina, vulva, perineum, rectum, and bladder. Pain can be also be referred to the thighs, buttocks, or lower abdomen. Irritative symptoms (eg, urinary urgency, vulvovaginal burning, rectal fullness) may be more prominent than pain. The diagnosis is clinical. Treatment is customized and based on reducing the response of the trigger point. Stress reduction (meditation, relaxation exercises), physical therapy (stretch/massage), heat, ice, or NSAIDs are recommended for mild cases. Pelvic floor physical therapy (manual myofascial release, stretching, and strengthening) is useful for many patients. More severe cases may require trigger point injections (bupivacaine), gabapentin, or botulinum toxin if muscle spasm can be identified. (See also Section I: “Pelvic Pain, Female.”)

REFERENCE

Srinivasan AK, Kaye JD, Moldwin R. Myofascial dysfunction associated with chronic pelvic floor pain: Management strategies. *Curr Pain Headache Rep.* 2007;11(5):359–364.

MYOGLOBIN NEPHROTOXICITY

DESCRIPTION Renal failure associated with the excessive deposit of myoglobin into the serum following massive muscle necrosis/rhabdomyolysis. Renal failure is initiated by acute tubular obstruction, and necrosis is caused by free chelatable iron and ischemia. Granular casts are found in the urine. Renal failure is initially manifested by oliguria and followed later by a polyuric state. (See also Section II: “Myoglobinuria and Rhabdomyolysis.”)

TREATMENT

- Myoglobin nephrotoxicity is prevented by maintaining fluid balance through the use of

diuretics and hydration, using isotonic saline initially.
- If renal failure develops, fluid retention should be avoided by limiting infusion rates.
- In polyuric states, vigilant replacement of electrolytes is required.

REFERENCE

Melli G, Chaudhry V, Cornblath DR. Rhabdomyolysis: An evaluation of 475 hospitalized patients. *Medicine (Baltimore)*. 2005;84(6):377–385.

MYOGLOBINURIA

DESCRIPTION 1st described by Fleischer in 1881, myoglobinuria refers to the presence of excessive amounts of myoglobin, a protein found in muscle, in the urine. Myoglobinuria occurs when serum levels exceed the renal threshold. Myoglobin is released into the serum following massive muscle necrosis (rhabdomyolysis) from crush, compartment syndrome, electrical injury, toxins, malignant hyperthermia, and other causes, and imparts a cola-like color to the urine. Diagnosis is made by electrophoresis separation and radioimmunoassay of urinary myoglobin. Serum creatinine kinase is elevated, and there is an absence of red cells in the urine. (See also Section I: “Rhabdomyolysis”; Section II: “Myoglobin Nephrotoxicity.”)

CAUSES
- Diabetic acidosis
- Fluid/electrolyte imbalance
- Infectious myositis
- Ischemia
- Malignant hyperthermia
- Neuroleptic malignant syndrome
- Rhabdomyolysis or compartment syndrome
- Toxins
- Trauma

TREATMENT
- Remove the causative agent.
- Protect against renal failure through correction of electrolyte imbalances, alkalinization of urine with sodium bicarbonate, hydration, and diuretics.

REFERENCE

Melli G, Chaudhry V, Cornblath DR. Rhabdomyolysis: An evaluation of 475 hospitalized patients. *Medicine (Baltimore)*. 2005;84(6):377–385.

NAGAMATSU INCISION

DESCRIPTION A dorsolumbar incision is made over either the 11th or 12th rib, which is resected. After rib removal, the diaphragm and pleura are retracted superiorly, and the kidney and the adrenal may be exposed.

REFERENCE

Montague DK. Surgical incisions. In: Novick AC, Streem SB, Pontes JE, eds. *Stewart's Operative Urology*. Baltimore, MD: Williams & Wilkins; 1989:15–40.

NATIONAL COMPREHENSIVE CANCER NETWORK (NCCN) GUIDELINES

DESCRIPTION The NCCN is a nonprofit alliance of NCI-designated Comprehensive Cancer Centers devoted to improving care for cancer patients. This includes the development of treatment guidelines for most cancers, including GU cancers such as prostate, bladder, kidney, and testes as well as screening guidelines. Patient friendly information is also available. Useful treatment algorithms are available on their site or as an app for mobile devices. Registration (no charge) is required. (See also Section II: "Prostate Cancer Screening Guidelines.")

REFERENCE

Online at www.nccn.org.

NATIONAL INSTITUTES OF HEALTH (NIH) CHRONIC PROSTATITIS SYMPTOM INDEX (CPSI)

DESCRIPTION The CPSI is a validated and reproducible measure of outcomes for men with prostatitis. With 9 questions, it captures the 3 domains of the prostatitis experience: Pain, urinary function, and quality of life. While not a diagnostic aid, it is useful for both research studies and clinical practice, in initially assessing patients, subsequently following their progress, and providing specific treatment. (See Section VII.)

REFERENCE

Litwin MS, McNaughton-Collins M, Fowler FJ Jr, et al. The National Institutes of Health chronic prostatitis symptom index: Development and validation of a new outcome measure. *J Urol*. 1999;162:369–375.

NECROSPERMIA

DESCRIPTION A condition in which the sperm are both nonmotile and nonviable. The etiology of this condition is variable.

REFERENCE

Chavez-Badiola A, Drakeley AJ, Finney V, et al. Necrospermia, antisperm antibodies, and vasectomy. *Fertil Steril.* 2008;89(3):723.e5–e7.

NELSON SYNDROME

DESCRIPTION The development of pituitary tumors (usually a chromophobe adenoma) seen in 10–20% of patients originally treated with bilateral adrenalectomy for Cushing disease. Believed to be caused by a lack of hypothalamic/pituitary feedback and resultant high levels of ACTH and related compounds, patients must be followed with ACTH levels and imaging of the sella turcica. Patients usually present 1–4 yr after bilateral adrenalectomy. Common symptoms include visual deficits (57%), hyperpigmentation, and headaches, however most patients are diagnosed based on screening labs and imaging. ACTH levels above 200 ng/L and evidence of pituitary mass enlargement on MRI are diagnostic.

TREATMENT

- Surgical excision
- Radiation therapy
- Prophylactic pituitary radiotherapy (shown to reduce the incidence of Nelson syndrome by 50%)

REFERENCE

Banasiak MJ, Malek AR. Nelson syndrome: comprehensive review of pathophysiology, diagnosis, and management. *Neurosurg Focus.* 2007;23(3):E13.

NEPHRITIS, RADIATION

DESCRIPTION Renal dysfunction occurs if ≥23 Gy of radiation therapy is administered to both kidneys during a period of ≤5 wk. Histologic exam shows hyalinized glomeruli, atrophic tubules, interstitial fibrosis, and hyalinization of the media of renal arterioles. Radiation-induced renal ischemia causes tubulointerstitial damage, which may take months to manifest. Acute radiation nephritis presents with rapidly progressing azotemia, moderate to malignant hypertension, anemia, and proteinuria. More than 50% of patients progress to chronic renal failure. Malignant hypertension may follow unilateral radiation and resolve with nephrectomy. This entity has essentially vanished due to refinement in radiation therapy techniques.

NEPHROCALCINOSIS, NEONATAL

DESCRIPTION Nephrocalcinosis with or without nephrolithiasis are commonly observed in both term and premature infants who have had difficult neonatal courses. Neonates with prolonged illness are at particular risk, especially those who still require oxygen at 28 days. While multifactorial, such as high calcium and phosphorous intake, loop diuretics appear to be the major cause in this group of patients. Loop diuretics (furosemide most commonly used) predispose to nephrocalcinosis by increasing urinary calcium excretion. Other factors such as immature renal function and physiologic hypercalciuria that occurs between 32 and 40 weeks of gestation contribute.

Nephrocalcinosis in infants with a birth weight <1,500 g may be as high as 64% and may be independent of diuretic use. In infants born <32 wk gestation, 27% had nephrocalcinosis with 70% having been treated with a loop diuretic. Other causes of neonatal nephrocalcinosis include William syndrome (supravalvular aortic stenosis and hypercalcemia), neonatal primary hyperparathyroidism and distal (type 1) renal tubular acidosis. The loop diuretic-induced hypercalciuria can be diminished and radiologic appearance of renal calcifications diminished by administrating a thiazide diuretic in place of or alternating with a loop diuretic. The long-term impact of nephrocalcinosis on renal outcome is unclear because data are limited and inconsistent. Long-term follow-up is recommended.

NEPHROGENIC ADENOMA (NA) AND METAPLASIA

DESCRIPTION A rare lesion occurring in the urinary tract that was once thought to be a metaplastic reaction to chronic irritation and has now been shown to originate from exfoliated and implanted renal epithelial cells. It is named for its histologic similarity to renal tubules and can cause hematuria, dysuria, and urinary frequency. On cystoscopy nephrogenic adenoma can appear papillary, nodular, or sessile and is very friable. It is typically unifocal. It is considered a benign lesion, however malignant transformation has been reported and therefore requires complete resection and long-term follow-up due to recurrence rates from 0.5–80% (Image ☼).

REFERENCE

Alexiev BA, LeVea CM. Nephrogenic adenoma of the urinary tract: A review. *Int J Surg Pathol.* 2012;20(2):123–131.

NEPHROGENIC SYNDROME OF INAPPROPRIATE ANTIDIURESIS

DESCRIPTION A clinical disorder of water balance resulting in an inability to excrete a free water load. Clinically patients appear similar to those with SIADH, however they have low serum levels of circulating vasopressin. Activating mutations of the V2R (vasopressin type 2 receptor) have been identified as a cause of this chronic condition. Treatment of this condition includes free water restriction and osmotic diuresis with urea. Targeted treatment with compounds that might inhibit V2R are under investigation.

Feldman BJ, Rosenthal SM, Vargas GA, et al. Nephrogenic syndrome of inappropriate antidiuresis. *N Engl J Med.* 20005;352:1885–1890.

NEPHROGENIC SYSTEMIC FIBROSIS/FIBROSING DERMATOPATHY (NSF/NFD)

DESCRIPTION NSF is a scleroderma-like skin disease that affects patients with renal

insufficiency. There is a strong association between the development of NSF and exposure to gadolinium contrast agents used in performing MRI in patients with advanced kidney disease. The skin lesions begin as patches, plaques, or papules, then coalesce to form a woody skin appearance. The skin thickening can limit joint motion. There is no known effective treatment. (See also Section I: "Contrast Allergy and Reactions.")

NEPHROMETRY SCORING SYSTEMS (PADUA, C-INDEX, RENAL)

DESCRIPTION Nephrometry is an attempt to create a common classification system to describe renal masses based on anatomical characteristics. 3 prominent scoring systems have emerged. PADUA (Preoperative aspects and dimensions used for anatomic classification), C-Index (centrality index), and RENAL (radius, exophytic/endophytic, nearness, anterior/posterior, location) all attempt to score and categorize renal tumors in an attempt to predict complexity of nephron-sparing surgery and surgical outcomes of these lesions.

REFERENCE

NEPHRONOPHTHISIS (JUVENILE, INFANTILE, AND ADOLESCENT)

DESCRIPTION A group of 4 diseases, known as the juvenile nephronophthisis–renal medullary cystic disease complex, that result in ESRD. Nephronophthisis is the most common cause of tubointerstitial nephropathy in children, and is inherited in an autosomal recessive pattern mapped to chromosome 2. 3 subtypes of nephronophthisis exist, based on the age of onset of ESRD. Juvenile nephronophthisis is the most common (1 in 50,000 births), with a median onset of 13 yr; infantile nephronophthisis usually causes ESRD by 5 yr; and adolescent nephronophthisis has a mean onset of 19 yr. The disease presents as failure to thrive, azotemia, polyuria, and polydipsia. Hypertension is less common. Microscopically, it resembles an interstitial nephritis with cysts. US reveals muddling of corticomedullary junction and small reniform kidneys with cysts found at the corticomedullary junction. Retinitis pigmentosa hepatic fibrosis and Bardet–Biedl syndrome are associated. Renal replacement therapy, as needed, is the treatment of choice. Extrarenal involvement is described and can involve the retina, liver, and brain. (See also Section I: "Medullary Cystic Kidney Disease.")

REFERENCE

Saunier S, Salomon R, Antignac C. Nephronophthisis. *Curr Opin Gen Dev*. 2005;15:324–331.

NEPHROPATHY, ANALGESIC

DESCRIPTION A chronic interstitial nephritis seen in patients who consume large quantities

of analgesics over many years. They usually suffer from chronic headaches or low back pain and have consumed a mixture of analgesics, including acetaminophen, aspirin, and NSAIDs. Their chronic use leads to recurrent papillary necrosis with impaired concentrating ability, sterile pyuria, and renal insufficiency. Removal of phenacetin from OTC pain medications has dramatically reduced the incidence of this condition. During periods of acute necrosis, patients may have flank pain, pyuria, hematuria, and acute ureteral obstruction from passage of sloughed, necrotic papillary tissue. IVP shows the ring sign, which refers to the contrast agent surrounding sloughed papilla, although the current use of IVP is limited due to contrast load. Renal US shows small kidneys, with irregular thinning of the renal cortex. Renal biopsy shows interstitial infiltrates and fibrosis. Noncontrast CT shows bilateral reduced renal size, bumpy renal contours, and papillary calcifications (ie, small, indented, and calcified kidneys). The mechanism of injury is believed to be a combination of injury from the production of toxic metabolites and medullary ischemia. These patients are at increased risk of developing TCC of the urinary tract. Cessation of drug use can lead to stabilization of renal function.

REFERENCE

Mihatsch MJ, Khanlari B, Brunner FP. Obituary to analgesic nephropathy—an autopsy study. *Nephrol Dial Transplant.* 2006;21(11):3139–3145.

NEPHROPATHY, ISCHEMIC

DESCRIPTION Ischemic nephropathy is described as a deterioration of renal function due to a reduction in renal blood flow, commonly caused by atherosclerotic renovascular disease or renal artery stenosis. The disease progresses with worsening renal failure and decreased overall survival. It can present as hypertension (HTN) with unexplained renal insufficiency, worsening azotemia with HTN, azotemia in the setting of coronary artery disease or peripheral vascular disease, ACE inhibitor-induced ARF, or flash pulmonary edema. Numerous tests are used to define the presence, size, and function of the kidneys, as well as to establish the presence of a vascular lesion and its clinical significance, including CT or MR angiography, conventional angiography, Doppler US, ACE-I renography or renal vein renin measurements. Controversy still exists on the appropriate management of renal artery stenosis. Options include medical therapy, percutaneous transluminal angioplasty with or without stent placement, as well as surgical revascularization or nephrectomy. (See also Section I: “Renal Artery Stenosis/Renovascular Hypertension.”)

REFERENCE

Chonchol M, Linas S. Diagnosis and management of ischemic nephropathy. *Clin J Am Soc Nephrol.* 2006;1:172–181.

NEPHROPATHY, MEMBRANOUS

DESCRIPTION Renal disease that manifests with nephrotic syndrome. Affecting mainly middle-aged adults, it can progress to either spontaneous remission or ESRD. It is the most common cause of nephrotic syndrome in nondiabetic adults. Proteinuria with microscopic hematuria is often present; massive proteinuria, hypertension, and impaired renal function on presentation, and male gender, are all poor prognostic factors. Believed to be related to in

situ formation of immune complexes, it is most commonly idiopathic, but may be secondary to diseases (malignancy, infection, systemic lupus erythematosus [SLE]) or drug use (gold, penicillamine). Immunofluorescence often reveals deposits of IgG and complement. Treatment is based on the risk of progression associated with proteinuria (low risk <4 g/protein/d; moderate 4–8 g/protein/d; high risk >8 g/protein/d, lasting >3 mo or associated with a reduced creatinine clearance). Low-risk patients are at high likelihood of spontaneous remission and are treated with nonimmunosuppressive therapy, including ACE inhibitors or angiotensin II receptor blockers. In high-risk disease, cyclophosphamide and chlorambucil, both given with glucocorticoids, are effective in inducing remission of proteinuria and preventing progression to ESRD. Other agents reported include cyclosporine and tacrolimus (plus low-dose prednisone 10 mg/d max). (See also Section I: "Nephrotic Syndrome.")

REFERENCE

Glassock RJ. Diagnosis and natural course of membranous nephropathy. *Semin Nephrol.* 2003;23(4):324–332.

NEPHROPATHY, MINIMAL CHANGE

DESCRIPTION A common cause of nephrotic syndrome, most often affecting children but can account for up to 15% of adult nephrotic syndrome. Sometimes called *minimal change disease*, this condition manifests as nephrotic syndrome, with massive proteinuria and anasarca without hypertension. RBCs in the urine are a common finding; histologic evaluation shows essentially no changes on light microscopy. Electron microscopy shows epithelial foot process fusion. The pathogenesis is unknown, but T-cell dysfunction is theorized. The nephropathy can be primary or secondary to medications, neoplasm, infection, allergy, or other renal glomerular diseases; it frequently undergoes spontaneous remission, is responsive to corticosteroid therapy, and rarely progresses to chronic renal failure. (See also Section I: "Nephrotic Syndrome.")

REFERENCE

Waldman M, Crew RJ, Valeri A, et al. Adult minimal-change disease: Clinical characteristics, treatment, and outcomes. *Clin J Am Soc Nephrol.* 2007;2(3):445–453.

NEPHROPATHY, OBSTRUCTIVE

DESCRIPTION Obstructive nephropathy occurs when renal deterioration is due to obstruction of the urinary system. The point of obstruction can be in the upper or lower urinary tract. Congenital, inflammatory, neoplastic, and anatomic etiologies of urinary obstruction are all common. Obstruction of the outflow from the kidney results in several changes that lead to renal fibrosis. The tubular injury in obstructive nephropathy is caused initially by the increased intratubular pressure and later by atrophy induced by reduced perfusion, inflammation, and ischemia. The recovery of renal function after relief of the obstruction is determined by the duration of the obstruction, baseline renal function, patient age, and degree of obstruction. With total obstruction of the ureter, relatively complete recovery of GFR can be achieved within 1 wk, whereas after 12 wk, little or no recovery is

seen. (See also Section I: “Hydronephrosis/Hydroureteronephrosis [Dilated Ureter/Renal Pelvis], Adult.”)

REFERENCE

Better OS, Arieff AI, Massry SG, et al. Studies on renal function after relief of complete unilateral ureteral obstruction of three months duration in man. *Am J Med.* 1973;54(2):234–240.

NEPHROPATHY, URATE (URATE NEPHROPATHY)

DESCRIPTION A disorder in which an abrupt deterioration in renal function occurs due to the renal tubular deposition of urate and uric acid crystals. Chronic renal injury from uric acid deposition is most often associated with gout and is uncommon today. 2 forms are recognized, acute and chronic. Acute urate nephropathy occurs almost exclusively in the setting of malignancies, such as leukemias and lymphomas, with rapid cell turnover leading to increased purine metabolism and loss of nucleotides in the plasma. This is further enhanced by added acceleration of cell lysis, which occurs with chemotherapy and radiation used in these patients, producing the so-called *tumor lysis syndrome*. Nucleotides are converted to urate by xanthine oxidase, resulting in hyperuricemia with levels of 25–90 mg/dL at the time of onset of renal dysfunction. Diagnosis requires the appropriate clinical setting of increased cell lysis (usually with chemotherapy), oliguria, marked hyperuricemia, and hyperuricosuria. A urinary uric acid-to-creatinine ratio >1 distinguishes this from other catabolic states with elevated serum urate levels and renal failure, such as trauma with rhabdomyolysis. (See also Section I: “Urolithiasis, Uric Acid”; Section II: “Gout, Urologic Considerations,” “Hyperuricosuria,” and Tumor Lysis Syndrome [TLS].”)

TREATMENT

- Prevention is the key, using xanthine oxidase inhibition with allopurinol and alkaline diuresis prior to initiation of chemotherapy.
- Alkalinization of urine in the acute tumor lysis syndrome is not possible in the setting of brisk diuresis.
- Rasburicase (Elitek) is recombinant urate oxidase that converts uric acid to water-soluble allantoin.
- Occasionally, dialysis is required to correct azotemia and reduce urate levels.

REFERENCE

Conger JD. Acute uric acid nephropathy. *Med Clin North Am* 1990;74:859–871.

NEPHROPTOSIS

DESCRIPTION Nephroptosis, also referred to as *floating kidney* or *renal ptosis,* is a condition in which the kidney drops into the pelvis when the patient stands up. It tends to be more common in women and is thought to be caused by a lack of perirenal fat. Patients are usually asymptomatic but colicky type pain can be attributed to this conditions, similar to a Dietl crisis. The pain is classically relieved by lying down. Imaging can demonstrate the renal descent and aid in diagnosis. Conservative management had been the mainstay of treatment,

although laparoscopic nephropexy is now recommended for symptomatic patients. (See also Section II: “Dietl Crisis.”)

REFERENCE

Barber NJ, Thompson PM. Nephroptosis and nephropexy-hung up on the past? *Eur Urology*. 2004;46:428–433.

NESBIT CHORDEE REPAIR

DESCRIPTION A surgical procedure in which ≥1 vertical ellipses are removed from the Tunica Albuginea on the longer convex side, and the ellipses are closed transversely, which results in shortening of the longer side to correct the penile curvature.

REFERENCE

Montague DK. Correction of chordee. In: Novick AC, Streem SB, Pontes JE, eds. *Stewart’s Operative Urology*. Baltimore, MD: Williams & Wilkins; 1989:822–825.

NEUROENDOCRINE TUMORS, GENITOURINARY

DESCRIPTION A group of tumors that share a characteristic morphology, often being composed of clusters and trabecular sheets of round blue cells, granular chromatin, and an attenuated rim of poorly demarcated cytoplasm. Neuroendocrine tumors include carcinoids, small (oat) cell carcinomas, medullary carcinoma of the thyroid, Merkel cell tumor, cutaneous neuroendocrine carcinoma, pancreatic islet cell tumors, and pheochromocytoma. Small (oat) cell carcinomas have been described most often in the prostate and bladder. Prostate cancer with neuroendocrine differentiation is considered a variant of Gleason 5 adenocarcinoma of the prostate. Undifferentiated carcinomas of the urinary bladder and prostate should be analyzed not only by means of hematoxylin and eosin but also by immunohistochemical staining for chromogranin A (Chr A) and synaptophysin (SNP), to demonstrate a neuroendocrine origin. Because the prognosis of small cell neuroendocrine cancers is very poor, aggressive multimodal therapy is often employed. (See also Section I: “Pheochromocytoma”; Section II: “Multiple Endocrine Neoplasia [MEN I, MEN II]”; “Prostate Cancer, Small Cell [Neuroendocrine].”)

REFERENCE

Helpap B. Morphology and therapeutic strategies for neuroendocrine tumors of the genitourinary tract. *Cancer*. 2002;95(7):1415–1420.

NEUROFIBROMATOSIS, UROLOGIC CONSIDERATIONS

DESCRIPTION A hereditary disorder characterized by cafe-au-lait spots, cutaneous fibromas, and neurofibromas; it is associated with renovascular lesions and pheochromocytomas. Vascular lesions are characterized by endothelial proliferation, with or without aneurysmal formation and cellular nodules in the vessel walls. The aorta is frequently involved, and the renal arteries may demonstrate long areas of stenosis that are generally best treated with revascularization rather than angioplasty. In addition, a 30-fold increase in the incidence of neurofibromatosis in patients with Wilms tumor has been reported.

REFERENCE

Saborio P, Scheinman J. Genetic renal disease. *Curr Opin Pediat.* 1998;10:174–183.

NEUROGENIC DETRUSOR OVERACTIVITY (NDO)

DESCRIPTION NDO patients are a heterogeneous group with both storage and voiding dysfunction. The NDO symptoms include urinary frequency, urgency, and incontinence. Neurologic conditions associated with NDO include multiple sclerosis (MS), spinal cord injury (SCI) Parkinson disease, cerebral palsy, and myelomeningocele. Neurogenic bladder dysfunction is present in 80.8% of individuals with MS, 90% with myelodysplasia, virtually all SCI patients with persistent neurologic deficits and 70% of ambulatory SCI patients. NDO impacts quality of life and can also result in risk of UTI and upper urinary tract damage.

Anticholinergic therapies such as oxybutynin are primarily used for patients with DO and poor compliance. CIC may be best for those who have poor bladder emptying. Although not FDA-approved neuromodulation via sacral nerve stimulation is useful in patients who have failed anticholinergics. Intra-detrusor injection of onabotulinum toxin-A is FDA approved in the management of NDO in patients refractory or intolerant of anticholinergics. In selected individuals, a chronic indwelling catheter may be the best management therapy. Surgical intervention (bladder augmentation, urinary diversion, continent urinary diversion, and ileovesicostomy) may be indicated for protection of the upper urinary tract in high-risk patients or to achieve continence. (See also Section I: “Neurogenic Bladder, General Considerations.”)

REFERENCE

Cone E, Ellsworth P. Neurogenic detrusor overactivity: An update on management options. *R I Med J*. 2013, Available at www.rimed.org, Accessed March 29, 2014.

NEUROMODULATION, UROLOGIC CONSIDERATIONS

DESCRIPTION Neuromodulation involves the use of electrical current to alter physiologic properties. This technology has been applied to lower urinary tract voiding dysfunction for the past decade by stimulation of the sacral nerve roots. Sacral neuromodulation was approved for use in patients with overactive bladder refractory to medical and behavioral therapy by the FDA in 1997. A recent multi-institutional clinical trial shows success rates as high as 68% for urge urinary incontinence, 56% for urgency–frequency, and 71% with unobstructive urinary retention at 5 yr after implantation. Posterior tibial nerve stimulation is also being used. (See also Section II: “Posterior Tibial Nerve Stimulation: Urgent PC [PTNS].”)

REFERENCE

Hubsher CP, Jansen R, Riggs DR, et al. Sacral nerve stimulation for neuromodulation of the lower urinary tract: How I do it. *Can J Urol.* 2012;19(5):6480–6484.

NEVES–ZINCKE CLASSIFICATION

DESCRIPTION A largely historic classification system for describing the level of tumor thrombus associated with a renal mass. The categories are renal vein, ≤2 cm above the renal

vein, infrahepatic >2 cm but below the intrahepatic vena cava, intrahepatic but below the diaphragm and atrial above the diaphragm. (See also Section I: "Renal Cell Carcinoma with Tumor Thrombus.")

REFERENCE

Neves RJ, Zincke H. Surgical treatment of renal cancer with vena cava extension. *BJU*. 1987;59(5):390–395.

NMP-22 TESTING

DESCRIPTION NMP-22 has been found to serve as a urinary marker for TCC. The NMP-22 test (Matritech, Inc., Newton, MA) is a quantitative immunoassay that measures NMP-22. The addition of NMP-22 testing to cytology may increase the sensitivity for recurrence detection in patients with superficial transitional cell bladder cancer. Patients with positive NMP-22 findings developed significantly more recurrences compared with those with negative NMP-22 findings in several studies.

REFERENCE

Gupta NP, Sharma N, Kumar R. Nuclear matrix protein 22 as adjunct to urine cytology and cystoscopy in follow-up of superficial TCC of urinary bladder. *Urology*. 2009;73(3):592–596.

NOCTURNAL ERECTIONS, NORMAL AND ABNORMAL

DESCRIPTION Nocturnal erections occur at night during REM sleep. The number of erections peak during puberty. Various criteria exist for what is considered normal erectile activity at night, but normal is usually 4–5 erectile episodes per night with a mean duration >30 min and an increase in circumference of >3 cm at the base and >2 cm at the tip, as well as maximal rigidity above 70% at both base and tip. (See also Section II: "Nocturnal Penile Tumescence Testing.")

REFERENCE

Lue TF, Broderick GA. Evaluation and nonsurgical management of erectile dysfunction and premature ejaculation. In: Wein AJ, Kavoussi LR, Novick AC, et al., eds. *Campbell-Walsh Urology*. 9th ed. Philadelphia, PA: Saunders Elsevier; 2007:765.

NOCTURNAL PENILE TUMESCENCE (NPT) TESTING

DESCRIPTION NPT refers to a recurring cycle of penile erections associated with rapid eye movement sleep. The primary goal of NPT testing is to distinguish between psychogenic and organic causes of impotence. Nocturnal monitoring devices measure the number of erectile episodes, maximal penile rigidity, tumescence, and duration of erections. This testing assumes that the mechanism for nocturnal erections is the same as that for erotically induced erections. (See also Section II: "Nocturnal Erections, Normal and Abnormal.")

REFERENCE

Greenstein A, Mabjeesh NJ, Sofer M, et al. Are consecutive nightly recordings required for

valid evaluation of sleep-associated erections? *Int J Impot Res.* 2007;19(2):196–199.

NOCTURNAL POLYURIA (NP)

DESCRIPTION NP is a condition in which the rate of urine output is excessive only at night, and total 24-hr output is within normal limits. NP is defined as the production of >1/3 of total 24-hr urine output between midnight and 8 AM (normal physiologic response is reduced urine output at night). A voiding diary (*frequency volume chart* or FVC) that records time and volume of each void over a 24-hr period for 7 days establishes if the patient is polyuric or nonpolyuric. True polyuria is present throughout the 24-hr period, whereas NP is confined to elevated night-time output. Altered sleep patterns caused by frequent trips to the bathroom can cause problems staying alert at work, major depression, and hypertension. Although traditional therapies in men have been directed toward medical or surgical treatment, NP does not respond well to these standard interventions. (See also Section II: "Polyuria and Voiding Diary [Frequency Volume Chart, FVC].")

TREATMENT

- Lifestyle changes: Limiting fluids in the late afternoon and evening, such as coffee, soft drinks, or tea.
- Taking diuretics early in the day.
- Desmopressin mimics the action of vasopressin in reducing nocturnal urine production.

REFERENCE

Kujubu DA, Aboseif SR. An overview of nocturia and the syndrome of nocturnal polyuria in the elderly. *Nat Clin Pract Nephrol.* 2008;4(8):426–435.

NOMOGRAMS, UROLOGIC

DESCRIPTION Nomograms are mathematical tools that allow for the prediction of various outcomes. Validated nomograms have been developed for all major urologic cancers, as well as for some benign urologic diseases. Useful online prediction tools are available on several sites including Memorial Sloan Kettering Cancer Center (www.mskcc.org/mskcc/html/5794.cfm) for prostate, bladder, and kidney cancer. SWOP is sponsored by the Prostate Cancer Research Foundation, Rotterdam (www.prostatecancer-riskcalculator.com/). It is an online multi-step Prostate Cancer Risk Calculator and assesses a man's prostate cancer risk and helps to avoid unnecessary biopsy.

REFERENCE

Kattan MW, Scardino PT. Evidence for the usefulness of nomograms. *Nat Clin Pract Urol.* 2007;4(12):638–639.

NONARTERITIC ANTERIOR ISCHEMIC OPTIC NEUROPATHY (NAION)

DESCRIPTION NAION describes the acute, painless loss of vision in 1 eye associated with optic disc edema (crowded optic disk). It is a common cause of acute optic neuropathy in adults. Associations have been found between NAION and the phosphodiesterase inhibitors sildenafil, vardenafil, and others. The mechanism and exact nature of this association are still

under investigation.

REFERENCE

NONSACRAL NEUROMODULATION

DESCRIPTION Neuromodulation involves the use of electrical current to alter physiologic properties. This technology has been applied to lower urinary tract voiding dysfunction for the past decade by stimulation of the sacral nerve roots. There has been recent interest into stimulation of more distal branches of the sacral nerve roots as well, including the pudendal, dorsal genital, and posterior tibial nerves. (See also Section II: “Neuromodulation, Urologic Considerations” and “Posterior Tibial Nerve Stimulation: Urgent PC [PTNS].”)

REFERENCE

Bennett RC, et al. Nonsacral neuromodulation. In: Goldman HB, Vasavada SP, eds. *Female Urology: A Practical Clinical Guide.* Totowa, NJ: Humana Press; 2007.

NOONAN SYNDROME

DESCRIPTION This autosomal dominant syndrome consists of multiple congenital anomalies, including characteristic facial features, short stature, and chest deformity. Over 1/2 of males with Noonan syndrome have unilateral or bilateral cryptorchidism. Females can have delayed sexual maturation, but normal development is expected. Renal anomalies occur in 10% of children. Because congenital cardiac anomalies are found in 1/2 of the patients, all patients with this syndrome should have cardiac evaluation and close follow-up. Growth hormone replacement may have value in treating short stature.

REFERENCE

Noonan JA. An update and review for the primary pediatrician. *Pediatrics*. 1997;33:549.

N-TELOPEPTIDE, URINARY (NTX)

DESCRIPTION NTX is a product of type I collagen breakdown that can be measured in the urine. Several studies suggest its utility as a marker for bone turnover in osteoporosis, and for response to treatment of bony metastasis and bisphosphonate therapy. Typical reference ranges are (bone collagen equivalent [BCE]): Normal adult male 21–83 nM BCE/mM creatinine; adult female premenopausal: 17–94 nM BCE/mM creatinine; postmenopausal 26–124 nM BCE/mM creatinine. A decrease of 30–40% from the NTX baseline after 3 mo of therapy is typical for treatment with bisphosphonate.

REFERENCE

NUTCRACKER SYNDROME

DESCRIPTION This syndrome occurs secondary to compression of the left renal vein by the superior mesenteric artery and the aorta. Patients are usually young and previously healthy. Presentation classically is due to gross hematuria caused by left renal vein hypertension. Pelvic pain may be present. Various modalities, including nephrectomy, autotransplantation, renocaval reimplantation, and venolysis have been employed. Gore-Tex graft renal vein interposition and anterior nephropexy have been successful (Image ☼).

REFERENCE

Wang L, Yi L, Yang L, et al. Diagnosis and surgical treatment of nutcracker syndrome: A single-center experience. *Urology*. 2009;73(4):871–876.

OBESITY, UROLOGIC CONSIDERATIONS

DESCRIPTION It is estimated that 300,000 deaths a year in the United States are associated with elevated body mass index (BMI). Cardiovascular comorbidities of obesity have been well established and there is mounting evidence that obesity impacts a number of urologic diseases. Strong correlations had been shown between obesity in women and stress urinary incontinence (SUI) secondary to increased abdominal pressure. Similarly, obese males have been shown to have increased lower urinary tract symptoms (LUTS). This may be attributable to an increase in adenoma size in BPH, although there is conflicting data regarding the effect of size on symptoms.

A direct link to obesity has also been shown in urologic stone formation. Obese patients with a stone to skin length >10 cm have poorer clearance rates with extracorporeal shock wave lithotripsy (ESWL). In addition, percutaneous nephrolithotomy (PCNL) is limited to patients who are not too obese for standard sheath and nephroscope lengths.

Research has shown an increase number of malignancies in patients who are obese. This is true with some urologic cancers. Prostate cancer has been shown to be more prevalent in obese patients as is adverse pathology. Renal cell carcinoma (RCC) is also associated with obesity.

The increased incidence in prostate cancer in obese men is postulated to result, at least partially, by conversion of testosterone to estradiol in adipocytes. Likewise, this aromatization of androgens leads to decreased fertility in young males. Sexual dysfunction is observed in obese men as a result of increased rates of hypertension, diabetes, and vascular disease. (See also Section II: “Body Mass Index (BMI), Urologic Considerations.”)

OBTURATOR NERVE INJURY, INTRAOPERATIVE

DESCRIPTION The obturator nerve, which provides motor innervation of medial thigh adductor muscles, can be injured in surgeries involving pelvic lymphadenectomy, such as prostatectomy and cystectomy. In addition, excessive hip flexion or cautery injury during surgery can cause neurapraxia of the obturator nerve. Postoperatively, EMG can be helpful in making the diagnosis. Symptoms include gait disturbance, pain, or anesthesia along the nerve’s sensory distributions along the inner thigh and scrotum. Thigh adduction will be impacted. The incidence of intraoperative obturator nerve injury is not well documented but thought to be rare. When transection of the obturator nerve is identified intraoperatively, surgical repair may be done by end-to-end anastomosis or grafting when achieving tension-free anastomosis is not possible. Nerve transection can be repaired with end-to-end approximation of nerve edges with four 6–0 to 10–nylon or Prolene epineural stitches, using magnification if possible. Efforts must be made to align the nerve fibers prior to approximation. An absorbable collagen implant nerve wrap/protector (NeuraWrap™), can facilitate the repair when applied to the new anastomosis. If the nerve is frayed and grossly devitalized, efforts can be made to trim both segments sharply. In the event of a significant gap, nerve-grafting techniques can be performed at a later date using a sural nerve (which is

a nonessential nerve) graft.

OBTURATOR REFLEX, UROLOGIC CONSIDERATIONS

DESCRIPTION Stimulation of the obturator nerve during surgical procedures (eg, transurethral resection of bladder tumors located on the posterolateral wall, or laparoscopic pelvic lymph node dissection) can cause unexpected adduction of the thigh. Surgeons must be aware of this response so as not to cause inadvertent injury, such as perforation of the bladder. The response can usually be prevented by muscle-paralyzing anesthetic agents.

O'LEARY–SANT SCORES (O'LEARY–SANT INTERSTITIAL CYSTITIS SYMPTOM INDEX [ICSI])

DESCRIPTION The ICSI is a validated questionnaire that documents and scores patient's urinary symptoms as well as the level those symptoms cause a problem in their life. The questionnaire can be administered without the supervision of a professional interviewer. It focuses on the symptoms of urinary urgency, frequency, nocturia, and dysuria/ pain over a 30-day period. It has been found useful as a tool to follow symptoms of but not the diagnosis of interstitial cystitis.

REFERENCE

OLIGOASTHENOTERATOSPERMIA

DESCRIPTION Oligoasthenoteratospermia describes very generalized abnormalities in sperm concentration, motility, and morphology. The cause of these combined defects in sperm parameters are commonly caused by the effects of a varicocele (most commonly cited cause), cryptorchidism, and other transient insults such as heat, drugs, or environmental toxins. *Trichomonas* has been implicated in some studies. Treatment involves the removal of potentially offending spermatotoxins and a repeat semen analysis in 3 mo. No good data exist on the use of agents such as bromocriptine, clomiphene citrate, human chorionic gonadotropin (hCG), or tamoxifen. (See also Section I: "Infertility"; Section II: "Semen Analysis, Abnormal Findings and Terminology"; "Semen Analysis, Technique, and Normal Values.")

REFERENCE

Cavallini G, Crippa A, Magli MC, et al. A study to sustain the hypothesis of the multiple genesis of oligoasthenoteratospermia in human idiopathic infertile males. *Biol Reprod.* 2008;79(4):667–673.

OLIGOSPERMIA

DESCRIPTION Oligospermia occurs when sperm density is <20 million/mL or with a total count of <50 million sperm. Severe oligospermia occurs if counts are <10 million/mL, and may be due to hormone deficiency. A count of <20 million/mL is associated with substantially decreased fertility rates. (See also Section I: "Infertility"; Section II: "Semen Analysis, Abnormal Findings and Terminology"; "Semen Analysis Technique, Normal Values.")

REFERENCE

OMPHALOCELE-EXSTROPHY OF THE BLADDER—IMPERFORATE ANUS-SPINA BIFIDA DEFECTS (OEIS) COMPLEX

DESCRIPTION This complex represents the most severe end of a spectrum of birth defects, the exstrophy-epispadias sequence, which, in order of increasing severity, includes phallic separation with epispadias, pubic diastasis, vesical exstrophy of the bladder and cloacal exstrophy, and OEIS complex. The incidence of the OEIS complex is rare (1 of 200,000–400,000 pregnancies). Exstrophy of the cloaca includes the persistence and exstrophy of a common cloaca that receives ureters, ileum, and a rudimentary hindgut and is associated with failure of fusion of the genital tubercles and pubic rami. Other anomalies include incomplete development of the lumbosacral vertebrae with spinal dysraphism; imperforate anus; cryptorchidism and epispadias in males; anomalies of the müllerian duct derivatives in females; and a wide range of urinary tract anomalies including renal defects. Omphalocele (a defect in the umbilical ring, through which the peritoneum and an amnion-covered sac herniate) is common, and most patients have a single umbilical artery. The etiology of the OEIS complex is still unclear; single defects in blastogenesis and mutations in homeobox genes, such as *HLXB9*, have been suggested as responsible. Although often fatal, extensive surgical reconstruction has been successful.

REFERENCE

Keppler-Noreuil K. Prenatal ascertainment of OEIS complex/cloacal exstrophy: 15 new cases and literature review. *Am J Med Genet A.* 2007;143A(18):2122–2128.

OPIOID-INDUCED HYPOGONADISM

DESCRIPTION Opioids are a considerable source of drug abuse and addiction worldwide. Chronic use of opiate medication whether under supervision or illicit causes hypogonadism by actions on opioid receptors in the hypothalamus with additional actions of elevating prolactin levels and direct suppression of the pituitary and testes. Testosterone levels have

been decreased as low as 50% after a single dose of opiate. Testosterone levels recover in 24–72 hr but can be suppressed up to a month depending on dose. Hypogonadism induced by opioids can be treated with hormone replacement therapy.

REFERENCE

OPITZ–FRIAS SYNDROME

DESCRIPTION Also called the *G syndrome* (named for 1 of the 1st patients), this condition is due to a defect of midline development, characterized by numerous congenital abnormalities, especially of the face. Many patients have hypertelorism and posteriorly rotated ears; hypospadias is almost always present. Other manifestations include cleft lip and palate, high tracheal bifurcation, duodenal stricture, imperforate anus, lung hypoplasia, and cardiac abnormalities. Inheritance is autosomal dominant with incomplete penetrance. Carriers show minimal abnormalities. It is more common in males, and perinatal mortality is around 30%.

REFERENCE

Conlon BJ, O'Dwyer TH. The G syndrome, Opitz oculo-genital-laryngeal syndrome, Opitz BBB/G syndrome, Opitz-Frias syndrome. *J Laryngol Otol.* 1995;109(3):244–246.

ORAL–FACIAL–DIGITAL (OFD) SYNDROME

DESCRIPTION At least 11 different types of oral–facial–digital (OFD) syndromes have been described. OFD type I is an X-linked dominant condition characterized by malformations of the face, oral cavity, and digits with polycystic kidney disease and variable involvement of the CNS. Facial milia, orofacial defects such as cleft palate, hand deformities, including shortening of the phalanges, and CNS defects are noted. Of urologic interest, renal cystic disease is found that resembles autosomal dominant polycystic kidney disease in appearance and course. Liver and pancreatic cysts may be observed. Polycystic kidney disease occurs in fewer than 50% of individuals with OFD type 1; the exact frequency is unknown. Renal cysts can develop from both tubules and glomeruli. The age of onset is most often in adulthood, but renal cysts in children have been described. ESRD has been reported in affected girls and women ranging in age from 11–70 yr. Recently it has been emphasized that the risk for significant renal disease may be greater than previously reported. Close monitoring of renal function if renal cystic disease present and renal replacement therapy, as needed.

REFERENCE

Toprak O, Uzum A, Cirit M, et al. Oral-facial-digital syndrome type 1, Caroli's disease and cystic renal disease. *Nephrol Dialys Transplant.* 2006;21(6):1705–1709.

ORCHITIS, GRANULOMATOUS

DESCRIPTION This condition encompasses a group of disorders that have similar clinical and pathologic findings. It is usually of sudden clinical onset during the 6th–7th decades of life. The patient may complain of a painful and swollen scrotum, and occasionally fever

and/or skin changes may be present. Often, the diagnosis is rendered postoperatively after inguinal orchiectomy is performed for presumed malignancy and histology shows chronic inflammation with granuloma. The most common cause is *Mycobacterium tuberculosis*. Less commonly, brucellosis, actinomycosis, and sarcoidosis are found. The condition can be a rare complication of intravesical bacillus calmette-Guérin therapy for urothelial cancer. If TB is suspected, antitubercular chemotherapy is warranted, with operative treatment for medical failures. For other causes, medical and/or surgical therapy can be utilized.

REFERENCE

Harving SS, Asmussen L, Roosen JU, et al. Granulomatous epididymo-orchitis, a rare complication of intravesical bacillus Calmette-Guérin therapy for urothelial cancer. *Scand J Urol Nephrol.* 2009;24:1–3.

ORGASMIC PAIN (PAINFUL EJACULATION)

DESCRIPTION Pain associated with ejaculation and orgasm is widely underreported. The nature, duration, and location of the pain can vary widely between patients. The exact cause of the pain is unknown but can be related to previous surgery (including RP), ejaculatory duct stones, pudendal nerve neuropathy, and antidepressant medications. Treatments include the use of conservative measures, anti-inflammatory medications, α-blockers, topiramate, steroid injections, relief of seminal duct obstruction, and surgical interventions such as neurolysis and fasciotomy of Alcock canal. (See also Section I: “Ejaculatory Disturbances [Delayed, Decreased, or Absent].”)

REFERENCE

ORTHO-PHTHALALDEHYDE (OPA) CHEMICAL DISINFECTANT

DESCRIPTION OPA 0.55% is a chemical disinfectant for instruments such as cystoscopes. It can irritate eyes, skin, nose, and other tissues. OPA is FDA approved as a high-level disinfectant (12 min at 20°C and 5 min at 25°C). Anaphylactic reactions have been reported in patients with bladder cancer who underwent repeated cystoscopy with scopes sterilized with OPA. OPA is contraindicated in patients with a history of bladder cancer but can be used in manual or automated reprocessing protocols.

REFERENCE

OSSIFYING RENAL TUMOR OF INFANCY

DESCRIPTION Rare, calcified tumor of infancy, usually resembling a renal pelvis calculus. Occurs usually in 1st year of life, with gross hematuria as the most common presenting symptom. Anatomic and histologic origins are unclear but are thought to be of urothelial origin. Lesions are apparently benign, with no reported cases of recurrence or metastasis. Surgical enucleation with renal-sparing procedure is the treatment, with careful follow-up

using renal sonograms, as necessary.

REFERENCE

OSTEONECROSIS OF THE JAW (ONJ), UROLOGIC CONSIDERATIONS

DESCRIPTION Osteonecrosis is a newly recognized complication of long-term therapy with bone strengthening agents in patients with metastatic cancer to the bone such as prostate, breast and renal cell carcinoma and in multiple myeloma. Bisphosphonates and denosumab decrease cancer-induced bone resorption thereby reducing SREs, pain, and improving quality of life. Initially identified as bisphosphonate-induced ONJ, it now recognized as a potential complication of denosumab as well. ONJ is classified as exposed necrotic maxillofacial bones for >8 wk in patients treated with bisphosphonates or denosumab who have not had radiation to the jaws. The exposed bone becomes infected with oral flora resulting in significant pain and need for oral surgery. A new term is bisphosphonate-related osteonecrosis of the jaws (BRONJ). Symptoms include pain, swelling, redness, or other signs of infection in the gums; gums or sockets that don't heal after dental work; loose teeth and numbness or a heavy feeling in the jaw. The risk of developing ONJ is related to the potency of the antiresorptive, the duration of exposure, and dentoalveolar trauma. Prospective studies of patients taking bisphosphonates for metastatic prostate cancer that include regular exam by dentists estimate an incidence as high as 20% which is much higher than retrospective studies that suggested an incidence of 3–6%. Dental clearance before initiating therapy is recommended as well as avoiding extensive dental work while on therapy.

REFERENCE

Walter C, Al-Nawas B, Grötz KA, et al. Prevalence and risk factors of bisphosphonate – associated osteonecrosis of the jaw in prostate cancer patients with advanced disease treated with Zoledronate. *Eur Urol.* 2008;54:1066–1072.

OSTEOPOROSIS AND OSTEOPENIA, UROLOGIC CONSIDERATIONS

DESCRIPTION Osteoporosis and osteopenia are conditions of decreased bone mineral density (BMD) that lead to an increased risk of fracture. Although traditional emphasis has been placed on diagnosing osteoporosis in women, as the male population ages, increased numbers of men are at risk for developing skelet al fractures. In addition, more men are being placed on long-term androgen-deprivation therapy (orchiectomy of LHRH analog) as treatment for prostate cancer, which further increases the risk for osteopenia and osteoporosis. A DEXA scan can be used prior to treatment to measure BMD. Central DEXA is the gold standard and measures the spine and hip BMD. The T-score is the number of SDs by which the patient's bone mass falls above or below the mean peak bone mass for a 30-yr-old healthy adult. For every 1 SD decrease in T-score, relative risk of fracture increases ~1.5–2.5-fold. According to the National Osteoporosis Foundation, a normal T-score is >–1, osteopenia is –1 to –2.5, and osteoporosis is <–2.5. Further, it is recognized that, in addition to cancer treatment–induced bone loss, many men may suffer skelet al related events (SRE's) as a

consequence of bony metastatic disease. Improving BMD may also decrease SREs (radiation for bone pain or to treat pathologic fractures or spinal cord compression, pathologic fractures, spinal cord compression, and vertebral body collapse or surgery to bone). (See also Section II: "Bone Mineral Density, Urologic Considerations.")

TREATMENT

- Calcium: 1,200 mg/d; it is recommended most cal-cium come from foods (dairy, green leafy vegetables)
- Vitamin D: At least 800–1,000 IU/d preferable from foods (fatty fish and oils, liver, fortified milk) with sun exposure of 30 min/d or supplements
- Exercise to include weight bearing
- Stop smoking; limit alcohol and caffeine
- Consider bisphosphonates:
  - Alendronate (Fosamax, Fosamax Plus D) approved for treatment of men with osteoporosis and treatment/prevention of osteoporosis in men taking glucocorticoids
  - Risedronate (Actonel, Atelvia) approved for treatment of men with osteoporosis and treatment/prevention of osteoporosis in men taking glucocorticoids.
  - Pamidronate (Aredia) for men with Paget disease, hypercalcemia of malignancy, malignant myeloma
  - Zoledronic acid (Zometa); 4 mg/monthly IV approved for bony metastasis but not male osteoporosis
  - Zoledronic acid (Reclast); 5 mg/yr IV in men with Paget disease and osteoporosis
- Consider denosumab: Injectable monoclonal antibody to RANK ligand, decreases osteoclast activity
  - Prolia: Men on ADT or osteoporosis 60 mg SC Q 6 mo
  - Xgeva : Men with metastasis, not men with osteoporosis: 120 mg SC Q every 4 wk.

OSTEOTOMY, UROLOGIC CONSIDERATIONS

DESCRIPTION Osteotomy is the surgical techn-ique of cutting bone to its shape, length, or alignment. This becomes of particular necessity in surgical repair of bladder exstrophy to correct a wide pubic diastasis. Advantages of pelvic osteotomy include decreased bladder dehiscence, improved continence, and less late pelvic organ prolapse in females.

REFERENCE

OVARIAN CANCER, UROLOGIC CONSIDERATIONS

DESCRIPTION Ovarian cancer is the leading cause of death from gynecologic cancer and is usually of epithelial origin. These tumors can often involve adjacent structures or cause extrinsic compression of the urinary tract, including the bladder and ureters, with the resultant need for urologic intervention.

REFERENCE

Coleman RL, Gershenson DM. Neoplastic diseases of the ovary: Screening, benign and malignant epithelial and germ cell neoplasms, sex-cord stromal tumors. In: Katz VL, et al., eds. *Comprehensive Gynecology*. 5th ed. St. Louis, MO: Mosby; 2007.

OVARIAN REMNANT SYNDROME

DESCRIPTION This condition is a rare complication of bilateral oophorectomy and occurs when remnants of ovarian cortex are inadvertently left behind. The remaining ovarian tissue becomes functional and cystic. Typically, patients present with pelvic pain that can be chronic or intermittent and a pelvic mass. Symptoms may begin weeks to 5 yr postoperatively. Ureteral obstruction has been reported. Excision of the ovarian remnant is the most widely accepted treatment method. Preoperative ovarian stimulation can help intraoperative identification of retained tissue. Surgery is associated with an 8–10% recurrence rate.

OVARIAN VEIN SYNDROME

DESCRIPTION Ureteral obstruction, usually right-sided, occurring secondary to occlusion by dilated ovarian veins. The ovarian veins lie adjacent to the ureters, and dilation of these veins, especially during pregnancy, is thought to result in ureteral obstruction. The obstruction is usually seen around the L3–L4 vertebral level. Symptoms include chronic flank pain, but colicky pain has also been found. The symptoms can also begin several days prior to menses and then regress. Diagnosis can be made by IV urogram, retrograde ureteropyelogram, and simultaneous angiography. Ureterolysis and ovarian vein resection can be performed using open or laparoscopic techniques.

OXALATE-ASSOCIATED RENAL DISEASE

DESCRIPTION Hyperoxaluria is associated with calcium oxalate nephrolithiasis. An increased oxalate production or absorption, or an idiopathic form, might be responsible for the disease. In cases of primary hyperoxaluria, stone formation usually starts during

childhood, with eventual tubulointerstitial nephropathy and chronic renal failure. Oxalate deposition in heart, joints, and other tissues (*oxalosis*) may occur. (See Section II: "Hyperoxaluria," for the causes of increased urinary oxylate.)

TREATMENT

- Pyridoxine supplements (200–400 mg/d) for primary hyperoxaluria
- Oral hydration; low-oxalate, low-fat diet for enteric hyperoxaluria
- Pyridoxine and thiazides for idiopathic hyperoxaluria

REFERENCES

Scheinman JI. Primary hyperoxaluria: Therapeutic strategies for the 90s. *Kidney Int.* 1991;40:389–399.

OXALATE, DIETARY

DESCRIPTION An excessive intake of oxalate-rich products, should be limited or avoided to prevent an oxalate load. This includes fruits and vegetables rich in oxalate such as wheat bran. This is particularly important in patients in whom an high oxalate excretion has been demonstrated. Vitamin C is a precursor of oxalate, but its role as a risk factor in calcium oxalate stone formation remains controversial. Some studies have shown that a daily intake of up to 4 g might be allowed without risk. However, a recent study demonstrated an increased risk in stone formation for men taking 1 g/d or more of vitamin C vs. <90 mg. It therefore seems justified to advise calcium oxalate stone formers to avoid excessive intake of vitamin C. (See also Section I: "Urolithiasis, Calcium Oxalate/Phosphate.") The following products have high oxalate content:

- Rhubarb, 530 mg oxalate/100 g
- Spinach, 570 mg oxalate/100 g
- Cocoa, 625 mg oxalate/100 g
- Tea leaves, 375–1,450 mg oxalate/100 g
- Nuts, 200–600 mg oxalate/100 g

REFERENCE

P53, UROLOGIC CONSIDERATIONS

DESCRIPTION The p53 gene produces a nuclear phosphorylation protein that has a tumor-suppression function. Loss of wild-type p53 is the most common genetic abnormality associated with TCC. Its presence is associated with high grade, late stage, and relapse. Potentially, it may be useful in grading tumors. In prostate cancer, p53 is associated with an increased probability of biochemical relapse and is found in a higher percentage of hormone-refractory cancers.

REFERENCE

PAD TESTING

DESCRIPTION Used as a clinical tool to assess the severity of urinary incontinence, often in association with a micturition diary. The pad test provides a gross/semi-quantitative measurement of urine loss over a given period of time. Several types have been described, but none has met with widespread approval. 1 technique has a patient take Pyridium 200 mg TID and then change pads every 6 hr for a 24-hr period. The amount of staining is an estimate of incontinence. Another approach is to weigh the pads (1 g = 1-mL urine).

REFERENCE

Ryhammer AM, Djurhuus JC, Laurberg S. Pad testing in incontinent women: A review. *Int Urogynecol J Pelvic Floor Dysfunct.* 1999;10(2):111–115.

PAGANO URETERAL ANASTOMOSIS

DESCRIPTION A 4–5-cm linear incision is made through the taenia of the colon, and the mucosa is dissected from the submucosa to the level of the mesentery. The ureters are pulled through the lateral muscular wall and implanted distally into the mucosa. The serosa is reapproximated while incorporating mucosa in the midline.

REFERENCE

Pagano F. Ureterocolonic anastomosis: Description of a technique. *J Urol.* 1980;123(3):355–356.

PAGE KIDNEY

DESCRIPTION This condition was 1st described in 1939, after hypertension was created by wrapping cellophane around a canine kidney. Applied clinically, this term was given to hypertension secondary to subcapsular or perirenal compression resulting in renal ischemia. Elevated renin secretion from the compromised kidney and decreased renin production from the contralateral renal unit result. Diagnosis can be made with US, CT, or MRI, demonstrating a surrounding hematoma or fibrous capsule. Clinical causes include blunt trauma, closed renal biopsy, anticoagulation, or tumor bleed. Treatment is directed at the primary cause.

Further therapy may include ACE inhibitors, open or percutaneous drainage, or nephrectomy. Spontaneous resolution can occur secondary to reabsorption of the hematoma.

REFERENCE

Sterns RH, Rabinowitz R, Segal AJ, et al. "Page kidney." Hypertension caused by chronic subcapsular hematoma. *Arch Intern Med.* 1985;145(1):169–171.

PAGET DISEASE, ANOGENITAL/EXTRAMAMMARY

DESCRIPTION Extramammary Paget disease is an adenocarcinoma of the epidermis that can exist in numerous areas, including the penis, scrotum, bladder, vulva, perianal area, umbilicus, axilla, and conjunctiva. An underlying adnexal neoplasm is associated 1/2 the time with an increased risk of other malignancies. Generally considered an adenocarcinoma that occurs in apocrine gland areas of the body, the mammary type originates from lactiferous ducts and extends into epidermis. The anogenital type is usually slow growing and resembles dermatitis clinically, rarely involving the penile or scrotal skin. Often associated with underlying carcinoma such as bladder, prostate, and urethral cancers. Typically presents in the 60s or 70s with lesions that appear as crusted, indurated, erythematous to whitish patches. Histologically, the intraepithelial neoplastic cells contain mucin and are PAS positive. Differential diagnosis includes SCC in situ or malignant melanoma. The lesions originate from pluripotent cells in epidermis that formed apocrine glands and may also result from extracutaneous adenocarcinoma that spread into the epidermis. Excision of skin lesion and evaluation for underlying malignancy should be performed.

REFERENCE

Balducci L, Crawford ED, Smith GF, et al. Extramammary Paget's disease: An annotated review. *Cancer Invest.* 1988;6:293–303.

PAGET DISEASE, BONE

DESCRIPTION This condition affects up 10% of elderly individuals, with a 3:1 male-to-female ratio. Bone pain is the most common presenting symptom. Paget disease of the spine may also be a cause of low back pain. The disorder is due to increased bone remodeling, bone hypertrophy, and bone deformity of uncertain origin. Paget disease, also called *osteitis deformans,* is characterized by an initial phase of intense osteoclastic resorption, followed by an increase in bone formation, but the new skelet al tissues are deformed and prone to inducing pain and fracture. Approximately 1/3 of Paget disease cases have monostotic disease, with pelvic involvement in 72%. In these cases, the lumbar spine is involved in 58%, the thoracic spine in 45%, and the femur and skull in 55% and 42%, respectively. Patients' elevated alkaline phosphatase or bone pain may be due to Paget disease or other diseases, such as liver disease, renal disease, or metastatic prostate cancer. Radiographically, the localized enlargement of bone is a characteristic feature. Areas of lysis due to osteoclastic reabsorption can also be present. It can be confused with metastatic prostate cancer to bone. Suspect Paget disease over metastatic prostate cancer when there is widening of the bone, thickening of the cortex, and a prominent trabecular pattern. MRI of the bone may help in differentiating the processes.

TREATMENT

- Pain reduction and decreasing long-term complications are the main goals.
- Inhibitors of osteoclastic bone resorption, such as bisphosphonates (zoledronic acid, risedronate, alendronate) are now the treatment of choice. (See Section II: "Osteoporosis and Osteopenia, Urologic Considerations.") Calcitonin is reserved for those intolerant of bisphosphonates.

PAINFUL BLADDER SYNDROME (PBS)

DESCRIPTION The ICS defines PBS as suprapubic pain related to bladder filling, accompanied by other symptoms such as increased day- and night-time frequency, in the absence of proven urinary infection or other obvious pathology. According to the ICS, PBS differs from interstitial cystitis in that the latter has cystoscopic and histologic findings. Treatment begins with conservative measures including dietary modifications, behavioral changes, and nonprescription medications, followed by intravesical therapy and prescription medications. Patients who fail these therapies can move to more invasive therapies including hydrodistention, neuromodulation, and finally urinary diversion or augmentation.

REFERENCE

PALLIATIVE RADIATION, UROLOGIC CONSIDERATIONS

DESCRIPTION The symptoms of advanced urologic malignancies are often treated with palliative radiation. Approximately 1/2 of prescribed radiotherapy is given for palliation of symptoms from incurable cancer. For example, 90% of patients with symptomatic bone metastases, commonly seen in metastatic prostate cancer, obtain some pain relief with a low-dose, brief course of palliative radiotherapy. Bone metastases can also result in erosion of cortical bone and tumor invasion into the extradural space, which elicits edema within the spinal cord and compression of the neurologic structures. The degree of edema within the cord is directly related to the neurologic impairment. Spinal cord compression from malignancy requires early diagnosis and treatment with emergency radiotherapy to prevent irreversible neurologic injury. Radiation therapy has also been shown to relieve clinical symptoms in 70–90% of patients with brain metastases, sometimes seen in patients with metastatic RCC.

REFERENCE

Hoegler D. Radiotherapy for palliation of symptoms in incurable cancer. *Curr Probl Cancer.* 1997;21(3):129–183.

PANCREATITIS, AUTOIMMUNE UROLOGIC CONSIDERATIONS

DESCRIPTION Autoimmune pancreatitis (AIP) has been referred to by a variety of names including sclerosing pancreatitis, tumefactive pancreatitis, and nonalcoholic destructive pancreatitis. It is recognized to be an immunoglobulin G4-related disease (IgG4-RD). IgG4-related kidney disease can include tubulointerstitial nephritis and membranous glomerulonephritis.

REFERENCE

Khosroshahi A, Stone JH. A clinical overview of IgG4-related systemic disease. *Curr Opin Rheumatol.* 2011;23(1):57–66.

PANETH CELL-LIKE CHANGE, PROSTATE

DESCRIPTION Describes the observation of prostatic glandular epithelium with distinct eosinophilic intracytoplasmic granules resembling Paneth cells, found in crypts of Lieberkühn in the small intestine. These cells are thought to represent a morphologic similarity to Paneth cells, rather than true Paneth cell metaplasia of the prostatic epithelium, due to the presence of PSA and PAP on immunohisto-chemistry. These changes have been described in normal, hyperplastic, dysplastic, and malignant prostate tissue, and must be differentiated from other prostatic intracytoplasmic inclusions including secretory vacuoles, melanin, CMV viral inclusions, or virus-like particles.

REFERENCE

Weaver MG, Abdul-Karim FW, Srigley J, et al. Paneth cell-like change of the prostate gland. *Am J Surg Pathol.* 1992;16(1):62–68.

PAPILLARY UROTHELIAL NEOPLASM OF LOW MALIGNANT POTENTIAL (PUNLMP)

DESCRIPTION The World Health Organization defines PUNLMP as a papillary urothelial tumor that resembles an exophytic urothelial papilloma, but shows increased cellular proliferation exceeding the thickness of normal urothelium. They are typically small (1–2 cm) and have little, if any, cytologic atypia. Treatment and follow-up are the same as for low-grade noninvasive urothelial carcinoma. (See also Section II: “WHO/ISUP Classification of Urothelial Neoplasms” [1998 and 2004].) (Image ☼)

REFERENCE

Eble JN, et al. *World Health Organization Classification of Tumours: Pathology and Genetics of Tumours of the Urinary System and Male Genital Organs*. Lyon: IARC Press; 2004.

PAPILLOMA, BLADDER

DESCRIPTION A controversial diagnostic entity of the urinary bladder. The papillary lesion is small and unifocal, with a delicate fibrovascular stalk, and covered in cytologically and architecturally normal urothelium. Typically found in a younger age group than bladder cancer. Recurrences are common, and future development of invasive urothelial tumors of the

urinary tract occurs in <10%. Many consider the lesion to be a very low-grade bladder cancer (grade I TCC) with limited potential to progress. Others propose that the terms low- and high-grade papillary urothelial carcinoma be replaced by low- and high-grade papillary intraurothelial neoplasia for all noninvasive urothelial cancers. (See also Section II: "WHO/ISUP Classification of Urothelial Neoplasms" [1998 and 2004].) (Image)

SYNONYMS
- WHO grade I papillary urothelial carcinoma
- Urothelial papilloma

TREATMENT
- Transurethral surgical resection is the main modality, with no defined role for intravesical therapy.
- These patients must be followed, due to the possible increased risk of having a urothelial malignancy.

REFERENCE
Van der Kwast TH, Zlotta AR, Fleshner N, et al. Thirty-five years of noninvasive bladder carcinoma: A plea for the use of papillary intraurothelial neoplasia as new terminology. *Anal Quant Cytol Histol.* 2008;30(6):309–315.

PAPILLOMA, RENAL PELVIS

DESCRIPTION An extraordinarily rare urothelial lesion in the upper urinary tract. A papilloma is a small, delicate proliferation with a fibrovascular core lined by normal urothelium. By WHO criteria, this is considered a benign lesion.

REFERENCE
Eble JN, et al. *World Health Organization Classification of Tumours: Pathology and Genetics of Tumours of the Urinary System and Male Genital Organs*. Lyon: IARC Press, 2004.

PAPILLORENAL SYNDROME

DESCRIPTION Also called *renal coloboma,* this is an autosomal dominant disorder characterized by bilateral congenital optic disc anomalies and hypoplastic kidneys. It is associated with mutations in the PAX2 gene. Many patients suffer from renal failure due to renal hypoplasia or chronic pyelonephritis from vesicoureteral reflux.

REFERENCE
Nguyen D, Riordan-Eva P. Abnormal optic discs and renal failure: Papillorenal syndrome. *Acta Ophthalmol Scand.* 2006;84:823–824.

PAQUIN URETERAL REIMPLANTATION

DESCRIPTION This repair is done using combined extravesical ureteral mobilization and intravesical implantation. A submucosal plane is developed toward the trigone with tenotomy scissors, and the freshly spatulated ureter is reimplanted.

REFERENCE
Atala A, Keating MA. Vesicoureteral reflux and megaureter. In: Walsh PC, Retik AB, Vaughan ED, et al., eds. *Campbell's Urology*. 7th ed. Philadelphia, PA: Saunders, 1998:1882–1896.

PARAPHILIAS, UROLOGIC CONSIDERATIONS

DESCRIPTION Paraphilias are psychosocial conditions referring to abnormal sexual behavior. These may be encountered in daily urologic practice and are often referred for psychologic intervention. Different kinds of paraphilias, based on the Diagnostic and Statistical Manual of Mental Disorders, 4th ed, Text Revision (DSM-IV-TR) classification are noted in the accompanying table.

SYNONYM
Sexual Deviation

Paraphilia Designation	Description
Exhibitionism	Exposure of genital to unsuspecting strangers (not considered the same as public urination).
Fetishism	Use of nonliving objects as repeatedly preferred or exclusive method of sexual excitement (eg, leather goods, clothing, undergarments, fabrics, shoes). (If female clothing is used in cross-dressing or devices are used for genital stimulation [eg, vibrator] this is not considered as fetishism).
Frotteurism	Touching and rubbing against a nonconsenting person.
Pedophilia	Children are the sexual target (perpetrator is ≥16 yo and ≥5 than 5 years older than the prepubescent child).
Sexual masochism	Perpetrator receives the humiliation/suffering (practice can lead to death, especially during "hypoxyphilia" or sexual arousal during hypoxia).
Sexual sadism	Perpetrator inflicts the humiliation/suffering on another.
Transvestic fetishism	Wearing clothing of the other sex for sexual arousal.
Voyeurism	Observing sexual activity or naked/disrobing individuals.
Paraphilias Not Otherwise Specified	Paraphilias that do not meet criteria for a specific DSM category such as telephone scatologia or coprolalia (obscene phone calls), necrophilia (corpses), partialism [exclusive focus on part of body], zoophilia [animals], coprophilia [feces], klismaphilia [enemas], and urophilia [urine]).

REFERENCE
American Psychiatric Association. *Diagnostic and Statistical Manual of Mental Disorders*. 4th ed. Text Revision (DSM-IV-TR) Arlington VA (2000).

PARASTOMAL HERNIA

DESCRIPTION A parastomal hernia is an incisional hernia related to an abdominal wall stoma. In urologic surgery, parastomal hernias occur infrequently (<5% of cases) and are more likely to arise in loop-type stomas than in end-type stomas. To prevent parastomal herniation, it is recommended that the stoma be placed through the rectus muscle and that the opening in the abdominal wall not be too large. In addition, some have placed mesh at the time of stoma creation to prevent hernia formation. Repair of a parastomal hernia follows the same principles as treating other types of incisional hernias and can be completed in an open or laparoscopic fashion, with or without mesh. (See also Section I: "Urostomy Problems.")

REFERENCE

Israelsson LA. Parastomal hernias. *Surg Clin N Am.* 2008;88:113–125.

PARATESTICULAR RHABDOMYOSARCOMA

DESCRIPTION Rhabdomyosarcoma is the most common spermatic cord sarcoma, arising from the mesenchymal elements of the paratesticular tissues and representing 40% of all paratesticular malignancies and 5% of all testicular and paratesticular malignancies. There is a bimodal age distribution, with peaks at 3–4 mo and yr. Patients present with a painless firm mass which can be a wide range of sizes. Roughly 40% have metastases at presentation. Ultrasounds reveals a heterogeneous mass. CT scan of the abdomen and pelvis, liver function tests, bone scan, and chest x-ray are required for staging. Several histologic patterns are described, with almost all being embryonal. After treatment, cross-sectional imaging and liver function tests are needed every 2–3 mo. (See also Section I: "Tunica Albuginea/Paratesticular Tumors and Cysts.")

TREATMENT

- Radical orchiectomy
- Boys 10 yr or older or those with evidence of retroperitoneal disease should undergo retroperitoneal lymph node dissection (RPLND)
- Those with evidence of lymphatic spread should undergo radiotherapy and multiagent chemotherapy

REFERENCE

PARAURETHRAL AND VAGINAL WALL MASSES

DESCRIPTION Paraurethral masses can be benign (urethral caruncles, Skene's gland abscess/cysts, mucosal prolapsed, ectopic ureterocele, urethral diverticulum, vaginal wall cyst, Gartner's duct cyst, leiomyoma, and hamartoma) or malignant (adenocarcinoma, SCC, TCC, histiocytoma, and sarcoma) and treatment varies upon the etiology of the lesion. The most common paraurethral mass is the urethral diverticulum, followed by the leiomyoma and the vaginal wall cyst. Masses may be asymptomatic or may cause pain and voiding

dysfunction. VCUG, MRI, CT, and double-balloon retrograde urography all have a high detection rate for urethral diverticula. Videourodynamics and cystoscopy are useful tools, particularly for masses causing voiding dysfunction. Physical exam may help distinguish benign from malignant conditions. Urethral malignancies do not normally present as paraurethral masses, but more commonly with complaints of bleeding and discharge.

PARTIN TABLES

DESCRIPTION Nomograms for patients with biopsy-proven prostate cancer, developed by Dr. Partin and associates at Johns Hopkins University, these charts incorporate PSA, TNM stage, and Gleason score. They are used to predict rate of lymph node and distant spread or whether patients have organ-confined cancer, and to aid in making accurate treatment decisions. The tables have been updated several times, using larger patient cohorts. Information is available online: http://urology.jhu.edu/prostate/partintables.php, Accessed March 3, 2014.

REFERENCE

Eifler JB, Feng Z, Lin BM, et al. An updated prostate cancer staging nomogram (Partin tables) based on cases from 2006 to 2011. *BJU Int.* 2013;111(1):22–29. Erratum in: *BJU Int.* 2013;111(3):524.

PATAU SYNDROME

DESCRIPTION This rare syndrome is associated with trisomy 13 and has a median survival of 3 mo. The incidence is 1 in 6,000 live births and is associated with multiple cardiac, neurologic, and renal abnormalities. Renal anomalies occur in about 80% of children. Unilateral renal agenesis, renal duplication, hydronephrosis, and polycystic kidneys have been associated with Patau syndrome.

REFERENCE

Martlew RA, Sharples A. Anesthesia in a child with Patau's syndrome. *Anesthesia.* 1995;50:980.

PATIENT PERCEPTION OF BLADDER CONDITION (PPBC)

DESCRIPTION The Patient Perception of Bladder Condition (PPBC) is a questionnaire that attempts to obtain a global assessment of the patient's bladder condition. It has been validated and shown to be responsive to changes. It has been translated into many languages and is widely available for use.

Which of the following statements describes your bladder condition best at the moment? Please mark X in 1 box only.
• My bladder condition does not cause me any problems at all. (1 pt)
• My bladder condition causes me some very minor problems. (2 pt)
• My bladder condition causes me some minor problems. (3 pt)
• My bladder condition causes me (some) moderate problems. (4 pt)
• My bladder condition causes me severe problems. (5 pt)
• My bladder condition causes me many severe problems. (6 pt)

REFERENCE

Coyne KS, Matza LS, Kopp Z, et al. The validation of the patient perception of bladder condition (PPBC): A single-item global measure for patients with overactive bladder. *Eur Urol*. 2006;49:1079–1086.

PATIENT PERCEPTION OF INTENSITY OF URGENCY SCALE (PPIUS)

DESCRIPTION A single-question tool to assess the patient's perception of the degree of urgency. PPIUS as a reliable measure of urgency in both clinical trials and real life settings. The question is as follows:

Patient Perception of Intensity of Urgency Scale	
0.	No urgency: I felt no need to empty my bladder but did so for other reasons.
1.	Mild urgency: I could postpone voiding as long as necessary without fear of wetting myself.
2.	Moderate urgency: I could postpone voiding for a short while without fear of wetting myself.
3.	Severe urgency: I could not postpone voiding but had to rush to the toilet in order not to wet myself.
4.	Urge incontinence: I leaked before arriving at the toilet.

REFERENCE

Notte S, Marshall TS, Lee M, et al. Content validity and test-retest reliability of patient perception of intensity of urgency scale (PPIUS) for overactive bladder. *BMC Urology*. 2012;12:26.

PCA3 (PROSTATE CANCER GENE 3 URINE ASSAY)

DESCRIPTION Prostate cancer antigen 3 (PCA3) is a gene that expresses a noncoding RNA. PCA3 is over expressed in 95% of prostate cancers and is upregulated 66-fold in cancerous tissue as compared to normal tissue. No other human tissues have yet been shown to produce PCA3. While serum PSA levels are known to be influenced by volume of BPH tissue, age, inflammation, trauma, and use of 5α-reductase inhibitors (finasteride, dutasteride), preliminary data indicate that these factors do not appear to influence PCA3 scores. Urine samples are collected after an "attentive" digital rectal exam (3 sweeps on each side of the prostate). 1st voided urine is then collected and sent to labs for analysis. PCA3 and PSA can

be detected in the urine utilizing reverse transcriptase PCR techniques on the collected cells. PCA3 expression is denoted against a background of prostate-specific genetic material, a PCA3 score (ie, a ratio of PCA3 to PSA mRNA). Studies have shown excellent specificity and sensitivity in men undergoing confirmatory prostate biopsy, and its role in the diagnosis of prostate cancer is currently evolving. A useful role of the new marker appears to be in men with persistently elevated serum PSA levels, but a negative initial biopsy.

PCA3/PSA mRNA Ratio vs. Serum PSA in Men with Previous Negative Biopsy

	Serum PSA	PCA3 Assay
Cut Point	4.0 ng/mL	PCA3/PSA = 35×10^{-3}
Sensitivity	83%	58%
Specificity	17%	74%
Odds Ratio of a Positive Rebiopsy	1.2	3.6

The Evaluation of Genomic Applications in Practice and Prevention (EGAPP) Working Group in 2013 found insufficient evidence to recommend PCA3 testing to inform decisions for when to rebiopsy previously biopsy-negative patients for prostate cancer or to inform decisions to conduct initial biopsies for prostate cancer in at-risk men. (See Also Section II: "Attentive Digital Rectal Exam (DRE)," "TMPRSS2-ERG Gene Fusion, Prostate Cancer," "Attentive Digital Rectal Exam Image." ☼)

PEARLY PAPULES OF PENIS

DESCRIPTION These are normal anatomic structures located on the proximal glans penis or corona. They appear as minute, dome-shaped, flesh-colored papules. The incidence is 19–30%. These lesions are asymptomatic and can be confused with genital warts. Histologically, these papules are angio-fibromas. No treatment is usually needed. Although these lesions represent a benign condition, psychological and cosmetic concerns often prompt patients to seek therapeutic removal. Multiple therapeutic modalities have been reported; however, use of CO_2 laser has proven to be the most effective to date.

PEDIATRIC-MODIFIED RISK INJURY FAILURE LOSS END-STAGE RENAL DISEASE (pRIFLE)

DESCRIPTION Acute kidney injury (AKI) is defined as a decrease in GFR, manifested by an elevated or rising creatinine. However, serum creatinine is often a delayed and imprecise test as it reflects GFR in individuals at steady state with stable kidney function, and may not estimate the GFR in a patient whose renal function is changing. Recognizing a need for a consensus definition of AKI called the RIFLE classification of AKI based on changes in creatinine and urine output were developed. The RIFLE criteria consists of 3 graded levels of injury (Risk, Injury, and Failure) based upon either the magnitude of elevation in serum creatinine or urine output, and 2 outcome measures (Loss and End-stage renal disease). This is a pediatric modification of the adult RIFLE classification (see table). The use of pRIFLE has been strongly advocated as a research and clinical tool. AKI defined by the pRIFLE criteria has been shown as an independent risk factor for mortality and morbidity. (See also Section I: "Acute Kidney Injury, Pediatric [Renal Failure, Acute].")

REFERENCE

Akcan-Arikan A, Zappitelli M, Loftis LL, et al. Modified RIFLE criteria in critically ill children with acute kidney injury. *Kidney Int.* 2007;71(10):1028–1035.

Pediatric Rifle (pRIFLE) Classification of Acute Kidney Injury

pRIFLE Stage	Estimated Creatinine Clearance (eCCl)	Urine Output
R = Risk for renal dysfunction	eCCl decreased by 25%	<0.5 mL/kg/h for 8 hr
I = Injury to the kidney	eCCl decreased by 50%	<0.5 mL/kg/h for 16 hr
F = Failure of kidney function	eCCl decreased by 75% or eCCl <35 mL/min/1.73 m^2	<0.3 mL/kg/h for 24 hr or anuria for 12 hr
L = Loss of kidney function	Persistent failure >4 wk	
E = End-stage renal disease	Persistent failure >3 mo

PEDICULOSIS PUBIS (CRAB LICE/PUBIC LICE)

DESCRIPTION Ectoparasitic infection (*Phthirus pubis*), marked by severe pruritus and tending to have an incubation period of ~4 wk. Signs include observation of the lice, 1–2 mm long gray-brown organisms, on the skin or on the hair shafts or the presence of "nits" (egg stage) on the hair shaft. The recommended regimens should not be applied to the eyes. Pediculosis of the eyelashes should be treated by applying occlusive ophthalmic ointment to the eyelid margins twice a day for 10 days. Bedding and clothing should be decontaminated (ie, either dry cleaned or machine-washed and dried using the heat cycle) or removed from body contact for at least 72 hr. Fumigation of living areas is not necessary. Nits need to be mechanically removed with a fine-toothed comb. Patients with pediculosis pubis should be

evaluated for other STI/STDs. Patients should be evaluated after 1 wk if symptoms persist. Retreatment might be necessary if lice are found or if eggs are observed at the hair-skin junction. Patients who do not respond to 1 of the recommended regimens should be retreated with an alternative regimen. Sex partners that have had sexual contact with the patient within the previous month should be treated. (See also Section I: "Sexually Transmitted Infections [STI] (Sexually Transmitted Diseases [STD]), general.")

TREATMENT

- CDC-recommended regimens: Permethrin 1% cream rinse applied to affected areas and washed off after 10 min OR Pyrethrins with piperonyl butoxide applied to the affected area and washed off after 10 min
- CDC Alternative Regimens: Malathion 0.5% lotion applied for 8–12 hr and washed off OR Ivermectin 250 μg/kg orally, repeated in 2 wk

REFERENCE

Centers for Disease Control and Prevention. Sexually Transmitted Diseases Treatment Guidelines, 2010. *MMWR*. 2010;59(No. RR-12).

PELIOSIS HEPATIS

DESCRIPTION Peliosis hepatis is a condition in which liver and splenic tissue is replaced with blood-filled cysts. This has been reported in patients receiving androgenic anabolic steroid therapy and other conditions. These cysts are sometimes present with hepatic dysfunction, or may be associated with liver failure. Can be easily confused with malignancy on imaging studies. Cysts are often not recognized until life-threatening liver failure or intra-abdominal hemorrhage develops. Withdrawal of drug usually results in complete disappearance of lesions.

REFERENCE

Neri M, Bello S, Bonsignore A, et al. Anabolic androgenic steroids abuse and liver toxicity. *Mini Rev Med Chem*. 2011;11(5):430–437. Review.

PELVIC FLOOR DYSFUNCTION

DESCRIPTION Pelvic floor dysfunction represents a constellation of symptoms that include lower urinary tract, bowel, sexual, and other local symptoms, including pelvic organ prolapse. These conditions are all associated with damage to the pelvic floor through disruption of the connective tissues or by primary or secondary neuropathy and myopathy. Many predisposing, inciting, and promoting factors can lead to pelvic floor dysfunction. Treatments range from conservative/behavioral therapies, to medications and surgical interventions.

REFERENCE

Bump RC, Norton PA. Epidemiology and natural history of pelvic floor dysfunction. *Obstet Gynecol Clin*. 1998;25:723–746.

PELVIC FRACTURE, UROLOGIC CONSIDERATIONS

DESCRIPTION Pelvic fractures can result in bladder and urethral injury. The length and tethered anatomy of the male urethra makes it more vulnerable to injury. Blood at the urethral meatus is the cardinal sign of urologic injury. For patients suspected of having a urethral injury, a retrograde urethrogram should be performed prior to insertion of a Foley catheter. This should be followed by a cystogram. Depending on the location and extent of trauma, several options exist for treatment including drainage of the bladder with a Foley catheter or suprapubic cystotomy, primary repair of the injury, or delayed repair after stabilization. (See also Section I: "Urethra, Trauma [Anterior AND Posterior].")

REFERENCE

Cass AS. The multiple injured patient with bladder trauma. *J Trauma.* 1984;24:731.

PELVIC LIPOSARCOMA

DESCRIPTION Liposarcoma can present as a tumor of the spermatic cord or as a paratesticular tumor. Treatment includes inguinal orchiectomy with high ligation of the cord; adjuvant treatment is controversial but could include postoperative radiotherapy. Chemotherapy options are limited. (See also Section I: "Tunica Albuginea/Paratesticular Tumors and Cysts.")

REFERENCE

Richie JP, Steele GS. Neoplasms of the testis. In: Wein AJ, Kavoussi LR, Novick AC, et al., eds. *Campbell-Walsh Urology.* 9th ed. Philadelphia, pa: Saunders Elsevier; 2007.

PELVIC ORGAN PROLAPSE QUANTIFICATION SYSTEM (POP-Q)

DESCRIPTION A quantitative description of pelvic support using the hymenal ring as the reference point. Negative numbers are assigned to structures that have not prolapsed beyond the hymen, and positive numbers to those that are protruding. 3 reference points are defined anteriorly and 3 points posteriorly. Once the measurements are complete, the patient is assigned to 1 of 4 stages as noted below. (See also Section I: "Pelvic Organ Prolapse (Cystocele and Enterocele)" and Section II: "Cystocele Grading: Baden–Walker, Pelvic Organ Prolapse Quantification (POP-Q).")

POP-Q Grading System

Stage	Degree of Prolapse
0	No prolapse demonstrated
I	The most distal portion of the prolapse is >1 cm above the level of the hymen
II	The most distal portion of the prolapse is ≤1 cm proximal or distal to the hymenal plane
III	The most distal portion of the prolapse protrudes >1 cm below the hymen but protrudes no farther than 2 cm less than the total vaginal length
IV	Complete vaginal eversion

This classification system exhibits excellent reliability, but it is more cumbersome to use than other systems and patient positioning can alter the results. (See also Section I: "Pelvic Prolapse, Cystocele and Enterocele.")

REFERENCE

PELVIC PAIN AND URGENCY/FREQUENCY (PUF) PATIENT SYMPTOM SCALE

DESCRIPTION Instrument for the evaluation and treatment of patients with Interstitial cystitis (IC)/Painful Bladder syndrome (PBS).

REFERENCE

Parsons CL, Dell J, Stanford EJ, et al. Increased prevalence of interstitial cystitis: previously unrecognized urologic and gynecologic cases identified using a new symptom questionnaire and intravesical potassium sensitivity. *Urology*. 2002;60(4):573–578.

PELVIC PAIN, MALE

See Section I: “Prostatitis, Chronic Nonbacterial, Noninflammatory (NIH CP/CPPS III A and B).”

PELVIS, BIFID, RENAL

DESCRIPTION A normal variant seen in ~10% of patients in which the renal pelvis is divided into 2 major calyces just inside the kidney. (See Pelvis, bifid, renal image ☼)

REFERENCE

Dähnert W. *Radiology Review Manual.* 6th ed. Philadelphia, PA: Lippincott Williams & Wilkins, 2007.

PELVIS, EXTRARENAL

DESCRIPTION Most often a normal anatomic variant and can be mistaken for a pathologic condition (hydronephrosis, parapelvic, or renal cyst, etc.). Calyces are normal appearing on imaging with an unobstructed extrarenal pelvis but will be dilated with hydronephrosis. The extrarenal pelvis can also be associated with conditions such as renal malrotation or ectopic kidney and rarely may cause urinary stasis and difficulties with infection and stones.

REFERENCE

Kidneys. In: Dalrymple NC, et al., eds. *Problem Solving in Abdominal Imaging.* Philadelphia, PA: Elsevier; 2009.

PEMPHIGUS FOLIACEUS AND VULGARIS

DESCRIPTION Pemphigus foliaceus and vulgaris refer to a group of rare autoimmune intraepidermal blistering diseases involving the skin and mucous membranes. The difference between pemphigus foliaceus and vulgaris involves the level of epidermis at which loss of cell–cell cohesion occurs. Almost all patients will have painful oral mucosal erosions and 50% may have cutaneous blisters involving the genitalia. The diagnosis is confirmed by light

microscopy and immunofluorescence. Pemphigus carries a high mortality rate of 10% from sepsis as a result of skin breakdown and treatment-associated side effects.

TREATMENT

- Topical steroids (eg, clobetasol propionate 0.05% cream [mild cases])
- Glucocorticoids (prednisone) and immunosuppressants (cyclophosphamide, azathioprine, and IV immunoglobulin) for severe cases

REFERENCE

Habif TP. Vesicular and bullous diseases. In: Habif TP, ed. *Clinical Dermatology*. 4th ed. Philadelphia, PA: Mosby; 2004.

PENILE AND CORPORAL BODY MASS

DESCRIPTION Penile masses are relatively rare lesions. Benign solid tumors of the penis include angioma, fibroma, lipoma, and myoma, as well as other dermatologic lesions. Abscesses and granulomas should be included in the differential. Malignant tumors of the penis are more often seen in adults and include squamous cell carcinoma (SCC), melanoma, and soft tissue sarcoma. Cystic lesions are usually periurethral gland and retention cysts due to sebaceous glands in the skin. For malignant lesions, wide excision is recommended. (See also Section II: “Penis, Mass [Noncutaneous].”)

REFERENCE

Kocakoc E, Kazez A, Dagli AF, et al. Postcircumcision granuloma: A rare cause of a penile mass in a boy. *J US Med.* 2006;25(12):1611–1613.

PENILE BRACHIAL PRESSURE INDEX (PBI)

DESCRIPTION The PBI can be defined as the penile systolic BP divided by the brachial systolic BP. A penile brachial index of ≤ 0.7 has been suggested to indicate arteriogenic impotence. However, due to several limitations, this test is considered an unreliable tool to exclude arteriogenic impotence.

REFERENCE

Metz P, Bengtsson J. Penile blood pressure. *Scand J Urol Nephrol.* 1981;15:161.

PENILE DOPPLER ULTRASOUND INDICATIONS AND PARAMETERS

DESCRIPTION This type of minimally invasive vasculogenic imaging is used for men with ED who have a potentially surgically treatable cause (eg, younger men who may have suffered traumatic straddle injuries and do not respond to oral or intracavernosal therapy). Penile Doppler US is used for evaluation of penile blood flow and requires intracavernous injection of vasodilators. Peak systolic velocity (PSV) in healthy individuals varies from 35–47 cm/s. A PSV <25 cm/s has a sensitivity of 100% and specificity of 95% in patients with abnormal pudendal arteriography. Patients with severe ED will have a cavernous artery luminal diameter <0.7 mm and an increase of $<75\%$ in diameter post-injection. Patients with veno-occlusive dysfunction will exhibit good PSV (>25 cm/s) and have persistent end

diastolic flow velocity of >5 cm/s with quick detumescence after stimulation. A resistive index calculation (RI = PSV – EDV/PSV) >0.9 (where EDV is end diastolic velocity) usually indicates no evidence of veno-occlusive dysfunction, whereas an RI of <0.75 was associated with venous leakage in 95% of cases.

REFERENCE

PENILE ENHANCEMENT AND LENGTHENING

DESCRIPTION Penile lengthening can be accomplished by release of the suspensory ligament of the penis and the use of penile weights. Increased girth can be obtained by the use of circumferential dermal fat grafts. There are reports of significant complications from lengthening and girth procedures including scarring, skin deformities, irregular fat nodules, scrotalization of the penis, and ED.

REFERENCE

Van Driel MF, Schultz WC, Van de Wiel HB, et al. Surgical lengthening of the penis. *Br J Urol.* 1998;82(1):81–85.

PENILE INTRAEPITHELIAL NEOPLASIA

DESCRIPTION Penile intraepithelial neoplasia is squamous cell carcinoma in situ and encompasses 3 clinical entities: Bowenoid papulosis (BP), erythroplasia of Queyrat (EQ), and Bowen Disease (BD), which vary in their epidemiology, clinical presentation, and malignant potential. BP is seen in young men and occurs on the penile shaft, but can also be seen on the glans or prepuce. Lesions are multiple, small, well-demarcated papules with a relatively benign course. EQ occurs in older uncircumcised men with plaques that are solitary, sharply defined, velvety, and red with malignant transformation in 10–33% of cases. While EQ refers to lesions of the mucocutaneous epithelium, BD refers to penile intraepithelial neoplasia on the follicle-bearing skin of the penis. BD is seen more commonly in elderly men and typically appears as a single, red, sharply defined plaque that can have areas of oozing or crusting and undergoes malignant transformation in approximately 5% of cases.

Brady KL, Mercurio MG, Brown MD. Malignant tumors of the penis. *Dermatol Surg.* 2013;39(4):527–547.

PENILE NECROSIS (GANGRENE) NON-FOURNIER GANGRENE

DESCRIPTION Penile gangrene is a rare, but serious consequence following infection or ischemic injury. Vascular compromise may be caused by tourniquet syndrome, priapism, venous thrombosis, anticoagulants, and can be seen in diabetics with ESRD. Color Doppler ultrasonography can provide important information regarding thrombosis or rupture of cavernosal and dorsal penile vessels. Treatment involves correction of the underlying etiology and debridement of the nonviable tissue.

REFERENCE
Sabharwal S, Banerji JS, Kekre NS. Penile skin necrosis mimicking penile gangrene: an unusual case. *Urol J.* 2013; 10(1):755.

PENILE PAIN SYNDROME

DESCRIPTION In contrast to other chronic pain syndromes of reproductive organs, chronic penile pain seems to be extremely rare. Penile pain can be understood by etiology, which includes *local conditions* such as dermatitis, infection, and ischemia; *referred pain* from bladder, prostate, lower back, and hips; *neuropathic pain* resulting from injury to dorsal nerve, pudendal nerve, or cauda equina; and *psychiatric conditions* that may lead to extreme hypersensitivity and allodynia. Persistent pain can be treated by treating the underlying disease (paraphimosis, priapism, Peyronie disease, herpes). 1 case in the literature described a patient with episodic penile pain attacks and an inguinal hernia whose pain resolved after herniorrhaphy. His pain was likely due to the irritation of the ilioinguinal nerve in the inguinal canal, which also supplies the ventral base of the penis. In psychosomatic pain, analgesics may be helpful; however tricyclic antidepressants or anticonvulsants have also proven effective.

REFERENCE
Baranowski AP, Abrams P, Fall M. *Urogenital Pain in Clinical Practice.* Boca Raton, FL: CRC Press, 2007:248–252.

PENILE PROSTHESIS, MODELS AND DESCRIPTIONS

DESCRIPTION The earliest attempts of implantable devices began in the 1930s with the 1st viable and widespread adoption of the Carrian intracorporal silicone-based prosthesis in the 1970s. A variety of commercial implantable penile prosthesis are available with the majority used inflatable units. Self-contained inflatable units are no longer manufactured. They are in 3 categories: Semi-rigid, 2-piece, and 3-piece inflatable (see table) (Image ☼).

Prosthesis Type	American Medical Systems	Mentor Corporation	Description	Advantages	Disadvantages
Semi-rigid	AMS Malleable 600 AMS Malleable 650	Acu-form	Malleable core rods that can be bent up and down	Low mechanical failure rate, easy to insert	Constant penile rigidity, increased risk of penile erosion
2-piece inflatable	Ambicor		2 cylinders connected to a small scrotal pump	Easy to insert	Increased risk of mechanical failure
3-piece inflatable	AMS 700 CX AMS 700 CXM AMS 700 CXR (65 mL reservoir) AMS 700 Ultrex	Alpha I Titan Titan Narrow Base	2 cylinders, large abdominal fluid reservoir, and scrotal pump	Penile girth and rigidity most similar to normal erection As above; increased penile length	Highest risk of mechanical failure, technically more difficult, risk of autoinflation with physical activity

[a] Commonly used systems as of March 2014.

(Accessed April 17, 2014)

PENILE REHABILITATION

DESCRIPTION Erectile dysfunction (ED following radical prostatectomy (RP) is believed to include neuropraxia, which results in temporarily reduced oxygenation and subsequent structural changes in penile tissue. Penile rehabilitation management of this veno-occlusive dysfunction has focused on tissue oxygenation. Cavernosal hypoxia, resultant fibrosis, and venous leak are hypothesized as the predominant mechanisms for postprostatectomy ED. While animal studies support the use of phosphodiesterase type 5 inhibitors (PDE5Is) in the setting of cavernous nerve damage but results from human studies are contradictory. Penile rehabilitation has been classically defined as the use of a device or pharmacologic agent to aid erectile function recovery after RP. A scheduled regimen of early pharmacologic (PDE5 inhibitors, prostaglandins) therapy, nonpharmacologic (vacuum erection devices) therapy, or a combination thereof immediately following RP is thought to increase potency rates and help maintain penile length and girth. PDE5 inhibitors may help with maintaining penile length. (See Section II: “Penile Shortening.”) The largest study to date found no long-term effect of either daily or on-demand PDE5I use after RP compared with placebo and the utility of prostaglandin and vacuum erection devices are questionable and high-quality studies are lacking.

PENILE SHORTENING

DESCRIPTION Penile shortening may occur congenitally in patients with bladder exstrophy and more commonly after radical prostatectomy (RP) and penile revascularization. Patients with bladder exstrophy have penile shortening because of diastasis of the pubic symphysis and short corporal lengths (<50% the size of controls). More commonly, patients may have shortening of the penis following RP because of unopposed sympathetic stimulation of the penis, fibrosis resulting from hypoxia (as a consequence of denervation), or possibly as a result of retraction of the penile structures into the pelvis. Treatment of Peyronie disease may result in minor penile shortening. Arterial revascularization surgery for vascular ED may result in penile shortening in 20% of patients as a result of scar formation.

In a prospective study of stretched flaccid penile length changes after RP, there was evidence of stretched flaccid penile length loss at 2 mo, but not at 6 mo after RP. PDE5 inhibitors use moderated stretched flaccid penile length loss, with patients who regularly used PDE5 inhibitors having no loss in stretched flaccid penile length.

radical prostatectomy. *BJU Int.* 2013;113(5b):E131–e136. doi: 10.1111/bju.12443 [Epub ahead of print].

PENILE SKIN BRIDGES (PENILE BANDS)

DESCRIPTION Penile skin bridges are a rare complication of neonatal circumcision. They are caused by skin adhesions that occur during childhood. With aging, the adhesions separate partially at the corona to form skin bridges. Treatment involves surgical excision with attachment of the skin edges to the distal penile shaft proximally and the glans distally. Careful surgical technique and proper dressing at the time of initial circumcision are simple procedures that may help prevent adherence of the distal preputial skin flap to the glans penis.

REFERENCE

Kamal BA. Penile skin bridges: causes and prevention. *Int Surg.* 2009;94(1):35–37.

PENILE, MASS (NONCUTANEOUS)

DESCRIPTION Penile soft tissue tumors are rare and comprise approximately 5% of penile tumors and most have been reported as isolated case reports. These tumors can be classified as benign or malignant, superficial or deep, and in terms of age at presentation. The most common benign soft tissue tumors are vascular neoplasms, followed by tumors of neural, myoid, and fibrous origin. The most commonly reported malignant soft tissue tumors are Kaposi sarcoma and leiomyosarcoma. Correct diagnosis of these tumors, by considering clinical information, histopathologic findings, and immunohistochemical stains, is important because their behavior and clinical management vary considerably. (See also Section II: “Penile and Corporal Body Mass.”)

PENIS, AGENESIS (APHALLIA)

DESCRIPTION Penile agenesis is a rare anomaly with an estimated incidence of about 1 in 10 million live births. Most cases have a 46, XY karyotype. The usual appearance is that of a well-developed scrotum with descended testes and an absent penile shaft. Associated anomalies are common. Associated urethral absence is usually accompanied by fatal anomalies. Immediate investigations for associated anomalies and karyotype are essential. Caused by failure of development of the genital tubercle, surgical reconstruction/gender reassignment is recommended in the newborn.

REFERENCE

Oesch IL, Pinter A, Ransley PG. Penile agenesis: A report of six cases. *J Pediatr Surg.* 1987;2:172–174.

PENIS, ANGIOSARCOMA

DESCRIPTION Approximately 32 cases of penile angiosarcoma have been reported. No site of predilection is demonstrated, and the tumor may be well circumscribed or diffuse. Death may occur 1 wk to 5 yr after presentation (mean: 13 mo). The application of immunoperoxidase staining for factor VIII, present in normal endothelial cells, aids in diagnosis.

TREATMENT

- Local excision with lymph node dissection
- Local radiotherapy
- Systemic chemotherapy with more widespread tumor

REFERENCE

Wu X, Chen Z, Ji H, et al. Angiosarcoma of the penis: a case report and literature review. *Int Urol Nephrol.* 2012;44(5):1341–1343.

PENIS, ARTIFICIAL NODULES (TANCHO NODULES, BULLETUS, FANG MUK, CHAGAN BALLS)

DESCRIPTION Tancho nodules are spherical foreign objects, in the form of beads, implanted in the subcutaneous tissue of the shaft of the penis proximal to the glans. They are placed to allegedly enhance the sexual pleasure of females during sexual intercourse. It is a practice common in southeast Asia, especially Thailand. However, non-Asian groups in Romania, Russia, and Middle East have adopted this practice as well. The incidence and severity of early or delayed complications are unknown but are probably underreported.

PENIS, BASAL CELL CARCINOMA

DESCRIPTION Basal cell carcinoma is a common cutaneous malignancy, but is very rare at the penis. Ultraviolet radiation is an important risk factor. Basal cell carcinoma of the penis most likely presents in the 5th–7th decades of life. The natural history is that of a slowly growing tumor with little propensity to metastasize. Lesions are successfully treated with simple local excision. (See also Section I: “Penis, Lesion, General.”)

PENIS, BOWENOID PAPULOSIS

DESCRIPTION Bowenoid papulosis of the penis are benign lesions that appear as rounded, reddish, single, or multiple papules on the glans or shaft of penis, although they can occur anywhere on the external genitalia or perianal regions of both male and females. These papules typically occur in sexually active patients who are 20–35 yr of age. They are caused by HPV and maybe confused with carcinoma in situ (CIS) of the penis. Histologically, these lesions show parakeratosis and acanthosis in squamous epithelium with disorganization of the epithelial cells. They can be distinguished from CIS by possessing less mitotic figures and cellular dysplasia. Treatment is local destruction, including superficial excision, laser surgery, and use of topical retinoic acid, podophyllum resin, and topical 5-fluorouracil. The recurrence rate is 20%.

REFERENCE

Bhojwani A, Biyani CS, Nicol A, et al. Bowenoid papulosis of the penis. *Br J Urol.* 2003;80(3):508.

PENIS, BURIED (CONCEALED/HIDDEN/TRAPPED)

DESCRIPTION This condition must be differentiated from an abnormally small penis. A buried or concealed penis refers to a normal-sized penis that is hidden because of the prepubic fat pad. Congenital causes or obesity can hide the penile shaft. The penis can usually be exposed by retracting skin lateral to the penile shaft. The iatrogenic hidden penis after circumcision is more properly called a *trapped penis*. Children who undergo neonatal circumcision with testicular swelling or with a hernia or a webbed penis are at risk for excess penile shaft skin loss and a trapped penis. Congenital buried penis is a spectrum characterized by a longer inner prepuce and may include in addition; short penile shaft, abnormal attachment of fundiform, and suspensory ligaments and excess supra-pubic fat. Congenital mega prepuce (CMP) is a variant. Theoretically, obese adults who undergo circumcision are also at risk for removal of excess shaft skin. Symptoms can sometimes be associated (balanitis, UTI, painful voiding, ballooning of the foreskin, and urinary retention) with the condition.

SYNONYM

Inconspicuous penis (general term for buried, trapped, or webbed penis)

TREATMENT

- Surgical correction is optional and controversial.
- Liposuction has been used in cases of extreme obesity.

REFERENCES

Donatucci CF, Ritter EF. Management of the buried penis in adults. *J Urol.* 1998;159(2):420–424.

Hadidi AT. Buried penis: Classification surgical approach. *J Pediatr Surg.* 2014;49(2):374–379. doi: 10.1016/j.jpedsurg.2013.09.066. Epub 2013 Nov 7.

PENIS, CUTANEOUS HORN

DESCRIPTION Cutaneous horn is a clinical diagnosis referring to a conical projection above the skin that resembles a miniature horn. The lesions usually arise in sun-exposed skin and are benign. Penile cutaneous horn is rare and is characterized by overgrowth of epithelium above a lesion that may be a wart, nevus, or tumor. It is important to note that the incidence of SCC is 33% when penile horn is present. Treatment is surgical excision with a margin of tissue at base. Careful histologic evaluation of the base and close clinical follow-up of the excision site are highly recommended.

REFERENCE

Vera-Donoso CD, Lujan S, Gomez L, et al. Cutaneous horn in glans penis: A new clinical case. *Scand J Urol Nephrol.* 2009;43(1):92–93.

PENIS, CYSTS

DESCRIPTION Epidermal cysts found on the ventral surfaces of the penis have been attributed to defective embryologic closure of the median raphe, anomalous developmental rests of the periurethral glands of Littré, development of apocrine cystadenomas ectopically, and anomalous budding and separation of urethral columnar epithelium from the urethra. Penile cysts are commonly found lying just beneath the median raphe and are most likely derived from urethral columnar epithelium. Patients are most often asymptomatic.

TREATMENT

Surgical excision

REFERENCE

Paslin D. Urethroid cysts. *Arch Dermatol.* 1983;119(1): 89–90.

PENIS, DUPLICATION (DIPHALLUS)

DESCRIPTION This is an extremely rare anomaly, with an incidence of 1 in 5–6 million births. According to Aleem's classification, the condition may be true diphallia (complete or partial), or bifid phallus (complete or partial bifid glans or bifid penis). Usually, the penises are unequal in size and lie side by side. Associated anomalies are frequent. Ultrasound may help in differentiating true complete diphallia (2 corpora cavernous in each penis) from complete bifid phallus (only 1 corpus cavernous in each penis). The condition is caused by a failure of fusion of paired mesodermal anlagen of the genital tubercle and treated by surgical reconstruction.

REFERENCE

Aleem AA. Diphallia: Report of a case. *J Urol.* 1972;108:357.

PENIS, FIXED DRUG ERUPTIONS

DESCRIPTION A fixed drug eruption is an allergy that produces a plaque or blister at the same cutaneous site each time the drug is ingested. The most common drugs with side effects afflicting the penis are tetracycline, phenolphthalein, sulfonamides, barbiturates, salicylates, penicillins, foscarnet, and Coumadin. Foscarnet can cause periurethral ulcerations and

coumadin can cause a hemorrhagic necrosis of the penis.

REFERENCE

English JC 3rd, Laws RA, Keough GC, et al. Dermatoses of the glans penis and prepuce. *J Am Acad Dermatol.* 1997;37(1):1–24.

PENIS, HEMANGIOMA (CAVERNOUS HEMANGIOMA)

DESCRIPTION Penile hemangiomas are rare, occurring in 1% of all patients with hemangiomas. They should be differentiated from cutaneous hemangiomas, which are more common and tend to involute with time. By contrast, penile hemangiomas tend to become larger and may require surgical intervention. The physical exam often does not reveal the extent of the lesion, and ultrasound or angiography should be performed to delineate the anatomy. Treatment is surgical excision or laser ablation.

SYNONYMS

- Cavernous hemangiomas
- Subcutaneous hemangiomas
- Penile hemangiomas

TREATMENT

Surgical excision or laser ablation

REFERENCE

Alter GJ, Trengove-Jones G, Horton CE Jr. Hemangioma of penis and scrotum. *Urology.* 1993;42(2):205–208.

PENIS, HIRSUTE PAPILLOMA (PEARLY PENILE PAPULES, CORONAL PAPILLAE)

DESCRIPTION Hirsute papillomas of the penis, more commonly known as *pearly penile papules*, are asymptomatic acral angiofibromas, typically distributed circumferentially on the corona and sulcus of the glans penis. The lesion is often confused with STI/STD's, and persists through life, gradually becoming less noticeable with increased age. Treatment is not required, but sometimes offered for cosmetic reasons. CO_2 laser is effective.

REFERENCE

Bylaite M, Ruzicka T. Images in clinical medicine. Pearly penile papules. *N Engl J Med.* 2007;357(7):691.

PENIS, HYPOPLASIA

DESCRIPTION A small or hypoplastic penis may be the result of gonadotropin deficiency, hypospadias, or epispadias. (See Section I: "Micropenis [Microphallus].")

REFERENCE

Schneck FX, Bellinger MF. Anomalies of the testes and scrotum and their surgical

management. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 9th ed. Philadelphia, PA: Saunders Elsevier; 2007.

PENIS, KAPOSI SARCOMA

DESCRIPTION Kaposi sarcoma of the penis is rare, with only 37 cases reported in literature. Although most are associated with HIV, cases have been described in immunocompetent patients. It is clinically identified by painless, red-violaceous nodules, as well as papules, plaques, and wart-like pedunculated lesions. The lesions are most commonly found on the glans, although the foreskin, urethral meatus, and scrotum can also be affected. Treatments described include local surgery, radiotherapy, electrocoagulation, laser, and injection of interferon-α into the lesion. (See also Section I: "Penis, Lesion, General.")

REFERENCE

Hernández-Bel P, López J, Sánchez JL, et al. Primary Kaposi sarcoma of the penis in an HIV-negative patient. *Actas Dermosifiliogr.* 2008;99(8):662–663.

PENIS, LEIOMYOMA

DESCRIPTION Penile leiomyoma is a rare benign tumor of smooth muscle that commonly involves the shaft, with glans penis involvement being next in frequency. These lesions tend to be small (1 cm in diameter), well-circumscribed, rubbery in consistency, with light yellow to white cut surfaces. Electron microscopy and immunohistochemistry should be used to confirm diagnosis. Multiple recurrences are rare. Primary excision of the tumor is the treatment of choice.

REFERENCE

Leoni S, Prandi S, Mora A. Leiomyoma of the prepuce. *Eur Urol.* 1980;6(3):188–189.

PENIS, LEIOMYOSARCOMA

DESCRIPTION Penile leiomyosarcoma is a very rare malignant smooth muscle tumor that usually occurs on the 5th–7th decades. Superficial lesions commonly arise from the dermis of the shaft or the smooth muscle of the glans penis and usually form subcutaneous-nodules. Deep leiomyosarcoma is less common, arising from the smooth muscle of the corpora cavernosa, and tends to invade the urethra and metastasize early. These tumors are firm, gray-white, lobulated, and poorly circumscribed, and can range in size from 3–8 cm. Electron microscopy and immunohistochemistry should be used to confirm diagnosis.

TREATMENT

- Primary excision of the tumor is the treatment of choice in low-grade (superficial) tumors; however, the tumor tends to recur locally.
- In high-grade (deep) malignancies, the treatment depends on the age of the patient, size, location of the tumor, and the degree of invasiveness.

REFERENCE

Kathuria S, Jablokow VR, Molnar Z. Leiomyosarcoma of the penile prepuce with

ultrastructural study. *Urology.* 1986;27(6):556–557.

PENIS, LENGTH, NORMAL

DESCRIPTION Data on pediatric penile length considerations are discussed in Section I: "Microphallus (Micropenis)." At birth, dimensions of the normal-term infant phallus are 3.5 ± 0.7 cm in stretched length and 1.1 ± 0.2 cm in diameter. In adults, concern over phallus size can direct some men to seek penile augmentation. There is no real delineation between normal and abnormal, since many variables (fat pad, erect vs. flaccid length) are present. For example, a large fat pad can cause a penis to become buried and give a shorter appearance. (See Section II: "Penis, Buried [Concealed, Trapped, or Hidden].") 1 recent study provided the following data for mean measurements in adults (length from penopubic skin to the meatus):

- Flaccid length: 8.85 cm; stretched length: 12.45 cm
- Erect length: 12.89 cm; flaccid girth: 9.71 cm; erect girth: 12.3 cm

REFERENCE

Wessels H, McAninich JW. Penis size: What is normal? *Contemp Urol.* 1997;6671.

PENIS, LEUKOPLAKIA

DESCRIPTION These lesions present as solitary or multiple white plaques, usually involving the penile meatus. Histologically, parakeratosis, hyperkeratosis, and hypertrophy of the rete pegs are present, with dermal edema and lymphocytic infiltration. Leukoplakia is commonly associated with in situ SCC and verrucous carcinoma of the penis. Thus, close follow-up of the excision site with periodic biopsy of incompletely excised lesions is necessary to detect early malignant change.

TREATMENT

- Elimination of chronic irritation and circumcision may be indicated.
- Surgical excision and radiation have been used in the treatment of leukoplakia.

REFERENCE

Bain L, Geronemus R. The association of lichen planus of the penis with squamous cell carcinoma in situ and with verrucous squamous carcinoma. *J Dermatol Surg Oncol.* 1989;15(4):413–417.

PENIS, MALIGNANT FIBROUS HISTIOCYTOMA (MFH)

DESCRIPTION MFH is a rare sarcoma of the penis that may present as a subcutaneous penile mass in a patient with penile pain, priapism, or urinary retention.

TREATMENT

- Superficial tumors are treated with wide local excision vs. total amputation.
- Deep tumors arising from the corpora are treated with total penile amputation.
- Local recurrence is common, and complete amputation should be considered even for superficial tumors.
- Regional metastases are rare, and lymphadenectomy is unnecessary unless adenopathy is palpable.

REFERENCE

Katona TM, Shienbaum AJ, Wyatt LL, et al. Malignant fibrous histiocytoma of the glans penis: A case report. *Anal Quant Cytol Histol.* 2006;28(1):39–42.

PENIS, MELANOMA

DESCRIPTION Melanoma of the penis is extremely rare. It presents as a reddish brown or blue black pigmented papule, plaque, or ulceration on the glans penis and less commonly on the prepuce. The depth of skin invasion (Clark classification) and thickness of the tumor (Breslow classification) are of prognostic importance.

TREATMENT

- Surgery is the mainstay of therapy via partial or total penile amputation.
- Foreskin lesions may be treated with circumcision.
- Glanular lesions may be treated with partial penectomy.
- Lesions on the shaft often require total penile amputation.

REFERENCE

Te CC, Vemulapalli S, Confer SD, et al. Recurrent malignant melanoma of the penis. *Urology*. 2008;72(5):1185, e15–16.

PENIS, METASTASIS TO

DESCRIPTION Metastatic disease to the penis is rare, with roughly 200 cases reported during the past 100 yr. The bladder, prostate, rectum, and rectosigmoid are responsible for the greatest number of metastases. However, distal primaries (eg, lung) have been reported. Several mechanisms might lead to this condition: Direct extension, retrograde lymphatic spread, retrograde venous spread, direct arterial extension, secondary embolism, tertiary embolism, instrumental spread, and paradoxical spread. Patients may develop masses or malignant priapism. Most patients die within 6 mo of presentation. Penectomy may be indicated for pain or relief of urinary obstruction (Image ☼).

REFERENCE

Bachrach P, Dahlen CP. Metastatic tumors to the penis. *Urology*. 1973;1(4):359–362.

PENIS, NEURILEMOMA (SCHWANNOMA)

DESCRIPTION Penile neurilemmoma, also known as schwannoma, is a rare entity. It is an encapsulated tumor that arises from the sheaths of peripheral nerves. These are solitary, slow-growing, and often asymptomatic lesions. Most penile schwannomas are unifocal, benign, and tend to occur on the dorsal penile shaft, where the penile dorsal nerve is located, although cases on the glans penis have also been reported. A family history of neurofibromatosis is usually present. Malignant schwannomas are often associated with neurofibromatosis type I. Surgical excision is the treatment of choice, and regular follow-up is recommended because recurrence of benign schwannomas has been reported.

REFERENCE

Loeser A, Katzenberger T, Meuller JG, et al. Solitary schwannoma of the glans. *Urology.* 2007;70(5):1007.e5–e6.

PENIS, NEUROFIBROSARCOMA (MALIGNANT SCHWANNOMA)

DESCRIPTION A malignant nerve sheath tumor arising from Schwann cells that very rarely occurs on the penis. These lesions most commonly occur on the dorsal aspect of the penis, near the dorsal nerve. Nodules from Peyronie disease are uncommon in this location. Patients may have a history of von Recklinghausen disease or neurofibromatosis, and an exam for café au lait spots and other nodules should be undertaken.

TREATMENT
- Complete excision
- Careful follow-up for recurrence
- Recurrent schwannomas may require total penectomy

REFERENCE

Suzuki Y, Ishigooka M, Tomaru M, et al. Schwannoma of the penis: Report of a case and review of the literature. *Int Urol Nephrol.* 1998;30(2):197–202.

PENIS, SCLEROSING LIPOGRANULOMA (PARAFFINOMA)

DESCRIPTION This is a foreign-body reaction resulting from injection of paraffin, petroleum jelly, bear grease, or other materials into penile shaft, in an attempt to increase penile girth. Injections of oil-based substances may also be performed for therapeutic or cosmetic purposes, but these procedures are usually performed by the patient or an untrained person practicing medicine fraudulently. Complications usually occur, including penile deformity, skin necrosis, ED, and painful intercourse (Image ☼).

TREATMENT
- Complete excision of affected skin and subcutaneous tissue
- Skin graft coverage (full- or split-thickness skin graft)
- Flap coverage (usually scrotal) is required if skin graft does not take.

REFERENCE

Jeong JH, Shin HJ, Woo SH, et al. A new repair for penile paraffinoma: Bilateral scrotal flaps. *Ann Plast Surg.* 1996;37(4):386–393.

PENIS, SCLEROSING NONVENEREAL LYMPHANGITIS

DESCRIPTION Sometimes referred to as *Mondor phlebitis of the penis,* these are firm and often asymptomatic subcutaneous cordlike swellings along the dorsal shaft of the penis or around the coronal sulcus. They can be confused with *lymphangioma circumscriptum*, a uncommon tumor of the lymphatic channels. The lesion is caused by thickening or thrombosis of the superficial veins of the penis, probably secondary to trauma. Treatment is not usually necessary, and the condition usually resolves in several weeks. Avoid vigorous sexual activity. Failure to resolve in a timely manner may require biopsy.

REFERENCE
Kumar B, Narang T, Radotra BD, et al. Mondor's disease of penis: A forgotten disease. *Sex Transm Infect.* 2005;81:480–482.

PENIS, STRANGULATION

DESCRIPTION Penile strangulation is caused by attachment of and encircling by a foreign object around the penis, which leads to entrapment and distal ischemia. These efforts are usually associated with an attempt to maintain a longer erection and sexual interest. Foreign objects used include iron rings, rubber bands, steel washers, and strings. Wearing constricting rings on the flaccid penis often result in the impossibility of their removal after erection, leading to vascular complications usually within a few hours. These injuries range from simple penile engorgement to ulceration, necrosis, urinary fistula, or even gangrene. The main objective in the treatment is acute decompression to avoid potential ischemic necrosis and autoamputation. Removing the constricting device is a challenge to the urologic surgeon, and each case requires an individual approach. Methods used include aspiration of the corpora, or the use of saws, grinders, and dental drills to remove object. The outcome is often good, but some can have serious complications such as penile amputation and urethrocutaneous fistula.

REFERENCE
Ivanovski O, Stankov O, Kuzmanoski M, et al. Penile strangulation: Two case reports and review of the literature. *J Sex Med.* 2007;4(6):1775–1780.

PENIS, SYRINGOMA

DESCRIPTION Syringomas are benign appendageal tumors that normally occur in adolescents on the face, neck, axillae, or abdomen. They are extremely rare on the penis; only 6 cases have been reported in the literature to date. On exam, 2–5-mm flesh-colored papules are seen. A punch biopsy can be obtained to relieve patient fears of STI/STD and cancer, and to rule out condyloma, lichen planus, and bowenoid papulosis, which may appear similarly. Because they are benign, treatment is usually considered cosmetic. CO_2 laser has proved effective, as well as surgical excision and cryotherapy with liquid nitrogen.

REFERENCE
Olson JM, Robles DT, Argenyi ZB, et al. Multiple penile syringomas. *J Am Acad Dermatol.* 2008;59(2 Suppl 1):S46–S47.

PENIS, THROMBOSIS OF DORSAL VEIN

DESCRIPTION Thrombosis of the superficial dorsal vein of the penis, also known as *Mondor disease*, is a rare, poorly understood clinical entity. Some predisposing factors include vigorous sexual activity, trauma, and surgery to the pelvis or external genitalia. It can also be a manifestation of metastatic pancreatic cancer, or can be associated with bladder and prostate cancers. Clinically, the patient complains of swelling and pain on the dorsal aspect of the penis. On exam, a cordlike structure is palpated. Doppler US can demonstrate a

noncompressible portion of the superficial dorsal vein, as well as a lack of venous flow signals. Treatment is conservative, as the disease is self-limited and often spontaneously resolves. Abstinence from sex and anticoagulation with heparin is sometimes recommended. NSAIDs may relieve pain and diminish inflammation. Thrombus excision may be the last resort in cases without resolution. Spontaneous thrombosis of the deep dorsal penile vein has also been described following trauma, or in a patient with thrombophilia. This condition improves with anticoagulation treatment.

REFERENCE

Kartsaklis P, Konstantinidis C, Thomas C, et al. Penile Mondor's disease: A case report. *Cases J.* 2008;1(1):411.

PENIS, TORSION

DESCRIPTION Congenital rotation of the penile shaft such that the median raphe spirals obliquely around the penile shaft. The external genitalia are otherwise normal, but this condition may be associated with hypospadias or ventral hood penile deformity. The torsion tends to occur in a counterclockwise direction (ie, the twist is to the left). Mainly a cosmetic issue, repair is usually not necessary if the rotation is $<60–90^{\circ}$.

TREATMENT

Mild cases require only simply freeing the penile shaft of its investing tissue.

REFERENCE

Pomerantz P, Hanna M, Levitt S, et al. Isolated torsion of penis. Report of six cases. *Urology.* 1978;11(1):37–39.

PENIS, VERRUCOUS CARCINOMA

DESCRIPTION Squamous cell carcinoma (SCC) of the penis represents about 1% of cancers in men in USA and 11–12% of all cancers in men in countries where circumcision is not routinely practiced. Verrucous carcinoma is an uncommon variant that accounts for only 5–16% of all penile SCCs. Diagnosis of verrucous carcinoma may be difficult because biopsies are usually performed on the superficial portion of the lesion. Therefore, it is crucial to perform a deep biopsy. Verrucous carcinoma exhibits an exophytic warty lesion of SCC and endophytic growth where cellular atypia is noted. (See also Section I: "Penis Cancer, General" and "Penis, Squamous Cell Carcinoma.")

SYNONYMS

- Giant condyloma
- Buschke–Lowenstein tumor

CAUSES

- Lack of circumcision
- Prior trauma
- Previous disease
- Poor hygiene
- Phimosis

- Tight prepuce

TREATMENT
Partial penectomy

REFERENCE
Kanik AB, et al. Penile verrucous carcinoma in a 37-yr-old circumcised man. *J Am Acad Dermatol.* 1997;37(2):329–331.

PENIS, WEBBED

DESCRIPTION A congenital condition in which the scrotal skin extends onto the ventral aspect of the penile shaft. Although there are usually no associated abnormalities, there are a few reports of hypoplasia of the distal urethra. Occasionally, a webbed penis is the result of a circumcision in which there was excess removal of ventral penile shaft skin. Cosmetic repair is performed, as needed.

REFERENCE
Dilley AV, Currie BG. Webbed penis. *Pediatr Surg Int.* 1999;15(5–6):447–448.

PENN POUCH

DESCRIPTION A continent urinary reservoir is created based on the Mitrofanoff principle, which uses the appendix as the catheterizable continent apparatus. The pouch is made from joining a detubularized colon and ileum.

REFERENCE
Benson MC, Olsson CA. Continent urinary diversion. In: Walsh PC, Retik AB, Vaughan ED, et al., eds. *Campbell's Urology*. 7th ed. Philadelphia, PA: Saunders, 1998:3190–3245.

PEREYRA URETHROPEXY

DESCRIPTION Pereyra, in 1959, was 1st to present a transvaginal approach to a urethropexy using a needle suture carrier, obviating the need for a transabdominal exposure. Through a T vaginal incision, the bladder neck and periurethral tissue are exposed. The suture carrier is passed through a suprapubic stab incision and, under digital guidance, delivered through the periurethral tissue. The bladder neck is then suspended with absorbable suture.

REFERENCE
Duggan ML. Another look at Pereyra's Stint urethropexy. *South Med J.* 1975;68(11):1381–1384.

PERINEAL GROOVES

DESCRIPTION Perineal groove is a rare congenital malformation characterized by a wet sulcus lined by mucous membrane, extending from the posterior fourchette to the anterior edge of the anus. There are 2 reasons for surgical correction: Cosmetic reasons and the groove

mucosa is often infected due to colonization by rectal germs. Patients present with inflammatory aspects of the groove mucosa, infection of the external genitalia, and urinary tract infection. Considering that infectious complications occur in about 50% of patients, surgical excision is often recommended. Generally, the tissue defect is closed by interrupted sutures and some advocate the use of surgical glue over the suture line to help prevent infection/movement of the skin edges and, therefore, the development of subsequent dehiscence.

REFERENCE

Esposito C, Giurin I, Savanelli A, et al. Current trends in the management of pediatric patients with perineal groove. *J Pediatr Adolesc Gynecol.* 2011; 24(5):263–265.

PERINEAL MASS

DESCRIPTION Perineal masses are classified as either benign or malignant and can arise from the perineum directly or from pelvic extension of gastrointestinal, genitourinary, or gynecologic structures. Benign conditions include soft tissue masses, traumatic saddle injury, infections leading to abscess formation, various fistulae, granulomatous disease, urethral foreign body, urolithiasis, Bartholin gland or prostatic cyst, and condyloma. Neoplasms that present as a perineal mass include sarcomas as well as malignancies of the prostate, urethra, anus, vagina, and metastases from other pelvic structures. Patients typically present with a palpable mass or with perineal, gluteal, or labial swelling. On occasion, clinical findings and symptoms suggest the underlying cause, such as inflammatory changes associated with infection. Cross-sectional imaging, with CT scan or MRI, is usually required to further define the anatomic origin, extent, and radiologic features of the lesion. Aggressive surgical treatment of mass lesions, in the form of wide local excision, is often the treatment of choice with the aim of negative resection margins without causing disturbances to urinary or anorectal function (Image ☼).

Tappouni RF, Sarwani NI, Tice JG, et al. Imaging of unusual perineal masses. *AJR Am J Roentgenol.* 2011;196(4):W412–W420.

PERINEAL PAIN, DIFFERENTIAL DIAGNOSIS

DESCRIPTION According to the ICS, *perineal pain syndrome* is the occurrence of persistent or recurrent episodic perineal pain which is either related to the micturition cycle or associated with symptoms suggestive of urinary tract or sexual dysfunction. Perineal pain is felt in the female, between the posterior fourchette (posterior lip of the introitus) and the anus, and in the male, between the scrotum and the anus. There is no proven infection or other obvious pathology. The ICS suggests that in men, the term prostatodynia (prostate-pain) should not be used as it leads to confusion between a single symptom and a syndrome. The differential diagnosis of perineal pain is long, with infectious, inflammatory, iatrogenic, anatomic, and other causes as listed below:

Infectious:

- Prostatitis

- Cystitis
- Epididymitis
- Orchitis
- Fournier gangrene
- Abscess
- Sexually transmitted infections (herpes, syphilis, chancroid)

Inflammatory:
- Interstitial cystitis (IC)/Painful bladder syndrome (PBS)
- Inflammatory dermatoses (lichen planus, lichen sclerosis, SLE, Behcet disease)

Iatrogenic:
- Sacral nerve stimulation
- Perineal sling
- Radiation therapy
- Cryotherapy
- Pelvic surgery

Prolapse:
- Bladder
- Urethra
- Vagina
- Uterus
- Rectum

Other:
- Ureteral stone
- Torsion (testicular, ovarian, appendix testis, appendix epididymis)
- Pudendal nerve entrapment
- Diabetic and HIV/AIDS neuropathy

Warfield CA, Bajwa ZH. Perineal pain. In: Warfield CA, Bajwa ZH, eds. *Principles and Practice of Pain Medicine.* 2nd ed. New York, NY: McGraw-Hill; 2005.

PERINEAL TRAUMA (STRADDLE INJURY)

DESCRIPTION This refers to fracture of all 4 pubic rami or simply to blunt force trauma to the perineum causing urethral injury or high-flow priapism. Patients with blood at the urethral meatus, perineal hematoma, or urinary retention after blunt force trauma should be suspected of having a urethral injury. A retrograde urethrogram should be performed in males and urethroscopy in females. Patients with urethral injuries may have an attempt at primary realignment with a catheter but suprapubic cystotomy remains the standard of care. Anastomotic urethroplasty should be considered the gold standard, with endoscopic treatments reserved for posterior urethral strictures <1 cm or strictures following anastomotic repair. Straddle injury may also cause nonischemic high-flow priapism from a cavernosal artery–corpora cavernosa fistula. This may require angiographic embolization if it fails to resolve on its own. (See also Section I: “Urethra, Trauma [Anterior and Posterior].”) (Image ☼)

REFERENCE

Park S, Mc Aninch JW. Straddle injuries to the bulbar urethra: Management and outcomes in 78 patients. *J Urol.* 2004;171(2 pt 1):722–725.

PERINEPHRIC MASS

DESCRIPTION Masses in the perinephric space may be due to tumor, fluid, inflammation, various proliferative disorders, or subcapsular renal diseases. Neoplasms include renal tumors, perinephric lymphoma, posttransplantation lymphoproliferative disorder, metastases, and various retroperitoneal tumors. Fluid may be present from hematoma, urinoma, abscess, or lymphangiomatosis. Inflammation is seen in conditions such as xanthogranulomatous pyelonephritis or pancreatitis. Proliferative diseases that appear as perinephric masses include extramedullary hematopoiesis, retroperitoneal fibrosis, sinus histiocytosis with massive lymphadenopathy (Rosai–Dorfman disease), and lipoid granulomatosis (Erdheim–Chester disease). In addition, subcapsular diseases, such as renal cortical necrosis or nephroblastomatosis, may also present as perinephric masses on cross-sectional imaging.

REFERENCE

Westphalen A, Yeh B, Qayyum A, et al. Differential diagnosis of perinephric masses on CT and MRI. *AJR Am J Roentgenol.* 2004;183(6):1697–1702.

PERINEPHRIC STRANDING

DESCRIPTION Fat stranding is seen on cross-sectional imaging as a linear or hazy increased attenuation within a region of fat, usually caused by fluid or inflammatory cells infiltrating the tissues and often accompanied by thickening of nearby fascial planes. Focal fat stranding can signal a focus of acute disease and should prompt inspection of adjacent structures. Perinephric stranding is commonly seen in healthy individuals, but when asymmetric, it may be secondary to an obstructive urinary calculus, pyelonephritis, inflammatory nephritis, renal infarction, neoplasm, or renal vein thrombosis.

REFERENCE

PERINEURAL INVASION, UROLOGIC CONSIDERATIONS

DESCRIPTION Perineural invasion most commonly refers to a pathologic finding on needle biopsy of prostate or radical prostatectomy specimens. Perineural invasion on needle biopsy specimens correlates with an increased risk of extraprostatic extension, lymph node metastases, and postoperative progression. Surprisingly, perineural invasion in RP specimens does not have any prognostic significance, perhaps because it represents spread of tumor along a plane of decreased resistance, as opposed to invasion into vascular or lymphatic structures, which portends a worse prognosis.

TREATMENT

Patients should be counseled on treatment options, nerve-sparing vs. non–nerve-sparing

surgery, and prognosis based upon PSA, Gleason score, and TNM stage and possibly perineural invasion.

PERIPHERAL NEUROPATHY, UROLOGIC CONSIDERATIONS

DESCRIPTION As it pertains to urology, peripheral neuropathy classically affects bladder and sexual function. The most common causes of peripheral neuropathy are diabetes, HIV/AIDS, alcoholism, side effects of chemotherapy, and B12 deficiency. The classic description of diabetic cystopathy is impaired bladder sensation, increased bladder capacity, decreased contractility, decreased flow rate, and increased residual volume. Patients may have involuntary bladder contractions and eventually develop areflexic bladders. Sexual function may be impaired, and patients may have ED or anorgasmia.

TREATMENT

- The underlying cause of neuropathy should be identified and treated, if possible.
- Careful evaluation for progression of disease should be sought, and patients may need to be on timed voiding or intermittent catheterization.
- Erectile dysfunction (ED) may require a vacuum erection device, medical therapy, or surgical intervention.

Sasaki K, Yoshimura N, Chancellor MB. Implications of diabetes mellitus in urology. *Urol Clin North Am.* 2003;30(1):1–12.

PERIURETERITIS

DESCRIPTION Most cases of periureteritis, or inflammatory changes surrounding the ureter, are secondary to infection from microorganisms that cause infections elsewhere in the genitourinary tract. Any associated anatomic abnormality of the ureter, including stricture, megaloureter, and ureterocele, predisposes an individual to ureteritis. Urinary obstruction, trauma, and abdominopelvic radiation are other causes for periureteral inflammation. The 1st step in treatment of periureteritis is treating the underlying etiology, including the treatment of infection, stricture, stone, or tumor. This term is not used in current peer-reviewed literature.

REFERENCE

Giambroni L, Monticelli L, Simeone C, et al. Ureteritis. *Arch Ital Urol Nefrol Androl.* 1993;65(1):31–33.

PERIURETHRAL ABSCESS

DESCRIPTION A life-threatening infection of the urethra and periurethral tissues that can spread rapidly to the adjacent soft tissues. It most commonly presents with scrotal edema (94%), fever (70%), urinary retention (19%), a draining abscess (11%), dysuria, and urethral discharge. Periurethral abscesses have been associated with gonococcal urethritis infections, urethral strictures, periurethral bulking agent injections, and urethral diverticulum. Drainage and broad spectrum antibiotics are the mainstay of treatment.

REFERENCE

Kenfak-Foguena A, Zarkik Y, Wisard M, et al. Periurethral abscess complicating gonococcal urethritis: Case report and literature review. *Infection*. 2010;38:497–500.

PERLMAN SYNDROME

DESCRIPTION An overgrowth syndrome characterized by fet al gigantism, visceromegaly, distinct facial features, and nephroblastomatosis. Similar overgrowth syndromes include Beckwith–Weidemann, Sotos, and the Simpson–Golabi–Behemel syndromes. Neonatal mortality is extremely high. The kidneys are often dysplastic, with numerous cysts and nephrogenic rests. The cause is unknown, and the diagnosis is based entirely on the phenotypic description.

REFERENCE

PFANNENSTIEL INCISION

DESCRIPTION A transverse incision is centered ~2 fingerbreadths above the pubic symphysis. A transverse incision is made through the anterior rectus fascia, and entry into the retropubic space can be gained by separating the rectus muscle in the midline. Useful for bladder and other lower abdominal procedures.

REFERENCE

Montague DK. Surgical incisions. In: Novick AC, Streem SB, Pontes JE, eds. *Stewarts Operative Urology*. Baltimore, MD: Williams & Wilkins; 1989:15–40.

PHI (PROSTATE HEALTH INDEX) (SEE SECTION II: "PROSTATE HEALTH INDEX (*PHI*) AND [-2] PROPSA")

PHIMOSIS, CLITORAL

DESCRIPTION Phimosis should be suspected in women with clitoral pain, itching, or burning. A physical exam may reveal a mild, moderate, or severe degree of an inability to visualize the entire clitoris. Initial conservative treatment involves testosterone and estrogen creams to improve the elasticity of the prepuce and potentially antifungal agents such as nystatin or fluconazole. Rarely, lichen planus may result in a white scarring of the clitoris, prepuce, and perineum. Treatment with clobetasol cream may improve symptoms. Women with refractory symptoms may require a dorsal slit.

REFERENCE

PHOSPHATE NEPHROPATHY, ACUTE

DESCRIPTION Acute phosphate nephropathy is characterized by acute and subsequent chronic renal failure following exposure to oral sodium phosphate (OSP) bowel purgatives. Renal biopsy demonstrates acute and chronic tubular injury with prominent tubular and interstitial calcium phosphate deposits. Risk factors include older age, female gender, hypertension (HTN), chronic kidney disease (CKD) and treatment with angiotensin converting enzyme (ACE) inhibitors, angiotensin receptor blockers, and diuretics. The pathologic mechanism of action involves hypovolemia-induced proximal salt and water reabsorption, delivery of a large phosphate load to the distal nephron, and precipitation of calcium phosphate in the distal tubule and collecting duct. Prevention of acute phosphate nephropathy is best achieved by avoiding sodium phosphate purgatives in high-risk patients, aggressive hydration, minimizing the dose, and maintaining a minimum of 12 hr between administrations.

REFERENCE

Markowitz GS, Perazella MA. Acute phosphate nephropathy. *Kidney Int.* 2009; 76(10):1027–1034.

PINWORMS, UROLOGIC CONSIDERATIONS

DESCRIPTION Approximately 209 million people are infected with intestinal pinworms (*Enterobius vermicularis*) worldwide. They most commonly reside in the large intestine, and females lay ~15,000 eggs nightly on the perineum, causing intense perineal itching and sleep disturbances. Occasionally, worms may ascend the vagina and uterus and enter the peritoneal cavity through the fallopian tubes, where they may lay eggs causing an intense inflammatory response resulting in fever, abdominal pain, adhesions, and granulomas. Involvement of the urinary tract is rare, and only 1 report exists of *Enterobius* in the bladder.

TREATMENT

- Mebendazole 100 mg PO once (1st-line) or pyrantel pamoate 11 mg/kg up to 1 g PO once (2nd-line)
- Treat household contacts
- Clean bedrooms and bedding

REFERENCES

PIPE STEM URETHRA

DESCRIPTION A form of intrinsic sphincter deficiency (ISD) caused by a fixed, open, and nonfunctioning urethra. This is usually the result of prior pelvic surgery, irradiation, or long-standing indwelling catheter drainage. Patients typically have a high bladder neck on cystoscopic exam and severe urinary incontinence.

TREATMENT

- Mid-urethral sling
- Urethrolysis
- Artificial urinary sphincter

REFERENCE

Ghoniem GM, Shaaban A. Sub-urethral slings for treatment of stress urinary incontinence. *Int Urogynecol J.* 1994;5(4):228–239.

PI-RADS PROSTATE MRI SCORING SYSTEM

DESCRIPTION The European Society of Urogenital Radiology (ESUR) developed a scoring system to present multi-parametric prostate MRI data in a simple but meaningful way in the diagnosis of prostate cancer. The system is similar to that used by breast radiologist (BI-RADS for x-ray mammography, breast ultrasound, and MRI). Multiple parameters for each lesion are scored on a 5-point scale and the overall score predicts the chance of the lesion being a clinically significant cancer.

- Score 1 = Clinically significant disease is highly unlikely to be present.
- Score 2 = Clinically significant cancer is unlikely to be present.
- Score 3 = Clinically significant cancer is equivocal.
- Score 4 = Clinically significant cancer is likely to be present.
- Score 5 = Clinically significant cancer is highly likely to be present.

REFERENCE

PLAP (PLACENTAL ALKALINE PHOSPHATASE)

DESCRIPTION PLAP is a fet al isoenzyme that has a different structure than the adult alkaline phosphatase. It is 1 of many tumor markers used for the diagnosis, staging, and monitoring of treatment response in patients with GCT, and it may be useful as a prognostic index. Although the individual sensitivity of PLAP is low, when combined with gamma-glutamyl transpeptidase, simultaneous determinations have shown elevations of 1 or both in 80% of patients with active disease.

REFERENCE

Javadpour N. Multiple biochemical tumor markers in testicular cancer. *Cancer.* 1983;52:887.

PLASMACYTOID UROTHELIAL CARCINOMA

DESCRIPTION Plasmacytoid urothelial carcinoma (PUC) is a rare and recently described histologic variant of urothelial carcinoma (TCC). Tumor tissue is predominantly manifested by infiltrating tumor cells with characteristics of plasmacytoid morphology. Cells appear medium-sized and dyscohesive with abundant eosinophilic cytoplasm, small hyperchromatic nuclei, and frequent mitotic features. In addition, immunohistochemical staining plays an important role in the diagnosis of PUC. The most common presenting symptom is hematuria, generally accompanied by irritative lower urinary tract symptoms. However, early diagnosis cannot be made due to the absence of hematuria until the later stages of disease. Due to the highly metastatic potential and poor prognosis of this variant of TCC, treatment options include deep TURBT for initial diagnosis, followed by radical cystectomy with adjuvant therapy.

PLASMACYTOMA, BLADDER

DESCRIPTION This tumor is characterized by a monotonous proliferation of plasma cells at variable stages of differentiation, with predominance of the immature variety. 5 cases have been reported in the literature, with a mean age of 54 yr, none of which had multiple myeloma at the time of diagnosis. Local suprapubic recurrences and regional lymph node metastasis may occur. Survival up to 12 yr after diagnosis has been reported.

TREATMENT

- Subtotal cystectomy
- Radiation and chemotherapy

REFERENCE

Yang C, Motteram R, Sandeman TF. Extramedullary plasmacytoma of the bladder: A case report and review of literature. *Cancer.* 1982;50:146–149.

PLASMACYTOMA, TESTICULAR

DESCRIPTION Neoplastic collections of plasma cells occurring in the testicles. Plasmacytomas are most commonly found in the head and neck region. These are very rare tumors, with an incidence of ~1 in 1,000 testicular tumors. They are most commonly associated with a previous or concurrent diagnosis of multiple myeloma and are generally not believed to occur as primary tumors. Presentation is a painless testicular mass. Treatment is radical orchiectomy and monitoring or management of multiple myeloma.

REFERENCE

Berrondo C, Gorman TE, Yap RL. Primary plasmacytoma of the testicle: a case report. *J Med Case Rep*. 2011;5:494.

PLOIDY ANALYSIS, BLADDER CANCER

DESCRIPTION *Ploidy* is the chromosomal content of cells, which can be measured using flow cytometry. Ploidy analysis, when considered as an independent variable, is a fair predictor of clinical outcome. Tumor stage and grade are considered to be the most important predictors of survival. Although ploidy may be more significant in predicting survival than grade, the addition of ploidy to the known stage and grade of a bladder tumor usually does not drastically alter the clinical management of a patient.

REFERENCE

Bittard H, Lamy B, Billery C. Clinical evaluation of cell deoxyribonucleic acid content measured by flow cyto-metry in bladder cancer. *J Urol.* 1996 ;(155):1887–1891.

PLOIDY ANALYSIS, PROSTATE CANCER

DESCRIPTION *Ploidy* is a variation in the number of chromosomes in a cell. *Aneuploidy* is a variation in the number of chromosomes in a cell that is other than a simple multiple of the number of chromosomes. In a prostate specimen, flow cytometry is used to measure the DNA content of the cells. *DNA ploidy* in addition to the histologic grading may improve the ability to predict the pathologic state and ultimately the prognosis of any given lesion. The frequency of aneuploidy increases with advancing tumor stage. Inherent problems with ploidy analysis include heterogeneity of DNA cell sampling, as well as whether it will change clinical management.

REFERENCE

Dejter SW, Cunningham RE, Noguchi PD, et al. Prognostic significance of DNA ploidy in carcinoma of prostate. *Urology.* 1989;33:361–366.

PNEUMORETROPERITONEUM

DESCRIPTION Pneumoretroperitoneum, the presence of air in the retroperitoneal space, unless immediately postoperatively, is always considered an abnormal finding. It can be due to a perforated retroperitoneal viscus or from residual air following a retroperitoneal surgical procedure. Duodenal, colonic, or rectal perforation can result from peptic ulcer disease, abdominal trauma, endoscopy, endoscopic retrograde cholangiopancreatography (ERCP), colonoscopy, colorectal carcinoma, diverticulitis, ischemic colitis, or foreign-body insertion.

Often accompanied by pneumoperitoneum, pneumomediastinum, or subcutaneous emphysema. Early diagnosis and treatment are important, as certain unrecognized conditions may become life-threatening (viscous perforation with sepsis). Treatment of the underlying etiology may be conservative or surgical, and allows for the pneumoretroperitoneum to resolve.

REFERENCE

Pretre R, Robert J, Mirescu D, et al. Pathophysiology, recognition and management of pneumoretroperitoneum. *Br J Surg*. 1993;80(9):1138–1140.

PNEUMOSCROTUM

DESCRIPTION Pneumoscrotum, the presence of air within the scrotum, can result from both pathologic and iatrogenic etiologies. This term includes both *scrotal emphysema*, which is subcutaneous air palpated as crepitus, and *pneumatocele*, where air is present within the tunica vaginalis and not directly palpable. Air may come from extraperitoneal (thoracic [pneumothorax], retroperitoneal), intraperitoneal (perforated viscus), or local (air-producing microorganisms) sources. The underlying cause must be recognized early, as certain conditions may be life-threatening (pneumothorax, Fournier gangrene, intestinal perforation) and treatment of the underlying cause allows the pneumoscrotum to resolve. Today, pneumoscrotum is sometimes seen after laparoscopic or robotic transperitoneal or extraperitoneal procedures and resolves spontaneously.

POLYARTERITIS NODOSA (PAN), UROLOGIC CONSIDERATIONS

DESCRIPTION PAN can affect many organ systems but usually presents with a systemic illness characterized by malaise, weight loss, myalgia, arthralgia and signs of end-organ damage. PAN is not well understood, but is believed to be caused by the deposition of immune complexes on the walls of primarily medium-sized arteries, causing deformative changes in those walls. This may lead to thickening and aneurysmal changes, causing acute renal hemorrhage and often leading to chronic renal failure. When left untreated, the 5-yr survival rate of PAN is 13% with some renal features being associated with poor prognosis: Renal insufficiency (serum creatinine >1.58 mg/dL) and proteinuria (>1 g/d). Corticosteroids and azathioprine are used in the treatment of PAN. The majority of patients with PAN have renal involvement. Flank pain is sometimes present and glomerular ischemic changes and renal artery vasculitis can cause renal failure (a small percentage of patients may require dialysis), hypertension, or both. Infrequently patients may develop pain over the testicular or ovarian area with testicular infarction reported. Spontaneous renal hemorrhage is also reported. Steroids with or without cyclophosphamide is the standard treatment.

REFERENCE

Pettigrew HD, Teuber SS, Gershwin ME. Polyarteritis nodosa. *Compr Ther*. 2007 Fall;33(3):144–149.

POLYEMBRYOMA

DESCRIPTION A mixed germ cell tumor (GCT) of the testis, containing embryonal carcinoma and yolk sac tumor. Histologic analysis reveals a distinctive, well-organized pattern of embryoid bodies in a myxoid stroma, which resembles extraembryonic mesenchyme. Due to the yolk sac component there may be substantial alpha fetoprotein (AFP) elevation. Treatment mirrors that for GCT.

REFERENCE

Ulbright TM. Germ cell neoplasms of the testis. *Am J Surg Pathol.* 1993;17(11):1075–1091.

POLYOMA VIRUS (BK, JC), UROLOGIC CONSIDERATIONS

DESCRIPTION The polyoma viruses may cause transplant renal nephropathy, ureteral obstruction or stricture, and hemorrhagic cystitis. BK virus may cause transplant renal nephropathy in up to 6% of transplant recipients, and may cause ureteral obstruction secondary to fibrosis. It is also thought to be the causative agent in the majority of patients with hemorrhagic cystitis following immunosuppression for bone marrow or solid organ transplantation. BK virus causes clinical disease of the genitourinary tract, due in part to its tropism for genitourinary epithelium. The JC virus causes a similar disease pattern but is less common. BK nephropathy occurs in up to 10% of kidney transplant recipients and causes graft failure in as many as 50% of individuals affected. BK and JC viruses can be diagnosed with PCR of the urine or blood. Urine cytology may demonstrate the so-called “decoy cells.’ Most renal transplant programs employ posttransplant screening programs. Decreasing immunosuppressive medications is essential. Additional therapies include agents such as

ciprofloxin and IVIG. (See also Section I: “Immunocompromised Patients, Urologic Considerations” and Section II: “BK Virus, Urologic Considerations.”)

REFERENCE

Hirsch HH, Brennan DC, Drachenberg CB, et al. Polyomavirus-associated nephropathy in renal transplantation: Interdisciplinary analyses and recommendations. *Transplantation*. 2005;79:1277–1286.

POLYORCHIDISM

DESCRIPTION This is a very rare condition characterized by multiple (>2) testicles. It may be the result of transverse division of the urogenital ridge. The majority of cases are asymptomatic and associated with inguinal hernia, torsion, or cryptorchidism. It is most often discovered as an asymptomatic swelling in the scrotum; the supernumerary testis usually occurs with its own separate epididymis and vas deferens. If a testicular tumor can be ruled out using US or MRI, and if surveillance indicates no other associated disorders, surgical exploration is not necessary.

TREATMENT

Surveillance, exploration, and biopsy, if indicated

REFERENCE

Arlen AM, Holzman SA, Weiss AD, et al. Functional supernumerary testis in a child with testicular torsion and review of polyorchidism. *Pediatr Surg Int*. 2014;30(5):565–568. [Epub ahead of print]

POLYTHELIA, UROLOGIC CONSIDERATIONS

Polythelia (the presence of extra nipples) is linked with abnormalities of the urinary tract and is usually found within the milk line extending from the axilla to pubic region. Urologic abnormalities include supernumerary kidneys, failure of renal formation, and carcinoma of the kidney. The association of polythelia and renal anomalies is not uniform but is supported by some studies. 1 group reported 40% of children with polythelia had obstructive renal anomalies or duplications of the excretory system. The presence of extra nipples in children should heighten the clinician’s suspicion of possible renal anomalies.

REFERENCE

Grossl NA. Supernumerary breast tissue: Historical perspectives and clinical features. *South Med J*. 2000;93(1):29–32.

POLYURIA

DESCRIPTION Generally defined as >3 L of urine output from a person without excessive fluid intake (2 L/m^2 in children). It is necessary to differentiate it from nocturnal polyuria (NP) (the production of >1/3 of total 24-hr urine output between midnight and 8 AM). Normally, a person’s urine output is decreased overnight, when compared to daytime urine output. It is useful to measure the urine osmolality to determine whether the polyuria is due

to a water diuresis (urine osmolality <250 mOsmol/kg) or a solute diuresis (urine osmolality >300 mOsmol/kg). Polyuria has numerous causes. A solute diuresis may be caused by excessive hypertonic saline infusion, high-protein feedings, uncontrolled diabetes, or postobstructive diuresis. A water diuresis can be caused by multiple conditions, including polydipsia, loop diuretics, diabetes insipidus, and infusion of hypotonic solutions. Correct the underlying cause. (See also Section II: "Nocturnal Polyuria.")

POSITRON EMISSION TOMOGRAPHY (PET) IMAGING, CHOLINE C 11

DESCRIPTION Choline C 11 injection is a radiotracer where choline is labeled with carbon C 11, a positron-emitting isotope. An active, carrier-mediated transport mechanism for choline allows for uptake into tumor cells where it is phosphorylated by choline kinase, an enzyme that is often upregulated in cancer. Therefore, these lesions can be differentiated from normal tissue on PET imaging. C-Choline PET/CT has been FDA approved in the detection of distant relapses in prostate cancer patients with a biochemical recurrence. In addition, accurate imaging of cancers within the prostate is important for patients with a high clinical suspicion for prostate cancer, but previous negative core biopsies. For these patients, targeted biopsy may improve detection rates of prostate cancer. This imaging study has been shown to accurately detect and locate major areas of prostate cancer and differentiate segments with prostate cancer from those with benign hyperplasia, chronic prostatitis, or normal prostatic tissue.

REFERENCE

Kitajima K, Murphy RC, Nathan MA. Choline PET/CT for imaging prostate cancer: an update. *Ann Nucl Med.* 2013;27(7):581–589.

POSITRON EMISSION TOMOGRAPHY (PET) IMAGING, UROLOGIC CONSIDERATIONS

DESCRIPTION The most common urologic applications for the PET scan are in seminoma, kidney cancer, and prostate cancer. Patients who are treated for seminoma and have a residual retroperitoneal mass >3 cm should have a PET scan performed. A positive scan implies viable tumor, whereas a negative scan implies freedom from disease. Emerging data from combination PET/CT scans show potential in identifying small renal masses with reported 94% sensitivity and 100% specificity rates for clear cell RCC, but is still considered experimental. PET scans may also be useful in prostate cancer for distinguishing local vs. distant failure, determining progression of disease, and assessing the degree of androgen receptor expression but are not yet standard of care studies.

POST MICTURITION SYMPTOMS

DESCRIPTION LUTS are conventionally classified into symptoms of storage, voiding, and postmicturition symptoms. Postmicturition symptoms include the sensation of incomplete bladder emptying and postmicturition dribble. These symptoms have an overall prevalence of ~10% of the population, are most often present in the setting of other storage or voiding symptoms, and are noted to increase with age in men. Incomplete bladder emptying is seen more commonly in women whereas men more often experience postmicturition dribbling. Despite the fact that the importance of these symptoms is not always highlighted, studies have shown that their presence can have a significant adverse effect on patient health-related quality of life.

REFERENCE

Maserejian NN, Kupelian V, McVary KT, et al. Prevalence of postmicturition symptoms in association with lower urinary tract symptoms and health-related quality of life in men and women. *BJU Int.* 2011;108(9):1452–1458.

POSTORGASMIC ILLNESS SYNDROME (POIS)

DESCRIPTION Post orgasmic illness syndrome (POIS) is characterized by debilitating mental and physical symptoms following orgasm that may last from a few hours to several days. Mental symptoms include cognitive dysfunction, irritability, discomfort, anxiety, and depression. Physical symptoms include fatigue, headache, and allergic or flu-like symptoms. Patients typically avoid sexual activity altogether or plan to engage in intercourse when they have adequate time to recover. Some hypothesize that allergy to one's own semen may contribute to the illness. Others believe that a lack of the neurosteroid progesterone, or defect in neurosteroid precursor synthesis, leads to the observed pathophysiology.

REFERENCE

Waldinger MD, Meinardi MM, Zwinderman AH, et al. Postorgasmic illness syndrome (POIS) in 45 Dutch Caucasian males: Clinical characteristics and evidence for an immunogenic pathogenesis (Part 1). *J Sex Med.* 2011;8(4):1164–1170.

POSTATROPHIC HYPERPLASIA OF THE PROSTATE

DESCRIPTION Postatrophic hyperplasia is a histologic pattern showing atrophic and hyperplastic glands, sometimes with a small acinar configuration. Atrophy followed by hyperplasia results in acini with nuclear enlargement. Nucleoli are enlarged as well. The basal cell layer may be difficult to see, but its presence rules out prostate cancer. Immunohisto-chemistry with 34βE12 stain, which stains for basal cell CK, may be helpful. This entity can be confused with prostate cancer on needle biopsy, but is a benign condition. (See also Section III: "Atypical Small Acinar Proliferation, Prostate [ASAP]"; "Atypical Adenomatous Hyperplasia of the Prostate.")

REFERENCE

Amin MB, Tamboli P, Varma M, et al. Postatrophic hyperplasia of the prostate gland: A detailed analysis of its morphology in needle biopsy specimens. *Am J Surg Pathol.*

1999;23(8):925–931.

POSTCOITAL PROPHYLACTIC ANTIBIOTICS

DESCRIPTION Women who suffer recurrent UTIs (≥2 infections in 6 mo or ≥3 infections in 1 yr) may have an association of their UTIs with sexual activity. Gram-negative organisms colonizing the vagina are often the cause. The problem is typically seen in premenopausal women. (See also Section I: "Urinary Tract Infection [UTI], Adult Female.")

TREATMENT

- Hydrate well and empty bladder immediately after intercourse (have not been proven to be uniformly effective in clinical trials).
- Cranberry juice/supplements have not been proven beneficial in trials
- Suppressive antibiotic therapy immediately after intercourse; single dose of the following has been reported: Trimethoprim-sulfamethoxazole, nitrofurantoin, cephalexin, and the fluoroquinolones; if pregnant: Cephalexin (250 mg) or nitrofurantoin (50 mg).

REFERENCE

Fiore DC, Fox CL. Urology and nephrology update: recurrent urinary tract infection. *FP Essent.* 2014;416:30–37.

POSTCOITAL TEST

DESCRIPTION A test that evaluates the interaction between sperm and cervical mucus. It determines the adequacy of sperm and the receptivity of cervical mucus. Testing consists of retrieving specimens from the posterior vaginal fornix, exocervix, and endocervical canal ~6–8 hr after intercourse. The test should be performed close to the time of ovulation, and couples are asked to abstain from sex for 48 hr prior to the test. These specimens are examined to determine the number of motile sperm, with 10 sperm/hpf considered adequate and excluding the cervical mucosa as cause of infertility. When these test results are poor, the specimens may be repeated on another occasion, 1–3 hr after coitus.

SYNONYM

Sims–Huhner Test

REFERENCE

Leushuis E, van der Steeg JW, Steures P, et al.; CECERM study group. Prognostic value of the postcoital test for spontaneous pregnancy. *Fertil Steril.* 2011;95(6):2050–2055.

POSTERIOR TIBIAL NERVE STIMULATION (PTNS)

DESCRIPTION PTNS provides retrograde stimulation to the sacral plexus through stimulation of the posterior tibial nerve. The currently available United States system is the Urgent PC (Uroplasty, Minnetonka, MN). It is FDA approved for the treatment of urinary urgency, urinary frequency, and urge incontinence (overactive bladder). Other uses described include nonobstructive urinary retention, neurogenic bladder, pediatric voiding dysfunction and chronic pelvic pain syndrome (CPP)/Painful bladder syndrome (PBS). The PTNS mechanism of action is unclear, and may be due to effects on different areas of the CNS or a

peripheral effect on the target organ. The -gauge disposable needle insertion point is 4–5 cm cephalad to the medial malleolus. The current is a continuous, square wave (duration of 200 μs, frequency of 20 Hz). The current is determined by the highest level that is tolerated by the patient. The stimulations sessions last for 30 min and are performed once a week for 10–12 wk PTNS was found to be effective in 37–100% of patients with OAB, in 41–100% of patients with nonobstructive urinary retention and in up to 100% of patients with CPP/PBS. (See also Section I: "Overactive Bladder (OAB)" and Section II: "Sacral Neuromodulation.") (Image ☼)

POSTOPERATIVE SPINDLE CELL NODULE, BLADDER

DESCRIPTION These benign lesions appear 5 wk to 3 mo after surgical procedures in the lower urogenital tract. They grossly resemble a sarcoma and develop after damage to the bladder wall. Microscopically, they appear as intersecting spindle cells intermingled with inflammatory infiltrates. The main differential diagnosis is leiomyosarcoma. They have been reported most commonly in the bladder and prostate.

SYNONYMS

- Postoperative spindle cell nodule of Proppe
- Pseudosarcoma

TREATMENT

Transurethral resection

REFERENCE

Young, RH. Non-neoplastic disorders of the urinary bladder (Chapter 5). In: Bostwick DG, ed. *Urologic Surgical Pathology*. 2nd ed. Philadelphia, PA: Mosby Elsevier; 2008:238.

POSTTRANSPLANT LYMPHOPROLIFERATIVE DISORDER

DESCRIPTION Posttransplant lymphoproliferative disorder (PTLD) is a heterogeneous disease that may occur in recipients of solid organ transplants and hematopoietic stem cell transplants. The risk of lymphoma is increased 20–120% compared with the general population. Epstein–Barr virus infection at the time of transplantation appears to be a significant risk factor. Based on morphologic, immunophenotypic, and molecular criteria, PLTD are classified into 4 pathologic categories: Early lesions, polymorphic, monomorphic, and classical Hodgkin lymphoma. A mainstay of therapy is reduction of immune suppression but often single-agent rituximab or even combination chemotherapy is needed.

REFERENCE

Jagadeesh D, Woda BA, Draper J, et al. Post transplant lymphoproliferative disorders: Risk, classification, and therapeutic recommendations. *Curr Treat Options Oncol.* 2012;13(1):122–136.

POSTVOID DRIBBLING

DESCRIPTION Urine that leaks out or the urethra at the end of micturition. It may be caused by bladder outlet obstruction, a urethral diverticulum, or vesicovaginal reflux of urine. Recent data suggests it may be a surrogate for median lobe hypertrophy.

REFERENCE

Hassler E, Krakau I, Häggarth L, et al. Questioning questions about symptoms of benign prostatic hyperplasia. *Fam Pract.* 2001;(3):328–332.

POTASSIUM SENSITIVITY TESTING

DESCRIPTION A diagnostic test proposed for Interstitial cystitis (IC)/Painful Bladder syndrome (PBS). The pathogenic mechanism of PBS/IC may involve increased epithelial permeability or loss of tight junctions between epithelial cells. Patients with a normal urothelium and sensory nerves will have no pain associated with the instillation of 400 mM (0.4 M) of potassium chloride solution into the bladder, whereas those with PBS/IC may have pain. Patients may be asked to rank their degree of pain on a visual analog scale. More recently, potassium chloride has been used to predict the responsiveness of patients to intravesical hyaluronic acid therapy.

REFERENCE

POTTER SYNDROME/POTTER SEQUENCE

DESCRIPTION A fetus with Potter syndrome (oligohydramnios sequence) a rare fatal disorder that occurs in sporadic and autosomal recessive forms with an incidence of 1 in 4,000 births may show signs of Potter facies (a flat nose, recessed chin, epicanthal folds, low-set ears) and limb abnormalities. These deformities are believed to be secondary to compression of the fetus due to severe oligohydramnios resulting from bilateral renal agenesis. Skelet al malformations may include hemivertebrae, sacral agenesis, and limb anomalies. Babies are often stillborn or die early in the neonatal period. Death usually results from respiratory insufficiency from lack of development of the alveolar sacs. (See also Section II: “Renal Agenesis [Bilateral and Unilateral].”)

REFERENCES

Shastry SM, Kolte SS, Sanagapati PR. Potters Sequence. *J Clin Neonatol.* 2012;1(3):157–159.

POUCHITIS

DESCRIPTION Pouchitis is the most common long-term complication in patients with restorative proctocolectomy and ileal pouch-anal anastomosis and is more completely described in the literature for this population. In patients undergoing continent catheterizable stoma, pain in the region of the stoma, along with an increase in pouch contractility is also

referred to as *pouchitis*. The increased intestinal segment contractility can cause temporary loss of the continence mechanism. The patient may complain of sudden, explosive loss of urine through the catheterizable stoma. Anecdotal reports of continent orthotopic neobladder also exist. Most cases involving urinary diversion are caused by a bacterial infection that responds to a 10-day course of antibiotics based on sensitivity testing.

REFERENCE

Colwell JC, et al. eds. *Fecal & Urinary Diversions: Management Principles*. Philadelphia, PA: Mosby Elsevier; 2012.

PRADER–WILLI SYNDROME

DESCRIPTION This is secondary to a chromosomal abnormality consisting of partial deletion of the long arm of chromosome 15 (q11–13). Children often present as obese, hypotonic, and retarded, with hypogonadism, and cryptorchidism. Obesity and behavioral problems are the major cause of morbidity and mortality in affected individuals.

REFERENCE

Cassidy SB. Prader-Willi syndrome. *J Med Genet.* 1997;34(11):917–923.

PRECOCIOUS PUBERTY

DESCRIPTION Precocious puberty is sexual development at an earlier age than expected. In general, signs of secondary sexual development in boys <9 and breast or pubic hair development in white girls <7 or in black girls <6 is precocious. Common causes include medications (exogenous estrogen or testosterone), idiopathic causes, pituitary and CNS tumors (hamartomas, others), CAH, adrenal tumor, ovarian cysts and tumors, McCune–Albright syndrome, Leydig cell tumors, hCG-secreting GCT, testotoxicosis, or pseudoprecocious puberty.

REFERENCE

Carel JC, Leger J. Clinical practice. Precocious puberty. *N Engl J Med.* 2008;358(22):2366–2377.

PREGNANCY, BACTERIURIA, PYURIA, AND URINARY TRACT INFECTION

DESCRIPTION Pregnant women with asymptomatic bacteriuria have a higher likelihood of developing a UTI and should be treated to reduce the incidence of pyelonephritis, sepsis, and fet al complications (low birth weight, prematurity, death). Pyuria in the presence of bacteriuria indicates UTI. Pyuria in the absence of bacteriuria should raise suspicion for nephrolithiasis, TB, or less commonly, malignancy of the urinary tract. Penicillins and cephalosporins (FDA category B) are generally agreed to be safe in pregnancy. Drugs with very high protein binding (eg, Ceftriaxone), may be inappropriate the day before parturition because of the possibility of bilirubin displacement and kernicterus risk. Fluoroquinolones should be AVOIDED in pregnancy. (See also Section I: “Bacteruria and Pyuria” and

"Pregnancy, Urolithiasis.")

TREATMENT

The following regimens have been reported in eradicating asymptomatic bacteriuria in pregnancy:

- Nitrofurantoin 100 mg BID × 5 days
- Amoxicillin 500 mg PO BID 3–7 days
- Amoxicillin-clavulanate 500 mg PO BID 3–7 days
- Cephalexin 500 mg 500 mg PO BID 3–7 days
- Fosfomycin 3 g orally as a single dose

The following regimens have been reported in treating cystitis in pregnancy modified based on urine culture results:

- Nitrofurantoin 100 mg orally every 12 hr for 5 days
- Cefpodoxime: 100 mg twice daily for 3–7 days
- Amoxicillin-clavulanate: 500 mg orally every 12 hr for 3–7 days
- Fosfomycin: 3 g orally as a single dose

The following regimens are reported for mild to moderate pyelonephritis in pregnancy:

- Ceftriaxone: 1 g every 24 hr
- Cefepime: 1 g every 12 hr
- Aztreonam: 1 g every 8 to 12 hr

The following regimens are reported for severe pyelonephritis with immunocompromise and/or incomplete urinary drainage.

- Ticarcillin-clavulanate: 3.1 g every 6 hr
- Piperacillin-tazobactam: 3.375 g every 6 hr
- Meropenem: 500 mg every 8 hr
- Ertapenem: 1 g every 24 hr
- Doripenem: 500 mg every 8 hr

PREGNANCY, HEMATURIA

DESCRIPTION Microscopic hematuria is a common finding during pregnancy, however it rarely impacts the outcome of the pregnancy. However, these patients should be assessed postpartum for continued microscopic hematuria to assess for further urologic or kidney disease.

REFERENCE

Brown MA, Holt JL, Mangos GJ, et al. Microscopic hematuria in pregnancy: Relevance to pregnancy outcome. *Am J Kid Dis.* 2005;45:667–673.

PREGNANCY, RADIOLOGIC CONSIDERATIONS

DESCRIPTION Urologists are commonly confronted with pregnant patients with hydronephrosis, renal colic, and stone disease. Imaging is difficult to interpret due to anatomic and physiologic changes in the gravid patient, as well as because of the concern of exposing a fetus to ionizing radiation. The maximum safe dose of radiation allowable to the fetus in the 1st trimester is thought to be 20,000 mrads, and 50,000 mrads in the 2nd and 3rd trimesters. The initial imaging modality of choice should be abdominal ± transvaginal color Doppler ultrasound (US) to evaluate renal resistive indices, ureteral dilation distal to the iliac vessels, and ureteral jets in the bladder. If further evaluation is needed, a diuretic magnetic resonance urogram (MRU) or low-dose CT reported average exposure 705 mrads) can be performed. In the OR, stent placement can be done with intraoperative US and, if absolutely necessary, fluoroscopy with shielding of the fetus by placement of lead below the patient's lower abdomen and pelvis. Iodinated contrast materials may be used in pregnancy, when indicated. Gadolinium is not recommended for use in the pregnant patient unless benefit justifies the potential fet al risk.

PREGNANCY, RENAL TRANSPLANTATION

DESCRIPTION Successful renal transplantation restores normal ovulatory function and the potential for successful conception. Pregnancy does not appear to affect long-term graft survival. However, pregnancies after renal transplant are at significant risk for maternal and fet al complications including hypertension, preeclampsia, and infection, as well as preterm delivery and fet al growth restriction. Renal transplantation is not a contraindication to vaginal delivery and care should be taken during cesarean section not to injure the renal unit. General safe guidelines for pregnancy after renal transplantation are good health and functioning renal unit 2 yr after transplantation without any evidence of infection or obstruction and on low doses of immunosuppression.

REFERENCE

Fuchs KM, Wu D, Ebcioglu Z. Pregnancy in renal transplant recipients. *Semin Perinatol.* 2007;31:339–347.

PREGNANCY, URINARY DIVERSION

DESCRIPTION Pregnancy after urinary diversion has not been well studied, and only 250 cases have been reported in the literature thus far. Patients have more difficulty getting pregnant because of their inherent underlying disease process, metabolic changes from urinary diversion, and because of the fixed position of the uterus from prior surgery. These

patients have special antepartum considerations from decreased perfusion of the bowel segment from compression of the conduit or neobladder by the uterus, malabsorption of food due to use of the terminal ileum, stomal prolapse from increased intra-abdominal pressure, stomal stenosis from impaired blood flow, difficulty catheterizing continent pouches from stretching of the efferent limb, and an increased risk of UTI from the presence of bacteriuria. Unique postpartum issues include adhesions of the small intestine that may complicate cesarean section, increased residual urine volumes from stretching of conduits or neobladders, and an increased risk of pelvic organ prolapse.

REFERENCE

Hautmann RE, Volkmer BG. Pregnancy and urinary diversion. *Urol Clin North Am.* 2007;31:71–88.

PREGNANCY, URINARY TRACT OBSTRUCTION

DESCRIPTION Urinary tract obstruction during pregnancy most commonly occurs from a ureteral stone or extrinsic compression from the gravid uterus. Patients will commonly present with flank pain. US, magnetic resonance urography, or low-dose CT may be used to evaluate for a ureteral stone and evidence of obstruction. Hydronephrosis is a common finding in pregnancy and may be found in 15%, 20%, and 50% of patients in their 1st, 2nd, and 3rd trimesters, respectively. It is more common on the right side, and is commonly thought to occur from progesterone-mediated ureteral dilation and extrinsic compression. (see also Section I: “Pregnancy, Urolithiasis” and Section II: “Pregnancy, Radiologic Considerations.”)

TREATMENT

- Initially, conservative with IV hydration and analgesic therapy.
- Patients who fail may require stent or nephrostomy tube placement. Stents can rapidly encrust due to increased urinary calcium excretion and should be changed in a timely fashion.
- Ureteroscopy and laser lithotripsy.

REFERENCE

McAleer SJ, Loughlin KR. Nephrolithiasis and pregnancy. *Curr Opin Urol.* 2004;14(2):123–127.

PREGNANCY, UROLOGIC MALIGNANCY

DESCRIPTION Urologic malignancies are rare in pregnancy but often misdiagnosed due to overlapping signs and symptoms with preeclampsia and eclampsia. The most common tumor is RCC, which may present as flank pain, hematuria, and a palpable mass. It is often identified incidentally on imaging. Pheochromo-cytomas have been reported to occur in 1 of 50,000 term pregnancies. They present with severe hypertension, headaches, palpitations, vomiting, visual changes, and without proteinuria unlike preeclampsia. Adrenal adenomas may present with Cushing syndrome. Renal angiomyolipoma may present with flank pain, hematuria, and retroperitoneal hemorrhage, although it is sometimes incidentally diagnosed on imaging.

Urothelial carcinoma of the upper or lower tracts is rare and presents with hematuria. If urine analysis reveals hematuria and the culture is negative, cytology, cystoscopy, and upper tract imaging are warranted.

TREATMENT

- Removal of pheochromocytomas is controversial, but medical therapy may be used until the 3rd trimester or delivery of the fetus.
- The size and type of tumor should dictate management for RCC, and laparoscopic nephrectomy has been shown to be safe in pregnant women.
- Angiomyolipoma (AML) with hemorrhage may be managed with embolization or partial or total nephrectomy.
- Urothelial cancer should be managed endoscopically given its propensity for aggressive growth and lymphatic invasion. Mitomycin should be avoided, and only 1 case report exists of using BCG.

REFERENCE

Martin FM, Rowland RG. Urologic malignancies in pregnancy. *Urol Clin North Am.* 2007;341):53–59.

PREGNANCY, UROLOGIC MEDICATIONS

DESCRIPTION Medications in pregnancy have not been well studied or documented. Urologic issues include antibiotics for UTIs and anesthesia for surgical procedures. Macrobid is a safe, well-tolerated antibiotic classified as a category B (no evidence of harm to human fetus) drug by the FDA. There is a recommendation against using this in the 3rd trimester because of the risk of hemolytic anemia in patients with G6PD deficiency. Fluoroquinolones are considered category C medications, but multiple studies have failed to demonstrate any evidence of harm. Penicillins are category B drugs, and often the medication of choice in pregnancy. General anesthesia may carry a slightly higher risk of fet al malformations and premature labor; this effect is directly related to the complexity and length of the procedure but the overall increased risk is thought to be minimal. (See also Section II: “Pregnancy, Bacteruria, Pyuria, and UTI.”)

REFERENCE

Shrim A, Garcia-Bournissen F, Koren G. Pharmaceutical agents and pregnancy in urology practice. *Urol Clin North Am.* 2007;34(1):27–33.

PREHN SIGN

DESCRIPTION Prehn sign is a clinical test used to aid in distinguishing epididymitis from testicular torsion although it is not always reliable. The physical lifting of the testicles is said to relieve the pain of epididymitis (positive Prehn sign), but does not relieve the pain of testicular torsion (negative Prehn sign). It is important to note that Prehn sign is not always reliable and Doppler ultrasound is a valuable tool in confirming the diagnosis.

REFERENCE

Lavallee ME, Cash J. Testicular torsion: Evaluation and management. *Curr Sports Med Rep*.

2005; 4(2):102–104.

PRENTISS MANEUVER

DESCRIPTION Additional cord length in an orchiopexy operation can be gained by incising the inguinal floor and ligating the inferior epigastric vessels. The internal ring and transversalis fascia are then closed lateral to the cord.

REFERENCE

Kelly CE. The relationship between pressure flow studies and ultrasound-estimated bladder wall mass. *Rev Urol.* 2005;Suppl 6:S29–S34.

PREPUTIAL STONES

DESCRIPTION Preputial stones (*preputial calculi*) are rare occurrences, generally found in adults and associated with poor genital hygiene, low socioeconomic status, and phimosis. Factors in preputial stone formation include obstruction, stasis, foreign body, nidus formation, and infection. Removal of stone and elimination of the predisposing condition is the treatment.

REFERENCE

Ellis DJ, Siegel AL, Elder JS, et al. Preputial calculus: A case report. *J Urol.* 1986;1362:464–465.

PRESSURE–FLOW STUDIES

DESCRIPTION The simultaneous measurement of bladder pressure and uroflow throughout the entire voiding cycle. Performed as part of urodynamic study, these studies improve on some of the imitations of uroflowmetry alone. Measurements for this study can include the variables that affect the study: Intravesical pressure, rectal pressure, intraurethral pressure, sphincter electromyogram, and urine flow rate. A small catheter is placed to fill the bladder and measure the flow. All variables are plotted and recorded simultaneously to compare the various readings during various points in the micturition study.

REFERENCE

Nitti VW. Pressure Flow urodynamic studies: the gold standard for diagnosing bladder outlet obstruction. *Rev Urol.* 2005;7(Suppl 6): S14–S21.

PRIAPISM, STUTTERING (INTERMITTENT PRIAPISM)

DESCRIPTION Priapism that is recurrent in nature should be treated initially as for ischemic priapism. Emphasis should be placed on long-term prevention using medical or self-injection therapy. (See also Section I: “Priapism.”)

SYNONYMS

- Recurrent priapism
- Intermittent priapism

TREATMENT

- Hormonal therapy (leuprolide, flutamide, bicalutamide)
- Self-injection therapy with phenylephrine

REFERENCE

Burnett AL, Bivalacqua TJ. Priapism: Current principles and practice. *Urol Clin North Am.* 2007;344:61–62.

PRIMITIVE NEUROECTODERMAL TUMORS (PNET) (EXTRASKELET AL EWING SARCOMA)

DESCRIPTION Primitive neuroectodermal tumors are part of the Ewing family of tumors (EFT) that include Ewing's sarcoma of the bone. Peripheral PNET is a very aggressive neoplasm that predominantly affects children and adolescents. Renal PNET is the most reported PNET of the genitourinary tract, however bladder, prostate, ureter, and seminal cord PNETs have also been reported. PNETs are often diagnosed as metastatic disease (25–50%) and the outcome is often poor; with a 5-yr survival rate (45–55%).

TREATMENT

Multimodal therapy including surgical resection, chemotherapy, and radiation.

REFERENCE

Ellinger J, Bastian PJ, Hauser S, et al. Primitive neuroectodermal tumor: Rare, highly aggressive differential diagnosis in urologic malignancies. *Urology*. 2006;68:257–262.

PRINCETON III CONSENSUS RECOMMENDATIONS: ERECTILE DYSFUNCTION (ED) AND CARDIOVASCULAR DISEASE

DESCRIPTION The recommendations of the 3rd Princeton Consensus Conference focus on (1) evaluation and management of cardiovascular risk in men with ED and no known CVD, (2) reevaluation and modification of the 2nd conference recommendation for evaluation of cardiac risk associated with sexual activity in men with known CVD, and (3) the role of testosterone replacement therapy (TRT) in ED and CVD management (Image ☼).

REFERENCE

Nehra A, Nehra A1, Jackson G, Miner M, et al. The princeton III consensus recommendations for the management of erectile dysfunction and cardiovascular disease. *Mayo Clin Proc*. 2012;87(8):766–778.

PROLACTIN, SERUM LEVEL

DESCRIPTION Elevated prolactin levels are associated with infertility and ED. Hyperprolactinemia may be caused by a pituitary tumor, stress, medications, hypothyroidism, or idiopathic causes. A pituitary tumor will result in low serum gonadotropin and testosterone levels and elevated prolactin levels. The mainstay of therapy for prolactinomas is medical management.

Elevated prolactin levels >50 ng/mL suggest a prolactinomas. Renal failure, stress,

medications, and hypothyroidism have serum prolactin value <50 ng/mL.

TREATMENT
- Cabergoline
- Bromocriptine
- Surgical excision

REFERENCE
Verhelst J, Abs R. Hyperprolactinemia: Pathophysiology and management. *Treat Endocrinol.* 2003;2(1):23–32.

PROLAPSE, STAGING SYSTEMS

DESCRIPTION Since the early 1960s multiple practitioners including Porges, Baden, Walker, and Beecham have attempted to classify pelvic organ prolapse. Then in 1996 the American Urogynecologic Society, the Society of Gynecologic Surgeons, and the ICS adopted the Pelvic Organ Prolapse Quantitation (POP-Q) exam. The POP-Q exam, in which 9 specific points of measurement are obtained in relation to the hymenal ring, has been demonstrated to be learned easily and performed quickly with highly reproducible exam findings. The most widely used classification systems used today are the Baden–Walker and POPQ systems. (See also Section II: “Cystocele Grading: Baden–Walker, Pelvic Organ Prolapse Quantification [POP-Q].”)

REFERENCE
Theofrastous JP, Swift SE: The clinical evaluation of pelvic floor dysfunction. *Obstet Gynecol Clin North Am.* 1998;25:783–804.

PROPANTHELINE STIMULATION TEST

DESCRIPTION This test is used when involuntary detrusor contractions are demonstrated during cystometry to predict the outcome of pharmacologic treatment with anticholinergics. Propantheline bromide is an anticholinergic with side effects that include dry mouth and blurred vision. Once involuntary detrusor contractions have been confirmed, 15 mg of propantheline bromide are administered parenterally. Once effects of the drug are noticed, cystometry is repeated. A positive response is defined as the complete abolition of involuntary detrusor contractions, or a 200% increase in the bladder volume at which they occur. If the parenteral dosage is effective, a favorable clinical response to the orally administered dose can be expected in most patients.

REFERENCE
Blaivis JG, Scott RM, Labib KB. Urodynamic evaluation as a test of sacral cord function. *Urology*. 1979;13:682–687.

PROPHYLACTIC ANTIBIOTICS, AUA GUIDELINES

DESCRIPTION Recommendations include limiting antibiotic prophylaxis to a maximum of 24 hr, no prophylaxis solely to prevent infectious endocarditis, and defining characteristics

for patients at higher risk. These characteristics include advanced age, anatomic anomalies of the urinary tract, poor nutritional status, smoking, chronic corticosteroid use, immunodeficiency, externalized catheters, colonized endogenous/exogenous material, distant coexistent infection, and prolonged hospitalization.

Recommendations for specific procedures and agents are found in Section VII: "Reference Tables: Antibiotic Prophylaxis: AUA guidelines."

REFERENCE

PROSTASCINT SCAN

DESCRIPTION A nuclear medicine imaging study designed to localize prostate cancer cells using a radiolabeled monoclonal antibody to PSMA (prostate-specific membrane antigen) called indium-111 capromab pendetide. Patients are injected, and single photon emission computed tomography is performed immediately after scan and 4–5 days later. This allows for washout of antibody from the blood and bowel. The test was initially designed to identify extraprostatic disease, and current applications include identifying the location of cancer recurrence following definitive therapy for prostate cancer. It has traditionally suffered from poor specificity and interobserver reliability and issues concerning uptake of mid abdominal lymph nodes. Recent data suggest that there may be renewed interest in integrating the ProstaScint scan in clinical decision making for deciding between local vs. systemic salvage therapy for PSA recurrence following definitive management of prostate cancer (Image ☼).

REFERENCE

Taneja S. ProstaScint Scan: Contemporary use in clinical practice. *Rev Urol.* 2004;S10:19–28.

PROSTATE CANCER SCREENING GUIDELINES

DESCRIPTION Screening asymptomatic men for prostate cancer is controversial. Concerns about over diagnosis and overtreatment of clinically important cancers are part of this reason. Many professional organizations have developed guidelines concerning prostate cancer screening that are summarized in the table. (See also Section II: "PSA, General Considerations" and Section VII: Reference Tables: Prostate Cancer Screening Guidelines.)

Organization	Recommendation (all PSA values in ng/mL)
American Cancer Society (ACS) (2010)	• No routine screening; After informed discussion for those who wish to be screened: – Screen with PSA, w/or w/o DRE, at age 50 with >10 yr life expectancy – Screen at age 45 with high risk[a]; age 40 with highest risk[b] – No screening with <10 yr life expectancy (age 75)
American College of Physicians (2013)	• Inform men age 50–69 about limited benefits and harms; screen only if patient wants it • Do not screen <age 50 if average risk, over 69, or <10–15-yr life expectancy
American Urological Association (2013)	• No screening under 40; not recommended if average risk 40–54; individualize if high risk[c] • Shared decision making for men age 55–69 • No screening over age 75 or any man <10–15-yr life expectancy • Reduce the harms of screening, a screening interval of 2 yr or more may be preferred
National Comprehensive Cancer Network (NCCN)(2014)	• Informed discussion with all • Baseline DRE & PSA age 45; if PSA <1 repeat age 50; if PSA >1, repeat every 1–2 yr • Age 50–70 with normal DRE & PSA <3, repeat every 1–2 yr • Use caution screening if >age 70 and only if very healthy; few >age 75 benefit from screening
USPSTF (2012)	• No role in any man unless symptoms (Grade D)

[a] African-American or have a 1st degree relative diagnosed with PCa at <65 yr of age
[b] Several 1st degree relatives diagnosed with PCa at <65 yr of age
[c] Positive family history or African-American race

PROSTATE CANCER, ACTIVE SURVEILLANCE AND WATCHFUL WAITING

DESCRIPTION Screening for prostate cancer can result in the diagnosis of prostate cancer in many men who are not likely to suffer any consequences or die from the disease. This often results in overtreatment of many men with prostate cancer. Deferred therapy for prostate cancer generally involves 2 different approaches although the terms are often used interchangeably, they are not completely identical:

- *Active surveillance* is a strategy aiming to individualize the management of early prostate cancer by selecting only those men with significant cancers for curative therapy. This involves actively monitoring the course of prostate cancer with the intent of intervention with definitive local therapy (eg, radiation therapy, RP) if cancer progression is documented.
- *Watchful waiting* uses less aggressive follow-up until the patient develops symptomatic disease progression, at which time he is often placed on hormonal treatment. (See also Section I: “Prostate Cancer, General” and “Prostate Cancer, Very Low Risk and Active Surveillance”; Section II: “Life Expectancy, Urologic Considerations.”)

PROSTATE CANCER, BASAL CELL CARCINOMA

DESCRIPTION A very rare variant of prostate cancer comprising $<0.01\%$ of malignant tumors. Lesions exist in 2 distinct forms, adenoid cystic carcinoma (ACC), and basaloid carcinoma (BC), that may occur clinically separate or as mixed tumors with 1 dominant pattern. Immunohistochemical analysis reveals strongly positive results for both 34βE12 and p63. Once thought to be a more indolent form of prostate cancer, current evidence supports the potential for local recurrence and metastasis and therefore suggests radical surgery with life-long follow-up as 1st-line management.

REFERENCE

PROSTATE CANCER, CIRCULATING TUMOR CELLS (CTC's)

DESCRIPTION Circulating tumor cells (CTC) can be detected using molecular techniques such as RT-PCR. An identification assay for actual circulating cells (CellSearch) is commercially available for use in patients with hormone-refractory prostate cancer. In patients with advanced prostate cancer, men with ≥ 5 CTCs per 7.5 mL blood prior to chemotherapy had a significantly shorter median survival (10 vs. 21 mo in those with <5 CTCs). The role of the CTC assay continues to evolve in the management of prostate cancer; it appears to be only valid at present for men with advanced, castrate resistant prostate cancer disease and is not as useful for earlier stages of disease. (See also Section II: "PSA, RT-PCR.")

REFERENCE

PROSTATE CANCER, DUCTAL ADENOCARCINOMA

DESCRIPTION These terms have been replaced by *ductal adenocarcinoma of the prostate.* It accounts for 0.2–0.8% of prostate adenocarcinoma. Due to its appearance, ductal adenocarcinoma was previously thought to arise from müllerian remnants and possess unique clinical features related to its origin. While further analyses have shown that these tumors do in fact arise from prostatic tissue. The lesion originates from periurethral prostatic ducts and may grow into an exophytic urethral lesion around the verumontanum. A mixture of cribriform and papillary structures is seen on microscopy, resembling endometrial adenocarcinoma of the uterus and hence the earlier descriptive terms. Histologically, these tumors are composed of tall columnar cells with clear to eosinophilic cytoplasm and large nucleoli. The cells form glands with scant intervening stroma. Prostatic ductal carcinoma cells express PSA. Prostate adenocarcinoma is also present in 77% of cases.

Early presentation is hematuria, irritative and obstructive symptoms and it tends to occur in older men (60–80 yr). Serum PSA levels and DRE at the time of diagnosis tend to underestimate disease. Cystoscopically it may appear multiple polypoid friable protruding from near the mouth of the prostatic utricle but often there are no defining endoscopic

findings. Sources are conflicting concerning the clinical presentation with some stating due to the early symptom presentation most are organ confined and others more likely to present with advanced stage cancer. The behavior has been compared to behaved similar to Gleason's 8 (4 + 4) acinar prostate adenocarcinoma.

SYNONYMS

- Ductal carcinoma of the prostate
- Endometrioid carcinoma, prostate
- Endometrial carcinoma of the prostate
- Papillary adenocarcinoma of the prostatic utricle

TREATMENT

Similar to high-grade acinar adenocarcinoma of prostate. Most in the literature have been managed by radical prostatectomy. Ductal carcinoma of the prostate tends to be hormone sensitive and advanced disease is initially responsive to androgen deprivation. The overall mortality was significantly worse in men with ductal prostate adenocarcinoma, almost 3-fold higher rate of death, as compared to acinar prostate adenocarcinoma.

PROSTATE CANCER, FAMILIAL

DESCRIPTION The risk of prostate cancer is directly dependent upon the number of affected 1st-degree relatives, the age of the relative when diagnosed, and whether the relative is a father or brother. Risk is also associated with a family history of breast cancer.

Relations	Risk of Prostate Cancer	Relations	Risk of Prostate Cancer
Any relative	1.93	Brother	2.84
Any 1st degree	2.22	1st degree dx <60 yr	2.16
Any 2nd degree	1.88		
Father	2.12	1st degree with breast cancer	1.24

REFERENCE

PROSTATE CANCER, LEIOMYOSARCOMA, AND OTHER UNCOMMON SARCOMAS

DESCRIPTION Leiomyosarcoma of the prostate is extremely rare and a highly aggressive neoplasm, accounting for <0.1% of primary prostate malignancies. It is the most common primary prostatic sarcoma of the prostate in adults and comprises 38–52% of adult prostatic sarcomas. Rhabdomyosarcoma most common in pediatric patients and can be seen in adults.

Other less common prostate sarcomas include MFH and prostatic stromal sarcoma. Presentation can include urinary obstruction frequency, urgency, hematuria, perineal and/or rectal, pain, constipation, burning on ejaculation, and constitutional symptoms. The diagnosis of prostate sarcoma was usually established with ultrasound-guided biopsy or transurethral resection, and PSA is usually normal. Multimodality therapy using surgery RP, radical cystectomy, pelvic exenteration with pre- or postoperative radiation and pre- or postoperative chemotherapy have been used with no standard of care. Doxorubicin-based combinations with agents such as cyclophosphamide, ifosfamide, vinblastine, or vincristine have been reported with mixed results.

PROSTATE CANCER, MUCINOUS ADENOCARCINOMA

DESCRIPTION These very rare tumors are histopathologically defined as having lakes of extracellular mucin comprising at least 25% of the primary prostate tumor. They generally are considered to have a slightly worse prognosis than typical adenocarcinoma of the prostate but other literature states the behavior is similar to adenocarcinoma of the prostate with no statistically significant difference in biochemical failure or survival. They can be hormonally refractory, and bone metastasis are common. Radiation and/or surgery can be considered.

PROSTATE CANCER, PREVENTION (CHEMOPREVENTION)

DESCRIPTION Numerous medications and nutraceuticals, including selenium, statins, and green teas, have been evaluated for the prevention of prostate cancer, but the most notable remain the 5α-reductase inhibitors (5 ARIs) finasteride and dutasteride. The Prostate Cancer Prevention Trial (PCPT) using finasteride demonstrated an almost 25% reduction in the incidence of prostate cancer but a slightly increased incidence of higher Gleason score cancers. Some have hypothesized that this may be due to selective inhibition of low-grade cancers along with a smaller prostate size resulting in less sampling error and better detection of higher-grade cancers already present. This is supported by whole-mount correlation from RP specimens. The REduction DUtasteride of prostate Cancer (REDUCE) trial using dutasteride (a dual 5α-reductase inhibitor) reported a 23% reduction in prostate cancer in high-risk men with a slight increase in high-grade cancers. The large SELECT trial using selenium and vitamin E was stopped prematurely because it did not appear that either agent alone or in combination reduced the risk of prostate cancer. In 2011, updated trial data

showed that the men taking vitamin E had a 17% increased risk of prostate cancer compared to men taking the placebo. In 2014, an analysis showed that men who started the trial with high levels of selenium, as assessed by measures of selenium in their toenail clippings, doubled their risk of developing a high-grade prostate cancer by taking selenium supplements and men who had low levels of selenium at the start of the trial doubled their risk of high-grade prostate cancer by taking vitamin E. Trial sponsors recommended that men avoid supplementation with these agents.

In 2008, ASCO and the AUA 2008 issued the following Clinical Practice Guidelines:

- Asymptomatic men, PSA <3.0 ng/mL who are regularly screened or anticipate undergoing annual PSA screening may benefit from a discussion of risks and benefits of 5-ARIs for 7 yr for the prevention of prostate cancer.
- Men taking 5-ARIs for LUTS should also discuss risks and benefits.
- A reduction of PSA by 50% at 12 mo is expected in men on 5-ARIs; the panel did not recommend a specific cut-point to trigger a biopsy for men taking a 5-ARI.

However at the present time there is no approved agent to prevent the development of prostate cancer.

PROSTATE CANCER RISK CALCULATORS

DESCRIPTION Usually in the form of tables or nomograms, these are predictive instruments developed to aid clinicians and patients alike in objectively assessing different aspects of prostate disease throughout its various stages of diagnosis and treatment. Most calculators are available online, with interactive modules that facilitate their incorporation into clinical practice (see below).

PROSTATE CANCER, RISK STRATIFICATION (D'AMICO CLASSIFICATION)

DESCRIPTION One challenge presented by prostate cancer is choosing the appropriate therapy based on the risk of disease progression. It is often useful to assign a relative risk to an individual. These risk groups were established from literature and based on known prognostic factors: PSA level, biopsy Gleason score, and 1992 AJCC T staging. 1 typical system, commonly referred to as the *D'Amico classification*, is described here. Note that this is risk of PSA progression posttherapy and not overall or disease-specific survival:

- Low risk: Stages T1c and T2a, PSA level of ≤ 10 ng/mL, and biopsy Gleason score of ≤ 6 ($< 25\%$ PSA progression at 5 yr post therapy)
- Intermediate risk: PSA levels ≤ 10–20 ng/mL, biopsy Gleason score of 7, or AJCC clinical stage T2b (25–50% PSA progression at 5 yr post therapy)
- High risk: T2c disease or a PSA level > 20 ng/mL or a biopsy Gleason score of ≥ 8 ($> 50\%$ PSA progression at 5-yr post therapy)

PROSTATE CANCER, SECONDARY HORMONAL THERAPY

DESCRIPTION In the setting of primary ADT failure (rising PSA with castrate level of testosterone considered to be a serum testosterone of < 50 ng/dL), is called castrate refractory prostate cancer (CRPC). A variety of strategies involving so-called "secondary hormonal therapy" can be applied. It should be noted that in all cases, castrate levels of testosterone should be maintained through the use of agents such as LHRH analogs while these additional therapies are applied. Common secondary hormonal therapies include:

- Antiandrogen withdrawal (See Section II: "Antiandrogen Withdrawal Syndrome [Flutamide Withdrawal Syndrome].")
- Administration of antiandrogens (eg, bicalutamide, nilutamide, flutamide)
- Administration of ketoconazole (ketoconazole has a weak and nonspecific inhibitory affect on several enzymes involved in androgen synthesis and has been widely used in combination with hydrocortisone for the treatment of CRPC)
- Estrogens, such as DES

To date, none of these agents have demonstrated a prolongation in overall survival in the prechemotherapy setting. The use of secondary hormonal manipulation is decreasing with the approval of multiple newer medications for CRPC. In the presence of metastasis (mCRPC) abiraterone acetate with low-dose prednisone and enzalutamide prolong overall survival

among men with metastatic CRPC who have been previously treated with docetaxel. Abiraterone acetate can be considered for men with metastatic CRPC the predocetaxel metastatic CRPC setting. Other new agents for mCRPC include sipuleucel-T, cabazitaxel and radium 223. (See also Section I: "Prostate Cancer, Rising PSA Following Androgen Ablation [Castrate Refractory Prostate Cancer, CRPC, mCRPC]".)

PROSTATE CANCER, SMALL CELL (NEUROENDOCRINE)

DESCRIPTION A rare subtype of prostate malignancy that has a rapidly fatal course. Considered to be a variant of Gleason 5 adenocarcinoma of the prostate, it is identical to small cell carcinomas of the lung and has neuroendocrine (small cell, oat cell) differentiation. In 50% of the cases, the tumors are mixed small cell carcinoma with adenocarcinoma. Histologically, prostatic SCCs of the prostate are part of a spectrum of anaplastic tumors of the prostate and are similar to SCCs of the lungs. Neuroendocrine cells are identified by special staining (ie, neuron-specific enolase [NSE] or other markers). It should be noted that the normal prostate does have some neuroendocrine positivity, but it is limited and can only be detected by staining. About 10% of acinar adenocarcinomas of the prostate can have Paneth-like cells (large eosinophilic cells) that are neuroendocrine, and it is recognized that adenocarcinoma of the prostate that is not classified as neuroendocrine can have some patchy cells that stain as neuroendocrine cells. Large numbers of Gleason 5 cells in a prostate sample should prompt a neuroendocrine staining workup of the sample. Tumors can exhibit a spectrum of differentiation, with a carcinoid-like pattern (low-grade neuroendocrine carcinoma) to the small cell undifferentiated type (oat cell), the highest grade of neuroendocrine tumor. Immunohistochemically, these cells can stain for serotonin, calcitonin, ACTH, hCG, and other markers. Most of these small cell tumors do not produce detectable levels of hormones but sometimes can produce detectable levels in the serum. They may also express and stain for PSA and acid phosphatase, but pure small cell carcinoma usually does not stain for PSA. The clinical behavior of small cell prostate carcinomas is characterized by extensive local disease, visceral disease, and low PSA levels despite large metastatic burden. At diagnosis, 70% of patients have metastatic disease, and visceral metastases are common (ie, liver). The average survival is <1 yr. Androgen receptor–positive tumors have a worse prognosis than do tumors that do not express the receptor median survival (10 mo vs. 30 mo). Diagnosis is made by TRUS biopsy, symptoms associated with metastasis, and elevated LFTs and CEA.

SYNONYMS

- Small cell anaplastic carcinoma of the prostate (SCCP)
- Oat cell carcinoma of the prostate
- Neuroendocrine prostate cancer
- Carcinoid of the prostate

TREATMENT

- These tumors respond poorly to androgen ablation, but this should be attempted.
- Surgery and/or radiation therapy may provide local control.
- Chemotherapy with agents such as VP-16 and cisplatinum have some activity.

REFERENCE

Nadal R, Schweizer M1, Kryvenko ON, et al. Small cell carcinoma of the prostate. *Nat Rev Urol.* 2014;11(4):213–219.

PROSTATE CANCER, SQUAMOUS AND ADENOSQUAMOUS

DESCRIPTION A rare lesion that can arise in patients infected with *Schistosoma haematobium*. It can be confused with more common conditions, such as squamous metaplasia of the prostate due to infarction, radiation, and hormonal therapy. Pure primary SCC of the prostate does not respond to estrogen therapy, and it does not develop elevated serum PSA or PAP levels with metastatic disease. Bone metastases are osteolytic instead of osteoblastic. Median survival is about 14 mo.

PROSTATE HEALTH INDEX (PHI) AND [–2] proPSA

DESCRIPTION The Beckman Coulter Prostate Health Index (phi) is a mathematical combination of total PSA (tPSA), free PSA (fPSA) and [–2] proPSA (an isoform of PSA). The mathematical equation is: ([–2] proPSA/fPSA) × (√tPSA). The phi has been shown to have a higher PCa predictive value than both total PSA and free PSA. The measurement of %[–2] proPSA improves the accuracy of prostate cancer detection in comparison with PSA or % of PSA, particularly in the group of patients with PSA between 2 µg/L and 10 µg/L. The phi may be able to reduce the number of unnecessary biopsies, maintaining a high cancer detection rate. Published results also showed that %[–2] proPSA and phi are related to the aggressiveness of the tumor.

PROSTATE URETHRAL ANGLE

DESCRIPTION The prostatic urethra runs through the prostate from the base to the apex, making an anterior angle of ~35° at the proximal verumontanum. In men with prostate hyperplasia this angle tends to be >35°. However, men without hyperplasia can also have an

increased prostatic urethral angle. On cystoscopic exam, an increased prostatic urethral angle (PUA) is often noted as a high bladder neck in men without prostatic enlargement. In preliminary clinical studies, the PUA was inversely associated with the urinary flow rate.

REFERENCE

Cho KS, Kim JH, Kim DJ, et al. Relationship between prostatic urethral angle and urinary flow rate: Its implication in benign prostatic hyperplasia pathogenesis. *Urology*. 2008;71:858–862.

PROSTATE, BASAL CELL HYPERPLASIA

DESCRIPTION Basal cell hyperplasia is important in that it is commonly associated with BPH and may sometimes be mistaken for prostate cancer. The prostatic epithelium consists of 3 major cell types: Epithelial, basal, and neuroendocrine cells. The basal cells are small and round with a scant cytoplasm and dark nuclei. These cells are less differentiated and almost devoid of secretory products; they are located between the secretory cells and rest on the basement membrane. Basal cells are negative for PSA and PAP. Typical basal cell hyperplasia consists of a proliferation of basal cells ≥ 2 cell layers thick at the periphery of prostate glands and acini. Basal cell proliferation in the prostate gland exhibits a spectrum from focal basal cell hyperplasia in the setting of nodular hyperplasia to a florid adenoid basal cell tumor. Many confusing names have been used in the literature fet alization of prostate, embryonal hyperplasia, basal cell tumor, basal cell adenoma, BC, adenoid cystic carcinoma. The differential diagnosis includes transitional cell hyperplasia, squamous metaplasia, urothelial carcinoma (TCC) of the prostate, and adenocarcinoma of prostate.

REFERENCE

Bhat S, Thomas A, Nazar M, et al. Basal cell hyperplasia of prostate-an entity a urologist must know. *Indian J Urol*. 2000;17:61–62.

PROSTATE, BENIGN ENLARGEMENT (BENIGN PROSTATE ENLARGEMENT [BPE])

DESCRIPTION Benign prostatic enlargement (BPE) is used when there is gland enlargement and is usually a presumptive diagnosis based on the size of the prostate. This term differs from BPH which is reserved for the histologic pattern it describes. A patient may have LUTS with or without BPE. (See also Section I: “Bladder Outlet Obstruction [BOO],” “Prostate, Benign Hyperplasia/ Hypertrophy [BPH]” and Section II: “Prostate, Benign Obstruction (Benign Prostatic Obstruction [BPO]).”)

REFERENCE

Abrams P, Chapple C, Khoury S, et al. Evaluation and treatment of lower urinary tract symptoms in older men. *J Urol*. 2009;181:1779–1778.

PROSTATE, BENIGN OBSTRUCTION (BENIGN PROSTATIC OBSTRUCTION [BPO])

DESCRIPTION BPO is used when obstruction has been proven by pressure–flow studies, or is highly suspected from flow rates and if the gland is enlarged. This is different from bladder outlet obstruction, the generic term for all forms of obstruction to the bladder outlet (eg, urethral stricture) including BPO. (See also Section I: "Bladder Outlet Obstruction [BOO]", "Prostate, Benign Hyperplasia/Hypertrophy [BPH]" and Section II: "Prostate, Benign Enlargement (Benign Prostate Enlargement [BPE]).")

REFERENCE

Abrams P, Chapple C, Khoury S, et al. Evaluation and treatment of lower urinary tract symptoms in older men. *J Urol.* 2009;181:1779–1787.

PROSTATE CALCULI

DESCRIPTION Calculi are more common in older males and are rarely found in children. They usually occur in clusters and are associated with other disease processes. Often found in a dilated prostatic utricle. They are generally asymptomatic but may cause symptoms such as decreased urinary stream, prostatism, and lower back pain; they are a rare source of chronic bacterial prostatitis. Calculi may form secondary to calcification of the corpora amylacea and simple precipitation of prostatic secretions.

TREATMENT

- Generally none
- Transurethral resection with laser lithotripsy as needed if markedly symptomatic

REFERENCE

Klimas R, Bennett B, Gardner WA Jr. Prostatic calculi: A review. *Prostate.* 1985;7(1):91–96.

PROSTATE, FEMALE

DESCRIPTION A coined radiologic expression that refers to an impression at the base of the female bladder seen on excretory urography or cystogram. The impression resembles an enlarged prostate in the male and can be caused by urethral diverticulum, benign and malignant tumors of the anterior vaginal wall, urethral neoplasm, and repair of SUI. Anatomically Skene paraurethral glands and ducts are considered homologous to the male prostate and immunohistochemical studies demonstrate expression of PSA and prostate-specific acid phosphatase (PSAP) in these paraurethral glands and ducts.

REFERENCES

Amis ES, Newhouse JH, eds. *Essentials of Uroradiology*. 1st ed. Boston: Little, Brown; 1991:289.

Zaviaĉiĉ M, Ablin R. The female prostate. *J Natl Cancer Inst.* 1998;90(9):713.

PROSTATE, HEMATURIA

DESCRIPTION Hematuria attributed to bleeding from the prostate is a diagnosis of exclusion. Patients should have an appropriate workup according to the guidelines provided by the AUA. Older patients with larger, more vascular prostates are more susceptible and can

be managed with 5α-reductase inhibitors or transurethral resection if bleeding is refractory to medical therapy. Most often idiopathic, bleeding can also be iatrogenic after prostate biopsy and endoscopic urologic procedures or due to locally advanced prostate cancer late manifestation.

TREATMENT

- 5α-reductase inhibitors (1st-line therapy for troublesome benign prostatic hypertrophy bleeding)
- Intravesical alum, silver nitrate, and formalin (2nd-line therapy)
- Transurethral resection or vaporization of the prostate

REFERENCE

Rastinehad AR, Ost MC, VanderBrink BA, et al. Persistent prostatic hematuria. *Nat Clin Pract Urol.* 2008;5(3):159–165.

PROSTATE, INFARCTION

DESCRIPTION The etiology of prostatic infarction is still unclear, although it has been linked to prostate hyperplasia. Histologic findings include infraction of prostatic epithelium, with hemorrhage and neutrophils in the intervening stroma. Recent infarcts generally do not have squamous metaplasia, whereas older ones do. Typically, the infarctions are multiple and located in the central and middle concentric zones of the middle 3rd of the prostate. Prostatic infarction may elevate PSA levels.

REFERENCE

Brawn PN, Foster DM, Jay DW, et al. Characteristics of prostatic infarcts and their effect on serum prostate-specific antigen and prostatic acid phosphatase. *Urology.* 1994;44(1):71–74.

PROSTATE, MASSAGE

DESCRIPTION Repetitive prostatic massage is not a new tool in the urologists' armamentarium. It can be used to localize lower UTIs or as a therapeutic modality. Once the most popular therapeutic maneuver used to treat prostatitis, it was abandoned as primary therapy almost 30 yr ago. Based on experience reported outside North America and anecdotal experiences of some patients and their physicians, some believe it has a role in certain forms of prostatitis, such as chronic non-bacterial prostatitis or chronic pelvic pain syndrome (CPPS). The prostate is massaged from the lateral border to the medial aspect on each side, from base to apex. Firm pressure is necessary to express prostatic fluid into the urethra. A sterile container should be held by the patient at the meatus to capture the expressed prostatic fluids. The test is contraindicated in acute bacterial prostatitis. (See also Section II: "Attentive Digital Rectal Exam [DRE]" "Expressed Prostatic Secretions [EPS]" and "Stamey Test [Three-glass test, Four-glass tests, Meares-Stamey Test].")

REFERENCE

Nickel JC, Alexander R, Anderson R, et al. Prostatitis unplugged? Prostatic massage revisited. *Techniques Urol.* 1999;5(1):1–7.

PROSTATE STENTS (UROLUME AND SPANNER)

DESCRIPTION The UroLume stent is a woven tubular mesh designed to treat obstructions secondary to BPH, recurrent bulbar urethral strictures (RBUS), or detrusor external sphincter dyssynergia (DSD or DESD) long-term. The cylinder is made of high strength, impact grade, super alloy wire. It has the potential to expand to a diameter of 14 mm (42F) and is available in lengths of 1.5, 2.0, 2.5, and 3.0 cm. UroLume is provided preloaded in a sterile, disposable delivery instrument. The outer diameter of the tool is 22F along the shaft and 24F at the tapered tip. Numerous problems have plagued the stent, including short-term problems with irritative voiding symptoms, painful ejaculation, and stent migration. Long-term problems include stent encrustation and ingrowth of epithelial tissue causing restenosis. It may have a role in patients who present with urinary retention and are considered at high risk for surgical intervention, but it should otherwise not be used for patients who can tolerate a surgical procedure.

The Spanner stent is similar to a Foley catheter in that it has a proximal port to drain urine, a balloon that resides at the bladder neck to prevent migration, and a stent that spans the prostatic urethra. Considered a temporary device, it may have a role in temporary management of bladder outlet obstruction following procedures such as brachytherapy or TUMT. Other stents such as the Memotherm (Angiomed Gmbh & Co.) are available outside the United States. EAU considers prostate stents are an alternative to catheterization for men unfit for surgery (Image ☼).

PROSTATIC ACID PHOSPHATASE (PAP)

DESCRIPTION Human PAP is a glycoprotein dimer of 102,000 MW. Its activity is much greater in the prostate than in any other tissue. PAP is not prostate-specific, and can be found in other tissues. Historically, PAP was used as a serum marker for the staging and detection of prostate cancer before the discovery of prostate-specific antigen (PSA). Although enzymatic elevation of PAP is associated with advanced prostate cancer, other causes of an elevated PAP are possible, including liver, skelet al, and renal disease. PAP is the primary target for the prostate cancer immunotherapy sipuleucel-t.

PROSTATIC URETHRAL POLYPS

DESCRIPTION Urethral polyps are rare abnormalities in male children who present with hematuria or obstructive symptoms. Strangury (slow and painful urination) may be seen, with large lesions on a long stalk. The diagnosis is best confirmed by voiding cystourethrography. These polyps are nearly always in the prostatic fossa, although anterior urethral polyps have been reported. These are benign lesions and are not related to the polypoid masses of sarcoma botryoides.

TREATMENT

Transurethral excision of the polyps

PROSTATIC UTRICLE ANOMALIES

DESCRIPTION The prostatic utricle is a small slitlike orifice found at the apex of the verumontanum. The utricle has been considered by most to be a remnant of the fused caudal ends of the müllerian ducts while others propose the origin is from the urogenital sinus. The most common anomaly associated with the prostatic utricle is a prostatic utricle cyst. Can be associated with unilateral renal agenesis, hypospadias, and cryptorchidism. Prostatic utricle cysts always arise from the level of the verumontanum and are always in the midline. Prostatic utricle cysts have been associated with LUTS, infertility, infection, stone formation, hypospadias, recurrent epididymitis, and neoplastic degeneration. However, prostatic utricle cysts are often asymptomatic (found in up to 4% of newborns and 1% of adults). The incidence of prostatic utricle cyst is 11–14% in association with hypospadias or intersex anomalies and up to 50% of perineal hypospadias. Rarely these may contain cancer (clear cell or squamous cell carcinoma). Differential diagnoses include müllerian duct cysts, bladder diverticulum, teratoma, seminal vesicle cyst, epididymal cyst, and wolffian duct cyst. Prostatic utricle cysts can be diagnosed on VCUG or trans rectal ultrasound.

Stones may also be found in the dilated prostatic utricle. These are considered to belong to the category of prostatic pseudocalculi (not caused by abnormal urine composition, but from deciduous epithelial cells of enlarged prostatic utricle). (See also Section II: “Müllerian Duct Remnants and Persistent Müllerian Duct Syndrome [PMDS] and Prostatic Utricle Calcification.”)

SYNONYMS

- Müllerian duct cyst (however müllerian duct cysts can be found anywhere along the path of müllerian duct regression, from the prostatic utricle into the scrotum whereas prostatic utricle cysts are always midline)
- Utricular cysts
- Utriculoceles
- Mega-utricles

TREATMENT

- Transurethral unroofing, endoscopic incision
- Surgical excision (suprapubic, transvesical, perineal, or laparoscopic)

PROSTATIC UTRICLE CALCIFICATION

DESCRIPTION The prostatic utricle is a remnant of the müllerian ducts. It is a small indentation located at the apex of the verumontanum. Enlargement of the prostatic utricle (EPU) is a rare abnormality which is associated with hypospadias and is the result of insufficient androgenic stimulation. The incidence of stones in EPU is unknown. 1 study found stones in 8 patients out of 44 (18.2%). Their size ranged from 3–18 mm and they were all composed of hydroxyapatite (HAP) crystal. Treatment includes transurethral utricle fenestration and stone removal. (See also Section II: “Prostatic Utricle Anomalies” and “Calcification, Prostate" (Image ☼).)

PROSTATITIS, ASYMPTOMATIC INFLAMMATORY (NIH IV)

DESCRIPTION A type of nonbacterial prostatitis that is not associated with any specific symptom but is seen as inflammation on prostate biopsy. No specific treatment is necessary. (See Section II: “Prostatitis, NIH Classification.”)

REFERENCE

Habermacher GM, Chason JT, Schaeffer AJ. Prostatitis/chronic pelvic pain syndrome. *Annu Rev Med*. 2006;57:195–206.

PROSTATITIS, MYCOTIC (FUNGAL PROSTATITIS)

DESCRIPTION A type of granulomatous prostatitis caused by fungi and typically associated with systemic mycosis or immunocompromised hosts. Fungal infections can include blastomycosis, coccidiomycosis, cryptococcosis, histoplasmosis, and *Candida*. Diagnosis is based on prostatic histology and culture results. For systemic therapy, see the specific causative agent. (See Section I: “Fungal Infections, Genitourinary” and “Prostatitis, Granulomatous.”)

SYNONYM

Fungal prostatitis

REFERENCE

Schwartz J. Mycotic prostatitis. *Urology*. 1982;19:1–5.

PROSTATITIS, NIH CLASSIFICATION SYSTEM

DESCRIPTION A classification proposed by an NIH working group that clearly defines the different types of prostatitis in order to improve the diagnosis and management of the disease. (See Section I: "Prostatitis, Acute, Bacterial [NIH I]," "Prostatitis, Chronic, Bacterial [NIH II],", "Prostatitis, Chronic Nonbacterial, Inflammatory & Noninflammatory [NIH CP/CPPS III A and B]" and Section II: "Prostatitis, Asymptomatic Inflammatory [NIH IV].") For an explanation of EPS (expressed prostatoc secretions) and VB3 (voided bladder urine 3) see Section II: Stamey Test (Three-glass Test, Four-glass Tests, Meares-Stamey Test)

- Category I: Acute bacterial prostatitis; acute infection of the prostate gland
- Category II: Chronic bacterial prostatitis; recurrent infection of the prostate
- Category III: Chronic non-bacterial prostatitis/CPPS; no demonstrable infection
  - Category IIIA: Inflammatory CPPS; WBCs in semen/EPS VB3
  - Category IIIB: Noninflammatory CPPS; no WBCs in semen/EPS VB3
- Category IV: Asymptomatic inflammatory prostatitis; no symptoms

REFERENCE

Krieger JN, Nyberg L Jr, Nickel JC. NIH consensus definition and classification of prostatitis. *JAMA*. 1999;282(3):236–237.

PROSTATITIS, STRESS

DESCRIPTION Classically defined as a subset of chronic abacterial noninflammatory prostatitis/prostatodynia in which a pattern of excessive tension could be identified as a trigger of the syndrome. Symptoms usually responded to anxiolytic agents or behavioral modifications. No longer considered an appropriate term in the NIH Prostatitis classification system.

REFERENCE

Miller HC. Stress prostatitis. *Urology* 1988;32:507.

PROSTATITIS, TUBERCULOUS

DESCRIPTION TB of the prostate is rare, and in many cases, it is diagnosed incidentally after a transurethral resection in the prostate chips. Tuberculous prostatitis results from hematogenous dissemination, with an incidence of 10% with men in TB. Symptoms are nonspecific. Irritative voiding may be the only complaints; other complaints include perineal pain and infertility. On exam, the prostate may be hard, irregular, and nodular. On labs, urine analysis can demonstrate microscopic hematuria or sterile pyuria. Acid-fast bacilli staining of urine and semen has a sensitivity of only 52%; however, culture can take up to 8 wk. A transrectal ultrasound can demonstrate collections or abscess, and an intravenous urogram (IVU) or CT Urogram (CTU) should be done because 72% of patients with prostatic TB have renal TB.

TREATMENT

- Hospitalization is usually unnecessary.
- Transurethral resection of the prostate in patients with obstructive symptomatology is reasonable.
- Medication includes a 3-drug regimen of isoniazid, pyrazinamide, and either ethambutol or streptomycin.
- In complicated cases, 9–12 mo therapy may be required. A negative prostatic biopsy to document successful treatment is recommended.

REFERENCE

Cek M, Lenk S, Naber KG, et al. EAU guidelines for the management of genitourinary TB. *Eur Urol*. 2005;48(3):353–362.

PROSTATODYNIA

DESCRIPTION Classically described as a symptom complex of multiple complaints including pain in the perineum, lower back, or upon ejaculation; slow stream; and hesitancy. Patients exhibit no evidence of prostatic inflammation. Dysuria, frequency, and systemic signs are usually absent. This term is not currently considered to be appropriate and has been replaced by the designation chronic pelvic pain syndrome or CPPS NIH Category III Chronic Abacterial Prostatitis. (See also Section I: "Prostatitis, Chronic Nonbacterial, Inflammatory & Noninflammatory [NIH CP/CPPS III A and B].")

REFERENCE

Orland SM, Hanno PM, Wein AJ. Prostatitis, prostatosis, and prostatodynia. *Urology*. 1985;25(5):439–459.

PROSTHESIS, INFECTED PENILE

DESCRIPTION A dreaded complication of penile prosthesis implantation. Rates of infection range from 1–8%; risk factors include spinal cord injury (SCI), diabetes mellitus especially (if poorly controlled with $HgbA_{1C} > 11.5\%$), history of UTI, and multiple prosthesis operations.

Infection usually occurs within 6 mo after implantation, but delayed infection is also reported. The most common symptom is persistent pain; patients also present with erythema, drainage, or fever. Causes of infection are *Staphylococcus epidermidis* (most common); gram-negative rods and yeast are also common. In the presence of an infection the implant and all foreign material should be removed. A salvage procedure, during which the wound is thoroughly washed with antiseptic solutions after device removal and placement of a new implant during the same procedure, has a high success rate and is becoming a popular approach. The alternative is device removal with return at a later date for placing a new implant, which entails a more difficult corporal dilation, and the resulting erection is noticeably shorter. (See also Section I: "Penile Prosthesis Problems [Infection/Extrusion/Malfunction] and Section II: "Mulcahy Protocol.")

TREATMENT

- Surgical removal

- Irrigation and antibiotic treatment
- Immediate salvage procedures with surgical removal
- Washout and immediate replacement have reported with good results: Vigorous intraoperative irrigation with 4 different solutions, including vancomycin; immediate reimplantation of a new inflatable penile prosthesis; and postoperative outpatient antibiotics, with oral ciprofloxacin or IV vancomycin or cefazolin.

REFERENCE

PRURITUS, EXTERNAL GENITALIA, MALE

DESCRIPTION The anogenital area is a common location for pruritic complaints in men and women. Itching can precede the appearance of a rash or other lesion. When the itching results in red, weeping skin with crusts, it is often called *eczematous dermatitis*. *Pruritus scroti* is a historic term for scrotal itching. The differential diagnosis of itching of the male external genitalia includes:

- Allergic reactions (allergic dermatitis)
- Cancer: Penile, scrotal, extra-mammary Paget disease (intraepidermal adenocarcinoma, found in areas with apocrine sweat glands).
- Candidal infection
- Chemical irritants: Detergents, fabric softeners, soaps, creams, ointments and sexual lubricants
- Dermatologic conditions: Seborrheic dermatitis, psoriasis, eczema (atopic dermatitis), lichen simplex chronicus (LSC)
- Fixed drug reaction
- HIV: Pruritus is 1 of the most frequent symptoms encountered in HIV infection and can even be the 1st clinical symptom
- Infestations: Pubic lice (“crabs”), scabies
- Nutritional deficiencies: Riboflavin, nicotinic acid
- Red scrotum syndrome possibly due to steroid abuse
- Sexually transmitted infections: Genital herpes
- Sunitinib toxicity
- Systemic illnesses: Diabetes mellitus, renal failure
- Tinea cruris: Also known as ringworm of the groin

Some patients manifest itching with or without a demonstrable local factor. The skin may appear normal or demonstrate excoriation (lichenification skin thickening) from rubbing, or both. These patients tend to have chronic illness (eg, diabetes) or depression with no pathogen identified. When treating anogenital pruritus, topic irritants and potential sensitizers must be eliminated and cleansing and toilet habits should be addressed. Treatment of the specific pathogen is essential. A short course of a high-potency topical steroid usually brings relief. Sedating antihistamines may limit nighttime symptoms. Some patients may require psychotropic agents for adequate sedation. Antidepressants may be required in patients refractory to standard treatment or those with underlying psychiatric disorders. (See

also Section II: “Scabies, Urologic Considerations.”)

PSA, GENERAL CONSIDERATIONS AND PSA DERIVATIVES

DESCRIPTION

- **PSA Background:**
  - PSA was initially approved by the FDA as prostate cancer monitoring test in 1986 and as an aid for prostate cancer detection in 1994 in combination with DRE. PSA is a glycoprotein secreted by both malignant and benign prostate cells. PSA functions as a serine protease with the primary function to split the seminal vesicle proteins to liquefy the seminal coagulum. PSA is expressed in nearly all prostate cancers, although its level of expression on a per cell basis, especially in poorly differentiated prostate cancers, is actually lower than in normal prostate epithelium. The disruption of the basement membrane of prostate cancer allows more PSA to "leak" into the circulation.
- **PSA Physiology:**
  - PSA is a kallikrein that is also known as human glandular kallikrein 3 (hK3). The kallikreins are a type of enzymes (serine proteases), that cleave protein peptide bonds.
  - PSA is produced as a proenzyme (proPSA) by the secretory cells of the prostate acini and secreted into the lumen, where the proPSA is cleaved to enzymatically active PSA.
  - PSA circulates in serum in complexed forms (bound to protease inhibitors) or in un-complexed (free or unbound) forms
  - Active PSA undergoes proteolysis to form inactive PSA, of which a small portion enters the bloodstream in an unbound state (free PSA).
    - 10–30% of PSA is free in the serum and composed of various PSA isoforms. It is composed of 3 distinct isoforms: ProPSA, BPSA and iPSA (for "intact PSA" which decreases with cancer).
    - The precursor form of PSA (pro-PSA), especially its truncated (-2) form is significantly increased in PCa patients.
  - Active PSA can also enter the bloodstream where it is rapidly bound and inactivated (complexed) by protease inhibitors (alpha-1-antichymotrypsin [ACT] and alpha-2-macroglobulin). Most of the PSA in serum exists as a complex with ACT.
  - With prostate cancer the disrupted basal membrane allows proPSA and several truncated PSA isoforms direct access to the circulation. This PSA

"leaking" into the blood has a larger fraction of the PSA produced by malignant tissue escaping proteolytic processing (ie, activation of proPSA to active PSA and degradation of active PSA to inactive PSA).

  - In men with a normal prostate (no cancer or infection), the majority of free PSA in the serum reflects protein inactivated by internal proteolytic cleavage. In contrast, the cleaved fraction is relatively decreased in prostate cancer. Thus, the percentage of free or unbound PSA is lower in the serum of men with prostate cancer (and conversely, the amount of complexed PSA is higher) compared with those without cancer.
  - These observations have resulted in the use of the ratio of free to total PSA and complexed PSA (cPSA) as a means of distinguishing prostate cancer and BPH.
- **PSA Collection:** The PSA blood sample should be centrifuged, and the serum separated in

2–3 hr. If the assay is not performed within the next 2–3 hr, the serum should be frozen.

- **PSA Basic Clinical Considerations:** There is a vast amount of clinical data available to guide the clinicians in the use of PSA in patient care. This section highlights some of the published PSA clinical data in a highly annotated form.
  - Routine PSA blood testing refers to Total PSA and is reported in ng/mL; SI units mcg/L are identical.
  - Half-life: of PSA is 2.2 days.
  - PSA measured repeatedly can vary due to intrinsic biologic and assay variability (6–14%).
  - For serial PSA measurements using the same lab with the same analytic method is recommended.
  - No diurnal variation in PSA levels exists.
  - Increased BMI is associated with lower PSA.
  - Lower limits of PSA detection: 1st-generation assays 0.2 ng/mL; 2nd-generation assays <0.1 ng/mL; 3rd-generation "ultrasensitive assays" as low as 0.003 ng/mL. (Note: The utility of "ultrasensitive" PSA testing has not been clearly established in the post radical prostatectomy setting).
- **Normal PSA:** The exact definition of an "abnormal" PSA is subject to controversy. The historically defined level of 4.0 ng/mL was considered to be normal. PSA 4.0–10 ng/mL were considered to be mostly due to BPH.
  - **Age-specific PSA reference ranges**: Accounts for increases in prostate volume with age.
    - 40–49 yr: 0 to 2.5 ng/mL
    - 50–59 yr: 0 to 3.5 ng/mL
    - 60–69 yr: 0 to 4.5 ng/mL
    - 70–79 yr: 0 to 6.5 ng/mL
  - **Race-specific PSA normal ranges:** Different ethnic and racial groups are reported to have different average PSA.

Age Range	Whites	African Americans	Asians
40–49 yr:	0–2.5 ng/mL	0–2.0 ng/mL	0–2.0 ng/mL
50–59 yr:	0–3.5 ng/mL	0–4.0 ng/mL	0–3.0 ng/mL
60–69 yr:	0–3.5 ng/mL	0–4.5 ng/mL	0–4.0 ng/mL
70–79 yr:	0–3.5 ng/mL	0–5.5 ng/mL	0–5.0 ng/mL

  - **Common causes of elevated PSA:**
  - BPH, prostate cancer, acute prostatitis, prostate trauma (prostate biopsy, TURP, instrumentation, cystoscopy, perineal trauma), urinary retention, prostatic infarction
  - Wait at least 6 wk after biopsy or TURP before measuring PSA to avoid false elevation; less time after cystoscopy.
  - Following relief of urinary retention PSA levels decrease by 50% in 24–48 hr
  - A routine DRE will not clinically significantly increase PSA whereas formal prostate massage may elevate PSA.
  - In a small subset of men, sexual activity (ejaculation) and vigorous bicycle riding may elevate PSA. It is prudent to refrain from ejaculation and aggressive bicycle riding for 48 hr before PSA testing.
  - PSA levels tend to increase with age (related to prostate volume). Most PSA is made in the transition zone of the prostate, the region of the prostate that increases in volume in men

with BPH.
- **Medication effects on PSA:**
- 5-ARI (finasteride/dutasteride) regardless of dose will reduce PSA by 50% at 6 mo; "correct" PSA by doubling value.
- Any increase in PSA from baseline in men on 5-ARI should raise the concern for the development of prostate cancer.
- Statins, thiazides, NSAID's and acetaminophen all appear to lower PSA. Whether the relatively small changes in PSA with these drugs has clinical relevance is unknown.
- Lowering serum testosterone to castrate levels (<50 ng/dL using androgen deprivation using LHRH analogs/antagonists) will significantly decrease PSA initially. However, if the prostate cancer develops castration resistant features, the PSA usually rises.
- Increasing testosterone levels through supplementation can sometimes increase PSA.
- α1-adrenergic antagonists for BPH (tamsulosin, others) and herbals such as saw palmetto do not impact PSA.

• **PSA and Prostate Cancer Treatment:**
- Due to the half-life, wait a minimum 3 wk following RP for PSA nadir.
- A widely accepted definition of cancer recurrence following RP: A PSA >0.2 ng/mL that has risen on at least 2 separate occasions at least 2 wk apart and measured by the same lab.
- Persistently detectable PSA immediately following RP suggests systemic disease.
- A slowly rising PSA after being undetectable for >2 yr is most likely to be a prostate bed recurrence following RP.
- PSA >20 ng/mL with a diagnosis of prostate cancer is associated with extraprostatic disease and/or metastasis.
  - AUA guidelines suggest that bone scans and CT/MRI imaging is unnecessary with a PSA <20 ng/mL and no symptoms suggestive of advanced disease.
- Positive bone scan and PSA: 2.3% PSA <10.0 ng/mL; 5.3% PSA 10.1–19.9 ng/mL; 16.2% PSA >20.0 ng/mL
- PSA nadir of <1.0 ng/mL is associated with best long-term outcome following radiation therapy.
- If measured during external beam radiation therapy for prostate cancer, PSA shows a progressive decline.
- Since prostatic glandular tissue remains after radiation, PSA levels are unlikely to fall to undetectable following radiation therapy unless androgen ablation is also used.
- Optimum outcome for interstitial prostate brachytherapy is a PSA <0.7 ng/mL at 5 yr.
- Recurrence after radiation therapy for prostate cancer:
  - 3 consecutive rises in PSA (1996 ASTRO definition)
  - 2 point rise in PSA above posttreatment nadir (2005 Phoenix definition).
- **PSA bounce:** An initial decline in PSA followed by a transient rise (the so-called "bounce") 12–18 mo following radiation therapy (brachytherapy up to 40% of cases, also described for external beam radiation).This transient rise may not be a recurrence and should be followed. The PSA increases are generally small (<0.8 ng/mL) but can sometimes reach 10 ng/mL and may last 6–18 mo. Ironically bounces may predict a good outcome.

- PSA should fall to a low level after high intensity focused ultrasound (HIFU) and cryotherapy and should not rise on successive occasions. Data is limited using other.
- Salvage radiation following RP; especially those with positive surgical margins receiving treatment when the PSA is low (ie, 0.5–1.5 ng/mL) and slowly rising; appear to have best outcomes.
- With metastatic disease on androgen deprivation, failure to nadir PSA <4.0 ng/mL 7 mo after initiation of therapy is associated with a poor prognosis (median survival: 1 yr). With PSA nadir of <0.2 ng/mL median survival is 6 yr.
- PSA increase after RP or radiation with no radiologic evidence of metastases, a PSA nadir of >0.2 ng/mL within 8 mo of androgen suppression is associated with a 20-fold greater risk of prostate cancer-specific mortality vs. a nadir of <0.2 ng/mL.

• **PSA Derivatives:** There is recent conflict in the literature if PSA-V or PSADT add value to the screening and detection of prostate cancer. The following information is based on published data that provide support for these derivatives.

- **PSA density (PSAD):** PSAD is a ratio of PSA to prostate size, as measured by transrectal ultrasound. (PSAD = PSA divided by prostate volume). Proposed as a method to differentiate benign vs. malignant with an elevated PSA of 4–10 ng/mL without evidence of prostate cancer on digital rectal exam. May also prevent unnecessary prostate biopsies.
  - Higher PSA density values (>0.15 ng/mL/cc) are more suggestive of prostate cancer; lower values suggest BPH.
  - Potential role as predictor for Gleason score upgrade after RP in patients with clinically low-risk disease.
  - PSA transition zone density (PSAD-TZ) is a similar concept but not commonly used.
- **PSA velocity (PSA-V):** Rate of PSA change over time; the utility of PSA velocity is in part limited by intra-patient variability; at least 3 consecutive measurements should be performed.
  - **PSA-V** >0.75 ng/mL/yr distinguished patients with prostate cancer from BPH or no prostate disease in 1 study. Other studies suggest >0.4 ng/mL/yr is better for cancer detection.
  - **PSA-V** <0.35 ng/mL/yr is often associated with the development of BPH
  - **PSA-V** >0.35 ng/mL/yr and PSA <4.0 ng/mL associated with prostate cancer death at 15 yrs.
  - **PSA-V** >2 ng/mL/yr in the year prior to diagnosis: Associated with an increased risk of prostate cancer death after RP or radiation.
  - **Very high PSA-V** (>3.0 ng/mL/year) is often associated with prostatic inflammation as the cause of the elevated PSA
- **PSA doubling time (PSA-DT):** Another reported measure of PSA change over time. PSADT is defined as the time it takes for a patient's PSA value to double based on an exponential growth pattern. Pretreatment PSA-DT has little diagnostic value but it can predict tumor progression, therapeutic outcome, and tumor-specific mortality.
  - PSA-DT <3 mo, prostate cancer-specific mortality rates 5 yr. After biochemical failure were 35% (Gleason scores ≤ 7) and 75% (Gleason Score ≥ 8).
  - PSA-DT ≥ 3 mo, the 5-yr prostate cancer-specific mortality rates for 4% (Gleason scores ≤ 7) and 15% (Gleason score ≥ 8).

- **Other PSA Based Tests**
  - **Free vs. total f/t) PSA:**
    - Prostate cancer has a lower percent of free PSA in the serum relative to benign prostate conditions.
    - In the PSA range of 2–10 ng/mL the lower the ratio of free/total(f/t) PSA, the increased likelihood of prostate cancer. The probability of cancer f/t PSA $<10\%$ is 56%; f/t value $>25\%$, 8% have cancer.
  - **Complexed PSA:**
    - Complexed PSA (cPSA) relies on the level of anti-chymotrypsin (ACT) bound PSA. This should provide similar enhanced specificity as the f/t PSA but requires only the measurement of a single analyte.
    - Compared to a PSA cutoff ≥ 4.0 ng/mL, cPSA cutoff of 3.75 ng/mL provides higher specificity (48% vs. 33%) for cancer diagnosis with a small decrease in sensitivity.
    - Complexed PSA is approved for monitoring men with prostate cancer.
  - **[-2] proPSA Percent:**
    - [-2]proPSA is 1 of the PSA isoforms that can leak into the circulation that is unbound. The ratio of [-2]proPSA to free PSA (expressed as percent [-2]proPSA or %[-2]proPSA) is under study for prostate cancer screening and is approved in the EU.
  - **Prostate Health Index (*phi*)**: The *phi* is a composite test which incorporates: PSA, free PSA, and [–2]pro-PSA.
    - The calculation involves a formula: $phi = ([-2]\ proPSA/fPSA \times \sqrt{PSA})$
    - Use of *phi* level of >27 for prostate biopsy (with total PSA 2–10 ng/mL), may decrease unnecessary biopsies and reduce over-detection of indolent prostate cancer.
    - Prostate cancer risk increases with increasing *phi* values.
    - The probability of finding cancer on biopsy: *phi* 0–24.9 = 11%; *phi* 25.0–34.9 = 28.25; *phi* 35.0–54.9; 32.7%; *phi* >55 = 52.1%.
    - Correlation of *phi* and high-grade prostate cancer (Gleason score of >7): *phi* 0–24.9 = 26.1%; *phi* 25.0–34.9 = 28.2%; 35.0–54.9 = 30.1% *phi*; *phi* >55 = 42.1%.
- **4K score (4-kallikrein panel):** Consists of these 4 kallikreins: PSA, freePSA, intactPSA, and human kallikrein 2 (hK2) are combined with a patient's age and digital rectal exam using a proprietary algorithm to calculate the probability of a finding of aggressive prostate cancer. Ordered after an elevated PSA to determine the need for biopsy if an aggressive cancer is suspected. hK2 is a prostate-specific kallikrein produced by the prostatic epithelium with approximately 80% DNA sequence homology with PSA and $>20{,}000$ times the activity of the relatively weak protease PSA.
- **PSA Screening.** The use of PSA as a screening test is controversial but remains in place using PSA and DRE in appropriate patients based on various organizations guidelines. (See Section II: "Prostate Cancer Screening Guidelines.")
  - Challenges related to PSA based screening for prostate cancer:
    - About 15% of men with a "normal" PSA level (<4 ng/mL) may have prostate cancer.
    - The Prostate Cancer Prevention Trial: With a PSA cutoff of 1.1 ng/mL 17% of cancers would be missed, including 5% poorly differentiated cancers.
    - 2 out of 3 men with an elevated PSA level don't have prostate cancer.
    - 1 out of 3 men with an elevated PSA level will have cancer.

- 2 out of 3 men who have a biopsy do not have cancer.
- Biopsies in 1 in 5 men can miss prostate cancer.

– There is no clear cutpoint between "normal" and "abnormal" PSA levels.
– Historically PSA >4.0 ng/mL has been most accepted as abnormal. It is a balance between missing important cancers at a curable stage and avoiding detection and treatment of insignificant disease and avoiding unnecessary prostate biopsies

• "Normal" PSA levels must be interpreted on an individual basis.
– **Population-based PSA levels** in a random sample of men without regard to any specific prostate condition or race.

Age Range	Median	PSA Range
<40 yrs	0.52 ng/mL	0.19–1.3 ng/mL
40–49 yr:	0.65 ng/mL	0.22–1.6 ng/mL
50–59 yr:	0.8 ng/mL	0.25–2.6 ng/mL
60–69 yr:	1.2 ng/mL	0.29–5.6 ng/mL

• 13% of men >55 yr have a PSA level of ≥ 4 ng/mL
• Positive predictive value of PSA in detecting prostate cancer (US Studies):
– PSA > 4.0 ng/mL: 30%
– PSA 4–10 ng/mL: 25%
– PSA >10 ng/mL: 42–64%
• Negative predictive value for PSA <4.0 ng/mL: 85%
• Based on biopsies from European Randomized Study of Screening for Prostate Cancer (ERSPC) the risk of finding prostate cancer based on PSA:

– <2.0 ng/mL	7.1%
– 2.0–3.9 ng/mL	18.7%
– 4.0–5.9 ng/mL	21.3%
– 6.0–7.9 ng/mL	28.6%
– 8.0–9.9 ng/mL	31.7%
– >10.0 ng/mL	56.5%

• Based on the following data there is some support for 1.5 ng/mL being the new "normal" PSA in mid-life.
– In one longitudinal PSA biopsy study baseline PSA level >1.50 ng/mL, the risk of prostate cancer increased from 12.3–76.8% at 7.6 yr.
– PSA >1.5 ng/mL between the ages of 45 and 49 yr account for nearly 1/2 of the prostate cancer deaths over the next 30 yr.
– PSA level at age 44–50 was very strongly associated with the likelihood of developing prostate cancer up to 25 yr later. The odds ratio for a PCA diagnosis:
- PSA ≤0.50 ng/mL; (population average = Odds Ratio 1.0).
- PSA 0.51–1.0 ng/mL: Odds ratio 2.51
- PSA 1.0–1.5 ng/mL: Odds ratio 7.02
- PSA 2.01–3.0 ng/mL:Odds ratio 9.01

PSA, RACE-ADJUSTED (SEE SECTION II “PSA, GENERAL CONSIDERATIONS AND PSA DERIVATIVES”)

PSA, RT-PCR

DESCRIPTION First clinically reported in 1992, RT-PCR is used to amplify mRNA transcripts of PSA. These PSA mRNA species should theoretically only be present in prostate tissues. Extraprostatic tissue of patients with biopsy-proven prostate cancer is tested, including peripheral blood, lymph nodes, and bone marrow, to detect PSA mRNA transcripts and presumably prostate cells in extraprostatic sites. It is being investigated as an assay to detect micrometa-stasis of prostate cancer before clinical presentation or evidence of disease spread (molecular staging). Its clinical utility as a diagnostic assay remains uncertain and is generally replaced by CTC assays.

PSA VELOCITY (PSAV) AND PSA DOUBLING TIME (PSADT) (SEE SECTION II "PSA, GENERAL CONSIDERATIONS AND PSA DERIVATIVES")

PSEUDODYSSYNERGIA (HINMAN SYNDROME)

DESCRIPTION A form of detrusor-external sphincter dyssynergia in which voluntary contraction of external sphincter occurs during detrusor contraction. It produces the functional voiding dysfunction seen in children with intractable voiding symptoms, men with chronic prostatitis or prostatodynia, and women with urethral syndrome. It may sometimes be a cause of urinary incontinence. This condition is thought to be a learned behavioral abnormality, possibly an overcompensation of the continence mechanism. Diagnosis is based on urodynamic evidence of increased or vacillating external sphincter activity during detrusor contraction, usually with simultaneous elevation of intra-abdominal pressure indicating voluntary nature of contraction, without clinical evidence of neurologic deficit. (See also Section II: "Hinman Syndrome [Hinman–Allen Syndrome, Nonneurogenic Neurogenic Bladder, Occult Neuropathic Bladder].")

SYNONYMS

- Nonneurogenic neurogenic bladder
- Hinman syndrome/Hinman–Allen syndrome in children
- Dysfunctional voiding syndrome
- Occult Neuropathic Bladder

TREATMENT

- Children must be motivated to participate in the therapy.
- Teach how to void and defecate properly.
- Timed voiding, voiding diary, double voiding, psychotherapy, and biofeedback may all be appropriate in select children.
- Anticholinergics may control instability; α-adrenergics may improve outlet resistance.
- Psychotherapy, with a change in parental attitude, can greatly improve the situation.
- Intermittent catheterization may be necessary in more difficult cases (eg, with upper tract changes, failure to respond to less invasive measures).
- Biofeedback

REFERENCE

PSEUDOMYXOMA OVARII-LIKE POSTTHERAPEUTIC ALTERATION IN PROSTATE ADENOCARCINOMA

DESCRIPTION *Pseudomyxoma ovarii*-like posttherapeutic alteration in prostate adenocarcinoma refers to histologic alterations observed in prostate cancer foci after exposure to total androgen blockade. Changes in nontumoral glands exposed to total androgen blockade characteristically display acinar atrophy, basal cell hyperplasia, squamous or

transitional cell metaplasia, and stromal hypercellularity. Conversely, tumor glands may shrink in size and extravasate mucin. This extravasated mucin resembles pseudomyxoma ovarii. This is an important distinction, as this appearance can be easily confused with mucinous carcinoma. It is important to recognize these posttreatment effects, as it may be the sole histologic evidence of therapeutic response and may guide definitive treatment after neoadjuvant hormone deprivation.

PSMA (PROSTATE-SPECIFIC MEMBRANE ANTIGEN)

DESCRIPTION A protein with intracellular, transmemberane, and extracellular components of prostatic epithelial cells. PSMA levels are reported to be elevated in hormone-refractory prostate cancer and with metastatic disease. Its use as a tumor marker is not as useful in screening as PSA. PSMA is a highly sensitive and specific immunomarker for the detection of metastatic prostate carcinoma, however cells of the small intestine, proximal renal tubules, and salivary glands also can also express PSMA. PSMA is an in vivo target for imaging utilizing radiolabeled mAb 7E11 (CYT-356, capromab), the ProstaScint Scan. PSMA is currently being targeted as a therapeutic intervention for advanced prostate cancer including monoclonal Ab-directed therapy (PSMA Specific Membrane Antigen Antibody Drug Conjugate [PSMA ADC]), radionuclides and anti-PSMA vaccines and other immunotherapies.

PSOAS ABSCESS, UROLOGIC CONSIDERATIONS

DESCRIPTION A psoas abscess is a discrete abscess or phlegmon in the retroperitoneum, adjacent to the psoas muscle. Usually the consequence of direct spread of infection from an adjacent structure; primary psoas abscesses are rare and are a result of hematogenous spread. A wide variety of etiologies are reported in the literature, including perinephric abscess; pyelonephritis; postoperative infection following renal, ureteral, or bladder surgery; complications from ESWL; and urothelial carcinoma metastasis. Clinical presentation includes fever, lower abdominal or back pain, referred lower extremity pain, limp, flexion deformity of the hip from a reflex spasm, flank mass, and a psoas sign. Rarely, a psoas abscess can directly obstruct the ipsilateral ureter or cause a retroperitoneal inflammatory response. Treatment can initially be medical using antibiotic therapy; however, failure to resolve requires drainage. (See also Section I: “Retroperitoneal Abscess; Retroperitoneal Masses and Cysts.” (Image ☼))

REFERENCE

Hamano S, Kiyoshima K, Nakatsu H, et al. Pyogenic psoas abscess: Difficulty in early

diagnosis. *Urol Int.* 2003;71:178–183.

PSOAS HITCH PROCEDURE

DESCRIPTION A surgical procedure used to replace short segments of distal ureteral loss or in combination with a ureteral reimplantation to provide a fixed posterior bladder wall. The bladder is mobilized and stretched superiorly along the axis of the ureteral deficit. The stretched bladder is then sutured to the fascia of the ilio-psoas muscle (Image ☼).

PSORIASIS, EXTERNAL GENITALIA

DESCRIPTION A chronic papulosquamous skin disease frequently affecting external genitalia, more commonly in males. Genital involvement is reported in 25–40% of patients with psoriasis. The lesions characteristically are sharply demarcated plaques with silvery, scaly patches. Psoriasis most frequently involves the penis in males and the mons pubis, labia majora, and inguinal crease in females. It is reported to increase the risk of squamous cell carcinoma (SCC) genitalia. Treatment includes topical steroids, tar preparations and maintaining good hygiene. (See Also Section II: “Pruritus, External Genitalia, Male.”)

PSYCHOGENIC POLYDIPSIA

DESCRIPTION Psychogenic polydipsia (PPD) is a clinical disorder characterized by polyuria and polydipsia, and is a common occurrence in inpatients with psychiatric disorders. The underlying pathophysiology of the syndrome is unclear, but multiple factors have been implicated, including a hypothalamic defect and adverse medication effects. Workup for PPD includes a comprehensive evaluation for other medical causes of polydipsia, polyuria, hyponatremia, and the syndrome of inappropriate secretion of antidiuretic hormone. Workup should include plasma and urine osmolality and plasma and urine sodium. Other tests may include a complete metabolic panel, urinalysis, urea, chest x-ray, and CT scan of the head.

TREATMENT

- Treatment for hyponatremia: Fluid restriction, furosemide (if hypervolemic), intravenous normal saline, or hypertonic saline
- Behavioral treatments: Fluid restriction, therapy including cognitive techniques
- Drug treatments: Atypical antipsychotics, clozapine, risperidone, olanzapine, β-blockers, demeclocycline, clonidine, ACE inhibitors, conivaptan

Dundas B, Harris M, Narasimhan M. Psychogenic polydipsia review: Etiology, differential, and treatment. *Curr Psychiatry Rep*. 2007;9:236.

PUDENDAL NERVE ENTRAPMENT/PUDENDAL NEUROPATHY

DESCRIPTION Compression of the pudendal nerve or its branches causing chronic perineal numbness or pain. The pudendal nerve carries sensations from the external genitalia, distal rectum, and the perineum. Symptoms can be seen if these nerve branches are compressed during pelvic surgery, a finding commonly seen in male and female pelvic sling operations (tension-free vaginal tape or transobturator tape) for incontinence, or it can occur spontaneously. A validated set of simple diagnostic criteria (Nantes criteria) include: (1) Pain occurs in the anatomic territory of the pudendal nerve, (2) is worsened by sitting, (3) the patient is not awakened at night by the pain, (4) no objective sensory loss is found on clinical exam, and (5) a positive response is seen to anesthetic pudendal nerve block. Exclusion criteria include purely coccygeal, gluteal, or hypogastric pain; exclusively paroxysmal pain; exclusive pruritus; or the presence of imaging abnormalities able to explain the symptoms. The diagnosis of pudendal neuralgia by pudendal nerve entrapment syndrome is essentially clinical. There are no specific clinical signs or complementary test results for this disease. However, a combination of criteria can be suggestive of the diagnosis. Initial symptoms should be managed conservatively with anti-inflammatory medications and analgesics. Physical therapy, infiltration with steroids, or surgical decompression are treatment options. If applicable, sling removal should be considered if symptoms persist >6 wk.

PULMONARY METASTASIS, UROLOGIC CONSIDERATIONS

DESCRIPTION The lungs are the site of potential metastasis in all GU cancers. It is the most common site of metastasis in RCC and a common metastatic site in prostate, urothelial carcinoma, and testicular tumors. Chest CT is more sensitive at detecting pulmonary nodules as it can detect lesions <1 cm, the typical minimal size for plain film detection. Since a direct correlation exists between the likelihood of malignancy and size of pulmonary nodule, lesions <1 cm in size are usually nonclinical. Therefore, plain chest x-ray is the screening test of choice. Malignant nodules usually appear as noncalcified soft tissue densities. Suspicious nodules on chest x-ray warrant a chest CT. Tissue diagnosis of suspicious lesions should be performed if doing so will alter the intervention. Although metastatic disease requires systemic therapy, resection of pulmonary RCC metastases have been shown to improve survival when compared to immunotherapy alone.

REFERENCE

Hofmann HS, Neef H, Krohe K, et al. Prognostic factors and survival after pulmonary resection of metastatic renal cell carcinoma. *Eur Urol.* 2005;48:77–81.

PURPLE URINE BAG SYNDROME

DESCRIPTION Purple urine bag syndrome (PUBS) is an uncommon disorder in which the urine bags of catheterized patients turn purple or blue. Most patients are bedridden, cognitively impaired, and constipated. The discoloration is attributed to indigo and indirubin pigments, which appear purple when combined. The pigments are created when ingested tryptophan is exposed to intestinal flora in patients with altered gut motility. PUBS is usually associated with organisms that have indoxyl phosphatase/sulfatase activity (*Klebsiella pneumonia, Providencia stuartii, Enterobacter, Proteus mirabilis, Morganella morganii,* and *Escherichia coli*).

TREATMENT

- Antibiotics to treat urinary tract infection
- Catheter change

REFERENCE

Keenan CR, Thompson GR: Purple Urine Bag Syndrome. *J Gen Internal Medicine.* 2011;26:1506.

PYELITIS CYSTICA

DESCRIPTION Ingrowth of urothelial cells into the lamina propria with subsequent liquefaction, giving a cystlike appearance. Identical to cystitis cystica, this lesion occurs in the renal pelvis and calyces. It is a rare condition, usually associated with chronic infection, and is more common in females, usually >50 yr of age. Presenting symptoms are related to chronic infections, including fever, dysuria, hematuria, and flank pain. Identified on radiographic studies as multiple small cysts up to 10 mm in diameter in the renal pelvis and calyces, and confirmed by endoscopic biopsy. Not thought to be a premalignant condition, but urine cytology and biopsy are recommended to rule out other neoplastic conditions. (See also Section I: “Filling Defect, Upper Urinary Tract [Renal Pelvis and Ureter].”)

REFERENCE

Gronlund A, Glenthøj A, Kvist E. Pyelitis cystica. *Scand J Urol Nephrol.* 1997;31(5):509–511.

PYELITIS GLANDULARIS

DESCRIPTION In this condition, combined urothelial hyperplastic and metaplastic changes of the renal pelvis occur and characteristic glandular structures are seen haphazardly arranged within the lamina propria. These glands are lined by mucin-secreting columnar epithelial cells, which differentiate them from other forms of urothelial hyperplasia such as Vonbrunn nests and pyelitis cystica. It is not uncommon to see later hyperplastic changes and pyelitis glandularis in a single specimen. Intracellular and luminal mucin can be demonstrated by mucicarmine stain. Most commonly, the overlying surface epithelium remains of the transitional cell type, although metaplastic squamous epithelium or mucous-secreting columnar cells may be seen. Pyelitis glandularis is commonly focal. Extensive lesions with columnar cell metaplasia of the surface urothelium bear a high resemblance to colonic mucosa. However, the absence of muscularis mucosa helps distinguish these 2 entities. (See also Section I: “Filling Defect, Upper Urinary Tract [Renal Pelvis and Ureter].”)

REFERENCE
Dabbs DJ. Cytology of pyelitis glandularis cystica. A case report. *Acta Cytol.* 1992;36(6):943–945.

PYELOGENIC CYST

DESCRIPTION A pyelogenic cyst is a smooth intrarenal diverticulum that communicates directly with the renal pelvis. Conversely, a calyceal diverticulum communicates indirectly to the renal pelvis through a calyx or infundibulum. Pyelogenic cysts are lined with transitional cell epithelium. Diagnosis is best made by CT urogram or delayed-phase or retrograde pyelography showing contrast pooling in the cyst. Asymptomatic pyelogenic cysts do not require treatment. Pain, persistent or recurrent infections, stones, and milk of calcium warrant surgical intervention through ureteroscopic, percutaneous, laparoscopic, or open surgical techniques.

REFERENCE
Canales B, Monga M. Surgical management of the calyceal diverticulum. *Curr Opin Urol.* 2003; 13(3):255–260.

PYOCYSTIS

DESCRIPTION Pyocystis is a severe UTI of the bladder associated with a nonfunctioning bladder or in patients with chronic oligo-/anuria. Also called vesical empyema. Commonly seen (20–30%) in patients with a neurogenic bladder treated with urinary diversion. Pyocystis should be suspected in patients with a nonfunctioning bladder or in those who are oligo/anuric presenting with systemic signs of infection. Bladder catheterization should be performed and the pus cultured. A positive culture is diagnostic; however, imaging studies such as CT may reveal diagnostic signs such as bladder wall thickening. Conservative medical therapy is often adequate, comprised of culture-specific antibiotics and bladder drainage. Some advocate periodic bladder irrigations and instillations with antibiotic solutions therapy are directed by the specific organisms isolated. Bladder irrigation with either saline or an antibiotic solution benefit is not clear. Cystectomy is reserved for refractory pyocystis.

REFERENCE
Bibb JL, Servilla KS, Gibel LJ, et al. Pyocystis in patients on chronic dialysis. A potentially misdiagnosed syndrome. *Int Urol Nephrol.* 2002;34(3):415–418.

PYONEPHROSIS

DESCRIPTION Infected, obstructed collecting system with grossly purulent drainage and suppurative necrosis of renal parenchyma. This can be a chronic, indolent infection, but it usually presents acutely with sepsis, flank pain, and ipsilateral loss of renal function. Immediate aspiration with retrograde or percutaneous catheter drainage is essential.

REFERENCE
Baumgarten DA, Baumgartner BR. Imaging and radiologic management of upper urinary tract infections. *Urol Clin N Am.* 1997;24(3):545–569.

PYOSPERMIA

DESCRIPTION The World Health Organization defines pyospermia as $>1\times10^6$ WBCs/mL semen (either peroxidase or by immunohistologic methods). Pyospermia (also referred to as *leukocytospermia*) has multifactorial causes, including infection, inflammation, and autoimmunity, and is considered to be 1 of the causes of male infertility. The short half-life of polymorphonuclear neutrophils (PMNs) in semen makes them a major source for factors that can be harmful to sperm. The differential diagnosis of symptomatic pyospermia includes infection, autoimmune disease, and inflammation of the accessory sex glands and lower male urogenital tract. Urogenital infections include acute and chronic prostatitis, seminal vesiculitis, epididymo-orchitis, cystitis, urethritis, urethral stricture, stone disease, foreign bodies, upper UTI, retrograde ejaculation, localized sepsis of the adjacent lower GI tract, and asymptomatic bacteriuria. The chronic infections that may result in pyospermia include fungal, mycobacterial, and congenital lesions causing infection of the urogenital tract. Autoimmune diseases that afflict the urogenital tract include Behçet syndrome and Reiter syndrome (Reactive arthritis/reactive arthritis triad). There is no defined medical management of pyospermia since the specific cause cannot be reliably identified. Options include antibiotic treatment (doxycycline, trimethoprim-sulfamethoxazole, ofloxacin) and other medications such as calcium dobesilate, propofol, rebamipide, N-acetyl-L-cysteine, glutathione, and vitamins C and E. Removal of cause and primary predisposing factors include the correction of any congenital or acquired defect in the GU tract harboring infection and inflammation, vesicourethral reflux, prostatic obstruction and infection, retrograde ejaculation, and urethral valves. Although antibiotics are a commonly used empiric therapy, studies have not confirmed their benefit, and a high rate of spontaneous resolution occurs without specific therapy. (See also Section II: “Semen Analysis, Abnormal Findings and Terminology”; “Semen Leukocytes.”)

REFERENCE

Pentyala S, Lee J, Annam S, et al. Current perspectives on pyospermia: A review. *Asian J Androl.* 2007;9(5):593–600.

Q-TIP TEST

DESCRIPTION The Q-tip test is useful to evaluate the urethral axis and evidence of hypermobility in the evaluation of urinary incontinence in the female. A cotton-tipped applicator is advanced per urethra to the level of the bladder neck and observed for changes in angle during straining maneuvers. Hypermobility suggests that a bladder neck suspension may restore continence.

REFERENCE

Dupont MC, Albo ME, Raz S, et al. Diagnosis of stress urinary incontinence. *Urol Clin N Am.* 1996;23(3):407–415.

QUAKEL CORPORAL SHUNT

DESCRIPTION Used for the treatment of priapism. Through a scrotal-perineal approach, a longitudinal incision is made in the outer bulbar urethra (making sure not to completely traverse and injure the urethra), and a parallel incision is made in the corporal body. After irrigating stagnant corporal blood, these 2 incisions are anastomosed.

REFERENCE

RADIATION EXPOSURE GUIDELINES

DESCRIPTION The National Council on Radiation Protection and Measurements has recommended maximum permissible dose limits for occupational exposure to members of the public, which apply to the sum of the effective doses from external radiation and the committed effective doses from internal exposures.

Occupational exposure

- The individual worker's lifetime effective dose should not exceed age in years times 10 mSv
- An annual effective dose limit of 50 mSv
- An annual dose limit of 150 mSv for the lens of the eye
- An annual dose limit of 500 mSv for localized areas of the skin and the hands and feet
- A monthly dose limit of 0.5 mSv to the fetus once a pregnancy is declared
- No occupational exposure should be permitted until age 18 yr

Public exposure

- An annual effective dose limit of 1 mSv for continuous exposure and 5 mSv for infrequent exposure
- An annual dose limit of 50 mSv for the hands and feet and localized areas of the skin and 15 mSv for the lens of the eye
- For educational and training purposes involving people aged <18 yr, an annual effective dose limit of 1 mSv

REFERENCE

Cuaron JJ, Hirsch AE, Medich DC, et al. Introduction to Radiation Safety and Monitoring. *J Am Coll Radiol.* 2011;8:259.

RADIATION, PELVIC, UROLOGIC CONSIDERATIONS

DESCRIPTION Pelvic radiation is commonly used as both a primary treatment for localized prostate cancer and also as a treatment for local recurrence after surgery or nodal disease. Muscle-invasive bladder cancer is also treated with radiation. Urologists often encounter patients who have received previous pelvic radiation for gynecologic cancers such as cervical, ovarian, or rectal cancer. Radiation can cause several urologic complications, including cystitis, ureteral stricture, secondary bladder malignancy, fistula, and retroperitoneal fibrosis. Previous pelvic radiation is a contraindication for orthotopic neobladder reconstruction, and urinary diversion should be performed using bowel and with placement of the stoma outside the radiation field.

REFERENCE

Duggan B, Nambirajan T, Johnston SR. Radiation-induced haemorrhagic cystitis. *Eur Urol.* 2003;43:111–123.

RADIATION PROCTITIS, UROLOGIC CONSIDERATIONS

DESCRIPTION One potentially serious complication of radiation therapy for prostate and other pelvic malignancies is radiation proctitis. Radiation proctitis refers to radiation-induced

injury to the rectal mucosa beginning 3 mo after treatment has ended. The incidence varies from 5–20%. Predisposing factors include prior lower abdominal surgery, diabetes, hypertension and possibly chemotherapy. Symptoms of radiation proctitis include tenesmus, bleeding, low-volume diarrhea, rectal pain, and less commonly, low-grade obstruction or fistula. Diagnosis is made with sigmoidoscopy.

TREATMENT

- Corticosteroids
- Sucralfate enemas
- Argon laser
- Bipolar electrocoagulation
- Formalin-soaked gauze
- Hyperbaric oxygen
- Surgery

REFERENCE

Babb R: Radiation proctitis: A review. *Am J Gastroenterol.* 1996;91:1309.

RADIATION, RENAL AND RETROPERITONEAL, UROLOGIC CONSIDERATIONS

DESCRIPTION Radiation therapy (RT) for RCC as primary therapy is ineffective, but it is useful for palliation of bone metastases. It can be utilized for renal sarcomas or lymphoma. Retroperitoneal radiation is used for seminoma but not for nonseminomatous testis tumors. Nonseminomatous germ cell tumors (NSGCT) are generally less radiosensitive, and RT is typically not used. Side effects of renal and retroperitoneal RT include retroperitoneal fibrosis, ureteral stricture or obstruction, hematuria, enteritis, cardiovascular complications, and secondary malignancy.

REFERENCE

Garcia-Serra AM, Zlotecki RA, Morris CG, et al. Long-term results of radiotherapy for early-stage testicular seminoma. *Am J Clin Oncol.* 2005;28:119–124.

RADIOPHARMACEUTICALS, UROLOGIC CONSIDERATIONS (STRONTIUM^{89}, SAMARIUM^{153}, RADIUM^{223})

DESCRIPTION Strontium^{89} and Samarium^{153} ethylene diamine tetramethylene phosphonate (EDTMP) are FDA-approved radioisotopes approved for the treatment of bony metastatic pain. Phosphorus^{32} has been used for bony metastases but is infrequently employed today. All of these agents are β-*emitters* that can cause significant bone marrow suppression, although myelosuppression has limited its application. These radioisotopes are infused intravenously and taken up in bony areas of high metabolic activity. The radioactive decay has a toxic effect on tumor cells, and relief of symptoms generally begins 1–4 wk after initial infusion.

Radium 223 is a newly approved α-*emitting* radioisotope for metastatic castrate resistant prostate cancer without visceral disease. Can palliate boney disease and also extend survival.

Less likely to impact bone marrow due to larger particle size and limited field effect. (See also Section VI: "Urologic Drug Reference.")

- α-emitters: Consists of helium nuclei; high linear energy transfer, will not penetrate a sheet of paper; number of DNA hits to kill a cell:1–10; induces double strand breaks that are more lethal and difficult to repair
- β-emitters: Consists of electrons; relatively low linear energy transfer; may be halted by an aluminum plate; 100–1,000 hits to kill cells; single strand breaks that are more easily repaired

RAPID PLASMA REAGIN (RPR) BLOOD TEST

DESCRIPTION The RPR test is a screening test for syphilis (*T. pallidum* infection). RPR detects serum antibodies to substances released by cells damaged by *T. pallidum*. It is 78%, 100%, and 95% sensitive in screening for primary, secondary, and tertiary syphilis, respectively. If a patient tests positive, a confirmatory treponemal particle agglutination or fluorescent treponemal antibody test should be ordered. False positives can be seen in some viral infections, and HIV can cause a false-negative reaction.

RAZ BLADDER NECK SUSPENSION (URETHROPEXY)

DESCRIPTION This is 1 of many surgical bladder neck suspension techniques aiming to fix the vesicourethral junction in a physiologic position to correct genuine stress incontinence in females. It is a modification of the Pereyra needle suspension. Through an inverted U-shaped incision in the anterior vaginal wall, the operator performs (1) retropubic urethrolysis, (2) fingertip guidance of a double-pronged suture carrier placed through a suprapubic opening, and (3) placement of helical nonabsorbable sutures through the urethropelvic ligament, otherwise known as the endopelvic fascia. Cystoscopy is performed after the sutures are placed. Best suited for patients with urethral and bladder neck hypermobility and no cystocele.

REFERENCE

Stothers L, Chopra A, Raz S. Surgery for female stress urinary incontinence. *Can J Urol.* 1995;2(Supp1):33–37.

RAZ VAGINAL WALL SLING

DESCRIPTION Technique to treat urinary incontinence due to intrinsic sphincter dysfunction or anatomic incontinence, this is a modification of the original Raz bladder neck suspension. This technique provides support for both the bladder neck and mid-urethra. In addition to the principal maneuvers described in the Raz urethropexy, the author incorporates a patch of anterior vaginal wall with the suspension sutures at the level of the bladder neck, which, in effect, creates a hammock that serves as a backboard to the bladder neck and mid-urethra.

REFERENCE

REACTIVE ARTHRITIS/REACTIVE ARTHRITIS TRIAD (FORMERLY REITER SYNDROME)

DESCRIPTION The preferred term today is *reactive arthritis*, a classic triad of polyarthritis, conjunctivitis, and nongonococcal urethritis; in women, cervicitis. Anterior uveitis and skin or genital rash may be seen. Thought to be a systematic inflammatory response triggered by microbial infection in the GU or GI tracts, the condition is a member of the spondyloarthritis family of disorders. The arthritis is usually asymmetric, with predominately lower extremity involvement. Joint aspiration is typically sterile. Association with HLA-B27 is noted, and may confer susceptibility. 2 forms exist: Sexually transmitted, in which symptoms emerge 10–14 days after exposure. Causes include *C. trachomatis*, *Salmonella* sp., *Shigella* sp., *Yersinia* sp., and *Ureaplasma urealyticum*. The overall prognosis is good, with spontaneous remission or remission following NSAID therapy within 6 mo of onset. A small proportion have chronic persistent arthritis; a few will develop ankylosing spondylitis more frequent (if HLA-B27 positive). Usual treatment includes supportive care NSAIDs, intra-articular or systemic steroids for polyarthritis. Antibiotic treatment is initiated for identified organisms, if possible, such as *C. trachomatis* doxycycline 100 mg PO BID for 7–14 days. (Note: The name change from Reiter syndrome to reactive arthritis is based in part on allegations that Dr. Reiter was an un-convicted war criminal.)

RECTOCELE, UROLOGIC CONSIDERATIONS

DESCRIPTION Rectocele generally presents as a posterior vaginal wall defect with varying degrees of prolapse. It can present with urologic symptoms including sexual dysfunction and voiding symptoms, as well as constipation. If a patient presents with voiding dysfunction, a urodynamic study should be performed with the rectocele reduced to unmask the patient's underlying urodynamic parameters. Prior to repair, it is important to determine if there is evidence of enterocele or cystocele, to determine the appropriate reconstructive procedure. Treatment can be conservative using a vaginal pessary or surgical using 1 of several

techniques, including open or laparoscopic, transvaginal, or endorectal. (See also Section I: "Pelvic Organ Prolapse [Cystocele and Enterocele].")

REFERENCE

Hall GM, Shanmugan S, Nobel T, et al. Symptomatic rectocele: What are the indications for repair? *Am J Surg*. 2014;207(3):375–379.

RED SCROTUM SYNDROME

DESCRIPTION The external genitalia can be affected by many inflammatory processes such as atopic and irritant dermatitis, psoriasis, or ichthyosis. A rare scrotal disease Red Scrotum Syndrome (RSS) affects males in their 2nd half of life and typically runs a chronic course. It may represent a localized phenotypical expression of erythromelalgia. RSS is characterized by persistent redness of the anterior 1/2 of the scrotum and may also involve the base of the penis. Symptoms include itching, burning, and pain sensations. It can develop after prolonged use of topical corticosteroids. It is often mistaken for eczema but itching is not common in RSS. Burning and hyperalgesia are typical in RSS and are not usual with eczema. The pain is aggravated by warmth, relieved by cold. Differential diagnosis includes atopic dermatitis, contact dermatitis, psoriasis, ichthyosis, mycosis such as tinea cruris, secondary syphilis and Langerhans cell histiocytosis among others. Oral doxycycline is used initially with gabapentin a 2nd-line therapy. (See also Section II: "Scrotal Skin Lesion.")

REFERENCE

Wollina U. Red scrotum syndrome. *J Dermatol Case Rep*. 2011;5(3): 38–41.

REED SYNDROME

DESCRIPTION Multiple cutaneous and uterine leiomyomatosis, also known as Reed syndrome, is an autosomal dominant condition. Individuals have an increased predisposition to develop benign smooth muscle tumors (leiomyomas) in the skin and uterus (fibroids). Subsets of these patients are at risk for renal cell cancer and have been determined to have mutations in the fumarate hydratase gene. The term hereditary leiomyomatosis and renal cell cancer refers to families with an increased prevalence of smooth muscle tumors and renal cell cancer as a result of the fumarate hydratase genetic defect. (See also Section II: "Leiomyomatosis, Hereditary" and "Renal Cell Carcinoma, Familial.")

REFERENCE

Emer JJ, Solomon S, Mercer SE. Reed's Syndrome A Case of multiple cutaneous and uterine leiomyomas. *J Clin Aesthet Dermatol*. 2011;4(12):37–42.

REFLUX NEPHROPATHY

DESCRIPTION Renal scarring secondary to reflux of sterile or infected urine from the bladder to the kidney. Girls are at increased risk of developing reflux nephropathy because of the increased incidence of UTI's. Most cases are associated with vesicoureteral reflux, and children are usually asymptomatic or may present with infection, hypertension, or renal failure in cases of severe scarring. Usually a radiographic diagnosis; US and voiding

cystourethrography identify the reflux, and renal scarring is detected radiographically by a cortical imaging agent such as DMSA technetium^{99m} (dimercaptosuccinic acid). Treatment is directed at the cause (such as vesicoureteral reflux antibiotic suppression or surgical correction). (See also Section I: "Vesicoureteral Reflux." and (Image ☼))

REFERENCE

Polito C, La Manna A, Rambaldi PF, et al. Long-term evolution of renal damage associated with unilateral vesicoureteral reflux. *J Urol.* 2007;178(3):1043–1047.

REIFENSTEIN SYNDROME

DESCRIPTION A form of incomplete male pseudohermaphroditism, usually presenting with perineoscrotal hypospadias and frequently cryptorchidism at birth, azoospermia and incomplete virilization at puberty, and infertility and gynecomastia at or after puberty. Caused by mutations in the DNA-binding domain of androgen receptor, with varying degrees of androgen receptor dysfunction. Patients are usually assigned to male sex at birth, and they exhibit elevated levels of testosterone and luteinizing hormone. Surgical repair of hypospadias and cryptorchidism as the treatment and supplemental testosterone is not beneficial. (See also Section II: "Androgen Insensitivity Syndrome [AIS or Androgen Resistance Syndrome], Complete and Partial.")

SYNONYMS

- Lubor Gilbert–Dreyfus Syndrome
- Type 1 incomplete male pseudohermaphroditism

REFERENCE

Androgen Insensitivity, Partial; PAIS: in Online Mendelian Inheritance in Man http://www.omim.org/entry/312300, Accessed March 6, 2014.

REINKE CRYSTALS

DESCRIPTION Cytoplasmic crystalloid inclusions found in human Leydig cells. The crystals are large, distinctive, and easily visible under light microscopy. It has been noted that their numbers increase with age; their function or significance is unknown.

REFERENCE

Kerr JB. Ultrastructure of the seminiferous epithelium and intertubular tissue of the human testis. *J Electron Microsc Technique.* 1991;19(2):215–240.

RENAL ADENOMA (PAPILLARY ADENOMA)

DESCRIPTION The most common renal epithelial neoplasm and found in 4–37% of autopsy specimens. Controversial if these are small adenocarcinomas. Strict diagnostic criterion include papillary, tubular, or tubulopapillary architecture, <5 mm and no resemblance to any renal malignancy.

REFERENCE

Grignon DJ, Eble JN. Papillary and metanephric adenomas of the kidney. *Semin Diagn Pathol.* 1998;15(1):41–53.

RENAL AGENESIS (BILATERAL AND UNILATERAL)

DESCRIPTION This condition is defined by the congenital absence of 1 or both kidneys:

- Bilateral renal agenesis: Incompatible with life as kidney function in utero is necessary in development of the lungs. Infants born with bilateral agenesis have hypoplastic lungs, oligohydramnios, anuria, and renal failure, as well as a well-described group of physical findings such as a flattened nose, low-set ears, bowed limbs, and a small chest collectively referred to as *Potter syndrome*. Bilateral agenesis is reported in 1 in 3,000 births but the actual incidence is unknown since many fetuses are believed to spontaneously abort without a diagnosis.
- Unilateral renal agenesis: In contrast, unilateral agenesis is usually asymptomatic and is often undetected throughout life. It occurs in 1 in 1,100 births, and is more common in males (1.8:1); the left kidney is more commonly missing. Commonly associated with müllerian duct, wolffian duct, and ureteric bud abnormalities and thus may involve the vas deferens, ureter, trigone, vagina, and seminal vesicles. 65% of patients have another urologic anomaly. Associated anomalies include reflux; contralateral UPJ obstruction including single umbilical artery; absence of ipsilateral ureter and hemi-trigone; vaginal atresia/agenesis (Mayer–Rokitansky syndrome); unilateral vas deferens agenesis/atresia; and seminal vesicle cysts. Unilateral renal agenesis is also associated with anomalies of other systems (such as cardiovascular in 30% valvular or septal cardiac anomalies); GI in 25%; imperforate anus or atresia of anus or esophagus; and vertebral or pharyngeal anomalies. If diagnosed, some clinicians propose yearly screening of BP and urinary protein levels because of the risk of hypertension, renal insufficiency, and proteinuria found in some adult studies. (See also Section II: “Potter Syndrome/Potter Facies.” and (Image ☼))

REFERENCE

Uetani N, Bouchard M. Plumbing in the embryo: Developmental defects of the urinary tracts. *Clin Genet.* 2009;75(4):307–317.

RENAL ANATOMY, NORMAL RADIOGRAPHIC FINDINGS (SIZES, CALYCES)

DESCRIPTION The kidney can be imaged by plain film, US, CT, MRI, radionuclide scanning, or pyelography, either IV excretory, antegrade, or retrograde. A normal adult kidney should measure 10–13 cm vertically, 5–7 cm transversely, and 3 cm anteroposteriorly. The right kidney tends to be shorter and wider than the left due to hepatic compression. The renal pedicle usually consists of a single renal artery and vein, although many normal anatomic variants exist. Typically each kidney has 2–3 major calyces and 8–14 minor calyces. Many normal variants of calyceal anatomy also exist, but pathologic findings include debris and filling defects; calyceal diverticulum, dilation of calyces or a single calyx suggests ureteral and infundibular obstruction, respectively (Image ☼).

REFERENCE

Singer A, Simmons MZ, Maldjian PD. Spectrum of congenital renal anomalies presenting in adulthood. *Clin Imaging*. 2008;32:183–191.

RENAL ARTERY ANEURYSM

DESCRIPTION A renal artery aneurysm is defined as a dilated segment of renal artery that exceeds twice the diameter of a normal renal artery. Although rare, the diagnosis and incidence of this entity have been steadily increasing due to the routine use of cross-sectional imaging. Incidence ranges from 0.3–1.0% on radiographic studies, accounting for 1% of all arterial aneurysms and 10% of visceral aneurysms. They are commonly bilateral or multiple 20% and 30%, respectively, and occur typically in the 5th–6th decades of life, slightly more frequently on the right. They are associated with hypertension (HTN), but a causal effect has not been shown. Spontaneous rupture is rare, but risk is increased during pregnancy. Presentation is usually secondary to HTN, flank pain, hematuria, or an incidental finding on radiographic study. Causes include atherosclerosis, congenital fibromuscular dysplasia, trauma, infectious disease (syphilis or TB), intrarenal aneurysms, collagen vascular diseases (PAN, Wegener granulomatosis).

TREATMENT

- Most studies recommend repair of renal artery aneurysms (RAAs) >2 cm, spontaneous rupture, or asymptomatic lesions in high-risk patients women of childbearing age or patients with a functional or anatomic solitary kidney. Recent data suggests that many of these patients with RAA >2 cm can be observed if symptomatic.
- Repair includes primary repair with excision of aneurysmal segment, or aortorenal bypass with vein. Extra-anatomic bypass (hepatorenal, gastroduodenal-renal, or splenorenal) is useful for a severely calcified aorta or when aortic cross-clamping is undesirable.
- Autotransplantation is useful for complex repairs with long ischemic time.
- Percutaneous treatment with embolization or occlusion of aneurysmal segments is reserved for high-risk surgical candidates.
- Intraluminal vascular stent: Investigational

RENAL ARTERY FIBROMUSCULAR DYSPLASIA

DESCRIPTION Fibromuscular diseases of the renal artery account for 1/3 of cases of renovascular hypertension. Treatment consists of antiplatelet therapy for asymptomatic individuals and percutaneous balloon angioplasty for patients with indications for intervention. Patients with macroaneurysms should be treated with either a covered stent or surgery. BP control with ACE inhibitor or angiotensin II receptor blocker. 4 pathologic entities have been described.

- *Intimal fibroplasia* affects mainly children and young male adults. Angiographically, a smooth focal stenosis is typically seen at the mid renal artery or its branches. Prompt repair is advised because of the progressive nature of the disease.
- *Fibromuscular hyperplasia* of smooth muscle and fibrous tissue is rare, progressive, and affects mainly children and young adults.
- *Medial fibroplasia* is the most common (80%), affecting women in their 30s. On angiogram, it has the appearance of a string of beads. This lesion does not dissect, and complete occlusion has not been reported. Angioplasty is the treatment of choice.
- *Perimedial fibroplasia* is a tightly stenotic, progressive lesion, affecting women 15–30 yr of age. On angiography, extensive collateral vessels are commonly identified. Follow potassium and creatinine after initiation of therapy. Revascularization using percutaneous angioplasty is the definitive treatment of choice.

RENAL CARCINOID TUMOR

DESCRIPTION Rare tumor derived from enterochromaffin or amine precursor uptake and decarboxylation (APUD) cells, occurring most commonly in the GI tract and lung, but also in ovaries, testes, thymus, pancreas, and hepatobiliary system. Primary renal lesions are extremely rare, with only 32 cases reported. The lesions are thought to originate in renal collecting cells undergoing intestinal metaplasia or from teratomatous epithelial cells within the kidney. Horseshoe kidneys are shown to have a markedly elevated risk of carcinoid tumor, although still very rare, and may have a more benign course.

REFERENCE

RENAL CELL CARCINOMA, CHROMOPHOBE

DESCRIPTION Chromophobe RCC is a subtype of RCC derived from the distal renal tubules, and it comprises about 3–5% of all RCCs. Tumor cells display a transparent cytoplasm with a plant cell appearance and a characteristic perinuclear halo. On electron microscopy, microvesicles are seen that stain positive for Hale's colloidal iron. There are 2 types. Type 1, or classic, is defined by loss of chromosomes 1, 2, 6, 10, 13, 17, or 21 and has a better prognosis than type 2, or eosinophilic variant. The eosinophilic variant is part of Birt–Hogg–Dubé syndrome. In general, chromophobe RCC has a better prognosis than other RCC histologies. Chromophobe RCC is difficult to distinguish from oncocytoma on biopsy, making definitive diagnosis difficult without a complete pathologic exam. CD82 and epithelial-related antigen (MOC31) may be helpful in the distinction between chromophobe RCC and renal oncocytoma. (See also Section I: "Renal Cell Carcinoma, General" and (Image ☼).)

REFERENCE

Klatte T, Han KR, Said JW, et al. Pathobiology and prognosis of chromophobe renal cell carcinoma. *Urol Oncol.* 2008;266:604–609.

RENAL CELL CARCINOMA, CLEAR CELL

DESCRIPTION This represents up to 85% of renal tumors. It is thought to arise from the proximal renal tubule and is characterized by a 3p deletion in over 90%. The Von Hippel–Lindau (VHL) gene is found on chromosome 3 (3p25–26) and is involved in the development of clear cell RCC in patients with VHL disease. In addition, VHL gene alterations are involved in the pathogenesis of sporadic RCC. The diffuse positivity for carbonic anhydrase 9 (CA9) is diagnostic for clear cell RCC. A worse prognosis is associated with higher nuclear grade or the presence of a sarcomatoid pattern. Tumors with predominant eosinophilic cells were classified as "granular cell" carcinoma but the 2004 WHO classification of renal tumors based on the presence of vasculature and genetic alterations included these under clear cell RCC. Treatment and staging are discussed elsewhere. (See also Section I: "Renal cell carcinoma, General" and "Von Hippel–Lindau Disease/Syndrome" and Section II: "Renal Cell Carcinoma, Familial." and (Image ☼))

SYNONYMS

- Hypernephroma (once thought to be adrenal origin)
- Grawitz tumor

REFERENCE

Delahunt B, Eble Jn. History of the development of the classification of renal cell neoplasia. *Clin Lab Med.* 2005;25(2):231–246.

RENAL CELL CARCINOMA, FAMILIAL

DESCRIPTION Approximately 2% of renal cell carcinomas (RCC's) can be inherited. Familial renal cancers are characterized by an early onset compared with sporadic cases and frequently comprise bilateral and multicentric tumors. Moreover, extrarenal features suggestive of a described familial renal cancer syndrome might be present. See table for common renal tumor familial syndromes. (See also Section I: "Renal Cell Carcinoma, General.")

Common Renal Tumor Familial Syndromes (All autosomal dominant inheritance)	Gene Protein (Chromosome)	Renal Tumor Type	Common Clinical Manifestations
Von Hippel–Lindau (VHL)	VHL (3p25)	Multiple bilateral clear cell renal cell carcinoma, renal cysts	Hemangioblastomas of the CNS; retinal angiomas; pheochromocytoma
Tuberous sclerosis	TSC1 (9q34) TSC2 (16p13)	Multiple bilateral angiomyolipomas; lymphangioleiomyomatosis	Cortical brain tubers and other lesions; mental retardation; epilepsy; facial angiofibromas; cardiac rhabdomyomas
Hereditary papillary renal cell carcinoma	c-MET (7q31)	Multiple bilateral papillary renal cell carcinoma type 1	
Birt–Hogg–Dubé (BHD)	BHD/Folliculin (17.p11.2)	Chromophobe; occasional clear cell renal cell carcinoma	Cutaneous fibrofolliculomas; lung cysts; spontaneous pneumothorax
Hereditary leiomyomatosis and renal cell carcinoma	Fumarate hydratase (FH) (1q42–43)	Papillary renal cell carcinoma type 2. Aggressive unilateral, early metastasizing with high fatality	Cutaneous leiomyomas; severely symptomatic uterine fibroids oncocytoma; transitional tumors

RENAL CELL CARCINOMA, PAPILLARY TYPES 1 AND 2

DESCRIPTION An uncommon variant of RCC, representing ~10–15% of cases. The lesions exhibit a tubulo-papillary growth pattern. A hereditary pattern is demonstrated in a small number of families, tending to be multifocal, bilateral, and associated with a loss of short arm of chromosome 3. Subtypes are cytologically classified as type 1 with small single-layer cells, and type 2 with large pseudostratified cells. Type 1 papillary RCC typically exhibits genetic alterations including gains of chromosome 7 and 17 and loss of Y, which has a better prognosis; type 2 has a more heterogeneous genetic alterations and a poorer prognosis. CK7 and AMACR are excellent markers for papillary RCC. (See also Section I: "Renal Cell Carcinoma, General" and (Image ☼).)

REFERENCE

Pignot G, Elie C, Conquy S, et al. Survival analysis of 130 patients with papillary renal cell carcinoma: Prognostic utility of type 1 and type 2 subclassification. *Urology*. 2007;69(2):230–235.

RENAL CELL CARCINOMA, SARCOMATOID

DESCRIPTION An uncommon histologic variant of RCC, with an approximate incidence of 5–10% of all cases. Histologically, the lesion is composed of clear cells and pleomorphic spindle cells resembling sarcoma. It tends to have a more malignant behavior and worse prognosis, with higher local recurrence, more frequent metastasis, and shorter survival. Sunitinib shows efficacy in advanced renal tumors with sarcomatoid differentiation particularly in patients with good performance status. (See also Section I: "Renal Cell Carcinoma, General" and "Renal Sarcoma, Adult and Pediatric." and (Image ☼))

REFERENCES

Oda H, Machinami R. Sarcomatoid renal cell carcinoma. A study of its proliferative activity. *Cancer.* 1993;71(7):2292–2298.

RENAL CELL CARCINOMA, TUBULOCYSTIC

DESCRIPTION Tubulocystic carcinoma of the kidney (TCCK), a newly described entity, is well-demarcated multicystic lesions giving a "wrapped bubble" or "spongy" appearance. Microscopically, the tumors were composed of tubules and cysts lined by a single layer of eosinophilic, columnar, cuboidal, flat, or hobnail cells with large nuclei and prominent nucleoli separated by a thin fibrotic stroma. In all TCCKs, the majority of neoplastic cells

showed immunohi-stochemical (CD10(+), RCC(+), vimentin(+), and AMACR(+)) and ultrastructural (abundant long brush border microvilli) characteristics of proximal renal tubules, but the cell of origin is unclear. The major differential diagnostic considerations are oncocytoma, multilocular cystic RCC, and cystic nephroma/mixed epithelial and stromal tumor of the kidney. It generally pursues an indolent clinical course. Nephrectomy/ partial nephrectomy of involved renal unit is usually necessary (Image ☼).

REFERENCE

RENAL CELL CARCINOMA, UNCLASSIFIED

DESCRIPTION A diagnostic category to which renal carcinomas should be assigned when they do not fit into 1 of the other categories, even after genetic analysis. In some series, this group has amounted to 3–5% of cases. Features which might prompt the assignment of a carcinoma to this category include apparent composites of recognized types, sarcomatoid morphology without recognizable epithelial elements, mucin production, mixtures of epithelial and stromal elements, and unrecognizable cell types. Unclassified RCC is associated with distinct and highly aggressive biologic behavior with poor clinical outcomes. Whenever feasible, immunotherapy with nephrectomy is warranted.

RENAL CELL CARCINOMA, XP11.2;TFE3 TRANSLOCATIONS

DESCRIPTION A number of sporadic cases of RCC have chromosomal translocations involving the TFE3 gene at chromosome Xp11.2. Children and young adults are affected without predilection for gender however there appears to be a female predilection in the adult population. The histologic features of such cases have been variably described as papillary RCC, clear cell RCC, or a unique type of pathology. Papillary RCC is the most reported subtype associated with the translocation. The TFE3 gene encodes a transcription factor related to the proto-oncogene product c-myc. RCC is likely due to TFE3 overexpression. TFE3, TFEB, and ALK protein expression are crucial in establishing the diagnosis. This is an aggressive disease and targeted therapy (sorafenib, sunitinib, temsirolimus) and VEGF-targeted therapy demonstrate some activity in advanced disease (Image ☼).

REFERENCE

RENAL CHOLESTEROL EMBOLISM SYNDROME

DESCRIPTION Cholesterol microembolism (also called cholesterol emboli and cholesterol crystal emboli) of the kidney is an uncommon cause of hypertensive emergencies, affecting mainly elderly men with atherosclerotic vascular disease. It is increasingly associated with thrombolytic therapy. Clinical findings include severe hypertension, digital gangrene, livedo reticularis, cerebrovascular accidents, GI hemorrhage or infarction, bowel perforation, retinal emboli, and eosinophilia. Dialysis for renal insufficiency might be necessary. Diagnosis is made from clinical history, physical exam, lab findings, and selective renal angiogram, and is confirmed by renal biopsy. In the kidneys, intralobular and arcuate arteries are most frequently affected. Treatment is supportive and preventative with management of hypertension and renal insufficiency through control of the underlying pathology.

CAUSES

- Angiographic manipulation
- Anticoagulant medications
- Cardiovascular surgery
- Iatrogenic
- Spontaneous

REFERENCE

Hitti WA, Anderson J. Cholesterol emboli-induced renal failure and gastric ulcer after thrombolytic therapy. *South Med J*. 2005;98(2):235–237.

RENAL CORTICAL ADENOMA

DESCRIPTION Also called *papillary adenoma of the kidney* this is a type of benign renal neoplasm. It falls under the general category of renal adenomas and is considered one of the most common of renal epithelial neoplasms. These small papillary tumors are characterized by scant cytoplasma (chromophilic cells), occasionally somewhat eosinophilic, with tubular-papillary patterns, limited but not encapsulated. Renal papillary adenoma defines papillary or tubular architecture of low nuclear grade with a maximum diameter of 5 mm. Based on autopsy series prevalence rate is 40% in patients older than 70. It has been postulated that papillary adenoma may progress to papillary RCC because of high coexistence, histopathologic similarity, and similar genetic alterations between papillary adenoma and papillary RCC. Cytogenetic changes of papillary adenomas include loss of the Y chromosome and combined trisomy of chromosomes 7 and 17. Histologic and genetic abnormalities of small renal adenomas are indistinguishable from larger papillary RCCs. Based on these findings it is now considered that these small benign lesions can increase in size and transform into papillary carcinomas. For this reason, the WHO 2004 renal cell tumors classification considered tumors with a maximum diameter of 5 mm as papillary adenomas. Renal papillary adenoma frequently develops in patients with acquired renal cystic disease and long-term hemodialysis and may have a different pathogenesis (Image ☼).

RENAL HEMANGIOMA

DESCRIPTION These benign vascular neoplasms are usually diagnosed in the 3rd–5th decades, with no sex predilection. The most common presenting symptom is intermittent hematuria. Angiographic appearance varies markedly, with hypervascular, hypovascular, and normal lesions being reported. In the past, a clinical finding of unilateral hematuria and a suggestive angiographic pattern were the basis of preoperative diagnosis. Currently, hemangioma can be identified ureteroscopically, without the need for a biopsy, where they may appear as small, red or bluish spots on the tip or base of a papilla, or they may be large, bulbous, erythematous lesions on the papillary tips. Pathologically, hemangiomas have the gross appearance of a well-demarcated lesion that shows a cluster of blood-filled vascular channels. Microscopically, the majority of cases conform to the typical features of cavernous hemangioma, with variable, large, blood-filled vascular tributaries in a disorganized tangle. Variation in vascular wall thickness and structure indicates arterial and venous components. The benign cytologic feature of flat lining endothelial cells allows for differentiation of this lesion from angiosarcoma.

TREATMENT

- Ureteroscopic electrocauterization or laser ablation using holmium, ND:YAG, or a combination of both
- Surgical resection

REFERENCE

Waller JI, Throckmorton MA, Barbosa E. Renal hemangioma. *J Urol.* 1995;74:186.

RENAL HEMANGIOPERICYTOMA

DESCRIPTION A rare primary sarcoma of the kidney, accounting for 1–3% of renal malignancies. Solid hypervascular mass with calcifications, originating from pericytes, located external to endothelial cells of capillaries, and enveloped by basement membrane. It can be metabolically active, secreting renin. Common presenting signs include flank pain, flank mass, hypertension, hypoglycemia, and hematuria. It can be treated by radical nephrectomy, with reports of nephron-sparing surgery.

REFERENCE

Brescia A, Pinto F, Gardi M, et al. Renal hemangiopericytoma: Case report and review of the literature. *Urology.* 2008;71(4):755.e9–e12.

RENAL LEIOMYOMA

DESCRIPTION A rare benign renal tumor, with an incidence of 5% on autopsy series, it originates from smooth muscle, usually from renal capsule or vessels, and less commonly from the renal pelvis. Radiographically, it can appear as a solid or cystic mass, difficult to

differentiate from RCC, thus usually prompting radical nephrectomy. Imaging findings that can help to suggest the diagnosis of renal leiomyomas are tumors that are hyperdense before contrast, with density similar to that of muscles, and with lower enhancement than the adjacent renal parenchyma. Most are peripheral, without involvement of the renal cortex and with well-defined margins. (See also Section I: "Renal Mass.")

RENAL LEIOMYOSARCOMA

See Section I: "Renal Sarcomas, Adult and Pediatric."

RENAL LYMPHANGIECTASIA

DESCRIPTION A very uncommon benign disorder of renal lymphatics with unknown pathophysiology, the condition can present with perinephric collections, ascites, abdominal pain, and reversible hypertension. Imaging demonstrates enlarged kidneys with fluid collections seen to be abutting the surrounding structures. Perinephric fluid analysis usually demonstrates elevated protein levels with leucocytes (mostly lymphocytes). Management alternatives range from percutaneous drainage in symptomatic cases to medical therapy (antihypertensives and diuretics).

REFERENCE

Ashraf K, Raza SS, Ashraf O, et al. Renal lymphangiectasia. *Br J Radiol.* 2007;8095(4):e117–118.

RENAL MALROTATION

DESCRIPTION The abnormal orientation of the kidney, such that the position of the renal pelvis is not antero-medial, and the calyces are not pointing laterally. This condition may occur in cases of ectopia, fusion, and incomplete renal ascent; it has an incidence of 1 in 390. Three types of renal malrotation have been described

- Nonrotation: The renal pelvis is anterior.
- Reverse rotation: The renal pelvis is lateral.
- Hyper-rotation: The renal pelvis is posterior.

Symptoms are usually absent; occasionally, vague abdominal pain and/or vomiting due to renal obstruction may occur. Patients may develop ureteral obstruction, infections, or calculi. Diagnosis is made typically on excretory urography with altered orientation of the calyces and pelvices. Retrograde pyelography is often useful in defining the anatomy. No treatment is necessary unless symptoms, stones, or obstruction become problematic. Follow-up US to evaluate for stones or hydronephrosis is recommended. (See also Section I: "Renal Ectopia.")

RENAL MASS, INDETERMINATE

DESCRIPTION An indeterminate renal mass is one that cannot be diagnosed confidently as benign or malignant at the time it is discovered. The American College of Radiology has provided appropriateness criterion for the radiographic evaluation of the indeterminate renal mass. The utility of radiologic procedures in the evaluation of the indeterminate renal mass are summarized in the table on the next page.

Radiologic Procedure	Rating	Comments
CT abdomen without and with contrast	9	Either CT or MRI is appropriate. Thin-section CT.
MRI abdomen without and with contrast	8	Either CT or MRI is appropriate. See statement regarding contrast in text under "Anticipated Exceptions."
US kidney retroperitoneal with Doppler	8	To clarify mass that is probably a hyperdense or simple cyst.
Biopsy and aspiration kidney	5	Depends on clinical scenario—the appearance and size of mass. US, CT, or MRI may be used for image guidance.
MRI abdomen without contrast	3	Can be useful to characterize simple cysts.
Tc-99m DMSA scan kidney	1	May be useful to rule out pseudomass of functioning renal tissue.
Arteriography kidney	1	To rule out arteriovenous malformation, arteriovenous fistula, or renal artery aneurysm.
X-ray intravenous urography	1	May be helpful to differentiate parenchymal masses from collecting system masses.
CT abdomen without contrast	1	

Rating Scale: 1, 2, 3, usually not appropriate; 4, 5, 6, may be appropriate; 7, 8, 9, usually appropriate

RENAL MEDULLARY CARCINOMA

DESCRIPTION This is an aggressive renal malignancy limited almost exclusively to young black patients with sickle cell trait and, less commonly, sickle cell disease. Typical age of presentation is 21–24 yr of age with a male predominance. Over 75% occur in the right kidney. Genetic testing has suggested a potential association with various chromosomal anomalies. It is considered a variant of collecting duct carcinoma. Patients usually present with gross hematuria, UTI, flank pain, an abdominal mass, and/or weight loss. Metastasis in the cervical nodes or brain are often the initial finding. Hematuria in the target population should prompt evaluation for renal medullary carcinoma. Imaging typically demonstrates a centrally located infiltrative lesion invading the renal sinus with peripheral caliectasis. Size ranges from 4–12 cm (averaging 7 cm) and usually associated with hemorrhage and necrosis. Metastatic disease is commonly present at diagnosis. Surgical resection is not usually curative. There is limited experience in the treatment of metastatic disease. Survival after diagnosis is usually $<$6–12 mo (Image ☼).

RENAL OSTEODYSTROPHY

DESCRIPTION Renal osteodystrophy is defined by the National Kidney Foundation as bone morphology alterations observed in chronic kidney disease. Several changes can occur, including osteitis fibrosa cystica due to secondary hyperparathyroidism, osteomalacia, or low bone turnover. The most common presenting symptoms are bone fracture and pain, and usually occurring once a patient is on dialysis. Treatment may include treating hyperphosphatemia, Calcitrol, vitamin D analogs, calcimimetics, or parathyroidectomy.

REFERENCE

Moe S, Drüeke T, Cunningham J, et al. Definition, evaluation, and classification of renal osteodystrophy: A position statement from Kidney Disease: Improving Global Outcomes (KDIGO). *Kidney Int.* 2006;69:1945–1953.

RENAL PSEUDOTUMOR

DESCRIPTION A benign condition of the kidney mimicking a renal neoplasm on radiographic studies. Most commonly is a *hypertrophied column of Bertin* (sometimes referred to as an *anomalous calyx*), a prominent medullary column usually located between the upper and middle pole calyceal infundibula that can appear as a renal mass but is homogeneous with surrounding renal parenchyma, with normal-appearing calyces. Other conditions giving appearance of renal tumor include persistent fet al lobulation, dromedary or splenic humps, arteriovenous malformation (AVM), extramedullary hematopoiesis, splenorenal fusion (extremely rare), lobar nephronia (focal glomerulonephritis), renal abscess, scarred kidney, regenerating nodule after reflux. xanthogranulomatous pyelonephritis (XGP), granulomatous diseases (sarcoidosis and malakoplakia) subepithelial renal pelvic hematoma (due to anticoagulant or vasculitis) and renal sinus lipomatosis. Contrast-enhanced ultrasound, CT, or MRI can all assist in characterization, but final diagnosis may require percutaneous biopsy or surgery. (See also Section I: “Renal Mass” and Section II: “Renal Mass Indeterminate.”)

RENAL SINUS ABNORMALITIES

DESCRIPTION The renal sinus is a central spacious cavity in which major branches of the renal artery and vein, along with the major and minor calyces of the collecting system, are located. It is usually filled with adipose tissue, lymphatic channels, nerve fibers, and fibrous tissue. Lesions that may develop in the sinus could be benign, including parapelvic simple cysts, lipomatosis, cysts, urinomas, and vascular lesions such as renal artery aneurysm or AV fistula. Malignant tumors originating in renal pelvis or parenchyma, such as TCC and RCC, may also protrude or even invade and obliterate renal sinus fat. Primary tumors, such as hemangioma, fibroma, leiomyoma, and MFH are rare but may develop in the space.

RENAL TRANSPLANT TYPES (STANDARD/EXTENDED/DONOR AFTER DEATH)

DESCRIPTION Renal transplant donors can be by living donors or deceased donors. Deceased donors are individuals who meet the criteria for brain death, but whose organs are being perfused by life-support methods, allowing adequate time for procurement. Donor after cardiac death is an expanded criteria donor. Nonheart beating donor (NHBD) death is characterized by irreversible absence of circulation. NHBDs are less than ideal because organs suffer ischemia during prolonged periods of circulatory dysfunction. Nearly /2 of all renal transplants are from deceased donors. Living donors can be either related or unrelated. On preoperative evaluation, normal renal function after donation is the goal. In line with this, the better functioning kidney is left with the donor. HLA-identical siblings have the highest graft survival rates followed by 1-haplotype siblings. In paired donor exchange, also known as kidney swap, 2 kidney recipients exchange willing donors whom they are incompatible with. This allows the donors to provide 2 recipients with grafts where previously no transplant would have been possible. Overall, living donor grafts have higher survival rates, with 80% surviving at the 5-yr mark compared to 67% of deceased donor grafts (Image ☼).

RENAL TRANSPLANTATION AND NEOPLASIA

DESCRIPTION Transplant recipients have an elevated risk of cancer. There is a very small risk of primary malignancy harbored in the graft being transferred to the recipient. The most common malignancies that form after transplantation are de novo malignancies. They are thought to occur secondary to chronic use of immunosuppressive drugs. After 10 yr of immunosuppression, kidney transplant recipients have a cumulative incidence of cancer as high as 20%. The most common are Kaposi's sarcoma and non-Hodgkin lymphoma. Compared to age and sex matched general population, kidney cancer recipients are 3–5-fold increased risk of developing skin cancers and urologic malignancies. Recipients who have been on hemodialysis are also at a higher risk of acquired cystic disease and subsequent primary renal malignancy.

RENAL TUMORS, WHO 2004 CLASSIFICATION

DESCRIPTION The 2004 World Health Organization (WHO) classification of the adult renal

epithelial neoplasms replaced the previous 1998 WHO classification. It incorporates other classifications (Mainz, Heidelberg) and describes entities based on both pathologic and genetic analyses. (See table)

WHO (2004) Classification of All Renal Tumors

Renal cell tumors
- Clear cell renal cell carcinoma
- Multilocular clear cell renal cell carcinoma
- Papillary renal cell carcinoma
- Chromophobe renal cell carcinoma
- Carcinoma of the collecting ducts of Bellini
- Renal medullary carcinoma
- Xp11 translocation carcinomas
- Carcinoma associated with neuroblastoma
- Mucinous tubular and spindle cell carcinoma
- Renal cell carcinoma, unclassified
- Papillary adenoma
- Oncocytoma

Metanephric tumors
- Metanephric adenoma
- Metanephric adenofibroma
- Metanephric stromal tumor

Nephroblastic tumors
- Nephrogenic rests
- Nephroblastoma
  - Cystic partially differentiated nephroblastoma

Mesenchymal tumors Occurring Mainly in Children
- Clear cell sarcoma
- Rhabdoid tumor
- Congenital mesoblastic nephroma
- Ossifying renal tumor of infants

Mesenchymal tumors Occurring Mainly in Adults
- Leiomyosarcoma (including renal vein)
- Angiosarcoma
- Rhabdomyosarcoma
- Malignant fibrous histiocytoma
- Hemangiopericytoma
- Osteosarcoma
- Angiomyolipoma
  - Epithelioid angiomyolipoma
- Leiomyoma
- Hemangioma
- Lymphangioma
- Juxtaglomerular cell tumor
- Renomedullary interstitial cell tumor
- Schwannoma
- Solitary fibrous tumor

Mixed mesenchymal and epithelial tumors
- Cystic nephroma
- Mixed epithelial and stromal tumor
- Synovial sarcoma

Neuroendocrine tumors
- Carcinoid
- Neuroendocrine carcinoma
- Primitive neuroectodermal tumor
- Neuroblastoma
- Pheochromocytoma

Hematopoietic and lymphoid tumors
- Lymphoma
- Leukemia
- Plasmacytoma

Germ cell tumors
- Teratoma
- Choriocarcinoma

Metastatic tumors

WHO Histologic Classification of Benign Renal Neoplasms

Renal Cell Tumors	Metanephric Tumors	Mesenchymal Tumors	Mixed Epithelial and Mesenchymal Tumors
Oncocytoma	Metanephric adenoma	Angiomyolipoma	Cystic nephroma
Papillary adenoma	Metanephric adenofibroma	Leiomyoma	Mixed epithelial and stromal tumor
	Metanephric stromal tumor	Hemangioma	
		Lymphangioma	
		Reninoma	
		Fibroma	
		Schwannoma	

REFERENCE

RENAL VEIN, LEIOMYOSARCOMA

DESCRIPTION A rare tumor arising from the smooth muscle element of the renal vein, occurring most commonly on the left side. The highest incidence is seen in 60–69 year olds and is twice as common in women. Only 32 cases of renal vein leiomyosarcoma have been reported in the literature. The renal vein is the most common site of venous leiomyosarcoma outside of the vena cava. Presenting symptoms include flank or abdominal pain, weight loss, and a palpable abdominal mass. 3-dimensional abdominal imaging imaging reveals a

homogeneous, well-circumscribed mass at or near the renal hilum, commonly encasing the renal vein. Mean survival is 28 mo, with an aggressive malignant pattern to distant sites, including lung, liver, bone, skin and soft tissue, and brain.

TREATMENT

- Aggressive surgical resection with nephrectomy and en-bloc resection
- Nonsurgical treatment with XRT and chemotherapy can be instituted but the efficacy is limited.

RENAL–RETINAL SYNDROME

DESCRIPTION Also called juvenile nephronophthisis with retinal disease or Senior-Loken syndrome (SLS) it is a subtype of juvenile nephronophthisis. (See Section II: "Juvenile Nephronophthisis.") It is an autosomal recessive disease characterized by development of retinitis pigmentosa- or Leber congenital amaurosis-like retinal dystrophy and a medullary cystic kidney disease. These patients have concomitant retinitis pigmentosa, which is slowly progressive and bilateral, with retinal degeneration. Rods are affected, leading to defective night vision that becomes symptomatic in early childhood. The disc may look yellow and waxy. Treatment is supportive, with renal replacement therapy as needed.

SYNONYMS

- Juvenile nephronophthisis with retinal disease
- Senior–Loken syndrome

RENIN, PLASMA AND RENAL VEIN

DESCRIPTION In suspected renovascular hypertension, an elevated renin level of >50% in the renal vein compared to the renal artery plasma level (estimated from the IVC renin level) of the affected kidney is diagnostic. Individual renal veins can be sampled to isolate ischemic individual renal segments using this same technique. Normal, morning plasma renin activity for seated subjects ranges from about 1– 4 ng/mL/h (0.8–3.0 nmol/L/h). Corresponding active renin concentrations are 8–35 mU/L. Renin is increased with diuretics (including spironolactone), dihydropyridine calcium channel blockers, angiotensin converting enzyme inhibitors and angiotensin receptor antagonists. Levels are decreased by β-blockers, clonidine, or α-methyldopa (all of which reduce β-sympathetic stimulation of renin release), or nonsteroidal anti-inflammatory agents (which promote salt retention and also inhibit renal prostaglandin production).

- Normal renin: Secondary adrenal insufficiency (ie, hypopituitarism or isolated ACTH deficiency); Cushing syndrome, but they can be low when there is a marked degree of

hypercortisolism.
- Low renin: Primary aldosteronism; with 11β-hydroxylase or 17α-hydroxylase deficiency (due to mutations in CYP11B1 and CYP17, respectively), which are hypertensive forms of CAH; primary glucocorticoid resistance; DOC-producing adrenal tumors; ectopic ACTH syndrome.

RENINOMA (RENIN-SECRETING JUXTAGLOMERULAR CELL TUMOR)

DESCRIPTION A rare renin-secreting tumor of the juxtaglomerular apparatus. Its usual presentation is in a young female with severe, refractory, frequently paroxysmal hypertension with hypokalemia, hyperaldosteronism, and elevated plasma renin levels. Selective renal vein sampling for renin may help localize the lesion. It is generally a benign tumor, although untreated hypertension can be fatal. Surgical intervention (open or laparoscopic) may be curative and in high-risk patients, radiofrequency ablation may be a less invasive alternative to radical nephrectomy (Image ☼).

REFERENCE

Chao CT, Chang FC, Wu VC, et al. Reninoma. *Kidney Int.* 2011;79(2);260.

RENO-ALIMENTARY FISTULA

DESCRIPTION A broad group of nonanatomic communications between the upper urinary collecting system and the alimentary canal, with nephrocolic and right renal pelvis and duodenal fistulas being the most common presentations. Symptoms vary from GI symptoms, such as nausea, vomiting, and diarrhea, to recurrent UTIs with flank pain and fever. Retrograde ureterography is generally needed to visualize the fistula. (See also Section II: “Fistula, Enterovesical.”)

CAUSES
- Renal inflammatory disease acute/chronic)
- Malignancy of either intestinal or renal origin
- Iatrogenic (eg, percutaneous surgery)
- Trauma
- Ulcer disease

TREATMENT
- Conservative: Stenting or nephrostomy tube
- Nephrectomy with removal of fistula tract and bowel resection

REFERENCE

Bissada NK, Cole AT, Fried FA. Reno-alimentary fistula: An unusual urological problem. *J Urol*. 1973;110:273–276.

RENO-BRONCHIAL FISTULA

DESCRIPTION Fistulous communication between pleural cavity and kidney, associated with pyelonephritis and perinephric abscess. Usually presents with flank or abdominal pain with an ipsilateral pneumonia. Patients commonly have a history of pyelonephritis or abdominal abscess. Fistulas involving the kidney are most commonly caused by iatrogenic trauma. These may include percutaneous nephrostomy or nephrolithotomy tract placement. Reno-bronchial fistulas usually develop from an upper pole approach to the kidney, where the pleural cavity may be traversed. It can involve pleural space alone or erode into lung parenchyma and bronchial tree. Diagnosis is made with CT.

SYNONYMS
- Nephrobronchial fistula
- Renal, bronchopleural fistula

CAUSES
- Pyelonephritis with perinephric abscess
- Xanthogranulomatous pyelonephritis
- Most common pathogens: *E. coli* and *Proteus* sp account for 1/3 of cases
- Tubercular infections also reported
- Iatrogenic trauma: Percutaneous nephrostomy, nephrolithotomy tract placement

TREATMENT
- Percutaneous or open drainage and antibiotic therapy acutely
- Nephrectomy may ultimately be required

REFERENCE

Qazi H, Manikandan R, Holmes ME, et al. Nephrobronchial fistula- A case report. *Int Urol Nephrol*. 2007;39(1):31–32.

RENOMEDULLARY INTERSTITIAL CELL TUMOR (MEDULLARY FIBROMA, RENAL HAMARTOMA)

DESCRIPTION Also referred to as *medullary fibromas and renal hamartomas*, this is a benign renal mesenchymal neoplasm. Rarely they are large and symptomatic. It is a common incidental finding in as many as 50% of adults at autopsy. Renomedullary interstitial cell tumor arises from interstitial cells of the medulla. They do not appear to have any effect on blood pressure. At gross exam, medullary fibromas are white or gray nodules within the renal pyramid. At histologic exam, this tumor is characterized by stellate spindle cells in the background of a basophilic stroma. It can be seen on CT as a small nonenhancing noncalcified hypoattenuating solid mass within the renal medulla. Although it is a benign tumor, it is difficult to differentiate this lesion from other malignancies of the kidney on radiologic basis and hence many patients undergo radical nephrectomy (Image ☼).

REPERFUSION INJURY, RENAL (RENAL ISCHEMIA AND REPERFUSION INJURY)

DESCRIPTION Ischemic acute kidney injury (AKI) is a syndrome that develops following a transient drop in total or regional blood flow to the kidney. Although reperfusion is essential for the survival of ischemic tissue, there is evidence that reperfusion itself causes additional cellular injury after a period of ischemia. This can occur during renal transplantation and with vascular clamping during partial nephrectomy. Studies comparing partial nephrectomy with and without clamping show that ischemia is associated with an increased risk of ARF and advanced chronic kidney disease. Oncologic outcomes and complications in partial nephrectomy without clamping are similar to those with clamping. The clinical sequelae of warm ischemia reperfusion renal injury of approximately 30 min in one study of laparoscopic partial nephrectomy are minimal, however advanced age and pre-existing azotemia increase the risk of renal dysfunction after partial nephrectomy, especially when the warm ischemia time exceeds 30 min. No renoprotective drug therapy has proven clinical utility and renal cooling has not been proven uniformly beneficial. Attempting partial nephrectomy without vascular clamping is optimal. If renal vascular clamping is necessary, it seems that this should be for <30 min to limit renal reperfusion injury.

RESIDUAL URINE (POSTVOID RESIDUAL [PVR])

DESCRIPTION PVR is the amount of urine remaining immediately after a void. It can be measured by US (bladder scan) or directly by catheterization. Significant variability occurs between PVR measurements in any 1 individual, and several separate measurements should be performed. The absolute value of PVR has little significance but can indicate voiding dysfunction in symptomatic individuals. Therefore, PVR should be part of any assessment of patients with incontinence, LUTS, recurrent UTI, suspected bladder outlet obstruction, or neurogenic bladder.

REFERENCE
Kaplan SA, Wein AJ, Staskin DR, et al. Urinary retention and postvoid residual urine in men: Separating truth from tradition. *J Urol.* 2008;180:47–54.

RESISTIVE INDICES (RI)

DESCRIPTION The RI is a measurement of renal blood flow using Doppler ultrasound (US). It is defined as the PSV minus the end-diastolic velocity divided by PSV. It used to evaluate upper tract urinary obstruction as well as graft function in transplanted kidneys. Although there are no accepted parameters of normal RI, values >0.7 suggest obstruction or graft hypoperfusion.

REFERENCE

Nezami N, Tarzamni MK, Argani H, et al. Doppler ultrasonographic indices after renal transplantation as renal function predictors. *Transplant Proc.* 2008;40:94–99.

RETE TESTIS, ADENOCARCINOMA

DESCRIPTION A rare, highly malignant tumor arising from rete testis that usually occurs in older men, but has been reported in men as young as 17. It commonly presents with a painless scrotal mass or symptoms related to metastasis. Pathology reveals papillary adenocarcinoma in the rete testis, commonly with local invasion. May be associated with maldescended testis or adenomatous hyperplasia of the rete testis. Prognosis is poor, with $<50\%$ survival at 1 yr. Metastatic sites include retroperitoneal lymph nodes, lungs, bone, and liver. The diagnostic criteria include:

- Tumor in mediastinum separate from the body of testis
- Transition in rete testis from normal epithelium to neoplastic cells
- No evidence of teratoma
- No primary tumor elsewhere
- Intact pariet al tunica

TREATMENT

- Radical orchiectomy is the mainstay of treatment.
- XRT and chemotherapy have limited efficacy for metastatic disease.
- Retroperitoneal lymph node dissection may have a role in the absence of metastasis.

REFERENCE

Sogni F. Primary adenocarcinoma of the rete testis: Diagnostic problems and therapeutic dilemmas. *Scand J Urol Nephrol.* 2008;(421):83–85.

RETE TESTIS, TUBULAR ECTASIA AND CYSTIC DYSPLASIA

DESCRIPTION Tubular ectasia of the rete testis is a benign condition (sometime called cystic ectasia of the rete testes) seen mostly in older men, which involves cystic dilatation of the rete testis often detected on ultrasound. Ovoid cluster of anechoic cystic spaces located peripherally in the mediastinum testis (without any solid component) and no flow within the lesion on Doppler imaging and normal adjacent testicular parenchyma are pathognomic for tubular ectasia of the rete testis. It is believed that this is secondary to obstruction of the epididymis as 85% of cases have coexisting epididymal abnormalities like epididymal cysts. Vasectomy, spermatoceles or epididymitis, may also be associated with dilatation of the rete testis. It must be differentiated from testicular neoplasm and MRI is potentially helpful. It is

unclear whether this lesion is a cause of infertility.

Cystic dysplasia of the rete testis is similar sonographically and histologically, but it is a congenital lesion that occurs in children. It is associated with ipsilateral renal or urogenital excretory duct malformations.

Both of these lesions (tubular ectasia and cystic dysplasia) must be differentiated from benign intratesticular varicocele and tumors such as adenocarcinoma of the rete testis.

RETROCAVAL/CIRCUMCAVAL URETER

DESCRIPTION A rare congenital anomaly in which the infrarenal vena cava (IVC) is derived from the right subcardinal or postcardinal vein, anterior to the ureter. The term*circumcaval ureter* refers to the ureter emerging medial to IVC after running behind it, whereas the term *retrocaval* applies to those ureters that only knuckle behind the IVC but re-emerge laterally. Males are affected 3 times more often than are females. Not all retrocaval/circumcaval ureters are obstructed, but if obstruction exists, surgical repair is typically warranted. CT is the best imaging modality for identification. Despite its congenital origin, symptoms are usually absent in childhood and present later in life. Less commonly, patients present with hematuria or UTI.

REFERENCE

RETROGRADE URETHROGRAM (RUG), TECHNIQUE

DESCRIPTION RUG is used to radiographically evaluate the urethra. It is most commonly used to evaluate urethral stricture disease or trauma. It is commonly performed by inserting a Foley catheter or Brodney clamp into the Fossa Navicularis. The balloon is inflated with a few milliliters of water to create a seal. Then 50 cc of contrast solution is injected into the urethra under low pressures while obtaining a series of x-rays. An oblique view allows best visualization of the entire urethra (Image ☼).

REFERENCE

Berná JD, Berná JD Jr, Aparicio Meson M. Urethrography in the male: The clamp method. *Acta Radiol.* 2009;50(2):233–237.

RETROPERITONEAL HEMATOMA

DESCRIPTION A retroperitoneal hematoma is hemorrhage contained within the retroperitoneum. Etiologies include disruption of the kidney or renal pedicle from trauma, postoperative hemorrhage, spontaneous hemorrhage of a renal mass typically

angiomyolipoma (or RCC), or abdominal vessel hemorrhage. Ecchymosis may be observed around the umbilicus (*Cullen sign*) or flank (*Grey–Turner sign*). Management is primarily conservative, including frequent hemoglobin levels, resuscitation, and transfusion, as necessary. However, if the patient is hemodynamically unstable and the bleeding is from a renal source, and they have an expanding pulsatile hematoma, or renal hemorrhage cannot be stopped with selective embolization, then surgical exploration is indicated. Further evaluation of the underlying pathology and follow-up imaging for resolution is warranted. (See also Section I: "Renal Angiomyolipoma"; "Retroperitoneal Abscess"; "Retroperitoneal Masses and Cysts" and (Image ☼).)

REFERENCE

Heyns CF. Renal trauma: Indications for imaging and surgical exploration. *BJU Int.* 2004;93:1165–1170.

RETROPERITONEAL LIPOSARCOMA

DESCRIPTION Retroperitoneal liposarcoma is the most common retroperitoneal sarcoma arising from adipose tissue. However retroperitoneal sarcomas are rare, with just 2.7 new cases per 1 million persons reported annually. They are usually identified incidentally or at a locally advanced stage when they cause symptoms from adjacent tissue invasion or compression. Compression of ureters can cause obstruction, but other symptoms can include early satiety, obstruction, or retroperitoneal bleeding. Contrast-enhanced CT or MRI should be used for diagnosis, staging, and surgical planning. On CT it appears as a large encapsulated mass containing variable amount of fatty (<–20 Hounsfield units) and soft tissue components. A germ cell tumor (GCT) must be ruled out by tumor markers, and a biopsy is necessary if there is diagnostic uncertainty. Complete resection is the only curative treatment. Radiotherapy can be used preoperatively for local control. (See also Section I: "Retroperitoneal Masses and Cysts." and (Image ☼))

REFERENCE

Chang IY, Herts BR. Retroperitoneal liposarcoma. *J Urol.* 2013;189(3):1093–1094.

RETROPERITONEAL LYMPHOMA

DESCRIPTION Lymphoma involving retroperitoneal lymph nodes; it can be the primary site of involvement or a site of metastasis. The lesion can cause extrinsic compression of ureters with obstructive uropathy. Positive diagnosis is made when a mass is visualized on CT or a ureteral obstruction is visualized with US or IVP. Differential diagnosis may include retroperitoneal fibrosis, retroperitoneal fat necrosis, lymphangiomas, ganglioneuroma, sarcomas, metastasis form other tumors such as prostate, or bladder or germ cell tumor metastasis. (See also Section I: "Retroperitoneal Masses and Cysts" and (Image ☼).)

TREATMENT

- CHOP chemotherapy (cyclophosphamide, adriamycin, vincristine, prednisolone) and radiation therapy
- Obstructive uropathy may require ureteral stenting or percutaneous decompression prior to

chemotherapy.

REFERENCE

RETROPERITONEAL RHEUMATOID NODULES

DESCRIPTION Rheumatoid nodules (*necrobiotic granulomas*) are a common extra-articular manifestation of rheumatoid arthritis, usually found in subcutaneous tissue. They have been reported in numerous other locations, including blood vessels, larynx, pharynx, sclera, and extradural space. GU involvement is rare and includes renal cortex and bladder. Retroperitoneal occurrence has been reported and can cause ureteral compression and obstruction requiring ureterolysis and repair. (See also Section I: “Retroperitoneal Masses and Cysts.”)

REFERENCE

Adelson GL, Saypol DC, Walker AN. Ureteral stenosis secondary to retroperitoneal rheumatoid nodules. *J Urol.* 1982;127(1):124–125.

RETROPERITONEAL SARCOMA

DESCRIPTION Retroperitoneal sarcomas are mesenchymal neoplasms. Approximately ½ of retroperitoneal sarcomas are high-grade tumors, with the most common type being liposarcoma, followed by leiomyosarcoma. Median age at presentation is, although they can occur at any age. At the time of presentation, more than 50% are >20 cm in size. They are typically incidentally diagnosed but when patients do present with symptoms they are abdominal or back pain and increased abdominal girth. Differential diagnosis of a retroperitoneal mass includes neoplasm from a retroperitoneal visceral structure, lymphoma, or a metastatic lesion. Retroperitoneal sarcomas carry a worse prognosis than extremity sarcomas due to the difficulty of complete resection, involvement of critical structures, and delay of diagnosis. Contrast-enchanced CT is the imaging modality of choice. In patients whom systemic therapy or radiation is deemed to be potentially beneficial, a biopsy is mandatory. Complete surgical resection is considered the only curative modality. Neoadjuvant chemotherapy or radiation should be based on optimizing the patient for surgical resection. (See also Section I: “Retroperitoneal Masses and Cysts.”)

REFERENCE

Mullinax JE, Zager JS, Gonzalez RJ. Current diagnosis and management of retroperitoneal sarcoma. *Cancer Control.* 2011;18(3):177–187.

RETROPERITONEUM, FAT NECROSIS

DESCRIPTION Retroperitoneal fat necrosis is a pathologic syndrome characterized by the histologic hallmarks of coalescence of fat cells into fat cysts bordered by foreign-body giant cell granulomas. Local injury to fat cells from trauma appears to be the initiating event of fat necrosis in the retroperitoneum. In addition, an inflammatory trigger such as acute

pancreatitis may also be an initiating event. Its presentation is similar to that of retroperitoneal fibrosis with insidious onset of abdominal or flank pain with the possibility of extrinsic ureteral obstruction.

RHABDOID TUMOR, MALIGNANT

DESCRIPTION The most lethal renal neoplasm, formerly believed to be a form of Wilms tumor. It comprises 2% of all renal tumors and primarily affects children and 85% are diagnosed before the age of 5. The incidence has increased from <0.1 per million in 1986 to 0.6 per million in 2005. It has a tendency to early metastatic spread. The most common presentation is an abdominal mass detected in these young patients. Extrarenal sites include central nervous system (35%), liver, and gastrointestinal tract. Presence of mutations in the hSNF5/INI1 gene on chromosome 22 is the hallmark. The lack of staining of the INI1 gene product is diagnostic. Younger patients have a worse prognosis compared with older patients. Radiotherapy is an essential part of multimodality therapy.

RIEGER SYNDROME

DESCRIPTION Also known as the *Axenfeld–Rieger Syndrome*, this is an autosomal dominant syndrome affecting multiple organ systems. It is manifested by ocular anomalies such as glaucoma; cardiovascular outflow tract malformations, craniofacial abnormalities and pituitary abnormalities which can result in severe endocrinologic sequelae. Genitourinary anomalies occur in the form of hypospadias. 2 major genes have been identified, PITX2 and FOXC1 on chromosome 25.

REFERENCE

RIFLE CRITERION FOR ACUTE RENAL INJURY

DESCRIPTION Also referred to as the RIFLE Classification System for AKI, it assesses levels of renal injury (**R**isk, **I**njury, and **F**ailure) based on the degree of elevation in serum creatinine or urine output, and 2 outcome measures (**L**oss and **E**nd-stage renal disease):

- Risk: $1.5\times$ increase in creatinine or 25% GFR decrease by 25% or urine output <0.5 mL/kg/h for 6 hr

- Injury: 2× increase in creatinine or 50% GFR decrease or urine output <0.5 mL/kg/h for 12 hr
- Failure: 3× increase in creatinine or 75% GFR decrease or urine output of <0.5 mL/kg/h for 24 hr, or anuria for 12 hr
- Loss: Complete loss of kidney function (eg, renal replacement therapy necessary) for >4 wk
- End stage renal disease (ESRD): Complete loss of kidney function (eg, renal replacement therapy necessary) for >3 mo

The RIFLE criteria correlates with prognosis, with a stepwise increase in the risk of death in patients who met the RIFLE criteria for various stages of AKI. Compared to patients without AKI, patients in the RIFLE stages of risk, injury, and failure had increased mortality risks of 2.4, 4.15, and 6.37, respectively. (See also Section I: "Acute Kidney Injury, Adult [Renal Failure, Acute].")

RIM SIGN (RIM NEPHROGRAM)

DESCRIPTION A radiographic appearance in which only a thin peripheral rind of renal tissue is visible. This condition occurs as a result of marked thinning of the parenchyma due to end-stage obstructive atrophy, and it usually denotes irretrievable renal function.

REFERENCE

Bedon WE, Levitt SB, Baker DH, et al. Hydronephrosis in infants and children: Value of high dosage excretory urography in predicting renal salvageability. *AJR Am J Roentgenol Radium Ther Nucl Med.* 1970;109:380–389.

ROBINOW SYNDROME

DESCRIPTION A skelet al dysplasia with both autosomal dominant and recessive inheritance pattern. It is characterized by short stature, limb shortening, genital hypoplasia (micropenis), and craniofacial abnormalities. The more phenotypically severe autosomal recessive form has been associated with mutations in the ROR2 gene on the long arm of chromosome 9.

REFERENCE

Person AD, Beiraghi S, Sieben CM, et al. WNT5A mutations in patients with autosomal dominant Robinow syndrome. *Dev Dyn.* 2010;239(1):327–337.

ROBSON STAGING SYSTEM

DESCRIPTION Robson's modification of Flocks and Kadesky's staging system for renal cell carcinoma (RCC) was the most commonly used in the United States. The fact that long-term

evaluation of patients with stage IIIA lesions, without disease extension into perinephric fat and lymph nodes, has shown survivals comparable to those of stages I and II, has currently led many investigators to prefer the TNM system prosed by IUAC. (See Section I: "Renal Cell Carcinoma, General"; Section VII: "TNM Kidney.")

- Stage I: Tumor is confined within the kidney parenchyma (no involvement of perinephric fat, renal vein, or regional nodes).
- Stage II: Tumor involves the perinephric fat but is confined within Gerota fascia (including adrenal).
- Stage IIIA: Tumor involves the renal vein or inferior vena cava.
- Stage IIIB: Tumor involves regional lymph nodes.
- Stage IIIC: Tumor involves both local vessels and regional lymph nodes.
- Stage IVA: Tumor involves adjacent organs other than the adrenals (colon, pancreas, etc.).
- Stage IVB: Distant metastases.

ROKITANSKY–KUSTER–HAUSER SYNDROME

DESCRIPTION Pathologic condition characterized by primary amenorrhea and infertility and by congenital aplasia of the uterus and upper 2/3 of the vagina. Also referred to in the literature as *Mayer–Rokitansky–Kuster–Hauser Syndrome*. The condition is usually discovered during evaluation of a normal-appearing girl who presents with failure of menstruation at the time of expected puberty. They have a normal female karyotype 46, XX and do develop normal secondary sexual characteristics. The syndrome may be caused by the lack of development of the müllerian ducts between the 5th and 6th wk of gestation. In some patients, cyclic abdominal pain suggestive of some functional endometrium is noted. Vaginal reconstruction with bowel or skin grafting is performed. It can also be associated with renal and skelet al abnormalities.

REFERENCE

Pizzo A, Laganà AS, Sturlese E, et al. Mayer-Rokitansky-Kuster-Hauser Syndrome: Embryology, genetics and clinical and surgical treatment. *ISRN Obstet Gynecol*. 2013;628717.

ROSEWATER SYNDROME

DESCRIPTION Rosewater syndrome is an infertility disorder associated with germ cell aplasia. On testicular biopsy, the seminiferous tubules contain only Sertoli cells. This is considered irreversible and precludes germ cell restoration. Not infrequently, tubular and peritubular fibrosis is associated with germ cell aplasia.

REFERENCE

Craig JM. The pathology of infertility. *Pathol Ann*. 1975;10:299.

ROVSING POLYCYSTIC KIDNEY OPERATION

DESCRIPTION A historically important surgical procedure that entails unroofing multiple renal cysts. This procedure does not prevent deterioration of renal function but may improve flank pain if the cysts cause obstruction of the collecting system.

REFERENCE

Yates-Bell JG. *Rovsing's Operation For Polycystic Kidney The Lancet* , Volume 269, Issue 6960, pp. 126–128; 1957.

ROVSING SYNDROME

DESCRIPTION This is a symptom complex associated with horseshoe kidney, in which the patient experiences pain (often periumbilical), nausea, and vomiting on hyperextension of the spine. It is due to compression of the isthmus of the fused kidney on the vena cava and aorta, accentuated by hypertension and accompanied by a sensation of fullness.

REFERENCE

Glenn JF. Analysis of 51 patients with horseshoe kidney. *N Engl J Med.* 1959;261:684.

SACRAL NEUROMODULATION

DESCRIPTION Sacral neuromodulation (SNM) is a 2nd-line treatment for lower urinary tract dysfunction, such as nonobstructive chronic urinary retention, urgency–frequency syndrome (overactive bladder), and urgency incontinence refractory to conservative and pharmacologic treatment. A continuous or cycling mode of electrical pulses are generated by an implanted device to activate or inhibit neural reflexes associated with lower urinary tract function via stimulation of the sacral nerves, which innervate the lower urinary tract and pelvic floor. The mechanism of action is unclear. 1 theory is that indirect stimulation of the pudendal nerve and direct inhibition of the preganglionic neurons suppresses detrusor over activity and therefore improves symptoms. An alternate theory is that stimulation may inhibit involuntary reflex voiding by altering the transmission of sensory input from the bladder to the pontine micturition center, inhibiting ascending afferent pathways but not the descending pathways. In the patient with nonobstructive urinary retention, SNM most likely causes an inhibition of the guarding reflex, with a reduction in sphincteric over activity that may reduce bladder outlet and urethral resistance.

Patients should have failed conservative management with medications and or behavioral therapies and should undergo extensive evaluation including UDS. The procedure of implantation occurs in usually 2 stages. Stage I consists of percutaneous placement of temporary wire leads into the S3 foramina. It can either be performed in the office or in the operating room. A 1–2-wk trial period occurs with the leads in place and voiding symptoms are reevaluated. If >50% improvement in symptoms occur, the patients moves on to Stage II which is always performed in the operating room. Permanent leads are placed as well as an implantable pulse generator. The most commonly used device is the InterStim™ (Medtronic, Minneapolis, Minnesota) (FDA-approved since 1997 for urge incontinence and since 1999 for urinary retention and significant symptoms of urgency–frequency) (Image ☼).

REFERENCE

SANI SCORE

DESCRIPTION The SANI (Survival after Nephrectomy and Immunotherapy) score is a tool for predicting survival for patients with metastatic RCC in response to the multimodality treatment of aggressive surgical resection and systemic immunotherapy. The regional lymph node status, the presence or absence of constitutional symptoms, the location of metastases, the presence or absence of sarcomatoid pathologic features, and TSH levels are incorporated into the scoring algorithm. Patients are stratified based on predicted survival into low-risk, intermediate-risk and high-risk groups for appropriate treatment regimens and for prospective trials of new therapies.

REFERENCE

2003;98:2566–2575.

SARCOMA, CLEAR CELL OF THE KIDNEY

DESCRIPTION Clear cell sarcoma of the kidney (CCSK) is a renal tumor that comprises ~5% of all primary renal tumors in children. It is the 2nd most common pediatric renal tumor after Wilms tumor (WT). The mean age of presentation is 36 mo. It is unique from WT in its potential for bone and brain metastases. Clinical presenting symptoms of patients with CCSK are similar to those of patients with WT including abdominal distension or mass, abdominal pain, and gross hematuria. The genetics and cell of origin remain poorly understood. Several histologic subtypes are described, the classic pattern, which is present in over 90% of tumors, is characterized by round/oval cells with clear cytoplasm with uniform nuclei.

TREATMENT

- Radical nephrectomy followed by treatment with multi-agent chemotherapy and radiation
- In most recent NWTS-5 trial, vincristine, doxorubicin, and cyclophosphamide, alternating with cyclophosphamide and etoposide for 24 wk, and postoperative radiotherapy the 5-yr overall survival (OS) 89%. 5-yr and recurrence free survival (RFS) was 100% for stage I.

REFERENCE

Gooskens SL, Furtwängler R, Vujanic GM, et al. Clear cell sarcoma of the kidney: A review. *Eur J Cancer.* 2012;48:2219–226.

SAW PALMETTO

DESCRIPTION The extract of the dried ripe fruit from the American dwarf saw palmetto plant *Serenoa repens* (also known as *Sabal serrulata*) is the most widely used phytotherapeutic compound for the treatment of BPH. Berries from saw palmetto were 1st used by Native Americans in the early 1700s to treat testicular atrophy, erectile dysfunction (ED), and prostate swelling or inflammation. The mechanism of action is not completely understood, but may include alteration of cholesterol metabolism, anti-inflammatory, antiestrogenic, and anti-androgenic effects, and decrease in available sex hormone-binding globulin. In a systematic review of 32 randomized, controlled trials which included 5,666 men, *Serenoa repens*, at double and triple the usual dose compared to placebo provides no improvement for nocturia, peak urine flow, and symptom scores for men with BPH. (See also Section V: “Alternative and Complementary Urologic Therapies.”)

SYNONYM

Serenoa Repens, Sabal serrulata, Saw Palmetto Berry

REFERENCE

SCABIES, UROLOGIC CONSIDERATIONS

DESCRIPTION An intensely pruritic parasitic infection that affects simultaneous areas of the

body, including the genitalia, anus, legs, hands, umbilicus, and axillae. Diagnosis can be made by identifying the mite (*Sarcoptes scabiei*), expressed from the papular or linear burrow-like lesion. Transmission occurs from fomites or by direct contact with infected individuals, including sexual contact.

TREATMENT

- Lindane 1% cream, washed off after 8 hr. Do not use in pregnant or lactating women or in children <2 yr.
- Permethrin 5% cream, washed off after 8–14 hr.
- Crotamiton 10% cream for 2 consecutive nights; wash off 24 hr after the 2nd application.
- Treat sexual partners and close contacts.

REFERENCE

Peterson CM, Eichenfeld LF. Scabies. *Pediatr Ann.* 1996;(252):97–100.

SCARDINO-PRINCE PYELOPLASTY

DESCRIPTION Used to treat UPJ obstruction. An inverted J-configured incision is started on the anterior surface of the pelvis and brought down across the UPJ obstruction to a –2-cm point beyond the obstruction. The upper apex of the flap is then flipped down to the apex of the ureterotomy, where a 5-0 chromic stay suture is placed. The medial aspect of the flap is sutured to the lateral edge of the ureterotomy. The lateral edge of the flap is sutured to the lateral aspect of the ureterotomy, and the pelvis is closed.

REFERENCE

SCHAEFER OBSTRUCTION GRADING SYSTEM

DESCRIPTION Schaefer's obstruction grading system (also called *Schaefer Nomogram*) allows the use of urodynamic evaluation in patients with BPH to determine the effectiveness of a TURP of alleviating their symptoms. Using the urodynamic parameters of pressure (p) and flow rate (Q), a ratio is plotted and every data point reflects bladder contractility outflow conditions. Using a linear approximation to the p/Q data, an assessment can be made of outflow conditions. By comparing urodynamic data before and after surgery for patients with BPH, obstruction is defined as those outflow conditions that improve after surgery. They are graded (Grade 0–Grade VI) with grade 0/I outflow conditions not improving after TURP and Grade VI being severely obstructed and seeing the most improvement after TURP.

REFERENCE

SCHILLER-DUVAL BODIES

DESCRIPTION Perivascular papillary structures seen in histologic specimens of yolk sac tumors, similar to the endodermal sinuses of Duval in the placenta of the rat (histo image).

REFERENCE

Moran CA, Suster S. Hepatoid yolk sac tumors of the mediastinum: A clinicopathologic and immunohistochemical study of four cases. *Am J Surg Pathol.* 1997;21(10):1210–1214.

SCHISTOSOMIASIS, UROLOGIC CONSIDERATIONS

DESCRIPTION A parasitic infection by the blood fluke *Schistosoma haematobium*. This condition has a broad spectrum of urologic manifestations due to the parasite's life cycle: Infection across the skin, hematogenous migration to perivesical venous plexus, transmural migration into bladder, and shedding into urine. Typically, patients will exhibit polypoid urothelial mucosal lesions (active infection) or "sandy patch" flat, tan lesions (inactive infection). Significant upper urinary tract obstruction is possible with chronic disease. Classic symptoms are hematuria and terminal dysuria. Infection has been linked to bladder cancer, occurring earlier in life (40–50 yo); this is most commonly squamous cell carcinoma (SCC) (60–90%) and adenocarcinoma (5–15%). The presence of fluke eggs in urinary sediment is diagnostic of schistosomiasis. (See also Section I: "Bladder Cancer, Squamous Cell Carcinoma" and (Image ☼).)

TREATMENT

- Medical management: Metrifonate and praziquantel
- Surgical management: Infection refractory to medical management; ureteral or bladder outlet obstruction; persistent or refractory hematuria; or malignancy

REFERENCE

Michaud DS. Chronic inflammation and bladder cancer. *Urol Oncol.* 2007;(253):260–268. Review.

SCHWANNOMA, RENAL

DESCRIPTION Also called *neurinoma* or *neurilemmoma*, a tumor arising from Schwann cell neural elements of the kidney. Schwannomas of renal origin are very rare with only 20 reported cases in the literature. They present in middle-aged patients with a male-to-female ratio of 1:2. They typically appear as spherical, solid, and well-circumscribed encapsulated lesions. The vast majority are benign, and the malignant degeneration is very rare. Partial or radical nephrectomy (open or laparoscopic technique) is the treatment of choice as there are no reliable preoperative diagnostic methods.

REFERENCE

Sfoungaristos S, Kavouras A, Geronatsiou K, et al. Schwannoma of the kidney with magnetic resonance images of non-homogenous renal mass-a case presentation. *Prague Med Rep.* 2011;112(2):137–143.

SCLERODERMA, UROLOGIC CONSIDERATIONS

DESCRIPTION Scleroderma (systemic sclerosis) is a systemic, acquired disorder of connective tissue, including cutaneous sclerosis, visceral organ fibrosis, and vascular lesions. The condition commonly affects kidneys, with renal disease affecting 10–50% of patients. Lower urinary tract manifestations are also reported, including bladder fibrosis, microscopic hematuria, urodynamic abnormalities, such as poor compliance and obstructive uropathy. LUTS include urinary urgency, frequency, and incontinence.

REFERENCE

Lally EV, Kaplan SR, Susset JG, et al. Pathologic involvement of the urinary bladder in progressive systemic sclerosis. *J Rheumatol.* 1985;12:778–781.

SCLEROSING ADENOSIS OF THE PROSTATE

DESCRIPTION A rare benign lesion arising in the transition zone of the prostate. It is a part of the histologic differential diagnosis of prostate cancer. It is characterized by a cellular proliferation of variably sized glands and solid nests surrounded by basement membrane material in a cellular stroma. The contours of the lesion can be well circumscribed or infiltrative, raising concern for carcinoma. The specimen will be immunoreactive with S-100 and smooth muscle actin, indicating a myoepithelial differentiation. Other features differentiating this condition from cancer are that cells have bland nuclei and are sometimes surrounded by a hyaline-like sheath. (See also Section II: “Atypical Adenomatous Hyperplasia of the Prostate” and “Postatrophic Hyperplasia of the Prostate.”)

REFERENCE

Harik LR, O’Toole KM. Non-neoplastic lesions of the prostate and bladder. *Arch Pathol Lab Med.* 2012;136(7):721–734.

SCROTAL PAIN SYNDROME (CHRONIC SCROTAL PAIN SYNDROME [CSPS])

DESCRIPTION CSPS is not well documented in the literature and may have overlap with CPPS. CPPS is defined as pain and discomfort in the pelvic area, perineum, scrotum, penis, and pelvis. CSPS is described as chronic or recurrent pain located in the scrotum. There is little evidence for the widely held belief that CSPS is predominantly the result of a chronic bacterial infection.

REFERENCE

Strebel RT, Schmidt C, Beatrice J, et al. Chronic scrotal pain syndrome (CSPS): The widespread use of antibiotics is not justified. *Andrology*. 2013;1(1):155–159.

SCROTAL PEARLS (SCROTOLITHS)

DESCRIPTION Benign calcifications within the scrotum, usually free floating. Usually diagnosed by ultrasound, these are described as a hyperechoic density in the scrotal wall that demonstrates acoustic shadowing. Scrotal pearls can occur from infection or trauma and themselves are rarely symptomatic. They may also be noticed as artifacts after torsion of the

appendix testis or epididymis.

REFERENCE

Chen P, John S. Ultrasound of the acute scrotum. *Appl Radiol.* 2006;353:8–17.

SCROTAL SKIN LESIONS

DESCRIPTION Scrotal skin lesions may be localized or a manifestation of more systemic diseases.

- Benign
  - Amyloidosis (rare)
  - Angiokeratoma of Fordyce: Small, 1–2-mm red, vascular papules seen predominantly in older men
  - Atopic/neurodermatitis: Itch/scratch cycle with lichenification with or without excoriation. The posterior scrotum is a common site.
  - Calcinosis, idiopathic scrotal
  - Contact dermatitis: Allergic or irritant: Pruritis, burning, and stinging
  - Crohn disease: "Metastatic." Crohn disease may have associated scrotal ulcers and edema.
  - Eczema frequently affects the genital region, particularly the scrotum. Patients present with lichenified erythematous plaques on the lateral scrotum. The eruption may develop into Lichen simplex chronicus (LSC) (also referred to as "Neurodermatitis") characterized by extensive lichenification and hypertrophy of the affected skin due to excessive scratching and rubbing
  - Epitheloid hemangioma, penis and scrotum
  - Fixed drug eruption: Erythematous, well-demarcated "burn-like" area, may evolve from erythema to vesicles or blebs
  - Folliculitis: Usually caused by *Staphylococcus aureus*
  - Genital lentiginoses: Hyperpigmented macules that may be confused with melanoma
  - Genital warts (condyloma): Uncommon on the scrotum
  - Ichthyosis: excessive amounts of dry surface scales; inherited or acquired
  - Insect bite
  - Juvenile gangrenous vasculitis, scrotal (pyoderma gangrenosum)
  - Langerhans cell histiocytosis
  - Lichen simplex chronicus (LSC): Reaction to chronic scratching (See Eczema above)
  - Lymphangioma
  - Molluscum contagiosum: Pearly white papular, smooth-surfaced umbilicated papules
  - Psoriasis: Well-demarcated papulosquamous plaques with silver scale; usually bleeds if scale removed
  - Red Scrotum Syndrome (RSS): Persistent redness of the anterior 1/2 of the scrotum and may involve the base of the penis as well. Treated with oral doxycycline PO and tacrolimus 0.1% ointment twice daily. Gabapentin can be used as 2nd-line therapy
  - Scabies: Red, linear, excoriated areas, often with papules, pustules, and burrows
  - Sebaceous cysts/epidermal inclusion cyst
  - Seborrhic dermatitis: Red scaling eruption ("inflammatory dandruff")
  - Secondary syphilis: Condyloma lata (moist, red, raised wheal-like lesions) or mucous

patches (reddish ulcers with a violaceous border)
  – Tinea cruris or jock itch: Involvement of the scrotum is uncommon
  – Vitiligo may appear similar to lichen sclerosis: Hypopigmented or depigmented areas
- Malignant
  – Basal cell carcinoma: Ulcerated lesion
  – Kaposi sarcoma: A purple, papular, plaque-like, or ulcerated lesion
  – Marjolin ulcer: Cancer arising from site of prior inflammation
  – Melanoma (uncommon)
  – Metastatic lesion: The scrotum is a rare site of cutaneous metastasis and associated with dermal and angiolymphatic invasion. The colon/rectum (34%), prostate (28%), and lung (14%) are the most frequent tumor origins.
  – Paget disease: Primary extramammary from apocrine ducts or sweat gland carcinoma; secondary is intraepithelial spread from underlying malignancy
  – Sarcoma: Leiomyosarcoma from the Dartos layer of the scrotum is most common, though still very rare
  – Squamous Cell carcinoma (SCC): Papule or plaque that enlarges and ulcerates in older men

SCROTAL TONGUE

DESCRIPTION Scrotal tongue is not a urologic condition. It refers to a deeply fissured tongue. Sometimes called a *geographic tongue*.

REFERENCE

Reamy BV, Derby R, Bunt CW. Common tongue conditions in primary care. *Am Fam Physician.* 2010;81(5):627–34. Review.

SCROTAL VARICES

DESCRIPTION Scrotal varices or varicocele is an abnormal dilation of the internal spermatic veins which drain the testis that can be palpated through the scrotal skin. Overall, they are present in 15% of the male population. Varicocele is the most common etiology of male factor infertility, being present in 35% of males with primary infertility and 81% with secondary infertility. They most commonly occur on the left secondary to drainage of the left internal spermatic vein into the left renal vein. Varicocele can impair testicular function with the likely mechanism being through thermal injury. Diagnosis is made through physical exam of the scrotum. Grade I varicocele is palpable with Valsalva only, grade II is palpable in the standing position, and grade III is visually apparent through the scrotal skin as a “bag of worms.” Scrotal ultrasound is not necessary unless the physical exam is unclear.

TREATMENT

- If a varicocele is not associated with infertility, decreased testicular volume or pain, it is considered subclinical and surgical correction is not indicated.
- Nonsurgical approach includes percutaneous radiographic occlusion and sclerotherapy.
- Surgical options include retroperitoneal, inguinal or subinguinal ligation, laparoscopic and microsurgical varicocelectomy.

REFERENCE

Hopps CV, et al. Varicocele: General considerations. In: Graham S, et al. *Glenn's Urologic Surgery*. 7th ed. Philadelphia, PA: Lippincott Williams & Wilkins; 2010.

SCROTUM, ACCESSORY AND ECTOPIC

DESCRIPTION *Accessory scrotum* is a rare condition in which a small empty pouch of scrotal tissue is attached to the scrotum or the perineum. *Ectopic scrotum* is an anomalously positioned hemiscrotum usually found near the external inguinal ring. The testis generally accompanies the hemiscrotum to its abnormal position and may be normal or dysplastic. These lesions are often accompanied by other GU anomalies (upper tract). Surgical repair involves an attempt to bring down the scrotum and the testis. If the gonad is dysplastic and the ectopic scrotum is rudimentary, removal of 1 or both structures is reasonable.

REFERENCE

Kumar V, Marulaiah M, Chattopadhyay A, et al. Unilateral inguinal ectopic scrotum with covered exstrophy. *Pediatr Surg Int*. 2002;18(5–6):511–513.

SCROTUM, BIFID

DESCRIPTION A disorder characterized by separation of the labioscrotal folds, seen with mid scrotal or perineal hypospadias and intersex disorders. Embryologically, it is a failure of the genital swellings to fuse at the midline. The condition represents a spectrum of penoscrotal transposition abnormalities. Surgical realignment at the midline and hypospadias repair is recommended management. (See Section II: "Scrotum, Engulfment [Penoscrotal Transposition]." and (Image ☼))

REFERENCE

Sule JD, Skoog SJ, Tank ES, et al. Perineal lipoma and the accessory labioscrotal fold: An etiological relationship. *J Urol*. 1994;151(2):475–477.

SCROTUM, ENGULFMENT (PENOSCROTAL TRANSPOSITION)

DESCRIPTION The most extreme form of penoscrotal transposition, in which the scrotum is located in a cephalad position with respect to the penis. A milder form is bifid scrotum. Major renal anomalies include complete agenesis of the urinary system, unilateral or bilateral renal agenesis, polycystic or dysplastic kidneys, horseshoe kidney, ectopic pelvic kidney, and obstructive uropathy. Abnormalities of the external genitalia include a disproportionately long flaccid penis, complete urethral atresia, and hypospadias. Treated by hypospadias repair with scrotoplasty using an inverted omega skin incision around the scrotal skin and the base

of the penis. This allows placement of the scrotal flaps beneath the penis.

REFERENCE

Parida SK, Hall BD, Barton L, et al. Penoscrotal transposition and associated anomalies: Report of five new cases and review of the literature. *Am J Med Genet.* 1995;59(1):68–75.

SCROTUM, EPIDERMAL INCLUSION CYST

DESCRIPTION Epidermal (epidermoid) inclusion cysts are benign tumors. They result from the implantation of epidermal tissue into the dermis or subcutis, from trauma or abnormal embryologic closure of the median raphe and urethral groove. These lesions appear solid on imaging and often contain a material that is a combination of keratin and cholesterol, often in a laminated configuration arising from a stratified squamous epithelial wall. They can be asymptomatic or more commonly rupture or become infected. Local excision is the treatment, since epidermoid inclusion cysts can mimic rare malignant tumors such as liposarcoma, fibrosarcoma, and even metastatic disease.

REFERENCE

Yang WT, Whitman GJ, Tse GM, et al. Extratesticular epidermal cyst of the scrotum. *AJR Am J Roentgenol.* 2004;183:1084.

SCROTUM, FAT NECROSIS

DESCRIPTION An uncommon lesion that is seen in prepubertal boys and can be a cause of acute scrotal pain. Typical presentation is an obese prepubertal child with recent exposure to cold, such as during swimming. Bilateral intrascrotal masses are present inferior to the testis. If the diagnosis is made with US and shows the classic presentation, conservative management can be employed.

REFERENCE

Donohue A, Utley WLF. Idiopathic fat necrosis in the scrotum. *Br J Urology.* 2008;47(3):331–333.

SCROTUM, GIANT NEUROLEMMOMA

DESCRIPTION Well-encapsulated tumors of neural elements (also called neurinoma or Schwannoma) within the scrotum. Most such tumors are benign, with malignant transformation as an extremely rare occurrence. Surgical removal of the lesion is the definitive treatment.

REFERENCE

Fernandez MJ, Martino A, Khan H, et al. Giant neurilemmoma: Unusual scrotal mass. *Urology.* 1987;30(1):74–76.

SCROTUM, HEMANGIOMA

DESCRIPTION These lesions should be differentiated from angiokeratoma of Fordyce that

appear in older men (see Section II: "Angiokeratoma of Fordyce [Penile and Scrotal Angiokeratomas]"). Hemangiomas represent 7% of all nonmalignant tumors and are the most common benign tumor of infancy; however, they involve the penis and scrotum only 1% of the time. Cutaneous hemangiomas also called (*strawberry angiomas*) may grow for up to 6–12 mo and then undergo involution. By age 7, complete regression will be seen in approximately 75–90% such that most do not need therapy. Subcutaneous hemangiomas are even more infrequent but tend to expand gradually and may clinically resemble a varicocele.

TREATMENT

- Large cutaneous lesions can be excised surgically or ablated with a laser.
- Subcutaneous lesions usually require surgical excision.

Leavitt DA, Hottinger DG, Reed RC, et al. A case series of genital vascular anomalies in children and their management: Lessons learned. *Urology*. 2012;80(4):914–918.

SCROTUM, HYPOPLASIA

DESCRIPTION The unilateral or bilateral underdevelopment of the scrotum, which simulates labia majora, is most commonly associated with cryptorchid testes and ambiguous genitalia. Some syndromes associated include: Prader–Willi syndrome (PWS), Genitopatellar syndrome, many others. For a complete listing see: http://monarch.monarchinitiative.org/phenotype/HP:0000046, Accessed March 8, 2014.

TREATMENT

- A testicular prosthesis can improve the cosmetic appearance of the scrotum.
- Testosterone cream can also be applied for an improved cosmetic result on the affected side.

REFERENCE

SCROTUM, IDIOPATHIC CALCINOSIS

DESCRIPTION Patients with this condition are typically young men who present with multiple hard nodules throughout the scrotal wall. Although the skin is usually intact, lesions may ulcerate. Thought to be caused by calcification of the scrotal dermal connective tissue (eccrine sweat glands) for unknown reasons. No therapy is necessary unless recurrent episodes of infection occur; then surgical excision may help.

SEAPI INCONTINENCE CLASSIFICATION SYSTEM

DESCRIPTION SEAPI is an acronym for **s**tress incontinence, **e**mptying ability, **a**natomy, **p**rotection, and **i**nstability. Is useful as a reliable and uniform method of following the short-

and long-term outcome of stress urinary incontinence (SUI) surgery. This system is similar to the TNM tumor staging classification system in that each component is graded with a score from 0 (no symptoms) to 3 (severe symptoms). After completion of the evaluation of the incontinent patient, a preoperative subjective and objective SEAPI score is determined. These scores are then compared with postoperative SEAPI scores to access treatment outcome. It has been found to have a high degree of reliability and internal consistency across a wife age range in both genders.

REFERENCE

Stothers L. Reliability, validity, gender differences in the quality of life index of the SEAPI-QMM incontinence classification system. *Neurourol Urodyn.* 2004;(233):223–228.

SEBORRHEIC DERMATITIS

DESCRIPTION Commonly referred to as *dandruff*, this condition can be seen on the penis, anus, or pubic hair. Pruritus is the rule, with the lesions in hair-bearing areas having a red base and waxy yellow crust. While the organism *Pityrosporon orbiculare* is suspected, the exact agent is unknown. Standard antidandruff shampoos are usually effective. Shampoo containing ketoconazole may be needed. Steroids should be used with caution, if at all, because this tends to be a lifelong problem. (See also Section II: “Pruritus, External Genitalia, Male.”)

REFERENCE

SEMEN ANALYSIS, ABNORMAL FINDINGS AND TERMINOLOGY

DESCRIPTION A significant overlap exists between fertile, subfertile, and infertile populations, therefore, absolute parameters for infertility (except for aspermia or azoospermia) are difficult to measure precisely. In general, fertile populations demonstrate mean sperm densities of 70–80 million/mL. Assisted reproduction techniques (ART’s) are now able to overcome many of these abnormalities. (See also Section I: “Infertility”; Section II: “Semen Analysis, Technique, and Normal Values.” and “Semen Analysis, Abnormal Findings and Terminology.”)

- Aspermia: No semen ejaculated
- Asthenospermia: $<50\%$ of spermatozoa with forward progression of 3–4
- Asthenozoospermia: Poor motility and/or poor forward progression
- Azoospermia: No spermatozoa found in semen
- Globozoospermia: Round-headed sperm devoid of acrosome
- Hematospermia: Blood present in an ejaculate/semen
- Hyperspermia: Volume of ejaculate >6.5 mL
- Hypospermia: Volume of ejaculate <1.5 mL
- Leukocytospermia/pyospermia: Excess white cells >1 WBC $\times$ 10^6/mL) in semen
- Necrozoospermia: No live sperm in ejaculated semen
- Normozoospermia/normospermia: Refer to a normal semen analysis
- Oligoasthenoteratospermia: Very generalized abnormalities in sperm concentration, motility,

and morphology; often associated with varicocele
- Oligoasthenoteratozoospermia: Signifies disturbance of all 3 variables (combinations of 2 prefixes may also be used)
- Oligozoospermia: Low concentration of sperm $<20 \times 10^6$/mL
- Polyspermia: Abnormally high sperm density $>250 \times 10^6$/mL
- Polyzoospermia: Excessive number of sperm in ejaculate sample
- Pyospermia/leukocytospermia: Excess white cells >1 WBC $\times 10^6$/mL in semen
- Teratozoospermia: Reduced percentage of morphologically normal sperm, usually $<50\%$ spermatozoa with normal morphology

SEMEN ANALYSIS, TECHNIQUE, NORMAL VALUES

DESCRIPTION *Normozoospermia/normospermia* are terms sometimes used to refer to a normal semen analysis. After 48–72 hr of abstinence, a semen specimen is collected in a wide-mouth polypropylene container with a screw top through masturbation without the use of any lubricants that could contaminate the sample. Care must be taken to capture all of the ejaculate. The sample is kept as close to body temperature as possible and delivered to the lab within 1.5 hr. Analysis includes (may vary slightly by lab) total seminal volume, sperm concentration, sperm motility, sperm morphology, fructose content, coagulation time, liquefaction time, viscosity, and leukocyte count. Newer computer-assisted systems (CASA) can also evaluate curvilinear velocity, straight-line velocity, linearity, and amplitude of lateral head displacements. Antisperm antibodies may be considered a secondary test. Normal parameters are established by most labs. The following are general reference parameters and are typically determined on at least 2 specimens. (See also Section I: “Infertility”; and Section II: “Semen Analysis, Abnormal”; also see Section II for topics on specific semen abnormalities.)

Typical Reference Lab Values for Routine Semen Analysis

Volume	1.5–5.0 mL
Appearance	White, viscid, opaque
pH	7.2–7.8
Sperm density	$>20 \times 10^5$/mL
Total sperm count	$>40 \times 10^6$/mL
Motility	>60%
Forward progression	>50% or >2 + on a scale of 0–4 (0, no movement; 4, excellent forward progression)
Morphology	>60% normal
Viability	>50% (by dye exclusion)
Fructose, quantitative	>13 μmol per ejaculate
Liquefaction	10–20 min (measured on a scale of 0–4)
Agglutination	Minimal dumping (increased clumping suggests inflammatory/immunologic process)

Normal Semen Analysis Parameters Published by the WHO

Parameter	Minimum Value
Volume	2.0 mL
Sperm concentration	20 million/mL
Motility	50%
Forward progression	3.0–4
Normal morphology (WHO)	30%
Normal morphology (Strict)	14%
Total sperm count	40 million
Total motile sperm	20 million
Total functional sperm	6 million

Based on data from Rowe PJ, et al., eds. WHO manual for the standardized investigation, diagnosis and management of the infertile male. New York: Cambridge University Press, 2000.

SEMEN LEUKOCYTES

DESCRIPTION The leukocyte is the most common nonsperm cell seen in semen analysis, and it may be confused with immature spermatozoa on microscopy. *Leukocytospermia* and *pyospermia* are terms used to describe excess white cells in the semen sample >1 WBC $\times$ 10^6/mL. Elevations usually are associated with infection, but may be linked to reactive oxygen species and may be present when there is no finding of infection or immune response. Leukocytospermia is often found in patients with unexplained infertility. Semen cultures are prone to contamination, and the use of antibiotics to treat pyospermia is controversial. (See also Section I: “Infertility”; Section II: “Semen Analysis, Abnormal Findings and Terminology”; “Semen Analysis, Technique, Normal Values” and “Pyospermia.”)

SEMINAL PLASMA HYPERSENSITIVITY (SEMINAL PLASMA ALLERGY) AND HYPERSENSITIVITY TO HUMAN SEMEN (HHS)

DESCRIPTION An allergic reaction to human semen that presents as a systemic reaction (ranging from mild to anaphylaxis) or a localized vaginal symptoms shortly after ejaculation into the vagina. 2 types described in the literature the more common reaction to human seminal plasma (allergic reactions to human seminal plasma [HSP] proteins) or a response to spermatozoa (hypersensitivity to human semen [HHS]). These conditions are likely underreported and may not be discussed or ascribed to dyspareunia or vulvovaginitis. These are seen exclusively in women (usually from 20–30 yr of age) and can be avoided through the use of condoms or less commonly through anti-allergy medications or allergen desensitization. Once established, it usually occurs with other male partners. In addition to the potential symptoms infertility is an issue.

SEMINAL VESICLE AGENESIS

DESCRIPTION Can be unilateral or bilateral (very rare). Unilateral agenesis results from an embryologic insult before separation of the ureteral bud from the mesonephric ducts. Unilateral agenesis is associated with ipsilateral agenesis of the ductus deferens and with renal agenesis in 79%, ipsilateral renal abnormalities in 12%, and only 9% had normal kidneys bilaterally. The contralateral seminal vesicle is often hypoplastic.

REFERENCE

Trigaux JP, Van Beers B, Delchambre F. Male genital tract malformations associated with ipsilateral renal agenesis: Sonographic findings. *J Clin Ultrasound.* 1991;19:3–10.

SEMINAL VESICLE, AMYLOIDOSIS

DESCRIPTION A benign localized condition characterized by subepithelial deposition of amyloid in the seminal vesicles. Amyloids are low–molecular-weight fibrils found in extracellular tissues; they consist of a variety of proteins. Its incidence increases with increased age and can often be misinterpreted as regional spread of bladder or prostate cancer. No treatment is necessary if asymptomatic.

REFERENCE

Erbersdobler A. Seminal vesicle amyloidosis does not provide any protection from invasion by prostate cancer. *BJU Int.* 2009;103(3):324–326.

SEMINAL VESICLE CALCULI AND CALCIFICATIONS

DESCRIPTION Calcification of vas deferens seems to be specific to diabetes melitus and may

be associated with calcification of the seminal vesicles. Other causes include: TB, schistosomiasis, gonorrhea, chlamydia, gonadal dysgenesis, and uremia with secondary hyperparathyroidism. Intraluminal seminal vesicle calcifications can be seen (Image ☼).

REFERENCE

Yadav R, Goel A, Sankhwar SN, et al. Incidentally detected bilaterally symmetrical seminal and vas calcification in young infertile male: A case report, literature review and algorithm for diagnosis. *Can Urol Assoc J.* 2012;6(5):E206–E208.

SEMINAL VESICLE, CARCINOMA

DESCRIPTION Primary tumors of the seminal vesicles are extremely rare as there are no more than 60 histologically confirmed reported cases. The seminal vesicles are often secondarily involved by cancer of surrounding structures such as prostate, bladder, or rectal carcinoma. Lymphoma of the seminal vesicles has been reported. Primary adenocarcinoma of the seminal vesicle (the most common primary type) occurs in patients >50. Immunohistochemistry is helpful in diagnosis. They are PSA and PSAP negative. RP and/or cystoprostatectomy including pelvic lymph node dissection, offers curative treatment. Adjuvant or neoadjuvant chemotherapy is of unproven worth, but a combination of hormonal deprivation and radiotherapy seems to be more effective than any chemotherapy.

REFERENCE

Campobasso D, Fornia S, Ferretti S, et al. Primary bilateral seminal vesicle carcinoma: Description of a case and literature review. *Int J Surg Pathol.* 2012;20(6):633–635.

SEMINAL VESICLE, CYSTS

DESCRIPTION Cysts, of either congenital or acquired origin, located in the seminal vesicles. Many studies in the past have linked such cysts to other GU issues, including renal agenesis, infertility, hematospermia, GU infection, and adult polycystic kidney disease. Causes are congenital, ejaculatory duct obstruction (EDO), or a basement membrane defect, especially in cysts associated with adult polycystic kidney disease. (See also Section I: “Seminal Vesicle Masses and Cysts" and Image ☼)

TREATMENT

- No treatment is necessary if asymptomatic.
- Aspiration, marsupialization, or excision, if symptomatic

REFERENCE

Labanaris AP, Zugor V, Meyer B, et al. A case of a large seminal vesicle cyst associated with ipsilateral renal agenesis. *Sci World J.* 2008;8:400–404.

SEMINAL VESICULITIS

DESCRIPTION Inflammation of the seminal vesicles that often occurs secondary to bacterial infection, causing prostatitis or epididymitis. Older literature referred to this condition as *pyospermia*. Symptoms are often vague and may include penile, scrotal, or perineal pain;

painful ejaculation; hematospermia; lower abdominal or back pain; and LUTS. Diagnosis is often 1 of exclusion of other more common causes made with positive cultures from the ejaculate as well as imaging via transrectal US, CT, or MRI. Pyospermia/leukocytospermia is prominent on semen analysis. Abscess formation is a complication of seminal vesiculitis and can be an initial presentation of the disease. Treatment includes culture-sensitive antibiotics, transrectal aspiration, or excision (open or laparoscopic seminal vesiculectomy) for severe cases. Transurethral seminal vesiculoscopy with irrigation has been described. (See also Section II: "Pyospermia.")

SEMINOMA WITH HIGH MITOTIC RATE (SEMINOMA, ANAPLASTIC)

DESCRIPTION Histologic subtype of seminoma, seen in up to 10% of all seminomas. Anaplastic seminoma is typically more aggressive and invasive compared to classic and spermatocytic seminoma, demonstrating increased mitotic activity and more β-hCG production than its counterparts. It is associated with increased local invasion and rate of metastatic growth as well. Patients usually present at a higher stage. Despite these findings, no survival difference after treatment has been reported when compared to classic seminoma, stage for stage. Treatment depends on tumor stage. Radical orchiectomy followed by either surveillance, radiation therapy, and/or chemotherapy are performed, depending on the extent of disease. (See also Section I: "Testis Cancer, Seminoma.")

REFERENCE

Neill M, Warde P, Fleshner N. Management of low-stage testicular seminoma. *Urol Clin N Am*. 2007;34(2):127–136.

SEMINOMA, CLASSIC

DESCRIPTION The most common histologic subtype of seminomatous germ cell tumor (GCT), it accounts for ~85% of cases. Typically presents in males in the 3rd–5th decades of life. Syncytiotrophoblastic elements are seen in 10% of lesions. These elements produce β-hCG, which can be used as a tumor marker to help assess resolution or recurrence of disease after treatment. Like all testicular tumors, treatment depends on tumor stage. Radical orchiectomy followed by either surveillance, radiation therapy, and/or chemotherapy are performed, depending on the extent of disease. (See also Section I: "Testis, Seminoma.")

REFERENCE

Neill M, Warde P, Fleshner N. Management of low-stage testicular seminoma. *Urol Clin N Am*. 2007;34(2):127–136.

SEMINOMA, SPERMATOCYTIC

DESCRIPTION Accounts for ~2% of all seminomatous germ cell tumor (GCT). Patients present later in life, usually in their 5th–6th decades. Unlike classic and anaplastic subtypes, spermatocytic seminoma rarely metastasizes. It is believed that this subtype arises from a different, more mature germ cell line, which likely contributes to its more favorable presentation. Due to its low metastatic potential, no further treatment is often recommended after radical orchiectomy. (See also Section I: "Testis cancer, Seminoma.")

REFERENCE

Neill M, Warde P, Fleshner N. Management of low-stage testicular seminoma. *Urol Clin N Am.* 2007;34(2):127–136.

SEX REVERSAL SYNDROME (XX MALE)

DESCRIPTION These patients demonstrate small, firm testes; frequent gynecomastia; a small to normal penis; and azoospermia. Testicular biopsy may demonstrate seminiferous tubule sclerosis, causing elevated gonadotropins and decreased testosterone levels. Individuals are shorter than average height. There is no increase in the incidence of mental retardation, but there is an increase in hypospadias. Although karyotyping demonstrates 46, XX, molecular biologic mapping suggests that portions of the Y chromosome are present. It has been hypothesized that the portion of the Y chromosome containing the testes-determining factor has been translocated. Diagnosis is based on karyotype, molecular biologic mapping, and PCR using Y-specific probes. If necessary, phenotypic gender assignment is done very early, and appropriate surgical correction is performed. After puberty, management is more difficult because of androlgic problems such as hypogonadism, micropenis, undescended testes, lack of secondary sex characteristics, and impotence. Treatment plans must address these issues.

SEX-HORMONE BINDING GLOBULIN (SHBG)

DEFINITION

Testosterone (T) circulates bound to either SHBG, albumin or corticosteroid binding globulin (CBG), or in an unbound form (free). SHBG-bound T is about 44% of the total T and is unavailable to cells. Albumin-bound T is about 50% of the total. Conditions that increase SHBG, include aging, hyperthyroidism, estrogens, HIV disease, anticonvulsants, hepatitis and hepatic cirrhosis. Conditions that decrease SHBG, include obesity, diabetes mellitus, hypothyroidism, androgenic steroids, nephrotic syndrome, acromegaly and glucocorticoids. The age-related SHBG increase means that older men may have a normal T levels even if they are hypogonadal, as they will have low levels of free or bioavailable T. Obesity, on the other hand, decreases SHBG and T, even when the available T may be normal.

available at http://www.auanet.org/common/pdf/education/clinical-guidance/Testosterone-Deficiency-WhitePaper.pdf, Accessed March 27, 2014.

SEXSOMNIA

DESCRIPTION Sexsomnia, also known as *somnambulistic sexual behavior* or *sleep sex* is a particular form of parasomnia (disruptive sleep disorders) characterized by atypical sexual behavior during sleep. The repertoire of sexual behavior during sleep can vary from explicit vocalizations with sexual content, violent masturbation, and complex sexual activities including oral sex, and vaginal or anal intercourse.

The exact etiology is unknown, but precipitating factors are stress, sleep deprivation/fragmentation, alcohol or drug consumption, excessive fatigue and physical overactivity in the evening

TREATMENT

- Benzodiazepines are 1st-line therapy
- Sleep hygiene and safety precautions should be implemented

REFERENCE

Andersen, ML, Poyares D, Alves RS, et al. Sexsomnia: Abnormal sexual behavior during sleep. *Brain Res Rev.* 2007;56:271–282.

SEXUAL ANHEDONIA/EJACULATORY ANHEDONIA

DESCRIPTION Lack of appropriate pleasure from sexual activity. Patients typically elicit a failure of genital response. Men have difficulty initiating or sustaining an erection; pre-menopausal women have difficulty with lubrication. Ejaculatory anhedonia describes lack of pleasure during ejaculation. Although a psychogenic etiology is often present, the clinician must rule out hormonal influences. Medications such as selective serotonin reuptake inhibitors have been reported to cause this phenomenon as well.

SEXUAL FUNCTION SURVEY (SFS) (INTERNATIONAL INDEX OF ERECTILE FUNCTION (IIEF)

DESCRIPTION The IIEF is a 15-item, self-administered questionnaire scale for the assessment of erectile function that has been linguistically validated in 10 languages. It addresses the relevant domains of male sexual function: Erectile function (EF), orgasmic function (OF), sexual desire (SD), intercourse satisfaction (IS), and overall satisfaction. EF is represented in items 1(5 and 15 of the questionnaire, with a score range of 0 or 1) to 5, a minimum score of 1, and a maximum score of 30. OF is represented in items 9 and 10, with a score range of 0–5, a minimum score of 0, and a maximum score of 10. SD is represented in

items 11 and 12, with a score range of –5, a minimum score of 2, and a maximum score of 10. IS is covered in items 6, 7, and 8, with a score range of 0–5, a minimum score of 0, and a maximum score of 15. OS is covered in items 13 and 14, with a score range of 1–5, a minimum score of 2, and a maximum score of 10. In general, the lower the score, the worse the erectile function. (See Section VII: "Reference Tables: International Index of Erectile Function [IIEF] [Sexual Function Survey].")

REFERENCE

Rosen RC, Riley A, Wagner G, et al. The International Index of Erectile Function (IIEF): A multidimensional scale for assessment of erectile dysfunction. *Urology.* 1997;49:822–830.

SEXUAL HEALTH INVENTORY FOR MEN (SHIM) SCORE

DESCRIPTION The SHIM, sometimes called IIEF-5 (International Index of Erectile Function), is a validated questionnaire that assesses male sexual function and can be used as an adjunct for the assessment and treatment of ED. This is an abridged version of the original 15-question IIEF questionnaire. The SHIM questionnaire consists of 5 questions pertaining to the quality of the patient's erections and sexual satisfaction over the last 6 mo. Each question is graded on a scale from 1–5. ED is then assessed based on the cumulative value of the SHIM score: 22–25, no ED; 17–21, mild ED; 12–16, mild to moderate ED; 8–11, moderate ED; 5–7, severe ED. (See Section VII for the SHIM Instrument.)

REFERENCE

SHY DRAGER SYNDROME, UROLOGIC CONSIDERATIONS

DESCRIPTION Shy Drager syndrome, also known as *multiple system atrophy*, is a progressive neurodegenerative disease in which the etiology is unknown. Bladder dysfunction causing urinary incontinence and erectile dysfunction (ED) are early features. Urinary urgency, frequency, incomplete bladder emptying as well as urinary retention or any combination are seen as urologic manifestations of Shy Drager syndrome. In addition, weakness of the striated urethral sphincter contributes to incontinence. DO is seen on urodynamic evaluation.

REFERENCE

SIGNET RING CARCINOMA, PROSTATE

DESCRIPTION A rare, high-grade neoplasm that carries a poor prognosis. A GI primary tumor should be considered with this pathology. Immunohistochemical exam demonstrates cytoplasmic immunoreactivity to PSA in signet-ring cancer cells, with intracytoplasmic vacuoles in the signet-ring cells staining positively for mucus with periodic acid-Schiff. This malignancy is more aggressive than other cell types; >50% of these patients die within a

year of diagnosis.

SILBER VASOEPIDIDYMOSTOMY

DESCRIPTION In 1978, Silber was the 1st to report the use of the microscope to perform a vasoepididymostomy. The distal epididymis is cut and, with aid of the microscope, the tubule exuding semen is identified. The freshly cut mucosal lumen of the vas deferens is anastomosed to this tubule, and the adventitia of the vas is then anchored to the epididymal tunic. The procedure is used in selected cases of obstructive infertility.

SKENE (PARAURETHRAL) GLAND ADENOCARCINOMA

DESCRIPTION An extremely rare primary urethral carcinoma occurring in approximately 1.5 women per million and constituting $<1\%$ of all female malignancies. Presence of PSA in tissue and/or serum confirms a Skene gland origin, due to its homology to the male prostate. PSA levels normalize after treatment. Complete excision, using a technique similar to repair of urethral diverticulum, is curative. Decision for radiotherapy is based on tumor size and location, with smaller, distal lesions generally undergoing surgical excision and RT, and large or proximal lesions treated with radiation therapy (RT) in an effort to preserve organ function.

REFERENCE

Champ CE, Hegarty SE, Shen X, et al. Prognostic factors and outcomes after definitive treatment of female urethral cancer: A population-based analysis. *Urology*. 2012;80(2):374–381.

SKENE (PARAURETHRAL) GLAND, INFLAMMATION/ADENITIS

DESCRIPTION Skene glands are homologous to the male prostate gland and are located along the anterior vaginal wall, adjacent to the urethral meatus. These glands may become infected and present as a tender, fluctuant periurethral nodule. Infection or inflammation of the Skene glands can cause exquisite tenderness and may be associated with dyspareunia and vulvar vestibulitis. The most common pathogen is *Neisseria gonorrhoeae*. Treatment includes culture of infected area along with surgical incision and drainage if abscess formation is present. Appropriate antibiotic therapy is administered. Other causes of vestibulitis or vulvodynia should be assessed and evaluated.

Fam Physician. 1999;(596):1547–1556.

SKIN TAGS, EXTERNAL GENITALIA (ACROCHORDON, PEDUNCULATED PAPILLOMA)

DESCRIPTION Benign, flesh-colored, soft pedunculated benign lesions that may occur anywhere on the body and generally are < 5 mm, although larger lesions can be seen. They may be pinkish, skin-colored, or hyperpigmented and are more common on obese individuals. Usually asymptomatic, these lesions are often found in skin folds (neck, axillae, groin) and rarely involve the external genitalia. They may accompany hamartomatous skin lesions (fibrofolliculomas and trichodiscomas) associated with Birt–Hogg–Dubé syndrome. Irritation and possibly HPV types 6/11 are possible causes. No treatment is necessary, and they are usually considered clinically insignificant. If treatment is desired for cosmesis or irritation, then the tags may be treated by electrocautery, simple scissor excision, suture ligation of the base, or cryotherapy.

REFERENCE

Emir L, Ak H, Karabulut A, et al. A huge unusual mass on the penile skin: Acrochordon. *Int Urol Nephrol.* 2004;36(4):563–565.

SLEEP APNEA, UROLOGIC CONSIDERATIONS

DESCRIPTION Patients with obstructive sleep apnea may have their condition exacerbated by testosterone replacement therapy (TRT); their sleep apnea status should be monitored closely and treated if possible. Sleep apnea also may cause nocturnal hypoxia and may be a factor for erectile dysfunction (ED). Obstructive sleep apnea may also be involved with nocturia and daytime overactive bladder in women.

SLING MATERIALS

DESCRIPTION Slings, usually mid-urethral, are a common option for the treatment of intrinsic sphincteric deficiency. Sling materials are either autologous, allografts, xenografts, or synthetic. (See also Section I: “Incontinence, Female”; “Incontinence, Male”; Section II: “Urethral Sling.”)

- Autologous grafts (harvested at the time of surgery):
  - Rectus fascia
  - Fascia lata
  - Vaginal wall
  - Round ligament

  – Dermis
- Allografts (processed by freeze-drying or solvent dehydration):
  – Cadaveric fascia
  – Cadaveric dermis
- Xenografts:
  – Porcine dermis
  – Porcine small intestinal submucosa
- Synthetic slings:
  – Marlex
  – Gore-Tex
  – Silicone
  – Transvaginal tape (polypropropylene mesh)

REFERENCE

Wilson TS, Lemack GE, Zimmern PE. Management of intrinsic sphincteric deficiency. *J Urol.* 2003;169(5):1662–1669.

SMEGMA

DESCRIPTION A substance composed of desquamated cells that originate from the epithelium of the glans penis and on the inner surface of the foreskin. Smegma is composed of 26% fat and 13% protein. It remains unclear whether smegma is only desquamated epithelial cells or whether secretions from preputial glands at the coronal sulcus contribute to smegma. The issue of smegma carcinogenicity is still controversial. Some believe that phimosis allows for retention of smegma, which is an irritant that produces malignant transformation of the epithelium by direct contact. 50% of men harbor *Mycobacterium smegmatis* in the preputial sac; this organism has been implicated in the conversion of sterols in smegma into carcinogenic compounds. Good puerperal hygiene is recommended if uncircumcised.

SMITH–LEMLI–OPITZ SYNDROME

DESCRIPTION An autosomal recessive multisystemic disease found in newborns that present with hypospadias and cryptorchidism. Anomalies in other systems include pernicious anemia, mental retardation, syndactyly, renal abnormalities, and microcephaly. These patients have an inborn error of cholesterol (biosynthesis defect of δ5,7-sterol, δ7-reductase), which results in deficiency of cholesterol and elevation of 7-dehydrocholesterol, a cholesterol precursor. Patients can take cholesterol with or without bile acids.

SMOKING, UROLOGIC CONSIDERATIONS

DESCRIPTION Smoking is a modifiable behavioral risk factor with an array of impact on urologic disorders. The smoking population attributable risk of bladder cancer is 50% in men and 52% in women. The relative risk of developing both renal parenchymal cancer as well as upper tract carcinoma ranged in men from 27–37% and 10–24% in women. In addition, there is a dose-response relationship as the risk of developing RCC is increased in lifelong smokers who smoke >20 cigarettes a day compared those who smoke less. Smoking may cause irreversible damage to neuromuscular and vaso-endothelial mechanisms of erectile function as though only 20% of the population are smokers, 40% of men with ED are currently smokers. Smoking has also been associated with increased risk of acquiring HIV and HPV (both high and low-risk strains). The semen parameters in men who smoke have been found to be significantly decreased, especially sperm motility.

SNODGRASS HYPOSPADIAS REPAIR

DESCRIPTION Snodgrass hypospadias repair, also known as *tubularized incised-plate urethroplasty*, is the most commonly performed operation to repair distal hypospadias. The key step in the procedure is a midline incision of the urethral plate. The urethral plate is then tubularized beginning at the neomeatus, turning all epithelium into the neo-urethral lumen.

REFERENCE

Snodgrass WT. Snodgrass technique for hypospadias repair. *BJU Int.* 2005;95:683–689.

SOAP-BUBBLE NEPHROGRAM

DESCRIPTION The Soap-bubble nephrogram seen on IVP is caused by end-stage obstruction atrophy, this is a radiographic appearance of the dilated pyelocalyceal system in which overlapping curved, white densities several millimeters in thickness appear after IV or intra-arterial injection of contrast material. Dilated calyces are represented by bubbles, and remnants of Bertin columns appear as thin opacities between adjacent calyces.

REFERENCE

Ransley PG. Opacification of the renal parenchyma in obstruction and reflux. *Pediatr Radiol.* 1976;4:226.

SODIUM CYANIDE NITROPRUSSIDE TEST

DESCRIPTION A qualitative test for cystinuria. The assay involves the conversion by cyanide of cystine to cysteine. Nitroprusside binds cysteine resulting in a purple color in 2–10 min. The test detects cystine levels above 75 mg/g creatinine. If positive a quantitative 24-hr collections should be performed. (See also Section I: “Urolithiasis, Cystine and Cystinuria (Hypercystinuria)” and Section II: “Metabolic Stone Evaluation [24-hr Urine Studies].”)

REFERENCE
Eggermann T, Venghaus A, Zerres K. Cystinuria: An inborn cause of urolithiasis. *Orphanet J Rare Dis*. 2012;7:19–29.

SOLITARY FIBROUS TUMOR, RENAL

DESCRIPTION Solitary fibrous tumors (SFTs) are mesenchymal tumors arising at any site. When involving the kidney, they arise from the capsule, renal pelvis, or hilar fatty tissue. They present similar to patients with RCC. On gross appearance, the tumor is solid with a pseudocapsule. Microscopically, it shows a spindle cell proliferation. Controversy exists concerning the diagnosis of SFT and hemangiopericytoma because of overlapping immunohistochemical features. No cases of metastasis from renal SFTs has been described.

TREATMENT
Radical nephrectomy with complete resection including negative margins is needed for a favorable prognosis.

REFERENCE
Makris A, Tabaza R, Brehmer B, et al. Solitary fibrous tumor of the kidney: A case report. *Can J Urol*. 2009;(165):4854–4856.

SPERM GRANULOMA

DESCRIPTION Sperm granulomas form from the testicular end of the vas deferens after vasectomy. Because sperm is highly antigenic, the inflammatory reaction creates a granuloma, which is usually asymptomatic. Some studies have shown that men who undergo vasectomy reversal have higher success rates if they have a sperm granuloma at the vasectomy site. A mass in the scrotum, often tender postvasectomy, is diagnostic.

TREATMENT
- When chronic post-vasectomy pain is localized to the sperm granuloma, the lesion should be excised and occluded with electrocautery.
- Post-vasectomy congestive epididymitis may be relieved with open-ended vasectomy, which will produce a pressure-relieving sperm granuloma.

REFERENCE
Awsare NS, Krishnan J, Boustead GB, et al. Complications of vasectomy. *Ann R Coll Surg Engl*. 2005;87(6):406–410.

SPERM PENETRATION ASSAY (SPA, HAMSTER TEST)

DESCRIPTION Also called *hamster oocyte penetration test* and in some publications (*Humster test*), a test for infertility that assesses the ability of sperm to penetrate the ovum. The zona pellucida from hamster oocytes is removed, which allows capacitated human sperm to penetrate it. This assay requires the sperm to be able to undergo capacitation, the acrosome reaction, fusion with the oolemma, and incorporation into the ooplasm. If sperm penetration is 10–30%, the sample is considered normal, but this bioassay is not standardized. Some studies have shown that IVF success is correlated with a positive SPA, while others have not.

These inconsistencies require that the physician become familiar with the lab performing this test. Although there are controversies surrounding SPA, it is a test that should be performed for unexplained infertility.

REFERENCE

Aitken RJ. Sperm function tests and fertility. *Int J Androl.* 2006;29(1):69–75.

SPERM VITALITY

DESCRIPTION Also referred to as *sperm viability or sperm motility*, this is 1 parameter in semen analysis during workup of male infertility. Determination of the percentage of viable and motile sperm in semen samples is helpful to determine if the sperm could be of therapeutic use for various fertilization techniques. (See also Section I: "Infertility"; Section II: "Semen Analysis, Technique, and Normal Values.")

REFERENCE

SPERMATIC CORD, LIPOSARCOMA

DESCRIPTION A rare soft tissue malignancy derived from mesenchymal tissue. It is often mistaken for hydrocele, cord lipoma, or incarcerated hernia and preoperative diagnosis is rare. Most malignant paratesticular tumors are sarcomas, but 5–7% are liposarcomas. High-resolution ultrasound, CT, and MRI have become imaging of choice. Tumors in the literature have been reported to range from 0.4 cm to as large as 50 cm. The majority of tumors are low grade and well differentiated. Late recurrences and metastases may be seen, particularly with high-grade lesions. Radical orchiectomy with wide local excision and high ligation of the spermatic cord, is the treatment. Liposarcoma is radiosensitive and radiotherapy can be used to prevent local recurrence. (See also Section I: "Spermatic Cord Mass and Tumors.")

REFERENCE

Li F, Tian R, Yin C, et al. Liposarcoma of the spermatic cord mimicking a left inguinal hernia: a case report and literature review. *World J Surg Oncol.* 2013;11:18.

SPINA BIFIDA/SPINA BIFIDA OCCULTA, UROLOGIC CONSIDERATIONS

DESCRIPTION Spina bifida is a birth defect that results in the incomplete closure of the embryologic neural tube, leading to incomplete development of the spinal cord and vertebrae. This usually involves the lumbar and sacral areas. As a result, many patients develop a neurogenic bladder dysfunction requiring long-term urologic care. Although 90% of patients born with spina bifida have normal upper urinary tracts, over 1/2 of these patients will show signs of renal deterioration if no urologic intervention is performed. Spina bifida occulta is the mildest form of spina bifida. The vertebrae may not fuse together, although the spinal cord and nerves are intact. Patients with spina bifida occulta may have no neurologic deficits at birth. Neurologic deficits that are present are usually mild compared to patients with spina bifida, and may develop later in life. Treatment involves aggressive urologic surveillance to

preserve renal and bladder function. A neonatal renal US and voiding cystourethrography are obtained to assess for hydronephrosis and vesicoureteral reflux. Up to 20% of patients with spina bifida will have reflux. A urodynamic study (UDS) is also performed during this period to evaluate bladder compliance, detrusor pressures, capacity, leak pressures, contractions, and sphincter dyssynergia. Some institutions recommend prophylactic antibiotics and CIC until the neonate's 1st UDS. Patients with poorly compliant bladders with elevated filling pressures (typically above 40 cm H_2O) are in danger of upper tract deterioration and are typically started on clean intermittent catheterization (CIC) and anticholinergic therapy. If a patient fails conservative medical therapy, surgical procedures such as intravesical botulinum toxin injection, vesicostomy, augmentation cystoplasty, or urinary diversion (continent or incontinent) may be appropriate treatment options. It should be stressed to patients and their families to have strict routine follow-up visits to evaluate bladder or upper tract deterioration. (See also Section I: "Myelodysplasia Spinal Dysraphism, Urologic Considerations" and (Image ☼).)

REFERENCE

SPINAL CORD COMPRESSION, UROLOGIC CONSIDERATIONS

DESCRIPTION Epidural spinal cord compression, if due to a urologic etiology, is most likely bone metastasis from prostate cancer. Other types of cancer (eg, breast, lung, kidney, GI) must also be kept in mind. Vertebral body metastases are present in the majority of patients dying from metastatic prostate cancer. Compression of the cord causes edema, venous congestion, and demyelination. Symptoms include back pain, progressive weakness, sensory loss, and paralysis. Bowel and bladder dysfunction are late findings. Neurologic impairment can progress overnight, so patients must be followed carefully. Survival of patients with spinal cord compression due to metastasis is relatively poor: 46% of patients survive <6 mo, and 20% <2 mo. Diagnosis is based on findings of CT and MRI. (See also Section I: "Spinal Cord Injury, Urologic Considerations.")

TREATMENT

- Glucocorticoids, high-dose steroids 100 mg IV then 24 mg IV every 6 hr for 3 days, then taper
- Orchiectomy, high-dose ketoconazole (200–400 mg PO TID) or LHRH antagonist degarelix) to rapidly reduce serum testosterone if hormone naïve
- External radiation therapy with or without vertebrectomy note decompressive laminectomy has not been as successful as vertebrectomy with spinal stabilization, as most disease is located anterior to the spinal cord.

Lancet. 2005;366(9486):643–648.

SPINAL SHOCK

DESCRIPTION After acute spinal cord injury (SCI), a period of areflexia and flaccid paralysis usually occurs below the level of injury. This period of spinal shock is variable; reflex detrusor activity usually returns after 2–12 wk, although it may take up to 1 yr. Urodynamic studies assessing bladder function are postponed until spinal shock resolves. Treatment is supportive during this period of detrusor areflexia. CIC is the recommended means of emptying the bladder, although an indwelling Foley catheter may be another alternative. (See also Section I: “Spinal Cord Injury, Urologic Considerations.”)

SPINDLE CELL NEOPLASM, UROLOGIC CONSIDERATIONS

DESCRIPTION Mucinous tubular and spindle cell carcinoma (MTSCC) is a rare neoplasm of the kidney and is classified by the WHO as a variant of RCC. It is considered a low-grade carcinoma with a favorable prognosis. It typically presents in adult women in a 4:1 ratio. It is believed to be derived from the epithelial cells of the loop of Henle or possibly the collecting duct. There are also rare case reports of spindle cell neoplasm of the bladder and penis. The histologic features are characterized by elongated tubules and cord arrangements, which are separated by mucinous stroma. The parallel tubular arrays have a spindle cell configuration. There are also rare case reports of spindle cell neoplasm involving the bladder and penis.

TREATMENT

- Complete surgical excision appears to be adequate treatment
- Those with true sarcomatoid changes have increased risk of recurrence, regional adenopathy, or distant metastases

SPINNING TOP URETHRA

DESCRIPTION Spinning top urethra (STU) is a widened posterior urethra seen mainly in girls that is seen on videourodynamics. The most common mechanism for dilatation of the posterior urethra is unstable bladder contractions are resisted by a voluntary increase in the tension of the external urinary sphincter. The increased pressure results in a dilation of the posterior urethra. It is seen in patients with voiding dysfunction.

Radiology. 1988;168(1):147–150.

SPLENIC INJURY DURING RADICAL NEPHRECTOMY

DESCRIPTION Of cases involving iatrogenic injury to the spleen, up to 12% have been reported to occur during nephrectomy. Splenic injuries usually tend to occur from excessive traction rather than direct injury or scalpel laceration; adequate exposure starting from an appropriate incision is essential. Capsular tears are the most common encountered event. The inferior portion of the spleen is typically involved, since the spleen has ligamentous associations (splenocolic, splenorenal, splenophrenic) with the kidney and other nearby organs and structures. The splenic artery can be found crossing the upper pole of the left kidney, dividing into segmental branches. Optimal treatment 1st involves recognizing splenic injury in a timely fashion intraoperatively. Depending on the extent of injury and condition of the patient, the decision is made to proceed with either salvage of the spleen or splenectomy. Splenic salvage techniques depend on severity of injury and includes the use of topical hemostatic agents, primary suture repair, partial segmental resection, or mesh repair. Complications associated with splenic injury repair or splenectomy include subphrenic abscess; injury to the stomach, colon, or tail of the pancreas; pancreatitis or pancreatic fistula formation; and pleural effusion.

SPLENOGONADAL FUSION

DESCRIPTION A rare congenital malformation in which an abnormal fusion exists between the spleen and the gonad or mesonephros derivatives. This fusion occurs in both sexes, but it is more common in males. Half of the cases are reported in children. The 2 types are continuous and discontinuous. In the continuous splenogonadal fusion, the main spleen is connected to the left gonad by a strand of tissue. This cord may be fibrous or splenic or contain beads of splenic tissue. The discontinuous type has no cord between the spleen and left gonad. 1/3 of all reported cases are associated with other congenital abnormalities, especially peromelia. The majority of cases present with scrotal mass or scrotal tenderness. Some are found incidentally during herniorrhaphy or orchidopexy. Although evaluation is usually done in the operating room, a technetium^{99} colloid liver spleen scan can easily identify splenic tissue in the scrotum if splenogonadal fusion is suspected preoperatively. Scrotal US does not help to diagnosis this entity.

TREATMENT

- Usually involves removing both the testis and adjoining mass.
- If the diagnosis of discontinuous splenogonadal fusion is made before surgery, the splenic nodule can simply be excised.
- For the continuous variety, exploratory laparotomy is necessary to identify the anatomy involved and deal with the continuous cord.

Gouw AS, Elema JD, Bink-Boelkens MT, et al. The spectrum of splenogonadal fusion. Case report and review of 84 reported cases. *Eur J Pediatr.* 1985;144(4):316–323.

SPLENULE/SPLENOSIS, UROLOGIC CONSIDERATIONS

DESCRIPTION A benign condition associated with splenic rupture, typically during splenic surgery or trauma. Autotransplantation of splenic tissue occurs via seeding of splenic pulp in the abdominal or thoracic cavities. Hematogenous spread has also been reported. Patients are asymptomatic, and the discovery of splenosis is usually incidental on imaging studies. Splenosis in the abdominal cavity has been mistaken for primary malignancies, such as primary RCC. Similarly, thoracic splenosis can mimic metastatic urologic malignancies as well. The diagnostic modality of choice is nuclear scintigraphy. Once splenosis is confirmed and malignancy is ruled out, no treatment is necessary due to the benign nature of the condition.

REFERENCE

Fremont RD, Rice TW. Splenosis, a review. *South Med J.* 2007;(1006):589–593.

SPORTS HERNIA (ATHLETIC PUBALGIA, SPORTSMAN'S HERNIA)

DESCRIPTION A sports hernia is a painful, soft tissue injury that occurs in the groin area. It most often occurs during sports that require sudden changes of direction or intense twisting movements and is considered an "overuse" injury. It is a musculo-tendinous injury that involves the insertion of abdominal muscles on the pubis and the upper aponeurotic insertion of the adductor muscles. The pain develops during exercise, is generally unilateral but occasionally bilateral, and is typically located in the supra-inguinal portion of lower abdomen lateral to rectus abdominis, sometimes radiating to the testis. Although a sports hernia may lead to a traditional, abdominal wall hernia, it is a different injury. A sports hernia is a strain or tear of any soft tissue (muscle, tendon, ligament) in the lower abdomen or groin area. Because different tissues may be affected and a traditional hernia may not exist, the medical community prefers the term *athletic pubalgia* to refer to this type of injury. The existence, significance and diagnosis of sports hernia are all controversial. The condition needs to be differentiated from a direct, indirect, or femoral groin hernia, adductor longus origin "tendonitis," or osteitis pubis based on history and physical exam. The symptoms are nonspecific and can include tenderness on palpation of the medial inguinal floor, tenderness on palpation over the pubic ramus, and exacerbated pain with resisted hip adduction. MRI may be useful in the differential. Rest, anti-inflammatory medications (NSAIDs) and physical therapy are beneficial. Rarely surgery may be necessary to repair the torn ligament or tendon.

SQUAMOUS METAPLASIA, GENITOURINARY

DESCRIPTION The replacement of normal urothelium by mature squamous epithelium. Nonkeratinizing squamous metaplasia is thought to be a normal variant in premenopausal women, occurring under hormonal influence. This form is commonly found in the trigone; cystoscopically, it appears as a white patch. Keratinizing squamous metaplasia, also known as vesical leukoplakia, is a response to chronic irritation and infection. Some patients go on to develop squamous carcinoma. Keratinizing squamous metaplasia often occurs with long-term urinary catheters, a bladder stone, vesical schistosomiasis; long-term observation is warranted for the development of squamous carcinoma of the bladder.

SYNONYMS

- Pseudomembranous trigonitis
- Vesical leukoplakia

TREATMENT

Transurethral resection ablation and biopsy in cases of keratinizing squamous metaplasia

REFERENCE

Ahmad I, Barnetson RJ, Krishna NS. Keratinizing squamous metaplasia of the bladder: A review. *Urol Int.* 2008;(813):247–251.

STAMEY PROCEDURE (URETHROPEXY)

DESCRIPTION Stamey was the 1st to report the use of the cystoscope to aid in the performance of a transvaginal urethropexy. In addition, the nonabsorbable sutures that are placed with a needle carrier incorporate a Dacron pledget to buttress the suture at the level of the bladder neck. Used to treat stress incontinence in women; of the patients who have undergone this procedure, 82% of 192 were improved, and 65% of the 192 would be willing to undergo the procedure again. Another study showed that although the Stamey procedure has a high early success rate, the long-term results were poor. After 5 yr, only 18% of 28 women remained dry. Concomitant abdominal hysterectomy, respiratory disease, and obesity were likely to point to a lower long-term cure rate. Possible complications include long-term erosion of sutures into the urinary tract and long-term urinary retention if sutures are tied too tightly.

REFERENCE

O'Sullivan DC, Chilton CP, Munson KW. Should Stamey colposuspension be our primary surgery for stress incontinence? *Br J Urol.* 1995;(754):457–460.

STAMEY TEST (3-GLASS TEST, 4-GLASS TEST, MEARES–STAMEY TEST)

DESCRIPTION The 3-glass test described by Meares and Stamey is a method of collecting urine, which can provide information on the site of the urinary tract origin of RBCs or bacteria. Although this method is effective in localizing the cause of hematuria, it is more commonly used in diagnosing prostatitis. A specimen is collected from the urethra, midstream urine, and prostatic secretions. The 1st-voided 10 mL of urine is the urethral specimen (VB1). The midstream urine of 10 mL (VB2) is collected after the patient has voided about 200 mL.

The patient is then instructed to stop voiding, at which time the physician massages the prostate and collects the prostatic fluid expressed prostatic secretions (EPS). Afterward, the patient voids again, and a 10-mL specimen (VB3) is collected. Cultures are sent on the 4 specimens hence the 3-glass or 4-glass test (nomenclature). When the bladder urine is sterile, urethral, and prostatic infection can be differentiated by comparing the bacterial colony counts of VB1 and prostatic EPS and VB3 counts. In urethral infections, the VB1 count is much higher than the EPS or VB3 count. The EPS and VB3 counts in prostatic infections significantly exceed the VB1 count. When interpreting bacterial colony counts, the clinician must take into account that the VB3 specimen is a 100× dilution of prostatic fluid. When the bladder urine is infected, the infection cannot be localized, because all specimens will show heavy growth of organisms. Note that this test is often replaced by the*2-glass test,* which collects a more convenient pre-/postprostatic massage urine sample. The premassage and postmassage 2-glass test has strong concordance with the 4-glass test and is a reasonable alternative when EPS are not obtained. The technique and diagnosis algorithm are discussed in Section I: “Prostatitis, General” and “Prostatitis, Chronic, Bacterial [NIH II].”

STAUFFER SYNDROME

DESCRIPTION A syndrome associated with nonmetastatic hepatic dysfunction commonly seen in cases of RCC. Symptoms include fever, fatigue, and weight loss. The patient has unusual liver function tests, WBC loss, and areas of hepatic necrosis without hepatic metastasis. The presence of hepatic dysfunction should not be a contraindication to surgery. Hepatic function usually returns to normal after nephrectomy. If the syndrome persists, it is a sign of recurrent tumor. Diagnostic indicators are elevation of alkaline phosphatase and bilirubin, hypoalbuminemia, prolonged PTT, and hypergammaglobulinemia.

REFERENCE

STEINSTRASSE

DESCRIPTION A German expression for “street of stones,” referring to multiple stone fragments in the ureter after extracorporeal shock wave lithotripsy. Characteristically, stone fragments are found in a line within the ureter, which may or may not be obstructed. The condition occasionally presents with renal colic, nausea, or vomiting. Observation is sufficient if symptoms are tolerable or absent; with severe colic or obstruction, treatment is ureteral stent placement, percutaneous nephrostomy, or ureteroscopic lithotripsy (Image ☼).

REFERENCE

STING PROCEDURE

DESCRIPTION This refers to subureteral transurethral injection (“STING”) of bulking agents to correct vesicoureteral reflux. The original coined term was subureteric Teflon injection (STING) using pyrolyzed Teflon (PTFE) particles suspended in glycerin. Due to concern over migration of the Teflon to the brain and lung it was abandoned in favor of other agents. Silicone was also used as a bulking agent (Macroplastique) and while effective was also abandoned due to safety concerns. Other materials such as glutahaldehyde crosss-linked bovine collagen [Contigen] and calcium hydroxyapatite (Coaptite) are also no longer used a bulking agents. Bulking agents such as Deflux (cross-linked dextranomer/hyaluronic acid copolymer) has been accepted and is currently in widespread use. The basic technique involves the periureteral injection at the 6 o’clock position of the ureteral orifice. A modification is the hydrodistention implantation technique (HIT) where the agent is injected inside the ureteral hiatus. Overall the success rate is inferior to that of open surgery. About 70% have reflux resolution after 1 procedure. With repeat STING procedures, the success rate increases to 90–95%. (See also Section I: “Vesicoureteral Reflux, Pediatric"; and Section II: “Bulking Agents, Injectable.”)

STRANGURIA

DESCRIPTION Slow, painful, spasmodic expulsion of urine in a drop-wise fashion, usually occurring at the end of micturition due to spasm of the bladder and urethra. Associated with an irritative process in the GU system, it often refers pain to the urethral meatus. Historically, the pathophysiology has been attributed to a significant inflammatory component. The term is not commonly used in human medicine, but is firmly entrenched in veterinary medicine.

SYNONYMS

- Strangury
- Terminal dysuria

REFERENCE

Wright B, Husbands E. Strangury: the case of a symptom with ancient origins. *BMJ Support Palliat Care.* 2011;1:49–50.

STREAK GONAD

DESCRIPTION Streak gonads are hypoplastic and dysfunctioning gonads mainly consisting

of fibrous tissue. Patients with streak gonad usually present with female phenotype, primary amenorrhea, infantile breast status, sparse pubic and axillary hair, infantile external genitalia and vagina, atrophic vaginal smear, immature uterus, high serum FSH, low urinary estrogen, and osteoporosis, as well as the streak gonad. Diagnosis is made by measuring FSH and urinary estrogen, and determining karyotype. (See Section II: "Gonadal Dysgenesis, Mixed and Pure.")

TREATMENT

- Management includes laparotomy with excision of any intra-abdominal testis or streak gonads. These masses progress to malignancies, which may develop before puberty.
- Female sex assignment and reconstructive surgery are advised in cases with severely deficient virilization of the genitalia.

REFERENCE

Calabrese F, Valente M. Mixed gonadal dysgenesis: Histological and ultrastructural findings in two cases. *Int J Gynecol Pathol.* 1996:(153):270–275.

STRICKLER URETERAL ANASTOMOSIS

DESCRIPTION Through an extracolonic approach, a small linear incision is made in the taenia, and a small clamp is used to create a submucosal 3–4-cm tunnel exiting out of the colon laterally. The ureter is delivered through the tunnel, the spatulated end is anastomosed to the mucosa, and the taenia is closed while incorporating ureter adventitia.

STRUVITE

DESCRIPTION The mineral name for magnesium ammonium phosphate hexahydrate ($NH_4MgPO_4{\cdot}6H_2O$) stones. Struvite stones (also sometimes known as triple phosphate stones) are composed of calcium magnesium ammonium phosphate and form only in urine infected by urea-splitting bacteria, such as Proteus, Providencia, and sometimes Klebsiella, Pseudomonas, and enterococci. Because of their potential for rapid growth and substantial morbidity, early detection and eradication are essential (See also Section I: "Urolithiasis, Staghorn") and (Image ☼).

STUDER POUCH

DESCRIPTION An orthotopic neobladder is made, based on 60 cm of marsupialized ileum, which is configured and sutured into a W to create a broad intestinal plate. In addition, a nontubularized segment of ileum extends from a limb of the W, simulating a chimney. The ureters are implanted into the chimney. The intestinal plate is anastomosed to the urethra and then closed into a sphere and connected to the urethra.

SUPERFICIAL INGUINAL POUCH OF DENIS-BROWNE

DESCRIPTION A superficial inguinal pouch is defined as the space distal to the internal inguinal ring, but above the inguinal canal, between the external oblique fascia and Scarpa fascia. Studies suggest that a testis in the superficial inguinal pouch is, in reality, a cryptorchid testis.

REFERENCE

Herzog B, Steigert M, Hadziselimovic F. Is a testis located at the superficial inguinal pouch (Denis-Browne pouch) comparable to a true cryptorchid testis? *J Urol.* 1992;(1482 Pt 2):622–623.

SUPERNUMERARY KIDNEY

DESCRIPTION A supernumerary kidney is a rare condition in which a free accessory renal organ exists as a distinct entity, with its own blood supply, with presence of 2 normal kidneys. It is distinguished by its small size and/or abnormal position. The kidney is either a component of a bifid ureteral system or a completely duplicated system. When diagnosed, treatment for a supernumerary kidney should be based on pathologic processes affecting the kidney rather than its redundant appearance or abnormal position. Association of a normal kidney with a 2nd or 3rd ipsilateral smaller kidney is an extremely rare anomaly with only a total of 81 cases reported through 2013.

SUPINE STRESS TEST

DESCRIPTION Nonurodynamic method to test for intrinsic sphincteric deficiency, it is performed by placing the patient in lithotomy position and filling the empty bladder with 200 cc saline under gravity. The patient is then asked to cough and perform a Valsalva maneuver. A test is deemed positive if fluid is seen leaking from the meatus at time of cough or Valsalva. Studies have shown that it is a relatively quick and inexpensive test that has a sensitivity of 93.5% and specificity of 90.0%.

SWYER SYNDROME (XY SEX REVERSAL)

DESCRIPTION A sex reversal disorder with a female phenotype and 46, XY genotype with pure gonadal dysgenesis. Patients have bilateral streak gonads and often present in adolescence as phenotypic females with delayed puberty. A 46, XY genotype may develop rapid breast or clitoral enlargement due to hormonally active gonadoblastomas within the streak gonads. The presence of the Y chromosome increases the risk of gonadal tumors and therefore a prophylactic bilateral salpino-gonadenectomy is often advised. (See also Section II: “Gonadal Dysgenesis [Mixed and Pure].”)

SYNDROME OF INAPPROPRIATE ANTIDIURETIC HORMONE (SIADH)

DESCRIPTION SIADH is the most frequent cause of hyponatremia. The condition usually results when plasma levels of antidiuretic hormone or arginine vasopressin are elevated when normal physiologic secretion of vasopressin from the posterior pituitary should be suppressed, causing a euvolemic hypo-osmolar hyponatremia. There are many causes of this syndrome of inappropriate diuresis, which include malignancies (such as small cell lung cancer, cancers of the GI tract, lymphoma), pulmonary diseases (pneumonia, TB, cystic fibrosis, asthma), disorders of the CNS (neurologic diseases as well as infection, bleeding, or trauma-related), and drugs. Intranasal desmopressin (DDAVP) to treat nocturnal enuresis can be associated with this condition. Acute management requires evaluation of the clinical status of the patient, assessment of the type of hyponatremia, and treatment based on the degree of hyponatremia. After the patient is stabilized, treatment can then be focused on determining the underlying cause of SIADH. If possible, removal or treatment of the underlying cause can result in full resolution. Long-term treatment consists of fluid restriction and possible use of pharmacologic agents such as demeclocycline (causes a nephrogenic DI) or vasopressin receptor antagonists.

SYSTEMIC LUPUS, UROLOGIC CONSIDERATIONS

DESCRIPTION The kidney (*lupus nephritis*) is the organ most commonly affected by systemic

lupus erythematosus (SLE), a chronic, multisystem autoimmune disease with no known cause. A variety of diseases related to SLE can affect the kidney, with renal biopsy usually necessary to identify the specific type. The renal manifestations of SLE vary from patient to patient. Proteinuria with or without an elevated creatinine is the most common manifestation of renal disease in SLE. Urine sediment typically shows >5 red and white blood cells per high power field and/or ≥ 1 cellular cast in more severe forms of disease. Immune complexes result in injury to the glomerulus, and the specific lesion is determined by renal biopsy. International Society of Nephrology classification divides the SLE glomerular disorders into different classes: Classes I and II (minimal mesangial lupus nephritis and mesangial proliferative lupus nephritis) are the mildest forms; classes III and IV (focal proliferative lupus nephritis and diffuse proliferative lupus nephritis) more severe forms; and classes V and VI (membranous lupus nephritis and advanced sclerosing lupus nephritis) are the most severe forms. These more severe forms of lupus nephritis can cause impaired renal function, proteinuria, and the nephrotic syndrome. In addition to these glomerulopathies, SLE can also result in interstitial nephritis and renal vascular disease. Rarely, certain medications (eg, anti-TNFα therapy [infliximab and etanercept], chlorpromazine, diltiazem, hydralazine, interferon-α, isoniazid [INH], minocycline, penicillamine, quinidine, methyldopa, procainamide) can cause drug-induced SLE. Mild forms are not treated, but more severe forms are treated with cytotoxic agents (cyclophosphamide therapy) and prednisone. Renal replacement may be needed in the most severe forms.

TABES DORSALIS

DESCRIPTION Tertiary syphilis involving the dorsal spinal roots and posterior spinal column. This condition can present with voiding dysfunction, presumably due to loss of bladder sensation, with high residual volumes and urinary retention. Urodynamic evaluation reveals detrusor atony and detrusor areflexia. (See Section I: "Syphilis.")

SYNONYMS
- Neurosyphilis
- Tabetic bladder
- Tertiary syphilis

TREATMENT
- Penicillin for syphilis
- Clean intermittent catheterization (CIC) for bladder atony

REFERENCE
Erturk E, Sheinfeld J, Davis RS. Voiding dysfunction in tertiary syphilis. *Urology*. 1987;30(3):284–286.

TAGHAANDAN

DESCRIPTION The practice of forcibly snapping or cracking an erect penis to achieve rapid detumescence. This is a common cause of penile fracture in Middle Eastern countries. In Iran, 69% of penile fractures are due to this mechanism and were encountered at an average of one per wk. Treated as described in Section I: "Penis, Trauma."

REFERENCE
Zargooshi J. Penile fracture in Kermanshah, Iran: Report of 172 cases. *J Urol*. 2000;164(2):364–366.

TAKAYASU ARTERITIS, UROLOGIC CONSIDERATIONS

DESCRIPTION A vasculitis of unknown origin involving mainly major vessels, which results in stenosis and aneurysmal dilatation. Involvement of renal arteries might lead to renovascular hypertension. The disease is progressive and difficult to manage and is often treated and diagnosed with angiography and surgery.

REFERENCES
Di Luccio GM, Lopes de Souza SA, Lopes FP, et al. Self-kidney transplantation in Takayasu arteritis. *Transplantation*. 2012;94(7):e47–e49.

TANNER STAGES/CLASSIFICATION OF SEXUAL MATURITY

DESCRIPTION The Tanner scale defines physical measurements of the onset and development of pubertal changes based on external primary and secondary sex characteristics, such as breast and genitalia development and the growth of pubic hair. It is useful in the evaluation of delayed or precocious puberty.

- **Pubic hair (boys and girls)**
  - Stage 1: Prepubertal (none or vellus hair similar to abdominal wall)
  - Stage 2: Sparse growth of long, slightly pigmented hair, straight or curled, at base of penis or along labia
  - Stage 3: Darker, coarser, and more curled hair, spreading sparsely over junction of pubes
  - Stage 4: Hair is adult in type, but covering smaller area than in adult; no spread to medial surface of thighs
  - Stage 5: Adult in type and quantity, with horizontal distribution (feminine type)
- **External genitalia (boys)**
  - Stage 1: Prepubertal
  - Stage 2: Enlargement of scrotum and testes; scrotum skin reddens and changes in texture
  - Stage 3: Enlargement of penis (length at 1st); further growth of testes
  - Stage 4: Increased size of penis, with growth in breadth and development of glans; testes and scrotum larger, scrotum skin darker
  - Stage 5: Adult genitalia
- **Breast development (girls)**
  - Stage 1: Prepubertal
  - Stage 2: Breast bud stage with elevation of breast and papilla; enlargement of areola
  - Stage 3: Further enlargement of breast and areola; no separation of their contour
  - Stage 4: Areola and papilla form a secondary mound above level of breast
  - Stage 5: Mature stage: Projection of papilla only, related to recession of areola

TERATOMA, SACROCOCCYGEAL, UROLOGIC CONSIDERATIONS

DESCRIPTION Sacrococcygeal tumors are usually diagnosed in the neonate (1 in 40,000 births) and less frequently in infants or adults. Females are more affected than males. Clinical presentation is usually in the form of palpable mass, skin discoloration, or hairy nevus. Related diseases include bilateral hydronephrosis, neurologic deficit, bladder or bowel dysfunction (obstruction or incontinence), high-output cardiac failure, or fet al hydrops. Sacrococcygeal tumors of the newborn are generally benign, whereas those discovered later have a 50% chance of being malignant. Wide, local excision of the tumor is primary management.

sacrococcygeal teratomas. *Pediatr Int.* 2008;50(4):576–580.

TESTICULAR FEMINIZATION SYNDROME

DESCRIPTION Now commonly described as *complete androgen insensitivity syndrome*, this syndrome involves phenotypic women with a 46, XY karyotype and normal development of testes in utero, but with a genetic defect in the androgen receptor that leads to insensitivity to androgens. (See also Section II: "Androgen Insensitivity Syndrome [AIS or Androgen Resistance Syndrome], Complete and Partial.")

REFERENCE

TESTICULAR PROSTHESIS

DESCRIPTION Prosthetic device implanted in the scrotum to help cope with the psychological distress of losing a testicle from torsion, malignancy, trauma, or agenesis. Studies have shown that the improved cosmetic result increases patient self-esteem, body image, and sexual function. Implants were typically made of silicone rubber filled with silicone gel until 1995, when they were taken off the US market due to concerns about the association of silicone and connective tissue disease. Currently, in the United States, the testicular prosthetic of choice is comprised of a silicone rubber shell filled with saline to achieve desired size and consistency. Implantation is fairly simple and well tolerated. It is most commonly placed in a subdartos, subcapsular, or subtunical position. The most common major complication reported was extrusion of the implant, occurring in 2% and the most common minor complication was postoperative discomfort or pain, occurring in 9% of patients (Image ☼).

TESTIS BIOPSY, INDICATIONS

DESCRIPTION Testicular biopsy was once considered a cornerstone in the diagnosis of unexplained male infertility and azoospermia, but its current indications are now limited to a specific subgroup of patients. Current practice guidelines limit biopsy to those with obstructive azoospermia, those who require TESE (testicular sperm extraction), and to confirm the diagnosis of carcinoma in situ (CIS) of the testis. In men with obstructive azoospermia confirmation of the presence of normal spermatogenesis is usually helpful before surgical correction of the obstruction. TESE often requires multiple testicular biopsies for sperm harvesting with part of the specimen to be used for histologic exam. In special

situations where ultrasonographic abnormalities indicate the potential presence of CIS, namely testicular microlithiasis, inhomogeneity, or a solid testicular mass, a testicular biopsy may prove to be helpful before orchiectomy.

TESTIS, CARCINOID

DESCRIPTION Carcinoid tumors of the testis are rare neoplasms that originate from neuroendocrine cells. Most carcinoid tumors are found in the GI tract, particularly in the ileum or appendix. Because of their neuroendocrine precursors, some tumors elicit endocrine activity; 88% secrete 5-hydroxyindoleacetic acid (5-HIAA), a metabolite of serotonin. Carcinoid syndrome results from the vasoactive substances secreted from the tumor and can cause symptoms such as flushing, sweating, wheezing, diarrhea, abdominal pain, and fibrosis of cardiac valves. Carcinoid tumors of the testis can be divided into 3 groups: Primary, metastasis from a primary site, or carcinoid tumor originating from a testicular teratoma. Most patients present with a painless scrotal mass; unlike germ cell tumor (GCT), there is no predilection for a particular age group. ~16% of patients have carcinoid syndrome. Tumors localized to the testis have an excellent prognosis; however long-term follow-up is needed, due to risk of late metastases.

As with all testicular neoplasms, treatment begins with radical orchiectomy, with high ligation of the spermatic cord. Chemotherapy or radiation therapy has been reported, but these treatment modalities have poor efficacy. Octreotide analogs have been reported to stabilize disease progression, as well as help relieve symptoms of carcinoid syndrome. Once discovered, other extratesticular sources of carcinoid tumor should be determined. 5-HIAA can be measured in the urine and can be a useful adjunct. GI endoscopy, CT scan, MIBG scintigraphy, or somatostatin receptor scintigraphy can be used to search for GI sources of carcinoid tumor.

TESTIS, CARCINOMA IN SITU (CIS)/INTRATUBULAR GERM CELL NEOPLASIA (ITGCN)

DESCRIPTION Testicular CIS is considered to be the precursor to all GCT, except for yolk sac tumors and spermatocytic seminoma. CIS may be present during infancy; however, lesions do not proliferate until adolescence, when hormonal influences come into play. Studies have shown that 50% of males with CIS developed invasive tumor growth within 5 yr; virtually all patients with CIS will progress to testicular cancer. Risk factors for testicular CIS are cryptorchidism, contralateral testis cancer, extragonadal GCT, infertility, and intersex patients with a Y chromosome. There is controversy concerning the screening, management, and treatment of testicular CIS. Diagnosis is made through testis biopsy. Treatment options involve surveillance, radiation, and orchiectomy. Cisplatin-based chemotherapy has been

associated with incomplete treatment and recurrence. High-risk patients may be offered testicular biopsy and subsequent treatment, although some physicians would advocate surveillance alone. Surveillance is a viable treatment option due to the long, protracted nature of CIS, the morbidity of treatment options, and the fact that effective treatment of GCT exist. Radiation (14–20 Gy) may be performed in the patient with a testicular tumor and contralateral CIS, or in the patient with bilateral CIS. Orchiectomy is offered to the patient with unilateral CIS and a normal contralateral testis. Extensive counseling regarding the risks and benefits of surveillance vs. biopsy and subsequent treatment is needed. The option to cryopreserve sperm should be offered as well. (See also Section II: “Testis, Microlithiasis” and (Image ☼).)

TESTIS, CYSTIC LYMPHANGIOMAS

DESCRIPTION Testicular cystic lymphangiomas, benign tumors of unknown etiology, are often misdiagnosed as other conditions like hernia, hydrocele, hematocele, varicocele, or possible torsion in children. Lymphangiomas are characterized by an extensive overgrowth of lymphatic vessels; 50% are present at birth, 90% are evident by the age of 2 yr. Gradual painless scrotal swelling is the common symptom. On palpation, the mass may be soft and spongy or firm and tense, usually not separable from the scrotal skin. Skin showing bluish/purplish discoloration or erythematous changes is often present. The ultrasound exam usually shows a complex multilocular septated cystic mass without perfusion. Often, these lesions are more extensive than expected according the preoperative investigations, with deep perineal, inguinal, pelvic, or retroperitoneal involvement. Complete excision is mandatory to prevent recurrence.

REFERENCE

Liniger B, Fleischmann A, Zachariou Z. Benign cystic lesions in the testis of children. *J Pediatr Urol.* 2012;8(3):226–233.

TESTIS, CYSTS

DESCRIPTION Intratesticular cysts, once considered rare, are being reported with an increasing prevalence as a result of the wider use of scrotal ultrasound (8–9.8% incidence in men undergoing ultrasound). Nonneoplastic testicular cysts include hydatid, epidermoid, simple, and cystic dysplasia. Hydatid cysts are rarely seen, except in the Middle East. These are very rare lesions and are generally clinically interpreted as neoplastic, until proven otherwise at the time of postorchiectomy pathology. Treatment has included enucleation and even radical orchiectomy over concern for malignancy. A more conservative approach with serial ultrasound scanning has been advocated if a clear distinction can be made between neoplastic and nonneoplastic testicular cysts. Selected cases can potentially be managed by intraoperative frozen section to demonstrate no malignancy and enucleation of the tumor

performed.

In children, testicular tumors are rare and the majority are benign, especially before puberty. Pediatric simple testicular cysts are very rare, as most cysts occur in men >40 yr. Most can be treated with testicle-sparing surgery. The differential diagnosis of testis cysts in the pediatric population:

- Infancy: Juvenile granulosa cell tumor, simple testicular cyst.
- Early childhood: Prepubertal teratoma, cystic lymphangioma, cystic dysplasia of the rete testis. Teratomas can present as solid, cystic, or mixed solid and cystic lesions and are always almost benign in children.
- In the older child/young adult epidermoid and dermoid cysts predominate (Image ☼).

TESTIS, DERMOID CYST

DESCRIPTION A primary non-germ cell tumor (GCT) representing 1% of testis tumors, with 1/2 of the patients presenting in their 20s. Grossly, the lesions present as encapsulated intratesticular nodules, which are round and sharply circumscribed, with firm consistency. The cut surface reveals a grayish white, cheesy, amorphous mass. The microscopic picture is that of dense fibrous tissue lined by keratinized stratified squamous epithelium with degeneration and macrocalcification. The benign behavior of these tumors is the rule. These are categorized separately from a mature testicular teratoma because of the malignant nature of the latter in postpubertal patients. Testicular ultrasound may aid in this tumor's differentiation from GCT. Most cases have been managed by radical orchiectomy, although local excision has been equally successful in a small number of patients.

REFERENCE

TESTIS, HEMANGIOMA

DESCRIPTION Testicular hemangioma is a very rare neoplasm; only 25 cases are in the English literature. Intratesticular tumors of vascular origin are extremely rare. Intratesticular hemangioma can mimic malignant testicular tumors on presentation and imaging. Testicular hemangiomas histologically comprise 3 types: Cavernous, capillary, and epithelioid. Patients usually present with testicular enlargement with or without tenderness. Although it is impossible to differentiate a hemangioma from a seminoma preoperatively, intraoperative frozen study may be helpful in the differential diagnosis. Frozen section must be performed if

the neoplasm has significant vascular proliferation identified by Doppler sonography. Since the lesion is benign, conservative surgical treatment by means of tumor enucleation with preservation of the testis is possible if intraoperative frozen section exam can be performed.

REFERENCE

Kryvenko ON, Epstein JI. Testicular hemangioma: A series of 8 cases. *Am J Surg Pathol.* 2013;37(6):860–866.

TESTIS, LEUKEMIA

DESCRIPTION Of children with acute lymphocytic leukemia (ALL), 5% will develop testicular disease at initial presentation or at 1st relapse. The testis is a common site of primary relapse (8%) after treatment of ALL. Children with T-cell lymphoblastic leukemia and/or a high initial leukemia cell burden are at higher risk of initial testicular involvement, as well as of testicular relapse. The condition commonly presents as either unilateral or bilateral testicular painless mass or swelling. Diagnosis is made with testicular biopsy.

Irradiation of both testes with 18–24 Gy plus systemic chemotherapy is the standard recommended treatment. Orchiectomy may be considered, depending on the extent of infiltration.

REFERENCE

Gutjahr P, Humpl T. Testicular lymphoblastic leukemia/lymphoma. *World J Urol.* 1995;13(4):230–232.

TESTIS, LYMPHOMA

DESCRIPTION Most common testicular malignancy in men >60, and the most common secondary neoplasms of the testis. Initial presentation is usually painless testicular swelling. Diagnosis is made through orchiectomy. Bilateral involvement occurs in ~50% of cases (10% are synchronous). Treatment is multimodal; orchiectomy is performed, followed by systemic chemotherapy (doxorubicin), CNS prophylaxis, and local radiation. (See also Section II: “Lymphoma, Urologic Considerations" and (Image ☼).)

REFERENCE

Vitolo U, Ferreri AJ, Zucca E. Primary testicular lymphoma. *Crit Rev Oncol Hematol.* 2008;65(2):183–189.

TESTIS, METASTASIS TO

DESCRIPTION Due to the nature of the disease, this metastasis usually presents in men >50. Spread to the testis may be hematogenous, lymphatic, or by direct extension. Most common primary malignancies are prostate, lung, GI tract, melanoma, and kidney cancers (Image ☼).

REFERENCE

Rosevear HM, Mishail A, Sheynkin Y, et al. Unusual Scrotal pathology: An overview. *Nat Rev Urol.* 2009;6(9):491–500.

TESTIS, MICROLITHIASIS

DESCRIPTION Numerous and diffuse calcifications throughout the entire testicle seen on transscrotal ultrasound. Advances in ultrasound technology have led to an increased detection of testicular microlithiasis. It is reported in undescended testicles (0.3% incidence), prepubertal Klinefelter syndrome, and male pseudohermaphroditism, and is slightly more common in prepubertal males. Infertility and malignancy have been reported to be associated with the condition, and some consider it possibly premalignant. Both seminomas and nonsemino-matous GCT have been described in association with microlithiasis. Others suggest an association with carcinoma in situ of the testicle, but this is not settled. Recent studies have a prevalence of 2% in boys who undergo scrotal US, most commonly bilateral, with increased risk of malignancy. Most advocate close surveillance of patients with testicular microlithiasis, such as yearly testicular ultrasound, physical exam, and judicious tumor marker determinations (Image ☼).

TESTIS, NORMAL SIZE

DESCRIPTION Testis size measurements can be made by ultrasound (US) (most accurate) or Prader orchidometer. At birth, testicular length is ~1.5 cm with a volume of 1.1 cm^3. In prepubertal boys, testicular length is usually <2 cm and volume <2 cm^3. Normal testicular size after puberty in an adult is about 4.5–5.5 cm with a volume ranging from 15–30 cm^3.

Keefer JR. Endocrinology. In: Siberry GK, Iannone R, eds. *Harriet Lane Handbook*. 15th ed. St. Louis, MO: Mosby; 2000.

Krone KD, Carroll BA. Scrotal ultrasound. *Radiol Clin North Am.* 1985;23:121–139.

TESTIS, RETRACTILE

DESCRIPTION A testicle that can ride high in the scrotum or near the external inguinal ring; caused by a brisk cremasteric reflex. The testicle is able to be gently manipulated into the scrotum. Usually considered a variant of normally descended testes, 32% of retractile testes may ultimately become undescended (ascending or acquired undescended), and this is seen more frequently in boys <7 yo. Boys with retractile testes should be followed annually until the outcome of descent or nondescent is clear, which in many cases won't be until puberty.

REFERENCE

Agarwal PK, Diaz M, Elder JS. Retractile testis: Is it really a normal variant? *J Urol.* 2006;175(4):1496–1499.

TESTIS, SEX CORD STROMAL TUMORS

DESCRIPTION These tumors arise from the supporting structures of the testis and not the germ cells. They usually present as a mass, are rarely hormonally active, and do not produce tumor markers such as hCG. Leydig cell tumors comprise about 3% of testicular neoplasms. They occur in both adults (80% of cases) and children. Sertoli cell tumors (<1% of testicular tumors) can be found in children and middle-aged adults, and ~10% can be malignant. Granulosa cell tumor is usually found in older men and can present with gynecomastia. The testicular juvenile granulosa cell tumor is the most common neoplasm of the testis in the 1st 6 mo of life (yolk sac tumors peak after 6 mo). Other tumors sometimes placed in this category include malignant mesothelioma of the tunica vaginalis, paratesticular rhabdomyosarcoma, and adenocarcinoma of the rete testis.

REFERENCE

Young RH. Sex cord-stromal tumors of the ovary and testis: Their similarities and differences with consideration of selected problems. *Mod Pathol.* 2005;18:S81–S98.

TESTIS, TERATOMA, EXTRAGONADAL

DESCRIPTION Primary tumors of extragonadal origin are rare. In a decreasing order of frequency, the most common sites are the mediastinum, retroperitoneum, sacrococcygeal region, and pineal gland. Theories include a displacement of primitive germ cells that takes place during early embryonic migration from the yolk sac endoderm, and pluripotential cells that persist in sequestered primitive rests during early somatic development. Histologically, all types of GCT are represented, with pure seminoma accounting for 1/2 of mediastinal and retroperitoneal tumors. Clinically, males are affected more often than females, with the exception of sacrococcygeal tumors, where females predominate. The majority of adults present with advanced local disease and distant metastasis. Patients with mediastinal extragonadal tumors are usually diagnosed in their 20s, with or without symptoms of chest pain, cough, or dyspnea. Patients with primary retroperitoneal tumors may present with abdominal or back pain, a palpable mass, or vascular obstruction. Tumors of the pineal gland usually present in children and young adults, with symptoms of increased intracranial pressure, oculomotor dysfunction, hearing loss, hypopituitarism, or hypothalamic disturbances. Fine needle aspiration (FNA) can be used to assist in the diagnosis, but carries the risk of insufficient cellular return. When suspicion for teratoma exists, it is important to differentiate between mature and immature teratoma as immature carries the risk of malignant transformation.

TREATMENT

- Intensive chemotherapy regimens have shown some success in primary retroperitoneal seminoma.
- The nonseminomatous version has done poorly despite surgery, radiotherapy, and chemotherapy.
- Primary radiation therapy has been much favored for pineal tumors (a CSF shunt may be required).

TESTIS, VASOCONGESTION FROM SEXUAL AROUSAL WITHOUT EJACULATION ("BLUE BALLS")

DESCRIPTION "Blue balls" is a colloquialism describing scrotal pain after sustained sexual arousal unrelieved because of lack of orgasm and ejaculation. This term has only been referred to in the pediatric literature. It is likely due to vasocongestion of the external genitalia associated with the physiology of sexual arousal but no formal studies are available in the peer-reviewed literature. As noted by Chalett and Neremberg "The medical literature completely lacks acknowledgment of condition." This is suspected to be more common among young male adults and should be considered in the differential diagnosis of acute testicular/scrotal pain in such patients.

REFERENCES
Chalett JM, Nerenberg LT. Blue balls: A diagnostic consideration in testiculoscrotal pain in young adults: A case report and discussion. *Pediatrics*. 2000;106:843–844.

TESTOSTERONE (FREE AND TOTAL) SERUM

DESCRIPTION Measurement of serum testosterone is most commonly used as the initial test for hypogonadism in males; it is less commonly used in the evaluation of virilism and hirsutism in females. Testosterone assays should be collected from 8–11 AM, due to higher morning plasma levels from the typical male circadian rhythm. In males, increased testosterone levels can be found in complete androgen resistance (testicular feminization syndromes). Decreased levels occur in hypogonadism, surgical orchiectomy, estrogen or LHRH analog or antagonist therapy, Klinefelter syndrome, hypopituitarism, and hepatic cirrhosis:

- Generally accepted normal ranges total testosterone (may vary by lab):
  - Prepubertal children: 5–20 ng/dL (0.17–0.7 nmol/L)
  - Men (≥17 yr): 300–1,000 ng/dL (10.4–34.7 nmol/L)
  - Women: 20–70 ng/dL (0.7–2.6 nmol/L)
- A total testosterone level (free plus protein bound) of <200 ng/dL (or 6.9 nmol/L) (American Association of Clinical Endocrinologists) or <300 ng/dL (or 10 nmol/L) (FDA) is associated with hypogonadism and warrants further workup in an adult.
- Free testosterone (adult male range 8.8–27 pg/mL) is a useful diagnostic test as well, as elevated or decreased sex hormone binding globulin (SHBG) changes the bioavailability of testosterone. It can be used as an adjunct to the patient with low total testosterone levels. For example, obesity is characterized by reduced total testosterone and normal free testosterone due to reduced protein binding.

- Serum SHBG concentrations increase with age. With increasing age, less of the total testosterone is free or biologically active, as SHBG binds testosterone with high affinity.
- Serum T peaks early morning and then declines over the course of the day until the nadir in the evening (15% lower than morning values, but may vary up to 50% in younger men).
- Testosterone replacement monitoring: For men on transdermal T preparations measure at any time; for men on injectable T measure T midway between injections. Target T should generally be in the range of 400–700 ng/dL (13.9–27.7 nmol/L). If higher, the dose should be reduced.
- Methods used to measure T: Radioimmunoassay (RIA), Enzyme-linked Immunoassay (EIA) and Liquid Chromatography-Mass Spectroscopy (LC-MS) with the AUA and other organizations working to establish standardization of assay methods.

TESTOSTERONE REPLACEMENT FOLLOWING LOCALIZED PROSTATE CANCER THERAPY

DESCRIPTION Both prostate cancer and hypogonadism become more prevalent as men age; up to 20% of men who undergo radical prostatectomy (RP) are found to be hypogonadal and many men who receive combined hormonal ablation and radiation may not recover testosterone to pre treatment levels. Patients with hypogonadism may have decreased muscle mass, ED, osteopenia, decreased libido, depression, and possibly increase cardiovascular risk. Studies have shown that TRT does not increase the risk of prostate cancer development in men with both normal and increased risk. In addition, in limited series, postprostatectomy testosterone replacement does not correlate with biochemical recurrence or increases in PSA. TRT may help to preserve erectile function and improve quality of life, but the supplementation of testosterone in hypogonadal men after treatment for prostate cancer remains controversial. All testosterone replacements in the United States contain warnings concern the use with a history of prostate cancer. The 2012 European Association of Urology (EAU) Guidelines are as follows:

- Following RP and without evidence of disease with symptoms of testosterone deficiency man can be cautiously considered for TRT
- Approach is considered “off label”
- Restrict to low risk: Preop Gleason <8; pT1-2; PSA <10 ng/mL
- Wait 1 yr postop
- With radiation therapy for prostate cancer if low-risk and hypogonadism, use TRT cautiously with monitoring (See also Section I: “Testosterone Replacement Therapy, General Principles.”)

TESTOSTERONE REPLACEMENT THERAPY, PROSTATE CANCER RISK

DESCRIPTION Multiple published review articles have shown that testosterone replacement therapy (TRT) does not cause prostate cancer or place patients at increased risk for the development of prostate cancer. A recent audit of the UK Androgen Study showed that initiating testosterone treatment had no statistically significant effect on the incidence of prostate cancer. These findings from this study show that, with careful monitoring, men with symptoms of testosterone deficiency can be treated safely with TRT without an increased risk of developing or progressing already present prostate cancer. (See also Section I: "Testosterone Replacement Therapy, General Principles.")

TETHERED CORD

DESCRIPTION Tethered cord is an acquired or congenital occurrence that results from tissue attachments causing restriction of the normal movement of the spinal cord. It is most often seen in patients with spina bifida or meningomyelocele who have undergone surgical closure of the spine. This may result in scar tissue formation that adheres to the spinal cord. Patients may also present with a congenital tethered cord, mostly seen in patients with spina bifida occulta. As the child moves or grows, the tethered spinal cord is stretched, causing direct trauma to the cord, as well as compromising blood flow by stretching blood vessels. Tethering may also occur after spinal cord injury (SCI) when scar tissue prevents fluid flow around the cord. This causes pressure to build up, as well as cyst formation. The degree of tethering and strain placed on the spinal cord is correlated to severity and time of presentation of symptoms. The constellation of symptoms caused by a tethered cord is called *tethered cord syndrome*. (See also Section I: "Myelodysplasia [Spinal Dysraphism], Urologic Considerations" and Section II: "Tethered Cord Syndrome" and "Spina Bifida/Spina Bifida Occulta, Urologic Considerations.")

REFERENCE

Agawalla PK, Dunn IF, Scott RM, et al. Tethered cord syndrome. *Neurosurg Clin N Am.* 2007;18(3):531–547.

TETHERED CORD SYNDROME

DESCRIPTION Late sequelae of spinal dysraphism, in which fixation or scarring of the spinal cord and conus medullaris, due to prior spinal surgery, prevents normal cephalad migration of spinal cord with childhood growth and causes spinal cord ischemia. Usually

manifests with changes in voiding pattern, or with neurologic or musculoskelet al deficits. Urodynamic evaluation typically reveals detrusor hyperreflexia or detrusor areflexia. Detrusor-external sphincter dyssynergia or poor detrusor compliance with elevated bladder pressure can also be seen and warrant aggressive intervention. MRI is usually diagnostic. (See also Section I: "Myelodysplasia [Spinal Dysraphism], Urologic Considerations" and Section II: "Tethered Cord" and "Spina Bifida/Spina Bifida Occulta, Urologic Considerations.")

TREATMENT

- Surgery to untether spinal cord
- Urologic intervention, based on urodynamic findings

REFERENCE

Palmer LS, Richards I, Kaplan WE. Subclinical changes in bladder function in children presenting with nonurologic symptoms of the tethered cord syndrome. *J Urol.* 1998;159(1):231–234.

THIERSCH-DUPLAY HYPOSPADIAS REPAIR

DESCRIPTION The distal urethral plate is tubularized to advance the meatus. The glans is reapproximated over the repair. Thiersch urethroplasty is the most commonly performed technique after surgical correction of penoscrotal transposition.

REFERENCE

Sunay M, Emir L, Karabulut A, et al. Our 21-year experience with the Thiersch-Duplay technique following surgical correction of penoscrotal transposition. *Urol Int.* 2009;82(1):28–31.

THOMPSON PYELOPLASTY

DESCRIPTION A surgical procedure initially introduced in 1969 that is used when insufficient renal pelvis is available to close lesions due to trauma or scarring. A triangular flap of renal capsule is sharply developed, then flipped over onto the renal pelvic opening and closed with 5-0 chromic sutures.

REFERENCES

Thompson IM, Baker J, Robards VL Jr, et al. Clinical experience with renal capsule flap pyeloplasty. *J Urology*. 1969:101:487–490.

THORACIC KIDNEY

DESCRIPTION A type of renal ectopia in which the kidney is found in the posterior mediastinum, partially or completely above the level of the diaphragm. The diaphragm is thin, yet envelops the protruding kidney, keeping it separate from the pleural cavity. Aside from the ectopic location, the renal anatomy is essentially normal; the kidney is usually not malrotated. The ureter may be longer due to its higher position, however it inserts into the

bladder orthotopically. Similarly, the renal vessels usually arise from their normal origins, although in some cases they may insert in a position more cranially. The vast majority of patients are asymptomatic. (See also Section I: "Renal Ectopia.")

REFERENCE

Donat SM, Donat PE. Intrathoracic kidney: A case report with a review of the world literature. *J Urol.* 1988;140(1):131–133.

TINEA CRURIS (JOCK ITCH)

DESCRIPTION Dermatophytic infection of the crural areas of the genitalia. Caused by dermatophytes *Trichophyton rubrum, Trichophyton mentagrophytes,* and *Epidermophyton floccosum.* Clinically, reddish brown lesions with an elevated red border can be identified in the crural area, inner thigh, and scrotum. Penis involvement is rare. Postinflammatory hyperpigmentation may occur as a result of chronic or recurrent disease. Culture or KOH exam is necessary to confirm diagnosis. Scraping should be performed on the active border of the lesion and reveals branching septate hyphae. Differential diagnosis includes erythrasma, psoriasis, and seborrheic dermatitis. Recurrent disease is not unusual, and treatment should be aimed toward active disease rather than postinflammatory hyperpigmentation. (See also Section II: "Pruritus, External Genitalia, Male.")

TREATMENT

- Prevent skin maceration by keeping skin dry.
- Apply antifungal agents on overt lesions. Agents include Lotrimin, Mycelex, Loprox, Spectazole, Lamisil, and others for up to 14 days.
- Rarely, oral agents may be needed if topical agents fail: Ketoconazole (Nizoral) for 14 days (requires baseline lab monitoring CBC, LFTs).

REFERENCE

TMPRSS2-ERG GENE FUSION, PROSTATE CANCER

DESCRIPTION Fusion of the transmembrane protease, serine 2 (TMPRESS2) and erythroblastosis virus E26 (ERG) genes is known as the TMPRSS2-ERG gene fusion. It is present in up to 80% of human prostate cancers. This gene fusion contributes to development of androgen-independence in prostate cancer through disruption of androgen receptor signaling. TMPRSS2:ERG, in combination with urine prostate cancer antigen 3 (PCA3), improved the performance of Prostate Cancer Prevention Trial risk calculator in predicting cancer on biopsy. The men were stratified into 3 groups based upon the levels of TMPRSS2:ERG and PCA3 in their urine: low, intermediate and high. Prostate cancer was diagnosed in each of the groups, respectively: 21%, 43%, and 69%. High-grade prostate cancer (>Gleason score), was diagnosed 7%, 20%, and 40% in each group, respectively. TMPRSS2:ERG and PCA3 urine analysis appears to enhance the utility of serum PSA for predicting prostate cancer risk and clinically relevant cancer on biopsy. (See also Section II: "PCA3 [Prostate Cancer Gene 3] Urine Assay.")

REFERENCE

Tomlins SA, et al. Urine TMPRSS2:ERG Fusion Transcript Stratifies Prostate Cancer Risk in Men with Elevated Serum PSA *Sci Transl Med* 3 August 2011: Vol. 3, Issue 94, p. 94.

TOILETING PROGRAMS

DESCRIPTION Type of behavioral training to treat urinary incontinence. The patient is instructed to establish a routine voiding schedule regardless of the sensation to void. Initially, the patient is told to void at frequent intervals (eg, every 1 hr); the time between voids is then slowly increased, usually until he or she establishes an acceptable period (usually 2–4 hr) of continence.

REFERENCE

Wallace SA, Roe B, Williams K, et al. Bladder training for urinary incontinence in adults. *Cochrane Database Syst Rev*. 2004;(1):CD001308.

TRANSESOPHAGEAL ECHOCARDIOGRAM (TEE), UROLOGIC CONSIDERATIONS

DESCRIPTION A useful diagnostic tool in the management of renal tumors with tumor thrombus; the TEE is used to identify the extent of tumor thrombus involvement in the inferior vena cava. This may be used for preoperative surgical planning or may be used intraoperatively as well.

REFERENCE

Zini L, Haulon S, Decoene C, et al. Renal cell carcinoma associated with tumor thrombus in the inferior vena cava: Surgical strategies. *Ann Vasc Surg.* 2005;19(4):522–528.

TRANSURETEROURETEROSTOMY, TECHNIQUE AND INDICATIONS

DESCRIPTION Transureteroureterostomy (TUU) is an alternative surgical technique used to treat distal ureteral strictures that are not amenable to more conventional reconstruction techniques. It is useful in patients with a history of prior pelvic radiation or in those with an obstructing pelvic malignancy. There must be adequate length of diseased ureter proximal to the strictured segment to allow a tension free anastomosis. Relative contraindications include patients with upper tract urothelial carcinoma, nephrolithiasis, retroperitoneal fibrosis, chronic pyelonephritis, and bladder pathology—including reduced bladder capacity, thickened bladder wall, or invasion carcinoma. In addition, reflux to the recipient ureter needs to be identified preoperatively with a voiding cystourethrogram and treated, if present.

TUU is performed through a midline incision where the diseased ureter is mobilized and divided just proximal to the strictured segment. A tunnel is then created under the mesentery of the sigmoid colon and the recipient ureter is incised anteriomedially. The spatulated donor ureter is then anastomosed to the recipient in a tension free end-to-side fashion over an indwelling double J ureteral stent.

TRANSSEXUALISM, UROLOGIC CONSIDERATIONS

DESCRIPTION Transsexualism, also known as *gender identity disorder*, is the strong desire to be and also identify with the opposite sex, which includes the desire to change the body hormonally and/or surgically to be similar to the aspired sex. This disorder causes severe impairment and distress. Treatment is multidisciplinary, and starts with an evaluation with an experienced mental health professional to discuss initiating hormonal and/or surgical procedures that are long-term and irreversible. Consultation with plastic surgeons, urologists, and gynecologists in high-volume centers is essential. Genital sex reassignment surgeries are available for male-to-female patients, and involve clitoroplasty, vulvuloplasty, and vaginoplasty. However, no consensus operative standard has been agreed upon regarding female-to-male reassignments, particularly regarding neophallus creation.

TRI-MIX

DESCRIPTION A custom-compounded formulation for intracorporal injection therapy of erectile dysfunction (ED). Typically consists of prostaglandin E1 (5.88 g/mL), papaverine (18 mg/mL), and phentolamine (0.6 mg/mL), but no dosage is considered standardized. It is usually administered to patients who cannot receive prostaglandin E1 injection alone due to lack of response.

REFERENCE

TRICHOMONIASIS

DESCRIPTION Sexually transmitted infection caused by the protozoan *Trichomonas vaginalis*. It is a rare cause of nongonococcal urethritis in men, common cause of vaginitis in women (from 4–35%). It is associated with a high prevalence of coinfection with other STDs. Signs and symptoms include urethral discharge, dysuria, and the presence of neutrophils in urethral secretions. Some women have symptoms characterized by a diffuse, malodorous, yellow-green vaginal discharge with vulvar irritation. However, many women have minimal or no symptoms. Because of the high prevalence of trichomoniasis in clinical and non-clinical settings, testing for *T. vaginalis* should be performed in women seeking care for vaginal discharge. *T. vaginalis* has, if any, only minor influence on male fertility. In women, it can

cause premature rupture of the membranes and preterm delivery, as well as tubal infertility and cervical neoplasia. Females may have an elevated vaginal pH of >4.5. A positive diagnosis is made by identification of the protozoan on wet mount (must be examined in <10–20 min). Culture on Diamond's medium may take up to 7 days; a more rapid commercial culture method is available (InPouch*T. vaginalis* culture system, with results in 3 days). FDA-cleared tests for trichomoniasis in women include OSOM Trichomonas Rapid Test (Genzyme Diagnostics, Cambridge, Massachusetts), an immunochromatographic capillary flow dipstick technology, and the Affirm VP III (Becton Dickenson, San Jose, California), a nucleic acid probe test that evaluates for*T. vaginalis, G. vaginalis, and C. albicans*. Each of these tests, which are performed on vaginal secretions, have a sensitivity of >83% and a specificity of >97%. Both tests are considered point-of-care diagnostics. Treatment is metronidazole 2 g PO or Tinidazole 2 g orally in a single dose for patient and sexual partners. It is not considered mandatory to identify the organism in partners before treating (CDC Expedited partner therapy). Metronidazole gel is considerably less efficacious for the treatment of trichomoniasis (<50%) than oral preparations of metronidazole. Topically applied antimicrobials (eg, metronidazole gel) are unlikely to achieve therapeutic levels in the urethra or perivaginal glands; therefore, use of this gel is not recommended. (See also Section I: "Sexually Transmitted Infections [STIs]; Sexually Transmitted Diseases [STDs], General"; Section II: "Vaginal Discharge, Urologic Considerations" and "Vaginosis" and (Image ☼).)

TRICHOTEMNOMANIA, PUBIC

DESCRIPTION Trichotemnomania is the obsessive compulsive habit of cutting or shaving hair that often includes the pubic area. It is considered a willful self-induced type of isolated alopecia. It is a distinct disorder that should not be confused with trichotillomania (pulling hair). Behavioral counseling is indicated. (See also Section II: "Trichotillomania, Pubic.")

REFERENCE

Happle R. Trichotemnomania: Obsessive-compulsive habit of cutting or shaving the hair. *J Am Acad Dermatol*. 2005;52(1):157–159.

TRICHOTILLOMANIA, PUBIC

DESCRIPTION Trichotillomania is defined by the Diagnostics and Statistic Manual of Mental Disorders, 4th edition (DSM-IV) as hair loss from a patient's repetitive self-pulling of hair leading to a noticeable loss of hair. Any body area, including the pubic region, can be involved. The disturbance causes clinically significant distress or impairment in social, occupational, or other important areas of functioning. Most individuals start pulling their hair during childhood or adolescence and may also consume the hair. Anxiety, depression and obsessive–compulsive disorders are frequently encountered in patients with trichotillomania. Treatment is a combination of education, behavior therapy and if necessary medication such as antidepressants. (See also Section II: "Trichotemnomania, Pubic.")

REFERENCE

Sah DE, Koo J, Price VH. Trichotillomania. *Dermatol Ther.* 2008;21(1):13–21.

TRIGONITIS

DESCRIPTION Sometimes referred to as *Pseudomembranous trigonitis,* this is a common cause of microscopic hematuria in women. Nonkeratinized squamous epithelium is commonly seen on the trigone and bladder neck in up to 86% of women of reproductive age and in up to 75% after menopause. Considered a normal finding and distinct from squamous metaplasia, which is considered a premalignant lesion. Cystoscopically, these are pale white-gray areas with irregular borders. This condition is not seen in men, except for some reports in men receiving estrogens for prostate cancer. Treatment is not necessary. (See also Section II: "Squamous Metaplasia, Genitourinary.")

TRISOMY 4 P

DESCRIPTION This trisomy features hypertelorism and GU anomalies in the form of hydronephrosis, hypospadias, and undescended testes.

REFERENCE

Barakat AY, Seikaly MG, Der Kaloustian VM. Urogenital abnormalities in genetic disease. *J Urol.* 1986;136:778–785.

TRISOMY 8

DESCRIPTION A trisomy associated with a large, square head; a prominent forehead; widely spaced eyes; a slender body; and GU anomalies in the form of hydronephrosis, horseshoe kidney, reflux, hypospadias, and undescended testis. Males are more frequently affected than females. In the absence of serious problems, life expectancy is normal. Complete trisomy 8 is lethal and often results in miscarriage during the 1st trimester.

REFERENCE

Hale NE, Keane JF Jr. Piecing together a picture of trisomy 8 mosaicism syndrome. *J Am Osteopath Assoc.* 2010;110(1):21–23.

TRISOMY 9

DESCRIPTION This trisomy is characterized by a small cranium and GU anomalies in the form of renal hypoplasia and hypospadias.

REFERENCE

Barakat AY, Seikaly MG, Derkaloustian VM. Urogenital abnormalities in genetic disease. *J Urol.* 1986;136:778.

TRISOMY 9 P

DESCRIPTION This trisomy produces strabismus and GU anomalies in the form of a pancake kidney and undescended testis.

REFERENCE

TRISOMY 10 Q

DESCRIPTION A trisomy characterized by oval, flat face and GU anomalies in the form of hydronephrosis and small penis.

REFERENCE

Mininberg D. The genetic basis of urologic disease. *AUA Update Series*. 1992;9:218.

TRISOMY 11 Q

DESCRIPTION A trisomy producing flat nose, wide glabella, cleft lip/palate, and micropenis.

REFERENCE

Mininberg D. The genetic basis of urologic disease. *AUA Update Series*. 1992;9:218.

TRISOMY 13

DESCRIPTION This trisomy is associated with polydactyly, congenital heart disease, and cystic kidney.

REFERENCE

Barakat AY, Seikaly MG, Der Kaloustian VM. Urogenital abnormalities in genetic disease. *J Urol*. 1986;136:778–785.

TRISOMY 18 (EDWARDS SYNDROME)

DESCRIPTION A trisomy producing hypertonia and GU anomalies in the form of hydronephrosis and small penis. Hypoplasia of the labia majora may cause a false impression of a large clitoris.

REFERENCE

Barakat AY, Seikaly MG, Der Kaloustian VM. Urogenital abnormalities in genetic disease. *J Urol*. 1986;136:778–785.

TRISOMY 20 P

DESCRIPTION A trisomy characterized by short nose, dental abnormalities, vertebral abnormalities, and polycystic kidney.

REFERENCE
Mininberg D. The genetic basis of urologic disease. *AUA Update Series.* 1992;9:218.

TRISOMY 21

DESCRIPTION See Section II: "Down Syndrome, Urologic Considerations."

TRISOMY 22

DESCRIPTION A trisomy producing microcephaly, low-set ears, cleft palate, beaked nose, and microphallus.

REFERENCE
Mininberg D. The genetic basis of urologic disease. *AUA Update Series.* 1992;9:218.

TRISOMY SYNDROME

DESCRIPTION A congenital condition characterized by the presence of 3 instead of the normal pair of homologous or sex chromosomes; these disorders often result in a wide range of phenotypical expressions, including GU anomalies. Examples include trisomy 13 and 18, which produce cryptorchidism; trisomy 4p and 9p, which produce micropenis; and trisomy 7, which is associated with sporadic papillary RCC.

REFERENCE

TRUE HERMAPHRODITISM (OVO-TESTICULAR DISORDER OF SEXUAL DIFFERENTIATION [OVO-DSD])

DESCRIPTION True hermaphrodite or ovo-testicular disorder of sexual differentiation (OVO-DSD) is 1 of the rarest variety of all disorders of sexual differentiation. Up to 90% have 46, XX karyotype with infrequent 46, XY/46, XX mosaicism and 46, XY. The gonads are asymmetrical having both ovarian and testicular differentiation on either sides separately or combined as ovotestis. In ovotestis, testis is always central and ovary polar in location. Testosterone and müllerian inhibitory substance (MIS) are either normal or low. However, for final diagnosis there must be histologic documentation of both types of gonadal epithelium. On the basis of location of gonads and histology these patients are classified as:

- Lateral: Testis and contralateral ovary (30%).
- Bilateral: Testicular and ovarian tissue identified on both sides, usually as ovotestis (50%).
- Unilateral: Ovotestis on 1 side and testis or ovary on other side (20%).

The commonest presentation is an abnormal external genitalia ranging from normal male to normal female. In many of these cases such distinction may not be present and chordee, hypospadias and cryptorchidism may be noted. Proper gender assignment to a neonate born with DSD is a social emergency of the newborn period. A few cases of malignancies like dysgerminoma and gonadoblastoma have been reported. (See also Section I: "Disorders of Sexual Development [DSD].")

TUBERCULOSIS, BLADDER AND URETHRA

DESCRIPTION The hematogenous dissemination of TB can affect the entire urinary system. Bladder TB is caused by a descending infection from renal TB. Urethral TB is rare and can present as periurethral fistulas and abscess. Symptoms include urinary frequency, urgency, and dysuria, with mucosal ulcerations and thickening, and diminished bladder capacity. (See also Section I: "Tuberculosis, Genitourinary.")

DIAGNOSIS

- Urine culture of acid-fast bacilli: Typically 1st morning void, requires multiple sequential cultures.
- Urethral TB is typically diagnosed on biopsy.
- Imaging such as IVU and CT may be normal, but can aid in diagnosis.

TREATMENT

- Combination antituberculous treatment: Typical regimen: 6 mo of rifampicin, isoniazid, pyrazinamide, and ethambutol
- Urethral TB may require suprapubic cystostomy tube drainage and urethral dilation for stricture.

REFERENCE
Raghavaiah NV. Tuberculosis of the male urethra. *J Urol*. 1979;122(3):417–418.

TUBERCULOSIS, MALE EXTERNAL GENITALIA

DESCRIPTION Rare manifestation of TB that may present as a papulonecrotic ulcer, tubercular cavernositis, or a solid nodule, which may be clinically indistinguishable from malignant disease. Diagnosis is confirmed on biopsy. Treatment is systemic antituberculous medication. (See also Section I: "Tuberculosis, Genitourinary.")

REFERENCE
Wu WC, Chen SC, Hsieh JT, et al. Penile tuberculosis associated with monoclonal gammopathy of undetermined significance. *J Formos Med Assoc*. 2006;105(9):753–755.

TUBERCULOSIS, PROSTATE AND EPIDIDYMIS

DESCRIPTION A recent case study of an HIV and tuberculosis (TB) population noted that 10% of genitourinary tuberculosis involves the testicle or prostate. Tuberculous prostatitis can present with an elevated PSA, irritative voiding symptoms, and a hard, nodular prostate. Tissue exam can distinguish it from carcinoma. Prostate involvement is thought to spread hematogenously. Another case report of post mortem tuberculosis patients showed that 10–14% of patients who died from TB had asymptomatic tuberculous prostatitis. Tuberculous epididymitis can be diagnosed with a urine culture positive for acid fast bacilli, a swollen, painful epididymis, and/or ultrasound findings showing edema predominantly in the tail of

the epididymis with marked heterogeneity. The presence of pulmonary or renal disease provides indirect evidence for the diagnosis. Spread of TB to the epididymis is controversial but is thought to occur either hematogenously, through lymphatics, retrograde from the urethra, or by direct extension. Conjugal transmission has been reported as well. (See also Section I: "Tuberculosis, Genitourinary, General Considerations.")

REFERENCE

Wise GJ, Shteynshlyuger A. An update on lower urinary tract tuberculosis. *Current Urology Reports.* 2008(9):305–313.

TUBEROUS SCLEROSIS

DESCRIPTION An autosomal dominant disease mapped to chromosome 16 or 9 that clinically presents with a classic triad of epilepsy, mental retardation, and adenoma sebaceum. Named for the tubers or periventricular calcifications seen on CT scan. Adenoma sebaceum describes the facial angiofibromas around nasolabial regions and cheeks. The renal system may be free of anomalies or may display cysts (10%), angiomyolipomas (AML) in (40–80%), or both. AML can bleed, with increasing risk at 3.5 cm. Renal failure is a result of parenchymal compression by expanding cysts. Hypertension may also occur. Renal cell carcinoma (RCC) is present in 2% of patients. (See also Section I: "Renal Angiomyolipoma.")

SYNONYMS

- Tuberous sclerosis complex
- Bourneville disease

TREATMENT

- Absolute indications for intervention include suspicion of malignancy, hemorrhage with significant hypotension or symptoms, persistent hematuria.
- Symptomatic AML or lesion >4 cm: Selective arterial embolization or nephron-sparing surgery.
- Surveillance best for lesions <4 cm.
- Embolization is 1st-line treatment for acute hemorrhage from AML.
- mTOR inhibitors are under study.

REFERENCE

Wong IY, Shortliffe LD. The management of renal angiomyolipomas in a patient with tuberous sclerosis. *Nat Clin Pract Urol.* 2009;6(3):168–172.

TUMOR LYSIS SYNDROME (TLS)

DESCRIPTION A syndrome associated with chemotherapy, radiation, and other treatments in which massive tumor lysis occurs, with subsequent release of large amounts of potassium, phosphate, and nucleic acids that are converted to massive amounts of uric acid. More commonly associated with chemotherapy of lymphomas and leukemias, it can be seen with any tumor type. Extensive metastatic tumor, pretreatment renal impairment, and markedly elevated LDH concentrations have been reported to be serious risk factors in developing TLS. Lab investigations would reveal hyperkalemia, hypocalcemia, hyperphosphatemia, and

concurrent metabolic acidosis, as well as severe hyperuricemia with eventual renal failure. If these patients are being treated with allopurinol, they are at risk of ARF and xanthine stone formation (See also Section II: "Nephropathy, Urate and Xanthine"; "Urolithiasis [Xanthinuria]."")

TREATMENT

- Prevention with adequate hydration (urine output of $>80–100$ mL/m^2/h).
- Cautious use of rasburicase; some recommend allopurinol.
- Urinary alkalinization should not be done, as it may cause further precipitation of calcium phosphate in the kidney and other tissues.

REFERENCE

Coiffier B, Altman A, Pui CH, et al. Guidelines for the management of pediatric and adult tumor lysis syndrome: An evidence-based review. *J Clin Oncol.* 2008;26(16):2767–2778.

TUNICA VAGINALIS TUMORS

DESCRIPTION Malignant mesothelioma of the tunica vaginalis is rare (0.3–5% of all malignant mesotheliomas) and often fatal. However, increased frequency has been reported since 1980. Most of the patients are 40–79 yr of age, with prior exposure to asbestos being reported in some. Microscopically, mesothelioma may be epithelial, fibrous, or a combination of both. The malignant nature of the disease is indicated by its frequent mitosis, nuclear atypia with prominent nucleoli, and invasion of adjacent structures or lymphatics. Positive staining with keratin and failure to stain with CEA indicate mesothelioma. In addition, an immunoperoxidase stain has been reported to be specific for the tumor. CT and aspiration cytology may aid in preoperative diagnosis. The most important differential diagnostic considerations include mesothelial hyperplasia, adenomatoid tumor, carcinoma of the rete testis, and serous papillary tumors. The prognosis for this entity is grave, with a median survival of 23 mo and aggressive therapy with radical orchiectomy remains the mainstay of treatment. Adjunct chemotherapy may be tried. However, its value has not been established. (See also Section I:"Paratesticular Tumors" and "Scrotum and Testicle, Mass.")

TURNER SYNDROME (XO SYNDROME)

DESCRIPTION A sex chromosome abnormality with a 46, XO karyotype. It is the most common sex chromosome abnormality with an incidence of 1:10,000 newborn females. Neonates may have lymphedema. Clinically, patients present with short stature, primary amenorrhea, webbed neck, shield-like chest, streak gonads, hypertension, and coarctation of the aorta. GU anomalies include horseshoe kidney, anomalous blood supply to the kidney, and infantile genitalia. The external genitalia are female but immature, and most women with Turner syndrome are infertile. Karyotype analysis should be performed to confirm the diagnosis. Any patient with Turner syndrome who presents with virilization should also be

evaluated for Y-chromosome mosaicism, as these individuals are at increased risk of gonadoblastoma or germ cell tumor.

TREATMENT

- Echocardiography at diagnosis to detect cardiovascular anomalies (coarctation of the aorta or a bicuspid aortic valve are most common causes of morbidity and mortality)
- Renal US to determine if GU abnormalities are present
- Hormonal therapy in the form of growth hormone, estrogen, and medroxyprogesterone, aimed toward maximizing final height, induction of secondary sexual characteristics, and menarche

REFERENCE

Stochholm K, Juul S, Juel K, et al. Prevalence, incidence, diagnostic delay, and mortality in Turner syndrome. *J Clin Endocrinol Metab*. 2006;91(10):3897–3902.

TURNER–WARWICK INLAY URETHROPLASTY

DESCRIPTION Through a midline scrotal incision, the urethral stricture is opened and scarred tissue is removed, leaving a strip of urethra in place. The edges of the scrotal incision are sutured to the urethral strip. In a 2nd stage, the mature marsupialized urethra is tubularized with the surrounding scrotal skin and closed.

REFERENCE

Devine CJ, Devine PC. Operations for urethral stricture. In: Novick AC, Streem SB, Pontes JE, eds. *Stewart's Operative Urology*. Baltimore, MD: Williams & Wilkins; 1989:550–680.

UISS-UCLA INTERNATIONAL KIDNEY CANCER STAGING SYSTEM

DESCRIPTION A prognostic system for renal cell carcinima (RCC) to differentiate survival; the system integrates the 3 most commonly used prognostic factors: Cancer TNM stage, Furman grade, and patient performance status. Patients are categorized after nephrectomy into 3 risk groups: Low-, intermediate-, and high-risk for localized and metastatic disease.

REFERENCE

Escudier B, Eisen T, Porta C, et al. Renal cell carcinoma: ESMO Clinical Practice Guidelines for diagnosis, treatment and follow-up. *Ann Oncol*. 2012;23(Suppl 7):vii65-vii71.

UNDERVIRILIZED MALE SYNDROME (MILD ANDROGEN INSENSITIVITY)

DESCRIPTION A disorder of androgen receptor function caused by androgen receptor gene mutation. Patients with androgen receptor mutations have a 46, XY karyotype and present with a spectrum of phenotypes from complete external feminization, to ambiguous genitalia, to phenotypically infertile male, which is also known as undervirilized male syndrome. These patients present with gynecomastia at puberty, and may have scarce body hair, small penis, and complaints of impotence. Spermatogenesis may or may not be impaired. Patients may have elevated luteinizing hormone, normal to slightly elevated testosterone, and high estradiol. Treatment may not be necessary, however, breast reduction surgery at puberty is sometimes necessary. Infertile men may benefit from assisted reproductive techniques (ART's). (See also Section II: "Androgen Insensitivity Syndrome [AIS or Androgen Resistance Syndrome], Complete and Partial.")

REFERENCE

Gottlieb B, Lombroso R, Beitel LK, et al. Molecular pathology of the androgen receptor in male (in)fertility. *Reprod Biomed Online*. 2005:42–48.

UNINHIBITED DETRUSOR CONTRACTION

DESCRIPTION Uninhibited detrusor contraction leads to an overactive bladder. Bladder overactivity can result from damage to central inhibitory pathways, sensitization of peripheral afferent terminals in the bladder that unmask primitive voiding reflexes, or changes in bladder smooth muscle cells. Cystometry is essential if a definitive diagnosis is required. (See Section I: "Overactive Bladder.")

SYNONYMS

- Overactive bladder
- Unstable bladder

TREATMENT

- Traditionally centers on the use of anticholinergic medications (oxybutynin, tolterodine, others)
- Estrogens may help in the postmenopausal woman.

REFERENCE
Anonymous. The overactive bladder: From basic science to clinical management consensus conference. *Urology*. 1997;50(Suppl 6A):1–114.

URACHAL ABNORMALITIES

DESCRIPTION The urachus is a tubular connection between the allantoic stalk and the dome of the bladder. Faulty embryologic resolution of this connection results in urachal abnormalities. Microscopic urachal remnants are common, appearing in 3% of autopsy specimens, and are almost always asymptomatic. Except for the asymptomatic urachal diverticulum, the treatment of all urachal abnormalities is surgical; ie, complete excision of the abnormal structure, including a cuff of bladder. Congenital urachal abnormalities can be divided into 4 types:

- Urachal sinus: The most common urachal abnormality. The urachal sinus arises from a persistent patent urachus that drains to the umbilicus; may present with wetness, purulence, or malodorous discharge.
- Urachal cyst: Persistence of part of this channel between the bladder and umbilicus, lacking communication to either structure. The 2nd most common urachal anomaly. Most commonly presents in an older child with signs of suppuration (Latin “calor, rubor, dolor”) in the lower abdominal wall. Occasionally, a urachal cyst will present as an asymptomatic midline lower abdominal mass or tenderness.
- Patent urachus: Persistence of the urachal channel between the bladder and umbilicus; an uncommon type of urachal abnormality.
- Urachal diverticulum of the bladder: May result from drainage of a urachal cyst to the bladder; presents with UTI

Urachal carcinoma is a malignant adenocarcinoma that presents later in life. (See also Section I: “Urachal Carcinoma” and “Umbilical Abnormalities, Urologic Considerations” and (Image ☼).)

REFERENCE

URACHAL CARCINOMA STAGING SYSTEMS

DEFINITION
Two staging systems have been reported by Sheldon and Ashley. No formal TNM classification exists specifically for urachal carcinoma. (See also Section I: “Urachal carcinoma.”)

Stage	Sheldon et al. (1984)	Ashley et al. (2006)
I	Confined to urachal mucosa	Confined to urachus and bladder
II	Invasion confined to urachus	Extension beyond muscularis of urachus or bladder
III	—	Metastatic to regional lymph nodes
IIIA	Extension to bladder	—
IIIB	Extension to abdominal wall	—
IIIC	Extension to peritoneum	—
IIID	Extension to other viscera	—
IV	—	Metastatic to nonregional lymph nodes or distant sites
IVA	Metastatic to lymph nodes	—
IVB	Metastatic to distant sites	—

Reproduced with permission from Mohile SG, et al. (2008).

REFERENCE

Mohile SG, Schleicher L, Petrylak DP. Treatment of metastatic urachal carcinoma in an elderly woman. *Nat Clin Pract Oncol.* 2008;5:55–58.

URATE, DIETARY

DESCRIPTION Foods rich in urate should be restricted in patients with hyperuricosuric calcium oxalate stone disease and in patients with uric acid stone disease. The intake of urate should not exceed 500 mg/day. Urate rich foods include:

- Calf thymus, 900 mg urate/100 g
- Liver, 260–360 mg urate/100 g
- Kidneys, 210–255 mg urate/100 g
- Poultry skin, 300 mg urate/100 g
- Herring with skin, sardines, anchovies, sprats, 260–500 mg urate/100 g.

REFERENCE

Tiselius HG, et al. EAU Guidelines on Urolithiasis. http://www.uroweb.org/fileadmin/user_upload/Guidelines/Urolithiasis.pdf, Accessed April 6, 2014.

UREAPLASMA UREALYTICUM

DESCRIPTION Common bacterial inhabitant of the lower GU tract in adult men and women who are sexually active. As an STI/STD it can also be transmitted venereally and from mother to offspring. It is the most common cause of nongonococcal and nonchlamydial urethritis, and can cause chorioamnionitis, pyelonephritis, and septic arthritis. It is implicated in chronic prostatitis in men and urgency–frequency symptoms in women and in HIV-related acute epididymitis. It is also sometimes associated with decreased fertility. Diagnosis is by culture, but specific media and growth conditions are necessary. Treatment is doxycycline 100 mg/d

for 2 wk or a single dose of azithromycin 1 g PO. (See also Section I: “Sexually Transmitted Infections [STIs] (Sexually Transmitted Diseases [STDs]), General.”)

REFERENCE

Frenkl TL. Sexually transmitted infections. *Urol Clin N Am.* 2008;35(1):33–46.

URETER, AGENESIS/ATRESIA

DESCRIPTION Bilateral ureteral agenesis is incompatible with life. Unilateral ureteral agenesis indicates failure of ureteral bud development and is often accompanied by ipsilateral renal agenesis or multicystic kidney. Ureteral atresia is caused by varying degrees of failure in ureteral bud development. When either atresia or agenesis is unilateral, it is usually asymptomatic and of no clinical significance. However, it can be associated with infection (UTI) on occasion.

REFERENCE

Morozumi M, Ogawa Y, Fujime M, et al. Distal ureteral atresia associated with crossed renal ectopia with fusion: Recovery of renal function after release of a 10 yr ureteral obstruction. *Int J Urol.* 1997;4(5):512–515.

URETER, DEVIATION

DEFINITION

The ureter is a retroperitoneal structure in adults and is typically 25–30 cm in length. The ureters are in close proximity to abdominal and pelvic viscera, lymph nodes, and vessels. The course of the ureter can be altered by extrinsic pathologic processes as well as congenital and normal anatomic variation. Normal course of ureters: Proximally lateral to the lumbar vertebral pedicles and distally medial to pelvic brim in the true pelvis. Lateral ureteral deviation is more common than medial deviation.

- Medial deviation:
  - Normal anatomic variant in up to 15%
  - Retroperitoneal fibrosis; usually involving the lower lumbar and sacral regions
  - Retrocaval ureter: “shepherd’s crook” configuration; the right ureter passes behind the IVC at approximately the level of L4 (most common location). The distal ureter lies medial to the dilated proximal ureteral segment
  - Retroiliac ureter (very rare)
  - Pelvic lipomatosis; associated with elevation and elongation of the bladder, rectum, and sigmoid and increased pelvic wall lucency
  - After abdominal perineal resection
  - Iliac lymphadenopathy
  - Aneurysmal dilation of the iliac vessels
  - Perianeurysmal fibrosis due to chronic leakage associated with aortoiliac aneurysms
  - Lower pole renal mass; usually medial deviation of proximal ureter
- Lateral deviation
  - Psoas muscle hypertrophy; more common in young men; lateral and/or anterior deviation of the middle 3rd of 1 or both ureters

– Retroperitoneal adenopathy (paracaval/paraaortic lymphadenopathy): Metastatic disease, lymphoma, testicular cancer
– Pelvic mass (fibroids, ovarian tumor and cysts)
– Aortic aneurysm
– Malrotated and horseshoe kidney
– Patent umbilical artery (children)
– Retroperitoneal tumors
– Neurogenic tumors
– Fluid collection (abscess, urinoma, lymphocele, hematoma)

REFERENCES

Bamberger MH. Ureteral Deviation: A sign of retroperitoneal anatomy and pathology. Available at http://www.medscape.com/viewarticle/410210_4, Accessed March 29, 2014.
Chapter 8.39 *Deviated Ureters.* In: Davies, SG ed. Chapman & Nakielny's Aids to Radiological Differential Diagnosis. 6th ed. Philadelphia, PA: Saunders Elsevier; 2013.

URETER, DIVERTICULUM

DESCRIPTION Diverticula can be congenital or acquired, although most have been discovered in adults. Most diverticula are solitary outpouchings involving the distal ureters and upper portions of the pelvis. They are true diverticula composed of a muscular wall, which is lined by transitional cell epithelium. Renal pelvic diverticula tend to be larger than those found in the ureter. Diverticula may be associated with other pathology, such as Ask-Upmark kidney. The most common complications are infection and/or stone formation. Unlike diverticula found in the bladder and urethra, major complications and development of urothelial carcinoma (TCC) are rare (Image ☼).

REFERENCE

McLoughlin LC, Davis NF, Dowling C, et al. Ureteral diverticulum: A review of the current literature. *Can J Urol.* 2013;20(5):6893–6896.

URETER, DUPLICATED AND BIFID

DESCRIPTION Duplication of ureters is a common anomaly. Duplication may be either complete or incomplete. Complete duplication is most often associated with vesicoureteral reflux, ectopic ureteral insertion, and ectopic ureterocele, all of which are more commonly found in females than in males. Incomplete duplication is most often associated with UPJ obstruction of the lower pole of the kidney. Common clinical presentations include UTIs and urinary incontinence. Diagnosis is made usually in childhood by US, excretory urography, and voiding cystourethrography.

Also known as *bifid ureter* (if partial duplication) or *double ureters* (if complete duplication). Treatment is ureteroneocystostomy in the presence of persistent reflux or ureteropyelostomy if obstructed without reflux (Image ☼).

REFERENCE

Fernbach SK, Feinstein KA, Spencer K, et al. Ureteral duplication and its complications.

Radiographics. 1997;17(1):109–127.

URETER, ECTOPIC (URETERAL ECTOPIA)

DESCRIPTION Ectopic ureters open in a position other than on the trigone and can be associated with both reflux and obstruction and with ureteroceles. They predispose to UTI and may cause hematuria or abdominal/flank pain. Up to 80% are associated with a duplicated collecting system in females and ~20% are nonduplicated ureters usually in males with an absent hemi-trigone. In females, the ureter typically inserts in the urethra or vagina (distal to the sphincter) and cause incontinence or constant dribbling. In males the sites include the posterior urethra or seminal vesicles (no incontinence is seen) and often present later in life. Treatment is usually partial nephroure-terectomy of the nonfunctioning upper pole moiety with nephrectomy often necessary for single ureter systems.

REFERENCE

Hanson GR, Gatti JM, Gittes KG. Diagnosis of ectopic ureter as a cause of urinary incontinence. *J Ped Urol*. 2007;3(1):53–57.

URETER, FIBROEPITHELIAL POLYPS

DESCRIPTION Fibroepithelial polyps are rare benign neoplasms. The majority of these polyps are found at the UPJ. Signs and symptoms usually associated with ureteral obstruction include flank pain and hematuria. In addition, varying degrees of hydroureteronephrosis and ureteral intussusception have been described. Grossly, ureteral polyps are intraluminal lesions, most commonly covered with transitional epithelium. The bulk of the polyp is composed of vascularized collagenous fibrous tissue, with or without areas of chronic inflammation and edema. Ureteroscopy is often necessary to confirm the diagnosis.

SYNONYMS

- Fibromyxoma
- Myxoma
- Fibroma
- Vascular fibrous polyps

TREATMENT

- Ureteroscopic resection
- Open ureterotomy with polypectomy or partial ureterectomy is a viable conservative treatment option if the diagnosis can be confirmed preoperatively
- Many patients undergo nephroureterectomy for suspected malignancy

REFERENCE

Wang ZJ, et al. Ureteral Fibroepithelial Polyp. *J Ultrasound Med.* 2008;27(11):1647–1649.

URETER, FISH HOOK (REVERSE J)

DESCRIPTION A radiographic appearance of the type I (low-loop) circumcaval ureter, in which the dilated proximal part of the ureter takes a characteristic fish hook or reverse J course. Ureteral dilation usually ends 1–2 cm lateral to the inferior vena cava, where the

ureter turns upward at the border of the psoas muscle.

REFERENCE

Kenawi MM, Williams DI. Circumcaval ureter: A report of four cases in children with a review of the literature and a new classification. *Br J Urol*. 1976;48:183.

URETER, HEMANGIOMA

DESCRIPTION Hemangiomas are benign ureteral tumors. They may be the most common cause of chronic unilateral hematuria. Symptomatology may include hematuria, pain, hydronephrosis, bladder irritations, and palpable tumor. Varicoceles have also been found, but less frequently. Like other ureteral tumors, hemangiomas usually cause incomplete obstruction and may eventually cause complete obstruction with dilation of the urinary tract. They present as red, slightly elevated structures, fairly diffusely, and demarcated from their surroundings. Urothelial malignancies must be excluded, especially in the elderly. Flexible ureteropyeloscopy is considered a good diagnostic and therapeutic option in selected patients with unilateral hematuria of uncertain etiology.

REFERENCE

Biyani CS, Mackay AM, Sissions G, et al. An unusual filling defect in the ureter. *Urol Int*. 1998;61(2):124–125.

URETER, J HOOKING

DESCRIPTION With progressive benign prostatic hypertrophy, elevation of the trigone occurs, resulting in a characteristic J hooking of the distal ureters. This is a reliable sign on IVP of significant prostatic hypertrophy.

REFERENCE

Amis ES, Newhouse JH, eds. *Essentials of Uroradiology*. 1st ed. Boston, MA: Little Brown, 1991:320.

URETER, LEIOMYOMA

DESCRIPTION Leiomyomas of the urinary tract are rare (neoplasms of mesenchymal origin comprise $<3\%$ of all primary ureteral tumors). These benign tumors are seen predominantly in the 4th–5th decades of life. The left ureter is more frequently affected. Immunohistochemical studies confirm the diagnosis. Conservative management (urethroscopic or partial ureterectomy) is the treatment of choice.

REFERENCE

Naruse K, Yamada Y, Aoki S, et al. A case of primary leiomyoma of the ureter. *Int J Urol*. 2007;14(3):248–250.

URETER, LEIOMYOSARCOMA

DESCRIPTION Leiomyosarcoma originating from the ureters is exceedingly rare, with only

13 reported cases of primary leiomyosarcoma of the ureter. It is a disease that is very difficult to diagnose, and furthermore, it has a poor 5-yr disease-specific survival. Patients present with flank pain, hematuria, and/or UTI. Radiographic exam includes IVP, retrograde pyelogram, and CT. Light microscopy immunohistochemical staining and electron microscopy should be used to confirm the diagnosis of leiomyosarcoma.

TREATMENT

- Tumor resection
- Possible nephroureterectomy, depending on tumor grade and stage
- Adjuvant radiation therapy may be helpful.

REFERENCE

Griffin JH, Waters WB. Primary leiomyosarcoma of the ureter. *J Surg Oncol.* 1996;62(2):148–152.

URETER, METASTASIS TO

DESCRIPTION Metastatic tumors of the ureter are uncommon, and 1 of the rarest causes of ureteric obstruction. Since their 1st mention in the literature in 1909 only ~400 cases are reported. Among 1/2 of the cases, the breast or gastrointestinal tract (colorectum) is the site for primary cancer. Prostate cancer and uterine cervical cancer are responsible for 30–40% of cases, with stomach and lung cancer being reported in the remaining case. A predilection exists for the lower 1/3 of the ureter. Many are asymptomatic with the majority autopsy reports.

REFERENCE

Arvind NK, Singh O, Gupta S, et al. Ureteral Metastasis as the presenting manifestation of pancreatic carcinoma. *Rev Urol.* 2013;15(3):124–130.

URETER, NEPHROGENIC ADENOMA (NA)

DESCRIPTION Nephrogenic adenoma (NA) is a rare metaplastic lesion of the ureter and assumed to be secondary to chronic irritation of the urothelium. It is a benign papillary and tubular proliferation in response to trauma, infection, or ionizing radiation. Although it can be seen anywhere in the urinary tract, it is most commonly observed in the bladder (55%). The incidence in ureter is ~4%. Biopsy and fulgeration are appropriate, as it is treated as a low-grade urothelial malignancy. Malignant transformation has not been described.

REFERENCE

Doluoglu OG, Acarer EY, Yavuz A, et al. Nephrogenic adenoma of the ureter. *Rare Tumors.* 2012;4(2):e28.

URETER, NEUROFIBROMA

DESCRIPTION Grossly, neurofibromas may be single or multiple and comprise different sized nodules. Histologically, they are composed of fascicles of elongated, spindle-shaped cells with thin, wavy nuclei in a collagenized background. Neurofibromas in the ureter are very

rare but have an increased incidence in von Recklinghausen disease. Neurofibromas frequently recur and can cause death by urinary obstruction and renal failure. Endoscopic or open excision is the treatment of choice.

REFERENCE

Bostwick DG, ed. *Urologic Surgical Pathology*. 1st ed. St. Louis, MO: Mosby; 1997.

URETER, PIPE-STEM

DESCRIPTION A radiographic appearance seen in late stages of tuberculous involvement of the ureter. On IVP, the ureter appears straight with a narrow lumen, due to diffuse fibrotic changes of the wall.

REFERENCE

Murphy DM, Fallon B, Lane V, et al. Tuberculous stricture of ureter. *Urology*. 1982;20:382–384.

URETER, RADIATION INJURY TO

DESCRIPTION Clinically, radiation injury to the ureter will present as obstruction. Upper urinary tract obstruction secondary to the effects of radiation is generally reported to occur in ~5% of patients with ureteral encroachment, and in <1% of all treated patients. The ureters are relatively resistant to the effects of radiation, although some factors are postulated to increase the chance of injury after radiation exposure, such as infection of the ureter, necrosis of the tumor invading the ureteral wall, and direct radiation injury to the ureteral wall. Radiation therapy of ≥8,000 Gy results in a 40% urologic complication rate. A dose of ≤6,000 Gy results in a <2% complication rate. (See also Section I: “Ureter, Obstruction.”)

REFERENCE

Resnick MI, Kursh ED. Extrinsic obstruction of the ureter. In: Walsh PC, Retik AB, Vaughan ED, et al., eds. *Campbell’s Urology*. 7th ed. Philadelphia, PA: Saunders; 1998:409–410.

URETER, RETROCAVAL (CIRCUMCAVAL, POSTCAVAL)

DESCRIPTION A retrocaval ureter is a congenital anomaly in which the problem arises from the inferior vena cava rather than the ureter. Normally, the vena cava derives from the supracardinal vein, which lies posterior to the ureter. If it derives from either the persistent right subcardinal or postcardinal vein, both of which lie anterior to the ureter, a portion of the lumbar ureter becomes trapped behind the vena cava. Clinically, a retrocaval ureter may present as ureteral obstruction with a Shepards crook deformity. Males are affected more than females and the presentation usually relates to the ureteral obstruction (pain infection, stones).

Two types have been described. Type 1 is the more common where the ureter crosses behind IVC at the level of 3rd lumbar vertebra assuming the appearance of a shephards crook or sickle shaped at the point of obstruction. Marked hydronephrosis usually present. Type 2 retrocaval ureter is less common and the ureter tends to cross at a much higher level relative to the renal pelvis and the degree of hydronephrosis is usually mild. Treatment is surgery

with transection of the ureter and reanastomosis in front of the inferior vena cava. (See "Ureter, Shepherd's Crook.")

REFERENCE

Chung BI, Gill IS. Laparoscopic dismembered pyeloplasty of a retrocaval ureter: Case report and review of the literature. *Eur Urol.* 2008;54(6):1433–1436.

URETER, SHEPHERD'S CROOK

DESCRIPTION Characteristic S-shaped appearance of the circumcaval/retrocaval ureter on excretory urography or retrograde ureterography. A normal-caliber ureter emerging at the medial aspect of the inferior vena cava runs inferiorly between it and the aorta. The elongation and dilatation of ureter above the site of the obstruction along with the course around the inferior vena cava cause a "shepherd's crook" or "sickle-shaped deformity." On frontal projection, the ureter is medial to the lower lumbar pedicles, where it crosses anterior to the right iliac vessels to enter the pelvis. Clinically, a retrocaval ureter may present as ureteral obstruction with pain, stones, or infection. Males are affected more than females. Treatment is surgery with transection of the ureter and reanastomosis in front of the inferior vena cava (See also Section II: "Ureter, Retrocaval [Circumcaval, Postcaval].")

REFERENCE

Kenawi MM, Williams DI. Circumcaval ureter: A report of four cases in children, with a review of the literature and a new classification. *Br J Urol.* 1976;48:183.

URETER, SPIRAL (CORKSCREW)

DEFINITION

A spirally twisted or "corkscrew" ureter is a very rare anomaly beyond the neonatal age. A spirally twisted ureter is not considered clinically significant, unless it causes obstruction and secondary hydronephrosis. Infants frequently have a "corkscrew" appearance of the proximal segment of the ureter seen on intravenous urography, but this has been considered an imaging finding of no postnatal clinical significance. It may represent persistence of normal fet al developmental structures, such as congenital folds. Corkscrew configuration of the ureter may also be the result of ureteric varicosities or extrinsic ureteric obstruction when seen later in life. Obstruction secondary to spiral deformity of the ureter may be due to involvement of the ureter by dense fibrous bands (Image ☼).

REFERENCE

Prodromos P, Payne D, Keeley F. Let's get it straight: the story of the spiral ureter. *Can J Urol.* 2012;19:6118–6120.

URETER, STONE PASSAGE STATISTICS

DEFINITION

The ureter is the smallest diameter structure of the urinary tract. It is also the area most likely to be obstructed by a stone. Most stones <5 mm in diameter are likely to pass spontaneously with the likelihood of spontaneous stone passage decreasing with increased stone size. It is

estimated that 2/3 of ureteral stones that pass spontaneously pass within 4 wk of the onset of symptoms.

Stone Size (mm)	Number of Days to Pass Stone (Mean)	Likelihood of Eventual Need for Intervention
2 or less	8	3%
3	12	14%
4–6	22	50%
>6	–	99%

REFERENCE

Kidney Stones. http://www.auanet.org/education/kidney-stones.cfm, Accessed April 5, 2014.

URETER, STRICTURE

DESCRIPTION Strictures are 1 of the main causes for ureteral obstruction that might lead to hydronephrosis and renal function impairment. Ureteral strictures may present with an insidious onset of irreversibly damaged renal parenchymal due to slow development of silent hydronephrosis. Common signs of symptomatic stricture are flank pain, elevated creatinine level, or decreased urine output. Imaging studies with contrast are an essential part of the diagnostic workup. The location and length of obstruction are important parameters for treatment planning. (See also Section I: “Ureter, Obstruction.” and (Image ☼))

CAUSES

- Congenital
- Extrinsic trauma
- Iatrogenic (gynecologic or other pelvic surgeries)
- Inflammatory and infectious factors (Crohn disease)
- Instrumentation (ureteroscopy)
- Malignant (intrinsic or extrinsic)
- Postchemotherapy and radiation therapy
- Sclerosing retroperitoneal fibrosis

TREATMENT

- Relieve the obstruction with concomitant antibiotic coverage, if needed.
- Surgical correction with endoscopic, laparoscopic, robotic, or open surgery.
- Reimplantation with excision for distal strictures.

REFERENCE

Ogan K, Abbott JT, Wilmot C, et al. Laparoscopic ureteral reimplant for distal ureteral strictures. *JSLS*. 2008;12(1):13–17.

URETER, VALVES

DESCRIPTION Ureteral valves obstruct the forward flow of fluid, causing a proximal hydronephrosis. About 35% of ureteral valves occur at the UPJ; 60% occur near the ureterovesical junction, and 5% in the upper ureter. Valves are 3 times more common in males. They are usually unilateral, although they may be bilateral, and, if so, usually lead to

renal failure. 75% of valves occur on the left side. Treatment depends on the location of the valve and may include ureteral reimplantation (distal ureter), endoscopic ablation (midproximal ureter), or UPJ repair.

REFERENCE

Amis ES, Newhouse JH, eds. *Essentials of Uroradiology*. 1st ed. Boston, MA: Little Brown; 1991:63.

URETERAL JETS

DESCRIPTION Ureteral jets have been studied to diagnose urinary tract obstruction. Ureteral jets are visualized on color Doppler ultrasound as ureteral urine passes into the bladder. Sensitivity of 100% and specificity of 90.9% in detecting ureteral obstruction has been reported based on the absence of the ureteral jet on a given side. Patients must be well hydrated and often a prolonged imaging interval is needed to document the presence or absence of the ureteral jet (Image ☼).

REFERENCE

Deyoe LA, Cronan JJ, Breslaw BH, et al: New techniques of ultrasound and color doppler in the prospective evaluation of acute renal obstruction: Do they replace the intravenous urogram? *Abdom Imaging*. 1995;20:58–63.

URETERAL STRICTURE FOLLOWING URINARY DIVERSION

DESCRIPTION Ureteral strictures are seen in 2–10% of patients who receive a cystectomy and urinary diversion for bladder cancer. The stricture is most commonly located at the ureteroenteric anastomosis and more commonly involves the left ureter. Considered a late complication, strictures usually present in the 6–12 mo postoperative time period. Ureteral recurrence of urothelial carcinoma should be ruled out. Treatment includes percutaneous nephrostomy, indwelling ureteral stent, balloon dilatation, or reanastomosis.

REFERENCE

Tal R, Sivan B, Kedar D, et al. Management of benign ureteral strictures following radical cystectomy and urinary diversion for bladder cancer. *J Urol*. 2007;178:538–542.

URETERITIS

DESCRIPTION A generic characterization given to describe inflammation of the ureter which can be further qualified into subtype descriptions based loosely on its etiologic factors. For example, postoperative ureteritis, infective ureteritis, and noninfective ureteritis. Noninfective causes of ureteritis include ureteral amyloidosis, eosinophilic ureteritis, IgG-4 associated ureteral inflammation, and idiopathic segmental ureteritis.

REFERENCE

Atsuta T, Shimizu Y, Masuda N, et al. First report of idiopathic segmental ureteritis successfully treated by steroid therapy. *Int J Urol*. 2012;19:583–586.

URETERITIS CYSTICA

DESCRIPTION A benign and rare condition, ureteritis cystica is characterized by multiple cysts and space-filling defects in urothelium. Usually asymptomatic, it may present with hematuria, and if obstruction occurs, may lead to stone formation, UTIs, and renal compromise. The etiology is unknown, but associated with chronic UTI. Space-filling defects seen on retrograde pyelography or excretory urography may appears as smooth, round or oval filling defects of varying sizes that protrude into the lumen. It can mimic other conditions such as bladder cancer, blood clots, air bubbles, radiolucent stones, fibroepithelial polyps, and sloughed renal papillae. It manifests as cystic areas of glandular metaplasia associated with chronic urothelial inflammation; this is more commonly seen in the bladder, called cystitis cystica. Treatment is ureteroscopy and the mechanical disruption of cysts or instillation of chemicals such as silver nitrate to relieve obstruction.

REFERENCE

Rothschild JG, Wu G. Ureteritis Cystica: A Radiologic Pathologic Correlation. *J Clin Imaging Sci.* 2011;1:23.

URETERONEOCYSTOSTOMY, TECHNIQUES AND INDICATIONS

DESCRIPTION Ureteral reimplantation, or ureteroneocystostomy, is used when there is an abnormality at the ureterovesical junction. Abnormalities include an obstructing ureterocele, megaureter, ureteral reflux, distal ureteral stricture, or iatrogenic injuries. The surgical treatment options can be classified on the basis of the ureteral approach to the bladder as intravesical, extravesical, or combined or on the relationship of the submucosal tunnel to the site of the original ureteral hiatus as suprahiatal or infrahiatal.

REFERENCE

Khoury AE, Bägli DJ. Vesicoureteral reflux. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 10th ed. Philadelphia, PA: Saunders; 2011.

URETHRA, ADENOCARCINOMA OF ACCESSORY GLANDS

DESCRIPTION In males, the urethral accessory glands can develop rare, aggressive neoplasms that are difficult to diagnose because of the local destructive nature of the lesions (Cowper and Littré glands). Cowper gland cancers are found in the bulbous urethra, while Littré gland lesions can arise along the entire urethra, but tend to arise distally. In females, the Skene glands can develop adenocarcinoma as well. Patients typically present with hematuria, dysuria, and progressive urinary obstruction. Management is similar to that for urethral adenocarcinoma. (See also Section II: “Cowper Gland Carcinoma”, “Skene (Paraurethral) Gland, Adenocarcinoma.”)

SYNONYMS

- Adenocarcinoma of Cowper gland
- Adenocarcinoma of Littré glands
- Adenocarcinoma of Skene (periurethral) glands

REFERENCE
Reuter VE. Urethra, Chapter 11. In: Bostwick DG, ed. *Urologic Surgical Pathology*. 2nd ed. Philadelphia, PA: Mosby Elsevier; 2008:608.

URETHRA, ADENOMATOUS POLYPS

DESCRIPTION Congenital, benign papillary-appearing lesions that occur most frequently in the prostatic urethra and contain benign prostatic epithelium. These have been reported in the anterior urethra. Cores of the papillary projections contain prostatic stroma and glands. The lesions typically present in the 1st decade of life, but can appear at any age. Hematuria, enuresis, and obstruction are common. Cystourethroscopy is usually diagnostic.

SYNONYMS
- Villous polyp of the urethra
- Ectopic prostatic tissue in the urethra

TREATMENT
Transurethral or suprapubic resection is curative.

REFERENCE
Chan JK, Chow TC, Tsui MS. Prostatic-type polyps of the lower urinary tract: Three histogenetic types? *Histopathology*. 2007;11(8):789–801.

URETHRA, BLEEDING (BLOOD AT MEATUS)

DESCRIPTION Usually associated with GU trauma, blood at the urethral meatus is the single most important sign of urethral injury. Patients often complain of abdominal pain or inability to urinate, and report a history of crush injury to the pelvis. Clinically, this finding is an absolute contraindication to immediate urethral catheter placement. Instead, urethrography should be performed (see below). This is distinct from idiopathic urethrorrhagia, which is bleeding from the urethra or blood spotting on the undergarments in preadolescents. Urethrorrhagia is a benign lesion and self-limited in most cases. (See also Section I: “Urethra, Trauma [Anterior and Posterior]”; Section II: “Urethrorrhagia, Idiopathic.”)

CAUSES
- Posterior urethral injury (prostatic and membranous urethra, proximal to urogenital diaphragm) associated with pelvic fracture and deceleration/shear injury
- Anterior urethral injury (bulbous and pendulous urethra, distal to urogenital diaphragm) associated with straddle injury and iatrogenic laceration
- Traumatic urethral catheterization; more common in men
- Nontraumatic causes: Idiopathic urethrorrhagia, malignancy (urethral, prostate, bladder), urolithiasis, urethral condyloma, urethral diverticulum, urethral stricture, benign prostatic bleeding, urethral hemangioma

TREATMENT
- In cases of urethral trauma, standard trauma management; shock and hemorrhage control
- Avoid urethral catheterization

- Retrograde urethrogram (12-Fr catheter in fossa navicularis with 3 cc in balloon; retrograde injection of 20–30 cc of water-soluble dye) to evaluate for extravasation beyond the urethra:
  - Positive extravasation: Immediate open bladder exploration with placement of suprapubic cystostomy tube; delayed urethral repair (3 mo after injury) with silicone urethral catheter placement concomitant with primary anastomosis
  - Negative extravasation: Careful urethral catheter placement; cystography

REFERENCE

Smith DR, et al. *Smith's General Urology*. New York, NY: McGraw-Hill; 2004:291–304.

URETHRA, CALCULI

DESCRIPTION Urethral calculi comprise <2% of all urinary stone disease in the Western world, with a greater incidence in men than women, given increased urethral length. They are classified as *migrant*, from the proximal GU system, or *native*, developing in the urethra itself. Stones <10 mm should pass spontaneously. Although native stones tend to be asymptomatic, urethral calculi may present with irritative voiding symptoms, hematuria, a palpable mass, and/or urethral discharge.

CAUSES

- Migrant calculi: See Section I: "Urolithiasis, Adult, General and Bladder Calculi"
- Native calculi: Urinary stasis (urethral strictures, diverticula, foreign-body entrapment, hair-bearing graft following urethroplasty), chronic infections (UTIs, schistosomiasis)

TREATMENT

- Depends on location and size of stone
- Acute retention: Suprapubic tube placement (allows for definitive planning)
- Trial of spontaneous expulsion with 2% intraurethral lidocaine
- Forceps extraction with or without meatotomy
- Antegrade massage/milking of calculus
- Retrograde manipulation with intravesical lithotripsy
- Intraurethral/endoscopic lithotripsy and fragment extraction
- Open urethrotomy (2-layer closure)

REFERENCE

Koga S, Arakaki Y, Matsuoka M, et al. Urethral calculi. *Br J Urol*. 1990;65(3):288–289.

URETHRA, CONDYLOMA (WARTS)

DESCRIPTION Condyloma (condylomata acuminatum, venereal warts) are a common finding in the lower genital tract, but a rare finding in the urinary tract. Condyloma of the urethra or bladder is often associated with immunosuppression. It is estimated that 0.5–5.0% of patients with condylomata of the genitalia may also have urethral involvement. Clinically, urethral involvement is suspected when pyuria or urethral discharge appears in a patient with genital verrucae. The cause is human papilloma virus (HPV), and primary treatment is ablative with cryotherapy, laser, or surgical excision. Urethral instillation via urethral syringe of fluorouracil injection mixed with lidocaine gel has also been reported. (See also Section I:

“Condylomata Acuminata [Venereal Warts]”) and (Image ☼).

URETHRA, DIVERTICULAR CARCINOMA

DESCRIPTION Carcinoma of the urethral diverticulum is a rare pathologic entity commonly found in females, with an average age at presentation of 52. Reported symptoms include urethral bleeding (most common), dysuria, vaginal mass, and urethral obstruction. Adenocarcinoma occurs more frequently than transitional and squamous cell cancers combined and carries a more favorable diagnosis. Female urethral diverticula can be diagnosed through MR imaging with a high index of suspicion in patients with recurrent UTIs, dysuria, urgency, and postvoid dribbling. (See Section I: “Urethra Diverticula, Female”; “Urethra, Carcinoma, General.”)

TREATMENT

- Surgical: Radical cystourethrectomy with pelvic node dissection is recommended by most authors.
- Diverticulectomy has been suggested for low-stage adenocarcinoma, if close follow-up is assured.

URETHRA, DIVERTICULUM, MALE

DESCRIPTION Urethral diverticulum are usually found in the ventral anterior urethra but have been reported from the bulbous to the mid pendulous. These can be acquired (often iatrogenic from the treatment of urethral pathology) and very rarely, congenital. Congenital urethral diverticula may be either saccular or tubular. The saccular type has a true neck and may cause urinary obstruction when the cavity fills at the beginning of micturition. The tubular or diffuse type is located proximal to the urethral bulb, where urinary stasis can cause infection and/or calculous formation. Most are asymptomatic unless infection or obstruction develops. A mass can be palpated in the ventral aspect of the anterior urethra, which empties with compression. The diagnosis is made by cystoscopy, urethrography, and voiding urethrography. Management can be endoscopic unroofing for small diverticulum with open repair reserved for larger lesions.

REFERENCE

Ballesteros Sampol JJ, Cortadellas Angel R, Juanpere Rodero N. Acquired male urethra diverticula. Report of seven cases. Bibliographic review. *Arch Esp Urol.* 2008;61(1):1–6.

URETHRA, DUPLICATION

DESCRIPTION Duplication of the urethra is rare and afflicts mainly boys. Duplication of the urethra may be complete, extending from the bladder to the dorsum of the penis, or partial, extending from the dorsal surface or, less commonly, the ventral surface of the penis and ending blindly. In only 15% of cases of duplicated urethra, whether complete or partial, is there a connection with the functional urethra. Urethral duplication is often associated with GU and GI abnormalities that maybe be severe. Most cases are asymptomatic, but the most common complication is infection. Patients may have urinary obstruction caused by compression of the functional urethra by a mass of material in the blind, accessory urethra. In other cases, patients may complain of incontinence or double urinary streams. Complete resection of the nonfunctioning urethra, if symptomatic, is curative.

REFERENCE

Arena S, Arena C, Scuderi MG, et al. Urethral duplication in males: Our experience in ten cases. *Pediatr Surg Int.* 2007;23(8):789–794.

URETHRA, FOREIGN BODY

DESCRIPTION Cases of self-inflicted foreign bodies in male urethra have been reported, including objects such as fishhooks, bones, screws, safety pins, and light bulbs. Cause for inserting foreign bodies varies, including psychiatric disorder, intoxication, and erotic stimulation. Endoscopic retrieval is usually successful using modern instruments. Open surgery may also be considered. IV perioperative antibiotics followed by PO antibiotics for 1 wk has been recommended. Delayed complications include stricture disease, therefore close urologic follow-up is recommended (Image ☼).

REFERENCE

Rahman NU, Elliott SP, McAninch JW. Self-inflicted male urethral foreign body insertion: Endoscopic management and complications. *BJU Int.* 2004;94(7):1051–1053.

URETHRA, HEMANGIOMA

DESCRIPTION Urethral hemangiomas are extremely rare tumors. The lesion is believed to be congenital, arising from the embryonic rest of unipotent angioblastic cells that fail to develop into normal blood vessels. The clinical presentation is bloody urethral discharge or frank urethral bleeding. These lesions are benign in nature. They are treated by local resection or ablation with electrocoagulation or laser. (See also Section II: “Urethra, Bleeding [Blood at Meatus].”)

REFERENCE

Parshad S, Yadav SP, Arora B, et al. Urethral hemangioma. An unusual cause of hematuria. *Urol Int.* 2001;66(1):43–45.

URETHRA, LEIOMYOMA

DESCRIPTION Rare benign neoplasm arising from smooth muscle. The majority occur in

females, with a peak age of 30–40 yr. It usually presents as an asymptomatic mass, or with dysuria, UTI or obstruction, and dyspareunia. The proximal urethra is most commonly involved. No etiology is known, but it is hormonally associated and many of these tumors enlarge in pregnancy. Treatment is local excision, and prognosis is excellent as no malignant transformation or local recurrence has been reported in the literature. (See also Section I: "Urethral Mass.")

REFERENCE

Pahwa M, Saifee Y, Pahwa AR, et al. Leiomyoma of the female urethra – a rare tumor: Case report and review of the literature. *Case Rep Urology*. 2012:1–2.

URETHRA, LEIOMYOSARCOMA

DESCRIPTION Leiomyosarcoma is a smooth muscle tumor that often exhibits necrosis, hemorrhage, and cystic degeneration. Leiomyosarcomas are extremely rare tumors that are more common in females than in males. Patients present with hematuria, pain, or mass. The prognosis is poor, and the treatment is radical excision with consideration of adjuvant radiation. (See also Section I: "Urethral Mass.")

REFERENCE

Ahalla Y, Tazi MF, Khallouk A, et al. Primary leiomyosarcoma of the male urethra: a case report. *Cases J*. 2009;2:207.

URETHRA, LEUKOPLAKIA

DESCRIPTION The term leukoplakia (also called *squamous metaplasia*) refers to the presence of grossly discernible white patches commonly seen on the mucosal surfaces of areas of squamous metaplasia. There seems to be an increased incidence in patients with diabetes, as well as in those with chronic irritation or infection. Generally believed to be a premalignant lesion caused by chronic infection or irritation, it may progress to squamous cell carcinoma (SCC). It is treated by biopsy and ablation.

REFERENCE

Benson RC, et al. Relationship of urethral leukoplakia to urothelial malignancy. *J Urol*. 1984;13:507–511.

URETHRA, LYMPHOMA

DESCRIPTION Primary malignant lymphoma rarely affects the lower urinary tract. When it does, it generally affects the bladder. Initial presentation within the urethra is extremely rare. Concurrent or subsequent regional or systemic lymphoma is generally the rule. Only 11 cases of lymphoma presenting in the urethra have been documented, and 10 were in women. (See Section II: "Lymphoma, Urologic Considerations.")

TREATMENT

- The high probability of regional or systemic extension is an argument against radiotherapy as a primary treatment.

• Chemotherapy is an excellent treatment, and the prognosis is good.

REFERENCE

Hatcher PA, Wilson DD. Primary lymphoma of the male urethra. *Urology*. 1997;49(1):142–144.

URETHRA, MALACOPLAKIA

DESCRIPTION This designation refers to a peculiar pattern of inflammatory reaction, characterized macroscopically by soft, yellow, slightly raised mucosal plaques (classic intracytoplasmic Michaelis–Gutmann bodies and von Hansemann cells). The disease shows a predilection for involving the bladder, ureter, renal pelvis, UPJ, and urethra. The disease predominates in females by a 4:1 ratio, and the peak age is in the 6th decade. Apart from symptoms associated with UTIs, the clinical manifestations are usually unremarkable. Most often, the bladder is involved, and symptoms of bladder irritability or hematuria may be present. Malacoplakia occurs with increased frequency in immunosuppressed transplant recipients. Pathogenesis is unknown, but an altered host response is suspected. There is an association with diabetes mellitus, alcoholic liver disease, sarcoidosis, and mycobacterial infection. When the lower urinary tract is involved, long-term antibiotics are successful.

REFERENCE

Karaiossifidi H, Kouri E. Malacoplakia of the urethra: A case of unique localization with follow-up. *J Urol*. 1992;148(6):1903–1904.

URETHRA, MALIGNANT MELANOMA

DESCRIPTION Primary urethral malignant melanoma is rare, with <100 cases reported in the literature. 90% of patients are diagnosed in the 6th–7th decades. 80% of cases were reported to be in the fossa navicularis and the meatus. The most common presentations are dysuria, hematuria, deviated urinary stream, or urinary obstruction. Endoscopically, a pigmented nodular mucosal mass or masses, which may be ulcerated, may be seen. Local recurrence is common. Metastasis is usually to inguinal and pelvic lymph nodes. Hematogenous spread to liver, lung, and brain is also common. Staging for urethral melanoma has not yet been standardized. Prognosis depends on the thickness of the lesion.

TREATMENT

• Surgical: Urethrectomy or penectomy with regional lymph node dissection
• The role of radiotherapy, immunotherapy, or chemotherapy is yet to be defined

URETHRA, MEATUS, NORMAL CALIBER

DESCRIPTION Normal limits of male urethral calibration are as follows:

- 6 wk–3 yr: 15% <8 Fr; 85% 10 Fr
- 4–10 yr: 8% tight at 8 Fr; 76% 12 Fr
- 11–12 yr: 5% <10 Fr; 75% 14 Fr

Normal limits for female urethra are as follows:
- 2–4 yr: 14 Fr
- 6–10 yr: 16 Fr
- 12 yr: 20 Fr
- >14 yr: 24 Fr

REFERENCE

URETHRA, METASTASIS TO

DESCRIPTION Primary urethral tumors are rare, accounting for <1% of urologic cancers in the United States with metastatic urethral involvement even more uncommon. This involvement is mainly a result of local spread from the surrounding organs. Metastatic lesions to the urethra usually originate from the prostate, bladder, and rectum, although origin from more distant sites such as testicle has been reported. In a patient with a known malignancy, pain, hematuria, and/or urethral obstruction may suggest the diagnosis.

URETHRA, NEPHROGENIC METAPLASIA (ADENOMA)

DESCRIPTION Nephrogenic metaplasia is a rare metaplastic lesion of urethral epithelium, with a classic triad of tubular, cystic, and papillary–polypoid patterns microscopically. Occurs at all ages, with a 3:1 male predominance. 15% of nephrogenic metaplasia is found in the urethra. Etiology is unknown, but resembles distal renal tubules and is associated with surgical trauma, calculi, indwelling catheter, chronic infections, and immunosuppression. This condition must be differentiated from prostatic carcinoma. Presenting symptoms include irritative voiding symptoms and hematuria, or the patient may be asymptomatic. Diagnosed by cystoscopy and biopsy, the clinical course is usually benign, although the problem may persist or recur. Rarely, a metaplastic lesion can cause carcinoma.

SYNONYMS
- Adenomatoid metaplasia
- Adenomatoid tumor
- Adenomatous metaplasia
- Hamartoma
- Tubular metaplasia

- Nephrogenic adenoma

TREATMENT
- Regular cystoscopic exam
- Removal of underlying cause
- Transurethral excision

REFERENCE
Xiao GQ, Burstein DE, Miller LK, et al. Nephrogenic adenoma: Immunohistochemical evaluation for its etiology and differentiation from prostatic adenocarcinoma. *Arch Pathol Lab Med.* 2006;130(6):805–810.

URETHRA, OBSTRUCTION

DESCRIPTION Urethral obstruction can occur anywhere from the meatus to bladder neck, and can be congenital or acquired. Posterior urethral valves are the most common cause of obstructive uropathy in boys. The incidence of posterior urethral valves is 0.25–0.5:10,000 births and anterior urethral valves occur 10 times less frequently than posterior valves. Other causes of urethral obstruction in both sexes include meatal stenosis, stricture, foreign body, phimosis (males), urethral calculus, urethral abscess, urethral diverticulum (acquired or congenital), or urethral neoplasm. (See also Section I: “Urethra, Mass.”)

REFERENCE
Narasimhan KL, Choudhary SK, Kaur B. Anterior urethral valves. *Indian Pediatr.* 2005;42:708–710.

URETHRA, POLYPS (FIBROEPITHELIAL, ADENOMATOUS, INFLAMMATORY)

DESCRIPTION Uncommon benign polypoid of papillary lesions of the urethra, these are usually limited to male patients and occur most often in children. Polyps vary in microscopic features, which result in their classification into fibroepithelial, adenomatous, or inflammatory. *Adenomatous polyps* are thought to represent prostatic glandular material from a congenital developmental error. *Fibroepithelial polyps* consist of stromal elements. *Inflammatory polyps* have a distinct inflammatory infiltrate. Presenting symptoms can include hematuria, hematospermia, obstruction, or UTI. Cystourethroscopy with biopsy is the test of choice. Transurethral resection with fulguration is the treatment of choice, along with removal of the source of inflammation (eg, catheter or stone removal) if present. (See Section II: “Cystitis, Polypoid and Papillary;” “Urethritis, Polypoid.”)

REFERENCE
Walsh IP, et al. Benign urethral polyps. *Br J Urol.* 1993;72:937–938.

URETHRA, PROLAPSE (FEMALE)

DESCRIPTION Prolapse of the urethra is a rare condition, described as complete eversion of urethral mucosa through the external urethral orifice; the etiology is unknown. It is primarily

associated with prepubertal girls and postmenopausal women with African American girls more commonly afflicted. Vaginal bleeding is often the presenting symptom, followed by urinary complications such as dysuria. Associated factors involve increased abdominal pressure, such as coughing or constipation, and trauma or infections of the vagina or urinary tract. Management ranges from conservative medical treatment to a variety of surgical corrective procedures, such as excision and urethroplasty. Medical treatment includes local hygiene, sitz bath, topical antibiotics, steroid, or topical estrogen creams (adults). Surgical intervention is indicated for more severe cases: significant bleeding, thrombosis, or gangrenous changes or if topical estrogen is contraindicated. Surgical treatment is usually accomplished with the modified Kelly–Burnam operation. The prolapsed mucosa is excised, and the mucocutaneous junction is reapproximated with absorbable sutures.

URETHRA, VILLOUS ADENOMA

DESCRIPTION An adenomatous lesion of the urethra, usually polypoid in nature, covered by mucinous material. Masses as large as 2–4 cm in the urinary tract have been described. Etiology is possibly due to an embryologic origin similar to that of the rectosigmoid. Urinary obstruction and/or hematuria can be presenting symptoms. Best treated by complete removal, due to the premalignant changes seen in some lesions and malignant potential seen in adenomas of the colon. These lesions are most commonly encountered in the male prostatic urethra. Histogenesis has been suggested to be secondary to residual cloacal epithelium in the prostatic urethra.

URETHRAL HYPERMOBILITY

DESCRIPTION Also called type II stress urinary incontinence (SUI), urethral hypermobility is caused by weak support of pelvic floor supporting structures, in which increased intra-abdominal pressure causes the descent of the bladder neck and proximal urethra. Women with hypermobility present with SUI, although some continent women have it as well. The degree of hypermobility is measured by the Q-tip test, in which a well-lubricated sterile cotton-tipped applicator is placed into the bladder and then withdrawn to the point of resistance. The patient is then asked to strain and the motion of the Q-tip is observed. Hypermobility is defined as a resting or straining angle 30% from horizontal. Treatment is periurethral collagen injection or pubovaginal sling procedure.

REFERENCE

Bakas P, Liapis A, Creatsas G. Q-tip test and tension free vaginal tape in management of female patients with genuine stress incontinence. *Gynecol Obstet Invest.* 2002;53(3):170–173.

URETHRAL PRESSURE PROFILE (UPP)

DESCRIPTION The UPP is a graphic representation of the intraluminal pressure along the length of the urethra. This static study provides no assessment of physiologic urethral function during voiding. The micturitional urethral pressure profile, however, is a dynamic study that can be performed by withdrawing a catheter from the urethra during micturition. The study can define the site of urethral obstruction by demonstrating a drop in urethral pressure immediately distal to the obstructive lesion in the urethra. Controversy exists on its use in clinical practice due to the variability in the reproduction of measurements and lack of standardization.

Valentini FA, Robain G, Marti BG. Is a sequence of tests during urethral pressure profilometry correlated with symptoms assessment in women? *Int Brazil J Urol.* 2012;38(6):809–817.

URETHRAL SLING, INDICATIONS AND ANATOMIC POSITIONS

DESCRIPTION A urethral sling is a surgically placed to support pelvic structures or lift the urethra to enhance the bladder and pelvic floor's ability to retain urine in patients with stress urinary incontinence (SUI). Slings can be made from autologous, allograft, xenograft, or synthetic tissues that provide strength. They can be placed at the proximal urethra (pubovaginal slings) or mid urethra (tension-free transvaginal tape [TVT] and transobturator [TOT] and other mid urethral slings). The urethral sling is a very effective treatment for SUI, with cure rates of 80–90% vs. other options such as the periurethral injection of bulking agents. Complications include erosion into surrounding structures such as vagina, urethra, and bladder, as well as bladder perforation, urinary tract infection, and new onset irritative voiding symptoms. (See also Section I: "Incontinence, Urinary, Adult Female"; Section II: "Sling Materials.")

URETHRA, STENOSIS/STRICTURE, FEMALE

DESCRIPTION A decrease in the caliber of the urethra, uncommon in females compared with males. Causes can include recurrent UTIs, previous endoscopic instrumentation, surgical

management of urethral pathology or diverticular repair, trauma (including childbirth), neoplasia, or pelvic radiation, or it can be idiopathic. The patient usually presents with recurrent UTI or obstructive urinary symptoms (weak stream, straining to urinate, incomplete emptying). Female urethral stricture has been formally defined as a fixed anatomic narrowing between the bladder neck and distal urethra of <14 Fr preventing catheterization, with the diagnosis confirmed by cystourethroscopy, and/or videourodynamics. Intermittent catheterization has been used successfully, with internal urethrotomy or urethroplasty also as options.

REFERENCES

Smith AL, Ferlise VJ, Rovner ES. Female urethral strictures: Successful management with long-term clean intermittent catheterization after urethral dilatation. *BJU Int.* 2006;98(1):96–99.

Tsivian A. Dorsal graft urethroplasty for female urethral stricture. *J Urol.* 2008;176(2):8-611–613.

URETHRAL SYNDROME

DESCRIPTION A nonspecific term used in the past to describe symptoms such as urinary frequency, urgency, dysuria, and pelvic/perineal discomfort having no obvious cause. Because this term is so nonspecific, it is not meaningful for diagnosis or treatment planning. A more effective approach is to delineate each of the patient's specific symptoms (eg, frequent voiding), then pursue the differential diagnosis and treatment options for each symptom. The concept of chronic or acute urethral syndrome is now essentially historical, and is no longer used in modern medical literature.

REFERENCE

Hanno PM. Painful bladder syndrome/interstitial cystitis and related disorders. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*, 9th ed. Philadelphia, PA: Saunders; 2007.

URETHRITIS, ACUTE

DESCRIPTION Syndrome of urethral inflammation marked by painful urination, urethral pruritus, and discharge. Usually caused by a STD/STI, but other causes are not uncommon. Untreated cases may gradually resolve, but complications, such as urethral stricture in males or pelvic inflammatory disease (PID) in women, may ensue. Cause is predominantly *N. gonorrhoeae* and *C. trachomatis* infection; often together. Less common infectious agents include *Ureaplasma urealyticum, Trichomonas vaginalis,* herpesvirus, and *Mycoplasma genitalium.* Rare noninfectious causes include foreign bodies, soaps, shampoos, douches, spermicides, and urethral instrumentation. Gram stain of discharge with >5 WBC/HPF strongly suggests urethritis. Intracellular gram-negative diplococci are strongly indicative of gonorrhea. Cultures may be difficult to obtain, but are important for antimicrobial sensitivity testing and should be performed in all symptomatic patients. Routine urine analysis may be normal in simple urethritis. st-void urine is often positive for leukocyte esterase and should show ≥ 10 WBC/HPF in acute urethritis. NAAT utilizing PCR assay on urine is very sensitive and specific, but costly. Wet prep of discharge may reveal *Trichomonas*; this is usually

reserved in males who fail adequate treatment for gonorrhea and chlamydia. Syphilis, HIV, and hepatitis B serology is performed as indicated to rule out concomitant STDs.

TREATMENT

- The United States Preventative Services Task Force recommends screening all sexually active women ≤25 yo and all other women at increased risk of infection.
- All sexual partners who came in contact with the patient within 60 days should be evaluated, tested, and treated for gonorrhea and chlamydia.
- Gonorrhea: Ceftriaxone 250 mg in a single IM PLUS Azithromycin 1 g orally in a single dose or doxycycline 100 mg orally twice daily for 7 days
- Chlamydia: Azithromycin: 1 g PO single dose or doxycycline: 100 mg PO BID for 7 days
- Trichomoniasis: Metronidazole 2 g PO single dose or 250 mg TID for 7 days or tinidazole 2 g PO in a single dose

REFERENCE

Centers for Disease Control and Prevention. Sexually Transmitted Diseases Treatment Guidelines, 2010. *MMWR*. 2010;59(No. RR-12).

URETHRITIS, CHRONIC, FEMALE

DESCRIPTION Chronic urethritis is a common urologic problems of females, as the distal urethra normally harbors pathogens. Infection may be increased by wearing contaminated diapers, by insertion of an indwelling catheter, by spread from cervical or vaginal infections, or by intercourse with an infected partner. Urethral inflammation may also occur from the trauma of intercourse or childbirth, particularly if urethral stenosis, either congenital or following childbirth, is present. The urethral mucosa is reddened, sensitive, and often stenotic. Granular areas are often seen, and polypoid masses are common. The symptoms resemble those of cystitis, although the urine is not infected. Complaints include dysuria, frequency, and nocturia. Discomfort in the urethra may be felt, particularly when walking. Urethral dilations may help if stenosis is found (dilate to 36 Fr). Empiric doxycycline or azithromycin can be tried.

URETHRITIS, POLYPOID

DESCRIPTION A urethral counterpart of polypoid cystitis, it occurs as single or multiple polypoid/papillary lesions. A nonneoplastic inflammatory lesion that is usually found in the prostatic urethra near the verumontanum. The lesions are edematous stroma with distended blood vessels and chronic inflammatory infiltrate. Usually resolves after removal of the inflammatory stimulus; if necessary, resection of the lesions usually leads to a cure. If the lesions persist, malignancy should be ruled out.

REFERENCE

Philadelphia, PA: Mosby Elsevier, 2008:598.

URETHRITIS, SENILE

DESCRIPTION After physiologic (or surgical) menopause, hypoestrogenism occurs and retrogressive (senile) changes take place in the vaginal (atrophy) and the urethral walls. Some eversion of the mucosa at the urethral orifice, from atrophy of the vaginal wall, is usually seen and can be misdiagnosed as a caruncle. Many postmenopausal women have symptoms of vesical irritability (burning, frequency, urgency) and stress incontinence. Dysuria may occur due to urine contact with the inflamed atrophic tissues themselves or because of the increased incidence of UTIs in these women. Best treated symptomatically or with DES vaginal suppositories 0.1 mg nightly for 3 wk. The patient may also benefit from other topical agents such as estradiol vaginal tablets or from conjugated estrogen cream or slow release intravaginal therapy such as the Estring.

URETHROCELE

DESCRIPTION Urethrocele is a form of pelvic prolapse in which the urethra protrudes into the anterior wall of the vagina, due to loss of the normal urethral support from damage such as childbirth. Cystocele is also commonly present. In women, a urethrocele can cause voiding difficulty, some degree of incontinence, UTI, and dyspareunia. The condition can also develop in children after urethroplasty, with distal obstruction causing proximal dilation of the neourethra; it is very rarely congenital. (See also Section I: "Pelvic Prolapse [Cystocele and Enterocele].")

In: Lentz GM, Lobo RA, Gershenson DM, Katz VL, eds., *Lentz: Comprehensive Gynecology*. 6th ed. Philadelphia, PA: Mosby; 2012.

URETHRORRHAGIA, IDIOPATHIC

DESCRIPTION Bleeding from the urethra or blood spotting on the undergarments in preadolescents average age (around 10 yr); this is a benign condition, self-limited in most cases. The etiology is unknown. Routine radiographic, lab, and endoscopic evaluation is unnecessary for evaluating urethrorrhagia. Watchful waiting is indicated, as the condition resolves in 71% and 91.7% of patients at 1 and 2 yr, respectively. Evaluation should be considered in patients with prolonged urethrorrhagia because urethral stricture may be

identified. (See also Section II: “Urethral, Bleeding [Blood at Meatus].”)

REFERENCE

URGE INCONTINENCE/URGE URINARY INCONTINENCE (UUI)

DESCRIPTION Urge urinary incontinence (UUI) is the involuntary leakage of urine immediately preceded by a sense of urgency; it is caused by detrusor muscle overactivity. Etiology is categorized into idiopathic; neurogenic, as from stroke or multiple sclerosis (MS); or nonneurogenic, including infection, bladder stones, and cancer. Initial workup includes a good history and physical, evaluation for other associated urinary symptoms, check of postvoid residual, urine analysis. Cystoscopy should be performed in the setting of simultaneous hematuria. Urodynamic evaluation can be considered in medically refractory patients. (See also Section I: “Incontinence, Female”; and “Incontinence, Male.”)

TREATMENT

- Symptomatic control mainstay of treatment.
- Dietary and behavioral modifications: Limiting caffeinated substances fluid intake, artificial sweeteners, and timed voiding should be the initial treatment.
- Biofeedback-assisted pelvic muscle training
- 1st-line medical therapy: Anticholinergics, β3-agonists
- 2nd-line therapy: Intravesical Botulinum toxin, sacral neuromodulation, and augmentation cystoplasty.

URGENCY PERCEPTION SCORE (UPS)

DESCRIPTION The UPS is a system based on the grade of sensation of bladder fullness at each micturition. This system proposes that urgency is always abnormal, that it lies on a continuum, and that it can be graded on a scale of 0–4 where 0 is no urge; 1, mild urge; 2, moderate can hold (>10–60 min); 3 severe can hold (<10 min); and 4, desperate urge must go (immediately). The UPS can be a useful tool in a bladder diary, and it becomes a treatment outcome tool because improvements can be shown as decreases in grade, and in number or urgency of voids.

URIC ACID NEPHROPATHY

DESCRIPTION Uric acid nephropathy can be both acute and chronic. Acute uric acid nephropathy is caused by intrarenal precipitation of uric acid crystals in the distal nephron (collecting tubules) due to its acidic environment. This can lead to obstruction of nephrons and development of ARF. Acute acid nephropathy more likely occurs in patients with leukemia and lymphomas undergoing chemotherapy (plasma urate concentration generally above 15 mg/dL or 893 μmol/L). Chronic uric acid nephropathy or gouty nephropathy occurs in individuals with more protracted forms of hyperuricemia. Monosodium urate crystals deposit in distal tubules, collecting ducts and the renal interstitium. Deposits induce a tophus from a fibrotic reaction. Tubular obstruction leads to cortical atrophy and scarring. Typically this form is a subtle disease with slow progression.

URINARY ASCITES (UROPERITONEUM)

DESCRIPTION Urinary ascites is usually seen in infants, because of the relative lack of dilation of the newborn collecting system, when compared to that in adults. The condition most often occurs in neonates due to intraperitoneal bladder or upper tract perforation as a result of distal urinary obstruction. It is rare in adults. The most common cause is posterior urethral valves, accounting for 70% of cases. Persistent cloaca may allow the reflux of urine into the peritoneal cavity without perforation. Mortality rate is as high as 70%. Signs and symptoms may include abdominal distention, acidosis, electrolyte abnormalities, and respiratory compromise from increased abdominal pressure. In older patients, hyponatremia and increased serum creatinine can be observed. Diagnosis includes imaging (CT or US), voiding cystourethrography, and paracentesis to check creatinine levels in ascitic fluid.

A newer cause of urinary ascites relates to urinary extravasation following laparoscopic or robotically assisted radical prostatectomy (RP). Since the peritoneum is opened as part of the procedure urinary extravasation becomes urinary ascites. It can lead to ileus.

TREATMENT

- Relieve obstruction (ie, ablation of posterior urethral valves).
- Catheter bladder drainage in posterior urethral valves and upper tract drainage may be necessary.
- Correct fluid balance and electrolyte abnormalities.
- Direct repair at the perforation site is usually not indicated (Image ☼).

assisted laparoscopic radical prostatectomy. *J Urol.* 2006;175(2):541–546; discussion 546.

URINARY DIVERSION, ELECTROLYTE, AND OTHER ABNORMALITIES

DESCRIPTION Fluid and electrolyte complications can arise from solute transfer from urine across a bowel segment used for urinary diversion. The specific segment of bowel used, the amount and time of contact of urine with bowel mucosa, the age of the conduit, and renal function are all factors that can affect fluid and electrolyte balances. In addition to the metabolic disturbances listed below, bowel segment absorption can be associated with abnormal drug metabolism. For example, methotrexate toxicity in patients with ileal conduits is well recognized, and patients with continent diversion who receive chemotherapy should be monitored closely and stay well hydrated; the reservoir is drained during treatment. Other drugs reported to be absorbed from intestinal segments in the urinary tract include phenytoin, theophylline, and antibiotics. Diabetics have enhanced ability to absorb glucose from intestinal reservoirs so screening with urine tests may be inaccurate. Glucose blood testing is recommended.

- Ileal and colonic conduits can produce hyperchloremic metabolic acidosis. The mechanism is the absorption of ammonium chloride (a weak acid) in exchange for carbonic acid (CO_2 and water). Treatment, if necessary, consists of urinary alkalinization (sodium bicarbonate, Bicitra, Polycitra) or blockade of chloride transport (chlorpromazine 25–50 mg TID or nicotinic acid 400 mg TID)
- Jejunum is least attractive for use in urinary diversions, due to its high absorptive capacity, and it is associated with hyponatremic, hyperkalemic metabolic acidosis with azotemia.
- Gastric segments cause a hypochloremic, hypokalemic metabolic alkalosis. This is not normally a significant problem unless renal failure develops and the segment needs to be taken down.
- Distal ileum resection may result in macrocytic anemia due to B12 deficiency over long periods and may require supplementation.

URINARY DIVERSION, RISK OF MALIGNANCY

DESCRIPTION Segments of bowel used for urinary diversion have an increased risk of malignant transformation. Some studies have shown an increase from 5% up to as high as 40% 10–20 yr after a urinary diversion. The etiology is unknown; adenocarcinomas, adenomatous polyps, sarcomas, TCCs, signet ring carcinomas, and SCCs have been identified. Many investigators now recommend annual screening in patients who have intestinal segments in contact with urine beginning 10 yr after the initial surgery. Patients who have previously undergone a ureterosigmoidostomy are at particularly increased risk for development of adenocarcinoma of the sigmoid colon along the anastamotic line. It is recommended that these patients undergo periodic colonoscopy to accurately define any morbidities from their previous diversion.

URINARY FLOW RATE (UROFLOWMETRY)

DESCRIPTION *Uroflowmetry* is the study of urinary flow rate. Urinary flow rate is defined as the product of detrusor contractility against bladder outlet resistance. Deviations from normal urinary flow rate may represent abnormalities of either process. It should not be used alone, but in combination with a determination of bladder residual volume and symptoms to determine the presence of bladder outlet obstruction. To interpret a uroflow, a voided volume of at least 125–150 mL is required for an adequate study. Some normal values are listed here, although clinical scenarios vary widely, with no given cutoff value to document the appropriateness of therapy:

- Males: <40 yr: >22 mL/s; 40–60 yr: >18 mL/s; >60 yr: >13 mL/s
- Female: <50 yr: >25 mL/s; >50 yr: >18 mL/s

A Q_{max} of <15 mL/s does not differentiate between obstruction and bladder hypocontractility. Men with >15 mL/s Q_{max} seem to have a poorer outcome with bladder outlet procedures such as prostatectomy. The study consists of a graphical flow rate pattern, along with values for maximum flow rate, also called peak flow rate (Q_{max}), average flow rate (Q_{ave}), maximum flow time, and total flow time. Various nomograms have been published to aid in the interpretation of uroflow data (Siroky, Abrhams, and Griffiths). A normal graphical flow rate pattern represents a bell-shaped curve. (See also Section II: “Pressure–Flow Studies.”)

URINARY RESIDUAL VOLUME (POSTVOID RESIDUAL)

DESCRIPTION Urinary residual volume is the amount of urine present in the urinary bladder immediately after a complete voiding. Also known as postvoid residual, it can assist in differentiating between disorders of emptying and disorders of storage in urinary incontinence. It provides clinical quantitative information on the degree of obstruction in certain conditions, such as BPH, or efficiency of bladder emptying in neurogenic bladder, for example. Chronic high urinary residual volumes can predispose a patient to bladder hypertrophy, ureterovesical reflux, increased intravesical pressure, incontinence, or loss of detrusor muscle tone. Residual volume is measured by US or catheterization and is usually interpreted in the context of uroflowmetry. Treatment of high urinary residual volumes is to treat the underlying cause and to provide bladder drainage.

URINARY RETENTION FOLLOWING BRACHYTHERAPY

DESCRIPTION Urinary retention occurs in up to 22% of patients who undergo brachytherapy. Risk factors for postbrachytherapy retention include a large prostate (>36 g) and elevated I-PSS scores prior to treatment. Medical therapy that may aid with retention include corticosteroids, celecoxib, and α-blockers. Clean intermittent catheterization (CIC) is done to allow drainage of urine. Patients who fail medical therapy can safely undergo a cautious transurethral resection of the prostate. A temporary Spanner urethral stent has also ben used.

REFERENCE

Mabjeesh NJ, Chen J, Stenger A, et al. Preimplant predictive factors of urinary retention after iodine 125 prostate brachytherapy. *Urology.* 2007;(703):548–553.

URINARY RETENTION, POSTOPERATIVE

DESCRIPTION Postoperative urinary retention occurs in 4% of surgical patients, although abnormal voiding is seen up to 80% of postop patients. Subclinical obstructive uropathy, overdistention of bladder during operation, sympathomimetic and anticholinergic medication use, and inability to stand after surgery are common causes. Treatment with decompression of the bladder using an indwelling Foley catheter or with clean intermittent catherization should also include early ambulation and a bowel regimen to prevent constipation, as well as limited use of narcotic pain meds.

URINARY TRACT INFECTION (UTI), CATHETER-RELATED (CAUTI, CA-UTI)

DESCRIPTION UTI is the most common hospital-acquired infection in the United States and a major focus to improve patient outcomes. Any passage of a urethral catheter can introduce bacteria into the bladder. Once the catheter is in place, bacteria enter the bladder around the catheter (extraluminal infection) and from intraluminal infection failure of closed drainage or contamination of the urine collection bag. The incidence of bacteriuria in patients with indwelling bladder catheters is directly related to the duration of catheterization. Even with optimal bladder care, 3–10% develop significant bacteriuria daily. Of these patients, 10–25% develop symptomatic UTI (catheter associated UTI or abbreviated CAUTI), and 4% may develop bacteremia. Avoiding unnecessary catheterization, removing the catheter as soon as possible, and appropriate catheter management (closed catheter drainage) are the most effective methods to reduce these infections. Silver-coated urinary catheters have been shown to reduce infections. Patients who require long-term bladder drainage should be managed

with intermittent catheterization, if possible. This approach is associated with a lower rate of bacteriuria and symptomatic UTI than management with long-term indwelling catheterization. Prophylactic antibiotics are not consistently of proven benefit. Catheter-associated urinary tract infection definitions by the CDC have recently been narrowed to exclude asymptomatic bacteriuria. (See alco Section I: "Urinary Tract Infection [UTI], Catheter Associated [CAUTI, CA-UTI].")

URINE, ABNORMAL COLOR

DESCRIPTION Normal urine is clear and pale to dark yellow due to the presence of urochrome. Foods, medications, metabolic products, and infection can cause abnormal urine colors. (See also Section IV: "Urine Studies."):

- Cloudy: Phosphaturia precipitated phosphate crystals in alkaline (urine), pyuria (UTI), fungal infection, chyluria, lipiduria, hyperoxaluria, diet high in purine-rich foods (hyperuricosuria)
- Colorless: Diabetes insipidus (DI), diuretics, excess fluid intake
- Brown: Nitrofurantoin, metronidazole, aloe, porphyria, bile pigments, myoglobin
- Brown-black: Bile pigments, melanin, acute intermittent porphyria, methemoglobin, medications: Cascara, chloroquine, ferrous salts/ iron dextran, levodopa, methocarbamol, methyldopa, metronidazole, nitrates, nitrofurantoin, quinine, senna, sulfonamides
- Deep yellow: Very concentrated urine, carrots, cascara
- Green-blue: Pseudomonal UTI; Medications: Indigo carmine, methylene blue, amitriptyline , indomethacin , doxorubicin, triamterene, methcarbamol
- Muddy: Pyuria, phosphaturia, chyluria
- Yellow-brown: Medications: Bismuth, chloroquine, cascara, metronidazole, nitrofurantoin, primaquine, senna, sulfonamides
- Orange-yellow: Bile pigments. Medications: Phenothiazines, phenazopyridine, laxatives, vitamin B, rifampin, warfarin, heparin, chlorzoxazone, sulfasalazine
- Pink or red: Hematuria, hemoglobinuria, myoglobinuria, porphyria, anthocyanin in beets, blackberries, rhubarb. Medications: phenolphthalein, rifampin, daunorubicin, doxorubicin, heparin, ibuprofen, methyldopa, phenothiazines, phenytoin, phenylbutazone, rifampin, salicylates, senna
- Tea-colored: Old blood

URINE, CYTOLOGY

DESCRIPTION Urine cytology is the microscopic evaluation of shed urothelial cells in the urine. A positive reading suggests the existence of urothelial malignancy. It is highly specific (94% for high-grade tumors), but has low sensitivity (40–60%) especially for low-grade tumors (11%). It is combined with cystoscopy and upper tract imaging for workup of urothelial malignancy. The urine is stained by a multichromatic staining process called Papanicolaou stain (Pap stain). It is used to differentiate different cell types.

URINE, FOAMING

DESCRIPTION Foaming urine is a clinical finding often associated with proteinuria and kidney disease and its observation dates back to Hippocrates. Increasing degrees of proteinuria produce decreasing degrees of surface tension. In addition, the ellipsoid shape of protein molecules at the air–water interface produces increased surface activity. These factors establish an environment in which molecules are unable to reorient in a monolayer due to electrostatic repulsion; this produces foam. Occasionally, foaming is transient and caused by a forceful urination into water in a toilet. (See also Section IV: “Urinalysis and Urine Studies.”)

TREATMENT

- Treat the underlying cause of proteinuria
- Qualitative dipstick analysis, 24-hr urine collection, renal workup

REFERENCE

Diskin CJ, Stokes TJ, Dansby LM, et al. Surface tension, proteinuria, and the urine bubbles of Hippocrates. *Lancet.* 2000;355:901–902.

URINE, ODOR

DESCRIPTION Urine odor is related to the volume, concentration, and composition of a variety of excreted chemicals and physiologic contributions from the urinary system. Normally, dilute urine ranges from odorless to mildly aromatic, often described as nutty or “urinous.” Changes in odor are often temporary and carry little prognostic indication; however, medical conditions can occasionally present with distinct urinary odors, as described below. (See also Section IV: “Urine Studies.”)

Condition	Urine Odor
Diseases	
Cystine decomposition, cystinuria	Sulfured
Dehydration	Strong
Diabetic ketoacidosis	Sweet, fruity odor
Enterovesicular fistula	Feculent
Retained urine	Ammonia-like
Stagnant urine, room temperature urine	Ammonia like
UTI	Pungent
Food and medications	
Asparagus	Pungent, rotten cabbage
Fish oils	Fishy
Vitamin B6	Pungent, vitamin-like
Inborn errors of metabolism	
Glutaric and isovaleric acidemia	Sweaty feet, acrid
Hawkinsinuria	Swimming pool
Hypermethioninemia	Boiled cabbage
Maple syrup urine disease	Maple syrup
Multiple carboxylase deficiency	Tomcat urine
Oasthouse urine disease	Hops-like
Phenylketonuria	Musty, mousey
Trimethylaminuria	Rotting fish
Tyrosinemia	Boiled cabbage, rancid butter

URINE, PARTICLES IN

DESCRIPTION In the gross observation of particulate matter in the urine, differential diagnoses include infection (bacterial, fungal), enterovesical fistula (mucus, feces, or undigested food particles), blood clots from hematuria of any cause, papillary necrosis, ATN, chyluria, urolithiasis, crystalluria, bilharzia (schistosomiasis), urothelial or other carcinoma with sloughing tissue, clumping of excessive urinary cast or protein, postoperative (eg, suture material), or vaginal contamination. The condition can be a normal finding with any form of urinary diversion that uses a bowel segment (usually mucous or sloughed epithelium). Note that a urine sample left standing at room temperature may cause precipitation of phosphate salts. Urine samples that will not be analyzed immediately (in <2 hr) should be refrigerated. Clearing of the specimen after addition of a small amount of acid indicates that precipitation of salts is the probable cause. (See also Section II: “Fecaluria.”)

URINOMA (PERINEPHRIC PSEUDOCYST)

DESCRIPTION A collection of urine outside the urinary tract (extravasation), commonly

seen from rupture of the collecting system (usually calyceal rupture) due to high pressures from obstruction (stones, posterior urethral valves, strictures, others), postoperative surgical leak (ureteral anastomosis, collecting system closure, urethral anastomosis, etc.), or traumatic disruption of the urinary tract (iatrogenic, penetrating, or blunt). Leakage of urine into the perirenal or periureteral tissues in excess of an amount that can be absorbed results in urinoma formation. The urine causes lipolysis of surrounding fat, creating a fibrous sac around the extravasated urine.*Perinephric pseudocyst* is the term sometimes used for an urinoma that surrounds the kidney. The urinoma fluid's creatinine level is typically elevated, indicating urine as the source. Urinoma must be distinguished from hematoma, abscess, or lymphocele. Classically, the urinoma is thin-walled and smooth, and the walls tend to enhance secondary to inflammatory neovascularity. In contrast, the walls of abscesses and hematomas tend to be thick and more irregular with even more prominent vascularity. Typically, urinomas demonstrate homogeneous Hounsfield units between –10 and +30 HU, and hematomas and abscesses demonstrate heterogeneous Hounsfield units. Treatment is directed at correcting the cause (relief of obstruction, stenting, or repair of leak). Small urinomas will reabsorb spontaneously, and drainage is not necessary. If the urinoma is large, CT- or US-guided drainage or aspiration can be performed. In perirenal urinomas due to trauma to the kidney, viability of the parenchyma must be assessed by contrast-enhanced CT. If nonviable tissue components extend to the collecting system (suggestive of necrosis), there is an increased risk for continued urine leak and debridement is necessary. (See also Section I: "Renal Trauma, Adult" and (Image ☼).)

REFERENCE

Heikkilä J, Taskinen S, Rintala R. Urinomas associated with posterior urethral valves. *Urology*. 2008;180(4):1476–1478.

URINOTHORAX

DESCRIPTION Urinothorax is rare and refers to the presence of urine in the pleural space. It usually occurs secondary to obstructive uropathy, from the leakage of urine into a retroperitoneal urinoma and then its passage into the pleural space directly or via lymphatics. Cases have been reported in the setting of interventions including percutaneous nephrolithotomy, ESWL, and others. It is classified as a transudate. The diagnosis can be confirmed by finding a pleural fluid-to-serum creatinine ratio >1 (often >10). Relief of obstruction causing the persistent urine leak and thoracentesis or chest tube placement is therapeutic.

URODYNAMICS, INDICATIONS AND NORMAL VALUES

DESCRIPTION A series of investigational tests to assess lower urinary tract function. Usual components include uroflowmetry, cystometry, abdominal pressure monitoring, electromyography, and voiding pressure–flow studies. Through simultaneous measurement of

bladder and abdominal pressures, the detrusor pressure can be inferred and used to interpret neuromuscular events during voiding. UDS can be used to identify contributing factors to voiding dysfunction and assess their relevance, predict consequences of that dysfunction on the upper tracts, to predict the consequences and outcomes of therapeutic intervention, to confirm or understand the effects of interventional techniques, and to investigate the reasons for treatment failure. See table for Normal UDS values in Adults (Image ☼)

Common Urodynamic Indications Include:

- Failure of empiric treatments
- Symptomatic voiding dysfunction prior to beginning incontinence therapy
- Inability to demonstrate incontinence clinically despite subjective patient complaints
- Significant morbidity of proposed incontinence treatment course:
- Following prior surgical therapy for incontinence, following pelvic radiation or radical pelvic surgery
- Known or suspected neurologic disorder that may influence bladder function (ie, Spinal Cord Injury)
- Simpler diagnostic tests have been inconclusive

Normal Urodynamic Values in Adults:

- Volume Voided (mL): 338 ± 234
- Voiding Time (sec): 28 ± 22
- Max Flow (mL/sec): M 24 ± 10, W 30 ± 10
- Average Flow (mL/sec): M 14 ± 5, W 22 ± 14
- Maximum Capacity (mL): M 552 ± 132, W 453 ± 146
- Compliance (mL/cm water): M 56 ± 37, W 71 ± 40
- Postvoid Residual (mL): 20 ± 50

M: men; W: women.

UROGENITAL DISTRESS INVENTORY (UDI-6)

DESCRIPTION The UDI-6 is a 6-item questionnaire that assesses LUTS, including incontinence, in women. It is a short form of an original 19-question inventory. All questions are relatively easily understood by patients, and individual responses have been shown to correlate with different types of urinary incontinence (#3 >2 = SUI; #1, #2 >2 = detrusor overactivity; #5 > all other scores = bladder outlet obstruction) (see table on previous page).

Urogenital Distress Inventory–Short Form					
Do you experience and, if so, how much are you bothered by:		Not at All	A Little Bit	Moderately	Greatly
UDI#1	Frequent urination	0	1	2	3
UDI#2	Urine leakage related to urgency	0	1	2	3
UDI#3	Urine leakage related to physical activity	0	1	2	3
UDI#4	Small amounts of urine leakage (drops)	0	1	2	3
UDI#5	Difficulty emptying your bladder	0	1	2	3
UDI#6	Pain or discomfort in the lower abdomen/genitalia	0	1	2	3

UROLITHIASIS, DRUG INDUCED

DEFINITION

Drug-induced renal calculi represent about 1–2% of all renal calculi. Drugs used for the treatment of HIV have become the most frequent cause of drug-containing urinary calculi. Protease inhibitors used in the management of HIV are documented to induce kidney stones, especially indinavir and atazanavir, and more recently darunavir. Triamterene, topiramate and zonisamide (anticonvulsants), methotrexate, guaifenesin/ephedrine, ceftriaxone, trimethoprim-sulfamethoxazole, vitamin D, and calcium supplements are also responsible for some cases of drug-induced urolithiasis. Patients with triamterene-containing stones are more likely to have a prior history of stone disease, suggesting that metabolic predisposition is an important risk factor. Renal calculi have been noted in up to 64% of low–birth-weight infants receiving furosemide loop diuretic therapy. Laxative abuse should be suspected in patients who form ammonium acid urate stones in the absence of bowel disease or urinary tract infection. Loop diuretics, carbonic anhydrase inhibitors, and abused laxatives can cause metabolic abnormalities that facilitate the formation of stones.

UROLITHIASIS, INDINAVIR AND OTHER PROTEASE INHIBITORS

DESCRIPTION Drug-induced renal calculi represent 1–2% of all renal calculi. In the last decade, drugs used for the treatment of HIV-infected patients have become the most frequent cause of drug-containing urinary calculi. Among these agents, protease inhibitors (PIs) are well known to induce kidney stones, especially indinavir and atazanavir, and more recently darunavir. A spectrum of asymptomatic crystalluria and renal colic secondary to urolithiasis, with or without dysuria or urgency, seen in patients who are HIV infected and being treated with indinavir and other PI's. Indinavir stones are not radiopaque nor are they always identified on unenhanced CT imaging. A high index of suspicion is necessary to make the diagnosis and stones may appear as a filling defect on contrast enhanced imaging. (See Section I: "HIV/AIDS, urologic considerations" and Section II: "HIV nephropathy.")

REFERENCE
Izzedine H, et al. HIV medication-based urolithiasis *Clin Kidney J*. 2014;7(2):121–126.

UROLITHIASIS, INFECTIOUS (STRUVITE)

DESCRIPTION Composed of magnesium, ammonium, and phophate mixed with carbonate; struvite stones directly correlate with the presence of urease-producing bacteria and active UTI. Associated with a urinary pH of >7.2, which causes struvite crystallization. They usually undergo rapid growth and may result in replacement of the entire pelvis with a stone. (See also Section I: "Urolithiasis, Staghorn" and Section II: "Struvite.")

CAUSES
- Foreign body in the urinary tract
- Neurogenic bladder
- Urinary diversion
- LUTS
- Indwelling catheter

REFERENCE
Vella M, Karydi M, Coraci G, et al. Pathophysiology and clinical aspects of urinary lithiasis. *Urol Int*. 2007;79(Suppl I):26–31.

UROLITHIASIS, MATRIX

DESCRIPTION Also called *matrix stone, matrix nephrolithiasis,* or *matrix calculus* in the literature, this rare renal calculus has been described as being composed of coagulated mucoids with little crystalline component. Found mostly in individuals with infection due to urease-producing organisms such as *Proteus*, matrix calculi can be confused with uric acid calculi because they are radiolucent. Matrix calculi, however, are usually associated with alkaline urine from a UTI, whereas uric acid calculi usually form in acidic sterile urine. Standard treatment techniques such as ureteroscopic lithotripsy are used. (See also Section I: "Urolithiasis, Adult, General.")

REFERENCE
Kim SH, Lee SE, Park IA. CT and ultrasound features of renal matrix stones with calcified center. *J Comput Assist Tomogr*. 1996;20(3):404–406.

UROLITHIASIS, MELAMINE

DESCRIPTION An increased incidence of kidney stones and renal failure recently reported in China are believed to be associated with ingestion of infant formula contaminated with melamine. Melamine (cyanuric acid, ammelide, ammeline) has industrial use as a resin or adhesive, and has been deliberately added to raw milk to boost its protein content. Although the mechanism is not clear, melamine is almost completely excreted by the kidney and appears to interact with cyanuric acid (a by-product or associated impurity) to form crystals. Low solubility promotes precipitation in renal tubules and causes progressive blockage and significant renal degeneration.

TREATMENT

- Immediately discontinue use of melamine-containing food products.
- Medically monitor renal function, fluid balance, and electrolyte status.
- Alkalize the urine.
- Treat acute kideny injury (AKI) if indicated; use blood or peritoneal dialysis.
- Consider surgical pyelolithotomy in refractory cases.

REFERENCES

World Health Organization. Melamine and cyanuric acid: Toxicity, preliminary risk assessment and guidance on levels in food 25 Sept 2008). Available online at: www.who.int/foodsafety/fs_management/melamine.pdf.

UROLITHIASIS, METHOTREXATE

DESCRIPTION Methotrexate is an anti-folate used to treat a wide variety of diseases including: Cancer, rheumatoid arthritis, lupus, ectopic pregnancy, and psoriasis. More than 90% of the drug is cleared in the urine. Drug and its metabolites are poorly soluble in acidic pH and can precipitate crystalline formation and subsequent tubular obstruction. Medication can also lead to an increase in uric acid levels in the body. Extremely rare with only a few reports of renal calculus to the FDA from using this medication. (See also Section I: "Urolithiasis, Adult, General" and Section II: "Urolithiasis, Drug Induced.")

TREATMENT

- Urine alkalinization
- Hydration to induce high urine flow rates

REFERENCE

Yarlagada SG, Perazella MA. Drug-Induced Crystal Nephropathy: an Update. *Expert Opin Drug Saf*. 2008;7(2):147–158.

UROLITHIASIS, TRIAMTERENE

DESCRIPTION Renal calculus consisting either completely or partially of triamterene, a potassium-sparing diuretic often used with hydrochlorothiazide in the treatment of hypertension. Promotion of nucleation and growth of renal calculi, especially calcium oxalate monohydrate, has been shown to occur from triamterene and its metabolites. They are usually radiopaque. Although rare, they usually occur in a patient with a history of urolithiasis. (See also Section II: "Urolithiasis, Adult, General.")

TREATMENT

- Avoid use of triamterene in patients with a history of urolithiasis.
- Discontinue use of triamterene in patients with triamterene urolithiasis.

REFERENCE

Carr MC, Prien EL Jr, Babayan RK. Triamterene nephrolithiasis: Renewed attention is

warranted. *J Urol*. 1990;1446:1339–1440.

UROLITHIASIS, XANTHINE

DESCRIPTION Renal calculus composed of xanthine are usually associated with hereditary xanthinuria, an autosomal recessively inherited inborn error of metabolism characterized by a deficiency of xanthine oxidase. Other causes include allopurinol use in patients with Lesch–Nyhan syndrome, APRT deficiency, or endogenous uric acid overproduction. Xanthine calculi can be confused with uric acid calculi because they are both radiolucent. Xanthine calculi, however, are associated with low serum uric acid levels. Treat with high fluid intake and standard lithotripsy or stone removal techniques. (See also Section II: "Urolithiasis, Adult, General.")

REFERENCE

Cameron JS, Moro F, Simmonds HA. Gout, uric acid, and purine metabolism in paediatric nephrology. *Pediatr Nephrol*. 1993;7:105–118.

URORADIOLOGY SIGNS

DESCRIPTION Uroradiology is rich with descriptions of imaging findings, often metaphorical, which have found common usage in the day-to-day practice of genitourinary radiology. (See Section VII: "Reference Tables: Uroradiology Signs.")

REFERENCE

Dyer RB, Chen MY, Zagoria RJ. Classic Signs in Uroradiology. *RadioGraphics*. 2004;24:S247–S280.

UROTHELIAL DYSPLASIA

DESCRIPTION Urothelial dysplasia represents an early morphologic manifestation of progressive alterations between normal urothelium and carcinoma in situ (CIS). Changes in cellular architecture restricted to the intermediate and basal cell layers. A flat lesion with changes including: Loss of nuclear polarity, nuclear enlargement, nucleolar prominence, nuclear membrane irregularity, and nuclear hyperchromasia. Should only be diagnosed when changes cannot be attributed to inflammation and there is not marked cytologic atypia of CIS. Urothelial dysplasia has the possibility of progressing to carcinoma.

REFERENCE

Hodges KB, Lopez-Beltran A, Davidson DD, et al. Urothelial dysplasia and other flat lesions of the urinary bladder: Clinicopathologic and molecular features. *Human Pathology*. 2010;41:155–162.

VACTERL/VATER ASSOCIATION

DESCRIPTION Also called VATER syndrome, a congenital abnormality involving defects in ≥3 of the following: Vertebral defects, anal atresia, cardiac defects, esophageal atresia and/or tracheo-esophageal fistula, renal dysplasia, and limb defects, especially radial limb defects.

REFERENCE

Botto LD, Khoury MJ, Mastroiacovo P, et al. The spectrum of congenital anomalies of the ATER association: An international study. *Am J Med Genet.* 1997;71:8–15.

VAGINAL AGENESIS

DESCRIPTION Absence or failure of formation of the vagina. Occurs in 1 in 4,000 to 1 in 5,000 female births. 50% of the time, vaginal agenesis is associated with renal abnormalities, such agenesis or ectopia. Uterine abnormalities are commonly associated as well. Etiology has been theorized to be a defect in the embryologic development of a single mesonephric duct. The patient usually comes to attention due to primary amenorrhea. Surgical reconstruction with the use of grafts or flaps is the treatment of choice.

REFERENCE

Marshall FF. Vaginal abnormalities. *Urol Clin North Am.* 1978;(51):155–159.

VAGINAL ATROPHY/VULVOVAGINAL ATROPHY, UROLOGIC CONSIDERATIONS

DESCRIPTION Vaginal atrophy/vulvovaginal atrophy (VVA) is thinning and inflammation of the vaginal walls secondary to lack of estrogen. Most common following menopause, the condition affects 50% of that population, but may also occur with breast-feeding and other low estrogen states. The condition presents as vaginal burning and itching with or without discharge; often linked with dyspareunia. It is often associated with increased urinary frequency, urgency, and/or dysuria. Increased number of UTIs and urinary incontinence have also been reported.

SYNONYMS

- Atrophic vaginitis
- Genitourinary atrophy

TREATMENT

- 1st-line therapy for symptomatic VVA: Nonhormonal lubricants during intercourse and, as indicated, regular use of long-acting vaginal moisturizers.
- Estrogen therapy is appropriate for moderate or severe symptomatic VVA and for milder symptoms unresponsive to initial treatment, including low-dose vaginal or systemic estrogen. Multiple factors figure into decision making for women with a history of breast or endometrial cancer: Patient preference, need, and understanding of potential risks, as well as consultation with the patient's oncologist if estrogens are to be used.
- Systemic estrogen therapy: Pill, patch, gel (note must use with progestin to avoid uterine

lining dysplasia). In general, a progestogen is not indicated for use with low-dose vaginal estrogen.
- Ospemifene is an option for dyspareunia.

Harms RW, et al. Vaginal atrophy. *MFMER*. 2006;(95):1–10.

VAGINAL DISCHARGE, UROLOGIC CONSIDERATIONS

DESCRIPTION Fluid flowing from the vaginal opening, which can be physiologic or pathologic. Timing, color, consistency, odor, and associated symptoms are all important aspects of the evaluation. (See also Section I: "Vaginitis/vulvovaginitis" and Section III: "Vaginal Discharge Algorithm.")

CAUSES
- Noninfective: Physiologic uterine sloughing, cervical ectopy, retained foreign bodies (eg, tampon), vulval dermatitis, urethral diverticulum, sexual abuse
- Nonsexually transmitted infective: Bacterial vaginosis, candidal infections
- Sexually transmitted infective: *C. trachomatis, N. gonorrhoeae, Trichomonas vaginalis* (Image)

VAGINAL DUPLICATION

DESCRIPTION A rare abnormality in embryologic development that results in duplication of the vagina. It is caused by failure of a primitive septum in the uterovaginal canal to regress or by abnormalities in the fusion of paramesonephric ducts during wk 8–9 of embryologic development of the upper vagina. The lower vagina develops from the urogenital sinus when the sinovaginal bulbs fuse. Abnormalities in the fusion can result in different vaginal abnormalities, including duplication. Presenting symptoms can include dysmenorrhea at menarche or a lower abdominal mass. Surgical correction of the septum is the treatment of choice for vaginal duplication.

REFERENCE

Burbige KA, Hensle TW. Uterus didelphys and vaginal duplication with unilateral obstruction presenting as a newborn abdominal mass. *J Urol.* 1984;132(6):1195–1198.

VAGINAL FUSION

DESCRIPTION Sometimes referred to as *vulvar fusion*, *vulvar atresia*, or *labial agglutination,* this is a complete or partial adherence of the labia minora. Usually presents between 3 mo and 4 yr of age with an incidence of 3.3%. The condition predisposes patients to

asymptomatic bacteriuria and recurrent UTIs. Rarely, near-complete fusion can cause urinary outlet obstruction with resultant bladder distention and/or hydronephrosis. Causes include diaper rash, infections, vulvovaginitis, irritants, mechanical trauma, and sexual abuse.

Treatment is initially observation, as spontaneous resolution can be seen. Medical treatment is topical estrogen cream for 4–8 wk, followed by 1–3 mo of topical petroleum jelly application to minimize recurrence.

REFERENCE

Leung AK, Robson WL, Kao CP, et al. Treatment of labial fusion with topical estrogen therapy. *Clin Pediatr*. 2005;44:245–247.

VAGINAL MASS, NEWBORN

DESCRIPTION Rare interlabial or periurethral lesions are found in young girls, each with strikingly similar gross appearances among the different etiologies listed below. Clinical exam should note exact location of lesion, urethral location, and urine flow. Workup depends on exam, although voiding cystourethrogram is usually warranted.

CAUSES

- Hydrocolpos (imperforate hymen)
- Paraurethral cyst
- Prolapsed ectopic ureterocele
- Rhabdomyosarcoma of the vagina
- Urethral polyp
- Urethral prolapse

REFERENCE

Nussbaum AR, Lebowitz RL. Interlabial masses in little girls. *Am J Roentgenol*. 1983;141(1):65–71.

VAGINAL PESSARIES, UROLOGIC CONSIDERATIONS

DESCRIPTION A passive intravaginal device used to maintain the correct anatomic position of the pelvic organs and aid in urinary continence. The overall prevalence of incontinence in individuals >65 is ~30%. Pessaries provide a noninvasive management option for that subset of patients with stress urinary incontinence (SUI). Despite a wide range in published results, when combined with pelvic floor muscle rehabilitation (ie, Kegel exercise, biofeedback), patients using a pessary should expect complete resolution in <20% of cases, but vast improvement of symptoms 50–75% of the time. This may be used as a final treatment mechanism in patients at high operative risk, or as a bridge to surgical correction of laxity in the pelvic anatomy.

REFERENCE

Junemann KP. The management of female stress urinary incontinence: II. The use of devices. *BJU Int*. 2001;87:449–455.

VAGINAL PROLAPSE

DESCRIPTION Disruption of the neuromuscular, ligamentous, or fascial components involved in normal vaginal support, resulting in the externalization of a portion of the vaginal canal. Despite a complex anatomic framework, implicated causative etiologies include the uterosacral and cardinal ligaments, as well as the endopelvic fascia. Urologically notable is the association with intraoperative ureteral injury during surgical correction (11%) and postoperative association with SUI once the pelvic anatomy is restored. (See also Section I: "Pelvic Prolapse [Cystocele and Enterocele].")

- Cystocele (bladder into vagina)
- Enterocele (small intestine into vagina)
- Rectocele (rectum into vagina)
- Urethrocele (urethra into vagina)
- Uterine prolapse (uterus into vagina)
- Vaginal vault prolapse (vaginal roof through vagina)

TREATMENT

- Abdominal sacrocolpopexy: Anterior and posterior grafts bridging vaginal wall to the sacral promontory via an abdominal incision
- Vaginal vault suspension: Apogee system (artificial recreation of the cardinal ligaments)
- Intravaginal sling plasty: Polypropylene sling recreation of the suspensory ligament
- Sacrospinous fixation: Elevation and fixation of vaginal apex to sacrospinous ligaments
- Iliococcygeal or uterosacral suspension: Via vaginal incision and fixation to surrounding structures

REFERENCE

Biller DH, Davila GW. Vaginal vault prolapse. *Clev Clin J Med.* 2005;72(4):S12–S19.

VAGINOSIS

DESCRIPTION The most common type of vaginal infection, resulting from an imbalance between the standard vaginal flora (*Lactobacillus* sp.) and potentially harmful organisms (typically *Gardnerella vaginalis, Mobiluncus, Bacteroides*, and *Mycoplasma*). Symptoms include a foul or "fishy" odor, milky white or gray discharge, and vaginal irritation especially prominent after sex. Diagnosis can be confirmed by elevated vaginal pH (typically pH >4.5), a positive "whiff test" malodorous/fishy odor when secretions are combined with 10% (KOH), or by the presence of "clue cells" epithelial cells (coated with bacteria) on microscopic normal saline wet mount. (See also Section I: "Vaginitis/vulvovaginitis" and Section II: "Trichomonas." (Image ☼))

TREATMENT

- Oral metronidazole 500 mg PO BID for 7 days
- Vaginal metronidazole (MetroGel) 1 applicatorful BID for 7 days
- Tinidazole (Tindamax) 2 g PO once a day for 2 days *OR* 1 g PO once a day for 5 days
- Avoid douches, feminine hygiene sprays

REFERENCE

Austin NM, Meyn LA, Hillier SL. Susceptibility of vaginal bacteria and tinidazole. *Anaerobe.* 2006;12:227–230.

VALSALVA MANEUVER

DESCRIPTION A maneuver affected by a forced expiratory effort against a voluntarily closed airway, which causes increased intrathoracic and intra-abdominal pressure and impedes venous return to the right atrium. The maneuver may increase the degree of varicocele dilatation, thus aiding in diagnosis. It can also be used to measure the pressure required to cause leakage in the absence of a bladder contraction, which correlates with the degree of urinary incontinence (called the "leak point pressure"). The Valsalva maneuver can also be used to aid in micturition in those with hypotonic bladders by increasing intravesical pressure. (See also Section II: "Leak Point Pressure.")

VANDERBILT CYSTECTOMY INDEX (VCI)

DESCRIPTION VCI is a health-related quality-of-life questionnaire for patients following radical cystectomy and urinary diversion. It consists of the 45 questions from the Functional Assessment of Cancer Therapy-General (FACT-G) as the core questionnaire. An additional 17 items were added from 3 other validated questionnaires designed to measure disease and treatment specific health outcomes. 4 from FACT-Bladder Cancer, 6 from FACT – Colorectal and 7 from the Functional Assessment of Incontinence Therapy-Urinary.

VANISHING TESTIS SYNDROME

DESCRIPTION A condition in which a normal genotypic 46, XY male has absent or rudimentary testes with otherwise normal differentiation of internal and external structures. Etiology is vascular compromise in utero, infection in utero, or testicular torsion in utero. Infertility is inevitable, despite aggressive testosterone replacement therapy to induce virilization.

SYNONYMS

- Bilateral anorchia
- Gonadal agenesis
- Testicular regression syndrome
- XY agonadism

TREATMENT
TRT to induce virilization

REFERENCE
Gong M, et al. Testicular torsion with contralateral vanishing testis. *Urology*. 1996;(482):306–307.

VAS DEFERENS, CALCIFICATION (CVD)

DESCRIPTION CVD is a rare finding primarily detected through radiologic exams. It usually presents asymptomatically. A majority of the patients with calcification of the vas deferens are diabetics in their 5th–6th decades. For these diabetic patients, CVD has a bilateral and symmetrical presentation. In addition, a minority of patients will present with post-inflammatory CVD, which usually has a unilateral and segmental presentation (Image ☼).

REFERENCE
Banerji S, Devasia A. Calcified Vasa Deferentia. *N Engl J Med.* 2011;364:2043

VAS DEFERENS, OBSTRUCTION

DESCRIPTION Genital duct obstruction is a potentially curable cause of male infertility that may be bilateral or unilateral and may occur at multiple locations (epididymal, vasal, or ejaculatory duct). The prevalence is 7–12% of infertile men. Unilateral obstruction should not adversely affect fertility, although it has been identified as a risk factor for developing antisperm antibodies. Complete obstruction yields the pathognomonic clinical findings of acidic, fructose-negative, low-volume ejaculate azoospermia. Diagnostic modalities include static imaging (TRUS, MRI, seminal vesicle aspiration) and dynamic imaging with vasography, seminal vesiculography testing. (See also Section I: “Infertility” and “Vas Deferens, Congenital Absence.”)

CAUSES
- Congenital: Malformations, congenital bilateral absence of the vas deferens (CBAVD), wolffian duct anomalies/agenesis
- Acquired: Infection, iatrogenic injury, vasectomy

TREATMENT
- Varies with etiology and location of obstruction
- Ejaculatory duct: Transurethral resection, balloon dilation, antegrade seminal vesicle lavage, laser incision, vasoepididymostomy
- Vasectomy (reversal vasovasostomy)
- Sperm retrieval (aspiration vs. open biopsy) with IVF/ICSI

REFERENCE
Jarow JP. Male infertility. In: Wein AJ, et al., eds. *Campbell-Walsh Urology*. 9th ed. Philadelphia, PA: Saunders; 2007.

VASCULITIS, UROLOGIC CONSIDERATIONS

DESCRIPTION Vasculitis is a common reaction to injury caused by a multitude of different processes, including autoimmunity, infection, and hypersensitivity. Various types include Henoch–Schönlein purpura, PAN, hypersensitivity angiitis, Wegener granulomatosis, and lymphomatoid granulomatosis. A very strong correlation exists between the presence of anti-neutrophil cytoplasmic antibodies (ANCA) and the various types of systemic vasculitis that cause crescentic glomerulonephritis and/or focal necrotizing glomerulonephritis. Depending on the type of vasculitis, patients present with different signs and symptoms. Furthermore, some types can progress to chronic renal failure. However, upon renal biopsy, similar pathologic presentations are demonstrated. Can also result in renal hemorrhage. (See also Section II: "Henoch-Schönlein Purpura.")

TREATMENT

- ANCA titers have proved to be extremely useful in the management of these patients. They are a help in diagnosis, and even more important as a guide to maintenance immunosuppressive therapy.
- Cytotoxic agents and corticosteroids are effective, depending on the type of vasculitis.

REFERENCE

Rees AJ. Vasculitis and the kidney. *Curr Opin Hephrol Hypertens*. 1996;(53):273–281.

VASECTOMY REVERSAL, GENERAL CONSIDERATIONS (VASOVASOSTOMY)

DESCRIPTION Usually accomplished with a 2-layer microsurgical vasovasotomy (8 10-0 nylon mucosal sutures, 10 9-0 nylon muscular sutures). Although surgical reversal of vasectomy can be technically performed on most patients, operative decision-making requires workup. Gynecologic and fertility evaluation of the female partner should be performed. Epididymal or testicular sperm aspiration combined with IVF/ICSI should be discussed. Results with microsurgical repair reach 85–90% success sperm (appearing in semen), with postprocedural conception rates at 50–70%.

TREATMENT

- Vasovasostomy (when some component of sperm are present, grade I–IV vas fluid)
- Vasoepididymostomy (when no sperm are present in vas fluid)
- Postoperative scrotal support with abstinence for 2 wk

REFERENCE

ASRM Practice Committee. Vasectomy Reversal. *Fertil Steril.* 2006;86(4):S268–S271.

VASOGRAPHY, TECHNIQUE AND INDICATIONS

DESCRIPTION Vasography is the radiologic procedure used to evaluate patency of the vas deferens and ejaculatory ducts. The procedure involves injection of the contrast material into the vas deferens. Recently, seminal vesicle aspiration and vesiculography mainly replaced vasography for the diagnosis of EDO. Therefore, the primary indication for vasography is the assessment of vasal obstruction within the inguinal vas deferens. Inguinal obstruction of the vas deferens should be suspected in patients with azoospermia and previous surgeries,

including orchiopexies, hernias repair, ureteral surgery, and even appendectomy (iatrogenic injuries to the vas deferens). 4 techniques for vasography have been described: Vasopuncture, vasotomy, retrograde catheterization via cystoscopy and transrectal puncture. Isolated vasography (by vas puncture) is rarely performed because of the risk of subsequent vasal scarring; it is usually a part of microsurgical reconstructive procedure. For this reason, it is not indicated to perform vasography at the time of testicular biopsy with the findings of normal spermatogenesis. If open vasography is planned, the bladder should be catheterized with a Foley catheter and balloon inflated with air to outline the bladder neck area. After scrotal exploration, the vas deferens is identified and isolated at the junction of the straight and convoluted portions. Under the operating microscope, the vasal sheath is incised vertically and vasal vessels preserved. A short segment of the vas is cleaned and hemitransected using a 15.0 ultrasharp knife until the lumen is revealed. The sheath of 25-gauge angiocatheter is inserted into the abdominal portion of the vas deferens. The vas is then flushed with normal saline (the term *vasogram* at this point is a misnomer, since no contrast is injected and no x-rays are taken). If injection is easily achieved with minimal pressure, the vas deferens is patent. In case of resistance to the injection, the formal vasogram is performed with 1:2 diluted nonionic contrast, while gentle pressure is applied to the Foley catheter to prevent reflux of the contrast into the bladder and the table is put in the slightly reversed Trendelenburg position. If obstruction is confirmed at the level of ejaculatory duct, methylene blue may be added to the contrast since it enables the control of the depth and efficacy of transurethral resection of the ejaculatory duct.

The application of a 32-gauge soft radiopaque epidural catheter has been described for the vasography. The catheter is advanced down the vas deferens, and the vasogram is performed. Because the catheter is radiopaque, its position in the vas can be confirmed prior to injection. If needed, the catheter could be advanced further to obtain better details. If no further microsurgical reconstruction is performed, the vasotomy site is closed with a microsurgical technique using 10-0 monofilament Prolene or nylon for mucosa, 9-0 nylon for muscularis, and 6-0 Prolene for the adventitial layer.

The puncture technique employs a 30-gauge lymphangiogram needle placed through the wall of the vas deferens in the direction of the prostate. This technique, also less invasive, may be associated with a higher risk of creating submucosal false passages, with subsequent scarring and obstruction. Complications include stricture of the vas deferens, hematoma, injury to the vasal blood supply, and sperm granuloma.

VENOUS LEAK SYNDROME

DESCRIPTION Venous leakage is a common cause of vascular impotence due to veno-occlusive dysfunction. Possible leak sites are the superficial and deep dorsal veins, cavernosal venous system, and glans or corpus spongiosum. The majority of patients have >1 leak site.

Diagnosis can be demonstrated by pharmacocavernosography (caversonography performed after the intracorporal injection of papaverine or phentolamine).

CAUSES

- Congenital
- Iatrogenic
- Neovascularity associated with inflammatory reactions secondary to stricture disease or Peyronie disease

TREATMENT

- Surgical correction
- Combination of pharmacologic injection therapy with a venous constriction system or a vacuum device

REFERENCE

VESICULOBULLOUS LESIONS, EXTERNAL GENITALIA

DESCRIPTION Dermatologic lesions on the external genitalia mandate screening for STI/STDs. They may be painful or painless, single or multiple, exophytic or ulcerated, confined to the genitalia or occurring elsewhere on the body. Treatments vary widely based on etiology, and may require partner treatment in the case of STDs. (See also Section I: "Penis, Lesion, General"; "Sexually Transmitted Disease.")

Vesiculobullous Lesions, External Genitalia

Etiology	Examples
Infective, Nonsexually transmitted	**Balanitis/posthitis:** Ulcerated lesion preceded by 2–3 days of irritation, usually associated with foul discharge and edema. **Folliculitis/furunculosis:** Hair follicle infection marked by pointed lesions with central pustules; usually enlarge and rupture leaving edema/erythema for days to weeks. **Pediculosis pubis:** Parasitic infestation (lice) with red, itchy papules and white/gray eggs visible attached to hair. **Scabies:** Mite infestation. Organisms burrow under skin causing crusted papules 1–10 cm at the genitalia with satellite lesions on the extremities. **Tinea cruris:** Superficial fungal infection (jock itch) with raised, scaling patches on the inner thigh or groin with severe pruritus.
Infective, Sexually transmitted	**Chancroid:** *H. ducreyi* infection (with 1 or more) painful, deep, ulcerated lesions on the genitalia; bleeds easily with marked lymphadenopathy. **Genital herpes:** HSV (usually 1 or 2) produces fluid-filled vesicles on genitals and/or mouth or anus, which may rupture leaving shallow painful ulcers. Associated with prodrome of numbness and tingling. **Genital warts:** HPV causes painless pink/red pedunculated lesions varying in size; may have cauliflower appearance and become malodorous. **Syphilis:** 2–4 wk following *T. pallidum* infection, ≥1 small, red, fluid-filled papules erupt to form a painless deep ulcer with a clear base; may become systemic and is associated with unilateral lymphadenopathy.
Noninfective	**Bowen disease:** Brownish red, raised, scaly plaque with well-defined borders; possible ulceration; premalignant. **Leukoplakia:** White, scaly patches on glans/prepuce with skin thickening and fissures; premalignant. **Penile cancer:** Painless, enlarging wartlike lesion on glans or foreskin; occasionally associated with pain and malodorous discharge. **Urticaria:** Systemic allergic reactions may present with genital hives; erythematous, intensely pruritic with systemic eruption. **Drug eruption:** Similar in appearance to urticaria; associated with phenolphthalein, barbiturates, tetracyclines, and sulfonamides.

REFERENCE

VIDEOURODYNAMICS

DESCRIPTION A technique in which urodynamic studies are performed at the same time as fluoroscopy of the lower urinary tract. The cystometry and pressure–flow studies are conducted in the same manner as regular urodynamics. The only difference is the addition of contrast and fluoroscopy. Radiation exposure is usually limited to <20 s. Adding simultaneous video enhances the evaluation of all patients, especially for more complex urodynamic problems. Videourodynamics is helpful when results from simple urodynamics do not agree with the clinical scenario. In complex bladder outlet obstruction, this technique can identify whether it occurs at the bladder neck, prostatic urethra, or distal sphincter. It is also helpful in the identification of bladder neck dysfunction in young men with voiding problems and in neurogenic patients with dyssynergia of the distal sphincter. In incontinence evaluation, videourodynamics can help identify the presence and degree of vesical neck hypermobility, degree of proximal urethral weakness, and degree and type of cystocele present. In neurogenic bladders, simultaneous video screening aids in diagnosing proximal and distal sphincter dyssynergia and demonstrates the presence of reflux and bladder diverticula. The presence of reflux, bladder and urethral diverticula, fistula, and stones can be identified and characterized. (See also Section II: “Urodynamics.”)

REFERENCE

McGuire EJ, Cespedes RD, Cross CA, et al. Video-urodynamic studies. *Urol Clin N Am*. 1996;23(2):309–321.

VILLOUS ADENOMA, BLADDER/URETHRA

DESCRIPTION Villous adenomas of the bladder and urethra are rare and histologically identical to those found in the colon. These tumors are more frequently found in the urachus at the dome of the bladder. On cystoscopy, these villous adenomas appear as exophytic papillary masses. Histologically, villous adenomas are complex branching papillary structures lined by a pseudostratified epithelium containing goblet cells. Often, this tumor is associated with cystitis glandularis. Villous adenoma of the urethra has been reported in both males and females. In males, villous adenoma may be associated with urinary retention, hematuria, and difficulty in micturition. In females, it may be less symptomatic and present with a slowly growing mass in the urethra. When villous adenomas are found, a primary intestinal tumor must be ruled out. After resection of the adenoma, the patient must be followed for recurrence or malignancy because their behavior is unpredictable. Diagnosis is made with urine cytology, cystogram, cystoscopy, or biopsy. Treatment is transurethral resection with selective cystectomy.

REFERENCE

Channer JL, Williams JL, Henry L. Villous adenoma of the bladder. *J Clin Pathol*. 1993;46(5):450–452.

VIMENTIN, STAINING

DESCRIPTION Monoclonal antibodies can be used to identify cell products or surface markers by directing antibodies against intermediate filaments. This facilitates the classification of otherwise poorly differentiated tumors. Vimentin is the predominant intermediate filament in mesenchymal cells, and it is found in all fibroblasts. Vimentin is less specific than the other intermediate filaments in immunocyto-chemistry because certain epithelial tumors (eg, RCC) may coexpress keratin and vimentin. (See also Section II: "Immunohistochemical Staining, Urologic Considerations.")

REFERENCE

Cotran R, et al., eds. *Pathologic Basis of Disease*. 5th ed. Philadelphia, PA: Saunders; 1995:299.

VINCENT CURTSY

DESCRIPTION Holding maneuver used by children to postpone voiding or suppress urinary urgency. Vincent curtsy is performed by squatting with a hand or heel pressed firmly into the perineum. Other common holding maneuvers including standing on tiptoe or forceful crossing of the legs (Image ☼).

REFERENCE

Vincent SA. Postural control of urinary incontinence. The curtsy sign. *Lancet*. 1966;2:631.

VITILIGO, UROLOGIC CONSIDERATIONS

DESCRIPTION A depigmentation of the skin in which sharply bordered patches become white. This is distinct from postinflammatory skin depigmentation in that there is no preceding inflammatory process. The etiology is probably autoimmune, and it is estimated to involve the external genitalia only in 0.3% of the adult male population. Treatment is optional and can include steroids, UV light, skin grafting, and cosmetic covering.

REFERENCES

Falabella R, Barona MI. Update on skin repigmentation therapies in vitiligo. *Pigment Cell Melanoma Res*. 2009;22(1):42–65.

Margolis DJ. Cutaneous diseases of the male external genitalia. In: Walsh PC, Retik AB, Vaughan ED, et al., eds. *Campbell's Urology*. 7th ed. Philadelphia, PA: Saunders; 1998.

VOIDING DIARY FREQUENCY VOLUME CHART (FVC)

DESCRIPTION A tool often used in association with pad testing to document the nature and severity of incontinence. A data sheet, maintained by the patient over a representative 24-hr period, typically documents the following:

- Time of urge to void
- Strength of urge or pain
- Time of actual void
- Voided volume
- Incontinence stress, urge, or unaware

- Amount of leakage small, medium, large

(See Section VII: "Voiding Diary.")

REFERENCE

Stav K, Dwyer PL, Rosamilia A. Women overestimate daytime urinary frequency: The importance of the bladder diary. *Urology*. 2009;18(15):2176–2180.

VOIDING SYMPTOMS, DEFINITIONS (ICS DEFINITIONS)

DESCRIPTION The ICS in 2002 published updated guidelines to define and categorize LUTS into 3 main groups including storage, voiding, and postmicturition, as defined and subdivided here:

- **Storage symptoms** are experienced during storage phase of bladder:
  - Increased day-time frequency
  - Nocturia: Complaint that individual wakes up more than once to void
  - Urgency: Complaint of sudden compelling desire to void that is difficult to defer
  - Urinary incontinence: Complaint of any involuntary loss of urine
- **Voiding symptoms** are experienced during voiding phase:
  - Slow stream
  - Splitting or spraying of urine stream
  - Intermittency during micturition
  - Hesitancy: Term used when individual has difficulty initiating micturition, resulting in a delay in the onset of voiding
  - Terminal dribble: Term used when an individual describes prolonged final part of micturition
- **Postmicturition symptoms** are experienced immediately after micturition:
  - Feeling of incomplete emptying
  - Postmicturition dribble describes the involuntary loss of urine after the patient finishes passing urine.

REFERENCE

Abrams P, Cardozo L, Fall M, et al. The standardization of terminology in lower urinary tract function. *Neurourol Urodyn*. 2002;21:167–178.

VULVAR MALIGNANCY, UROLOGIC CONSIDERATIONS

DESCRIPTION Vulvar carcinoma encompasses any malignancy that arises in the skin, glands, or underlying stroma of the perineum, including the mons pubis, labia minora, labia majora, Bartholin glands, or clitoris. Early detection lesions (<2 cm) allow for local resection without node dissection. Cases presenting late in the course of disease may require radical en-bloc resection of the tumor and surrounding organs, known as *pelvic exenteration*. Total exenteration refers to removal of the uterus, tubes, ovaries, parametrium, bladder, rectum or rectal segment, vagina, urethra, and a portion of the levator muscles. In an anterior exenteration, the rectum is spared, whereas in a posterior exenteration, the bladder and urethra are preserved. Urinary diversion (usually a continent catheterizable pouch) will be

provided by the urologist as a portion of the pelvic reconstruction.

REFERENCE

Gershenson DM, Miller B, Morris M, et al. Pelvic exenteration for primary and recurrent vulvar cancer. *Gynecol Oncol*. 1995;58:202–205.

VULVODYNIA

DESCRIPTION Vulvar discomfort, most often described as burning pain, occurring in the absence of relevant or visible findings or specific, clinically identifiable, neurologic disorder. Lifetime prevalence reported at 16%. The condition is often reported with dyspareunia, but not associated with urinary complaints. However, 11% of women with vulvodynia will concomitantly be diagnosed with interstitial cystitis.

REFERENCE

Clemens JQ, Bogart JM. Symptoms of interstitial cystitis, painful bladder syndrome and similar diseases in women: A systematic review. *J Urol*. 2007;177:450–456.

VURD SYNDROME

DESCRIPTION VURD stands for *vesicoureteral reflux associated with renal dysplasia*. This term applies to children with posterior urethral valves in which there is massive reflux into a dysplastic nonfunctioning kidney; ~15% of the patients with posterior urethral valves have this syndrome. Some believe that severe unilateral vesicoureteral reflux is protective of the contralateral nonrefluxing kidney. Diagnosis is made using kidney US, voiding cystourethrogram, nuclear imaging of kidneys, and serum creatinine levels. The patient should be observed 1st to see if kidney function returns. If function does not return, then nephrectomy is considered.

REFERENCE

Donnelly LF, Gylys-Morin VM, Wacksman J, et al. Unilateral vesicoureteral reflux: Association with protected renal function in patients with posterior urethral valves. *AJR*. 1997;168(3):823–826.

WAGR SYNDROME (WILMS TUMOR-ANIRIDIA-GENITAL ANOMALY RETARDATION)

DESCRIPTION WAGR is one of the Wilms tumor–associated syndromes, presenting in children <3 yr. It causes mental retardation and GU manifestations in the form of renal hypoplasia, ectopia, fusions, duplications, cystic disease, hypospadias, cryptorchidism, and pseudoher-maphroditism. Physical exam may also reveal ear deformities, umbilical/inguinal hernias, and aniridia.

REFERENCE

Kirsch AJ, Snyder HM III. What's new and important in pediatric urologic oncology. *AUA Update Series*. 1998;17:83.

WALLACE URETERAL ANASTOMOSIS

DESCRIPTION A surgical procedure used in urinary diversion in which the spatulated ureters are laid adjacent and the apex of each is sutured to the other. The medial and lateral walls of the ureters are then sutured together in either an interrupted or running fashion. The Y configured ureters are then anastomosed to the end of the small bowel segment used for the reservoir.

REFERENCE

McDougal WS. Use of intestinal segments and urinary diversion. In: Walsh PC, Retik AB, Vaughan ED, et al., eds. *Campbell's Urology*. 7th ed. Philadelphia, PA: Saunders; 1998:3137–3144.

WALTER REED STAGING SYSTEM, TESTIS CANCER

DESCRIPTION Lymphangiographic criteria used to evaluate the presence and location of testicular neoplasm metastases. The following lymphangiographic patterns were found to be useful in assessing metastatic disease: Filling defects, lymph node enlargement and masses, lymphatic obstruction and collateral vessel formation, and an increase or decrease in the number of lymph nodes.

REFERENCE

Maier JG, Schamter DT. The role of lymphangiography in the diagnosis and treatment of malignant testicular tumors. *AJR*. 1972;114:482.

WATERHOUSE URETHRAL STRICTURE REPAIR

DESCRIPTION Through a combined abdominal and perineal approach, a wedge of pubis is resected with a Gigli saw. The membranous stricture is identified and excised. The distal urethra is mobilized off the corporal bodies, and the spatulated urethral edges are reanastomosed.

REFERENCE

Devine CJ, Devine PC. Operations for urethral stricture. In: Novick AC, Streem SB, Pontes JE, eds. *Stewarts Operative Urology.* Baltimore, MD: Williams & Wilkins; 1989:650–680.

WATERHOUSE–FRIDERICHSEN SYNDROME

DESCRIPTION Acute adrenocortical insufficiency in children suffering from septicemia with *Pseudomonas* or meningococcemia, leading to acute hemorrhagic destruction of both adrenal glands.

REFERENCE

Rao RH, Vagnucci AH, Amico JA, et al. Bilateral massive adrenal hemorrhage: Early recognition and treatment. *Ann Intern Med.* 1989;116:227.

WEDDELLITE

DESCRIPTION Mineralogic name for renal calculi composed of calcium oxalate dihydrate. (See Section I: "Urolithiasis, Calcium Oxylate/Phosphate.")

WEGENER GRANULOMATOSIS, UROLOGIC CONSIDERATIONS

DESCRIPTION Systemic granulomatous vasculitis, most commonly affecting the upper and lower respiratory tracts and the kidneys, involving small arteries and venules. Respiratory infiltrates or sinusitis are commonly the presenting symptoms, as well as constitutional symptoms (weight loss, fever, etc.). Renal involvement is usually vasculitis-induced chronic renal failure, but acute fulminant glomerulonephritis and occasional interstitial nephritis can be present. Red cells, red cell and other casts, and proteinuria are noted. Other urologic manifestations include granulomatous necrotizing prostatitis, urethritis, or epididymoorchitis. Hemorrhagic cystitis is common, but usually iatrogenic secondary to cyclophosphamide treatment. Progressive renal insufficiency with ESRD occurs in up to 25% of patients.

DIAGNOSIS

- Granulomatous necrotizing vasculitis: Lung biopsy
- Focal necrotizing glomerulonephritis: Renal biopsy
- Red cell casts in voided urine: Glomerulonephritis
- Antineutrophil cytoplasmic antibodies: Useful for follow-up

TREATMENT

- Cyclophosphamide
- Corticosteroids
- Other cytotoxic and immunosuppressive agents: Methotrexate, cyclosporine, FK-506
- Surveillance cystoscopy when cyclophosphamide used

REFERENCE

Aasarød K, Iversen BM, Hammerstrøm J, et al. Wegener's granulomatosis: Clinical course in 108 patients with renal involvement. *Nephrol Dial Transplant.* 2000;(155):611–618.

WEISS CRITERION

DESCRIPTION Most commonly used histopathologic system to provide diagnostic criteria for malignant adrenocortical tumors. Originally proposed in 1984, it has since undergone 1 revision. Original Weiss Criteria requires ≥3 of the following:

- Fuhrman nuclear grade III or IV
- 5+ mitotic figures/HPF on 10+ fields
- Atypical mitotic figures (spindles)
- Clear or vacuolated cells <25% or tumor
- Diffuse architecture >1/3 of tumor (patternless organization)
- Microscopic necrosis
- Venous invasion
- Sinusoidal invasion
- Capsular invasion

Modified Weiss Criteria using "1" if factor is present in tumor, 0 otherwise:

- 2× mitotic rate + 2× clear cytoplasm + abnormal mitoses + necrosis + capsular invasion
- Score total of ≥3 suggests malignancy

REFERENCE

WHEWELLITE

DESCRIPTION Mineralogic name for renal calculi composed of calcium oxalate monohydrate. (See also Section I: "Urolithiasis, Calcium Oxylate/Phosphate.")

WHITAKER TEST

DESCRIPTION An antegrade pressure–flow study to assess for renal obstruction. It is used to determine if pelvocaliectasis or hydronephroureterosis seen radiographically represents functional obstruction or anatomic dilation. This is a technically difficult, invasive test, requiring placement of a percutaneous antegrade catheter into the renal pelvis, with simultaneous monitoring of bladder and renal pelvic pressures during set flow rate of 10 mL/min. Elevation of renal pelvic pressure over bladder pressure indicates some degree of renal obstruction. A Foley catheter must be in the bladder.

Renal Pelvis, Bladder Pressure Differential	Degree of Obstruction
<13 cm H_2O	Normal
14–20 cm H_2O	Mild obstruction
21–34 cm H_2O	Moderate obstruction
>35 cm H_2O	Severe obstruction

SYNONYMS

- Urodynamic antegrade pyelogram
- Ureteral perfusion test

• Pressure–flow Whitaker exam

REFERENCE

Whitaker RH. The Whitaker test. *Urol Clin N Am.* 1979;6(3):529–539.

WHITLOCKITE

DESCRIPTION Mineralogic name for renal calculi composed of tricalcium phosphate. (See Section II: "Urolithiasis, Calcium Oxylate/Phosphate.")

WHO 2004 HISTOLOGIC CLASSIFICATION OF TUMORS OF THE URINARY TRACT

DESCRIPTION This is the 2004 World Health Organization classification of tumors of the urinary tract. It primarily covers the renal pelvis, ureter, bladder and urethra. See Section II: WHO/ISUP classification of urothelial neoplasms (1998 and 2004) for an analysis of the changes in the specific bladder/urothelial classification.

WHO 2004 Histologic Classification of Tumors of the Urinary Tract

Urothelial Tumors
Infiltrating urothelial carcinoma
- with squamous differentiation
- with glandular differentiation
- with trophoblastic differentiation

Nested
Microcystic
Micropapillary
Lymphoepithelioma-like
Lymphoma-like
Plasmacytoid
Sarcomatoid
Giant cell
Undifferentiated
Noninvasive urothelial neoplasias
Urothelial carcinoma in situ
Noninvasive papillary urothelial carcinoma, high grade
Noninvasive papillary urothelial carcinoma, low grade
Noninvasive papillary urothelial neoplasm of low malignant potential (PUNLMP)
Urothelial papilloma
Inverted urothelial papilloma

Squamous neoplasms
Squamous cell carcinoma
Verrucous carcinoma
Squamous cell papilloma

Glandular neoplasms
Adenocarcinoma
Enteric
Mucinous
Signet-ring cell
Clear cell
Villous adenoma

Neuroendocrine tumors
Small-cell carcinoma
Carcinoid
Paraganglioma

Melanocytic tumors
Malignant melanoma
Nevus

Mesenchymal tumors
Rhabdomyosarcoma
Leiomyosarcoma
Angiosarcoma
Osteosarcoma
Malignant fibrous histiocytoma
Leiomyoma
Hemangioma
Other

Hematopoietic and lymphoid tumors
Lymphoma
Plasmacytoma

Miscellaneous tumors
Carcinoma of Skene, Cowper and Littre glands
Metastatic tumors and tumors extending from other organs

Lyon: IARC Press; 2004.

WHO/ISUP CONSENSUS CLASSIFICATION OF UROTHELIAL NEOPLASMS (1998, 2004, AND 2010)

DESCRIPTION At a consensus conference of the World Health Organization (WHO) and the International Society of Urologic Pathologists (ISUP) in 1998, the WHO/ISUP classification of urothelial neoplasms of the bladder was developed. The innovations of this consensus included the elimination of grades of dysplasia, with high-grade dysplasia equated with carcinoma in situ, as well as a condensation of cytologic grading of urothelial carcinoma (ie, grades 1–3) into low- and high-grade carcinoma. In addition, a new entity was recommended for low-grade papillary lesions, entitled papillary urothelial neoplasm of low malignant potential (PUNLMP) in 2004. The most recent update adopted the use of the term urothelial instead of transitional to describe urothelium. The WHO/ISUP classification:

- Normal urothelium
- Flat urothelial hyperplasia
- Papillary urothelial hyperplasia
- Dysplasia (low-grade intraurothelial neoplasia)
- Carcinoma in situ (high-grade intraurothelial neoplasia)
- Reactive urothelial atypia
- Papilloma
- PUNLMP
- Papillary carcinoma, low-grade
- Papillary carcinoma, high-grade
- Invasive neoplasms
- Lamina propria invasion
- Muscularis propria (detrusor muscle) invasion

WILMS TUMOR STAGING SYSTEM, INTERNATIONAL SOCIETY OF PEDIATRIC ONCOLOGY (SIOP)

DESCRIPTION Developed by the International Society of Pediatric Oncology, this staging system is based on postchemotherapy surgical evaluation. It is used extensively in Europe. The National Wilms Tumor Staging System is based upon surgical evaluation before chemotherapy. It is used throughout the United States and Canada (see table below). (See also Section I: “Wilms Tumor”; Section II: “Wilms Tumor Staging System, National NWTS”; “Wilms Tumor Staging System, International Society of Pediatric Oncology SIOP.”)

REFERENCES

Ahmed HU. An update on the management of Wilms’ tumour. *J Surg Oncol.* 2007;33(7):824–831.

WILMS TUMOR STAGING SYSTEM, NATIONAL (NWTS)

DESCRIPTION A unified system developed to aid in the conduct of clinical trials now widely used for clinical staging treatment decisions (see table). The National Wilms Tumor Study (NWTS) system is based upon surgical evaluation prior to the administration of chemotherapy. It is used throughout the United States and Canada. The SIOP system is based upon postchemotherapy surgical evaluation and is used extensively in Europe. (See also Section I: "Wilms Tumor"; Section II: "Wilms Tumor Staging System, International Society of Pediatric Oncology [SIOP].")

WINTER CORPORAL SHUNT

DESCRIPTION A shunt between the corpora and glans penis created to treat priapism. A Tru-Cut biopsy needle is inserted through the tip of the glans and into the corpora, and a core of tissue is removed. Through the same glans puncture site, the Tru-Cut can be reinserted in order to create 2 fistulas at the end of both corpora. It is also referred to as a *percutaneous glanducavernous shunt.*

REFERENCE

Thomas AJ. Surgery for priapism. In: Novick AC, Streem SB, Pontes JE, eds. *Stewarts Operative Urology.* Baltimore, MD: Williams & Wilkins; 1989:826–832.

Wilms Tumor Staging System, International Society of Pediatric Oncology (SIOP)

Stage	Following Chemotherapy
I	Tumor is limited to kidney or surrounded with fibrous pseudocapsule if outside of the normal contours of the kidney, the renal capsule or pseudocapsule may be infiltrated with the tumor, but it does not reach the outer surface, and is completely resected (resection margins clear) The tumor may be protruding into the pelvic system and dipping into the ureter (but it is not infiltrating their walls) The vessels of the renal sinus are not involved Intrarenal vessel involvement may be present
II	The tumor extends beyond kidney or penetrates through the renal capsule and/or fibrous pseudocapsule into perirenal fat but is completely resected (resection margins clear) The tumor infiltrates the renal sinus and/or invades blood and lymphatic vessels outside the renal parenchyma but is completely resected The tumor infiltrates adjacent organs or vena cava but is completely resected
III Residual tumor confined to the abdomen	Incomplete excision of the tumor, which extends beyond resection (margins gross or microscopical tumor remains postoperatively) Any abdominal lymph nodes are involved Tumor ruptures (before or intraoperatively irrespective of other criteria for staging) The tumor has penetrated through the peritoneal surface Tumor thrombi are present at resected margins of vessels or ureter, transected or removed piecemeal by surgeon The tumor has been surgically biopsied (wedge biopsy) prior to preoperative chemotherapy or surgery Regional lymph node involvement was considered stage II in the previous SIOP staging system
IV	Hematogenous metastases (lung, liver, bone, brain, etc.) or lymph node metastases outside the abdomino-pelvic region
V	Bilateral renal tumors at diagnosis

Wilms Tumor Staging System, International Society of Pediatric Oncology (SIOP)	
Stage	**Following Chemotherapy**
I	Tumor is limited to kidney or surrounded with fibrous pseudocapsule if outside of the normal contours of the kidney, the renal capsule or pseudocapsule may be infiltrated with the tumor, but it does not reach the outer surface, and is completely resected (resection margins clear) The tumor may be protruding into the pelvic system and dipping into the ureter (but it is not infiltrating their walls) The vessels of the renal sinus are not involved Intrarenal vessel involvement may be present
II	The tumor extends beyond kidney or penetrates through the renal capsule and/or fibrous pseudocapsule into perirenal fat but is completely resected (resection margins clear) The tumor infiltrates the renal sinus and/or invades blood and lymphatic vessels outside the renal parenchyma but is completely resected The tumor infiltrates adjacent organs or vena cava but is completely resected
III Residual tumor confined to the abdomen	Incomplete excision of the tumor, which extends beyond resection (margins gross or microscopical tumor remains postoperatively) Any abdominal lymph nodes are involved Tumor ruptures (before or intraoperatively irrespective of other criteria for staging) The tumor has penetrated through the peritoneal surface Tumor thrombi are present at resected margins of vessels or ureter, transected or removed piecemeal by surgeon The tumor has been surgically biopsied (wedge biopsy) prior to preoperative chemotherapy or surgery Regional lymph node involvement was considered stage II in the previous SIOP staging system
IV	Hematogenous metastases (lung, liver, bone, brain, etc.) or lymph node metastases outside the abdomino-pelvic region
V	Bilateral renal tumors at diagnosis

WOLFFIAN DUCT REMNANTS

DESCRIPTION Normally, an embryo develops 2 sets of paired (müllerian and wolffian mesonephric) ducts. In females, virilization of the molffian system fails to occur, and wolffian vestiges may persist as the epoophoron, Gartner duct, or the appendix vesiculosa, commonly forming paraovarian cysts. In males, virilization of the wolffian duct gives rise to the epididymis, vas deferens, ejaculatory duct and seminal vesicles. The rostral end of the wolffian duct occasionally persists as a vestigial remnant, the appendix epididymis. Remnants of the mesonephric tubules may persist as a cystic structure, the *paradidymis.* (See also Section I: "Torsion, Testis; Testicular Appendages.")

SYNONYMS

- Paradidymis
- Appendix epididymis

REFERENCE

Wilson JD, Griffin JE, George FW, et al. The role of gonadal steroids in sexual differentiation. *Recent Prog Horm Res.* 1981;37:1–39.

WOUND DEHISCENCE, UROLOGIC CONSIDERATIONS

DESCRIPTION Development of a postoperative gap or defect in the peritoneal suture line, with or without evisceration. Prevalence is in 1–3% of patients and carries a risk of mortality as high as 44%. Risk factors include anemia, hypoalbuminemia, advanced age, male gender, chronic lung disease, malnutrition, wound infection, and emergent procedure. Surgical variables include suture type, use of prosthetic material, incision location, hypothermia, perfusion, and oxygenation. Primary repair of initial dehiscence carries a 56% success rate with sutures and/or retentions, whereas the use of an interposition mesh confers an initial 100% success rate.

REFERENCE

Abbott DE, Dumanian GA, Halverson AL. Manage-ment of laparotomy wound dehiscence. *Am Surg.* 2007;73(12):1224–1227.

WOUND INFECTION, POSTOPERATIVE, UROLOGIC CONSIDERATIONS

DESCRIPTION Surgical site infections and postoperative UTIs are common causes of patient morbidity, complicating 5% and 20% of clean cases, respectively. Patient-related risk factors include advanced age, anatomic urinary anomalies, poor nutrition, tobacco use, corticosteroid use, immunodeficiency, external/indwelling catheters, distant infection, and prolonged hospitalization. The need for periprocedural antimicrobial prophylaxis has been well documented. Antibiotics should be given within 60 min of procedure start time, and selected based on patient history, as well as anticipated procedure. (See Section II: "Prophylactic Antibiotics, AUA Guidelines"; Section VII: "Antibiotic Prophylaxis: AUA Guidelines.")

TREATMENT

- Cellulitis: Antimicrobial therapy and local wound care
- Superficial abscesses: Opening of the surgical wound, drainage and local wound care

REFERENCE

Wolf JS Jr, Bennett CJ, Dmochowski RR, et al. Best practice policy statement on urologic surgery antimicrobial prophylaxis. *J Urol.* 2008;179:1379–1390.

WUNDERLICH SYNDROME

DESCRIPTION Clinical condition classically described as spontaneous renal bleeding of nontraumatic origin, confined to the subcapsular and perirenal space. Presentation may be insidious, but the *Lenk triad* (flank pain, palpable mass, and deterioration with hypovolemic shock) has been described in the event of an acute onset.

CAUSES

- Angiomyolipoma
- Cysts (pancreatic, etc.)
- Idiopathic
- Tumor urothelial carcinoma, renal cell carcinoma
- Vasculitis and/or inflammation

REFERENCE

Albi G, del Campo L, Tagarro D. Wunderlich syndrome: Causes, diagnosis and radiologic management. *Clin Radiol.* 2002;57:840–845.

XANTHOGRANULOMATOSIS (ERDHEIM–CHESTER DISEASE)

DESCRIPTION Erdheim–Chester disease is a rare non-Langerhans form of histiocytosis with a poor prognosis. This disease occurs most commonly in patients older than 50 presenting with xanthoma-like skin nodules and bilateral lower limb bone pain. More disseminated forms of the disease can have renal failure caused by retroperitoneal and perinephric infiltrative or constrictive changes. These patients can also have cardiopulmonary insufficiency and CNS involvement and may have a progressive and fatal disease. The pathophysiology is unknown with limited treatments.

X-LINKED SPINAL AND BULBAR ATROPHY SYNDROME (KENNEDY SYNDROME)

DESCRIPTION Kennedy syndrome is a late-onset, bulbar–spinal type of muscular atrophy. There is an X-linked recessive inheritance genetic marker CAG repeat sequences in the androgen receptor gene (on chromosome X). The majority of evidence of altered androgen sensitivity is restricted to exaggerated or persistent adolescent gynecomastia, and the mildly high LH, testosterone, and estradiol levels characteristic of other forms of androgen insensitivity. The condition becomes prominent in the 4th–5th decades, with proximal muscle wasting and weakness; bulbar signs; fasciculations in skelet al muscles; subtle signs of endocrine dysfunction, such as diabetes, gynecomastia, or testicular atrophy; and oligospermia. The progression is very slow, and these patients can expect a normal lifespan; it is essential to distinguish this syndrome from other, often more severe neurologic diseases.

REFERENCE

Jordan CL, Lieberman AP. Spinal and bulbar muscular atrophy: A motoneuron or muscle disease? *Curr Opin Pharmacol.* 2008;8(6):752–758.

XX GONADAL DYSGENESIS (46, XX)

DESCRIPTION Clinically, patients present with primary amenorrhea and lack of secondary sexual characteristics. This presentation is consistent with ovarian failure and may be

associated with a host of X-chromosome aberrations. Specifically, 46, XX gonadal dysgenesis is marked by normal female chromosome constitution and hypergonadotropic hypergonadism with concurrent ovarian failure. Etiologies may be sporadic or inherited, but the condition is rarely linked to other somatic abnormalities. Other clinical manifestations include short stature, episodic metabolic acidosis, and normal intelligence.

SYNONYMS
- Ovarian failure
- Ovarian dysgenesis
- Streak ovaries

REFERENCE
Hisama FM, Zemel S, Cherniske EM, et al. 46, XX gonadal dysgenesis, short stature and recurrent metabolic acidosis in two sisters. *Am J Med Genetics.* 2001;98:121–124.

XX MALE REVERSAL SYNDROME (XX MALE)

DESCRIPTION A rare disorder of phenotypic males who have a 46, XX karyotype. Physical exam may reveal short stature; small, firm testes; a small- to normal-sized penis; hypospadias; and gynecomastia. Azoospermia is typical. Seminiferous tubule sclerosis can be shown on testicular biopsy. Lab investigation reveals high gonadotropin levels and decreased testosterone levels. In most cases, DNA fragments from the short arm of the Y chromosome can be detected in the distal end of the short arm of the X chromosome.

REFERENCE
Petit C, de la Chapelle A, Levilliers J, et al. An abnormal terminal X-Y interchange accounts for most but not all cases of human XX maleness. *Cell.* 1987;49:595.

XXX SYNDROME (TRIPLE X SYNDROME, TRIPLO-X)

DESCRIPTION Triple X chromosome abnormality occurs in ~1.2 in 1,000 liveborn females. There are no specific diagnostic features. Menstrual irregularities and mental retardation have been reported. Fertility is usually preserved, and many XXX females have normal offspring.

REFERENCE
Sills JA, Brown JK, Grace E, et al. XXX syndrome associated with immunoglobulin deficiency and epilepsy. *J Pediatr.* 1978;93:469.

XXXY SYNDROME

DESCRIPTION Rare variant of Klinefelter syndrome (47, XXY), with an additional X chromosome (48, XXXY). Phenotype is similar to 47, XXY, with more pronounced features; these patients frequently exhibit microphallus, hypoplastic testicles, cryptorchidism, hypospadias, and gynecomastia. They are infertile (azoospermia), usually are mentally retarded, and have characteristic facies.

TREATMENT
Supplemental testosterone may be beneficial for virilization at puberty.

REFERENCE

Linden MG, Bender BG, Robinson A. Sex chromosome tetrasomy and pentasomy. *Pediatrics.* 1995;96(4 Pt 1):672–682.

XXY SYNDROME (KLINEFELTER SYNDROME)

DESCRIPTION A syndrome characterized by the presence of an extra X chromosome (usually 47 XXY), resulting in a hypogonadal male. It is the most common chromosomal aberration among men, with an estimated frequency of 1:500 among newborns. Caused by a nondisjunction of the meiotic chromosomes of the gametes from either parent, affected individuals are tall, with a eunuchoid habitus, small firm testes, and gynecomastia. Mental retardation and psychiatric disturbances have also been identified. Elevated gonadotropins and azoospermia are typically present. Seminiferous tubular sclerosis is a common finding on testicular biopsy. The diagnosis may be made with a chromatin-positive buccal smear, indicating the presence of an extra X chromosome. Karyotypes usually demonstrate 47, XXY or the milder mosaic pattern, 46, XY, 47, XXY.

TREATMENT

- No therapy improves spermatogenesis in Klinefelter syndrome.
- In mosaic Klinefelter syndrome with severe oligospermia, intracytoplasmic injection with IVF is technically possible.

YOLK SAC TUMOR, BLADDER

DESCRIPTION Yolk sac tumor of the bladder is very rare and appears to have a predilection for the urachal remnant. It has the same pathologic characteristics as its counterparts in any other part of the body, and it is managed in the same way. (See Section II: "Yolk Sac Tumor, Prostate.")

REFERENCE

Huang HY, Ko SF, Chuang JH, et al. Primary yolk sac tumor of the urachus. *Arch Pathol Lab Med.* 2002;126(9):1106–1109.

YOLK SAC TUMOR, PROSTATE

DESCRIPTION Extragonadal GCT located in the prostate, similar to yolk sac tumor also called *endodermal sinus tumor*) found in the testis. A primary site of presentation in the prostate is extremely rare, with only a few reported cases. An increased incidence of extragonadal GCT is reported with Klinefelter syndrome. α-fetoprotein levels are commonly elevated, and are used as a tumor marker; human chorionic gonadotropin is not elevated. Schiller–Duval bodies are evident on histology. Treatment is multimodal, using cisplatinum-based combination chemotherapy and radical surgery.

REFERENCE

YOUNG CLASSIFICATION OF POSTERIOR URETHRAL VALVES

DESCRIPTION Young described 3 general types of posterior urethral valves:

- Type I: The valves are continuous with the verumontanum and take an anterior course, dividing into 2 fork-like processes in the region of the bulbomembranous junction. Usually, anterior fusion of the valves is not complete; however, some cases exhibit complete anterior fusion and cleft between the folds posteriorly. A subdivision of type I consists of a single, instead of double, valve. Type I valves are the most common.
- Type II: Same as type I, but the valve, rather than taking an anterior course, tends to pass from the upper aspect of the verumontanum toward the internal sphincter, where it divides into 2 forklike processes. (Note: Type II valves are now thought to be nonexistent.)
- Type III: The valves have no relation to the verumontanum; instead, they are attached to the entire circumference of the urethra at any level, with a small opening in the center; they have been called *iris valves* due to their resemblance to the iris of the eye. Incomplete varieties of this type (crescentic or semilunar) have been described. Type III valves are a more distal diaphragmatic obstruction, similar to a urethral membrane.

REFERENCE

Young HH, et al. Congenital obstruction of the posterior urethra. *J Urol.* 1919;3:289.

YOUNG-DEES-LEADBETTER BLADDER RECONSTRUCTION

DESCRIPTION This procedure is used to achieve a functional bladder neck closure (ie, establish continence) in children with exstrophy; and also for urinary incontinence in nonexstrophy conditions, although the technique is generally no longer widely used. Through an anterior cystotomy, a rectangular area between the distal urethra and trigone is demarcated. Flaps lateral to this are developed and used to tubularize a neourethra over a 10-Fr catheter.

REFERENCE

Ouckett JW, Caldamone AA. Bladder and urachus. In: Kelalis P, King L, Belman B, eds. *Clinical Pediatric Urology*. 2nd ed. Philadelphia, PA: Saunders; 1985:735.

YOUNG SYNDROME

DESCRIPTION Obstructive azoospermia in patients with frequent respiratory infections or bronchiectasis. Motile sperm, with normal cilia and vas deferens are present. The condition is caused by inspissated secretions, causing epididymal obstruction, and treated by vasoepididymostomy; fertility rates remain poor.

REFERENCE

Hughes TM 3rd, Skolnick JL, Belker AM. Young's syndrome: An often unrecognized correctable cause of obstructive azoospermia. *J Urol.* 1987;137(6):1238–1240.

ZELLWEGER SYNDROME (CEREBROHEPATORENAL SYNDROME)

DESCRIPTION A family of diseases of inborn errors of metabolism caused by agenesis or disruption of peroxisomes (subcellular organelles). It follows an autosomal recessive inheritance pattern, with an incidence of 1 in 25,000 to 1 in 50,000 live births. Characteristics include severe developmental delay, sensorineural deafness, renal cortical cysts, retinal dysfunction, hepatomegaly, and characteristic facies (thus, cerebrohepatorenal syndrome). Usually lethal in childhood, rare patients survive into adolescence and adulthood. Positive diagnosis is made by serum assay of very long-chain fatty acids and dihydroxyacetone phosphate acyl transferase. Hyperoxaluria and nephrocalcinosis may also be present. No known treatment exists.

REFERENCE

van Woerden CS, Groothoff JW, Wijburg FA, et al. High incidence of hyperoxaluria in generalized peroxisomal disorders. *Mol Genet Metab.* 2006;88(4):346–350.

ZINNER SYNDROME

DESCRIPTION Ejaculatory duct obstruction (EDO) resulting from a unilateral seminal vesicle cyst with associated ipsilateral kidney agenesis, the condition is caused by a congenital müllerian/wolffian/utricular abnormality. Although EDO accounts for <1% of infertility, it is a treatable entity, using transurethral resection of ejaculatory duct.

REFERENCE

ZIPPER ENTRAPMENT

DESCRIPTION Usually an emergency department presentation, this penile problem usually results from the entrapment of the foreskin between the fastener device and zipper teeth as a result of the caudal motion of the zipper. Often occurs in children 3–6 yr of age. Treatment should not include extraction of the foreskin or urgent circumcision, but instead should involve the release of the zipper median bar using orthopedic bone pliers (see below). An alternate method of release involves cutting the closed portion of the actuator (zipper teeth) with trauma shears to release the closed portion of the zipper from around the tissue.

- To remove a zipper, local anesthetic is injected into the area. Mineral oil is used to lubricate the zipper, and then 1 attempt is made to unzip the zipper. If this attempt is unsuccessful, a sturdy wire cutter (diagonal cutter) is used to cut the median bar on the top of the zipper slider, which connects its front and back plates. Then the slider falls off in 2 pieces, and the zipper teeth come apart readily (Image ☼).

ZONA PELLUCIDA BINDING ASSAY

DESCRIPTION An assay used to counsel patients about their chances of success with IVF. Being species-specific, the human sperm-zona pelllucida binding requires human oocytes. Different sources of oocytes can be used, such as postmortem, IVF surplus, or surgical specimens. Oocytes are bisected, and 1/2 of the zona acts as the control. Different preservation methods are available, such as salt storage, dimethyl sulfoxide freezing, or ultra-low-temperature freezing. The assay is essentially composed of 2 steps: Initial attachment, followed by irreversible binding. After repeated rinsing, the number of tightly bound spermatozoa to ZP is counted using phase contrast microscopy. This can be expressed as the hemizona index, which is the number of the patient's bound spermatozoa divided by the bound spermatozoa from the fertile control donor, multiplied by 1,003. Using a cut off of 35%, the hemizona index has been used by some to predict IVF success rate. (See also Section II: "Sperm Penetration Assay [Hamster Test].")

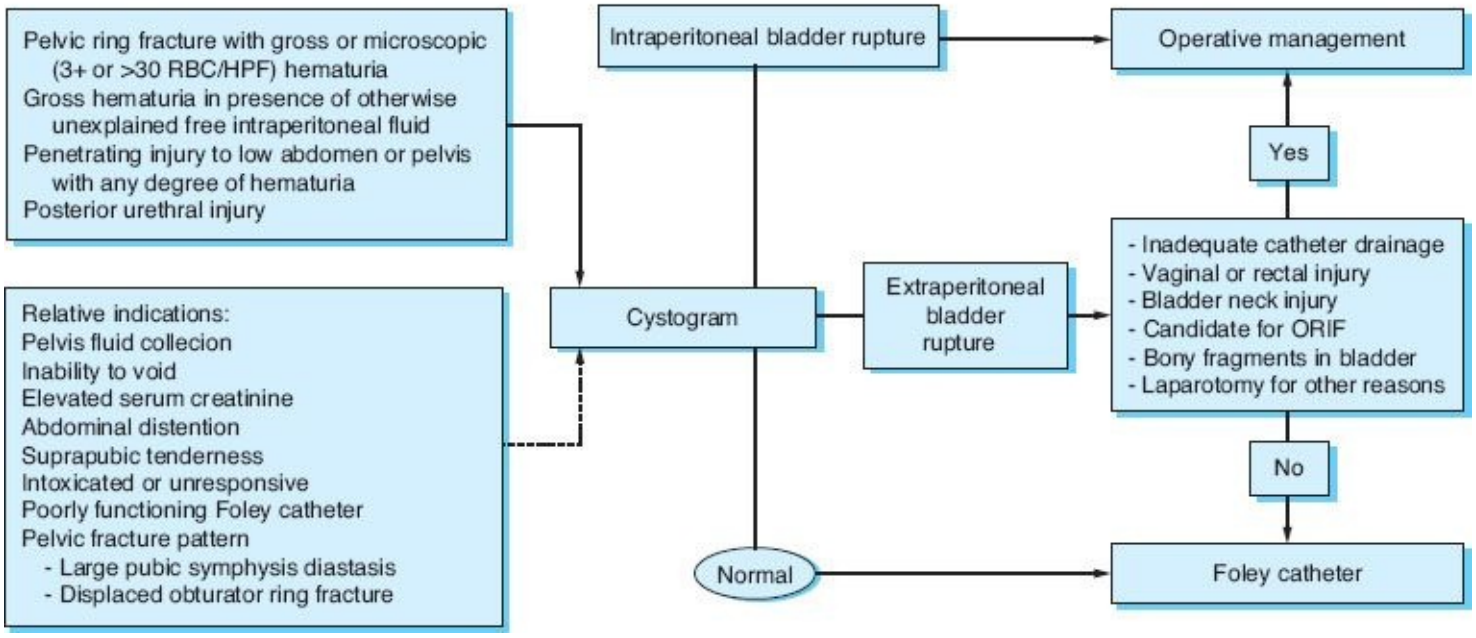
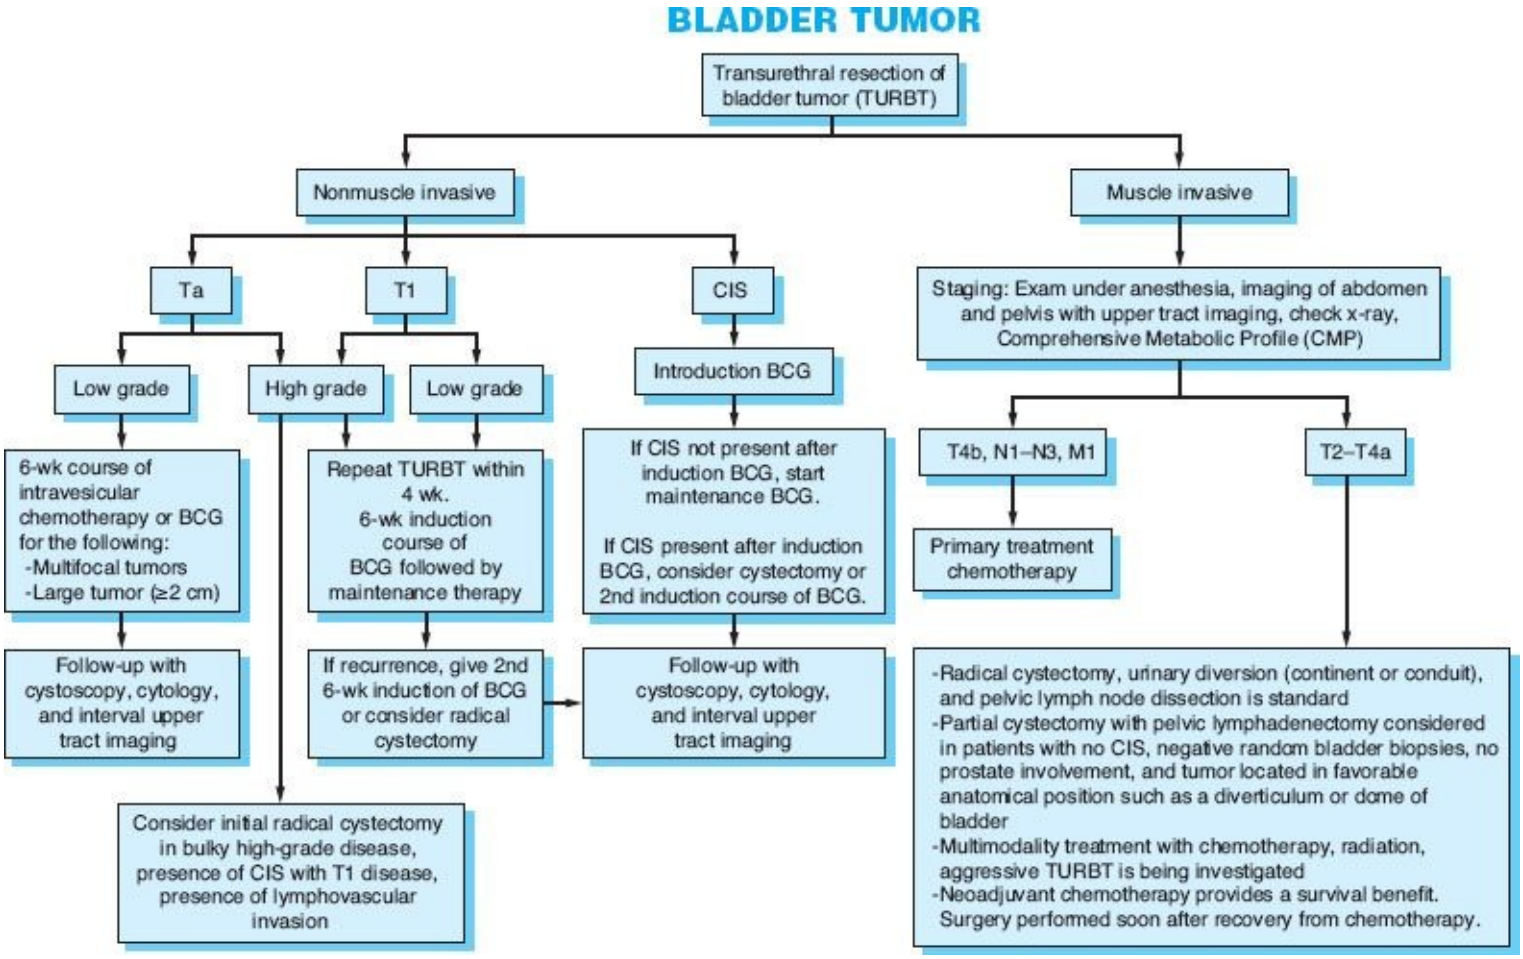
Bladder Trauma

BLADDER TRAUMA



Bladder Tumor



BLADDER TUMOR
Transurethral resection of bladder tumor (TURBT)
Nonmuscle invasive
Muscle invasive
Ta
T1
CIS
Staging: Exam under anesthesia, imaging of abdomen and pelvis with upper tract imaging, check x-ray, Comprehensive Metabolic Profile (CMP)
Low grade
High grade
Low grade
Introduction BCG
T4b, N1–N3, M1
T2–T4a
6-wk course of intravesicular chemotherapy or BCG for the following:
-Multifocal tumors
-Large tumor (≥2 cm)
Repeat TURBT within 4 wk.
6-wk induction course of BCG followed by maintenance therapy
If CIS not present after induction BCG, start maintenance BCG.
If CIS present after induction BCG, consider cystectomy or 2nd induction course of BCG.
Primary treatment chemotherapy
Follow-up with cystoscopy, cytology, and interval upper tract imaging
If recurrence, give 2nd 6-wk induction of BCG or consider radical cystectomy
Follow-up with cystoscopy, cytology, and interval upper tract imaging
-Radical cystectomy, urinary diversion (continent or conduit), and pelvic lymph node dissection is standard
-Partial cystectomy with pelvic lymphadenectomy considered in patients with no CIS, negative random bladder biopsies, no prostate involvement, and tumor located in favorable anatomical position such as a diverticulum or dome of bladder
-Multimodality treatment with chemotherapy, radiation, aggressive TURBT is being investigated
-Neoadjuvant chemotherapy provides a survival benefit. Surgery performed soon after recovery from chemotherapy.
Consider initial radical cystectomy in bulky high-grade disease, presence of CIS with T1 disease, presence of lymphovascular invasion

SECTION IV

Urinalysis and Urine Studies

Section Editor: Leonard Gomella, MD, FACS

URINALYSIS AND URINE STUDIES

I. URINE ANALYSIS

URINE ANALYSIS PROCEDURE

For a routine urine analysis, a fresh (<1 hr old), clean-catch urine sample is acceptable. If the analysis cannot be performed immediately, refrigerate the sample. (When urine stands at room temperature for a long period, casts and red blood cells undergo lysis, and the urine becomes alkalinized with precipitation of salts.)

1. Pour 5–10 mL of well-mixed urine into a centrifuge tube.
2. Check for appearance (color, turbidity, odor). If a urine sample looks grossly cloudy, it is sometimes advisable to examine an unspun sample. If an unspun sample is used, make note that you have done so. In general, for routine urine analysis, a spun sample is more desirable.
3. Spin a capped sample at 3,000 rpm for 3–5 min.
4. While the sample is in the centrifuge, use the dipstick (Chemstrip, etc.) to perform the dipstick evaluation on the remaining sample. Read the results according to the color chart on the bottle. Allow the correct amount of time before reading the test (usually 1–2 min) to avoid false results. Chemstrip 10 provides 10 tests (specific gravity, pH, leukocytes, nitrite, protein, glucose, ketone, urobilinogen, bilirubin, and blood). Other strips may provide less. Agents that color the urine (eg, phenazopyridine [Pyridium]) may interfere with the reading. Dipstick specific gravity is also available on some assay strips.
5. Decant and discard the supernatant. Mix the remaining sediment by flicking it with your finger and pouring or pipetting 1 or 2 drops onto a microscope slide. Cover with a coverslip.
6. Examine 10 low-power fields (LPFs; 10× objective) for epithelial cells, casts, crystals, and mucus. Casts are usually reported as number per low-power field and tend to collect around the periphery of the coverslip.
7. Examine several high-power fields (HPFs; 40× objective) for epithelial cells, crystals, RBCs, WBCs, bacteria, and parasites (trichomonads). RBCs, WBCs, and bacteria are usually reported as number per high-power field.

Normal Urine Analysis Values

- Appearance: Yellow, clear, or straw-colored
- Specific gravity:
  - Neonate: 1.012
  - Infant: 1.002–1.006
  - Child and adult: 1.001–1.035 (with normal fluid intake 1.016–1.022)
- pH:
  - Newborn/neonate: 5–7
  - Child and adult: 4.6–8.0
- Negative for bilirubin, blood, acetone, glucose, protein, nitrite, leukocyte esterase, reducing substances
- Trace: Urobilinogen
- RBC: The exact definition of microscopic hematuria is debated, but is generally defined as

>3 RBC/HPF (40×).
- WBC: 0–4/HPF
- Epithelial cells: Occasional
- Hyaline casts: Occasional
- Bacteria: None
- Crystals: Some limited crystals, based on urine pH (see below)

Differential Diagnosis for Routine Urine Analysis

- **Appearance** (see Section II Urine, Abnormal Color; Section II Urine, Foaming; Urine, Odor; and Urine, Particles in)
- **pH:**
  - Acidic: High-protein (meat) diet, ammonium chloride, mandelic acid and other medications, acidosis (due to ketoacidosis [starvation, diabetes], chronic obstructive pulmonary disease [COPD])
  - Basic: Urinary tract infections (UTIs), renal tubular acidosis, diet (high-vegetable, milk, immediately after meals), sodium bicarbonate therapy, vomiting, metabolic alkalosis, diuretic therapy
- **Specific gravity:**
  - Usually corresponds to osmolarity, except with osmotic diuresis. A value >1.023 indicates normal renal concentrating ability:
    - Increased: Volume depletion, congestive heart failure (CHF), adrenal insufficiency, diabetes mellitus, inappropriate antidiuretic hormone (ADH), increased proteins (nephrosis); if markedly increased (1.040–1.050), suspect artifact or excretion of radiographic contrast media.
    - Decreased: Diabetes insipidus, pyelonephritis, glomerulonephritis, water load with normal renal function
- **Bilirubin:**
  - Positive: Obstructive jaundice (intrahepatic and extrahepatic), hepatitis (Note: False positive with stool contamination)
- **Blood:**
  - Positive: See Section I Hematuria, gross and microscopic, adult and Hematuria, gross and microscopic, pediatric
  - Note: If the dipstick is positive for blood, but no RBCs are seen, free hemoglobin may be present from trauma, from a transfusion reaction, or from lysis of RBCs (RBCs will lyse if the pH is <5 or >8), or there may be myoglobin present because of a crush injury, burn, or tissue ischemia.
- **Glucose:**
  - Positive: Diabetes mellitus, pancreatitis, pancreatic carcinoma, pheochromocytoma, Cushing syndrome, shock, burns, pain, steroids, hyperthyroidism, renal tubular disease, iatrogenic causes

(Note: The glucose oxidase technique in many kits is specific for glucose and will not react with lactose, fructose, or galactose.)

- **Ketones:**
  - Detects primarily acetone and acetoacetic acid and not β-hydroxybutyric acid:
  - Positive: Starvation, high-fat/low-carbohydrate diet, diabetic ketoacidosis, vomiting,

diarrhea, hyperthyroidism, pregnancy, febrile states (especially in children)

- **Nitrite:**
  - Many bacteria will convert nitrates to nitrite. (See also the section on Leukocyte Esterase, below.)
    - Positive: Infection (A negative test does not rule out infection, because some organisms, such as *Streptococcus faecalis* and other gram-positive cocci, will not produce nitrite, and the urine must also be retained in the bladder for several hours to allow the reaction to take place.)
- **Protein:**
  - Indication by dipstick of persistent proteinuria should be quantified by 24-hr urine studies:
    - Positive: Pyelonephritis, glomerulonephritis, Kimmelstiel-Wilson syndrome (diabetes), nephrotic syndrome, myeloma, postural causes, preeclampsia, inflammation, and malignancies of the lower tract, functional causes (fever, stress, heavy exercise), malignant hypertension, congestive heart failure
- **Leukocyte esterase** (see Section I Pyuria.):
  - This test detects ≥5 WBCs/HPF or lysed WBCs. When combined with the nitrite test, it has a predictive value for UTI of 74% if both tests are positive, and >97% if both tests are negative:
    - Positive: Infection (false-positive with vaginal contamination)
- **Reducing substance:**
  - Positive: Glucose, fructose, galactose, false-positives (vitamin C, salicylates, antibiotics, etc.)
- **Urobilinogen:**
  - Positive: Cirrhosis, CHF with hepatic congestion, hepatitis, hyperthyroidism, suppression of gut flora with antibiotics (Note: With obstructive jaundice, urobilinogen is usually normal, but bilirubin is elevated.)

Urine Sediment

Many labs no longer do microscopic examinations unless specifically requested or if the dipstick test shows evidence of an abnormal finding (such as positive leukocyte esterase):

- **RBCs:** Trauma, pyelonephritis, genitourinary tuberculosis (TB), cystitis, prostatitis, stones, tumors (malignant and benign), coagulopathy, and any cause of blood on dipstick test (see above on hemoglobin)
- **WBCs:** Infection anywhere in the urinary tract, TB, renal tumors, acute glomerulonephritis, radiation, interstitial nephritis (analgesic abuse)
- **Epithelial cells:** Acute tubular necrosis (ATN), necrotizing papillitis (most epithelial cells are from an otherwise unremarkable urethra)
- **Parasites:** *Trichomonas vaginalis, Schistosoma haematobium* infections
- **Yeast:** *Candida albicans* infection (especially in diabetics, immunosuppressed patients, or if a vaginal yeast infection is present)
- **Spermatozoa:** Normal in males immediately after intercourse or nocturnal emission
- **Crystals:** Note that urine should be examined fresh and warm because clouding due to phosphate precipitation may be observed when urine cools:
  - Abnormal: Cystine, sulfonamide, leucine, tyrosine, cholesterol

- Normal in acidic urine: Oxalate (small square crystals with a central cross), uric acid
- Normal in alkaline urine: Calcium carbonate, triple phosphate (resemble coffin lids)

• **Contaminants:** Cotton threads, hair, wood fibers, amorphous substances (all usually unimportant)
• **Mucus:** Large amounts suggest urethral disease (normal from ileal conduit or other forms of urinary diversion).
• **Glitter cells:** WBCs are lysed in hypotonic solution.
• **Casts:** The presence of casts in a urine sample localizes some or all of the disease process to the kidney itself:
  - Hyaline casts (occasionally acceptable, unless they are numerous), benign hypertension, nephrotic syndrome, after exercise
  - RBC casts: Acute glomerulonephritis, lupus nephritis, subacute bacterial endocarditis (SBE), Goodpasture disease, after a streptococcal infection, vasculitis, malignant hypertension
  - WBC casts: Pyelonephritis
  - Epithelial (tubular) casts: Tubular damage, nephrotoxin, virus
  - Granular casts: Breakdown of cellular casts leads to waxy casts; dirty brown granular casts typical for ATN
  - Waxy casts (end stage of granular casts): Severe, chronic renal disease; amyloidosis
  - Fatty casts: Nephrotic syndrome, diabetes mellitus, damaged renal tubular epithelial cells
  - Broad casts: Chronic renal disease

II. SPOT OR RANDOM URINE STUDIES

The so-called spot urine is often ordered to aid in diagnosing various conditions. It relies on only a small sample (10–20 mL) of urine:

• **Spot urine for β_2 microglobulin** (< 0.3 mg/L):
  - A marker for renal tubular injury:
    - Increased: Diseases of the proximal tubule (ATN, interstitial nephritis, pyelonephritis), drug-induced nephropathy (aminoglycosides), diabetes, trauma, sepsis

• **Spot urine for electrolytes:**
  - The usefulness of this assay is limited because of large variations in daily fluid and salt intake, and the results are usually indeterminate if a diuretic has been given. (See also Section I Anuria and oliguria, adult and Anuria and oliguria, pediatric.)
    - Sodium < 10 mEq/L (mmol/L): Volume depletion, hyponatremic states, prerenal azotemia (CHF, shock, etc.), hepatorenal syndrome, glucocorticoid excess
    - Sodium > 20 mEq/L (mmol/L): Syndrome of inappropriate antidiuretic hormone (SIADH), ATN (usually > 40 mEq/L), postobstructive diuresis, high salt intake, Addison disease, hypothyroidism, interstitial nephritis
    - Chloride < 10 mEq/L (mmol/L): Chloride-sensitive metabolic alkalosis (vomiting, excessive diuretic use), volume depletion
    - Potassium < 10 mEq/L (mmol/L): Hypokalemia, potassium depletion, extrarenal loss

• **Spot urine for protein** (normal: < 10 mg/dL [0.1 g/L] or < 20 mg/dL [0.2 g/L] for a sample taken in the early morning)
  - See Section I Proteinuria for the differential diagnosis of protein in the urine.

- **Spot urine for eosinophils** (present with Hansel/Wright staining and white light microscopy):
  - Associated with acute interstitial nephritis (especially nephritis associated with drug hypersensitivity) or acute cystitis
  - Present with interstitial nephritis; absent with tubular disorders (ATN).
- **Spot urine for erythrocyte morphology:**
  - The morphology of RBCs in a sample of urine that tests positive for blood may give some indication of the nature of the hematuria. Eumorphic red cells are typically seen in cases of postrenal, nonglomerular bleeding. Dysmorphic red cells are more likely associated with glomerular causes of bleeding. Each reference lab has standards, but as a general rule, the presence of >90% dysmorphic erythrocytes in patients with asymptomatic hematuria indicates a renal glomerular source of bleeding, especially if associated with proteinuria and/or casts (ie, IgA nephropathy, poststreptococcal GN, sickle cell disease or trait, etc.). If <90% eumorphic erythrocytes or even mixed results (10–90% eumorphic erythrocytes), this indicates a post-renal cause of hematuria, requiring a complete urologic evaluation (ie, hypercalcuria, urolithiasis, cystitis, trauma, tumors, hemangioma, exercise-induced, benign prostatic hypertrophy [BPH], etc.).
- **Spot urine for osmolality** (ranges from 40–1,400 mOsm/kg water [mmol/kg]; varies with water intake):
  - Patients with normal renal function should concentrate >400–800 mOsmol/kg (mmol/kg) after a 14-hr fluid restriction; <200–400 mOsmol/kg (mmol/kg) is a sign of renal impairment:
    - Increased: Dehydration, CHF, hypercalcemia, SIADH, adrenal insufficiency, glycosuria, high-protein diet
    - Decreased: Excessive fluid intake, diabetes insipidus, acute renal failure, medications (acetohexamide, glyburide, lithium)
- **Spot urine for myoglobin** (qualitative negative):
  - Positive: Skelet al muscle conditions (crush injury, electrical burns, carbon monoxide poisoning, delirium tremens, surgical procedures, malignant hyperthermia), polymyositis

III. CREATININE CLEARANCE AND GLOMERULAR FILTRATION RATE

CREATININE CLEARANCE

- **Normal:**
  - **Adult male:** Total creatinine 1–2 g/24 h (8.8–17.7 mmol/d); clearance 85–125 mL/min/1.73 m^2
  - **Adult female:** Total creatinine 0.8–1.8 g/24 h (7.1–15.9 mmol/d); clearance 75–115 mL/min 1.73 m^2 (1.25–1.92 mL/s/1.73 m^2)
  - **Child:** Total creatinine (>3 yr) 12–30 mg/kg/ 24 h; clearance 70–140 mL/min/1.73 m^2 (1.17–2.33 mL/s/1.73 m^2)
  - **Decreased:** A decreased creatinine clearance results in an increase in serum creatinine, usually secondary to renal insufficiency. See Section I Renal Failure, Acute, and Renal Failure, Chronic for the differential diagnosis of increased serum creatinine.
  - **Increased:** Early diabetes mellitus, pregnancy

DETERMINATION OF CREATININE CLEARANCE

Creatinine clearance (CrCl) is a sensitive indicator of early renal insufficiency and is a measure of glomerular filtration rate (GFR); however, the GFR does not provide information on the etiology of the renal disease. CrCl decreases with age, with a CrCl of 10–20 mL/min indicating severe renal failure, and usually the need for dialysis. The National Kidney Disease Education Program (NKDEP) recommends using an estimation of GFR (eGFR) from serum creatinine in adults (>18yr) with chronic kidney disease (CKD) and those at risk for CKD (diabetes, hypertension, and family history of kidney failure).

Methods

1. Formal 24-hr Urinary Collection for Creatinine Clearance

Order a concurrent serum creatinine (SCr) and a 24-hr urine creatinine. A shorter time interval can be used (eg, 12 hr), but the formula must be corrected for this change; a 24-hr sample is less prone to collection error.

$$\text{Clearance} = \frac{(\text{Urine creatinine} \times \text{total urine volume})}{(\text{plasma creatinine} \times \text{time})}$$

Where time = 1,440 min if 24-hr collection is used

Example: The following are calculations of (a) CrCl from a 24-hr urine sample with a volume of 1,000 mL, (b) a urine creatinine of 108 mg/100 mL, and (c) a SCr of 1 mg/100 mL (1 mg/dL), where time = 1,440 min if 24-hr collection is used.

$$\text{Clearance} = \frac{(108\ \text{mg}/100\ \text{mL})\ (1{,}000\ \text{mL})}{(1\ \text{mg}/100\ \text{mL})\ (1{,}440\ \text{min})} = 75\ \text{mL/min}$$

To determine if there is a valid, full 24-hr collection, the sample should contain 18–25 mg/kg/24 h of creatinine for adult males or 12–20 mg/kg/24 h for adult females. If the patient is an adult (150 lb = body surface area of 1.73 m^2), adjustment of the clearance for body size is not routinely done. Adjustment for pediatric patients is a necessity.

If the values in the previous example were for a 10-yr-old boy who weighed 70 lb (1.1 m^2), the clearance would be:

$$75\ \text{mL/min}\ (1.73\ m^2 \div 1.1\ m^2) = 118\ \text{mL/min}$$

2. Estimated Creatinine Clearance (eGFR)

Estimated glomerular filtration rate (eGFR) is based on SCr combined with other factors such as age, sex, and race and has generally replaced 24-hr urinary CrCl determinations. Online calculators for adults and children are found at: http://nkdep.nih.gov/lab-evaluation/gfr-calculators.shtml (Accessed April 19, 2014)

Reference Table for Population Mean eGFRs from National Health and Nutrition Examination Survey (NHANES) III*

Age (Yr)	Mean eGFR* (mL/min/1.73 m^2)
20–29	116
30–39	107
40–49	99
50–59	93
60–69	85
70+	75

*For diagnostic purposes the NKDEP recommends laboratories report eGFR values ≥60 as "≥60 mL/min/1.73 m^2," not as an exact number.
*Coresh J, Astor BC, Greene T, et al. Prevalence of chronic kidney disease and decreased kidney function in the adult US population: Third national health and nutrition examination survey. *Am J Kidney Dis*. 2003;41(1):1–12.

Adult:

A. Modification of Diet in Renal Disease (MDRD) equation (*Ann Intern Med*. 1999;130, 137–147): Although more cumbersome than Cockcroft-Gault, the MDRD equation is believed to be more accurate. The equation does not require weight; results are normalized to 1.73^2 body surface area (BSA), an accepted adult average BSA:

$$\text{GFR (mL/min/1.73 m}^2) = 175 \text{ for } (S_{Cr})^{-1.154} \times (\text{age})^{-0.203} \times (0.742 \text{ if female}) \times (1.210 \text{ if African American})$$

B. Cockcroft–Gault equation:

CrCl estimate

$$= \frac{(140 - \text{age}) \times \text{wt (kg)} \text{ (if female} \times 0.85)}{\text{SCr} \times 72}$$

Children:

Use the **Schwartz equation:**

$$\text{GFR (mL/min/1.73 m}^2) = k \text{ (height)/SCr}$$

Where:

- k = Constant (0.33, premature infant; 0.45, term infants to 1 yr; 0.55, children to 13 yr; 0.65, adolescent males; 0.55, adolescent females)
- Height in cm, and SCr in mg/dL

IV. 24-HR URINE STUDIES

- **Calcium, urine:** See also Section II Hypercalcuria (Absorptive, Renal and Resorptive) and Metabolic Stone Evaluation (24 hr Urine Studies)
  - Normally ordered as part of a urolithiasis metabolic evaluation:
    - Normal: Calcium-free diet <150 mg/24 h (3.7 mmol/d); average calcium diet (600–800 mg/24 h) 100–250 mg/24 h (2.5–6.2 mmol/d)
    - Increased: Hyperparathyroidism, hyperthyroidism, hypervitaminosis D, distal renal tubular acidosis (type I), sarcoidosis, immobilization, osteolytic lesions (bony metastasis, multiple myeloma), Paget disease, glucocorticoid excess
    - Decreased: Medications (thiazide diuretics, estrogens, oral contraceptives),

hypothyroidism, renal failure, steatorrhea, rickets, osteomalacia, vitamin D deficiency

- **Catecholamines, fractionated** (norepinephrine, epinephrine, and dopamine):
  - Used to evaluate pheochromocytoma and paraganglioma. Avoid drugs that can interfere with the test, leading to falsely high catecholamines: Tricyclic antidepressants, labet alol, levodopa, methyldopa, sotalol, benzodiazepines, amphetamines, decongestants, and most psychoactive agents. All these drugs should be discontinued 2 wk prior to testing:
    - Normal: Values are variable and depend on the assay method used. Norepinephrine 15–80 mg/24 h (89–473 nmol/24 h), epinephrine 0–20 mg/24 h (SI: 0–118 nmol/24 h), dopamine 65–400 mg/24 h (SI: 384–2,364 nmol/24 h)
    - Increased: Pheochromocytoma (levels are > twice the upper normal value), paraganglioma, epinephrine administration, presence of drugs (see above)
- **Cortisol, free:**
  - Used to evaluate adrenal cortical hyperfunction; screening test of choice for Cushing syndrome:
    - Normal: 10–55 μg/24 h (SI: 27–150 nmol)
    - Increased: Cushing syndrome (adrenal hyperfunction from a pituitary tumor secreting ACTH or ectopic secretion of ACTH by other tumors such as bronchial carcinoid or adrenal tumor secreting cortisol), stress during collection, pregnancy
- **Cystine:**
  - Used to detect cystinuria, homocystinuria:
  - Normal: <30–40 mg/d (0.13 mmol/d):
    - Increased: Homozygotic cystinuria: 400 mg/d (1.7 mmol/d); heterozygotes cystinuria and Fanconi syndrome: Up to 250 mg/d (1 mmol)
- **Electrophoresis, protein (24-hr urine protein, 24-hr urine globulins):**
  - Used to evaluate overall renal function; screen for myeloma, macroglobulinemia, lymphoma, amyloidosis; can differentiate types of proteinuria (see table below)

		Electrophoretic Zones				
Pattern Description (Type of Proteinuria)	Protein, Total (mg/d)	Albumin	α_1	α_2	β	γ
Normal	<150	±			±	±
Glomerular, mild	<1,500	++		+	+	
Glomerular, severe	>1,500	+++		++	++	
Glomerular, nonselective	>3,000	+++	++	++	++	++
Tubular	<1,500	Tr/+	Tr	++	++	Tr
Mixed, glomerular & tubular		+++	+	++	+	+
Albuminuria	>150	++				
Overflow, acute phase response		Tr/+	++	++	Tr	Tr
Overflow, monodonal spike					Sp/++	Sp/++

KEY: Tr = trace; Sp = spike; ± = may or may not be present; + = mildly elevated; ++ = moderately elevated; +++ = markedly elevated.

- **5-Hydroxyindoleacetic acid (5-HIAA):**
  - 5-HIAA is a serotonin metabolite and is useful in diagnosing carcinoid syndrome:
    - Normal: 2–8 mg (SI: 10.4–41.6 mmol)/24-hr urine collection
    - Increased: Carcinoid tumors (except rectal), certain foods (banana, pineapple, tomato, walnuts, avocado), phenothiazine derivatives
- **Heavy met als:**
  - Measures exposure to arsenic (total), arsenic (inorganic), cadmium, lead, and mercury,

usually following occupational or environmental exposure:
  - Normal: Arsenic (total): 0–50 μg/24 h (<50 μg/L); arsenic (inorganic): <20 μg/L; cadmium: <3.0 μg/24 h (<2 μg/g creatinine); lead: <80 μg/24 h (< 50 μg/L); mercury: <20 μg/L
  - Increased: Indicative of exposure
- **Metanephrines:**
  - These metabolic products of epinephrine and norepinephrine are a primary screening test for pheochromocytoma and paraganglioma (in conjunction with urinary catecholamines). Avoid drugs that can interfere with the test, leading to falsely high catecholamines: Tricyclics antidepressants, labet alol, levodopa, methyldopa (Aldomet), sotalol, benzodiazepines, amphetamines, decongestants, and most psychoactive agents. All these drugs should be discontinued 2 wk prior to testing:
    - Normal: <1.3 mg/24 h (7.1 mmol/L) for adults, but variable in children
    - Increased: Pheochromocytoma, paraganglioma, false positive with drugs (see above)
- **Protein** (see Section I Proteinuria):
  - Normal: <150 mg/24 h (<0.15 g/d)
  - Increased: Nephrotic syndrome is usually associated with >4 g/24 h.
- **17-Ketogenic steroids (17-KGS, corticosteroids):**
  - Overall adrenal function test, largely replaced by serum or urine cortisol levels:
    - Normal: Males: 5–24 mg/24 h (17–83 mmol/24 h); females: 4–15 mg/24 h (14–52 mmol/24 h)
    - Increased: Adrenal hyperplasia (Cushing syndrome), adrenogenital syndrome
    - Decreased: Panhypopituitarism, Addison disease, acute steroid withdrawal
- **17-Ketosteroids, total (17-KS):**
  - Measures dehydroepiandrosterone (DHEA), androstenedione (adrenal androgens); largely replaced by assay of individual elements in the blood (serum DHEA-S and serum androstenedione):
    - Normal: Adult males: 8–20 mg/24 h (28–69 mmol/L); adult females: 6–15 mg/dL (21–52 mmol/L). Note: Low values in prepubertal children
    - Increased: Adrenal cortex abnormalities (congenital adrenal hyperplasia, adrenal carcinoma, Cushing syndrome)
    - Decreased: Panhypopituitarism, Addison disease
- **Urea nitrogen, urine** (urine nitrogen, nitrogen balance, blood urea nitrogen (BUN):
  - Measures urine nitrogen concentration:
    - Normal: 12,000–20,000 mg/24 h
    - Increased: Nitrogen wasting with hyperalimentation, bladder tap with amniocentesis
    - Decreased: Poor nitrogen balance with hyperalimentation
- **Vanillylmandelic acid (VMA):**
  - VMA is the urinary product of both epinephrine and norepinephrine; the 24-hr urinary VMA excretion has poor diagnostic sensitivity and specificity compared to fractionated 24-hr urinary fractionated metanephrines. Can be affected by many foods. No longer recommended by most endocrinologists:
    - Normal: <7–9 mg/24 h (35–45 mmol/L)
    - Increased: Pheochromocytoma, paraganglioma, factitious (chocolate, coffee, tea,

methyldopa)

SECTION V

Alternative and Complementary Urologic Therapies

Section Editors: Franklin Lowe, MD, MPH
Sven Wenske, MD

Introduction

National Center for Complementary and Alternative Medicine (NCCAM), a division of the National Institutes of Health (NIH), conducts and support research and provides information about complementary health. In a recent national survey, 38% of adults used some form of complementary and alternative medicine (1). “Complementary medicine” refers to use of Complementary and Alternative Medicine (CAM) together with conventional medicine, such as using acupuncture in addition to usual care to help lessen pain. Most use of CAM by Americans is complementary. “Alternative medicine” refers to use of CAM in place of conventional medicine. “Integrative medicine” combines treatments from conventional medicine and CAM for which there is some high-quality evidence of safety and effectiveness. It is also called integrated medicine.

CAM practices are often grouped into broad categories, such as natural products, mind and body medicine, and manipulative and body-based practices. Although these categories are not formally defined, they are useful for discussing CAM practices and some CAM practices may fit into more than 1 category. This chapter provides an overview of some of the CAM practices that are used or are related to the practice of urology.

Mind and Body Medicine

Mind and body practices focus on the interactions among the brain, mind, body, and behavior, with the intent to use the mind to affect physical functioning and promote health. Many CAM practices embody this concept in different ways. Meditation techniques, yoga, and acupuncture are some of these techniques.

Acupuncture, the application of solid needles inserted into defined spots in the skin, has been described thousands of years ago as part of ancient Chinese medicine. Although its main application has been to treat a variety of chronic conditions, such as back pain, obesity, addictions, and many others, more recently acupuncture has found its way into modern medicine and is nowadays part of daily clinical routine in many urologic practices. Especially urologic diseases that are difficult to treat, such as premature ejaculation, lower urinary tract symptoms (LUTS) and overactive bladder (OAB), chronic prostatitis/chronic pelvic pain syndrome (CPPS), or side effects (eg, hot flashes) of androgen-deprivation therapy (ADT) for advanced/metastatic prostate cancer, are the primary targets of acupuncture in urology (2).

Results from a clinical study in patients with LUTS or CPPS, 1 of the most difficult to treat urologic conditions, or patients with increased urinary frequency and urgency after radical prostatectomy, showed good results of acupuncture in decreasing symptoms and improving quality of life (3). Good success has also been reported in studies on patients that receive acupuncture for hot flashes, 1 of the most common side effects of ADT. A randomized placebo-controlled study showed recently the effects of acupuncture in the treatment of premature ejaculation in comparison to placebo and the standard treatment using paroxetine (4). Whereas paroxetine reduced the validated Premature Ejaculation Diagnostic Tool (PEDT) score from 17 to 10.5, acupuncture achieved a reduction from 16 to 11, which was significantly better than placebo. Usually, treatments are being applied twice per week for the 1st 6 wk. If patients respond to the treatment and if symptoms improve, the treatment frequency is reduced to once per week, and continues for a total of 12 wk. After that, a maintenance treatment schedule may be needed to prevent recurrent or increasing symptoms.

While the mechanisms of acupuncture are still not entirely understood, the main hypothesis

is that certain neurotransmitters (eg, serotonin, endorphins) are being released under needle stimulation, and that there exists an alternative connective tissue communication system unrelated to the peripheral and central nervous systems.

In addition to acupuncture, also pelvic floor muscle training (PFMT), relaxation, and yoga have all been shown to decrease muscle contractions and stress of the pelvic floor. One analysis from Stanford University studied the treatment of intra- and extrapelvic myofascial trigger point release therapy, and training in paradoxical relaxation including cognitive behavioral methods in patients with CPPS, with good results (5).

Overall, especially after exhausting standard treatments for common benign urologic disorders, acupuncture and other complementary and integrative therapies offer good alternative treatment approaches with limited potential for adverse events.

Manipulative and Body-Based Practices

Manipulative and body-based practices focus primarily on the structures and systems of the body, including the bones and joints, soft tissues, and circulatory and lymphatic systems. 2 commonly used therapies fall within this category: Spinal manipulation and massage therapy. Limited data is available but the literature suggests that 2 methods of manual therapy (myofascial physical therapy and global therapeutic massage) may benefit patients with urologic CPPS (6).

ACTIVE HEXOSE CORRELATED COMPOUND (AHCC)

AHCC is derived from the mycelia (branches) of shiitake (*Lentinula edodes*) of the basidiomycete mushroom family. It has been derived through hybridization of different shiitake subtypes. Characteristic for AHCC is its high content of **α**-glucans (a carbohydrate) and its low molecular weight, which renders it highly absorbable in the body. 1st described in an animal model in 1998, AHCC was shown to enhance immune response in an in vivo adenocarcinoma model in rats (12). Numerous subsequent human clinical studies have been performed on AHCC, showing that AHCC increases the activity of natural killer (NK) cells, T-cells, and dendritic cells that are all essential components of the human immune system. However, AHCC was also shown to act as an *immune regulator* through downregulation of an overactive immune system, thereby supporting the body's normal response to inflammatory processes during which the immune system may be upregulated. AHCC found urologic application in humans in a more recent study from 2009, where it was found to be beneficial in the treatment of castrate-resistant prostate cancer, reflected in a significant PSA response in a patient with metastatic castrate-resistant disease (13). As a complementary immunotherapy in patients with cancer, viral and nonviral hepatitis, HIV, and other immunocompromised patients, AHCC is being widely used, especially in Asia.

AFRICAN PLUM (*Pygeum africanum*)

The extract, tadenan, is derived from the bark of the African plum tree and is taken for the treatment of benign prostatic hypertrophy (BPH) and LUTS. Pygeum is usually found in most combination prostate health formulations. Its mode of action is thought to be via inhibition of fibroblast growth and anti-inflammatory effects. Some inconclusive data show a decrease in symptoms and an increase in flow rate. However, the T-IPSS study, a randomized double-

blind, placebo-controlled trial using tadenan was completed but never released or published (11). Only some minor gastrointestinal side effects have been noted with this product.

BAZOTON (*Radix urticae*)

This plant extract has been used in the treatment of benign prostatic hypertrophy (BPH). The active ingredients are thought to include its steroid–glycoside composition. It is an inhibitor of sex-steroid-binding globulin. There is a paucity of clinical data that show it decreases symptom scores, and it has little effect on flow rates. Side effects are minor and usually related to its smell and taste.

BROCCOLI SEED EXTRACT (*Sulforaphane*)

Multiple epidemiologic mouse models and cell-based studies indicate that the broccoli-derived isothiocyanate *Sulforaphane [(-)-1-isothiocyanato-(4R)-methylsulfinylbutane]* may affect the development of various types of cancers and especially prostate tumors. A recent analysis by Traka et al. (15) in PTEN-deficient mice showed that *sulforaphane* had positive effects to counteract changes downstream of PTEN loss. The PTEN is a tumor suppressor gene, and its deletion in an epithelial stem cell can be an early initiating event leading to prostatic intraepithelial neoplasia (PIN), and subsequently to cancer. The authors also found a significant overlap in changes in gene expression induced by *sulforaphane* in mouse prostate tissue with PTEN loss, with that induced in prostate tissue of men consuming a broccoli-rich diet.

CAPSAICIN (*capsicum*)

Capsaicin is the main pungent ingredient of hot peppers. It has been used as an intravesical therapy for overactive bladder (OAB). The mode of action is by selective activation of sensory nerve fibers and by a neurotoxic effect on afferent C fibers. Multiple studies have documented its efficacy in terms of symptom improvement and urodynamic changes (16). Adverse effects include suprapubic pain, hematuria, and incontinence, which are all self-limiting.

COMMON NATURAL PRODUCTS USED IN UROLOGY

This area of CAM includes use of a variety of herbal medicines (also known as botanicals), vitamins, minerals, and other “natural products.” Many are sold over the counter as dietary supplements. Some uses of dietary supplements – eg, taking a multivitamin to meet minimum daily nutritional requirements or taking calcium to promote bone health – are not thought of as CAM. The World Health Organization has estimated that 80% of the world's population uses some type of herbal medicine. Women are more likely than men to use complementary and alternative medicine (7).

These common agents are not US Food and Drug Administration (FDA) approved, but are available through health food stores and other commercial outlets. Phytotherapies and other supplements are under study, but few have undergone trials in the United States. Most have not demonstrated any significant efficacy, and many of these products are sold as part of combination therapies, and sold under various trade names. There have been growing

concerns about the potential toxicities of these products and their interactions with standard pharmaceuticals. According to the FDA, manufacturers of dietary supplements can make claims about how their products affect the structure or function of the body, but they may not claim to prevent, treat, cure, mitigate, or diagnose a disease without prior FDA approval. The FDA does monitor many of these compounds for undisclosed ingredients that can impact their efficacy. Limited data is available on the substances in urology. However, there is an increasing amount of peer-reviewed literature that provides some support for a few of these alternative therapies while others have not been able to clearly demonstrate efficacy (8). A challenge for any natural compound is standardization of the product (9). The large NIH-sponsored CAMUS trial studied increasing doses of saw palmetto on lower urinary tract function. Unfortunately when subject to rigorous study parameters, increasing doses of a saw palmetto fruit extract did not reduce LUTS more than placebo (10).

CRANBERRY JUICE AND SUPPLEMENTS (*Vaccinium macrocarpon*)

Cranberry is widely used to prevent UTIs; it was originally believed that this fruit acidified the urine (17). However, cranberry appears to work by inhibiting the adhesion of type I and P-fimbriated uropathogens (eg, uropathogenic *Escherichia coli*) to the uroepithelium, thus impairing colonization and subsequent infection. It contains a unique blend of organic acids – quinic, malic, and citric – as well as nondialyzable polymeric compounds that provide this antibacterial adherence effect.

Studies using cranberry juice, cranberry–lingonberry juice, and cranberry tablets compared with placebo for preventing UTIs, bacteriuria, or pyuria concluded that cranberry juice and cranberry products significantly reduced UTIs among women with recurrent infections (18,19). Recommended doses range from 90 to 480 mL of cranberry cocktail twice daily or 15–30 mL of unsweetened 100% cranberry juice daily. The frozen concentrate has almost 30 times the strength of the juice, and 30–45 mL BID has been used. Capsule doses range between 1 and 6 capsules of 300–400 mg concentrated extract BID. High pediatric doses of $>$300 mL daily have been associated with adverse effects such as hypersensitivity or gastrointestinal distress such as diarrhea.

The findings of several reviews support the potential use of cranberry products in the prophylaxis of recurrent UTIs in young and middle-aged women, but it should not be used as a substitute for antibiotics, as it is an ineffective treatment for established infections. Patients with a history of nephrolithiasis should avoid the use of cranberry products (possible increases in urinary calcium and oxalate concentration). Due to the heterogeneity of clinical study designs and the lack of consensus regarding the dosage regimen and formulation to use, cranberry products cannot be broadly recommended for the prophylaxis of recurrent UTIs at this time. Note that it may potentiate anticoagulant effects of warfarin.

FLAXSEED (*Linum usitatissimum*)

Flaxseed is a member of the genus *Linum* in the family *Linaceae,* and contains high levels of dietary fiber as well as lignans, an abundance of micronutrients and ω-3 fatty acids. The lignans in flaxseed may provide some health benefits against cancers that are sensitive to hormones, such as breast and prostate. Some reports have published the effect of flaxseed on

lowering PSA and androgens. A randomized trial analyzing prostatectomy specimens in men randomized to flaxseed supplementation 3 wk before surgery showed significant differences in tumor proliferation rate, index, and apoptotic rate between men that had been randomized to take flaxseed supplements vs. those that stayed on normal diet (20,21). An effect on biochemical outcome and prostate cancer mortality has not been shown.

GINKGO BILOBA

Primarily used for memory deficits, dementia, and neurologic dysfunction, ginkgo biloba is also promoted as a treatment for impotence and selective serotonin reuptake inhibitor (SSRI)-induced sexual dysfunction, with a recommended dose range of 60–80 mg standardized dry extract orally BID or TID (22). Studies have shown small cognition benefits with dementia, but no other demonstrated benefit in healthy adults (23). Use cautiously with aspirin (ASA), salicylates, and warfarin.

GOSHA-JINKI-GAN (GJG)

Gosha-jinki-gan (GJG) is a traditional Chinese blended herbal medicine composed of 10 different herbs. In canine studies, bladder contraction mediated by pelvic nerve stimulation and induced by acetylcholine administration was significantly inhibited by administration of 100 mg/kg GJG; effects were similar to that seen with 0.1 mg atropine. Human studies have reported mild improvements in International Prostate Symptom Scores (IPSS) and OAB symptoms in some patients (7). Mild adverse events include nausea, diarrhea, and urinary frequency.

GREEN TEA

In addition to several potent antioxidants, such as epigallocatechin-3-gallate (EGCG), in green tea, mainly its polyphenolic compounds have been suggested to decrease prostate cancer development and decelerate prostate cancer progression in several in vitro and in vivo animal studies (24,25). High green tea consumption in Japan may at least partially explain the low prostate cancer prevalence in Japanese men, as green tea plays a major role in the Asian diet. Despite the fact that results in human studies have mostly been controversial, some well-designed studies have also demonstrated a significant reduction in incidence of prostate cancer incidence in men with high-grade PIN who drink green tea. However, the protective role of tea in prostate cancer is still controversial (26).

HEATHER (*Calluna vulgaris*)

The medicinal portion of common heather consists of the entire herb (leaves, flower, roots) ground and boiled to create a product that is taken for its diuretic properties in the treatment of kidney ailments and BPH/LUTS. Active compounds are thought to include flavonoids and sitosterols. The claimed efficacy has never been documented. No clinical trials are available.

HORNY GOAT WEED (*Epimedium*)

Epimedium is a Chinese herbal remedy promoted as a safe and natural alternative to

sildenafil citrate (27,28). However, extracts of epimedium are strongly estrogenic due to the presence of novel potent phytoestrogens of the prenyl-flavone family. It has been reported to cause tachyarrhythmias.

LYCOPENE

Lycopene is a major carotenoid component of tomato, red pepper, and other red fruits and vegetables. The pigment acts basically as an antioxidant, protecting cells against damage from free radicals. In several studies it was found to have potential anticancer activity in many types of cancer, as numerous studies reported on inverse associations between lycopene intake and prostate cancer prevalence and grade (29). Overall, the protective effect of lycopene is unclear, as controversial results have been published. When taken, lycopene is better absorbed by the body when it is consumed in cooked, instead of raw or fresh products (30).

MODIFIED CITRUS PECTIN (MCP)

Pectin, a carbohydrate consisting of thousands of polysaccharide molecules, is found abundantly in the peels of apples, citrus fruits, and plums, but is also found in most other plants. Regular pectin is not absorbable by the human body, but in modified citrus pectin (MCP) the pectin has been altered through breaking of its long polysaccharide chains. It has been shown to inhibit cancer growth and breast and prostate cancer metastases in animal models, and was found to suppress cancerous proliferation and induce apoptosis of prostate cancer cells in vitro (31). MCP showed also antimetastatic properties, and potential for increasing apoptotic responses of tumor cells to chemotherapy by inhibiting antiapoptotic functions of galectin-3, and has therefore been established in the literature for its potential use in the treatment of multiple human malignancies (prostate, colon, breast, liver, and melanoma).

ω-3 FATTY ACIDS (FISH OIL)

These naturally occurring compounds, ω-3 fatty acids, polyunsaturated essential fatty acids, cannot be produced by the human body, but are required for normal performance of numerous organs and cell functions. However, there is a wide range of conflicting results in the literature on health benefits, especially in the cancer prevention and treatment.

One of the most extensive reviews of the literature on this topic from MacLean et al. (32) from 2006 in the Journal of the American Medical Association concluded that there is no association between ω-3 fatty acids and the prevention or the prevalence of cancer. A more recent analysis concluded similarly, also taking into account difficulties in assessing patient's exact dietary habits, but ω-3 fatty acids were consequently deemed neither a risk factor nor a beneficial factor with regard to cancers (33). However, as ω-3 fatty acids improve appetite and help gain weight, they may be of benefit in patients with advanced cancer and cachexia, as this may contribute to improved quality of life.

PC-SPES

This product is no longer commercially available because of issues associated with quality control. It was found to be tainted with diethylstilbestrol, warfarin, and alprazolam. It was used for treatment of prostate cancer, particularly in hormone-refractory patients. It consisted of 8 Chinese herbs (*Chrysanthemum, Isatis,* licorice*, Ganoderma lucidum, Panax pseudoginseng, Rabdosia rubescens, Scutellaria* [skullcap]*,* and saw palmetto berry) (34). It had potent antiestrogenic effects. Its use was associated with deep venous thrombosis, breast tenderness, loss of libido, and decreased PSA and testosterone levels. Other companies have made similar combinations but have not achieved a widespread usage (35).

PANAX GINSENG (*Korean red ginseng*)

This product has been used for numerous indications in traditional Chinese medicine. It is frequently used for decreased libido and erectile dysfunction. It reportedly has androgenic effects and stimulation, although improvements in penile endothelial L-arginine–nitric oxide activity have been suggested (36,37). Clinical trials are not conclusive of its effectiveness.

PERMIXON (*Serenoa repens*)

This is the branded saw palmetto extract produced in France. It is the lipidosterolic extract of the dried fruit (berry) of the dwarf palm. It is the most widely studied of all phytotherapies for the treatment of BPH/LUTS. From in vitro studies, it has been postulated to have many mechanisms of action including antiprostaglandin, antiandrogenic, and antiestrogenic effects (38). It has almost no effect upon prostate size and no effect upon PSA levels (39). There are no known significant health risks or adverse effects.

POMEGRANATE (*Punica granatum*)

Pomegranate juice is known for its high vitamin C content, as well as vitamin B5 (pantothenic acid), potassium, and natural phenols, such as ellagitannins and flavonoids with extremely effective free radical-scavenging properties.

Increasing evidence shows that pomegranate juice has potential to inhibit growth and reduce the invasion of prostate cancer cells both in vitro and in vivo. A phase II clinical trial, in which patients with rising PSA after primary treatment with curative intent of prostate cancer were given 8 oz of pomegranate juice per day, showed that the mean PSA doubling time increased significantly in men under treatment with pomegranate juice from 15 to 54 mo ($p < 0.001$) (40). Several subsequent studies have shown that pomegranate juice affects many of the cellular processes involved in cell death and also affects signaling pathways that could inhibit cell migration and invasion (41).

PUMPKIN SEED (*Cucurbita pepo*)

Fresh and dried seeds are taken whole or ground for the treatment of BPH or OAB. Active compounds are thought to be phytosterols (42,43). There are no recent clinical trials and therefore no evidence establishing its efficacy. There are no known side effects.

RESVERATROL

Resveratrol is a potent antioxidant found in wine, especially in high concentration in Pinot noir, but also in grapes and berries. Research has demonstrated that it inhibits cancer growth through reduction of cell proliferation and metastasis, and induction of cell apoptosis. On a molecular level, it has been shown that mechanisms involved are inhibition of Akt and suppression of IGF-1 receptor expression (44). These antitumor effects of resveratrol were observed in in vitro and in vivo xenograft studies with the common prostate cancer cell lines PC3, DU145, and LNCaP.

RYE POLLEN (*Secale cereale*)

A pollen extract obtained by microbial digestion and extraction by water and organic solvents. Cernilton is the branded product. Active ingredients are thought to be β-sitosterols (45). It is used for the treatment of BPH and prostatitis and CPPS (46). In vitro inhibition of epithelial and stromal cell growth has been demonstrated (45). No long-term conclusive clinical studies exist. Side effects are reportedly minimal.

SAW PALMETTO BERRY (*Serenoa repens, Sabal serrulata*)

There are many different extraction processes and therefore many different brands of saw palmetto. The composition of these brands is variable. A recent NIH-sponsored double-blind, placebo-controlled study using the Indena brand showed no statistical difference between placebo and saw palmetto berry for treatment of BPH/LUTS. Permixon brand is the most widely studied product (see “Permixon” above). Minimal side effects are associated with saw palmetto. Saw palmetto berry extract (SPBE) compounds are also sold for “prostate health.” SPBE includes ingredients such as β-sitosterol and stigmasterol with no reliable clinical data to support their use. A recent large meta-analysis documented no significant clinical benefit of *Serenoa repens* on LUTS or prostate volume (10). Saw palmetto extract does not affect serum prostate-specific antigen more than placebo, even at relatively high dose (47). In addition it appears safe with the saw palmetto extract used in the CAMUS trial showed no evidence of toxicity at doses up to 3 times the usual clinical dose during an 18-mo period.

SELENIUM

A trace mineral that may prevent the development of prostate cancer. Epidemiologic studies suggest a chemopreventive effect (48). 1 study of patients with high-grade PIN suggested that selenium reduced the incidence of prostate cancer on subsequent biopsy. The National Cancer Institute–sponsored SELECT trial was a 10-yr prospective trial that began in 2001 of over 35,000 men studying the prostate cancer chemopreventive effects of selenium and vitamin E alone and in combination (49). The data monitoring safety board (DMSB) halted the trial in the fall of 2008. Their concerns were that the supplements did not appear to offer any benefit. In particular, there was a statistically nonsignificant trend to increasing prostate cancer with vitamin E alone and increased diabetes risk in men on selenium alone.

SOUTH AFRICAN STAR GRASS (*Hypoxis rooperi*)

This extract is taken for BPH/LUTS. The active compound is thought to be β-sitosterols,

which are thought to induce apoptosis by transforming growth factor (TGF)-β_1; this is unproven clinically (50). Initial studies showed dramatic improvements in symptom scores and flow rates; however, confirmatory studies are still needed (51). Adverse effects are believed to be minimal.

STINGING NETTLE (*Urtica dioica, Urticae radix*)

Bazoton is a branded form of this extract; (see Bazoton section above). The clinical evidence of the effectiveness of nettle root is based primarily on open studies, and the significance of this must be confirmed (14, 52). Minimal toxicity is associated with stinging nettle use.

VITAMIN D3 (*Cholecalciferol*)

As a fat-soluble vitamin, vitamin D3 plays a key role in overall health, as it mainly maintains calcium and phosphate homeostasis. However, it has also been shown to exhibit antineoplastic effects on various types of cancer, such as colon, breast, and prostate cancers (53).

The Institute of Medicine (IOM) has reviewed and updated the dietary reference intakes (DRIs) for vitamin D. It found that there is strong evidence to support the use of vitamin D with calcium for bone health but that it was lacking for other health conditions. Dosages for patient with various health issues differ. The recommended daily allowance (RDA), as set in 2011, is based on age, as follows: For those 1–70 yr of age, 600 IU daily; for those 71 yr and older, 800 IU daily; and for pregnant and lactating women, 600 IU daily. The IOM further recommended that serum 25(OH)D levels of 20 ng/mL (50 nmol/L) is adequate, and levels $>$50 ng/mL (125 nmol/L) could have potential adverse effects. However, dosages for urologic patients may differ based on underlying health disorders and concomitant medications (underlying osteopenia, ADT, therapy with RANK-ligand inhibitors [Denosumab] or bisphos-phonates in patients with metastatic prostate cancer, etc.).

VITAMIN E (γ-*TOCOPHEROL*)

Vitamin E, another fat-soluble essential vitamin, was initially thought to prevent prostate cancer risk. However, the National Cancer Institute–sponsored SELECT trial, studying prostate cancer chemopreventive effects of selenium and vitamin E, reported in 2009 controversial results with no benefits of vitamin E supplementation (see “Selenium”) (54). Moreover, the follow-up publication in 2011 even reported a significantly increased prostate cancer risk in healthy men with dietary supplementation with vitamin E (55). In addition, vitamin E supplementation above dosages of $>$400 IU per day were found to significantly increase risks of cardiovascular events.

YOHIMBINE (PAUSINYSTALIA YOHIMBE) YOCON, YOHIMEX

An extract of the bark of the yohimbe tree has been used for erectile dysfunction and decreased libido. The mechanism of action is as an α-adrenergic antagonist. Conflicting studies show both positive and no effect when compared to placebo (56). It appears to have greatest utility for men with psychogenic impotence. Despite the advent of phosphodiesterase

5 (PDE5) inhibitors, there is still widespread utilization of this over-the-counter product. Side effects include anxiety, tremors, dizziness, hypertension, and tachycardia. Do not use with antidepressants (eg, MAOIs or similar agents).

ZYFLAMEND

Zyflamend, a formulation containing 10 different herbs, is a dietary supplement marketed for the support of cardiovascular and joint function and healthy inflammation response. It is thought to have anti-inflammatory, antiangiogenic, and antiproliferative properties. Several in vitro studies have shown that Zyflamend decreases COX-1 and COX-2 enzymatic activity, induces apoptosis, and reduces androgen receptor expression in LNCaP cells (57). Moreover, it was found to inhibit arachidonic acid pathways, in human prostate cancer PC3 cells. Moreover, it also inhibits the proliferation of oral squamous carcinoma, pancreatic cancer, and melanoma cells in vitro. In an animal model, it inhibited the growth of both hormone-naïve and castrate-resistant prostate cancer, and reduced the expression of PSA. However, the latter could not be shown in a phase I clinical trial in men with PIN at Columbia University Medical Center, where Zyflamend was well tolerated, but did not lead to any significant changes in serum PSA levels (58).

SECTION VI

Urologic Drug Reference

Section Editors: T. Ernesto Figueroa, MD, FAAP, FACS
Leonard G. Gomella, MD, FACS
Kevin R. Loughlin, MD, MBA, FACS
Jack H. Mydlo, MD

This section is designed to be a quick reference of medications commonly used in urology or of those that have significant impact on the GU system. Although some general information about the drug may be presented, this is not intended to be a complete authoritative listing for each medication; the focus here is on the practice of urology. You should be familiar with all the indications, contraindications, adverse effects, and drug interactions of any medication that you prescribe. Such detailed information is beyond the scope of this book but can be found in the manufacturer's package insert, product website, in the *Physicians' Desk Reference* (PDR), or from the American Hospital Formulary Service.

Medications are listed by generic name, with some of the more common trade names noted. Common uses and urology-specific uses are listed in addition to the official labeled indications (FDA approved), because many available medications are used to treat various conditions based only on the medical literature, and these uses are not listed in the package insert. Asterisks are placed before and after the official US FDA approved indications. This additional use information is based on the editorial review of the literature and is representative of urology practice patterns primarily in the US. Where no pediatric dosage is provided, the implication is that the use of the agent is not well established in this age group. Controlled substances are indicated by the symbol [C]. Increasingly, drug interaction and medication side effects can be related to a drug's metabolism and the cytochrome P450 enzymes are essential for the metabolism of many medications. There are more than 50 CYP450 enzymes, but the CYP1A2, CYP2C9, CYP2C19, CYP2D6, and CYP3A enzymes metabolize 90% of drugs and are predominantly expressed in the liver. The table at the end of the chapter (page 975) summarizes some of the common medications and their CYP450 interactions that are noted for many of the medications listed here.

MEDICATION KEY

Medications are in alphabetical order by generic name. Some of the more commonly recognized trade names in the US are listed for each (in parentheses after the generic name). If a drug is available without prescription, it is noted as OTC (over-the-counter).

GENERIC DRUG NAME (SELECTED COMMON BRAND NAMES) [CONTROLLED SUBSTANCE DESIGNATION] [OTC]

WARNING: Summarized versions of the Black Box precautions deemed necessary by the FDA. These are significant precautions and contraindications concerning the individual medication.**Uses:** This includes both FDA-labeled indications bracketed by ** and other "off-label" uses of the medication. Because many medications are used to treat various conditions based on the medical literature, and these uses are not listed in their package insert, we list common uses of the medication in addition to official labeled indications (FDA approved) based on input from our editorial board. **Action:** How the drug works. This information is helpful in comparing classes of drugs and understanding side effects and contraindications. *Spectrum:* Specifies activity against selected microbes for antimicrobials. **Dose:** ***Adults & Peds:*** Where no specific pediatric dose is given, the implication is that this drug is not commonly used or indicated for that age group. At the end of the dosing line, important dosing

modifications may be noted (ie, take with food, avoid antacids, etc.). **W/P (Warning/Precautions):** (Pregnancy/fet al risk categories, breast-feeding [as noted below]) Cautions concerning the use of the drug in specific settings. **CI:** Contraindications. **Disp (Dispense):** Common dosing forms. **SE (Side Effects):** Common or significant side effects. **Notes:** Other key useful information about the drug including additions made by our editorial board.

CONTROLLED SUBSTANCE CLASSIFICATION

Medications under the control of the US Drug Enforcement Agency (DEA) (Schedules I–V controlled substances) are indicated by the symbol (C). Most medications are uncontrolled and do not require a DEA prescriber number or a special prescription pad. The following is a general description for the schedules of DEA-controlled substances.

Schedule (C-I) I: All nonresearch use forbidden (eg, heroin, etc.).

Schedule (C-II) II: High addictive potential; medical use accepted. No telephone call-in prescriptions; no refills.

Schedule (C-III) III: Low to moderate risk of physical dependence, high risk of psychologic dependence; prescription usually must be rewritten after 6 mo or 5 refills (eg, acetaminophen plus codeine).

Schedule (C-IV) IV: Limited potential for dependence; prescription rules same as for schedule III (eg, benzodiazepines, propoxyphene).

Schedule (C-V) V: Very limited abuse potential; prescribing regulations often same as for uncontrolled medications; some states have additional restrictions.

FDA FETAL RISK CATEGORIES

Category A: Adequate studies in pregnant women have not demonstrated a risk to the fetus in the 1st trimester of pregnancy; there is no evidence of risk in the last 2 trimesters.

Category B: Animal studies have not demonstrated a risk to the fetus, but no adequate studies have been done in pregnant women.

OR

Animal studies have shown an adverse effect, but adequate studies in pregnant women have not demonstrated a risk to the fetus during the 1st trimester of pregnancy, and there is no evidence of risk in the last 2 trimesters.

Category C: Animal studies have shown an adverse effect on the fetus, but no adequate studies have been done in humans. The benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.

OR

No animal reproduction studies and no adequate studies in humans have been done.

Category D: There is evidence of human fet al risk, but the potential benefits from the use of the drug in pregnant women may be acceptable despite its potential risks.

Category X: Studies in animals or humans or adverse reaction reports, or both, have demonstrated fet al abnormalities. The risk of use in pregnant women clearly outweighs any possible benefit.

Category ?: No data available (not a formal classification; included to provide complete dataset).

BREAST-FEEDING CLASSIFICATION

No formally recognized classification exists for drugs and breast-feeding. This shorthand is based on information from the *Clinician's Pocket Drug Reference, 2015.*

+ Compatible with breast-feeding
M Monitor patient or use with caution
± Excreted, or likely excreted, with unknown effects or at unknown concentrations
?/– Unknown excretion, but effects likely to be of concern
– Contraindicated in breast-feeding
? No data available

This chapter is based on data in and modified from Gomella LG, Haist S, Adams A, eds. *Clinicians' Pocket Drug Reference, 2015 Edition*. New York: McGraw Hill, 2015, DailyMed (http://www.dailymed.nlm.nih.gov), Drugs@FDA (http://www.accessdata.fda.gov) and manufacturers web sites. Reproduced with permission of the copyright holder where appropriate.

ABIRATERONE (ZYTIGA)

USES: *Castrate-resistant metastatic PCa*
ACTIONS: CYP17 inhibitor;↓ testosterone precursors.
DOSE: 1,000 mg PO qd w/ 5 mg prednisone BID; w/o food 2 hr ac and 1 hr pc; ↓ w/ hepatic impair.
W/P: [X, N/A] w/ severe CHF, monitor for adrenocortical insuff/excess, w/ CYP2D6 substrate/CYP3A4 inhib or inducers; do not use with severe liver insufficiency.
CI: Pregnancy.
DISP: Tabs 250 mg.
SE: Fatigue, joint swelling/discomfort, edema, hot flush, diarrhea, vomiting, cough, ↑ BP, dyspnea, UTI, contusion; common lab abnormalities: Anemia, ↑ alkaline phosphatase, hypertriglyceridemia, lymphopenia, hypercholesterolemia, hyperglycemia, ↓ K^+, ↑ AST, ↓ PO_4, ↑ ALT.

NOTES: Follow BP, edema status, LFTs, K^+; CYP17 inhib may ↑mineralocorticoid SEs; prednisone ↓ACTH limiting SEs (hypokalemia and hypertension); if taken with food excess absorption of drug.

ACETAMINOPHEN [APAP, *N*-ACETYL-*p*-AMINOPHENOL] (ACEPHEN, OFIRMEV IV [Rx] , TYLENOL, OTHER GENERIC) [OTC]

WARNING: May cause acute liver failure; associated w/ doses > 4,000 mg/d & taking APAP in >1 product.
USES: *Mild–mod pain, HA, fever*
ACTIONS: Nonnarcotic analgesic; ↓ CNS synth of prostaglandins & hypothalamic heat-

regulating center.

DOSE:

Adults: 325–650 mg PO or PR q4–6h or 1,000 mg PO 3–4 ×/d; max. 4 g/d. *IV:* <50 kg: 15 mg/kg IV q6h or 12.5 mg/kg IV q4h; max. 75 mg/kg/d. ≥50 kg: 650 mg IV q4h or 1,000 mg IV q6h; max. 4 g/d.
Peds: ***<12 y.*** 10–15 mg/kg/dose PO or PR q4–6h; max. 5 doses/24 h. Administer q6h if CrCl 10–50 mL/min & q8h if CrCl <10 mL/min. *IV:* 15 mg/kg IV q6h or 12.5 mg/kg IV q4h; max. 75 mg/kg/d.
W/P: [C, +] w/ hepatic/renal impair in elderly & w/ EtOH use (>3 drinks/d); w/ >4 g/d; EtOH liver Dz, G6PD deficiency; w/ warfarin; serious skin rxns (SJS, TEN, AGEP).
CI: Hypersens.
DISP: Tabs melt away/dissolving 80, 160 mg; tabs: 325, 500, 650 mg; chew tabs 80, 160 mg; gel caps 500 mg; liq 160 mg/5 mL, 500 mg/15 mL; drops 80 mg/0.8 mL; *Acephen* supp 80, 120, 325, 650 mL; Inj 10 mg/mL.
SE: Hepatotoxic; OD hepatotoxic at 10 g; 15 g can be lethal; Rx w/ *N*-acetylcysteine.
NOTES: No anti-inflammatory or plt-inhibiting action; avoid EtOH; 2014 MedWatch Safety Alert: FDA recommends providers stop using combo products w/> 325 mg APAP/dosage unit. No data that >325 mg APAP/dose is beneficial and this ↑ liver injury risk. ↓ dose also ↓ risk of APAP overdose. Most manufacturers have complied w/ 2011 FDA request to limit APAP to 325 mg/dosage unit; some Rx combos w/ >325 mg of APAP/dosage unit remain available. FDA advisory has rec ↓ in max. dose to 3,000 mg/d.

ACETAMINOPHEN/CODEINE (TYLENOL NO. 2, 3, AND 4) [C-III, C-V]

USES: *Mild–mod pain (No. 2–3); mod–severe pain (No. 4)*
ACTIONS: Combined APAP & narcotic analgesic.

DOSE:

Adults: 1–2 tabs q4–6h PRN or 30–60 mg/codeine q4–6h based on codeine content (max. dose APAP = 4 g/d).
Peds: APAP 10–15 mg/kg/dose; codeine 0.5–1 mg/kg dose q4–6h (guide: 3–6 yr, 5 mL/dose; 7–12 yr, 10 mL/dose) max. 2.6 g/d if < 12 yr; ↓ in renal/hepatic impairment.
W/P: [C, ?] Alcoholic liver disease; G6PD deficiency.
CI: Hypersensitivity.
DISP: Tabs 300 mg APAP + codeine (No. 2 = 15 mg, No. 3 = 30 mg, No. 4 = 60 mg); susp (C-V) APAP 120 mg + codeine 12 mg/5 mL.
SE: Drowsiness, dizziness, N/V.
NOTES: See Acetaminophen note

ACETAZOLAMIDE (DIAMOX)

WARNING: Fatalities due to reactions to sulfonamides (e.g., Stevens–Johnson syndrome [SJS], toxic epidermal necrolysis [TEN], hepatic necrosis, agranulocytosis, aplastic anemia, and other blood dyscrasias. Sensitizations w/ a sulfonamide is readministration. With serious reactions occur, d/c use. Caution w/ high-dose aspirin and acetazolamide, as anorexia,

tachypnea, lethargy, coma, and death have been reported.
USES: *Diuresis, drug and CHF edema, glaucoma, prevent high-altitude sickness, refractory epilepsy*, metabolic alkalosis, resp stimulant in COPD.
ACTIONS: Carbonic anhydrase inhibitor; ↓ renal excretion of hydrogen & ↑ renal excretion of Na^+, K^+, HCO_3^-, & H_2O.

DOSE:

Adults: *Diuretic:* 250–375 mg IV or PO q24h. *Metabolic alkalosis:* 500 mg IV. *Diuretic*: 5 mg/kg/24 h PO or IV. *Alkalinization of urine:* 5 mg/kg/dose PO BID–TID; ↓ dose w/ CrCl 10–50 mL/min; avoid if CrCl < 10 mL/min.
W/P: [C, +/−]
CI: ↓ sodium and/or potassium; severe kidney/liver disease, adrenal failure, hyperchloremic acidosis, cirrhosis (hepatic encephalopathy risk), long-term use w/ chronic angle-closure glaucoma.
DISP: Tabs 125, 250 mg; ER caps 500 mg; Inj 500 mg/vial, powder for recons.
SE: Malaise, met allic taste, drowsiness, photosensitivity, hyperglycemia.
NOTES: Follow Na^+ & K^+; watch for metabolic acidosis; check CBC & plts; SR forms not for epilepsy.

ACETOHYDROXAMIC ACID (LITHOSTAT)

USES: *Adjunct for chronic urea-splitting UTI*, struvite calculi.
ACTION: ↓ Bacterial urease, ↓ ammonia and alkalinity in the urine d/t urea-splitting organisms.

DOSE:
Adults: 250 mg PO 3–4×/d, total 10–15 mg/kg/d; max. 1.5 g/day.
Peds: 10 mg/kg/d PO.
W/P: [X, −]; w/ pre-existing psych disorders.
CI: Patient amenable to definitive surgery; infection with nonurea-splitting organisms, SCr >2.5 mg/dL, females who do not use contraception, pregnancy, component hypersensitivity.
DISP: Tablets 250 mg.
SE: Hemolytic anemia, bone marrow suppression, hepatotoxicity, flushing, rash, nervousness, tremor, anorexia, N/V.
NOTES: Take on empty stomach (follow CBC and LFTs).

ACETYLCYSTEINE (ACETADOTE, MUCOMYST)

USES: *Mucolytic, antidote to acetaminophen hepatotox/OD, adjuvant treat chronic bronchopulmonary diseases & cystic fibrosis* prevent contrast-induced renal dysfunction.
ACTIONS: Splits mucoprotein disulfide linkages; restores glutathione in acetaminophen OD to protect liver.
DOSE: *Antidote:* PO or NG: 140 mg/kg load, then 70 mg/kg q4h × 17 doses (dilute 1:3 in carbonated beverage or OJ), repeat if emesis w/in 1 hr of dosing. *Acetadote:* 150 mg/kg IV over 60 min, then 50 mg/kg over 4 hr, then 100 mg/kg over 16 hr. *Prevent renal dysfunction:* 600–1,200 mg PO BID × 2 day.

W/P: [B, ?].
DISP: Soln, inhaled and oral 10%, 20%; Acetadote IV soln 20%.
SE: Bronchospasm (inhaled), N/V, drowsiness, anaphylactoid reactions w/ IV.
NOTES: Activated charcoal adsorbs PO acetylcysteine for acetaminophen ingestion; start treatment for acetaminophen OD w/in 6–8 hr.

ACYCLOVIR (ZOVIRAX, GENERIC)

USES: **Herpes simplex* (HSV) (genital/mucocutaneous, encephalitis, keratitis), *Varicella zoster*, *Herpes zoster* (shingles) infections*.
ACTIONS: Interferes w/ viral DNA synth.

DOSE:

Adults: Dose on IBW if obese (>125% IBW) PO. *Initial genital HSV:* 200 mg PO q4h while awake (5 caps/d) × 10 days or 400 mg PO TID × 7–10 days. *Chronic HSV suppression:* 400 mg PO BID. *Intermittent HSV Treat:* As initial, except Treat × 5 days, or 800 mg PO BID, at prodrome. *Topical: Initial herpes genitalis:* Apply q3h (6×/d) for 7 days. *HSV encephalitis:* 10 mg/kg IV q8h × 10 days. *Herpes zoster:* 800 mg PO 5/d for 7–10 days. *IV:* 10 mg/kg/dose IV q8h 7 days.
Peds: *Genital HSV:* ***3 mo–12 y:*** 40–80 mg/kg/d divided 3–4 doses (max 1 g); ***≥12 yr:*** 200 mg 5 times day or 400 mg 3 times a day for 5–10 d; IV: 5 mg/kg/dose q8h for 5–7 d Shingles: ***<12 y:*** 30 mg/kg/d PO or 1,500 mg/m^2/day IV ÷ q8h for 7–10 d; ↓ w/ CrCl <50 mL/min.
W/P: [B, +].
CI: Component hypersens.
DISP: Caps 200 mg; tabs 400, 800 mg; susp 200 mg/5 mL; Inj 500 & 1,000 mg/vial; Inj soln, 50 mg/mL oint 5% and cream 5%.
SE: Dizziness, lethargy, malaise, confusion, rash, IV site inflammation; transient ↑ Cr/BUN.
NOTES: PO better than topical for herpes genitalis.

ALDESLEUKIN [IL-2] (PROLEUKIN)

WARNING: Restrict to pts w/ nl cardiac/pulmonary functions as defined by formal testing. Caution w/ Hx of cardiac/pulmonary disease. Administer in hospital setting w/ physician experienced w/ anticancer agents. Assoc w/ capillary leak syndrome (CLS) characterized by ↓ BP and organ perfusion w/ potential for cardiac/respiratory tox, GI bleed/infarction, renal insufficiency, edema, and mental status changes. ↑risk of sepsis and bacterial endocarditis. Treat bacterial infection before use. Pts w/ central lines are at ↑ risk for infection. Prophylaxis w/ oxacillin, nafcillin, ciprofloxacin, or vancomycin may reduce staphylococcal infection. Hold w/ mod–severe lethargy or somnolence; continued use may result in coma.
USES: *Met RCC & melanoma*.
ACTIONS: Acts via IL-2 receptor; many immunomodulatory effects.
DOSE: 600,000 IU/kg q8h × max. 14 doses days 1–5 and days 15–19 of 28-day cycle (FDA dose/schedule for RCC); other schedules (eg, “high dose” 720,000 IU/kg IV q8h up to 12 doses, repeat 10–15 days later).
W/P: [C, ?/−].
CI: Organ allografts; abnormal thallium stress test or PFT.

DISP: Powder for recons 22 × 10^6 IU, when reconstituted 18 MIU/mL = 1.1 mg/mL.
SE: Flu-like syndrome (malaise, fever, chills), N/V/diarrhea, ↑ bili; capillary leak syndrome; ↓ BP, tachycardia, pulm & periph edema, fluid retention, & Wt gain; renal & mild hematologic tox (↓Hgb, plt, WBC), eosinophilia; cardiac tox (ischemia, atrial arrhythmias); neurotox (CNS depression, somnolence, delirium, rare coma); pruritic rashes, urticaria, & erythroderma common.

ALENDRONATE (BINOSTO, FOSAMAX, FOSAMAX PLUS D, GENERIC)

USES: *Treat & prevent osteoporosis male & postmenopausal female, Treat steroid-induced osteoporosis, Paget disease*.
ACTIONS: ↓ Nl & abnormal bone resorption, ↓ osteoclast action.
DOSE: *Osteoporosis:* Treat: 10 mg/d PO or 70 mg qwk; Fosamax plus D 1 tab qwk. *Steroid-induced osteoporosis:* Treat: 5 mg/d PO, 10 mg/d postmenopausal not on estrogen. *Prevention:* 5 mg/d PO or 35 mg qwk. *Paget disease:* 40 mg/d PO × 6 mo.
W/P: [C, ?] Not OK if CrCl <35 mL/min, w/ NSAID use.
CI: Esophageal anomalies, inability to sit/stand upright for 30 min, ↓ Ca^{2+}.
DISP: Tabs 5, 10, 35, 40, 70 mg. *Fosamax plus D*: Alendronate 70 mg w/ cholecalciferol (vit D_3) 2,800 or 5,600 IU. *Binosto:* Effervescent 7 mg tablet.
SE: Abdominal pain, acid regurgitation, constipation, diarrhea/N, dyspepsia, musculoskelet al pain, jaw osteonecrosis (w/ dental procedures, chemo).
NOTES: Take 1st thing in a.m. w/ H_2O (8 oz) >30 min before 1st food/beverage of day; do not lie down for 30 min after. Use Ca^{2+} & vit D supl w/ regular tab; may ↑ atypical subtrochanteric femur fractures.

ALFUZOSIN (UROXATRAL, GENERIC)

USES: *Symptomatic BPH*.
ACTIONS: α-Blocker.
DOSE: 10 mg PO daily immediately after the same meal; do not crush/chew.
W/P: [B, ?/−] w/ any Hx ↓ BP; use w/ PDE5 inhibitors may ↓ BP; may ↑ QTc interval; d/c with angina; intraoperative floppy iris syndrome during cataract surgery; w/ CrCl <30 mL/min.
CI: w/ CYP3A4 inhibitor (eg, ketoconazole, itraconazole, ritonavir); mod–severe hepatic impairment; protease inhibitors for HIV.
DISP: Tabs 10 mg ER.
SE: Postural ↓ BP, dizziness, headache, fatigue, rare priapism.
NOTES: Do not cut or crush.

ALLOPURINOL (ALOPRIM, ZYLOPRIM, GENERIC)

USES: *Gout, hyperuricemia of malignancy, uric acid urolithiasis, recurrent calcium oxalate calculi (w/ urinary uric acid >800 mg/d in males and 750 mg/d in females.*
ACTIONS: Xanthine oxidase inhibitor; ↓ uric acid production.
DOSE:

Adults: *PO:* Initial 100 mg/d; usual 300 mg/d; max. 800 mg/d; ÷ dose if >300 mg/d. *IV:* 200–400 mg/m²/d (max. 600 mg/24 h); (after meal w/ plenty of fluid).
Peds: Only for hyperuricemia of malignancy if <10 yr: 10 mg/kg/d PO (max. 800 mg) or 50–100 mg/m² q8h (max. 300 mg/m²/d); 200–400 mg/m²/d IV (max. 600 mg) ↓ in renal impairment.
W/P: [C, M] Life-threatening syndrome (diffuse desquamative skin rash, fever, hepatic dysfunction, eosinophilia, worsening renal function); 80% have pre-existing renal insufficiency.
DISP: Tabs 100, 300 mg; Inj 500 mg/30 mL (Aloprim).
SE: Rash, N/V, renal impairment, angioedema.
NOTES: Aggravates acute gout; begin after acute attack resolves; IV dose of 6 mg/mL final conc as single daily Inf or ÷ 6-, 8-, or 12-hr intervals

ALPROSTADIL, INTRACAVERNOSAL (CAVERJECT, CAVERJECT IMPULSE, EDEX)

USES: *Erectile dysfunction.*
ACTIONS: A form of prostaglandin E_1; relaxes smooth muscles, dilates cavernosal arteries, ↑ lacunar spaces w/ blood entrapment.
DOSE: 2.5–60 µg intracavernosal; titrate in office.
W/P: [X, −].
CI: ↑ risk of priapism (eg, sickle cell, hematologic malignancies); penile deformities/implants; men in whom sexual activity inadvisable.
DISP: *Caverject:* 5-, 10-, 20-, 40-µg powder for Inj vials ± diluent syringes 10-, 20-, 40-µg amp. *Caverject impulse:* Self-contained syringe (29G) 10 & 20 µg (volume 0.5 mL), *Edex:* 10-, 20-, 40-µg cartridges.
SE: Local pain w/ Inj, priapism risk.
NOTES: Counsel about priapism, penile fibrosis, & hematoma risks.

ALPROSTADIL, URETHRAL SUPPOSITORY (MUSE)

USES: *Erectile dysfunction.*
ACTIONS: A form of prostaglandin E_1; urethral absorption; vasodilator, relaxes smooth muscle of corpus cavernosa.
DOSE: 125–250 µg PRN to achieve erection (max. 2 systems/24 h) duration 30–60 min.
W/P: [X, −].
CI: ↑ Priapism risk (especially sickle cell, myeloma, leukemia), penile deformities/urethral stricture/implants; men in whom sex inadvisable; component hypersensitivity.
DISP: 125, 250, 500, 1,000 µg w/ transurethral applicator system (microsuppositories 1.4 mm diameter by 3 mm or 6 mm length).
SE: ↓ BP, dizziness, syncope, penile/testicular pain, urethral burning/bleeding, priapism.
NOTES: Titrate dose in office; store in refrigerator; do not expose to temps >86 F; @ room temp max. storage 14 days.

ALVIMOPAN (ENTEREG)

WARNING: For short-term hospital use only (max. 15 doses).
USES: *Accelerate the time to upper and lower gastrointestinal recovery following partial large or small bowel resection surgery with primary anastomosis.*
ACTIONS: Opioid (μ) receptor antagonist; selectively binds GI receptors, antagonizes effects of opioids on GI motility/secretion.
DOSE: 12 mg 30 min–5 hr preop PO, then 12 mg BID up to 7 days; max. 15 doses.
W/P: [B,?/−] Not rec in complete bowel obstruction surgery, hepatic/renal impairment.
CI: Therapeutic opioids >7 consecutive days prior.
DISP: Caps 12 mg.
SE: ↓ K^+, dyspepsia, urinary retention, anemia, back pain.
NOTES: Hospitals must be registered to use.

AMIFOSTINE (GENERIC)

USES: *Xerostomia prophylaxis during RT (head, neck, etc.) where parotid is in radiation field; ↓ renal tox w/ repeated cisplatin (label specifies ovarian ca).*
ACTIONS: Prodrug, dephosphorylated to active thiol metabolite, free radical scavenger binds cisplatin metabolites.
DOSE: Chemo prevent: 910 mg/m^2/d 15-min IV Inf 30 min prechemo; *Xerostomia Px*: 200 mg/m^2 over 2 min 1×/d 15 min prerad.
W/P: [C,?/−].
DISP: 500-mg vials powder, reconstitute in NS.
SE: Transient ↓ BP (>60%), N/V, flushing w/ hot or cold chills, dizziness, ↓ Ca^{2+}, somnolence, sneezing, serious skin infection.
NOTES: Does not ↓ effectiveness of cyclophosphamide + cisplatin chemotherapy.

AMIKACIN (AMIKIN)

WARNING: May cause nephrotoxicity, neuromuscular blockade, & respiratory paralysis.
USES: *Serious gram(−) bacterial infections* & mycobacteria.
ACTIONS: Aminoglycoside; ↓ protein synth. *Spectrum:* Good gram(−) bacterial coverage: *Pseudomonas* & *Mycobacterium* sp.

DOSE:
Adults & Peds: *Conventional:* 5–7.5 mg/kg/dose q8h; once daily; 15–20 mg/kg q24h; ↑ interval w/ renal impairment. *Neonates < 1,200 g, 0–4 wk:* 7.5 mg/kg/dose q18–24h. *Age <7 d, 1,200–2,000 g:* 7.5 mg/kg/dose q12h *>2,000 g:* 7.5–10 mg/kg/dose q12h. *Age >7 d, 1,200–2,000 g:* 7.5–10 mg/kg/dose q8–12h *>2,000 g:* 7.5–10 mg/kg/dose q8h.
W/P: [O, +/−] Avoid w/ diuretics.
DISP: Inj 50 & 250 mg/mL.
SE: Renal impairment, oto toxicity.
NOTES: May be effective in gram (−) resistance to gentamicin & tobramycin; follow Cr; Levels: *Peak:* 30 min after Inf. *Trough* <0.5 hr before next dose. *Therapeutic: Peak* 20–30 μg/mL. *Trough:* <8 μg/mL. *Toxic peak* >35 μg/mL; *half-life:* 2 hr.

AMILORIDE (MIDAMOR, GENERIC)

WARNING: ↑ K^+ esp renal disease DM, elderly
USES: *HTN, CHF, & thiazide or loop diuretic induced ↓ K^+*
ACTIONS: K^+-sparing diuretic; interferes w/ K^+/Na^+ exchange in distal tubule & collecting duct

DOSE:
Adults: 5–10 mg PO daily (max 20 mg/d)
Peds: 0.4–0.625 mg/kg/d; ↓ w/ renal impairment
W/P: [B, ?] avoid CrCl <10 mL/min
CI: ↑ K^+, acute or chronic renal disease, diabetic neuropathy, w/ other K^+-sparing diuretics
DISP: Tabs 5 mg
SE: ↑ K^+; headache, dizziness, dehydration, impotence
NOTES: Check K^+

AMINOCAPROIC ACID (AMICAR)

USES: *Excessive bleeding from systemic hyperfibrinolysis & urinary fibrinolysis.*
ACTIONS: ↓ Fibrinolysis; inhibits TPA, inhibits conversion of plasminogen to plasmin.

DOSE:

Adults: 4–5 g IV or PO (1st hr) then 1 g/h IV or 1.25 g/h PO × 8 hr or until bleeding controlled; 30 g/d max.
Peds: 100 mg/kg IV (1st hr) then 1 g/m^2/h; max. 18 g/m^2/d; ↓ w/ renal insufficiency.
W/P: [C, ?] Not for upper urinary tract bleeding (firm clot obstruction risk).
CI: DIC.
DISP: Tabs 500 mg, syrup 1.25 g/5 mL; Inj 250 mg/mL.
SE: ↓ BP, ↓ HR, dizziness, headache, fatigue, rash, GI disturbance, skelet al muscle weakness, ↓ plt function.
NOTES: Urinary fibrinolysis (a normal physiologic phenomenon), may contribute to excessive urinary tract fibrinolytic bleeding associated with surgical hematuria (eg, following prostatectomy and nephrectomy) or nonsurgical hematuria (polycystic or neoplastic diseases, radiation cystitis). Administer × 8 hr or until bleeding controlled; has also been administered by bladder irrigation; obvious clots should be cleared before stating and saline CBI can help effectiveness.

AMINOGLUTETHIMIDE (CYTADREN)

USES: *Cushing syndrome,* adrenocortical carcinoma, breast cancer & PCa.
ACTIONS: ↓ Adrenal steroidogenesis & conversion of androgens to estrogens; 1st gen aromatase inhibitor.
DOSE: Initial 250 mg PO 4 × d, titrate q1–2wk max. 2 g/d; w/ hydrocortisone 20–40 mg/d; ↓ w/ renal insufficiency.
W/P: [D, ?].
DISP: Tabs 250 mg.

SE: Adrenal insufficiency, hypothyroidism, masculinization, ↓ BP, N/V, rare hepatotox, rash, myalgia, fever, drowsiness, lethargy, anorexia.
NOTES: No longer available in the US.

AMITRIPTYLINE (ELAVIL)

WARNING: Antidepressants may ↑ suicide risk; consider risks/benefits of use. Monitor pts closely.
USES: *Depression (not bipolar depression)* peripheral neuropathy, chronic pain, tension HAs, migraine headache prophylaxis PTSD* enuresis, interstitial cystitis.
ACTIONS: Tricyclic antidepressants; ↓ reuptake of serotonin & norepinephrine by presynaptic neurons.

DOSE:

Adults: *Initial:* 25–150 mg PO hs; may ↑ to 300 mg hs.
Peds: Do not use if <12 yr unless for chronic pain, *Initial:* 0.1 mg/kg PO hs, ↑ over 2–3 wk to 0.5–2 mg/kg PO hs; taper to D/C.
W/P: CV disease, seizures [D, +/−] narrow-angle glaucoma, hepatic impairment.
CI: w/ MAOIs or w/in 14 days of use, during AMI recovery.
DISP: Tabs 10, 25, 50, 75, 100, 150 mg; Inj 10 mg/mL.
SE: Strong anticholinergic SEs; OD may be fatal; urine retention, sedation, ECG changes BM suppression, orthostatic ↓ BP, photosensitivity.
NOTES: Levels: *Therapeutic:* 100–250 ng/mL, *Toxic:* >500 ng/mL; levels may not correlate w/ effect.

AMLODIPINE (NORVASC)

USES: *HTN, stable or unstable angina,*
ACTIONS: Calcium channel blocker; relaxes coronary vascular smooth muscle.
DOSE: 2.5–10 mg/d PO; ↓ w/ hepatic impairment.
W/P: [C, ?].
DISP: Tabs 2.5, 5, 10 mg.
SE: Edema, headache, palpitations, flushing, dizziness.
NOTES: Take w/o regard to meals.

AMLODIPINE/OLMESARTAN (AZOR)

WARNING: Use of renin–angiotensin agents in PREGNANCY can cause injury and death to fetus, D/C immediately when PREGNANCY detected.
USES: *Hypertension.*
ACTIONS: Calcium channel blocker w/ angiotensin II receptor blocker.

DOSE:

Adults: Initial 5 mg/20 mg, max. 10 mg/40 mg q day.
W/P: [D, −] w/ K^+ supl or K^+-sparing diuretics, renal impairment, RAS, severe CAD, AS.
CI: PREGNANCY.

DISP: Tabs amlodipine/olmesartan 5 mg/20 mg, 10/20, 5/40, 10/40.
SE: Edema, vertigo, dizziness, ↓ BP.

AMLODIPINE/VALSARTAN (HA EXFORGE)

WARNING: Use of renin–angiotensin agents in PREGNANCY can cause fet al injury and death, D/C immediately when PREGNANCY detected.
USES: *HTN.*
ACTIONS: Calcium channel blocker w/ angiotensin II receptor blocker.

DOSE:

Adults: Initial 5 mg/160 mg, may ↑ after 1–2 wk, max. 10 mg/320 mg q day, start elderly at 1/2 initial dose.
W/P: [D /−] w/ K^+ supl or K^+-sparing diuretics, renal impairment, RAS, severe CAD.
CI: PREGNANCY.
DISP: Tabs amlodipine/valsartan 5/160, 10/160, 5/320, 10 mg/320 mg.
SE: Edema, vertigo, nasopharyngitis, URI, dizziness, ↓ BP.

AMLODIPINE/VALSARTAN/HCTZ (EXFORGE HCT)

WARNING: Use of renin–angiotensin agents in PREGNANCY can cause fet al injury and death, D/C immediately when PREGNANCY detected.
USES: *Hypertension (not initial Treat).*
ACTIONS: Calcium channel blocker, angiotensin II receptor blocker, & thiazide diuretic.
DOSE: 5–10/160–320/12.5–25 mg 1 tab 1 × day may ↑ dose after 2 wk; max. dose 10/320/25 mg.
W/P: [D, −] w/ severe hepatic or renal impairment.
CI: Anuria, sulfonamide allergy.
DISP: Tabs amlodipine/valsartan/ HCTZ: 5/160/12.5, 10/160/12.5, 5/160/25, 10/160/25, 10/320/25 mg.
SE: Edema, dizziness, headache, fatigue, ↑/↓ K^+ ↑ BUN, ↑ SCr, nasopharyngitis, dyspepsia, N, back pain, muscle spasm, ↓ BP.

AMMONIUM ALUMINUM SULFATE [ALUM] [OTC]

USES: *Hemorrhagic cystitis when saline bladder irrigation fails.*
ACTIONS: Astringent, forms precipitates over bleeding surface.

DOSE:
Adult/Peds: 1–4% soln w/ constant NS bladder irrigation 200–250 mL/h.
W/P: [+/−].
DISP: Powder for recons; (typical 50 g in 5 L sterile water).
SE: Encephalopathy possible; check aluminum levels, especially w/ renal insufficiency; spasms; can precipitate & occlude catheters.
NOTES: Safe w/o anesthesia & w/ vesicoureteral reflux; effect often takes several days.

AMOXICILLIN (AMOXIL, MOXATAG, GENERIC)

USES: *Ear, nose, & throat, lower resp, skin, urinary tract infections from susceptible gram(+) bacteria* endocarditis prophylaxis, *H. pylori* eradication w/ other agents (gastric ulcers).
ACTIONS: β-Lactam antibiotic; ↓ cell wall synth. *Spectrum:* gram(+) (*Streptococcus* sp, *Enterococcus* sp); some gram(−) (*H. influenzae, E. coli, N. gonorrhoeae, H. pylori,* & *P. mirabilis*).

DOSE:

Adults: 250–500 mg PO TID or 500–875 mg BID ER 775 mg 1 × d.
Peds: 25–100 mg/kg/24 h PO ÷ q8h, ↓ in renal impairment.
W/P: [B, +].
DISP: Caps 250, 500 mg; chew tabs 125, 200, 250, 400 mg; susp 50, 125, 200, 250 mg/mL & 400 mg/5 mL; tabs 500, 875 mg; tab ER 775 mg.
SE: Diarrhea; rash.
NOTES: Cross-hypersens w/ PCN; many *E. coli* strains resistant; chew tabs contain phenylalanine.

AMOXICILLIN/CLAVULANIC ACID (AUGMENTIN, AUGMENTIN ES-600, AUGMENTIN XR)

USES: *Ear, lower resp, sinus, urinary tract, skin infections caused by β-lactamase–producing *H. influenzae, S. aureus,* & *E. coli.**
ACTIONS: β-Lactam antibiotic w/ β-lactamase inhibitor. *Spectrum:* gram(+) same as amoxicillin alone, MSSA; gram(−) as w/ amoxicillin alone, β-lactamase–producing *H. influenzae, Klebsiella* sp, *M. catarrhalis.*

DOSE:

Adults: 250–500 mg PO q8h or 875 mg q12h; XR 2,000 mg PO q12h.
Peds: 20–40 mg/kg/d as amoxicillin PO ÷ q8h or 45–90 mg/kg/d ÷ q12h; ↓ in renal impairment; take w/ food.
W/P: [B, enters breast milk].
DISP: Supplied (as amoxicillin/clavulanic): Tabs 250/125, 500/125, 875/125 mg; chew tabs 125/31.25, 200/28.5, 250/62.5, 400/57 mg; susp 125/31.25, 250/62.5, 200/28.5, 400/57 mg/5 mL; susp ES 600/42.9 mg/5 mL; XR tab 1,000/62.5 mg.
SE: Abdominal discomfort, N/V/diarrhea, allergic reaction, vaginitis.
NOTES: Do not substitute two 250-mg tabs for one 500-mg tab (possible OD of clavulanic acid); max. clavulanic acid 125 mg/dose.

AMPHOTERICIN B (FUNGIZONE)

USES: *Severe, systemic fungal infections; oral & cutaneous candidiasis.*
ACTIONS: Binds ergosterol in the fungal membrane to alter permeability.

DOSE:
Adults & Peds: 0.25–1.5 mg/kg/24 h IV over 2–6 h (25–50 mg/d or q other day). Total

varies w/ indication ↑ PR, N/V.
W/P: [B, ?].
DISP: Powder (Inj) 50 mg/vial.
SE: ↓ K^+/Mg^{2+} from renal wasting; anaphylaxis, headache, fever, chills, nephrotoxic, ↓ BP, anemia, rigors.
NOTES: Check Cr/LFTs/K^+/Mg^{2+}; ↓ in renal impairment; pretreatment w/ acetaminophen & diphenhydramine ± hydrocortisone can ↓ SE.

AMPHOTERICIN B CHOLESTERYL (AMPHOTEC)

USES: *Aspergillosis if intolerant/refractory to conventional amphotericin B*, systemic candidiasis.
ACTIONS: Binds ergosterol in fungal membrane, alters permeability.

DOSE:
Adults & Peds: 3–4 mg/kg/d; 1 mg/kg/h Inf, 7.5 mg/kg/d max.; ↓ w/ renal insufficiency.
W/P: [B, ?].
DISP: Powder for Inj 50, 100 mg/vial.
SE: Anaphylaxis; fever, chills, headache, ↓ PLT, N/V, ↑ HR, ↓ K^+, ↓ Mg^{2+}, nephrotoxic, ↓ BP, infusion reactions, anemia.
NOTES: Do not use in-line filter; check LFTs/lytes.

AMPHOTERICIN B LIPID COMPLEX (ABELCET)

USES: *Refractory invasive fungal infection in pts intolerant to conventional amphotericin B.*
ACTIONS: Binds ergosterol in fungal membrane, alters permeability.

DOSE:
Adults & Peds: 2.5–5 mg/kg/d IV × 1 daily.
W/P: [B, ?].
DISP: Inj 5 mg/mL.
SE: Anaphylaxis; fever, chills, headache, ↓ K^+, ↑ SCr ↓ Mg^{2+}, nephrotoxic, ↓ BP, anemia.
NOTES: Filter w/ 5-μm needle; do not mix in electrolyte-containing solns; if Inf >2 hr, manually mix bag.

AMPHOTERICIN B LIPOSOMAL (AMBISOME)

USES: *Refractory invasive fungal infection w/ intolerance to conventional amphotericin B; cryptococcal meningitis in HIV; empiric for febrile neutropenia; visceral leishmaniasis.*
ACTIONS: Binds ergosterol in fungal membrane, alters membrane permeability.

DOSE:
Adults & Peds: 3–6 mg/kg/d, Inf 60–120 min; varies by indication; ↓ in renal insufficiency.
W/P: [B, ?].
DISP: Powder Inj 50 mg.
SE: Anaphylaxis, fever, chills, headache, ↓ K^+, ↓ Mg^{2+} peripheral edema, insomnia, rash, ↑ LFTs, nephrotoxic, ↓ BP, anemia.

NOTES: Do not use <. 1-μm filter.

AMPICILLIN (GENERIC)

USES: *Resp, GU, or GI tract infections, meningitis d/t gram(−) & (+) bacteria; SBE prophylaxis.*
ACTIONS: β-Lactam antibiotic; ↓ cell wall synth. *Spectrum:* gram(+) (*Streptococcus* sp, *Staphylococcus* sp, *Listeria*); gram(−) (*Klebsiella* sp, *E. coli, H. influenzae, P. mirabilis, Shigella* sp, *Salmonella* sp).

DOSE:

Adults: 1,000 mg–2 g IM or IV q4–6h or 250–500 mg PO q6h; varies by indication.
Peds Neonates: ***<7 days:*** 50–100 mg/kg/24 h IV ÷ q8h.***Term infants:*** –150 mg/kg/24 h ÷ q6–8h IV or PO. ***Children >1 mo:*** 200 mg/kg/24 h ÷ q6h IM or IV; 50–100 mg/kg/24 h ÷ q6h PO up to 250 mg/dose; ↓ w/ renal impairment; take on empty stomach.
W/P: [B, M] Cross-hypersensitivity w/ PCN.
DISP: Caps 250, 500 mg; susp, 125 mg/5 mL, 250 mg/5 mL; powder (Inj) 125, 250, 500 mg, 1, 2, 10 g/vial.
SE: Diarrhea, rash, allergic reaction.
NOTES: Many *E. coli* resistant.

AMPICILLIN-SULBACTAM (UNASYN, GENERIC)

USES: *Gynecologic, intra-abdominal, skin infections d/t β-lactamase–producing *S. aureus, Enterococcus, H. influenzae, P. mirabilis*, & *Bacteroides* sp.*
ACTIONS: β-Lactam antibiotic & β-lactamase inhibitor. *Spectrum:* gram(+) & (−) as for amp alone; also *Enterobacter, Acinetobacter, Bacteroides.*

DOSE:

Adults: 1.5–3 g IM or IV q6h.
Peds: 100–400 mg ampicillin/kg/d (150–300 mg Unasyn) q6h; ↓ w/ renal insufficiency.
W/P: [B, M].
DISP: Powder for Inj 1.5, 3 g/vial, 15 g bulk package.
SE: Allergic reactions, rash, diarrhea, Inj site pain.
NOTES: A 2:1 ratio ampicillin:sulbactam.

ANIDULAFUNGIN (ERAXIS)

USES: *Candidemia, esophageal candidiasis, other *Candida* infections (peritonitis, intra-abdominal abscess).*
ACTIONS: Echinocandin; ↓ cell wall synth. *Spectrum: C. albicans, C. glabrata, C. parapsilosis, C. tropicalis.*
DOSE: *Candidemia, others*: 200 mg IV × 1, then 100 mg IV daily [Tx ≥ 4 days after last (+) culture]; 1.1 mg/min max. Inf rate.
W/P: [B, ?/−].
CI: Echinocandin hypersens.

DISP: Powder 50, 100 mg/vial.
SE: Histamine-mediated Inf reactions (urticaria, flushing, ↓ BP, dyspnea, etc.), fever, N/V/diarrhea, ↓ K^+, headache, ↑ LFTs, hep, worsening hepatic failure.
NOTES: ↓ Inf rate to <1.1 mg/min w/ Inf reactions.

APIXABAN (ELIQUIS)

WARNING: ↑ Risk of spinal/epidural hematoma w/ paralysis & ↑ thrombotic events w/ D/C in afib pts; monitor closely.
USES: *Prevent CVA/TE in nonvalvular afib.*
ACTIONS: Factor Xa inhibitor.
DOSE: 5 mg BID; 2.5 mg w/2 of the following: >80 yr, Wt <60 kg, SCr ≥1.5; 2.5 mg w/ strong dual inhibitor of CYP3A4 and P-glycoprotein; if on 2.5 mg do **NOT** use w/ strong dual inhibitor of CYP3A4 and P-glycoprotein.
W/P: [B, −] Do not use w/ prosthetic valves.
CI: Pathologic bleeding & apixaban hypersens.
DISP: Tabs 2.5, 5 mg.
SE: Bleeding.
NOTES: If missed dose, do **NOT** double next dose; no antidote to reverse; anticoagulant effect can last 24 hr after dose.

APREPITANT (EMEND, ORAL)

USES: *Prevents N/V associated w/ emetogenic cancer chemotherapy (eg, cisplatin) (use in combo w/ other antiemetics)*, postop N/V.*
ACTIONS: Substance P/neurokinin 1 (NK_1) receptor antagonist.
DOSE: 125 mg PO day 1, 1 hr before chemotherapy, then 80 mg PO q a.m. days 2 & 3; postop N/V: 40 mg w/in 3 hr of induction.
W/P: [B, ?/−]; substrate & mod CYP3A4 inhibitor; CYP2C9 inducer; ↓ effect OCP and warfarin.
CI: Use w/ pimozide or cisapride.
DISP: Caps 40, 80, 125 mg.
SE: Fatigue, asthenia, hiccups.
NOTES: See also Fosaprepitant (Emend, Injection).

ASPIRIN (BAYER, ECOTRIN, ST. JOSEPH'S) [OTC]

USES: *CABG, PTCA, carotid endarterectomy, ischemic stroke, TIA, ACS/MI, arthritis, pain, headache, fever, inflammation*, Kawasaki disease.
ACTIONS: Prostaglandin inhibitor by COX-2 inhibitor.

DOSE:

Adults: *Pain, fever:* 325–650 mg q4–6h PO or PR (4 g/d max.). *Plt inhibitor:* 81–325 mg PO daily.
Peds: *Antipyretic:* 10–15 mg/kg/dose PO or PR q4–6h; for all uses 4 g/d max.; avoid w/ CrCl <10 mL/min, severe liver disease.

W/P: [C, M] linked to Reye syndrome; avoid w/ viral illness in peds <16 yr.
CI: Allergy to ASA, chickenpox/ flu Sxs, syndrome of nasal polyps, angioedema, & bronchospasm to NSAIDs, bleeding disorder.
DISP: Tabs 325, 500 mg; chew tabs 81 mg; EC tabs 81, 162, 325, 500 mg, effervescent tabs 500 mg; supp 300, 600 mg; caplets 81, 375, 500 mg.
SE: GI upset, erosion, & bleeding.
NOTES: D/C 1 wk preop; avoid/limit EtOH; Salicylate levels: *Therapeutic:* 100–250 μg/mL; *Toxic:* >300 μg/mL.

ATENOLOL (TENORMIN, GENERIC)

WARNING: Avoid abrupt withdrawal (esp. CAD pts), gradual taper to ↓, acute ↑ HR, HTN +/− ischemia.
USES: *HTN, angina, post-MI.*
ACTIONS: Selective β-adrenergic receptor blocker.
DOSE: *HTN & angina:* 25–100 mg/d PO; ↓ in renal impairment.
W/P: [D, M] DM, bronchospasm; abrupt D/C can exacerbate angina & ↑ MI risk.
CI: ↓ HR, cardiogenic shock, cardiac failure, 2nd-/3rd-degree AV block, sinus node dysfunction, pulm edema.
DISP: Tabs 25, 50, 100 mg.
SE: ↓ HR, ↓ BP, 2nd-/3rd-degree AV block, dizziness, fatigue.

ATENOLOL & CHLORTHALIDONE (TENORETIC)

USES: *HTN.*
ACTIONS: β-Adrenergic blockade w/ diuretic.
DOSE: 50–100 mg/d PO based on atenolol; ↓ dose w/ CrCl <35 mL/min.
W/P: [D, ?/−] DM, bronchospasm.
CI: See atenolol; anuria, sulfonamide, cross-sensitivity.
DISP: Atenolol 50 mg/chlorthalidone 25 mg, atenolol 100 mg/chlorthalidone 25 mg.
SE: ↓ HR, ↓ BP, 2nd-/3rd-degree AV block, dizziness, fatigue, ↓ K^+, photosensitivity.

ATROPINE, BENZOIC ACID, HYOSCYAMINE SULFATE, METHENAMINE, METHYLENE BLUE, PHENYL SALICYLATE (URISED)

USES: *Lower urinary tract discomfort.*
ACTIONS: Methenamine in acidic urine releases formaldehyde (antiseptic), methylene blue/benzoic acid (mild antiseptic), phenyl salicylate (mild analgesic), hyoscyamine and atropine (parasympatholytic; ↓ muscle spasm).

DOSE:

Adults: 2 tablets PO QID.
Peds: ***>6 yr:*** Individualize.
W/P: [C, ?/−]; avoid w/ sulfonamides.
CI: Narrow-angle glaucoma, pyloric/duodenal obstruction, bladder outlet obstruction, coronary artery spasm.

DISP: Tablet; atropine 0.03 mg/benzoic acid 45 mg/hyoscyamine 0.03 mg/methenamine 40.8 mg/methylene blue 5.4 mg/phenyl salicylate 18.1 mg.
SE: Rash, dry mouth, flushing, ↑ pulse, dizziness, blurred vision, urine/feces discoloration, voiding difficulty.
NOTES: Take w/ plenty of fluid; can cause crystalluria; see also hyoscyamine and methenamine listings.

AVANAFIL (STENDRA)

USES: *Erectile dysfunction.*
ACTIONS: ↓ Phosphodiesterase type 5 (PDE5) (responsible for cGMP breakdown); ↑ cGMP activity to relax smooth muscles to ↑ flow to corpus cavernosum; onset 30–45 min (delayed 1–1.25 hr with high fat meal).
DOSE: (Men only) 100 mg PO as early as 15 min before sex activity, no more than 1 ×/d; ↑/↓ dose 50–200 mg based on effect; do not use w/ strong CYP3A4 inhibitor; use 50 mg w/ mod CYP3A4 inhibitor; w/ or w/o food.
W/P: [C, ?] Priapism risk; hypotension w/ BP meds or substantial alcohol; seek immediate attention w/ hearing loss or acute vision loss (may be NAION; w/ CYP3A4 inhibitor (eg, ketoconazole, ritonavir, erythromycin) ↑ effects; do not use w/ severe renal/ hepatic impairment.
CI: w/ Nitrates or if sex not advised.
DISP: Tabs 50, 100, 200 mg.
SE: Headache, flushing, nasal congestion, nasopharyngitis back pain.
NOTES: More rapid onset than sildenafil (15–30 min).

AXITINIB (INLYTA)

USES: *Advanced RCC.*
ACTIONS: Tyrosine kinase inhibitor.

DOSE:

Adults: 5 mg PO q12h; if tolerated >2 wk, ↑ to 7 mg q12h, then 10 mg q12h; w/ or w/o food; swallow whole; ↓ dose by ½ w/ moderate hepatic impairment; avoid w/ or ↓ dose by ½ if used w/ strong CYP3A4/5 inhibitor.
W/P: [D, ?] w/ brain mets, recent GI bleed.
DISP: Tabs 1, 5 mg.
SE: N/V/diarrhea/C, HTN, fatigue, asthenia, ↓ appetite, ↓ Wt, ↑ LFTs, hand–foot syndrome, venous/arterial thrombosis; hemorrhage, ↓ thyroid, GI perf/ fistula, proteinuria, hypertensive crisis, impaired wound healing, reversible posterior leukoencephalopathy syndrome.
NOTES: Hold 24 hr prior to surgery.

AZATHIOPRINE (AZASAN, IMURAN)

WARNING: May ↑ neoplasia w/ chronic use; mutagenic and hematologic tox possible.
USES: *Adjunct to prevent renal transplant rejection, rheumatoid arthritis*, SLE, Crohn's disease, ulcerative colitis.

ACTIONS: Immunosuppressive; antagonizes purine metabolism.

DOSE:

Adults: *Crohn and ulcerative colitis:* Start 50 mg/d, ↑ 25 mg/d q1–2wk, target dose 2–3 mg/kg/d.
Adults & Peds: *Renal transplant:* 3–5 mg/kg/d IV/PO single daily dose, then 1–3 mg/kg/d maint; *rheumatoid arthritis:* 1 mg/kg/d once daily or ÷ BID × 6–8 wk, ↑ 0.5 mg/kg/d q4wk to 2.5 mg/kg/d; ↓ w/ renal insufficiency.
W/P: [D, ?/−].
CI: PREGNANCY.
DISP: Tabs 50, 75, 100 mg; powder for Inj 100 mg.
SE: GI intolerance, fever, chills, leukopenia, ↑ LFTs, bilirubin, ↑ risk infections, thrombocytopenia.
NOTES: Handle Inj w/ cytotoxic precautions; interaction w/ allopurinol; do not administer live vaccines on drug; check CBC and LFTs; dose per local transplant protocol, usually start 1–3 days pretransplant.

AZITHROMYCIN (ZITHROMAX)

USES: *Community-acquired pneumonia, pharyngitis, otitis media, skin infections, nongonococcal (chlamydial) urethritis, chancroid & PID; Treat & prevention of MAC in HIV.*
ACTIONS: Macrolide antibiotic; bacteriostatic; ↓ protein synth. *Spectrum: Chlamydia, H. ducreyi, H. influenzae, Legionella, M. catarrhalis, M. pneumoniae, M. hominis, N. gonorrhoeae, S. aureus, S. agalactiae, S. pneumoniae, S. pyogenes.*

DOSE:

Adults: *Resp tract infections:* PO: Caps 500 mg day 1, then 250 mg/d PO × 4 days. *Nongonococcal urethritis:* 1 g PO × 1 *Gonorrhea, uncomplicated:* 2 g PO × 1; *Prevent MAC:* 1,200 mg PO once/wk.
Peds: *Otitis media:* 10 mg/kg PO day 1, then 5 mg/kg/d days 2–5. *Pharyngitis* (≥2 yr): 12 mg/kg/d PO × 5 days; take susp on empty stomach; tabs OK w/ or w/o food; ↓ w/ CrCl < 0 mL/mg.
W/P: [B, +] May ↑ QTc w/ arrhythmias.
DISP: Tabs 250, 500, 600 mg; Z-Pack (5-day, 250 mg); Tri-Pack (500-mg tabs × 3); susp 2 g; single-dose packet (Zmax) ER susp (2 g); susp 100, 200 mg/5 mL; Inj powder 500 mg; 2.5 mL.
SE: GI upset, met allic taste.

AZTREONAM (AZACTAM)

USES: *Aerobic gram(−) UTIs, lower resp, intra-abdominal, skin, gynecologic infections & septicemia.*
ACTIONS: *Monobactam:* ↓ Cell wall synth. *Spectrum:* gram(−) (*Pseudomonas, E. coli, Klebsiella, H. influenzae, Serratia, Proteus, Enterobacter, Citrobacter*).

DOSE:

Adults: 1–2 g IV/IM q6–12h. *UTI:* 500 mg–1 g IV q8–12h. *Meningitis:* 2 g IV q6–8h.
Peds: 90–120 mg/kg/d ÷ q6–8h ↓ in renal impairment.
W/P: [B, +].
DISP: Inj (soln), 1 g, 2 g/50 mL Inj powder for recons 1 g, 2 g.
SE: N/V/diarrhea, rash, pain at Inj site.
NOTES: No gram(+) or anaerobic activity; OK in PCN-allergic pts.

BACITRACIN, TOPICAL (BACIGUENT); BACITRACIN & POLYMYXIN B, TOPICAL (POLYSPORIN); BACITRACIN, NEOMYCIN, & POLYMYXIN B, TOPICAL (NEOSPORIN); BACITRACIN, NEOMYCIN, POLYMYXIN B, & HYDROCORTISONE, TOPICAL (CORTISPORIN)

USES: Prevent/Treat of *minor skin infections.*
ACTIONS: Topical antibiotic w/ added components (anti-inflammatory & analgesic).
DOSE: Apply sparingly BID–QID.
W/P: [C, ?] Not for deep wounds, puncture, or animal bites.
DISP: Bacitracin 500 U/g oint; bacitracin 500 U/polymyxin B sulfate 10,000 U/g oint & powder; bacitracin 400 U/neomycin 3.5 mg/ polymyxin B 5,000 U/g oint; bacitracin 400 U/neomycin 3.5 mg/polymyxin B 5,000 U/hydrocortisone 10 mg/g oint; Bacitracin 500 U/neomycin 3.5 mg/polymyxin B 5,000 U/lidocaine 40 mg/g oint.
NOTES: Ophthal, systemic, & irrigation forms available, not generally used d/t potential tox.

BASILIXIMAB (SIMULECT)

WARNING: Use only under the supervision of a physician experienced in immunosuppression Treat in an appropriate facility.
USES: *Prevent acute transplant rejection.*
ACTIONS: IL-2 receptor antagonists.

DOSE:
Adults & Peds: ***> 35 kg:*** 20 mg IV 2 hr before transplant, then 20 mg IV 4 days posttransplant.
Peds: ***< 35 kg:*** 10 mg 2 hr prior to transplant; same dose IV 4 days posttransplant.
W/P: [B, ?/−].
CI: hypersensitivity to murine proteins.
DISP: Inj powder 10, 20 mg.
SE: Edema, ↓ BP, HTN, headache, dizziness, fever, pain, infection, GI effects, electrolyte disturbances.
NOTES: A murine/human MoAb.

BCG [BACILLUS CALMETTE-GUéRIN] (THERACYS, TICE BCG)

WARNING: Contains live, attenuated mycobacteria; transmission risk; handle as biohazard; nosocomial & disseminated infections reported in immunosuppressed.
USES: *Intravesical treatment and prophylaxis of bladder CIS and for the prophylaxis of primary or recurrent stage Ta and/or T1 papillary tumors following TUR; not recommended

for Ta low-grade papillary tumors, unless they are judged to be at high risk of recurrence.*
ACTIONS: Attenuated live BCG culture, immunomodulator.
DOSE: Bladder cancer (FDA label), 1 vial prepared & instilled in bladder for 2 hr. Repeat once/wk × 6 wk; then 1 maintenance Tx at 3, 6, 12, 18, & 24 mo after.
W/P: [C, ?] Asthma w/ TB immunization.
CI: Immunosuppression, pregnancy, steroid use, febrile illness, symptomatic UTI, gross hematuria, w/ traumatic catheterization.
DISP: Powder 81 mg (*TheraCys*), 50 mg (*Tice BCG*) (both reconstituted to 50 mL volume).
SE: Intravesical: Hematuria, urinary frequency, dysuria, bacterial UTI, rare BCG sepsis malaise, fever, chills, pain, N/V, anorexia, anemia.
NOTES: Do not administer less than 2 wk after resection; do not administer intravesical forms SQ or IM; optimal number of induction instillations and optimal frequency and duration of maintenance instillations remain unknown; SWOG regimen BCG weekly ×6 then 3 weekly doses at 3/6/12/18/24/30 mo; with intravesical use, dispose/void in toilet w/ chlorine bleach; reduced dose administration (1/3, 1/10, 1/100th) used to manage side effects but not widely practiced.

BELATACEPT (NULOJIX)

WARNING: May ↑ risk of posttransplant lymphoproliferative disorder (PTLD) mostly CNS; ↑ risk of infection; for use by physicians experienced in immunosuppressive therapy; ↑ risk of malignancies; not for liver transplant.
USES: *Prevent rejection in EBV positive kidney transplant recipients.*
ACTIONS: T-cell costimulation blocker.
DOSE: Day 1 (transplant day, preop) & day 5 10 mg/kg; end of wk 2, wk 4, wk 8, wk 12 after transplant 10 mg/kg; Maint: End of wk 16 after transplant 4 wk 5 mg/kg.
W/P: [C, −] w/ CYP3A4 inhibitor/inducers, other anticoagulants or plt inhibitor.
CI: EBV seronegative or unknown EBV status.
DISP: 250 mg Inj.
SE: Anemia, N/V/diarrhea, UTI, edema, constipation, ↑ BP, pyrexia, graft dysfunction, cough, headache, ↑/↓ K^+, ↓ WBC.
NOTES: REMS; use in combo w/ basiliximab, mycophenolate mofetil (MMF), & steroids; PML w/ excess belatacept dosing.

BELLADONNA & OPIUM SUPPOSITORIES (GENERIC) [C-II]

USES: *Mod–severe pain associated w/ bladder spasms.*
ACTIONS: Antispasmodic, analgesic.

DOSE:
Adult: 1 supp PR 1–2/d (up to 4 doses/d).
Peds: ***10–15 kg:*** 1/4–1/2 suppository PRN.
W/P: [C, ?].
CI: Glaucoma, resp depression, severe renal or hepatic disease, convulsive disorder, acute alcoholism.
DISP: 30 mg opium/16.2 mg belladonna extract; 60 mg opium/16.2 mg belladonna extract.

SE: Anticholinergic (eg, sedation, urinary retention, constipation).

BENAZEPRIL (LOTENSIN)

WARNING: When used in pregnancy during the 2nd and 3rd trimesters, ACE inhibitors can cause injury and even death to the developing fetus.
USES: *HTN.*
ACTIONS: ACE inhibitor.
DOSE: 10–80 mg/d PO.
W/P: [D, −].
CI: Angioedema.
DISP: Tabs 5, 10, 20, 40 mg.
SE: Symptomatic ↓ BP w/ diuretics; dizziness, headache, ↑ K^+, nonproductive cough, ↑ SCr.

BENZOCAINE (AMERICAINE, HURRICANE, LANACANE, VARIOUS [OTC])

USES: *Topical anesthetic, lubricant on ET tubes, catheters, etc.; pain relief in external otitis, cerumen removal, skin conditions, sunburn, insect bites, mouth and gum irritation, hemorrhoids.*
ACTIONS: Topical local anesthetic.

DOSE:
Adults & Peds: ***>1 yr.*** *Anesthetic lubricant:* Apply evenly to tube/instrument; other uses per manufacturer instructions.
W/P: [C, −] Do not use on broken skin; see provider if condition does not respond; avoid in infants and those w/ pulmonary diseases.
DISP: Many site-specific OTC forms: creams, gels, liquids, sprays, 2–20%.
SE: Itching, irritation, burning, edema, erythema, pruritus, rash, stinging, tenderness, urticaria; methemoglobinemia (infants or in COPD).
NOTES: Use minimum amount to obtain effect; methemoglobinemia S/Sxs: headache, lightheadedness, SOB, anxiety, fatigue, pale, gray or blue colored skin, and tachycardia.

BETHANECHOL (URECHOLINE, GENERIC)

USES: *Acute postoperative and postpartum nonobstructive (functional) urinary retention and for neurogenic atony of the urinary bladder with retention.*
ACTIONS: Stimulates cholinergic smooth muscle in bladder & GI tract.

DOSE:

Adults: Initial 5–10 mg PO, then repeat qh until response or 50 mg, typical 10–50 mg TID–QID, 200 mg/d max. TID–QID; 2.5–5 mg SQ TID–QID & PRN.
Peds: (Not FDA approved) 0.3–0.6 mg/kg/24 h PO ÷ TID–QID; take on empty stomach.
W/P: [C, −].
CI: Bladder outlet obstruction, PUD, epilepsy, hyperthyroidism, ↓ HR, COPD, AV conduction defects, Parkinsonism, ↓ BP, vasomotor instability.
DISP: Tabs 5, 10, 25, 50 mg.

SE: Abdominal cramps, diarrhea, salivation, ↓ BP.
NOTES: For overdose: SQ atropine 0.6 mg (adult), children 0.01 mg/kg (max. 0.4 mg).

BEVACIZUMAB (AVASTIN)

WARNING: Associated w/ GI perforation, wound dehiscence, & fatal hemoptysis.
USES: *Met colorectal cancer w/5-FU, NSCLC w/ paclitaxel and carboplatin; glioblastoma; metastatic RCC w/ IFN-α.*
ACTIONS: Vascular endothelial GF inhibitor.

DOSE:

Adults: *RCC:* 10 mg/kg IV q2wk w/ IFN-α.
W/P: [C, −] Do not use w/in 28 days of surgery if time for separation of drug & anticipated surgical procedures is unknown; D/C w/ serious adverse effects.
CI: None.
DISP: 100 mg/4 mL, 400 mg/16 mL vials.
SE: Wound dehiscence, GI perforation, tracheoesophageal fistula, arterial thrombosis, hemoptysis, hemorrhage, HTN, proteinuria, CHF, Inf reactions, diarrhea, leukopenia.
NOTES: Monitor for ↑ BP & proteinuria.

BICALUTAMIDE (CASODEX, GENERIC)

USES: *Stage D_2 metastatic prostate cancer with GnRH agonists (eg, leuprolide, goserelin).*
ACTIONS: Nonsteroidal antiandrogen/androgen receptor inhibitor.
DOSE: 50 mg/d.
W/P: [X, ?].
CI: Women.
DISP: Caps 50 mg.
SE: Hot flashes, ↓ loss of libido, impotence, edema, pain, diarrhea/N/V, gynecomastia, ↑ LFTs.
NOTES: 150 mg daily is not FDA approved for use alone or with other treatments.

BISACODYL (DULCOLAX) [OTC]

USES: *Constipation; preop bowel prep.*
ACTIONS: Stimulates peristalsis.

DOSE:

Adults: 5–15 mg PO or 10 mg PR PRN.
Peds: ***<2 yr:*** 5 mg PR PRN. ***>2 yr:*** 5 mg PO or 10 mg PR PRN (do not chew tabs or give w/in 1 hr of antacids or milk).
W/P: [C, ?].
CI: Abdominal pain or obstruction; N/V.
DISP: EC tabs 5, 10 mg supp 10 mg, enema soln 10 mg/30 mL.
SE: Abdominal cramps, proctitis, & inflammation w/ supps.

BLEOMYCIN SULFATE (GENERIC)

WARNING: Idiopathic reaction (↓ BP, fever, chills, wheezing) in lymphoma pts; pulm fibrosis; should be administered by chemo- experienced physician.
USES: *Testis cancer; Hodgkin disease & NHLs; cutaneous lymphomas; & squamous cell cancer (head & neck, larynx, cervix, skin, penis); malignant pleural effusion sclerosing agent.*
ACTIONS: Induces DNA breakage (scission).
DOSE: (Per protocols) Typical dosing: squamous cell carcinoma, non-Hodgkin's lymphoma, testicular carcinoma: 0.25–0.50 U/kg (10–20 U/m^2) IM/IV/SC weekly or twice weekly; ↓ w/ renal impairment.
W/P: [D, ?].
CI: W/ hypersensitivity, idiosyncratic reaction.
DISP: Powder (Inj) 15, 30 U.
SE: Hyperpigmentation & allergy (rash to anaphylaxis); fever in 50%; lung tox (idiosyncratic & dose related); pneumonitis w/ fibrosis; Raynaud phenomenon, N/V.
NOTES: Test dose 1 U, especially in lymphoma pts; lung tox w/ total dose >400 U or single dose >30 U; avoid high FiO_2 in general anesthesia to ↓ tox.

BOTULINUM TOXIN TYPE A [ONABOTULINUMTOXINA] (BOTOX, BOTOX COSMETIC)

WARNING: Effects may spread beyond Tx area leading to swallowing/breathing difficulties (may be fatal); Sxs may occur hours to weeks after injection.
USES: *Overactive bladder with symptoms of urge urinary incontinence, urgency, and frequency, in adults w/ inadequate response or intolerant of an anticholinergic medication; urinary incontinence due to detrusor overactivity associated with a neurologic condition (eg, SCI, MS) in adults who have an inadequate response to or are intolerant of an anticholinergic medication. Glabellar lines (cosmetic) <65 yr, blepharospasm, cervical dystonia, axillary hyperhidrosis, strabismus, chronic migraine, upper limb spasticity. *
ACTIONS: Neurotoxin, ↓ ACH release from nerve endings; denervates sweat glands/muscles.

DOSE:

Adults: *Bladder:* 100 U of *Botox* (max. recommended dose). Dilution is 100 U/10 mL. Needle inserted ~2 mm into the detrusor, and 20 injections of 0.5 mL each (total volume of 10 mL) should be spaced ~1 cm apart; avoid the trigone. ***Reinjection:*** When the clinical effect of the previous injection has diminished (median time in clinical studies was 169 days [~24 wk]), but no sooner than 12 wk from the prior bladder injection.
W/P: [C, ?] w/ neurologic disease; do not exceed rec doses; sedentary pt to resume activity slowly after Inj; aminoglycosides and nondepolarizing muscle blockers may ↑↑ effects; local or total anesthesia.
CI: Hypersensitivity to components, infection at Inj site.
DISP: Inj powder, single-use vial (dilute w/ NS); (*Botox cosmetic*) 50, 100 U; (*Botox*) 100, 200 U vials; store 2–8°C.
SE: Anaphylaxis, erythema multiforme, dysphagia, dyspnea, syncope, headache, narrow-angle glaucoma, Inj site pain.

NOTES: Prophylactic antibiotics, except aminoglycosides, should be administered 1–3 days pretreatment, on the treatment day, and 1–3 days posttreatment; do not exceed total dose of 360 U q12–16wk; Botulinum toxin products not interchangeable; other botulinum toxins are not FDA approved for bladder use: abobotulinumtoxinA (*Dysport*), incobotulinumtoxinA (*Xeomin*) [rimabotulinumtoxinB] (Myobloc).

BROMOCRIPTINE (PARLODEL)

USES: *Parkinson disease, hyperprolactinemia, acromegaly, pituitary tumors.*
ACTIONS: Agonist to striatal dopamine receptors; ↓ prolactin secretion.
DOSE: Initial, 1.25 mg PO BID; titrate to effect, w/ food.
W/P: [B, −].
CI: Uncontrolled HTN, pregnancy, severe CAD or CVS disease.
DISP: Tabs 2.5 mg; caps 5 mg.
SE: ↓ BP, Raynaud phenomenon, dizziness, N, GI upset, hallucinations.

BUMETANIDE (BUMEX)

WARNING: Potent diuretic, may result in profound fluid & electrolyte loss.
USES: *Edema from CHF, hepatic cirrhosis, & renal disease.*
ACTIONS: Loop diuretic; ↓ reabsorption of Na^+ & Cl^-, in ascending loop of Henle & the distal tubule.

DOSE:

Adults: 0.5–2 mg/d PO; 0.5–1 mg IV/IM q8–24h (max. 10 mg/d).
Peds: 0.015–0.1 mg/kg PO q6–24h (max. 10 mg/d).
W/P: [C, ?/−].
CI: Anuria, hepatic coma, severe electrolyte depletion.
DISP: Tabs 0.5, 1, 2 mg; Inj 0.25 mg/mL.
SE: ↓ K^+, ↓ Na^+, ↑ Cr, ↑ uric acid, dizziness, ototox.
NOTES: Monitor fluid & lytes.

BUPIVACAINE (MARCAINE, SENSORCAINE, GENERIC)

WARNING: Avoid 0.75% for OB anesthesia d/t reports of cardiac arrest and death.
USES: *Local or regional anesthesia or analgesia for surgery, dental and oral surgery procedures, diagnostic and therapeutic procedures, and for obstetrical procedures.*
ACTIONS: Local anesthetic onset 7–30 min; duration 5–7 hr; max.

DOSE:

Adults: 0.25% for infiltration anesthesia; max. dose 3 mg/kg.
Peds: 0.5 ml/kg of 0.25% .
W/P: [C, −] Severe bleeding, ↓ BP, shock & arrhythmias, local infections at site, septicemia.
CI: Obstetrical paracervical block anesthesia.
DISP: Inj 0.25%, 0.5%, 0.75%; with epinephrine 0.25%, 0.5%.
SE: ↓ BP, ↓ HR, dizziness, anxiety.

BUPIVACAINE, LIPOSOME (EXPAREL)

WARNING: Avoid 0.75% for OB anesthesia d/t reports of cardiac arrest and death.
USES: *Single-dose infiltration into the surgical site for postsurgical analgesia.
ACTIONS: Long lasting amide local anesthetic.

DOSE:
Adults & Peds: 0.25% for infiltration anesthesia; max. dose 3 mg/kg (eg, hemorrhoidectomy dose: 266 mg volume: 20 mL.
W/P: [C, −] Monitor of cardiovascular/neurologic status/vital signs; caution with hepatic disease; do not use other bupivacaine forms within 96 hr.
CI: Obstetrical paracervical block anesthesia.
DISP: 20 mL single-use vial, 1.3% (13.3 mg/mL) stored in refrigerator.
SE: N, vomiting, constipation.
NOTES: Do not mix with lidocaine; administer lidocaine and liposomal bupivacaine 20 min apart.

BUPRENORPHINE (BUPRENEX) [C-III]

USES: *Mod–severe pain.*
ACTIONS: Opiate agonist–antagonist.
DOSE: 0.3–0.6 mg IM or slow IV push q6h PRN.
W/P: [C, −].
DISP: 0.3 mg/mL.
SE: Sedation, ↓ BP, resp depression.
NOTES: Withdrawal potential if opioid dependent.

BUTABARBITAL, HYOSCYAMINE HYDROBROMIDE, PHENAZOPYRIDINE (PYRIDIUM PLUS)

USES: *Relieve urinary tract pain w/ UTI, procedures, trauma.*
ACTIONS: Phenazopyridine (topical anesthetic), hyoscyamine (parasympatholytic, ↓ spasm), butabarbital (sedative).
DOSE: 1 PO QID, pc & hs; w/ antibiotic for UTI, 2 days max.
W/P: [C, ?].
DISP: Tab butabarbital/hyoscyamine/phenazopyridine, 15 mg/0.3 mg/150 mg.
SE: headache, rash, itching, GI distress, methemoglobinemia, hemolytic anemia, anaphylactoid-like reactions, dry mouth, dizziness, drowsiness, blurred vision.
NOTES: Colors urine orange, may tint skin, sclera; stains clothing/contacts; see also Phenazopyridine.

BUTORPHANOL (STADOL) [C-IV]

USES: *Anesthesia adjunct, pain & migraine headache.*
ACTIONS: Opiate agonist–antagonist w/ central analgesic actions.
DOSE: 0.5–4 mg IM or IV q3–4h PRN.; ↓ in renal impairment.
W/P: [C, +].

DISP: Inj 1, 2 mg/mL; nasal 1 mg/spray (10 mg/mL).
SE: Drowsiness, dizziness, nasal congestion.
NOTES: May induce withdrawal in opioid dependency.

CABAZITAXEL (JEVTANA)

WARNING: Neutropenic deaths reported; check CBCs, CI w/ ANC ≤1,500 cells/mm^3; severe hypersens (rash/erythema, ↓ BP, bronchospasm) may occur, D/C drug & Tx; CI w/ Hx of hypersens to cabazitaxel or others formulated w/ polysorbate 80.
USES: *Hormone refractory metastatic PCa after taxotere.*
ACTIONS: Microtubule inhibitor.
DOSE: 25 mg/m^2 IV Inf (over 1 hr) q3wk w/ prednisone 10 mg PO daily; premed w/ antihistamine, corticosteroid, H_2 antagonist; do not use w/ bili >ULN, AST/ALT ≥1.5 × ULN.
W/P: [D, ?/−] w/ CYP3A inhibitor/inducers.
CI: See “Warning"
DISP: 40 mg/mL Inj.
SE: ↓ WBC, ↓ Hgb, ↓ plt, sepsis, N/V/diarrhea, constipation, Abdominal/back/jt pain, dysgeusia, fatigue, hematuria, neuropathy, anorexia, cough, dyspnea, alopecia, pyrexia, hypersens reaction, renal failure.
NOTES: Monitor closely pts >65 yr.

CALCITONIN (FORTICAL, MIACALCIN)

USES: *Miacalcin*: *Paget disease, emergent Treat hypercalcemia, postmenopausal osteoporosis*; *Fortical:* *Postmenopausal osteoporosis.*
ACTIONS: Polypeptide hormone (salmon derived), inhibits osteoclasts.
DOSE: *Paget disease:* 100 U/d IM/SQ initial, 50 U/d or 50–100 units q1–3d maint. *Hypercalcemia:* 4 U/kg IM/SQ q12h; ↑ to 8 U/kg q12h, max. q6h. *Osteoporosis:* 100 U/q other day IM/SQ; intranasal 200 U = 1 nasal spray/d.
W/P: [C, ?].
DISP: *Fortical, Miacalcin* nasal spray 200 IU/activation; Inj, *Miacalcin* 200 U/mL (2 mL).
SE: Facial flushing, N, Inj site edema, nasal irritation, polyuria, may ↑ granular casts in urine.
NOTES: For nasal spray alternate nostrils daily; ensure adequate calcium and vit D intake; *Fortical* is rDNA derived from salmon.

CALCITRIOL (ROCALTROL, CALCIJEX)

USES: *Predialysis reduction of ↑ PTH levels to treat bone disease; ↑ Ca^{2+} on dialysis.*
ACTIONS: 1,25-Dihydroxycholecalciferol (vit D analog); ↑ Ca^{2+} and phosphorus absorption; ↑ bone mineralization.

DOSE:

Adults: *Renal failure:* 0.25 µg/d PO, ↑ 0.25 µg/d q4–8wk PRN; 0.5–4 µg 3×/wk IV, ↑ PRN. *Hypoparathyroidism:* 0.5–2 µg/d.
Peds: *Renal failure:* 15 ng/kg/d, ↑ PRN; maint 30–60 ng/kg/d. *Hypoparathyroidism:* ***<5 yr:***

0.25–0.75 µg/d. >***6 yr:*** 0.5–2 µg/d.
W/P: [C, ?] ↑ Mg^{2+} possible w/ antacids.
CI: ↑ Ca^{2+}; vit D tox.
DISP: Inj 1 µg/mL (in 1 mL); caps 0.25, 0.5 µg; soln 1 µg/mL.
SE: ↑ Ca^{2+} possible.
NOTES: Check to keep Ca^{2+} WNL; use nonaluminum phosphate binders and low phosphate diet to control serum phosphate discomfort.

CALCIUM ACETATE (PHOSLO)

USES: *ESRD-associated hyperphosphatemia.*
ACTIONS: Ca^{2+} supl w/o aluminum to ↓ PO_4 absorption.
DOSE: 2–4 tabs PO w/ meals; usual 2,001–2,668 mg PO w/ meals.
W/P: [C, +].
CI: ↑ Ca^{2+} renal calculi.
DISP: Gel-Cap 667 mg.
SE: Can ↑ Ca^{2+}, hypophosphatemia, constipation.
NOTES: Monitor Ca^{2+}.

CALCIUM CARBONATE (TUMS, ALKA-MINTS) [OTC]

USES: *Hyperacidity-associated w/ peptic ulcer disease, hiatal hernia, etc.*, calcium supplementation.
ACTIONS: Neutralizes gastric acid.
DOSE: 500 mg–2 g PO PRN, 7 g/d max.; ↓ w/ renal impairment.
W/P: [C, ?].
CI: ↑ cancer, ↓ phos, renal calculi, suspected digoxin tox.
DISP: Chew tabs 350, 420, 500, 550, 750, 850 mg; susp.
SE: ↑ Ca^{2+}, ↓ PO^{4-}, constipation.

CALCIUM GLUBIONATE (CALCIONATE) [OTC]

USES: *Treat & prevent calcium deficiency.*
ACTIONS: Calcium supplement.
DOSE:
Adults: 1,000–1,200 mg/d ÷ doses.
Peds: 200–1,300 mg/d.
W/P: [C, ?].
DISP: OTC syrup 1.8 g/5 mL = elemental Ca 115 mg/5 mL.
SE: ↑ Ca^{2+}, ↓ PO^{4-}, constipation.

CALCIUM SALTS (CHLORIDE, GLUCONATE, GLUCEPTATE)

USES: *Calcium replacement*, VF, calcium blocker tox (calcium channel blocker),* severe ↑

hypermagnesemic tetany, hyperphosphatemia in ESRD.*
ACTIONS: calcium supl/replacement.

DOSE:

Adults: *Replacement:* 1–2 g/d PO. *Tetany:* 1 g CaCl over 10–30 min; repeat in 6 hr PRN; *Hyperkalemia/hypermagnesemia/calcium channel blocker overdose:* 500–1,000 mg (5–10 mL of 10% soln) IV; repeat PRN; comparable dose of 10% calcium gluconate is 15–30 mL.
Peds: *Tetany:* 10 mg/kg CaCl over 5–10 min; repeat in 6–8 hr or use Inf (200 mg/kg/d max.). *Hyperkalemia/hypermagnesemia/calcium channel blocker overdose:* Calcium chloride or gluconate 20 mg/kg (0.2 mL/kg) slow IV/IO, repeat PRN; central venous route preferred.
Adults & Peds: ↓ calcium d/t citrated blood Inf: 0.45 mEq Ca/100 mL citrated blood Inf (↓ in renal impairment).
W/P: [C, ?].
CI: ↑ Ca^{2+}, suspected digoxin tox.
DISP: CaCl Inj 10% = 100 mg/mL = Ca 27.2 mg/mL = 10-mL amp; Ca gluconate Inj 10% = 100 mg/mL = Ca 9 mg/mL; tabs 500 mg = 45-mg Ca, 650 mg = 58.5-mg Ca, 975 mg = 87.75-mg Ca, 1 g = 90-mg Ca; Ca gluceptate Inj 220 mg/mL = 18-mg/mL Ca.
SE: ↓ HR, cardiac arrhythmias, ↑ Ca^{2+}, constipation.
NOTES: CaCl 270 mg (13.6 mEq) elemental Ca/g & calcium gluconate 90 mg (4.5 mEq) Ca/g. RDA for Ca intake: ***Peds <6 mo:*** 200 mg/d; ***6 mo–1 yr:*** 260 mg/d; ***1–3 yr:*** 700 mg/d; ***4–8 yr:*** 1,000 mg/d; ***10–18 yr:*** 1,300 mg/d.***Adults:***, 000 mg/d; ***>50 yr:*** 1,200 mg/d.

CAPTOPRIL (CAPOTEN, OTHERS)

USES: *HTN, CHF, MI*, LVD, diabetic nephropathy.
ACTIONS: ACE inhibitor.

DOSE:

Adults: *HTN:* Initial, 25 mg PO BID–TID; ↑ to maint q1–2wk by 25 mg increments/dose (max. 450 mg/d) to effect. *CHF:* Initial, 6.25–12.5 mg PO TID; titrate PRN *LVD:* 50 mg PO TID. *DN:* 25 mg PO TID.
Peds: *Infants:* 0.15–0.3 mg/kg/dose PO ÷ 1–4 doses; ***Children:*** Initial, 0.3–0.5 mg/kg/dose PO; ↑ to 6 mg/kg/d max. in 2–4 ÷ doses; 1 hr ac; ↓ dose renal impairment.
W/P: [D, −].
CI: Hx Angioedema.
DISP: Tabs 12.5, 25, 50, 100 mg.
SE: Rash, proteinuria, cough, ↑ K^{+}.

CARBOPLATIN (GENERIC)

WARNING: Administration only by physician experienced in cancer chemotherapy; ↓ PLT, anemia, ↑ infection; BM suppression possible; anaphylaxis and V may occur.
USES: *Ovarian*, lung, head & neck, testicular, urothelial, & brain cancer, NHL & allogeneic & ABMT in high doses.
ACTIONS: DNA cross-linker; forms DNA-platinum adducts.
DOSE: Per protocols based on target (Calvert formula: mg = AUC × [25 + calculated

GFR]); adjust based on plt count, CrCl, & BSA (Egorin formula); up to 1,500 mg/m^2 used in ABMT setting (per protocols).
W/P: [D, ?] severe hepatic tox.
CI: Severe BM suppression, excessive bleeding.
DISP: Inj 50-, 150-, 450-, 650-mg vial (10 mg/mL).
SE: Pain, ↓ Na^+/Mg^{2+}/Ca^{2+}/K^+, anaphylaxis, ↓ BM, N/V/diarrhea, nephrotoxic, hematuria, neurotox, ↑ LFTs.
NOTES: Physiologic dosing based on Calvert or Egorin formula allows ↑ doses w/ ↓ tox.

CASPOFUNGIN (CANCIDAS)

USES: *Invasive aspergillosis refractory/intolerant to standard Treat, candidemia & other candida Inf*, empiric Treat in febrile neutropenia w/ presumed fungal infection.
ACTIONS: Echinocandin; ↓ fungal cell wall synth; highest activity in regions of active cell growth.
DOSE: 70 mg IV load day 1, 50 mg/d IV; slow Inf over 1 hr; ↓ in hepatic impairment.
W/P: [C, ?/−] Do not use w/ cyclosporine.
CI: Allergy to any component.
DISP: Inj 50, 70 mg powder for recons.
SE: Fever, headache, N/V, thrombophlebitis at site, ↑ LFTs ↓ BP, edema, ↑ HR, rash, ↓ K, diarrhea, Inf reaction.
NOTES: Monitor during Inf; limited experience beyond 2 wk of Treat.

CEFACLOR (GENERIC)

USES: *Bacterial infections of the upper & lower resp tract, skin, bone, urinary tract.*
ACTIONS: 2nd-gen cephalosporin; ↓ cell wall synth. *Spectrum:* More gram(−) activity than 1st-gen cephalosporins; effective against gram(+) (*Streptococcus* sp, *S. aureus*); good gram(−) against *H. influenzae, E. coli, Klebsiella, Proteus.*

DOSE:

Adults: 250–500 mg PO > q8h.
Peds: 20–40 mg/kg/d PO ÷ 8–12 hr; ↓ renal impairment.
W/P: [B, M].
CI: Cephalosporin/PCN allergy.
DISP: Caps 250, 500 mg; tabs ER 500 mg; susp 125, 250, 375 mg/5 mL.
SE: N/diarrhea, rash, eosinophilia, ↑ LFTs, headache, rhinitis, vaginitis.

CEFADROXIL (GENERIC)

USES: *Infections skin, bone, upper & lower resp tract, urinary tract.*
ACTIONS: 1st-gen cephalosporin; ↓ cell wall synth. *Spectrum:* Good gram(+) (group A β-hemolytic *Streptococcus, Staphylococcus*); gram(−) (*E. coli, Proteus, Klebsiella*).

DOSE:

Adults: 1–2 g/d PO, 2 ÷ doses.

Peds: 30 mg/kg/d ÷ BID; ↓ in renal impairment.
W/P: [B, M].
CI: Cephalosporin/PCN allergy.
DISP: Caps 500 mg; tabs 1 g; susp, 250, 500 mg/5 mL.
SE: N/V/diarrhea, rash, eosinophilia, ↑ LFTs.

CEFAZOLIN (ANCEF, KEFZOL, GENERIC)

USES: *Infections of skin, bone, upper & lower resp tract, urinary tract.*
ACTIONS: 1st-gen cephalosporin; β-lactam ↓ cell wall synth. *Spectrum:* Good gram(+) bacilli & cocci (*Streptococcus, Staphylococcus* [except *Enterococcus*]); some gram(−) (*E. coli, Proteus, Klebsiella*).

DOSE:

Adults: 1–2 g IV q8h.
Peds: 25–100 mg/kg/d IV ÷ q6–8h; ↓ in renal impairment.
W/P: [B, M].
CI: Cephalosporin/PCN allergy.
DISP: Inj.
SE: Diarrhea, rash, eosinophilia, ↑ LFTs, Inj site pain.
NOTES: Widely used for surgical prophylaxis.

CEFDINIR (GENERIC)

USES: *Infections of the resp tract, skin, and skin structure.*
ACTIONS: 3rd-gen cephalosporin; ↓ cell wall synth. *Spectrum:* Many gram(+) & (−) organisms; more active than cefaclor & cephalexin against *Streptococcus, Staphylococcus*; some anaerobes.

DOSE:

Adults: 300 mg PO BID or 600 mg/d PO.
Peds: 7 mg/kg PO BID or 14 mg/kg/d PO; ↓ in renal impairment.
W/P: [B, M] w/ PCN-sensitive pts.
CI: Hypersensitivity to cephalosporins.
DISP: Caps 300 mg; susp 125, 250 mg/5 mL.
SE: Anaphylaxis, diarrhea, rare pseudomembranous colitis, headache.

CEFDITOREN (SPECTRACEF)

USES: *Acute exacerbations of chronic bronchitis, pharyngitis, tonsillitis; skin infections.*
ACTIONS: 3rd-gen cephalosporin; ↓ cell wall synth. *Spectrum:* Good gram(+) (*Streptococcus* & *Staphylococcus*); gram(−) (*H. influenzae* & *M. catarrhalis*)

DOSE:
Adults & Peds: ***>12 yr:*** *Skin also pharyngitis, tonsillitis:* 200 mg PO BID × 10 days. *Chronic bronchitis:* 400 mg PO BID × 10 days; avoid antacids w/in 2 hr; take w/ meals; ↓ in renal impairment.

W/P: [B, ?] Renal/ hepatic impairment.
CI: Cephalosporin/PCN allergy, milk protein, or carnitine deficiency.
DISP: Tabs 200, 400 mg.
SE: headache, N/V/diarrhea, colitis, nephrotoxic, hepatic dysfunction, SJS, TEN, allergic reactions.
NOTES: Causes renal excretion of carnitine; tabs contain milk protein.

CEFEPIME (MAXIPIME, GENERIC)

USES: *Comp/uncomp UTI, pneumonia, empiric febrile neutropenia, skin/soft-tissue infections, comp intra-abdominal infections.*
ACTIONS: 4th-gen cephalosporin; ↓ cell wall synth. *Spectrum:* gram(+) *S. pneumoniae, S. aureus*, gram(−) *K. pneumoniae, E. coli, P. aeruginosa, & Enterobacter* sp.

DOSE:

Adults: 1–2 g IV q8–12h.
Peds: 50 mg/kg q8h for febrile neutropenia; 50 mg/kg BID for skin/soft-tissue infections; ↓ in renal impairment.
W/P: [B, +]; seizure risk w/ CrCl < 60 mL/ min; adjust dose w/ renal insufficiency.
CI: Cephalosporin/PCN allergy.
DISP: Inj 500 mg, 1, 2 g.
SE: Rash, pruritus, N/V/diarrhea, fever, headache, (+) Coombs test w/o hemolysis.
NOTES: Can give IM or IV; concern over ↑ death rates not confirmed by FDA.

CEFIXIME (SUPRAX)

USES: *Resp tract, skin, bone, & urinary tract infections.*
ACTIONS: 3rd-gen cephalosporin; ↓ cell wall synth. *Spectrum: S. pneumoniae, S. pyogenes, H. influenzae, & enterobacteria.*

DOSE:

Adults: 400 mg PO ÷ daily–BID.
Peds: 8 mg/kg/d PO ÷ daily–BID; ↓ w/ renal impairment.
W/P: [B, ?].
CI: Cephalosporin/PCN allergy.
DISP: Tabs 400 mg, 100, 200 mg chew tab, susp 100, 200 mg/5 mL.
SE: N/V/diarrhea, flatulence, & abdominal pain.
NOTES: Check renal & hepatic function; use susp for otitis media.

CEFOTAXIME (CLAFORAN, GENERIC)

USES: *Infections of lower resp tract, skin, bone & jt, urinary tract, meningitis, sepsis, PID, GC.*
ACTIONS: 3rd-gen cephalosporin; ↓ cell wall synth. *Spectrum:* Most gram(−) (not *Pseudomonas*), some gram(+) cocci *S. pneumoniae, S. aureus* (penicillinase/nonpenicillinase producing), *H. influenzae* (including ampicillin resistant), not *Enterococcus*; many PCN-

resistant pneumococci.

DOSE:

Adults: *Uncomplicated infection:* 1 g IV/IM q12h; *Mod–severe infection:* 1–2 g IV/IM q 8–12 h; *Severe/septicemia:* 2 g IV/IM q4–8h; *GC urethritis, cervicitis, rectal in female:* 0.5 g IM × 1; rectal GC men 1 g IM × 1;
Peds: 50–200 mg/kg/d IV ÷ q6–8h; ↓ w/ renal/hepatic impairment.
W/P: [B, +] Arrhythmia w/ rapid Inj; w/ colitis.
CI: Cephalosporin/PCN allergy.
DISP: Powder for Inj 500 mg, 1, 2, 10 g, premixed Inf 20 mg/mL, 40 mg/mL.
SE: diarrhea, rash, pruritus, colitis, eosinophilia, ↑ transaminases.

CEFOTETAN (GENERIC)

USES: *infections of the upper & lower resp tract, skin, bone, urinary tract, abdominal, & gynecologic system.*
ACTIONS: 2nd-gen cephalosporin; ↓ cell wall synth. *Spectrum:* Less active against gram(+) anaerobes including *B. fragilis*; gram(−), including *E. coli, Klebsiella, & Proteus.*

DOSE:

Adults: 1–3 g IV q12h.
Peds: 20–40 mg/kg/dose IV ÷ q12h (6 g/d max.) ↓ w/ renal impairment.
W/P: [B, +] May ↑ bleeding risk; w/ Hx of PCN allergies, w/ other nephrotoxic drugs.
CI: Cephalosporin/PCN allergy.
DISP: Powder for Inj 1, 2, 10 g.
SE: Diarrhea, rash, eosinophilia, ↑ transaminases, hypoprothrombinemia, & bleeding (d/t MTT side chain).
NOTES: May interfere w/ warfarin.

CEFOXITIN (GENERIC)

USES: *Infections of the upper & lower resp tract, skin, bone, urinary tract, Abdominal, & gynecologic system.*
ACTIONS: 2nd-gen cephalosporin; ↓ cell wall synth. *Spectrum:* Good gram(−) against enteric bacilli (ie, *E. coli, Klebsiella,* & *Proteus*); anaerobic: *B. fragilis.*

DOSE:

Adults: 1–2 g IV q6–8h.
Peds: 80–160 mg/kg/d ÷ q4–6h (12 g/d max.); ↓ w/ renal impairment.
W/P: [B, M].
CI: Cephalosporin/PCN allergy.
DISP: Powder for Inj 1, 2, 10 g.
SE: Diarrhea, rash, eosinophilia, ↑ transaminases.

CEFPODOXIME (GENERIC)

USES: *Treat resp, skin, & urinary tract infections.*

ACTIONS: 3rd-gen cephalosporin; ↓ cell wall synth. *Spectrum: S. pneumoniae* or non–β-lactamase–producing *H. influenzae*; acute uncomplicated *N. gonorrhoeae*; some uncomplicated gram(−) (*E. coli, Klebsiella, Proteus*)

DOSE:

Adults: 100–400 mg PO q12h.
Peds: 10 mg/kg/d PO ÷ BID; ↓ in renal impairment, w/ food.
W/P: [B, M].
CI: Cephalosporin/PCN allergy.
DISP: Tabs 100, 200 mg; susp 50, 100 mg/5 mL.
SE: Diarrhea, rash, headache, eosinophilia, ↑ transaminases.
NOTES: Drug interactions w/ agents that ↑ gastric pH.

CEFPROZIL (GENERIC)

USES: *Treat resp tract, skin, & urinary tract infections.*
ACTIONS: 2nd-gen cephalosporin; ↓ cell wall synth. *Spectrum:* Active against MSSA, *Streptococcus,* & gram(−) bacilli (*E. coli, Klebsiella, P. mirabilis, H. influenzae, Moraxella*).

DOSE:

Adults: 250–500 mg PO daily–BID.
Peds: 7.5–15 mg/kg/d PO ÷ BID; ↓ in renal impairment.
W/P: [B, M].
CI: Cephalosporin/PCN allergy.
DISP: Tabs 250, 500 mg; susp 125, 250 mg/5 mL.
SE: Diarrhea, dizziness, rash, eosinophilia, ↑ transaminases.
NOTES: Use higher doses for otitis & pneumonia.

CEFTAROLINE (TEFLARO)

USES: *Tx skin/skin structure infection (SSSI) & community-acquired pneumonia.*
ACTIONS: Unclassified ("5th gen") cephalosporin; ↓ cell wall synthesis. *Spectrum:* gram(+) *Staph aureus* (MSSA/MRSA), *Strep pyogenes, Strep agalactiae, Strep pneumoniae*; gram(−) *E. coli, K. pneumoniae, K. oxytoca, H. influenzae.*

DOSE:

Adults: 600 mg IV q12h; CrCl 30–50 mL/min: 400 mg IV q12h; CrCl 15–29 mL/min: 300 mg IV q12h; CrCl < 15 mL/min: 200 mg IV q12h; Inf over 1 hr.
W/P: [B, ?/−] monitor for *C. difficile*-associated diarrhea.
CI: Cephalosporin sensitivity.
DISP: Inj 600 mg.
SE: Hypersens reaction, diarrhea/N, rash, constipation, ↓ K^+, phlebitis, ↑ LFTs.

CEFTAZIDIME (FORTAZ, TAZICEF, GENERIC)

USES: *Treat resp tract, skin, bone, urinary tract infections, meningitis, & septicemia.*
ACTIONS: 3rd-gen cephalosporin; ↓ cell wall synth. *Spectrum: P. aeruginosa* sp, good gram(−)

activity.

DOSE:

Adults: 500–2 g IV/IM q8–12h.
Peds: 30–50 mg/kg/dose IV q8h 6g/d max.; ↓ renal impairment.
W/P: [B, +] PCN sensitivity.
CI: Cephalosporin/PCN allergy.
DISP: Powder for Inj 500 mg, 1, 2, 6 g.
SE: Diarrhea, rash, eosinophilia, ↑ transaminases.
NOTES: Use only for proven or strongly suspected infection to ↓ development of drug resistance.

CEFTIBUTEN (CEDAX)

USES: *Treat resp tract, skin, urinary tract infections, & otitis media.*
ACTIONS: 3rd-gen cephalosporin; ↓ cell wall synth. *Spectrum: H. influenzae & M. catarrhalis*; weak against *S. pneumonia.*

DOSE:

Adults: 400 mg/d PO.
Peds: 9 mg/kg/d PO; ↓ in renal impairment; take on empty stomach (susp).
W/P: [B, +/−].
CI: Cephalosporin/PCN allergy.
DISP: Caps 400 mg; susp 90 mg/5 mL.
SE: diarrhea, rash, eosinophilia, ↑ transaminases.

CEFTRIAXONE (ROCEPHIN, GENERIC)

WARNING: Avoid in hyperbilirubinemic neonates or coinfusion w/ calcium-containing products.
USES: *Resp tract (pneumonia), skin, bone, abdominal & urinary tract infections, meningitis, septicemia, GC, PID, perioperative.*
ACTIONS: 3rd-gen cephalosporin; ↓ cell wall synth. *Spectrum:* Mod gram(+); excellent β-lactamase producers.

DOSE:

Adults: 1–2 g IV/IM q12–24h.
Peds: 50–100 mg/kg/d IV/IM ÷ q12–24h; decrease dose with renal insufficiency.
W/P: [B, +]. Postrenal acute renal failure (PARF) in children may require stenting.
CI: Cephalosporin allergy; hyperbilirubinemic neonates.
DISP: Powder for Inj 250 mg, 500 mg, 1, 2, 10 g; premixed 20, 40 mg/mL.
SE: Diarrhea, rash, ↑ WBC, thrombocytosis, eosinophilia, ↑ LFTs.

CEFUROXIME (CEFTIN [PO] , ZINACEF [PARENTERAL] , GENERIC)

USES: *Upper & lower resp tract, skin, bone, urinary tract, abdominal, gynecologic infections.*

ACTIONS: 2nd-gen cephalosporin; ↓ cell wall synth. *Spectrum:* Staphylococci, group B streptococci, *H. influenzae, E. coli, Enterobacter, Salmonella, & Klebsiella.*

DOSE:

Adults: 750 mg–1.5 g IV q8h or 250–500 mg PO BID.
Peds: 75–150 mg/kg/d IV ÷ q8h or 20–30 mg/kg/d PO ÷ BID; ↓ w/ renal impairment; take PO w/ food.
W/P: [B, +].
CI: Cephalosporin/PCN allergy.
DISP: Tabs 250, 500 mg; susp 125, 250 mg/5 mL; powder for Inj 750 mg, 1.5, 7.5 g.
SE: Diarrhea, rash, eosinophilia, ↑ LFTs.
NOTES: Cefuroxime film-coated tabs & susp not bioequivalent; do not substitute on a mg/mg basis; IV crosses blood–brain barrier.

CELECOXIB (CELEBREX)

WARNING: ↑ Risk of serious CV thrombotic events, MI, & stroke; can be fatal; ↑ risk of serious GI adverse events including bleeding, ulceration, & perforation of the stomach or intestines; can be fatal.
USES: *Osteoarthritis, rheumatoid arthritis, ankylosing spondylitis, acute pain, primary dysmenorrhea.*
ACTIONS: NSAID; ↓ COX-2 pathway.
DOSE: 100–200 mg/d or BID; ↓ w/ hepatic impairment; take w/ food/milk.
W/P: [C/D (3rd tri), ?] w/ renal impairment.
CI: Sulfonamide allergy, perioperative CABG.
DISP: Caps 50, 100, 200, 400 mg.
SE: See “Warning"; GI upset, HTN, edema, renal failure, headache.
NOTES: Watch for Sxs of GI bleed; no effect on plt/bleeding time; can affect drugs metabolized by P-450 pathway.

CEPHALEXIN (KEFLEX, GENERIC)

USES: *Skin, bone, upper/lower resp tract (streptococcal pharyngitis), otitis media, uncomp cystitis infections.*
ACTIONS: 1st-gen cephalosporin; ↓ cell wall synth. *Spectrum: Streptococcus* (including β-hemolytic)*, Staphylococcus, E. coli, Proteus, & Klebsiella.*

DOSE:
Adults & Peds: *>15 yr:* 250–1,000 mg PO QID; Treat cystitis 7–14 days (4 g/d max.).
Peds: *<15 yr:* 25–100 mg/kg/d PO ÷ BID–QID; ↓ in renal impairment; w/ or w/o food.
W/P: [B, +].
CI: Cephalosporin/ PCN allergy.
DISP: Caps 250, 500 mg; susp, 125, 250 mg; susp 125, 250 mg/5 mL.
SE: Diarrhea, rash, eosinophilia, gastritis, dyspepsia, ↑ LFTs, *C. difficile* colitis, vaginitis.

CHLOROTHIAZIDE (DIURIL)

USES: *HTN, edema.*
ACTIONS: Thiazide diuretic; decreases urine calcium.

DOSE:

Adults: 500 mg–1 g PO daily–BID; 500–1,000 mg/d IV (for edema only).
Peds: *>6 mo:* 10–20 mg/kg/24 h PO ÷ BID; 4 mg/kg ÷ daily bio IV; OK w/ food.
W/P: [C, +].
CI: Sensitivity to thiazides/sulfonamides, anuria.
DISP: Tabs 250, 500 mg; susp 250 mg/5 mL; Inj 500 mg/vial.
SE: ↓ K^+, Na^+, dizziness, hyperglycemia, hyperuricemia, hyperlipidemia, photosensitivity.
NOTES: Do not use IM/SQ; take early in the day to avoid nocturia; use sunblock; monitor lytes.

CHLORTHALIDONE (GENERIC)

USES: *HTN, edema.*
ACTIONS: Thiazide diuretic.

DOSE:

Adults: 25–100 mg PO daily.
Peds: (Not FDA approved) 0.3–2 mg/kg/dose PO 3×/wk or 1–2 mg/kg/d PO;↓ in renal impairment; OK w/ food, milk.
W/P: [B, +].
CI: Cross-sensitivity w/ thiazides or sulfonamides; anuria.
DISP: Tabs 25, 50, 100 mg.
SE: ↓ K^+, dizziness, photosensitivity, ↑ glucose, hyperuricemia, sexual dysfunction; 25–50 mg/d for idiopathic hypercalciuria.

CHOLECALCIFEROL [VITAMIN D_3] (DELTA D)

USES: Dietary supl to Treat vit D deficiency.
ACTIONS: ↑ intestinal Ca^{2+} absorption.
DOSE: 400–1,000 IU/d PO.
W/P: [A (D doses above the RDA), +].
CI: ↑ Ca^{2+}, hypervitaminosis, allergy.
DISP: Tabs 400, 1,000 IU.
SE: Vit D tox (renal failure, HTN, psychosis).
NOTES: 1 mg cholecalciferol = 40,000 IU vit D activity.

CIPROFLOXACIN (CIPRO, CIPRO XR)

WARNING: ↑ Risk Achilles tendon rupture and tendonitis, ↑ in pts >60 yr, on steroids or with organ transplant; avoid w/ myasthenia gravis, may ↑ muscle weakness.
USES: *Treat lower resp tract, sinuses, skin & skin structure, bone/joints, complex intra-abdominal infection (w/ metronidazole), typhoid, infectious diarrhea, uncomp GC, inhal anthrax, UTI including prostatitis; Peds only for multi resistant UTI not as first agent.*

ACTIONS: Quinolone antibiotic; ↓ DNA gyrase. *Spectrum:* Broad gram(+) & (–) aerobics; little *Streptococcus*; good *Pseudomonas, E. coli, B. fragilis, P. mirabilis, K. pneumoniae, C. jejuni,* or *Shigella.*

DOSE:

Adults: 250–750 mg PO q12h; XR 500–1,000 mg PO q24h; or 200–400 mg IV q12h; ↓ in renal impairment.
Peds: 6–10 mg/kg/day IV.
W/P: [C, ?/−] Children <18 yr due to cartilage concerns; avoid in myasthenia gravis.
CI: Component sensitivity; w/ tizanidine.
DISP: Tabs 100, 250, 500, 750 mg; tabs XR 500, 1,000 mg; susp 5 g/100 mL, 10 g/100 mL; Inj 200, 400 mg; premixed piggyback 200, 400 mg/100 mL.
SE: Restlessness, N/V/diarrhea, rash, ruptured tendons, ↑ LFTs, peripheral neuropathy risk.
NOTES: Avoid antacids; reduce/restrict caffeine intake; interactions w/ theophylline, caffeine, sucralfate, warfarin, antacids, most tendon problems in Achilles, rarely shoulder and hand.

CISPLATIN (PLATINOL, PLATINOL AQ, GENERIC)

WARNING: Anaphylactic-like reaction, ototox, cumulative renal tox; doses >100 mg/m^2 q3–4wk rarely used, do not confuse w/ carboplatin.
USES: *Testicular, bladder, ovarian*, SCLC, NSCLC, breast, head & neck, & penile cancers; osteosarcoma; peds brain tumors.
ACTIONS: DNA binding; denatures double helix; intrastrand cross-linking.
DOSE: 10–20 mg/m^2/d for 5 days q3wk; 50–120 mg/m^2 q3–4wk (per protocols); ↓ w/ renal impairment.
W/P: [D, −] Cumulative renal tox may be severe; ↓ BM, hearing impairment, pre-existing renal insufficiency.
CI: w/ renal impairment, hearing impairment, myelosuppression, platinum-containing compound allergy.
DISP: Inj 1 mg/mL.
SE: Allergic reactions, N/V, nephrotoxic (↑ w/ administration of other nephrotoxic drugs; minimize by NS Inf & mannitol diuresis), high-frequency hearing loss in 30%, peripheral "stocking glove"-type neuropathy, cardiotox (ST-, T-wave changes), ↓ Mg^{2+}, mild ↓ BM, hepatotox; renal impairment dose related & cumulative.
NOTES: Give taxanes before platinum derivatives; check Mg^{2+}, lytes before & w/in 48 hr after cisplatin.

CITRIC ACID, GLUCONOLACTONE, AND MAGNESIUM CARBONATE (RENACIDIN)

USES: *Chemolysis of calculi/incrustations in the urinary tract composed of apatite (calcium carbonate-phosphate) or struvite (magnesium ammonium phosphates) in nonsurgical candidates; adjunctive therapy to dissolve residual apatite/struvite fragments postop; partial dissolution of calculi to facilitate surgical removal.*

ACTIONS: Dissolution of calculi by exchange of Mg^{2+} from irrigating solution for insoluble Ca^{2+} in calcification. Mg^{2+} salts are soluble in the citrate irrigating solution, dissolving calculus.
DOSE: *Intermittent bladder irrigation:* 30–50 mL via Foley, clamped for 30 min, repeated TID for encrustations and 4–6×/d for bladder stones; irrigation via dual nephrostomy tube (inflow/outflow) or into ureteral catheter with nephrostomy drainage; essential to keep pressure <80 cm H_2O by manometer.
W/P: [C, ?] Caution w/ irrigating the renal pelvis of patients with impaired renal function. Observe for early signs/symptoms of hypermagnesemia (nausea, lethargy, confusion and hypotension). Severe hypermagnesemia may result in hyporeflexia, dyspnea, apnea, coma, cardiac arrest, and subsequent death. Monitor magnesium levels and deep tendon reflexes should be evaluated.
CI: Obstructed urinary tract, extravasation, UTI.
DISP: Solution.
SE: Hypermagnesemia, irritation, sepsis, other infections.
NOTES: Suby solution G was modified by addition of magnesium salts to create Renacidin.

CLARITHROMYCIN (BIAXIN, BIAXIN XL)

USES: *Upper/lower resp tract, skin/skin structure infections, *H. pylori* infections, & infections caused by nontuberculosis (atypical) *Mycobacterium*; prevention of MAC infections in HIV infection.*
ACTIONS: Macrolide antibiotic, ↓ protein synth. *Spectrum: H. influenzae, M. catarrhalis, S. pneumoniae, M. pneumoniae, & H. pylori.*

DOSE:

Adults: 250–500 mg PO BID or 1,000 mg (2 × 500 mg XL tab)/d. *Mycobacterium:* 500 mg PO BID.
Peds: ***>6 mo:*** 7.5 mg/kg/dose PO BID; ↓ w/ renal impairment.
W/P: [C, ?] Antibiotic-associated colitis; rare ↑ QT & ventricular arrhythmias; not rec w/ PDE5 inhibitor.
CI: Macrolide allergy; w/ Hx jaundice w/ Biaxin; w/cisapride, pimozide, astemizole, terfenadine, ergotamines; PDE5 inhibitors (sildenafil, others); w/ colchicine & renal impairment; w/ statins; w/ ↑ QT or ventricular arrhythmias.
DISP: Tabs 250, 500 mg; susp 125, 250 mg/5 mL; 500 mg XL tab.
SE: ↑ QT interval, causes met allic taste, N/diarrhea, abdominal pain, headache, rash.
NOTES: Multiple drug interactions, ↑ theophylline & carbamazepine levels; do not refrigerate susp.

CLINDAMYCIN (CLEOCIN, CLEOCIN-T, OTHERS)

WARNING: Pseudomembranous colitis may range from mild to life threatening.
USES: *aerobic & anaerobic infections; topical for severe acne & Vag infections.*
ACTIONS: Bacteriostatic; interferes w/ protein synth. *Spectrum:* Streptococci (eg, pneumococci), staphylococci, & gram(+) & (–) anaerobes; no activity against gram(−)

aerobes.

DOSE:

Adults: *PO:* 150–450 mg PO q6–8h. *IV:* 300–600 mg IV q6h or 900 mg IV q8h. *Vag cream*: 1 applicator hs × 7 days. *Vag supp:* Insert 1 qhs × 3 days. *Topical:* Apply 1% gel, lotion, or soln BID.
Peds: ***Neonates:*** (Avoid use; contains benzyl alcohol) 10–15 mg/kg/24 h ÷ q8–12h. ***Children >1 mo:*** 10–30 mg/kg/24 h ÷ q6–8h, to a max. of 1.8 g/d PO or 4.8 g/d IV. *Topical:* Apply 1%, gel, lotion, or soln BID; ↓ in severe hepatic impairment.
W/P: [B, +] Can cause fatal colitis.
CI: Hx pseudomembranous colitis.
DISP: Caps 75, 150, 300 mg; susp 75 mg/5 mL; Inj 300 mg/2 mL; Vag cream 2%, topical soln 1%, gel 1%, lotion 1%, Vag supp 100 mg.
SE: Diarrhea may be *C. difficile* pseudomembranous colitis, rash, ↑ LFTs.
NOTES: D/C drug w/ diarrhea, evaluate for *C. difficile.*

CLOMIPHENE (CLOMID, SEROPHENE, GENERIC)

USES: *Tx ovulatory dysfunction in women desiring pregnancy.*
ACTIONS: Nonsteroidal ovulatory stimulant; estrogen antagonist, increases FSH and LH through blocking feedback inhibition on the pituitary.
DOSE: 50 mg × 5 days; if no ovulation ↑ to 100 mg × 5 days @ 30 d later; ovulation usually 5–10 days postcourse, time coitus w/ expected ovulation time.
W/P: [X, ?/−] r/o pregnancy & ovarian enlargement.
CI: Hypersensitivity, uterine bleed, pregnancy, ovarian cysts (not due to polycystic ovary syndrome), liver disease, thyroid/adrenal dysfunction.
DISP: Tabs 50 mg.
SE: Ovarian enlargement, vasomotor flushes.
NOTES: Off-label use in males to increase testosterone or for low sperm counts; >10% of men with azoospermia and hypoandrogenism have return of sperm to ejaculate after T normalizes using clomiphene.

CLONIDINE, ORAL (CATAPRES)

USES: *HTN* opioid, EtOH, & tobacco withdrawal, ADHD.
ACTIONS: Centrally α-adrenergic stimulant.

DOSE:

Adults: 0.1 mg PO BID, adjust daily by 0.1–0.2-mg increments (max. 2.4 mg/d).
Peds: 5–10 μg/kg/d ÷ q8–12h (max. 0.9 mg/d); ↓ in renal impairment.
W/P: [C, +/−] Avoid w/ β-blocker, elderly, severe CV disease, renal impairment; use w/ agents that affect sinus node may cause severe ↓ HR.
CI: Component sensitivity.
DISP: Tabs 0.1, 0.2, 0.3 mg.
SE: drowsiness, orthostatic ↓ BP, xerostomia, constipation, ↓ HR, dizziness.
NOTES: More effective for HTN if combined w/ diuretics; withdraw slowly, rebound HTN w/

abrupt D/C of doses >0.2 mg BID; (Duraclon epidural inj) used for chronic cancer pain.

CLOPIDOGREL (PLAVIX, GENERIC)

USES: *Reduce atherosclerotic events, acute coronary syndrome.*
ACTIONS: ↓ Plt aggregation.
DOSE: 75 mg/d; *ACS:* 300–600 mg PO loading dose, then 75 mg/d PO; full effects take several days.
W/P: [B, ?] Active bleeding; risk of bleeding from trauma & other; TTP; liver disease; other CYP2C19 (eg, fluconazole); OK w/ ranitidine, famotidine.
CI: Coagulation disorders, active/ intracranial bleeding; CABG planned w/in 5–7 days.
DISP: Tabs 75, 300 mg.
SE: ↑ Bleeding time, GI intolerance, headache, dizziness, rash, thrombocytopenia, ↓ WBC.
NOTES: Plt aggregation to baseline ~5 days after D/C, plt transfusion to reverse acutely; clinical response highly variable.

CLOTRIMAZOLE (LOTRIMIN, MYCELEX, OTHERS) [OTC]

USES: *Candidiasis & tinea infections.*
ACTIONS: Antifungal; alters cell wall permeability. *Spectrum:* Oropharyngeal candidiasis, dermatophytoses, superficial mycoses, cutaneous candidiasis, & vulvovaginal candidiasis.
DOSE: *PO: Prophylaxis:* 1 troche dissolved in mouth TID. *Treat:* 1 troche dissolved in mouth 5×/d for 14 days. *Vag 1% cream:* 1 applicator-full hs for 7 days. *2% cream:* 1 applicator-full hs for 3 days. *Tabs:* 100 mg vaginally hs for 7 days or 200 mg (2 tabs) vaginally hs for 3 days or 500-mg tabs vaginally hs once. *Topical*: Apply BID 10–14 days.
W/P: [B (C if PO), ?] Not for systemic fungal infection; safety in children <3 yr not established.
CI: Component allergy.
DISP: 1% cream; soln; troche10 mg; vag cream 1%, 2%.
SE: *Topical:* Local irritation; *PO:* N/V, ↑ LFTs.
NOTES: PO prophylaxis for immunosuppressed pts.

CLOTRIMAZOLE/BETAMETHASONE (LOTRISONE)

USES: *Fungal skin infections.*
ACTIONS: Imidazole antifungal & anti-inflammatory. *Spectrum:* Tinea pedis, cruris, & corporis.

DOSE:
Children ≥ 17 yr, Adults: Apply & massage into area BID for 2–4 wk.
W/P: [C, ?] Varicella infection.
CI: Children <12 yr.
DISP: Cream 1/0.05% 15, 45 g; lotion 1/0.05% 30 mL.
SE: Local irritation, rash.
NOTES: Not for diaper dermatitis or under occlusive dressings.

CODEINE [C-II]

USES: *Mild–mod pain; symptomatic relief of cough.*
ACTIONS: Narcotic analgesic; ↓ cough reflex.

DOSE:

Adults: *Analgesic:* 15–60 mg PO or IM q4h PRN; 360 mg max./24 h. *Antitussive:* 10–20 mg PO q4h PRN; max. 120 mg/d.
Peds: *Analgesic:* 0.5–1 mg/kg/dose PO q4–6h PRN. *Antitussive:* 1–1.5 mg/kg/24 h PO ÷ q4h; max. 30 mg/24 h; ↓ in renal/hepatic impairment.
W/P: [C (D if prolonged use or high dose at term), +] CNS depression, Hx drug abuse, severe hepatic impairment.
CI: Component sensitivity.
DISP: Tabs 15, 30, 60 mg; soln 30 mg/5 mL; Inj 15, 30 mg/mL.
SE: Drowsiness, constipation, ↓ BP.
NOTES: Usually combined w/ acetaminophen for pain or w/ agents (eg, terpin hydrate) as an antitussive; 120 mg IM = 10 mg IM morphine.

COLLAGENASE CLOSTRIDIUM HISTOLYTICUM (XIAFLEX)

WARNING: Corporal rupture and other serious penile injuries reported. Restricted distribution though XIAFLEX REMS Program.
USES: *Adult men with Peyronie's disease w/ a palpable plaque and curvature of at least 30 degrees; adults w/ Dupuytren's contracture with a palpable cord.*
ACTION: Collagenase that hydrolyzes collagen.
DOSE: (Peyronie's) 0.58 mg (0.25 mL)/injection into plaque; treatment course is max. 4 cycles (1 cycle = 2 injection procedures and 1 penile modeling procedure; see below); interval of 6 wk between cycles.
W/P: [N/A, N/A] Provider and facility must be certified by REMS program; avoid injection into other structures.
CI: Peyronie's plaques involving the penile urethra.
DISP: 0.9 mg vial w/ 3 mL diluent.
SE: Corporal rupture, severe hematoma, mild allergic reactions (pruritus).
NOTES: For details of procedure see package insert; administer only by experienced provider; If the deformity is <15 degrees after any treatment cycle subsequent cycles should not be administered

- Prior to each treatment cycle, identify the area as follows:
  - Induce an erection (eg, intracavernosal injection of 10 or 20 μg alprostadil).
  - Locate the plaque at the point of max. concavity (or focal point) in the bend of the penis.
  - Mark the point with a surgical marker, the target area in the plaque for the injection.
- Injection procedure:
  - Use local/topical anesthetic.
  - Use 1 mL syringe w/ 27G ½-inch needle to inject 0.25 mL Xiaflex transversely throughout the plaque; apply pressure/dressing as needed afterward.
  - The 2nd injection of each treatment cycle is 1–3 days after the 1st injection and located 2–3 mm apart from the 1st injection site.

- Penile modeling 1–3 days after 2nd injection:
  - Use local anesthetic if desired.
  - Grasp plaque 1 cm proximal and distal; use target plaque as fulcrum point, using both hands to apply firm steady pressure to elongate/stretch the plaque. Goal is to create bending opposite the plaque.
  - Hold pressure for 30 s and release; after 30 s rest; repeat 3 times.
  - Patient should perform self-modeling with spontaneous erection and stretch flaccid penis 3×/d.

CONIVAPTAN HCL (VAPRISOL)

USES: Euvolemic & hypervolemic hyponatremia.
ACTIONS: Dual arginine vasopressin V_{1A}/V_2 receptor antagonist.
DOSE: 20 mg IV × 1 over 30 min, then 20 mg cont IV Inf over 24 hr; 20 mg/d cont IV Inf for 1–3 more days; may ↑ to 40 mg/d if Na^+ not responding; 4 day max. use; use large vein, change site q24h.
W/P: [C, ?/−] Rapid ↑ Na^+ (> 12 mEq/L/24 h) may cause osmotic demyelination syndrome; impaired renal/hepatic function; may ↑ digoxin levels; CYP3A4 inhibitor.
CI: Hypovolemic hyponatremia; w/ CYP3A4 inhibitor; anuria.
DISP: Inj 20 mg /100 mL.
SE: Inf site reactions, headache, N/V/diarrhea, constipation, ↓ K^+, orthostatic ↓ BP, thirst, dry mouth, pyrexia, pollakiuria, polyuria, infection.
NOTES: Monitor Na^+, vol and neurologic status; D/C w/ very rapid ↑ Na^+; mix only w/ 5% dextrose.

CORTISONE

See Steroids Systemic and Topical Pages 968, 969

CYANOCOBALAMIN [VITAMIN B_{12}] (NASCOBAL)

USES: *Pernicious anemia & other vit B_{12} deficiency states; ↑ requirements d/t pregnancy; thyrotoxicosis; liver or kidney disease* supplementation may be necessary with urinary diversion if distal terminal ileum resected.
ACTIONS: Dietary vit B_{12} supl.

DOSE:

Adults: 30 µg/d × 5–10 days intranasal: 500 µg once/wk for pts in remission, 100 µg IM or SQ daily for 5–10 days, then 100 µg IM 2×/wk for 1 mo, then 100 µg IM monthly.
Peds: Use 0.2 µg/kg × 2 day test dose; if OK 30–50 µg/d for 2 or more wk (total 1,000 µg) then maint: 100 µg/mo.
W/P: [A (C if dose exceeds RDA), +].
CI: Allergy to cobalt; hereditary optic nerve atrophy; Leber disease.
DISP: Tabs 50, 100, 250, 500, 1,000, 2,500, 5,000 µg; Inj 1,000 µg/mL; intranasal (Nascobal) gel 500 µg/0.1 mL.

SE: Itching, diarrhea, headache, anxiety.
NOTES: PO absorption erratic; OK for use w/ hyperalimentation.

CYCLOPHOSPHAMIDE (CYTOXAN, NEOSAR)

USES: *Hodgkin disease & NHLs; multiple myeloma; small cell lung, breast, & ovarian cancers; mycosis fungoides; neuroblastoma; retinoblastoma; acute leukemias; allogeneic & ABMT in high doses; severe rheumatologic disorders (SLE, JRA, Wegner granulomatosis) "minimal change" nephrotic syndrome in children.*
ACTIONS: Alkylating agent.

DOSE:

Adults: (Per protocol) 500–1,500 mg/m^2; single dose at 2- to 4-wk intervals; 1.8 g/m^2–160 mg/kg (or at 12 g/m^2 in 75-kg individual) in the BMT setting (per protocols).
Peds: *SLE:* 500 mg–1g/m^2 q mo. *JRA:* 10 mg/kg q2wk; ↓ w/ renal impairment.
W/P: [D, −] w/ BM suppression, hepatic insufficiency.
CI: Component sensitivity.
DISP: Tabs 25, 50 mg; Inj 200 mg, 500 mg, 1 g, 2 g.
SE: ↓ BM; hemorrhagic cystitis, SIADH, alopecia, anorexia; N/V; hepatotox; rare interstitial pneumonitis; irreversible testicular atrophy possible; cardiotox rare; 2nd malignancies (bladder, ALL), risk 3.5% at 8 yr, 10.7% at 12 yr.
NOTES: Hemorrhagic cystitis prophylaxis: cont bladder irrigation & MESNA uroprotection; encourage hydration, long-term bladder cancer screening.

CYCLOSPORINE (GENGRAF, NEORAL, SANDIMMUNE)

WARNING: ↑ Risk neoplasm, ↑ risk skin malignancies, ↑ risk HTN and nephrotoxic.
USES: *Organ rejection in kidney, liver, heart, rheumatoid arthritis; psoriasis.*
ACTIONS: Immunosuppressant; reversible inhibition of immunocompetent lymphocytes; a calcineurin.

DOSE:
Adults & Peds: *PO:* 15 mg/kg/12 h pretransplant; after 2 wk, taper by 5 mg/wk to 5–10 mg/kg/d. *IV:* If NPO, give 1/3 PO dose IV; ↓ in renal/hepatic impairment.
W/P: [C, −] Dose-related risk of nephrotoxic/hepatotox/serious fatal infections; calcium channel antagonists (eg, diltiazem, verapamil, and nicardipine) and certain antibiotics (eg, erythromycin, doxycycline, and ketoconazole) increase levels of cyclosporine and predispose to nephrotoxicity; some antibiotics (eg, nafcillin, trimethoprim–sulfamethoxazole, isoniazid, and rifampin) and certain anticonvulsants (eg, phenytoin, phenobarbital, and carbamazepine) decrease levels of cyclosporine and thereby predispose the patient to infection; drugs that enhance the nephrotoxicity w/o altering blood levels: Amphotericin B, acyclovir, and NSAIDs; live, attenuated vaccines may be less effective; may induce fatal malignancy; many drug interactions; ↑ risk of infections after D/C.
CI: Renal impairment; uncontrolled HTN; w/ lovastatin, simvastatin.
DISP: Caps 25, 100 mg; PO soln 100 mg/mL; Inj 50 mg/mL.
SE: May ↑ BUN & Cr and mimic transplant rejection; HTN; headache; hirsutism.

NOTES: Administer in glass container; *Neoral* & *Sandimmune* not interchangeable; monitor BP, Cr, CBC, LFTs, interaction w/ St. John's wort; Levels: *Trough:* Just before next dose: *Therapeutic:* Variable 150–300 ng/mL RIA; acute cyclosporine toxicity (level > 300 ng/mL) causes vasoconstriction and renal ischemia (reversed by reducing the dosage). Chronic toxicity results in fixed vascular lesions and irreversible renal ischemia.

CYSTEAMINE (CYSTAGON, PROCYSBI DELAYED RELEASE)

USES: *Nephropathic cystinosis in children and adults.*
ACTIONS: Converts cystine into cysteine.
DOSE: New patient: ¼–⅙ of the maintenance dose; peds up to 12 yr: Maint 1.3 g/m²/d; patients >12 yrs and >110 lb: 2.0 g/d, divided 4 times (Cystagon) or BID (Procysbi); at least 2 hr after and at least 30 min before eating.
W/P: [C, +/−] Stop if skin rash develops.
DISP: *Cystagon* Caps 50, 150 mg; *Procysbi* Caps DR 25, 75 mg.
SE: Nausea, vomiting, anorexia and abdominal pain, lethargy.
NOTES: Follow WBC cystine or plasma cysteamine levels.

DABIGATRAN (PRADAXA)

WARNING: Pradaxa D/C w/o adequate anticoagulation may ↑ stroke risk; epidural or spinal hematomas may occur.
USES: *↓ Risk stroke/systemic embolism w/ nonvalvular afib; treat DVT and PE in patients who have been treated with a parenteral anticoagulant for 5–10 days.*
ACTIONS: Thrombin inhibitor.
DOSE: *CrCl > 30 mL/min:* 150 mg PO BID; *CrCl 15–30 mL/min*: 75 mg PO BID; do not chew/break/open caps.
W/P: [C, ?/−] Avoid w/ P-glycoprotein inducers (ie, rifampin); bleed risk ↑ w/ age.
CI: Active bleeding, prosthetic valve, hypersensitivity to dabigatran.
DISP: Caps 75, 150 mg.
SE: Bleeding, gastritis, dyspepsia.
NOTES: See label to convert between anticoagulants; caps sensitive to humidity (30-day life after opening bottle); routine coags not needed; ↑ PTT/INR/TT; w/ nl TT, no drug activity; half-life 12–17 hr.

DACLIZUMAB (ZENAPAX)

WARNING: Administer under skilled supervision in properly equipped facility.
USES: *Prevent acute organ rejection.*
ACTIONS: IL-2 receptor antagonist.
DOSE: 1 mg/kg/dose IV; 1st dose pretransplant, then 1 mg/kg q14d × 4 doses.
W/P: [C, ?].
CI: Component sensitivity.
DISP: Inj 5 mg/mL.
SE: Hyperglycemia, edema, HTN, ↓ BP, constipation, headache, dizziness, anxiety, nephrotox, pulm edema, pain, anaphylaxis/hypersens.

NOTES: Administer w/in 4 hr of prep.

DACTINOMYCIN (COSMEGEN)

WARNING: Administer under skilled supervision in properly equipped facility; powder and soln toxic, corrosive, mutagenic, carcinogenic, and teratogenic; avoid exposure and use precautions.
USES: *Choriocarcinoma, Wilms' tumor, Kaposi and Ewing sarcomas, rhabdomyosarcoma, uterine and testicular cancer.*
ACTIONS: DNA-intercalating agent.

DOSE:

Adults: 15 μg/kg/d for 5 d q3–6 wk or 400–600 μg/m^2 for 5d q3–6 wk
Peds: Sarcoma (per protocols); ↓ in renal impairment
W/P: [D, ?]
CI: Concurrent/recent chickenpox or herpes zoster; infants < 6 mo
DISP: Inj 0.5 mg
SE: Myelo/immunosuppression, severe N/V/diarrhea, alopecia, acne, hyperpigmentation, radiation recall phenomenon, tissue damage w/ extrav, hepatotox.
NOTES: Classified as antibiotic but not used as antimicrobial.

DALBAVANCIN (DALVANCE)

USES: *Acute bacterial SSSI.*
ACTIONS: Glycopeptide antibacterial (blocks cell wall synth). *Spectrum:* Includes methicillin-susceptible/resistant strains and Streptococcus pyogenes, enterococcus.
DOSE: 2-dose regimen: 1,000 mg then 500 mg 1 wk later.
W/P: [C, ?/−] Anaphylaxis reported; avoid rapid inf; ↑ALT, *C. difficile*-associated diarrhea reported.
CI: Component hypersensitivity.
DISP: 500 mg powder to reconstitute.
SE: N, D, HA.
NOTES: Not approved in peds.

DALTEPARIN (FRAGMIN)

WARNING: ↑ Risk of spinal/epidural hematoma w/ LP.
USES: *Unstable angina, non–Q-wave MI, prevent & Treat DVT following surgery (hip, abdominal), pt w/ restricted mobility, extended therapy Treat for PE/DVT in cancer pt.*
ACTIONS: LMW heparin.
DOSE: *DVT prophylaxis:* 2,500–5,000 U SQ 1–2 hr preop, then daily for 5–10 days. *Systemic anticoagulation:* 200 U/kg/d SQ or 100 U/kg BID SQ. *Cancer:* 200 IU/kg (max. 18,000 IU) SQ q24h × 30 days, mo 2–6 150 IU/kg SQ q24h (max, 18,000 IU).
W/P: [B, ?] w/ renal/hepatic impairment, active hemorrhage, cerebrovascular disease, cerebral aneurysm, severe HTN.
CI: Heparin-induced thrombocytopenia; pork product allergy; w/ mifepristone.

DISP: Inj multiple ranging from 2,500 U (16 mg/0.2 mL) to 25,000 U/mL (3.8 mL) prefilled vials.
SE: Bleeding, pain at site, ↓ plt.
NOTES: Predictable effects eliminates lab monitoring; not for IM/IV use.

DANTROLENE (DANTRIUM, REVONTO)

WARNING: Hepatotox reported; D/C after 45 days if no benefit observed.
USES: *Treat spasticity d/t upper motor neuron disorders (eg, spinal cord injuries, stroke, CP, MS); malignant hyperthermia.*
ACTIONS: Skelet al muscle relaxant.

DOSE:

Adults: *Spasticity:* 25 mg PO daily; ↑ 25 mg to effect to 100 mg PO q8h (400 mg/d max.).
Peds: 0.5 mg/kg/dose/d; ↑ by 0.5 mg/kg dose TID to 2 mg/kg/ dose TID (max. 400 mg/d).
Adults & Peds: *Malignant hyperthermia: Treat:* Cont rapid IV, start 1 mg/kg until Sxs subside or 10 mg/kg is reached. *Postcrisis follow-up:* 4–8 mg/kg/d in 3–4 ÷ doses for 1–3 days to prevent recurrence.
W/P: [C, ?] Impaired cardiac/pulm/hepatic function.
CI: Active hepatic disease; where spasticity needed to maintain posture or balance.
DISP: Caps 25, 50, 100 mg; powder for Inj 20 mg/vial.
SE: Hepatotoxic, ↑ LFTs, drowsiness, dizziness, rash, muscle weakness, diarrhea/N/V, pleural effusion w/ pericarditis, blurred vision, hep, photosensitivity.
NOTES: Monitor LFTs; avoid sunlight/EtOH/CNS depressants.

DARBEPOETIN ALFA (ARANESP)

WARNING: Associated w/ ↑ CV, thromboembolic events and/or mortality; D/C if Hgb > 12 g/dL; may increase tumor progression and death in cancer pts.
USES: *Anemia associated w/ CRF*, anemia in nonmyeloid malignancy w/ concurrent chemotherapy.
ACTIONS: ↑ Erythropoiesis, recombinant erythropoietin variant.
DOSE: 0.45 µg/kg single IV or SQ qwk; titrate, do not exceed target Hgb of 12 g/dL; use lowest doses possible, see PI to convert from *Epogen.*
W/P: [C, ?] May ↑ risk of CV &/or neurologic SE in renal failure; HTN; w/ Hx seizures.
CI: Uncontrolled HTN, component allergy.
DISP: 25, 40, 60, 100, 200, 300 µg/mL, 150 µg/0.75 mL in polysorbate or albumin excipient.
SE: May ↑ cardiac risk, CP, hypo/hypertension, N/V/diarrhea, myalgia, arthralgia, dizziness, edema, fatigue, fever, ↑ risk infection.
NOTES: Longer half-life than *Epogen*; check weekly CBC until stable.

DARIFENACIN (ENABLEX)

USES: *Overactive bladder with symptoms of urge urinary incontinence, urgency and frequency. *
ACTIONS: Muscarinic receptor antagonist.

DOSE: 7.5 mg/d PO; 15 mg/d max. (7.5 mg/d w/ mod hepatic impairment or w/ CYP3A4 inhibitor); w/ drugs metabolized by CYP2D6; swallow whole.
W/P: [C, ?/−] w/ hepatic impairment.
CI: Urinary/gastric retention, uncontrolled narrow-angle glaucoma, paralytic ileus.
DISP: Tabs ER 7.5, 15 mg.
SE: Xerostomia/ eyes, constipation, dyspepsia, abdominal pain, retention, abnormal vision, dizziness, asthenia.

DEGARELIX (FIRMAGON)

USES: *Advanced PCa.*
ACTIONS: Reversible LHRH antagonist, ↓ LH and testosterone w/o flare seen w/ LHRH agonists (transient ↑ in testosterone).
DOSE: Initial 240 mg SQ abdomen in two 120 mg doses (40 mg/mL); maint 80 mg SQ (20 mg/mL) q28d.
W/P: [Not for women] ↑ QT interval; anaphylaxis, urticaria and angioedema reported.
CI: Women.
SUPPLIED: Inj vial 120 mg (3 mL) (initial); 80 mg (4 mL) (maint).
SE: Inj site reactions, hot flashes, ↑ Wt, ↑ serum GGT.
NOTES: Requires 2 Inj initially (volume); 44% testosterone castrate (<50 ng/dL) at day 1, 96% day 3.

DENOSUMAB (PROLIA, XGEVA)

USES: *Tx osteoporosis postmenopausal women; ↑ BMD in men on ADT (*Prolia*); prevent skelet al events w/ bone mets from solid tumors (*Xgeva*).*
ACTIONS: RANK ligand (RANKL) inhibitor (human IgG2 MoAb); inhibits osteoclasts.
DOSE: *Prolia:* 60 mg SQ q6mo; *Xgeva*: 120 mg SQ q4wk; in upper arm, thigh, abdominal.
W/P: [X (Xgeva), D (Prolia), ?/−].
CI: Hypocalcemia.
DISP: Inj *Prolia* 60 mg/mL; *Xgeva* 70 mg/mL.
SE: ↓ Ca^{2+}, hypophosphatemia, serious infections, dermatitis, rashes, eczema, jaw osteonecrosis, pancreatitis, pain (musculoskelet al, back), fatigue, asthenia, dyspnea, N, abdominal pain, flatulence, hypercholesterolemia, anemia, cystitis.
NOTES: Give w/ calcium 1.000 mg & vit D 400 IU/d.

DESMOPRESSIN (ddAVP, DDAVP NASAL SPRAY, STIMATE)

WARNING: (Parenteral form) Not for hemophilia B or w/ factor VIII antibody; not for hemophilia A w/ factor VIII levels <5%.
USES: **Oral:* Central diabetes insipidus; primary nocturnal enuresis, bleeding d/t uremia; *Nasal spray:* Central diabetes insipidus; *Stimate Nasal spray:* Hemophilia A, & type I von Willebrand disease; *Parenteral:* Central diabetes insipidus; hemophilia A, & type I von Willebrand disease.*
ACTIONS: Synthetic analog of vasopressin (human ADH) (1-deamino-8-D-arginine vasopressin, ddAVP; ddAVP is a neuropeptide that differs from endogenous vasopressin by a

2-amino acid substitute which gives the compound potent antidiuretic effect but no vasopressor activity); ↑ factor VIII.
DOSE: *DI: Intranasal:* **Adults:** 0.1–0.4 mL (10–40 μg/d in 1–3 ÷ doses). **Peds:** ***3 mo–12 yr:*** 0.05–0.3 mL/d (5 μg/d) in 1 or 2 doses. *Parenteral:*
Adults: 0.5–1 mL (2–4 μg/d in 2 ÷ doses); converting from nasal to parenteral, use 1/10 nasal dose. *PO:* .05 mg BID; ↑ to max. of 1.2 mg. *Hemophilia A & von Willebrand disease (type I):*
Adults & Peds: ***>10 kg:*** 0.3 μg/kg in 50 mL NS, Inf over –30 min. **Peds:** ***<10 kg:*** As above w/ dilution to 10 mL w/ NS. *Nocturnal enuresis:* ***>6 yr:*** 20 μg intranasally hs or 0.2–0.6 mg hs PO.
W/P: [B, M] Avoid overhydration.
CI: (Varies by manufacturer) Hemophilia B; CrCl <50 mL/min, severe classic von Willebrand disease; pts w/ factor VIII antibodies; hyponatremia.
DISP: Tabs 0.1, 0.2, 0.4 mg; Inj 4 μg/mL; nasal spray 0.1 mg/mL (10 μg/spray) 1.5 mg/mL (150 μg/spray)
SE: Facial flushing, headache, dizziness, vulval pain, nasal congestion, pain at Inj site, ↓ Na^+, H_2O intoxication.
NOTES: In very young & old pts, ↓ fluid intake to avoid H_2O intoxication & ↓ Na^+;↓ urine output, ↑ urine osm, ↓ plasma osm; GI tract absorption limited (5%), the oral form is 1/10–1/20th the potency of the nasal form. Use of ddAVP for nocturia treatment is off-label (non-FDA approved) in the US. ddAVP has potentially severe side effects and should not be used over the age of 65.

DEXAMETHASONE (DECADRON)

See Steroids, Systemic and Steroids, Topical Pages 968, 969

DEXPANTHENOL (ILOPAN-CHOLINE [ORAL] , ILOPAN)

USES: *Minimize paralytic ileus, Treat postop distention.*
ACTIONS: Cholinergic agent.

DOSE:

Adults: *Relief of gas:* 2–3 tabs PO TID. *Prevent postop ileus:* 250–500 mg IM stat, repeat in 2 hr, then q6h PRN. *Ileus:* 500 mg IM stat, repeat in 2 hr, then q6h, PRN.
W/P: [C, ?].
CI: Hemophilia, mechanical bowel obst.
DISP: Inj 250 mg/mL; cream 2% (Panthoderm cream [OTC]).
SE: GI cramps.

DIAZEPAM (VALIUM, DIASTAT, GENERIC) [C-IV]

USES: *Anxiety, EtOH withdrawal, muscle spasm, status epilepticus, panic disorders, amnesia, preop sedation.*
ACTIONS: Benzodiazepine.

DOSE:

Adults: *Anxiety, muscle spasm:* 2–10 mg PO BID–QID or IM/IV q3–4h PRN. *Preop:* 5–10 mg PO or IM 20–30 min or IV just prior to procedure.
Peds: *Sedation, muscle relaxation:* 0.04–0.3 mg/kg/dose q2–4h IM or IV to max. of 0.6 mg/kg in 8 hr, or 0.12–0.8 mg/kg/24 h PO ÷ TID–QID; ↓ w/ hepatic impairment.
W/P: [D, ?/−].
CI: Coma, CNS depression, resp depression, narrow-angle glaucoma, severe uncontrolled pain, pregnancy.
DISP: Tabs 2, 5, 10 mg; soln 5 mg/mL; Inj 5 mg/mL; rectal gel 2.5, 5, 10, 20 mg/mL.
SE: Sedation, amnesia, ↓ HR, ↓ BP, rash, ↓ resp rate.
NOTES: 5 mg/min IV max in adults or 1–2 mg/min in peds (resp arrest possible); IM absorption erratic; avoid abrupt D/C.

DIBUCAINE (NUPERCAINAL) [OTC]

USES: *Hemorrhoids & minor skin conditions.*
ACTIONS: Topical anesthetic.
DOSE: Insert PR w/ applicator BID & after each bowel movement; apply sparingly to skin.
W/P: [C, ?] Topical use only.
CI: Component sensitivity.
DISP: 1% oint w/ rectal applicator.
SE: Local irritation, rash.

DICLOFENAC, ORAL (CATAFLAM, VOLTAREN, VOLTAREN-XR, ZORVOLEX)

WARNING: May ↑ risk of CV events & GI bleeding; CI in postop CABG.
USES: *Arthritis (RA/OA) & pain, oral and topical, actinic keratosis.*
ACTIONS: NSAID.
DOSE: RA/OA: 150–200 mg/d ÷ 2–4 doses DR; 100 mg/d XR; *Zorvolex*: 18 or 35 mg PO TID; w/ food or milk.
W/P: [C (avoid after 30 wk), ?] CHF, HTN, renal/hepatic dysfunction, & Hx PUD, asthma; different forms not interchangeable.
CI: NSAID/aspirin ASA allergy; porphyria; following CABG.
DISP: Tabs 50 mg; tabs DR 25, 50, 75, 100 mg; XR tabs 100 mg; *Zorvolex*: 18, 35 mg caps.
SE: *Oral:* Abd cramps, heartburn, GI ulceration, rash, interstitial nephritis.
NOTES: Do not crush tabs; watch for GI bleed; check CBC, LFTs.

DICLOXACILLIN (GENERIC)

USES: *Treat of pneumonia, skin, & soft-tissue infections, & osteomyelitis caused by penicillinase-producing staphylococci.*
ACTIONS: Bactericidal; ↓ cell wall synth. *Spectrum: S. aureus* & *Streptococcus.*

DOSE:

Adults: 150–500 mg QID (2 g/d max.)
Peds: ***< 40 kg:*** 12.5–100 mg/kg/d ÷ QID; take on empty stomach.
W/P: [B, ?].
CI: Component or PCN sensitivity.
DISP: Caps 125, 250, 500 mg.
SE: N/diarrhea, abdominal pain.
NOTES: Monitor PTT if pt on warfarin.

DILTIAZEM (CARDIZEM, CARDIZEM CD, CARDIZEM LA, CARDIZEM SR, CARTIA XT, DILACOR XR, DILTIA XT, TAZTIA XT, TIAZAC)

USES: *Angina, prevention of reinfarction, HTN, AF or A flutter, & PAT.*
ACTIONS: Calcium channel blocker.
DOSE: *HTN:* SR: 60–120 mg PO BID; ↑ to 360 mg/d max. *CD or XR:* 120–360 mg/d (max. 540 mg/d) or LA 180–360 mg/d.
W/P: [C, +] ↑ Effect w/ amiodarone, cimetidine, fentanyl, Li, cyclosporine, digoxin, β-blockers, theophylline.
CI: SSS, AV block, ↓ BP, AMI, pulm congestion.
DISP: *Cardizem CD:* Caps 120, 180, 240, 300, 360 mg; *Cardizem LA*: Tabs 120, 180, 240, 300, 360, 420 mg; *Cardizem SR:* Caps 60, 90, 120 mg; *Cardizem:* Tabs 30, 60, 90, 120 mg; *Cartia XT:* Caps 120, 180, 240, 300 mg; *Dilacor XR:* Caps 120, 180, 240 mg; *Diltia XT:* Caps 120, 180, 240 mg; *Tiazac:* Caps 120, 180, 240, 300, 360, 420 mg; Inj 5 mg/mL; *Taztia XT:* 120, 180, 240, 300, 360 mg.
SE: Gingival hyperplasia, ↓ HR, AV block, ECG abnormalities, peripheral edema, dizziness,

headache.
NOTES: *Cardizem CD, Dilacor XR, & Tiazac* ***not*** interchangeable.

DIMETHYL SULFOXIDE [DMSO] (RIMSO-50)

USES: *Interstitial cystitis.*
ACTIONS: Unknown.
DOSE: Intravesical, 50 mL, retain for 15 min; repeat q2wk until relief.
W/P: [C, ?].
CI: Component sensitivity.
DISP: 50% soln.
SE: Cystitis, eosinophilia, GI, & taste disturbance.

DIPHENHYDRAMINE (BENADRYL, GENERIC) [OTC]

USES: *Treat & prevent allergic reactions, motion sickness, potentiate narcotics, sedation, cough suppression, & Treat of extrapyramidal reactions.*
ACTIONS: Antihistamine, antiemetic.

DOSE:

Adults: 25–50 mg PO, IV, or IM TID–QID.
Peds: ***>2 yr:*** 5 mg/kg/24 h PO or IM ÷ q6h (max. 300 mg/d); ↑ dosing interval w/ mod–severe renal insufficiency.
W/P: [B, −] Elderly, narrow-angle glaucoma, BPH, w/ MAOI.
CI: Acute asthma.
DISP: Tabs & caps 25, 50 mg; chew tabs 12.5 mg; elixir 12.5 mg/ 5 mL; syrup 12.5 mg/5 mL; liq 12.5 mg/5 mL; Inj 50 mg/mL, cream, gel, liq 2%.
SE: Anticholinergic (eg, xerostomia, urinary retention, sedation).

DIPHENOXYLATE/ATROPINE (LOMOTIL, LONOX, GENERIC) [C-V]

USES: *Diarrhea.*
ACTIONS: Constipating meperidine congener, ↓ GI motility.

DOSE:

Adults: Initial, 5 mg PO TID–QID until controlled, then 2.5–5 mg PO BID; 20 mg/d max.
Peds: ***>2 yr:*** 0.3–0.4 mg/kg/24 h (of diphenoxylate) BID–QID, 10 mg/d max.
W/P: [C, ?/−] Elderly, w/ renal impairment.
CI: Obstructive jaundice, diarrhea d/t bacterial infection; children <2 yr.
DISP: Tabs 2.5 mg diphenoxylate/0.025 mg atropine; liq 2.5 mg diphenoxylate/0.025 mg atropine/5 mL.
SE: Drowsiness, dizziness, xerostomia, blurred vision, urinary retention, constipation.

DOCETAXEL (TAXOTERE)

WARNING: Do not administer if neutrophil count <1,500 cells/mm^3; severe reactions possible in hepatic dysfunction.

USES: *Breast, ovarian, non-small cell lung, gastric, head, neck, and prostate cancers.*
ACTIONS: Antimitotic agent; promotes microtubular aggregation; semisynthetic taxoid.
DOSE: *Prostate cancer:* 75 mg/m^2 over 1 hr IV q3wk w/ prednisone 5 mg PO BID; ↓ dose w/ ↑ bili levels.
W/P: [D, −].
CI: Sensitivity to meds w/ polysorbate 80, component sensitivity.
DISP: Inj 20 mg/0.5 mL, 80 mg/2 mL.
SE: ↓ BM, neuropathy, N/V, alopecia, fluid retention syndrome; cumulative doses of 300–400 mg/m^2 w/o steroid prep & post-Tx & 600–800 mg/m^2 w/ steroid prep; allergy possible (rare w/ steroid prep).
NOTES: Check bili/SGOT/SGPT prior to each cycle; frequent CBC during Treat.

DOCUSATE CALCIUM (SURFAK)/DOCUSATE POTASSIUM (DIALOSE)/ DOCUSATE SODIUM (DOSS, COLACE) [OTC]

USES: *Constipation; adjunct to painful anorectal conditions (hemorrhoids).*
ACTIONS: Stool softener.

DOSE:

Adults: 50–500 mg PO ÷ daily–QID.
Peds: ***Infants–3 yr:*** 10–40 mg/24 h ÷ daily–QID. ***3–6 yr:*** 20–60 mg/24 h ÷ daily–QID. ***6–12 yr:*** 40–150 mg/24 h ÷ daily–QID.
W/P: [C, ?].
CI: Use w/ mineral oil; intestinal obst, acute abdominal pain, N/V.
DISP: *Calcium:* Caps 50, 240 mg. *Potassium:* Caps 100, 240 mg. *Na:* Caps 50, 100 mg; syrup 50, 60 mg/15 mL; liq 150 mg/15 mL; soln 50 mg/ mL; enema 283 mg/mL.
SE: Rare abdominal cramping, diarrhea.
NOTES: Take w/ full glass of water; no laxative action; do not use >1 wk.

DORIPENEM (DORIBAX)

USES: *Complicated intra-abdominal infection and UTI including pyelo.*
ACTIONS: Carbapenem, ↓ cell wall synth, a β-lactam. *Spectrum:* Excellent gram(+) (except MRSA and *Enterococcus* sp), excellent gram(−) coverage including β-lactamase producers, good anaerobic.
DOSE: 500 mg IV q8h, ↓ w/ renal impairment.
W/P: [B, ?].
CI: Carbapenem β-lactams hypersens.
DISP: 250, 500 mg vial.
SE: Headache, N/diarrhea, rash, phlebitis.
NOTES: May ↓ valproic acid levels; overuse may ↑ bacterial resistance; monitor for *C. difficile*-associated diarrhea 0.5%.
SE: Irritation, bitter taste, superficial keratitis, ocular allergic reaction.

DOXAZOSIN (CARDURA, CARDURA XL, GENERIC)

USES: *HTN & symptomatic BPH.*
ACTIONS: α_1-Adrenergic blocker; relaxes bladder neck smooth muscle.

DOSE:
Adult: *HTN:* Initial 1 mg/d PO; may be ↑ to 16 mg/d PO. *BPH:* Initial 1 mg/d PO, may ↑ to 8 mg/d; XL 4–8 mg q a.m.
Peds: (not FDA) <6 yr 0.5 mg daily; >6 yr 1 mg daily.
W/P: [C, ?] w/ Liver impairment; use w/ PDE5 inhibitor (eg, sildenafil) can cause ↓ BP.
CI: Component sensitivity.
DISP: Tabs 1, 2, 4, 8 mg; XL 4, 8 mg.
SE: Dizziness, headache, drowsiness, fatigue, malaise, sexual dysfunction, doses >4 mg ↑ postural ↓ BP risk; intraoperative floppy iris syndrome.
NOTES: 1st dose hs; syncope may occur w/in 90 min of initial dose.

DOXORUBICIN (ADRIAMYCIN, GENERIC)

USES: *Acute leukemias; Hodgkin disease & NHLs; soft tissue, osteo & Ewing sarcoma; Wilms' tumor; neuroblastoma; bladder, breast, ovarian, gastric, thyroid, & lung cancers*; intravesical for bladder cancer.
ACTIONS: Intercalates DNA; ↓ DNA topoisomerase I & II.
DOSE: 60–75 mg/m^2 q3wk; ↓ w/ hepatic impairment; IV use only ↓ cardiotox w/ weekly (20 mg/m^2/wk) or cont Inf (60–90 mg/m^2 over 96 hr); (per protocols).
W/P: [D, ?].
CI: Severe CHF, cardiomyopathy, pre-existing ↓ BM, previous Treat w/ total cumulative doses of doxorubicin, idarubicin, daunorubicin.
DISP: Inj 10, 20, 50, 150, 200 mg.
SE: ↓ BM, venous streaking & phlebitis, N/V/diarrhea, mucositis, radiation recall phenomenon, cardiomyopathy rare (dose related).
NOTES: Limit of 550 mg/m^2 cumulative dose (400 mg/m^2 w/ prior mediastinal irradiation); dexrazoxane may limit cardiac tox; tissue damage w/ extrav; red/orange urine; tissue vesicant w/ extrav, treat w/ dexrazoxane; liposomal formulations available; intravesical regimens include 30–50 mg in 25–50 mL saline, retain for 2 hr.

DOXYCYCLINE (ADOXA, ORACEA, VIBRAMYCIN, VIBRA-TABS)

USES: *Broad-spectrum antibiotic* acne vulgaris, uncomplicated GC, chlamydia, PID, Lyme disease, skin infections, anthrax, malaria prophylaxis.
ACTIONS: Tetracycline; bacteriostatic; ↓ protein synth. *Spectrum:* Limited gram(+) and (−), *Rickettsia* sp, *Chlamydia, M. pneumoniae, B. anthracis*

DOSE:

Adults: 100 mg PO q12h on 1st day, then 100 mg PO daily–BID or 100 mg IV q12h; acne q day, chlamydia × 7 days, Lyme × 21 days, PID × 14 days.
Peds: ***>8 yr:*** 5 mg/kg/24 h PO, 200 mg/d max ÷ daily–BID.
W/P: [D, −] hepatic impairment.
CI: Children <8 yr, severe hepatic dysfunction.

DISP: Tabs 20, 50, 75, 100, 150 mg; caps 50, 75, 100, 150 mg; *Oracea* 40 mg caps (30 mg timed release, 10 mg DR); syrup 50 mg/5 mL; susp 25 mg/5 mL; Inj 100/vial.
SE: Diarrhea, GI disturbance, photosensitivity.
NOTES: ↓ Effect w/ antacids; tetracycline of choice w/in renal impairment.

d-PENICILLAMINE (CUPRIMINE, DEPEN)

WARNING: Physicians planning to use penicillamine should thoroughly familiarize themselves with its toxicity, special dosage considerations, and therapeutic benefits. Penicillamine should never be used casually. Each patient should remain constantly under the close supervision of the physician. Patients should be warned to report promptly any symptoms suggesting toxicity.
USES: *Refractory rheumatoid arthritis, Wilson disease, cystinuria.*
ACTIONS: Chelating agent.

DOSE:
Adult: *Cystinuria:* Titrate to keep cystine excretion 100–200 mg/d (<100 mg/d with history of urolithiasis), 1–4 g/d PO in divided doses q6h, typical dose 2 g/d.
Peds: Titrate to keep cystine excretion 100–200 mg/d (<100 mg/d with history of urolithiasis), 30 mg/kg/d in 4 divided doses.
W/P: [D, −]; w/ other meds that act as hematopoietic depressants.
CI: Hypersensitivity to components, renal insufficiency, previous aplastic anemia due to drug, pregnancy.
DISP: Caps 250 mg.
SE: Allergic reactions in up to 33%; agranulocytosis, aplastic anemia, diarrhea, anorexia, abdominal pain, dermatologic manifestations, nephrotic syndrome.
NOTES: Do not d/c therapy in cystinuria; interruptions of a few days can cause hypersensitivity with resumption of therapy; monitor CBC, UA (proteinuria, hematuria), urinary cysteine levels; use THIOLA if intolerant of d-penicillamine.

DULOXETINE (CYMBALTA)

WARNING: Antidepressants may ↑ risk of suicidality; consider risks/benefits of use. Closely monitor for clinical worsening, suicidality, or behavior changes; not for peds.
USES: *Depression, diabetic peripheral neuropathic pain, generalized anxiety disorder (GAD), fibromyalgia, chronic osteoarthritis & back pain.*
ACTIONS: Selective serotonin & norepinephrine reuptake inhibitor (SSNRI).
DOSE: *Depression:* 40–60 mg/d PO ÷ BID. *DM neuropathy:* 60 mg/d PO; *GAD:* 60 mg/d, max. 120 mg/d; *Fibromyalgia, Osteoarthritis/back pain:* 30–60 mg/d, 60 mg/d max.
W/P: [C, ?/−]; use in 3rd tri; avoid if CrCl <30 mL/min, narrow-angle glaucoma, w/ fluvoxamine, inhibitor of CYP2D6 TCAs, phenothiazines, type class 1C anti-arrhythmics.
CI: ↑ risk serotonin syndrome w/ MAOIs [linezolid or IV meth blue] MAOI use w/in 14 days, w/ thioridazine, narrow-angle glaucoma, hepatic insufficiency.
DISP: Caps delayed release 20, 30, 60 mg.
SE: N, dry mouth, somnolence, fatigue, constipation, ↓ appetite, hyperhidrosis.
NOTES: Swallow whole; monitor BP; avoid abrupt D/C; approved for stress incontinence in

some countries (not US).

DUTASTERIDE (AVODART)

USES: *Symptomatic BPH to improve symptoms, ↓ risk of retention and BPH surgery alone or in combo w/ tamsulosin.*
ACTIONS: 5α-reductase inhibitor; ↓ intracellular dihydrotestosterone (DHT).
DOSE: *Monotherapy:* 0.5 mg PO/d. *Combination:* 0.5 mg PO q day w/ tamsulosin 0.4 mg q day.
W/P: [X, −] Hepatic impairment; pregnant women should not handle pills; R/O cancer before starting.
CI: Women, peds.
DISP: Caps 0.5 mg.
SE: ↑ Testosterone, ↑ TSH, impotence, ↓ libido, gynecomastia, ejaculatory disturbance, may ↑ risk of high-grade prostate cancer.
NOTES: No blood donation until 6 mo after D/C; ↓ PSA, check new baseline PSA at 6 mo (corrected PSA × 2); any PSA rise on dutasteride suspicious for cancer; now available in fixed dose combination w/ tamsulosin (see *Jalyn*); not approved to prevent prostate cancer.

DUTASTERIDE/TAMSULOSIN (JALYN)

USES: *Symptomatic benign prostatic hyperplasia (BPH) in men with an enlarged prostate.*
ACTIONS: 5α-Reductase inhibitor (↓ intracellular DHT) w/ α-blocker.
DOSE: 1 capsule daily after same meal.
W/P: [X, −] w/ CYP3A4 and CYP2D6 inhibitor may ↑ SEs; pregnant women should not handle pills; R/O cancer before starting; intraoperative floppy iris syndrome (tamsulosin related) discuss w/ ophthalmologist before cataract surgery; rare priapism; w/ warfarin; may ↑ risk of high-grade prostate cancer.
CI: Women, peds, component sens.
DISP: Caps 0.5 mg dutasteride w/ 0.4 mg tamsulosin.
SE: Impotence, decreased libido, ejaculation disorders, and breast disorders.
NOTES: No blood donation until 6 mo after D/C; ↓ PSA, check new baseline PSA at 6 mo (corrected PSA × 2); any PSA rise on dutasteride suspicious for cancer (see dutasteride and tamsulosin individual listings).

ECONAZOLE (ECOZA, SPECTAZOLE, GENERIC)

USES: *Tinea, cutaneous *Candida,* & tinea versicolor Infxns.*
ACTIONS: Topical antifungal.
DOSE: Apply to areas BID *Candida;* (daily for tinea versicolor) for 2–4 wk.
W/P: [C, ?].
CI: Component sensitivity.
DISP: Topical cream 1%; *Ecoza* foam 1%.
SE: Local irritation, pruritus, erythema.
NOTES: Early Sx/clinical improvement; complete course to avoid recurrence.

ENALAPRIL (ENALAPRILAT, EPANED KIT, VASOTEC)

WARNING: ACE inhib used during PRG can cause fet al injury & death.
USES: *HTN, CHF, LVD*, DN.
ACTIONS: ACE inhib.

DOSE:

Adults: 2.5–40 mg/d PO; 1.25 mg IV q6h.
Peds: 0.05–0.08 mg/kg/d PO q12–24h; ↓ w/ renal impairment.
W/P: [C (1st tri; D 2nd & 3rd tri), +] D/C immediately w/ PRG, w/ NSAIDs, K^+ suppl.
CI: Bilateral RAS, angioedema.
DISP: Tabs 2.5, 5, 10, 20 mg; *Enalaprilat* IV 1.25 mg/mL; *Epaned Kit* powder for oral (1 mg/mL).
SE: ↓ BP w/ initial dose (esp w/ diuretics), ↑ K^+, ↑ Cr, cough, angioedema.
NOTES: Monitor Cr; D/C diuretic for 2–3 days prior to start.

ENOXAPARIN (LOVENOX)

WARNING: Recent or anticipated epidural/spinal anesthesia, ↑ risk of spinal/epidural hematoma w/ subsequent paralysis.
USES: *Prevention & Treat of DVT; Treat PE; unstable angina & non–Q-wave MI.*
ACTIONS: LMW heparin; inhibit thrombin by complexing w/ antithrombin III.

DOSE:

Adults: *Prevention:* 30 mg SQ BID or 40 mg SQ q24h. *DVT/PE Treat:* 1 mg/kg SQ q12h or 1.5 mg/kg SQ q24h.*;* CrCl < 30 mL/min ↓ to 1 mg/kg SQ q day.
Peds: *Prevention:* 0.5 mg/kg SQ q12h. *DVT/PE Treat:* 1 mg/kg SQ q12h; ↓ dose w/ CrCl < 30 mL/min.
W/P: [B, ?] Not for prophylaxis in prosthetic heart valves.
CI: Active bleeding, heparin-induced thrombocytopenia Ab, heparin, pork sens.
DISP: Inj 10 mg/0.1 mL (30-, 40-, 60-, 80-, 100-, 120-, 150-mg syringes); 300-mg/mL multi-dose vial.
SE: Bleeding, hemorrhage, bruising, thrombocytopenia, fever, pain/hematoma at site, ↑ AST/ALT.
NOTES: No effect on bleeding time, plt function, PT, or aPTT; monitor plt for heparin-induced thrombocytopenia, clinical bleeding; may monitor antifactor Xa; not for IM.

ENZALUTAMIDE (XTANDI)

USES: *Metastatic castration-resistant prostate cancer w/ or w/o previous docetaxel.*
ACTIONS: Androgen receptor inhibitor.
DOSE: (men only): 160 mg daily, do not chew/open caps.
W/P: [X, −] w/ seizure risk; avoid w/ strong CYP2C8 inhibitor, strong/mod CYP3A4 or CYP2C8 induc, avoid CPY3A4, CYP2C9, CYP2C19 substrates w/ narrow therapeutic index.
CI: Pregnancy
DISP: Caps 40 mg.

SE: Headache, dizziness, insomnia, fatigue, anxiety, MS pain, muscle weakness, paresthesia, back pain, spinal cord compression, cauda equina syndrome, arthralgias, edema, URI, lower resp infection, hematuria, ↑ BP.
NOTES: If on warfarin check INR

EPHEDRINE (GENERIC)

USES: *Acute bronchospasm, bronchial asthma, nasal congestion*, ↓ BP, narcolepsy, enuresis, & myasthenia gravis.
ACTIONS: Sympathomimetic; stimulates α/β receptors; bronchodilator.

DOSE:
Adults: *Congestion:* 12.5–25 mg PO q4h PRN w/ expectorant; ↓ *BP:* 25–50 mg IV q5–10min, 150 mg/d max.
Peds: 0.2–0.3 mg/kg/dose IV q4–6h PRN.
W/P: [C, ?/−].
CI: Arrhythmias; narrow-angle glaucoma.
DISP: Caps 25 mg; Inj 50 mg/mL; nasal spray 0.25%.
SE: CNS stimulation (nervousness, anxiety, trembling), tachycardia, arrhythmia, HTN, xerostomia, dysuria.
NOTES: Protect from light; monitor BP, HR, urinary output; can cause false (+) amphetamine EMIT; take last dose 4–6 hr before hs; abuse potential, OTC sales mostly banned/restricted retrograde ejaculation 50 mg QID × 2 wk.

EPOETIN ALFA [ERYTHROPOIETIN, EPO] (EPOGEN, PROCRIT)

WARNING: ↑ Mortality, serious CV/thromboembolic events, and tumor progression. Renal failure pts experienced ↑ greater risks (death/CV events) on erythropoiesis-stimulating agents (ESAs) to target Hgb levels 11 g/dL. Maintain Hgb 10–12 g/dL. In cancer pt, ESAs ↓ survival/time to progression in some cancer when dosed Hgb ≥ 2 g/dL. Use lowest dose needed. Use only for myelosuppressive chemotherapy. D/C following chemotherapy. Preop ESA ↑ DVT. Consider DVT prophylaxis.
USES: *CRF-associated anemia, zidovudine treat in HIV-infected pts, cancer chemotherapy; ↓ transfusions associated w/ surgery.*
ACTIONS: Induces erythropoiesis.

DOSE:
Adults & Peds: 50–150 U/kg IV/SQ 3×/wk; adjust dose q4–6wk PRN. *Surgery:* 300 U/kg/d × 10 days before to 4 days after; ↓ dose if Hct ~36% or Hgb, ↑ > ≅ 12 g/dL or Hgb ↑ >1 g/dL in 2-wk period; hold dose if Hgb >12 g/dL.
W/P: [C, ?/−].
CI: Uncontrolled HTN.
DISP: Inj 2,000, 3,000, 4,000, 10,000, 20,000, 40,000 U/mL.
SE: HTN, headache, fatigue, fever, tachycardia, N/V.
NOTES: Refrigerate; monitor baseline & posttreatment Hct/Hgb, BP, ferritin.

ERTAPENEM (INVANZ)

USES: *Complicated intra-abdominal, acute pelvic, & skin infections, pyelonephritis, community-acquired pneumonia.*
ACTIONS: α-carbapenem; β-lactam antibiotic, ↓ cell wall synth. *Spectrum*: Good gram(+/–) & anaerobic coverage, not *Pseudomonas,* PCN-resistant pneumococci, MRSA, *Enterococcus,* β-lactamase (+) *H. influenzae, Mycoplasma, Chlamydia.*

DOSE:

Adults: 1 g IM/IV daily; 500 mg/d in CrCl <30 mL/min.
Peds: ***3 mo–12 yr:*** 15 mg/kg BID IM/IV, max. 1 g/d.
W/P: [B, ?/−] seizure Hx, CNS disorders, β-lactam & multiple allergies, probenecid ↓ renal clearance.
CI: Component hypersens or amide anesthetics.
DISP: Inj 1 g/vial.
SE: Headache, N/V/diarrhea, Inj site reactions, thrombocytosis, ↑ LFTs.
NOTES: Can give IM × 7 days, IV × 14 days; 137 mg Na^+ (6 mEq)/g ertapenem; do not mix with dextrose infusion.

ERYTHROMYCIN (E-MYCIN, EES, ERY-TAB, ERYPED, ILOTYCIN, GENERIC)

USES: *Bacterial infections; bowel prep, acne vulgaris *; ↑ GI motility (*prokinetic*).
ACTIONS: Bacteriostatic; interferes w/ protein synth. *Spectrum:* Group A streptococci (*S. pyogenes*), *S. pneumoniae, N. gonorrhoeae* (if PCN-allergic), *Legionella, M. pneumonia.*

DOSE:

Adults: *Base* 250–500 mg PO q6–12h or *ethylsuccinate* 400–800 mg q6–12h; 500 mg–1 g IV q6h. *Prokinetic:* 250 mg PO TID 30 min ac.
Peds: 30–50 mg/kg/d PO ÷ q6–8h or 20–40 mg/kg/d IV ÷ q6h, max. 2 g/d.
W/P: [B, +] Pseudomembranous colitis risk, ↑ tox of carbamazepine, cyclosporine, digoxin, methylprednisolone, theophylline, felodipine, warfarin, simvastatin/lovastatin; ↓ sildenafil dose w/ use.
CI: Hepatic impairment, pre-existing liver disease (estolate), use w/ pimozide ergotamine dihydroergotamine.
DISP: *Lactobionate (Ilotycin): Powder for Inj* 500 mg, 1 g. *Base:* Tabs 250, 333, 500 mg; caps 250 mg. *Stearate (Erythrocin):* Tabs 250, 500 mg. *Ethylsuccinate (EES, EryPed):* Chew tabs 200 mg; tabs 400 mg; susp 200, 400 mg/5 mL.
SE: Headache, abdominal pain, N/V/diarrhea; ↑ QT, torsades de pointes, ventricular arrhythmias/tachycardias (rarely); cholestatic jaundice (estolate).
NOTES: 400 mg ethylsuccinate = 250 mg base/estolate; w/ food minimizes GI upset; lactobionate contains benzyl alcohol (caution in neonates).

ESTERIFIED ESTROGENS (MENEST)

WARNING: ↑ Risk endometrial cancer. Do not use in the prevention of CV disease or

dementia; ↑ risk of MI, stroke, breast cancer, PE, DVT, in postmenopausal.
USES: *Vasomotor Sxs or vulvar/Vag atrophy w/ menopause; female hypogonadism, palliation of advanced prostate cancer.*
ACTIONS: Estrogen supl.
DOSE: *Menopausal vasomotor Sx:* 0.3–1.25 mg/d, cyclically 3 wk on, 1 wk off; add progestin 10–14 days w/ 28-day cycle w/ uterus intact; *Vulvovaginal atrophy:* Same regimen except use 0.3–1.25 mg; *Hypogonadism:* 2.5–7.5 mg/d PO × 20 days, off × 10 days; add progestin 10–14 days w/ 28-day cycle w/ uterus intact.
W/P: [X, −].
CI: Undiagnosed genital bleeding, breast cancer, estrogen-dependent tumors, thromboembolic disorders, thrombophlebitis, recent MI, pregnancy, severe hepatic disease.
DISP: Tabs 0.3, 0.625, 1.25, 2.5 mg.
SE: N, headache, bloating, breast enlargement/tenderness, edema, venous thromboembolism, hypertriglyceridemia, gallbladder disease.
NOTES: Use lowest dose for shortest time (see WHI data [www.whi.org]).

ESTRADIOL, GEL (DIVIGEL)

WARNING: ↑ Risk endometrial cancer. Do not use to prevent CV disease or dementia; ↑ risk MI, stroke, breast cancer, PE, and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥65 yr).
USES: *Vasomotor Sx in menopause.*
ACTIONS: Estrogen.
DOSE: 0.25 g q day on right or left upper thigh (alternate).
W/P: [X, +/−] May ↑ thyroid binding globulin (TBD) w/ thyroid disease.
CI: Alcohol, caution around flames until dry, not for Vag use.

ESTRADIOL, METERED GEL (ELESTRIN, ESTROGEL)

WARNING: ↑ Risk endometrial cancer. Do not use to prevent CV disease or dementia; ↑ risk MI, stroke, breast cancer, PE, and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥65 yr).
USES: *Postmenopausal vasomotor Sxs.*
ACTIONS: Estrogen.
DOSE: Apply 0.87–1.7 g to upper arm skin q day; add progestin × 10–14 days/28-day cycle w/ intact uterus; use lowest effective estrogen dose.
W/P: [X, ?].
CI: AUB, breast cancer, estrogen-dependent tumors, hereditary angioedema, thromboembolic disorders, recent MI, PREGNANCY, severe hepatic disease.
DISP: Gel 0.06%; metered dose/activation.
SE: Thromboembolic events, MI, stroke, ↑ BP, breast/ovarian/endometrial cancer, site reactions, Vag spotting, breast changes, abdominal bloating, cramps, headache, fluid retention.
NOTES: Wait >25 min before sunscreen; avoid concomitant use for >7 days; BP, breast exams.

ESTRADIOL, ORAL (DELESTROGEN, ESTRACE, FEMTRACE, GENERIC)

WARNING: ↑ Risk endometrial cancer. Do not use to prevent CV disease or dementia; ↑ risk MI, stroke, breast cancer, PE, and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥65 yr).
USES: *Atrophic vaginitis, menopausal vasomotor Sxs, prevent osteoporosis, ↑ low estrogen levels, palliation breast and PCa.*
ACTIONS: Estrogen.
DOSE: *PO:* 1–2 mg/d, adjust PRN to control Sxs. *Vag cream:* 2–4 g/d × 2 wk, then 1 g 1–3×/wk. *Vasomotor Sx/Vag atrophy:* 10–20 mg IM q4wk, D/C or taper at 3- to 6-mo intervals. *Hypoestrogenism:* 10–20 mg IM q4wk. *PCa:* 30 mg IM q12wk.
W/P: [X, −].
CI: Genital bleeding of unknown cause, breast cancer, porphyria, estrogen-dependent tumors, thromboembolic disorders, thrombophlebitis; recent MI; hepatic impairment.
DISP: Tabs 0.5, 1, 2 mg; depot Inj (*Delestrogen*) 10, 20, 40 mg/mL.
SE: N, headache, bloating, breast enlargement/tenderness, edema, ↑ triglycerides, venous thromboembolism, gallbladder disease.
NOTES: When estrogen used in postmenopausal w/ uterus, use w/ progestin.

ESTRADIOL, SPRAY (EVAMIST)

WARNING: ↑ Risk endometrial cancer. Do not use to prevent CV disease or dementia; ↑ risk MI, stroke, breast cancer, PE, and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥65 yr)
USES: *Vasomotor Sx in menopause.*
ACTIONS: Estrogen supl.
DOSE: 1 spray on inner surface of forearm.
W/P: [X, +/−] May ↑ PT/PTT/plt aggregation w/ thyroid disease.
CI: Undiagnosed genital bleeding, breast cancer, estrogen-dependent tumors, thromboembolic disorders, thrombophlebitis, recent MI, PREGNANCY, severe hepatic disease.
DISP: 1.53 mg/ spray (56-spray container).
SE: N, headache, bloating, breast enlargement/tenderness, edema, venous thromboembolism, ↑ BP, hypertriglyceridemia, gallbladder disease.
NOTES: Contains alcohol, caution around flames until dry; not for Vag use.

ESTRADIOL, TRANSDERMAL (ALORA, CLIMARA, ESTRADERM, VIVELLE DOT)

WARNING: ↑ Risk endometrial cancer. Do not use to prevent CV disease or dementia; ↑ risk MI, stroke, breast cancer, PE, and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥65 yr)
USES: *Severe menopausal vasomotor Sxs; female hypogonadism.*
ACTIONS: Estrogen supl.
DOSE: Start 0.0375–0.05 mg/d patch 1–2×/wk based on product (*Climara* 1×/wk; *Alora* 2×wk) adjust PRN to control Sxs; w/ intact uterus cycle 3 wk on 1 wk off or use cyclic progestin 10–14 days.

W/P: [X, −] See estradiol.
CI: Pregnancy, AUB, porphyria, breast cancer, estrogen-dependent tumors, Hx thrombophlebitis, thrombosis.
DISP: Transdermal patches (mg/24 h) 0.025, 0.0375, 0.05, 0.06, 0.075, 0.1.
SE: N, bloating, breast enlargement/tenderness, edema, headache, hypertriglyceridemia, gallbladder disease.
NOTES: Do not apply to breasts, place on trunk, rotate sites; see estradiol, oral notes.

ESTRADIOL, VAGINAL (ESTRING, FEMRING, VAGIFEM)

WARNING: ↑ Risk endometrial cancer. Do not use to prevent CV disease or dementia; ↑ risk MI, stroke, breast cancer, PE, and DVT in postmenopausal (50–79 y). ↑ Dementia risk in postmenopausal (≥ 65 y).
USES: *Postmenopausal Vag atrophy *(Estring)** *vasomotor Sxs and vulvar/vag atrophy associated w/ menopause *(Femring)** *atrophic vaginitis (*Vagifem)**
ACTIONS: Estrogen supl.
DOSE: *Estring:* Insert ring into upper 3rd of Vag vault; remove and replace after 90 d; reassess 3–6 mo; *Femring:* Use lowest effective dose, insert vaginally, replace q3mo; *Vagifem:* 1 tab vaginally q day × 2 wk, then maint 1 tab 2×/ wk, D/C or taper at 3–6 mo.
W/P: [X, −] May ↑ PT/PTT/plt aggregation w/ thyroid disease, toxic shock reported.
CI: Undiagnosed genital bleeding, breast cancer, estrogen- dependent tumors, thromboembolic disorders, thrombophlebitis, recent MI, pregnancy, severe hepatic disease.
DISP: *Estring ring:* 0.0075 mg/24 h; *Femring ring:* 0.05 and 0.1 mg/d *Vagifem tab (Vag):* 10 µg.
SE: Headache, leukorrhea, back pain, candidiasis, vaginitis, Vag discomfort/hemorrhage, arthralgia, insomnia, abdominal pain; see estradiol, oral notes.

ESTRADIOL/LEVONORGESTREL, TRANSDERMAL (CLIMARA PRO)

WARNING: ↑ Risk endometrial cancer. Do not use to prevent CV disease or dementia; ↑ risk MI, stroke, breast cancer, PE, and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥65 yr).
USES: *Menopausal vasomotor Sx; prevent postmenopausal osteoporosis.*
ACTIONS: Estrogen & progesterone.
DOSE: 1 patch 1×/wk.
W/P: [X, −] w/ ↓ thyroid.
CI: AUB, estrogen-sensitive tumors, Hx thromboembolism, liver impairment, pregnancy, hysterectomy.
DISP: Estradiol 0.045 mg/levonorgestrel 0.015 mg/day patch.
SE: Site reaction, Vag bleed/spotting, breast changes, abdominal bloating/ cramps, headache, retention fluid, edema, ↑ BP.
NOTES: Apply in lower abdomen; for osteoporosis give Ca^{2+}/vit D supl; follow breast exams.

ESTRADIOL/NORETHINDRONE (ACTIVELLA, FEMHRT, GENERIC)

WARNING: ↑ Risk endometrial cancer. Do not use to prevent CV disease or dementia; ↑ risk MI, stroke, breast cancer, PE, and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in

postmenopausal (≥65 yr).
USES: *Menopause vasomotor Sxs; vulvar and vaginal atrophy; prevent osteoporosis.*
ACTIONS: Estrogen/progestin; plant derived.
DOSE: 1 tab/d start w/ lowest dose combo.
W/P: [X, −] w/ ↓ Ca^{2+}/thyroid.
CI: Pregnancy; Hx breast cancer; estrogen-dependent tumor; abnormal genital bleeding; Hx DVT, PE, or related disorders; recent (w/in past year) arterial thromboembolic disease (CVA, MI).
DISP: *Femhrt:* Tabs 2.5/0.5, 5 μg/1 mg; *Activella:* Tabs 1/0.5, 0.5 mg/0.1 mg.
SE: Thrombosis, dizziness, headache, libido changes, insomnia, emotional instability, breast pain.
NOTES: Use in women w/ intact uterus; caution in heavy smokers; combo also used as oral contraceptive.

ESTRAMUSTINE PHOSPHATE (EMCYT)

USES: *Palliative treatment of metastatic and/or progressive carcinoma of the prostate.*
ACTIONS: Estradiol w/ nitrogen mustard; exact mechanism unknown.
DOSE: 14 mg/kg/d in 3–4 ÷ doses; on empty stomach, no dairy products.
W/P: [NA, not used in females].
CI: Active thrombophlebitis or thromboembolic disorders.
DISP: Caps 140 mg.
SE: N/V, exacerbation of pre-existing CHF, edema, hepatic disturbances, thrombophlebitis, MI, PE, gynecomastia in 20–100%.
NOTES: Low-dose breast irradiation before may ↓ gynecomastia.

ESTROGEN, CONJUGATED (PREMARIN)

WARNING: ↑ Risk endometrial cancer. Do not use to prevent CV disease or dementia; ↑ risk MI, stroke, breast cancer, PE, and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥65 yr).
USES: *Mod–severe menopausal vasomotor Sxs; atrophic vaginitis; hypoestrogenism; palliation of advanced breast and prostate cancer; prevention osteoporosis.*
ACTIONS: Estrogen replacement.
DOSE: 0.3–1.25 mg/d PO; intravaginal cream 0.5–2 g × 21 days, then off × 7 days or 0.5 mg twice weekly.
W/P: [X, −].
CI: Severe hepatic impairment, genital bleeding of unknown cause, breast cancer, estrogen-dependent tumors, thromboembolic disorders, thrombosis, thrombophlebitis, recent MI.
DISP: Tabs 0.3, 0.45, 0.625, 0.9, 1.25 mg; Vag cream 0.625 mg/g.
SE: ↑ Risk of endometrial cancer, gallbladder disease, thromboembolism, headache, & possibly breast cancer.
NOTES: Generic products not equivalent.

ESTROGEN, CONJUGATED/MEDROXYPROGESTERONE (PREMPRO,

PREMPHASE)
WARNING: ↑ Risk endometrial cancer. Do not use to prevent CV disease or dementia; ↑ risk MI, stroke, breast cancer, PE, and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥65 yr).
USES: *Mod–severe menopausal vasomotor Sxs; atrophic vaginitis; prevent postmenopausal osteoporosis.*
ACTIONS: Hormonal replacement.
DOSE: *Prempro* 1 tab PO daily; *Premphase* 1 tab PO daily.
W/P: [X, −].
CI: Severe hepatic impairment, genital bleeding of unknown cause, breast cancer, estrogen-dependent tumors, thromboembolic disorders, thrombosis, thrombophlebitis.
DISP: (As estrogen/medroxyprogesterone) *Prempro:* Tabs 0.3/1.5, 0.45/1.5, 0.625/2.5, 0.625/5 mg; *Premphase:* Tabs 0.625/0 (days 1–14) & 0.625/5 mg (days 15–28).
SE: Gallbladder disease, thromboembolism, headache, breast tenderness.
NOTES: See WHI (www.whi.org); use lowest dose/shortest time possible.

ESTROGEN, CONJUGATED SYNTHETIC (CENESTIN, ENJUVIA)

WARNING: ↑ Risk endometrial cancer. Do not use to prevent CV disease or dementia; ↑ risk MI, stroke, breast cancer, PE, and DVT in postmenopausal (50–79 yr). ↑ Dementia risk in postmenopausal (≥65 yr).
USES: *Vasomotor menopausal Sxs, vulvovaginal atrophy.*
ACTIONS: Multiple estrogen replacement.
DOSE: For all w/ intact uterus progestin × 10–14 days/28-day cycle; *Vasomotor:* 0.3–1.25 mg (*Enjuvia*) 0.625–1.25 mg (*Cenestin*) PO daily; *Vag atrophy:* 0.3 mg/d.
W/P: [X, −].
CI: See Estrogen, conjugated.
DISP: Tabs, *Cenestin*, 0.3, 0.45, 0.625, 0.9, 1.25 mg; *Enjuvia* ER 0.3, 0.45, 0.625, 0.9, 1.25 mg.
SE: ↑ Risk endometrial/breast cancer, gallbladder disease, thromboembolism.

ETHAMBUTOL (MYAMBUTOL, GENERIC)

USES: *Pulmonary TB* and other mycobacterial infections, mycobacterium avium complex (MAC).
ACTION: ↓ RNA synthesis.

DOSE:
Adults & Peds: ***>12 yr:*** 15–25 mg/kg/d PO single dose; ↓ in renal impairment, take w/ food, avoid antacids.
W/P: [C, +].
CI: Unconscious patients, optic neuritis.
DISP: Tablets 100, 400 mg.
SE: Headache, hyperuricemia, acute gout, abdominal pain, ↑ LFTs, optic neuritis (decreased visual acuity), GI upset.

ETIDRONATE DISODIUM (DIDRONEL, GENERIC)

USES: *Paget disease, heterotopic ossification.*
ACTIONS: ↓ Nl & abnormal bone resorption.
DOSE: *Paget disease:* 5–10 mg/kg/d PO ÷ doses (for 3–6 mo). ↑ Ca^{2+}*:* 20 mg/kg/d IV × 30–90 days.
W/P: [B PO (C parenteral),?] Bisphosphonates may cause severe musculoskelet al pain.
CI: Esophageal abnormalities.
DISP: Tabs 200, 400 mg.
SE: GI intolerance (↓ by ÷ daily doses); hyperphosphatemia, hypomagnesemia, bone pain, abnormal taste, fever, convulsions, nephrotoxic.
NOTES: Take PO on empty stomach 2 hr before or 2 hr pc; not approved for osteoporosis.

ETOPOSIDE [VP-16] (ETOPOPHOS, GENERIC)

WARNING: Should be administered under the supervision of a qualified physician experienced in the use of chemotherapy. Severe myelosuppression with resulting infection or bleeding may occur.
USES: *Small cell lung cancer* testicular cancer, Hodgkin disease, & NHLs, peds ALL, & BMT in high doses.*
ACTIONS: Topoisomerase II inhibitor.
DOSE: 50 mg/m^2/d IV for 3–5 days; 50 mg/m^2/d PO for 21 days (PO availability = 50% of IV); 2–6 g/m^2 or 25–70 mg/kg in BMT (per protocols); ↓ in renal/hepatic impairment.
W/P: [D, −].
CI: IT administration.
DISP: Caps 50 mg; Inj 20 mg/mL.
SE: N/V (emesis in 10–30%), ↓ BM, alopecia, ↓ BP w/ rapid IV, anorexia, anemia, leukopenia, ↑ risk secondary leukemias.

EVEROLIMUS (AFINITOR, AFINITOR DISPERZ)

USES: **Afinitor:* Hormone receptor positive, HER2-negative breast cancer w/ exemestane after failure of letrozole or anastrozole; unresectable progressive neuroendocrine tumors of pancreatic origin (PNET); advanced renal cell carcinoma (RCC) after failure of sunitinib or sorafenib; adults with renal angiomyolipoma and tuberous sclerosis complex (TSC), not requiring immediate surgery. *Afinitor and Afinitor Disperz:* Pediatric and adult with tuberous sclerosis complex (TSC) who have subependymal giant cell astrocytoma (SEGA) that requires therapeutic intervention but cannot be resected.*
ACTIONS: mTOR inhibitor.
DOSE: 10 mg PO daily, ↓ to 5 mg w/ SE or hepatic impairment; avoid w/ high-fat meal.
W/P: [D, ?] Avoid w/ live vaccines; w/ CYP3A4 inhibitor.
CI: Compound/rapamycin-derivative hypersens.
DISP: Tabs 2.5, 5, 7.5, 10 mg; Disperz for suspen 2, 3, 5 mg.
SE: Noninfectious pneumonitis, ↑ infection risk, oral ulcers, asthenia, cough, fatigue, diarrhea, ↑ glucose/SCr/lipids; ↓ hemoglobin/WBC/plt.
NOTES: Follow CBC, LFT, glucose, lipids; see also everolimus (*Zortress*).

EVEROLIMUS (ZORTRESS)

USES: *Prevent renal and liver transplant rejection; combo w/ basiliximab w/ ↓ dose of steroids and cyclosporine.*
ACTIONS: mTOR inhibitor (mammalian rapamycin target).
DOSE: 0.75 mg PO BID, adjust to trough levels 3–8 ng/ mL.
W/P: [D, ?].
CI: Compound/rapamycin-derivative hypersens.
DISP: Tabs 0.25, 0.5, 0.75 mg.
SE: Peripheral edema, constipation, ↑ BP, N, ↓ Hct, UTI, ↑ lipids.
NOTES: Follow CBC, LFT, glucose, lipids; *Trough level* 3–8 ng/mL w/ cyclosporine see also everolimus (*Afinitor*).

FAMCICLOVIR (FAMVIR, GENERIC)

USES: *Acute herpes zoster (shingles) & genital herpes.*
ACTIONS: ↓ Viral DNA synth.
DOSE: *Zoster:* 500 mg PO q8h × 7 days. *Simplex:* 125–250 mg PO BID; ↓ w/ renal impairment.
W/P: [B, −].
CI: Component sensitivity.
DISP: Tabs 125, 250, 500 mg.
SE: Fatigue, dizziness, headache, pruritus, N/diarrhea.
NOTES: Best w/in 72 hr of initial lesion.

FEBUXOSTAT (ULORIC)

USES: *Hyperuricemia and gout.*
ACTIONS: Xanthine oxidase inhibitor (enzyme that converts hypoxanthine to xanthine to uric acid).
DOSE: 40 mg PO 1 × day, ↑ 80 mg if uric acid not <6 mg/dL after 2 wk.
W/P: [C, ?/−].
CI: Use w/ azathioprine, mercaptopurine, theophylline.
SUPPLIED: Tabs 40, 80 mg.
SE: ↑ LFTs, rash, myalgia.
NOTES: OK to continue w/ gouty flare or use w/ NSAIDs.

FENTANYL, INJECTION (SUBLIMAZE, GENERIC) [C-II]

USES: *Short-acting analgesic in anesthesia* & patient controlled analgesia.
ACTIONS: Narcotic analgesic.

DOSE:

Adults: 1–2 µg/kg *or* 25–100 µg/dose IV/IM titrated; *Anesthesia:* 5–15 µg/kg; *Pain:* 200 µg over 15 min, titrate to effect.
Peds: 1–2 µg/kg IV/IM q1–4h titrate; ↓ in renal impairment, elderly.
W/P: [B,+] To be used only by those experienced with medication; hypotension possible w/

tranquilizer use.
CI: Opioid intolerance.
DISP: Inj 0.05 mg/mL.
SE: Sedation, ↓ BP, ↓ HR, constipation, N, resp depression, miosis.
NOTES: 50 µg = 0.05 mg = 1 mL; 0.1 mg fentanyl = 10 mg morphine IM.

FENTANYL, TRANSDERMAL (DURAGESIC, GENERIC) [C-II]

WARNING: Potential for abuse and fatal OD; resp depression possible; accidental exposure can be fatal; initiation of CYP 3A4 inhibitors (or discontinuation of CYP 3A4 inducers) can result in a fatal OD; avoid heat to application site, can cause OD.
USES: *Persistent mod–severe chronic pain in pts already tolerant to opioids.*
ACTIONS: Narcotic.
DOSE: Apply patch to upper torso q72h; dose based on narcotic requirements in previous 24 hr; start 25 µg/h patch q72h; ↓ in renal impairment.
W/P: [B, +] w/ CYP3A4 inhibitor or D/C CYP3A4 inducer may ↑ fentanyl effect, w/ Hx substance abuse.
CI: Not opioid tolerant, short-term pain management, postop outpatient pain in outpatient surgery, mild pain, PRN use, ↑ ICP, resp depression, severe renal/hepatic impairment, peds <2 yr.
DISP: Patches 12.5, 25, 50, 75, 100 µg/h.
SE: Resp depression (can be fatal), sedation, ↓ BP, ↓ HR, constipation, N, miosis.
NOTES: 0.1 mg fentanyl = 10 mg morphine IM; do not cut patch; peak level in PREGNANCY 24–72 hr.

FENTANYL, TRANSMUCOSAL (ABSTRAL, ACTIQ, FENTORA, LAZANDA, ONSOLIS, GENERIC) [C-II]

WARNING: Potential for abuse and fatal OD; use only in pts w/ chronic pain who are opioid tolerant; CI in acute/postop pain; do not substitute for other fentanyl products; fentanyl can be fatal to children, keep away; use w/ strong CYP3A4 inhibitor may ↑ fentanyl levels. *Abstral, Onsolis* restricted distribution.
USES: *Breakthrough cancer pain w/ tolerance to opioids.*
ACTIONS: Narcotic analgesic, transmucosal absorption.
DOSE: Titrate to effect.

- *Abstral:* Start 100 µg SL, 2 doses max. per pain breakthrough episode; wait 2 hr for next breakthrough dose; limit to <4 breakthrough doses w/ successful baseline dosing.
- *Actiq*: Start 200 µg PO × 1, may repeat × 1 after 30 min.
- *Fentora*: Start 100 µg buccal tab × 1, may repeat in 30 min, 4 tabs/dose max.
- *Lazanda:* Through TIRF REMS Access Program; initial 1 × 100 µg spray; if no relief, titrate for breakthrough pain as follows: 2 × 100 µg spray (1 in each nostril); 1 × 400 µg; 2 × 400 µg (1 in each nostril); wait 2 hr before another dose; max. 4 doses/24 h.
- *Onsolis*: Start 200 µg film, ↑ 200 µg increments to max. four 200-µg films or single 1,200-µg film.

W/P: [B, +] resp/CNS depression possible; CNS depressants/CYP3A4 inhibitor may ↑ effect;

may impair tasks (driving, machinery); w/ severe renal/hepatic impairment.
CI: Opioid intolerant pt, acute/postop pain.
DISP:
- *Abstral:* SL tabs 100, 200, 300, 400, 600, 800 µg
- *Actiq:* Lozenges on stick 200, 400, 600, 800, 1,200, 1,600 µg
- *Fentora:* Buccal tabs 100, 200, 400, 600, 800 µg
- *Lazanda:* Nasal spray metered dose audible and visual counter, 8 doses/bottle, 100/400 µg/spray
- *Onsolis:* Buccal soluble film 200, 400, 600, 800, 1,200 µg

SE: Sedation, ↓ BP, ↓ HR, constipation, N/V, ↓ resp, dyspnea, headache, miosis, anxiety, confusion, depression, rash dizziness.
NOTES: 0.1 mg fentanyl = 10 mg IM morphine.

FERRIC CARBOXYMALTOSE (INJECTAFER)

USES: *Iron-deficiency anemia.*
ACTIONS: Fe Supl.

DOSE:

Adults: ≥50 kg: 2 doses 750 mg IV separated by 7 days; <50 kg: 2 doses of 15 mg/kg IV separated by 7 days.
W/P: [C, M] Hypersens rxn (monitor during & 30 min after inf).
CI: Component hypersens.
DISP: Inj 750 mg iron/15 mL single-use vial.
SE: N, HTN, flushing, hypophosphatemia, dizziness, HTN.

FERROUS GLUCONATE (FERGON [OTC] , OTHERS)

WARNING: Accidental OD of iron-containing products is a leading cause of fatal poisoning in children <6 yr. Keep out of reach of children.
USES: *Iron-deficiency anemia* & Fe supl.
ACTIONS: Dietary supl.

DOSE:

Adults: 100–200 mg of elemental Fe/d ÷ doses.
Peds: 4–6 mg/kg/d ÷ doses; on empty stomach (OK w/ meals if GI upset occurs); avoid antacids.
W/P: [A,?].
CI: Hemochromatosis, hemolytic anemia.
DISP: Tabs Fergon 240 (27 mg Fe), 246 (28 mg Fe), 300 (34 mg Fe), 324 mg (38 mg Fe).
SE: GI upset, constipation, dark stools, discoloration of urine, may stain teeth.
NOTES: 12% elemental Fe; false (+) stool guaiac; keep away from children; severe tox in OD.

FERROUS GLUCONATE COMPLEX (FERRLECIT)

USES: *Iron-deficiency anemia or supl to erythropoietin Treat therapy.*
ACTIONS: Fe supl.
DOSE: *Test dose:* 2 mL (25 mg Fe) IV over 1 hr, if OK, 125 mg (10 mL) IV over 1 hr. *Usual cumulative dose:* 1 g Fe over 8 sessions (until favorable Hct).
W/P: [B, ?].
CI: Non–Fe-deficiency anemia; CHF; Fe overload.
DISP: Inj 12.5 mg/mL Fe.
SE: ↓ BP, serious allergic reactions, GI disturbance, Inj site reaction.
NOTES: Dose expressed as mg Fe; may infuse during dialysis.

FERROUS SULFATE (OTC)

USES: *Fe-deficiency anemia & Fe supl.*
ACTIONS: Dietary supl.

DOSE:

Adults: 100–200 mg elemental Fe/d in ÷ doses.
Peds: 1–6 mg/kg/d ÷ daily–TID; on empty stomach (OK w/ meals if GI upset occurs); avoid antacids.
W/P: [A, ?] ↑ Absorption w/ vit C; ↓ absorption w/ tetracycline, fluoroquinolones, antacids, H_2 blockers, proton pump inhibitor.
CI: Hemochromatosis, hemolytic anemia.
DISP: Tabs 187 (60 mg Fe), 200 (65 mg Fe), 324 (65 mg Fe), 325 mg (65 mg Fe); SR caplets & tabs 160 (50 mg Fe), 200 mg (65 mg Fe); gtt 75 mg/0.6 mL (15 mg Fe/0.6 mL); elixir 220 mg/5 mL (44 mg Fe/5 mL); syrup 90 mg/5 mL (18 mg Fe/5 mL).
SE: GI upset, constipation, dark stools, discolored urine.

FERUMOXYTOL (FERAHEME)

USES: *Iron-deficiency anemia in chronic kidney disease.*
ACTIONS: Fe replacement.

DOSE:

Adults: 510 mg IV × 1, then 510 mg IV × 1 3–8 days later; give 1 mL/s.
W/P: [C, ?/−] Monitor for hypersens & ↓ BP for 30 min after dose, may alter MRI studies.
CI: Iron overload; hypersens to ferumoxytol.
DISP: IV soln 30 mg/mL (510 mg elemental Fe/17 mL).
SE: N/diarrhea, constipation, dizziness, hypotension, peripheral edema, hypersens reaction.
NOTES: Check hematologic response 1 mo after 2nd dose.

FESOTERODINE (TOVIAZ)

USES: * Overactive bladder w/ urge urinary incontinence, urgency, frequency.*
ACTIONS: Competitive muscarinic receptor antagonist, ↓ bladder muscle contractions.
DOSE: 4 mg PO qd, ↑ to 8 mg PO daily PRN.
W/P: [C, /?] Avoid >4 mg w/ severe renal insufficiency or w/ CYP3A4 inhibitor (eg,

ketoconazole, clarithromycin); w/ bladder outlet obstruction, ↓ GI motility/constipation, narrow-angle glaucoma, myasthenia gravis.
CI: Urinary/gastric retention, or uncontrolled narrow-angle glaucoma, hypersens to class.
DISP: Tabs 4, 8 mg.
SE: Dry mouth, constipation, ↓ sweating can cause heat prostration.

FIDAXOMICIN (DIFICID)

USES: **Clostridium difficile*-associated diarrhea.*
ACTIONS: Macrolide antibiotic.
DOSE: 200 mg PO BID × 10 days.
W/P: [B, +/−] Not for systemic infection or <18 yr; to ↓ resistance, use only when diagnosis suspected/ proven.
DISP: Tabs 200 mg.
SE: N/V, abdominal pain, GI bleed, anemia, neutropenia.

FINASTERIDE (PROSCAR [GENERIC] , PROPECIA)

USES: *BPH & androgenetic alopecia.*
ACTIONS: ↓ 5-α-reductase.
DOSE: *BPH:* 5 mg/d PO. *Alopecia:* 1 mg/d PO; food ↓ absorption.
W/P: [X, −] Hepatic impairment.
CI: Pregnant women should avoid handling pills, teratogen to male fetus.
DISP: Tabs 1 mg (*Propecia*), 5 mg (*Proscar*).
SE: ↓ Libido, vol ejaculate, erectile dysfunction, gynecomastia; may slightly ↑ risk of high-grade prostate cancer.
NOTES: Both ↓ PSA by ~50%; reestablish PSA baseline 6 mo (double PSA for "true" reading); 3–6 mo for effect on urinary Sxs; continue to maintain new hair, not for use in women.

FLAVOXATE (GENERIC)

USES: *Relief of Sx of dysuria, urgency, nocturia, suprapubic pain, urinary frequency, incontinence.*
ACTIONS: Antispasmodic.
DOSE: 100–200 mg PO TID–QID.
W/P: [B, ?].
CI: GI obst, GI hemorrhage, ileus, achalasia, BPH.
DISP: Tabs 100 mg.
SE: Drowsiness, blurred vision, xerostomia.
NOTE: Urispas brand discontinued.

FLUCONAZOLE (DIFLUCAN, GENERIC)

USES: *Candidiasis (esophageal, oropharyngeal, urinary tract, Vag, prophylaxis); cryptococcal meningitis, prophylaxis w/ BMT.*
ACTIONS: Antifungal; ↓ cytochrome P-450 sterol demethylation. *Spectrum:* All *Candida* sp

except *C. krusei.*

DOSE:
Adults: 100–400 mg/d PO or IV. *Vaginitis:* 150 mg PO daily.
Peds: 3–6 mg/kg/d PO or IV; 12 mg/kg/d/systemic infection; ↓ in renal impairment.
W/P: [C, Vag candidiasis (D high or prolonged dose), −] Do not use w/ clopidogrel (↓ effect).
CI: Hypersensitivity, terfenadine with high dose fluconazole; w/ drugs that ↑ QT interval and are metabolized via CYP3A4 (cisapride, astemizole, erythromycin, pimozide, quinidine).
DISP: Tabs 50, 100, 150, 200 mg; susp 10, 40 mg/mL; Inj 2 mg/mL.
SE: Headache, rash, GI upset, ↓ K^+, ↑ LFTs.
NOTES: PO (preferred) = IV levels; cong anomalies w/ high dose 1st tri.

FLUDROCORTISONE ACETATE (GENERIC)

USES: *Adrenocortical insufficiency, Addison disease, salt-wasting adrenogenital syndrome.*
ACTIONS: Mineralocorticoid.

DOSE:

Adults: 0.1–0.2 mg/d PO.
Peds: 0.05–0.1 mg/d PO.
W/P: [C, ?].
CI: Systemic fungal infections; known hypersensitivity.
DISP: Tabs 0.1 mg.
SE: HTN, edema, CHF, headache, dizziness, convulsions, acne, rash, bruising, hyperglycemia, hypothalamic—pituitary–adrenal suppression, cataracts.
NOTES: For adrenal insufficiency, use w/ glucocorticoid; dose adjustments based on plasma renin activity.

FLUOROURACIL, INJECTION [5-FU] (GENERIC)

WARNING: Administration by experienced chemotherapy physician only; pts should be hospitalized for 1st course d/t risk for severe reaction.
USES: *Palliative management of carcinoma of the colon, rectum, breast, stomach and pancreas*, head, neck, bladder cancers.
ACTIONS: Inhibits thymidylate synthetase (↓ DNA synth, S-phase specific).
DOSE: 370–1,000 mg/m^2/d × 1–5 days IV push to 24-hr cont Inf; protracted venous Inf of 200–300 mg/m^2/d (per protocol); 800 mg/d max.
W/P: [D, ?] ↑ Tox w/ allopurinol; do not give live vaccine before 5-FU.
CI: Poor nutritional status, depressed BM function, thrombocytopenia, major surgery w/in past mo, G6PD enzyme deficiency, pregnancy, serious infection, bili >5 mg/dL.
DISP: Inj 50 mg/mL.
SE: Stomatitis, esophagopharyngitis, N/V/diarrhea, anorexia, ↓ BM, rash/dry skin/photosensitivity, tingling in hands/feet w/ pain (palmar-plantar erythrodysesthesia), phlebitis/discoloration at Inj sites.
NOTES: ↑ Thiamine intake; contraception OK.

FLUOROURACIL, TOPICAL [5-FU] (CARAC, EFUDEX, FLUOROPLEX, GENERIC)

USES: *Basal cell carcinoma (when standard therapy impractical); actinic/solar keratosis* carcinoma in situ (CIS) of the penis,
ACTIONS: Inhibits thymidylate synthetase (↓ DNA synth, S-phase specific),
DOSE: 5% cream BID × 2–6 wk,
W/P: [D, ?] Irritant chemotherapy,
CI: Component sensitivity,
DISP: Cream 0.5, 1, 5%; soln 1%, 2%, 5%.
SE: Rash, dry skin, photosensitivity.
NOTES: Healing may not be evident for 1–2 mo; wash hands thoroughly; avoid occlusive dressings; do not overuse; typical penile regimen described: apply 12 hr every 48 hr for 28 days.

FLUOXETINE (GABOXETINE, PROZAC, PROZAC WEEKLY, SARAFEM, GENERIC)

WARNING: Closely monitor for worsening depression or emergence of suicidality, particularly in ped pt.
USES: *Depression, OCD, panic disorder, bulimia (*Prozac*)* premature ejaculation* PMDD (*Sarafem*).*
ACTIONS: SSRI.
DOSE: 20 mg/d PO (max. 80 mg/d ÷ dose); weekly 90 mg/wk after 1–2 wk of standard dose. *Bulimia:* 60 mg q a.m. *Panic disorder:* 20 mg/d. *OCD:* 20–80 mg/d. *PMDD:* 20 mg/d or 20 mg intermittently, start 14 days prior to menses, repeat w/ each cycle; ↓ in hepatic failure.
W/P: [C, ?/−] Serotonin syndrome w/ MAOI, SSRI, serotonin agonists, linezolid; QT prolongation w/ phenothiazines; do not use w/ clopidogrel (↓ effect).
CI: w/ MAOI/thioridazine (wait 5 wk after D/C before MAOI).
DISP: *Prozac:* Caps 10, 20, 40 mg; scored tabs 10, 20 mg; *Prozac Weekly:* SR weekly caps 90 mg; soln 20 mg/5 mL. *Sarafem:* Caps 10, 15, 20 mg.
SE: N, nervousness, Wt loss, headache, insomnia.

FLUOXYMESTERONE (GENERIC) [C-III]

USES: *Hypogonadism (primary, hypogonadotropic), delayed puberty in males; postmenopausal metastatic breast cancer.*
ACTIONS: Synthetic androgen; ↓ secretion of LH & FSH (feedback inhibition).
DOSE: *Breast cancer:* 10–40 mg/d ÷ × 1–3 mo. *Hypogonadism:* 5–20 mg/d.
W/P: [X, ?/−] ↑ Effect w/ anticoagulants, cyclosporine, insulin, lithium, narcotics.
CI: Men with carcinomas of the breast or with known/suspected prostate cancer; women who are/may become pregnant.
DISP: Tabs 10 mg.
SE: Priapism, edema, virilization, amenorrhea & menstrual irregularities, hirsutism, alopecia, acne, N, cholestasis; suppression of factors II, V, VII, & X, & polycythemia; ↑ libido, headache, anxiety,

NOTES: Radiographic exam of hand/wrist q6mo in prepubertal children; ↓ total T_4 levels.

FLUTAMIDE (GENERIC)

WARNING: Liver failure & death reported. Measure LFTs before, monthly, & periodically after; D/C immediately if ALT 2 × ULN or jaundice develops.
USES: Advanced *PCa* (w/ LHRH agonists); w/ radiation & LHRH agonists for localized CaP.
ACTIONS: Nonsteroidal antiandrogen.
DOSE: 250 mg PO TID (750 mg total).
W/P: [D, ?].
CI: Severe hepatic impairment.
DISP: Caps 125 mg.
SE: Hot flashes, loss of libido, impotence, N/V/diarrhea, gynecomastia, hepatic failure, aniline-like toxicity (methemoglobinemia, hemolytic anemia, cholestatic jaundice).
NOTES: Check LFTs, avoid EtOH.

FONDAPARINUX (ARIXTRA)

WARNING: When epidural/spinal anesthesia or spinal puncture is used, pts anticoagulated or scheduled to be anticoagulated w/ LMW heparins, heparinoids, or fondaparinux are at risk for epidural or spinal hematoma, which can result in long-term or permanent paralysis.
USES: *DVT prophylaxis* w/ hip fracture, hip or knee replacement, abdominal surgery; w/ DVT or PE in combo w/ warfarin.
ACTIONS: Synth inhibitor of activated factor X; a pentasaccharide.
DOSE: *Prophylaxis* 2.5 mg SQ daily, up to 5–9 days; start >6 hr postop; Tx: 7.5 mg SQ daily (<50 kg: 5 mg SQ daily; >100 kg: 10 mg SQ daily); ↓ w/ renal impairment.
W/P: [B, ?] ↑ Bleeding risk w/ anticoagulants, anti-plts, drotrecogin alfa, NSAIDs.
CI: Wt <50 kg, CrCl <30 mL/min, active bleeding, SBE ↓ plt w/ anti-plt Ab.
DISP: Prefilled syringes w/ 27G needle: 2.5/0.5, 5/0.4, 7.5 /0.6, 10/0.8 mg/mL.
SE: Thrombocytopenia, anemia, fever, N.
NOTES: D/C if plts <100,000 cells/μL; only give SQ; may monitor antifactor Xa levels.

FORMALIN (40% FORMALDEHYDE)

(Note: This medication is not FDA approved for this use. Medication usually prepared by hospital pharmacy.)
USES: Intractable hemorrhagic cystitis refractory to conservative management.
ACTIONS: Fixation of bladder wall mucosa through protein cross-linking.
DOSE: Fill bladder to capacity with 1–2% formalin initially under gravity (<15 cm water) for up to 10–15 min; must be under general or spinal anesthesia with patient in reverse Trendelenburg (minimize reflux); if needed can repeat with higher concentration (4–10%).
W/P: [C, ?].
DISP: Formalin solution 1–10%.
SE: Bladder fibrosis, skin irritation with contact, reflux resulting in acidosis, ureteral fibrosis and obstruction or papillary necrosis; extravasation causes peritonitis and/or fistulas.
NOTES: Cystogram required to rule out reflux and bladder perforation; coat perineum

petroleum jelly and vaginal vault packed with petroleum gauze to protect shin from formalin contact.

FOSFOMYCIN (MONUROL, GENERIC)

USES: *Uncomplicated UTI in women.*
ACTIONS: ↓ Cell wall synth. *Spectrum:* gram(+) *Enterococcus,* staphylococci, pneumococci; gram(−) (*E. coli, Salmonella, Shigella, H. influenzae, Neisseria,* indole(−) *Proteus, Providencia); B. fragilis* & anaerobic gram(−) cocci are resistant.
DOSE: 3 g PO in 90–120 mL of H_2O single dose; ↓ in renal impairment.
W/P: [B, ?] Not for pyelo;↓ absorption w/ antacids/Ca salts.
CI: Component sensitivity.
DISP: Granule packets 3 g.
SE: Headache, GI upset.
NOTES: May take 2–3 days for Sxs to improve.

FOSINOPRIL (GENERIC)

USES: *HTN, CHF*, diabetic nephropathy.
ACTIONS: ACE inhibitor.
DOSE: 10 mg/d PO initial; max. 40 mg/d PO; ↓ in elderly; ↓ in renal impairment.
W/P: [D, +] ↑ K^+ w/ K^+ supls, ARBs, K^+-sparing diuretics; ↑ renal after effects w/ NSAIDs, diuretics, hypovolemia.
CI: Hereditary/idiopathic angioedema or angioedema w/ ACE inhibitor, bilateral RAS.
DISP: Tabs 10, 20, 40 mg.
SE: Cough, dizziness, angioedema, ↑ K^+.

FUROSEMIDE (LASIX [ORAL] , GENERIC)

USES: *CHF, HTN, edema*, ascites.
ACTIONS: Loop diuretic; ↓ Na & Cl reabsorption in ascending loop of Henle & distal tubule.
DOSE:
Adults: 20–80 mg PO or IV BID.
Peds: 1 mg/kg/dose IV q6–12h; 2 mg/kg/ dose PO q12–24h (max. 6 mg/kg/dose); ↑ doses w/ renal impairment.
W/P: [C, +] ↓ K^+, ↑ risk digoxin tox & ototox w/ aminoglycosides, cisplatin (especially in renal dysfunction).
CI: Sulfonylurea allergy; anuria; hepatic coma; electrolyte depletion.
DISP: Tabs 20, 40, 80 mg; soln 10 mg/mL, 40 mg/5 mL; Inj 10 mg/mL.
SE: ↓ BP, hyperglycemia, ↓ K^+.
NOTES: Check lytes, renal function; high doses IV may cause ototox.

GABAPENTIN (NEURONTIN, GENERIC)

USES: *Postherpetic neuralgia (PHN); adjunct in partial seizures*; chronic pain synds.

ACTIONS: Anticonvulsant; GABA analog.

DOSE:
Adults & Peds: > ***12 yr:*** *Anticonvulsant:* 300 mg PO TID, ↑ max. 3,600 mg/d. *PHN:* 300 mg day 1, 300 mg BID day 2, 300 mg TID day 3, titrate (1,800–3,600 mg/d);
Peds: ***3–12 yr:*** 0–15 mg/kg/d ÷ TID, ↑ over 3 days, ***3–4 yr:*** 40 mg/kg/d given TID. ≥***5 yr:*** 25–35 mg/kg/d ÷ TID, 50 mg/kg/d max. ↓ w/ renal impairment.
W/P: [C, ?] Use in peds 3–12 yr w/ epilepsy may ↑ CNS-related adverse events.
CI: Component sensitivity.
DISP: Caps 100, 300, 400 mg; soln 250 mg/5 mL; scored tab 600, 800 mg.
SE: Somnolence, dizziness, ataxia, fatigue.
NOTES: Not necessary to monitor levels; taper ↑ or ↓ over 1 wk.

GANCICLOVIR (CYTOVENE, VITRASERT, GENERIC)

Toxicity includes granulocytopenia, anemia and thrombocytopenia. In animal studies ganciclovir was carcinogenic, teratogenic and caused aspermatogenesis. Ganciclovir for injection indicated only in the treatment of CMV retinitis in immunocompromised patients and to prevent CMV at risk transplant patients.
USES: *Treat & prevent CMV retinitis, prevent CMV disease* in transplant recipients.
ACTIONS: ↓ Viral DNA synth.

DOSE:
Adults & Peds: *IV:* 5 mg/kg IV q12h for 14–21 days, then maint 5 mg/kg/d IV × 7 d/ wk or 6 mg/kg/d IV × 5 d/wk.
Adults: *PO:* Following induction, 1,000 mg PO TID. *Prevention:* 1,000 mg PO TID; w/ food; ↓ in renal impairment.
W/P: [C, −] ↑ Effect w/ immunosuppressives, imipenem/cilastatin, zidovudine, didanosine, other nephrotoxic Treat.
CI: ANC <500 cells/mm^3, plt <25,000 cells/mm^3, intravitreal implant.
DISP: Caps 250, 500 mg; Inj 500 mg, ocular implant 4.5 mg.
SE: Granulocytopenia & thrombocytopenia, fever, rash, GI upset.
NOTES: Not a cure for CMV; handle Inj w/ cytotoxic cautions; no systemic benefit w/ implant.

GEMCITABINE (GEMZAR, GENERIC)

USES: *Pancreatic cancer (single agent), breast cancer w/ paclitaxel, NSCLC w/ cisplatin, ovarian cancer w/ carboplatin*, gastric cancer, urothelial carcinoma (systemic and intravesical).
ACTIONS: Antimetabolite; nucleoside metabolic inhibitor; ↓ ribonucleotide reductase; produces false nucleotide base-inhibiting DNA synth.
DOSE: 1,000–1,250 mg/ m^2 over 30 min–1 hr IV Inf/wk × 3–4 wk or 6–8 wk; modify dose based on hematologic function (per protocol).
W/P: [D, ?/−] Hemolytic uremic syndrome (HUS), pulmonary toxicity, embryofet al toxicity, ↑ radiation therapy toxicity, capillary leak syndrome, posterior reversible encephalopathy syndrome (PRES).

CI: Pregnancy.
DISP: Inj 200 mg, 1 g.
SE: ↓ BM, N/V/diarrhea, drug fever, skin rash.
NOTES: Reconstituted soln 38 mg/mL; monitor hepatic/renal function; intravesical regimen described: 40 mg/mL (2,000 mg in 50 mL saline) weekly.

GENTAMICIN, INJECTABLE (GENERIC)

USES: *Septicemia, serious bacterial infection of CNS, urinary tract, resp tract, GI tract, including peritonitis, skin, bone, soft tissue, including burns; severe infection *P. aeruginosa* w/ carbenicillin; group D streptococci endocarditis w/ PCN-type drug; serious staphylococcal infections, but not the antibiotic of 1st choice; mixed infection w/ staphylococci and gram(−).*
ACTIONS: Aminoglycoside, bactericidal; ↓ protein synth. *Spectrum:* gram(−) (not *Neisseria, Legionella, Acinetobacter*); weaker gram(+) but synergy w/ PCNs.

DOSE:

Adults: *Standard:* 1–2 mg/kg IV q8–12h or daily dosing 4–7 mg/kg q24h IV. *Gram(+) Synergy:* 1 mg/kg q8h.
Peds: ***Infants <7 days <1,200 g:*** 2.5 mg/kg/dose q18–24h. ***Infants >1,200 g:*** 2.5 mg/kg/dose q12–18h. ***Infants >7 days:*** 2.5 mg/kg/dose IV q8–12h. ***Children:*** 2.5 mg/kg/d IV q8h; ↓ w/ renal insufficiency; if obese, dose based on IBW.
W/P: [C, +/−] Avoid other nephrotoxics.
CI: Aminoglycoside sensitivity.
DISP: Premixed Inf 40, 60, 70, 80, 90, 100, 120 mg; ADD-Vantage Inj vials 10 mg/mL; Inj 40 mg/mL; IT preservative-free 2 mg/mL.
SE: Nephro/oto/neurotox.
NOTES: Follow CrCl, SCr, & serum conc for dose adjustments; use IBW to dose (use adjusted if obese >30% IBW); OK to use intraperitoneal for peritoneal dialysis-related infections. *Levels: Peak:* 30 min after Inf; *Trough:* <0.5 hr before next dose; *Therapeutic: Peak:* 5–8 μg/mL, *Trough:* <2 μg/mL, if >2 μg/mL associated w/ renal tox.

GOSERELIN (ZOLADEX)

USES: *Used with flutamide for the management of locally confined carcinoma of the prostate and palliative treatment of advanced carcinoma of the prostate, *endometriosis, breast cancer.
ACTIONS: LHRH agonist, transient ↑ then ↓ in LH, w/ ↓ testosterone.
DOSE: 3.6 mg SQ (implant) q28d or.10.8 mg SQ q3mo; usually upper abdominal wall.
W/P: [X, −].
CI: Pregnancy, breast-feeding, 10.8-mg implant not for women.
DISP: SQ implant 3.6 (1 mo), 10.8 mg (3 mo).
SE: Hot flashes, ↓ libido, gynecomastia, & transient exacerbation of cancer-related bone pain (“flare reaction” 7–10 days after 1st dose).
NOTES: Inject SQ into fat in abdominal wall; do not aspirate; females must use contraception.

HEPARIN (GENERIC)

USES: *Treat & prevention of DVT & PE*, unstable angina, AF w/ emboli, & acute arterial occlusion.
ACTIONS: Acts w/ antithrombin III to inactivate thrombin & ↓ thromboplastin formation.

DOSE:

Adults: *Prophylaxis:* 3,000–5,000 U SQ q8–12h. *DVT/PE Treat:* Load 50–80 U/kg IV (max. 10,000 U), then 10–20 U/kg IV qh (adjust based on PTT).
Peds/Infants: Load 50 U/kg IV bolus, then 20 U/kg/h IV by cont Inf. ***Children:*** Load 50 U/kg IV, then 15–25 U/kg cont Inf or 100 U/kg/dose q4h IV intermittent bolus (adjust based on PTT).
W/P: [C, +] ↑ Risk of hemorrhage w/ anticoagulants, ASA, anti-plt, cephalosporins w/ MTT side chain.
CI: Uncontrolled bleeding, severe thrombocytopenia, suspected ICH.
DISP: Unfractionated Inj 10, 100, 1,000, 2,000, 2,500, 5,000, 7,500, 10,000, 20,000, 40,000 U/mL.
SE: Bruising, bleeding, thrombocytopenia.
NOTES: Follow PTT, thrombin time, or activated clotting time; little PT effect; therapeutic PTT 1.5–2 control for most conditions; monitor for heparin-induced thrombocytopenia w/ plt counts; new "USP" formulation heparin is ~10% less effective than older formulations.

HEXAMINOLEVULINATE (CYSVIEW)

USES: *An optical imaging agent used in the cystoscopic detection of nonmuscle invasive papillary cancer of the bladder in patients suspected or known to have lesion(s) on the basis of a prior cystoscopy. Used with the Karl Storz D-Light C photodynamic diagnostic (PDD) system to perform cystoscopy with blue (360–450 nm) and white light.
ACTIONS: An ester of the heme precursor, aminolevulinic acid; concentrates in abnormal cells and fluoresces red under blue light.
DOSE: 50 mL instilled intravesically; cysto 30 min after evacuation of Cysview, but no less than 1 or more than 3 hr after instillation.
W/P: [C, −] Not a replacement for random bladder biopsies; not for repetitive use; false positive fluorescence: inflammation, cystoscopic trauma, scar tissue or previous bladder biopsy.
CI: Porphyria, gross hematuria, BCG or intravesical chemo w/in 90 days; hypersensitivity product.
DISP: Kit w/ 100 mg Cysview and 50 mL diluent.
SE: Bladder spasm, dysuria, hematuria, bladder pain, procedural pain, urinary retention, headache, anaphylaxis.
NOTES: Perform a complete cysto under white light and then under blue light. Document information about location and appearance of suspicious lesions and areas seen under both white and blue lights. Abnormalities of the bladder mucosa during blue light cystoscopy are characterized by the detection of red, homogenous and intense fluorescence. Necrotic cells generally do not fluoresce. (Product is Hexvix in Europe)

HISTRELIN ACETATE (SUPPRELIN LA, VANTAS)

USES: *Advanced PCa [*Vantas*], central precocious puberty [*Supprelin LA*].*
ACTIONS: GNRH agonist; paradoxically ↑ release of GnRH w/ ↓ LH from anterior pituitary; in men ↓ testosterone.
DOSE: *Vantas*: 50 mg SQ implant q12mo inner aspect of the upper arm; *Supprelin LA:* 1 implant q12mo.
W/P: [X, −] Transient "flare reaction" at 7–14 days after 1st dose [LH/testosterone surge before suppression]); w/ impending cord compression or urinary tract obstruction; ↑ risk DM, CV disease, MI.
CI: GNRH sensitivity, pregnancy.
DISP: 50 mg 12-mo SQ implant.
SE: Hot flashes, fatigue, implant site reaction, testis atrophy, gynecomastia.
NOTES: Nonsteroidal antiandrogen (eg, bicalutamide) may block flare in men w/ PCa.

HUMAN PAPILLOMAVIRUS RECOMBINANT VACCINE (CERVARIX [TYPES 16, 18] , GARDASIL [TYPES 6, 11, 16, 18])

USES: *Prevent cervical cancer, precancerous genital lesions (*Cervarix and Gardasil*), genital warts, anal cancer and oral cancer (*Gardasil*) d/t to HPV types 16, 18 (*Cervarix*) and types 6, 11, 16, 18 (*Gardasil*) in females 9–26 yr*; prevent genital warts, anal cancer, and anal intraepithelial neoplasia in males 9–26 yr (*Gardasil*).*
ACTIONS: Recombinant vaccine, passive immunity.
DOSE: 0.5 mL IM, then 1 and 6 mo (*Cervarix*), or 2 and 6 mo (*Gardasil*) (upper thigh or deltoid).
W/P: [B, ?/−].
DISP: Single-dose vial & prefilled syringe: 0.5 mL.
SE: Erythema, pain at Inj site, fever, syncope, venous thromboembolism.
NOTES: 1st cancer prevention vaccine, 90% effective in preventing CIN 2 or more severe disease in HPV naive populations; report adverse events to Vaccine Adverse Events Reporting System (VAERS: 1-800-822-7967); continue cervical cancer screening. Hx of genital warts, abn Pap smear, or + HPV DNA test is not contraindication to vaccination.

HYDROCHLOROTHIAZIDE (MICROZIDE, GENERIC)

USES: *Edema, HTN,* prevent stones in hypercalciuria.
ACTIONS: Thiazide diuretic; ↓ distal tubule Na^+ reabsorption; Thiazides urine calcium ↓ possibly by an increase in calcium absorption in the proximal tubule, induced by volume contraction.

DOSE:

Adults: 25–100 mg/d PO single or ÷ doses; 200 mg/d max.
Peds: ***<6 mo:*** 2–3 mg/kg/d in 2 ÷ doses. ***>6 mo:*** 2 mg/kg/d in 2 ÷ doses.
W/P: [D, +] Idiosyncratic reaction, resulting in acute transient myopia and acute angle-closure glaucoma; latent DM may become manifest.
CI: Anuria, sulfonamide allergy, renal insufficiency.

DISP: Tabs 25, 50, mg; caps 12.5 mg; PO soln 50 mg/5 mL.
SE: ↓ K^+, hyperglycemia, hyperuricemia, ↓ Na^+; sun sensitivity.
NOTES: Follow K^+, may need supplementation.

HYDROCHLOROTHIAZIDE/AMILORIDE (MODURETIC, GENERIC)

USES: *HTN.*
ACTIONS: Combined thiazide & K^+-sparing diuretic.
DOSE: 1–2 tabs/d PO.
W/P: [D, ?].
CI: Renal failure, sulfonamide allergy.
DISP: Tabs (amiloride/HCTZ) 5 mg/50 mg.
SE: ↓ BP, photosensitivity, ↑ K^+/ ↓ K^+, hyperglycemia, ↓ Na^+, hyperlipidemia, hyperuricemia.

HYDROCHLOROTHIAZIDE/SPIRONOLACTONE (ALDACTAZIDE, GENERIC)

USES: *Edema, HTN.*
ACTIONS: Thiazide & K^+-sparing diuretic.
DOSE: 25–200 mg each component/d, ÷ doses.
W/P: [D, +].
CI: Sulfonamide allergy.
DISP: Tabs (HCTZ/spironolactone) 25/25, 50/50 mg.
SE: Photosensitivity, ↓ BP, ↑ or ↓ K^+, ↓ Na^+, hyperglycemia, hyperlipidemia, hyperuricemia.

HYDROCHLOROTHIAZIDE/TRIAMTERENE (DYAZIDE, MAXZIDE, GENERIC)

USES: *Edema & HTN.*
ACTIONS: Combo thiazide & K^+-sparing diuretic.
DOSE: *Dyazide:* 1–2 caps PO daily–BID. *Maxzide:* 1 tab/d PO.
W/P: [D, +/−].
CI: Sulfonamide allergy.
DISP: (Triamterene/HCTZ) 37.5/25, 75/50 mg.
SE: Photosensitivity, ↓ BP, ↑ or ↓ K^+, ↓ Na^+, hyperglycemia, hyperlipidemia, hyperuricemia.
NOTES: HCTZ component in Maxzide more bioavailable than in Dyazide.

HYDROCODONE (ZOHYDRO ER)

WARNING: Addiction, abuse, misuse, overdose and death risk. Fatal respiratory depression; overdose especially in children can be fatal. With pregnancy neonatal opioid withdrawal syndrome possible. Do not consume alcohol.
USES: *Pain severe enough to require daily, around-the-clock, long-term opioid.*
ACTIONS: Opioid analgesic.

DOSE: *1st Opioid Analgesic:* 10 mg cap Q 12 hr. *Not Opiod tolerant:* 10 mg cap Q 12 hr (Opioid tolerant: Receiving, for >1 wk, at least 60 mg oral morphine/d, 25 μg transdermal fentanyl/h, 30 mg oral oxycodone/d, 8 mg oral hydromorphone/d, 25 mg oral oxymorphone/d, or an equianalgesic dose of another opioid) increase in increments of 10 mg every 12 hr every 3–7 days to effect; Conversion from other oral opioids see package insert.
W/P: [D, +/−] see "Warning"; w/ other CNS depressants, monitor elderly, debilitated for resp depression; CYP3A4 inhibitors may ↑ effect.
CI: Significant respiratory depression; severe bronchial asthma or hypercarbia; paralytic ileus; hypersensitivity to ingredients.
DISP: ER caps 10/15/20/30/40/50 mg.
SE: Constipation, nausea, somnolence, fatigue, headache, dizziness, dry mouth, vomiting, pruritus, others.
NOTES: Swallow capsules whole; do not crush/chew; not a PRN use drug.

HYDROCODONE/ACETAMINOPHEN (HYCET, LORCET, GENERIC) [C-III]

WARNING: Acetaminophen has been associated with acute liver failure (liver transplant and death possible). Most cases associated with doses >4,000 mg/d and often involve more than 1 acetaminophen-containing product.
USES: *Mod–severe pain.*
ACTIONS: Narcotic analgesic w/ nonnarcotic analgesic.

DOSE:

Adults: 1–2 caps or tabs PO q4–6h PRN; soln 15 mL q4–6h.
Peds: Soln (*Hycet*) 0.27 mL/kg q4–6h.
W/P: [C, M].
CI: CNS depression, severe resp depression.
DISP: Many formulations; specify hydrocodone/acetaminophen dose; caps 5/500 mg; tabs 2.5/500, 5/300, 5/325, 5/500, 7.5/300, 7.5/325, 7.5/500, 7.5/650, 7.5/750,10/300, 10/325, 10/500, 10/650, 10/660, 10/750 mg; soln Hycet (fruit punch) 7.5 mg hydrocodone/325 mg acetaminophen/15 mL.
SE: GI upset, sedation, fatigue.
NOTES: Do not exceed >4 g acetaminophen/d; see Acetaminophen note.

HYDROCODONE/IBUPROFEN (REPREXAIN, VICOPROFEN, GENERIC) [C-III]

USES: *Mod–severe pain (<10 days).*
ACTIONS: Narcotic w/ NSAID.
DOSE: 1–2 tabs q4–6h PRN.
W/P: [C, M] Renal insufficiency; ↓ effect w/ ACE inhibitor & diuretics; ↑ effect w/ CNS depressants, EtOH, MAOI, ASA, tricyclic antidepressants, anticoagulants.
CI: Component sensitivity.
DISP: Tabs 2.5/5/7.5/10 mg hydrocodone/200 mg ibuprofen.
SE: Sedation, fatigue, GI upset.
NOTES: Not for arthritis.

HYDROCORTISONE, RECTAL (ANUSOL-HC SUPPOSITORY, CORTIFOAM RECTAL, PROCTOCORT, OTHERS, GENERIC)

USES: *Painful anorectal conditions*, radiation proctitis, ulcerative colitis.
ACTIONS: Anti-inflammatory steroid.

DOSE:

Adults: Ulcerative colitis: 10–100 mg PR daily–BID for 2–3 wk.
W/P: [B, ?/−].
CI: Component sensitivity.
DISP: *Hydrocortisone acetate:* Rectal aerosol 90 mg/applicator; supp 25 mg. *Hydrocortisone base:* Rectal 0.5%, 1%, 2.5%; rectal susp 100 mg/60 mL.
SE: Minimal systemic effect.

HYDROCORTISONE, SYSTEMIC (CORTEF, SOLU-CORTEF, GENERIC)

See also Steroids Systemic and Topical.
USE: Adrenal insufficiency.
ACTION: Glucocorticoid.
DOSE: 2 mg/kg IV/IO bolus; max. dose 100 mg.
W/P: [B, −].
CI: Viral, fungal, or tubercular skin lesions; serious infections (except septic shock or TB meningitis).
SE: *Systemic:* ↑ Appetite, insomnia, hyperglycemia, bruising.
NOTES: May cause hypothalamic–pituitary–adrenal axis suppression.

HYDROMORPHONE (DILAUDID, DILAUDID HP, GENERIC) [C–II]

WARNING: A potent Schedule II opioid agonist; highest potential for abuse and risk of resp depression. HP formula is highly concentrated; do not confuse w/ standard formulations, OD and death could result. Alcohol, other opioids, CNS depressants ↑ resp depressant effects.
USES: *Mod–severe pain.*
ACTIONS: Narcotic analgesic.
DOSE: 1–4 mg PO, IM, IV, or PR q4–6h PRN; 3 mg PR q6–8h PRN; ↓ w/ hepatic failure.
W/P: [B (D if prolonged use or high doses near term), ?] ↑ Resp depression and CNS effects, CNS depressants, phenothiazines, tricyclic antidepressants.
CI: CNS lesion w/ ↑ ICP, COPD, cor pulmonale, emphysema, kyphoscoliosis, status asthmaticus; HP-Inj form in OB analgesia.
DISP: Tabs 2, 4, 8 mg scored; liq 5 mg/5 mL or 1 mg/mL; Inj 1, 2, 4 mg, *Dilaudid HP* is 10 mg/mL; supp 3 mg.
SE: Sedation, dizziness, GI upset.
NOTES: Morphine 10 mg IM = hydromorphone 1.5 mg IM.

HYDROXYZINE (ATARAX, VISTARIL, GENERIC)

USES: *Anxiety, sedation, itching.*
ACTIONS: Antihistamine, antianxiety.

DOSE:
Adults: *Anxiety/sedation:* 50–100 mg PO or IM QID or PRN (max. 600 mg/d). *Itching:* 25–50 mg PO or IM TID–QID.
Peds: 0.5–1.0 mg/kg/24 h PO or IM q6h; ↓ w/ hepatic impairment.
W/P: [C, +/−] ↑ Effects w/ CNS depressants, anticholinergics, EtOH.
CI: Component sensitivity.
DISP: Tabs 10, 25, 50 mg; caps 25, 50 mg; syrup 10 mg/5 mL; susp 25 mg/5 mL; Inj 25, 50 mg/mL.
SE: Drowsiness, anticholinergic effects.
NOTES: Used to potentiate narcotic effects; not for IV/SQ (thrombosis & digital gangrene possible).

HYOSCYAMINE (ANASPAZ, CYSTOSPAZ, LEVSIN, OTHERS, GENERIC)

USES: *Spasm w/ GI & bladder disorders.*
ACTIONS: Anticholinergic.

DOSE:

Adults: 0.125–0.25 mg (1–2 tabs) SL/PO TID–QID, ac & hs; 1 SR caps q12h.
W/P: [C, +] ↑ Effects w/ amantadine, antihistamines, antimuscarinics, haloperidol, phenothiazines, tricyclic antidepressants, MAOI.
CI: Bladder outlet obstruction, GI obst, narrow-angle glaucoma, myasthenia gravis, paralytic ileus, ulcerative colitis, MI.
DISP: (*Cystospaz-M, Levsinex*) time-release caps 0.375 mg; elixir (EtOH); soln 0.125 mg/5 mL; Inj 0.5 mg/mL; tab 0.125 mg; tab (*Cystospaz*) 0.15 mg; XR tab (*Levbid*) 0.375 mg; SL (*Levsin SL*) 0.125 mg.
SE: Dry skin, xerostomia, constipation, anticholinergic SE, heat prostration w/ hot weather.
NOTES: Administer tabs ac.

HYOSCYAMINE, ATROPINE, SCOPOLAMINE, & PHENOBARBITAL (DONNATAL, OTHERS, GENERIC)

USES: *Irritable bowel, spastic colitis, peptic ulcer*, spastic bladder.
ACTIONS: Anticholinergic, antispasmodic.
DOSE: 0.125–0.25 mg (1–2 tabs) TID–QID, 1 caps q12h (SR), 5–10 mL elixir TID–QID or q8h.
W/P: [D, M].
CI: Glaucoma, obstructive uropathy, GI obstruction, unstable patient with hemorrhage, severe ulcerative colitis.
DISP: Many combos/manufacturers. Caps *(Donnatal, others):* Hyoscyamine 0.1037 mg/atropine 0.0194 mg/scopolamine .0065 mg/phenobarbital 16.2 mg. Tabs *(Donnatal, others):* Hyoscyamine 0.1037 mg/atropine .0194 mg/scopolamine 0.0065 mg/phenobarbital 16.2 mg. *LA (Donnatal):* Hyoscyamine 0.311 mg/ atropine 0.0582 mg/scopolamine 0.0195 mg/phenobarbital .6 mg. Elixirs *(Donnatal, others):* Hyoscyamine 0.1037 mg/atropine .0194 mg/scopolamine 0.0065 mg/phenobarbital 16.2 mg/5 mL.
SE: Sedation, xerostomia, constipation.
NOTE: FDA has classified the indications as “possibly” effective.

IBANDRONATE (BONIVA, GENERIC)

USES: *Treat osteoporosis in postmenopausal women.*
ACTIONS: Bisphosphonate, ↓ osteoclast-mediated bone resorption.
DOSE: 2.5 mg PO daily or 150 mg 1 × mo on same day (do not lie down for 60 min after); 3 mg IV over 15–30 s q3mo; w/ low risk for fracture, consider D/C after 3–5 yr.
W/P: [C, ?/−] Do not use w/ CrCl <30 mL/min; w/ inability to stand/sit upright for 60 min (PO); anaphylaxis reported; tissue damage with inappropropriate IV administration.
CI: Hypocalcemia, component hypersensitivity.
DISP: Tabs 2.5, 150 mg, Inj IV 3 mg/3 mL.
SE: Osteonecrosis of the jaw (ONJ) (avoid extensive dental procedures) N/diarrhea, headache, dizziness, asthenia, HTN, infection, dysphagia, esophagitis, esophageal/gastric ulcer, musculoskelet al pain.
NOTES: Take 1st thing in a.m. w/ water (6–8 oz) >60 min before 1st food/beverage & any meds w/ multivalent cations; give adequate Ca^{2+} & vit D supls; possible association between bisphosphonates & severe muscle/bone/joint pain; may ↑ atypical subtrochanteric femur fractures.

IBUPROFEN, ORAL (ADVIL, MOTRIN, MOTRIN IB, RUFEN, OTHERS, GENERIC) [OTC]

WARNING: May ↑ risk of CV events & GI bleeding.
USES: *Arthritis, pain, fever.*
ACTIONS: NSAID.

DOSE:

Adults: 200–800 mg PO BID–QID (max. 2.4 g/d).
Peds: 30–40 mg/kg/d in 3–4 ÷ doses (max. 40 mg/kg/d); w/ food.
W/P: [C (D ≥30 wk gestation), +] May interfere w/ ASAs anti-plt effect if given <8 hr before ASA.
CI: 3rd-tri PREGNANCY, severe hepatic impairment, allergy, use w/ other NSAIDs, upper GI bleeding, ulcers.
DISP: Tabs 100, 200, 400, 600, 800 mg; chew tabs 50, 100 mg; caps 200 mg; susp 50 mg/1.25 mL, 100 mg/2.5 mL, 100 mg/5 mL, 40 mg/mL (Motrin IB & Advil OTC 200 mg are the OTC forms).
SE: Dizziness, peptic ulcer, plt inhibition, worsening of renal insufficiency.

IBUPROFEN, PARENTERAL (CALDOLOR)

WARNING: May ↑ risk of CV events & GI bleeding.
USES: *Mild–mod pain, as adjunct to opioids, ↓ fever.*
ACTIONS: NSAID.
DOSE: *Pain:* 400–800 mg IV over 30 min q6h PRN; *Fever:* 400 mg IV over 30 min, the 400 mg q4–6h or 100–200 mg q4–6h PRN.
W/P: [C <30 wk, D after 30 wk, ?/−] May ↓ ACE effects; avoid w/ ASA, and <17 yr.
CI: Hypersensitivity NSAIDs; asthma, urticaria, or allergic reactions w/ NSAIDs, periop CABG.

DISP: Vials 400 mg/4 mL, 800 mg/8 mL.
SE: N/V, headache, flatulence, hemorrhage, dizziness.
NOTES: Keep well hydrated; use lowest dose/shortest duration possible.

IFOSFAMIDE (IFEX, GENERIC)

WARNING: Administer only under supervision by an MD experienced in chemotherapy; hemorrhagic cystitis, myelosupp; confusion, coma possible.
USES: *Testis cancer, 3rd line with other agents.*
ACTIONS: Alkylating agent.
DOSE: (Per protocol) 1.2 g/m^2/d for 5-day bolus or cont Inf; 2.4 g/m^2/d for 3 days; w/ mesna uroprotection; ↓ in renal/hepatic impairment.
W/P: [D, M] ↑ Effect w/ phenobarbital, carbamazepine, phenytoin; St. John's wort may ↓ levels.
CI: ↓ BM function, PREGNANCY.
DISP: Inj 1, 3 g.
SE: Hemorrhagic cystitis, nephrotoxic, N/V, mild–mod leukopenia, lethargy & confusion, alopecia, ↑ LFT.
NOTES: Administer w/ mesna to prevent hemorrhagic cystitis; WBC nadir 10–14 days; recovery 21–28 days.

IMIPENEM/CILASTATIN (PRIMAXIN, GENERIC)

USES: *Serious infections: Lower respiratory, UTI, intra-abdominal, gyn, sepsis, bone and joint, skin and skin structure, endocarditis, polymicrobial infections* d/t susceptible bacteria.
ACTIONS: Bactericidal; ↓ cell wall synth. *Spectrum:* gram(+) (*S. aureus,* group A & B streptococci), gram(−) (not *Legionella*), anaerobes.

DOSE:

Adults: 250–1,000 mg (imipenem) IV q6–8h, 500–750 mg IM.
Peds: 60–100 mg/kg/24 h IV ÷ q6h; ↓ if CrCl is <70 mL/min.
W/P: [C, +/−] Probenecid ↑ tox.
CI: Peds pts w/ CNS infection (↑ seizure risk) & <30 kg w/ renal impairment.
DISP: Inj (imipenem/cilastatin) 250/250, 500/500 mg.
SE: Seizures if drug accumulates, GI upset, thrombocytopenia.

IMIPRAMINE (TOFRANIL, GENERIC)

WARNING: Close observation for suicidal thinking or unusual changes in behavior.
USES: *Depression, enuresis in children >6 yo.*
ACTIONS: Tricyclic antidepressant; ↑ CNS synaptic serotonin or norepinephrine.

DOSE:

Adults: *Hospitalized:* Initial 100 mg/24 h PO in ÷ doses; ↑ over several wk 300 mg/d max. *Outpatient:* Maint 50–150 mg PO hs, 300 mg/24 h max.
Peds: *Antidepressant:* 1.5–5 mg/kg/24 h ÷ daily–QID. *Enuresis:* ***>6 yr:*** 10–25 mg PO qhs; ↑

by 10–25 mg at 1–2-wk intervals (max. 50 mg for 6–12 yr, 75 mg for >12 yr); Treat for 2–3 mo, then taper.
W/P: [D, ?/−].
CI: Use w/ MAOIs, narrow-angle glaucoma, recovery from AMI, pregnancy, CHF, angina, CV disease, arrhythmias.
DISP: Tabs 10, 25, 50 mg; caps 75, 100, 125, 150 mg.
SE: CV Sxs, dizziness, xerostomia, discolored urine.
NOTES: Less sedation than amitriptyline; retrograde ejaculation 25 mg TID × 2 wk.

IMIQUIMOD CREAM (ALDARA, ZYCLARA, GENERIC)

USES: *Anogenital warts, HPV, condylomata acuminata (*Aldara, Zyclara*); actinic keratosis (*Zyclara*); basal cell carcinoma (*Aldara*)* penile CIS.
ACTIONS: Inducer of interferon-α, enhances cell-mediated cytolytic activity.

DOSE:
Adults/Peds: ***>12 yr:*** *Warts:* 1 × day up to 8 wk (*Zyclara*); apply 3×/wk, leave on 6–10 h & wash off w/ soap & water, continue 16 wk max. (*Aldara*); *Actinic keratosis*: apply daily two 2 × wk cycle separate by 2 wk; *Basal cell:* Apply 5 d/wk × 6 wk, dose based on lesion size (see label).
W/P: [B, ?] Topical only, not intravaginal or intra-anal.
CI: Component sensitivity.
DISP: 2.5% packet, 3.75% packet or pump (*Zyclara*); single-dose packets 5% (250-mg cream *Aldara*).
SE: Local skin reactions, flu-like syndrome.
NOTES: Not a cure; may weaken condoms/Vag diaphragms, wash hands before & after use; efficacy was not demonstrated for molluscum contagiosum in children 2–12 yr; typical penile regimen described: apply 12 hr every 48 hr for 28 days.

INDIGO CARMINE, INJECTION [INDIGOTINDISULFONATE] (GENERIC)

USES: *Localization of ureteral orifices during cystoscopy,* identification of urinary tract injury intraoperatively.
ACTIONS: Excreted and appears in urine as blue color usually within 10 min of injection.
DOSE: 5 mL IV (preferred) or IM.
W/P: [C, ?].
CI: Allergy to compound.
DISP: 5 mg vials for injection; do not dilute or inject with other solutions.
SE: Mild pressor, rare idiosyncratic reaction.
NOTES: May transiently alter pulse oximeter; originally used as a renal function test. Label is not officially approved by the FDA.

INDOMETHACIN (INDOCIN, TIVORBEX, GENERIC)

WARNING: May ↑ risk of CV events & GI bleeding; not for post-CABG pain
USES: *Arthritis (gouty, osteo, rheumatoid); ankylosing spondylitis; close ductus arteriosus; ** *Tivorbex*: acute pain*

ACTIONS: ↓ Prostaglandins.

DOSE:

Adults: 25–50 mg PO BID–TID, max. 200 mg/d. ***Infants:*** 0.2–0.25 mg/kg/dose IV; may repeat in 12–24 hr max 3 doses; w/ food.
W/P: [C, +].
CI: ASA/NSAID sensitivity, peptic ulcer/active GI bleed, precipitation of asthma/urticaria/rhinitis by NSAIDs/ASA, premature neonates w/ NEC, ↓ renal Fxn, active bleeding, thrombocytopenia, 3rd tri PRG.
DISP: Inj 1 mg/vial; caps 25, 50 mg; susp 25 mg/5 mL; *Tivorbex*: 20, 40 mg caps.
SE: GI bleeding or upset, dizziness, edema.
NOTES: Monitor renal Fxn.

INTERFERON ALFA-2B (INTRON-A)

WARNING: Can cause or aggravate fatal or life-threatening neuropsychiatric autoimmune, ischemic, and infectious disorders. Monitor closely (systemic).
USES: *Hairy cell leukemia, Kaposi sarcoma, melanoma, CML, chronic hep B & C, follicular NHL, condylomata acuminate,* RCC, superficial bladder cancer.
ACTIONS: Antiproliferative; modulates host immune response; ↓ viral replication in infected cells.
DOSE: Per protocols.
Adults: Per protocols. *Condyloma*: 1 MU/lesion (max. 5 lesions) 3×/wk (on alternate days) for 3 wk. *Bladder CIS:* High dose (50–100 MU) intravesically weekly; different regimens described; typically 6 wk. *Bladder carcinoma, superficial BCG refractory*: Used in combination with intravesical BCG (either standard or reduced dose BCG) with 50–100 MU interferon-α 2b for 6 wk; maintenance regimens described.
CI: Benzyl alcohol sensitivity, decompensated liver disease, autoimmune hep immunosuppressed, pregnancy, CrCl <50 mL/ min in combo w/ ribavirin.
DISP: Inj forms: powder 10/18/50 MIU; soln 6/10 MIU/mL (see also polyethylene glycol [PEG]-interferon).
SE: Flu-like Sxs, fatigue, anorexia, neurotox at high doses; up to 40% neutralizing Ab w/ Treat; not FDA approved for intravesical use; with systemic therapy follow baseline CXR and ECG; CBC w/ diff/platelets (baseline and routinely), LFTs, creatinine, electrolytes, triglycerides, thyroid function.

IRBESARTAN (AVAPRO)

WARNING: D/C immediately if pregnancy detected.
USES: *HTN, diabetic nephropathy*, CHF.
ACTIONS: Angiotensin II receptor antagonist.
DOSE: 150 mg/d PO, may ↑ to 300 mg/d.
W/P: [C (1st tri; D 2nd/3rd tri), ?/−].
CI: Component sensitivity; w/ aliskiren in diabetics
DISP: Tabs 75, 150, 300 mg
SE: Fatigue, ↓ BP, ↑ K

ISONIAZID (INH)

WARNING: Severe & sometimes fatal hep may occur usually w/in 1st 3 mo of Tx, although may develop after mo of Tx.
USES: *Treat & prophylaxis of TB.*
ACTIONS: Bactericidal; interferes w/ mycolic acid synth, disrupts cell wall.

DOSE:

Adults: *Active TB:* 5 mg/kg/24 h PO or IM (usually 300 mg/d) or *DOT:* 15 mg/kg (max. 900 mg) 3×/wk. *Prophylaxis:* 300 mg/d PO for 6–12 mo or 900 mg 2×/wk.
Peds: *Active TB:* 10–15 mg/kg/d daily PO or IM 300 mg/d max. *Prophylaxis:* 10 mg/kg/24 h PO; ↓ in hepatic/renal dysfunction.
W/P: [C, +] Liver disease, dialysis; avoid EtOH.
CI: Acute liver disease, Hx INH hep.
DISP: Tabs 100, 300 mg; syrup 50 mg/5 mL; Inj 100 mg/ mL.
SE: Hep, peripheral neuropathy, GI upset, anorexia, dizziness, skin reaction.
NOTES: Use w/ 2–3 other drugs for active TB, based on INH resistance patterns when TB acquired & sensitivity results; prophylaxis usually w/ INH alone. IM rarely used. ↓ Peripheral neuropathy w/ pyridoxine 50–100 mg/d. See CDC guidelines (http://www.cdc.gov/tb/) for current TB recommendations.

ITRACONAZOLE (ONMEL, SPORANOX, GENERIC)

WARNING: CI w/ cisapride, pimozide, quinidine, dofetilide, or levacetylmethadol. Serious CV events (eg, ↑ QT, torsades de pointes, VT, cardiac arrest, and/or sudden death) reported w/ these meds and other CYP3A4 inhibitor. Do not use for onychomycosis w/ ventricular dysfunction. Negative inotropic effects have been observed following IV administration D/C/reassess use if S/Sxs of HF occur during Tx.
USES: *Fungal infections (aspergillosis, blastomycosis, histoplasmosis, candidiasis, onychomycosis).*
ACTIONS: Azole antifungal, ↓ ergosterol synth.
DOSE: Dose based on indication. 200 mg PO daily–TID (caps w/ meals or cola/grapefruit juice); PO soln on empty stomach; avoid antacids.
W/P: [C, −] Numerous interactions.
CI: See “Warning"; pregnancy or considering pregnancy; ventricular dysfunction CHF.
DISP: Caps 100 mg; soln 10 mg/mL.
SE: N/V, rash, hepatotoxic, ↓ K^+, CHF, ↑ BP, neuropathy.
NOTES: Soln & caps not interchangeable; useful in pts who cannot take amphotericin B; follow LFTs.

KETOCONAZOLE, ORAL (NIZORAL, GENERIC)

WARNING: (Oral use) Risk of fatal hepatotox. Concomitant dofetilide, quinidine, pimozide, cisapride, methadone, disopyramide, dronedarone, ranolazine are CI d/t serious CV adverse events.
USES: *Systemic fungal infections (*Candida,* blastomycosis, histoplasmosis, etc.); refractory

topical dermatophyte infection*; PCa when rapid ↓ testosterone needed or hormone refractory; Cushing's disease medical therapy when surgery not possible.
ACTIONS: Azole, ↓ fungal cell wall synth; high dose blocks P450, to ↓ testosterone production.
DOSE: *PO:* 200 mg PO daily; ↑ to 400 mg PO daily for serious infection. *PCa:* 400 mg PO TID w/ hydrocortisone 20–40 mg divided BID; best on empty stomach.
W/P: [C, −/−] w/ Any agent that ↑ gastric pH (↓ absorption); may enhance anticoagulants; w/ EtOH (disulfiram-like reaction); numerous interactions including statins, niacin; do not use w/ clopidogrel (↓ effect).
CI: CNS fungal infections, w/ dofetilide, quinidine, pimozide, cisapride, methadone, disopyramide, dronedarone, ranolazine. Ketoconazole can cause elevated plasma concentrations of these drugs and may prolong QT intervals.
DISP: Tabs 200 mg.
SE: N, rashes, hair loss, headache, ↑ Wt gain, dizziness, disorientation, fatigue, impotence, hepatox, adrenal suppression, acquired cutaneous adherence ("sticky skin syndrome").
NOTES: Monitor LFTs; can rapidly ↓ testosterone levels at high dose.

KETOROLAC, INJECTION (GENERIC)

WARNING: For short-term (≤5 days) Treat of mod–severe acute pain; CI w/ PUD, GI bleed, post CABG, anticipated major surgery, severe renal insufficiency, bleeding diathesis, L&D, nursing, and w/ ASA/NSAIDs. NSAIDs may cause ↑ risk of CV/thrombotic events (MI, stroke). PO CI in peds <16 yr, dose adjustments for <50 kg.
USES: *Pain.*
ACTIONS: NSAID; ↓ prostaglandins.

DOSE:

Adults: 15–30 mg IV/IM q6h; 10 mg PO QID only as continuation of IM/IV; max. IV/IM 120 mg/d, max. PO 40 mg/d; ↓ if >65 yr, elderly, w/ renal impairment, <50 kg.
Peds: ***2–16 yr:*** 1 mg/kg IM × 1 dose; 30 mg max.; IV: 0.5 mg/kg, 15 mg max.; do not use for >5 days.
W/P: [C (D 3rd tri), −] w/ ACE inhibitor, diuretics, BP meds, warfarin.
CI: See "Warning"; as prophylactic analgesic before any major surgery.
DISP: Tabs 10 mg; Inj 15 mg/mL, 30 mg/mL.
SE: Bleeding, peptic ulcer disease, ↑ Cr & LFTs, ↑ BP, edema, dizziness, allergy.
NOTES: Volume depletion increases renal toxicity.

KETOROLAC, NASAL (SPRIX)

WARNING: For short-term (5 days) use; CI w/ PUD, GI bleed, suspected bleeding risk, postop CABG, advanced renal disease or risk of renal failure w/ vol depletion; risk CV thrombotic events (MI, stroke). Not indicated for use in children.
USES: *Short-term (<5 days) Treat pain requiring opioid level analgesia.*
ACTIONS: NSAID; ↓ prostaglandins.
DOSE: ***<65 yr:*** 31.5 mg (one 15.75-mg spray each nostril) q6–8h; max. 126 mg/d. ***≥65 yr, w/ renal impairment or <50 kg:*** 15.75 mg (one 15.75-mg spray in only 1 nostril) q6–8h;

max. 63 mg/d.
W/P: [C (D 3rd tri), −] Do not use w/ other NSAIDs; can cause severe skin reactions; do not use w/ critical bleeding risk; w/ CHF.
CI: See “Warning"; prophylactic to major surgery/L&D, w/ Hx allergy to other NSAIDs recent or Hx of GI bleed or perforation.
DISP: Nasal spray 15.75-mg ketorolac/100-μL spray (8 sprays/bottle).
SE: Nasal discomfort/rhinitis, ↑ lacrimation, throat irritation, oliguria, rash, ↓ HR, ↓ urine output, ↑ ALT/AST, ↑ BP.
NOTES: Discard open bottle after 24 hr.

KUNECATECHINS [SINECATECHINS] (VEREGEN)

USES: *External genital/perianal warts.*
ACTIONS: Unknown; green tea extract.
DOSE: Apply 0.5-cm ribbon to each wart 3×/d until all warts clear; not >16 wk.
W/P: [C, ?].
DISP: Oint 15%.
SE: Erythema, pruritus, burning, pain, erosion/ulceration, edema, induration, rash, phimosis.
NOTES: Wash hands before/after use; not necessary to wipe off prior to next use; avoid on open wounds, may weaken condoms & Vag diaphragms, use in combo is not recommended.

LACTOBACILLUS (LACTINEX GRANULES) [OTC]

USES: *Control of diarrhea*, especially after antibiotic Treat.
ACTIONS: Replaces normal intestinal flora, lactase production; *Lactobacillus acidophilus* and *Lactobacillus helveticus*.

DOSE:
Adults & Peds: ***>3 yr:*** 1 packet, 1–2 caps, or 4 tabs QD–QID
W/P: [A, +] Some products may contain whey.
CI: Milk/lactose allergy.
DISP: Tabs, caps; granules in packets (all OTC).
SE: Flatulence.
NOTES: May take granules on food.

LANTHANUM CARBONATE (FOSRENOL)

USES: *Hyperphosphatemia in end-stage renal disease.*
ACTIONS: Phosphate binder.
DOSE: 750–1,500 mg PO daily in ÷ doses, w/ or immediately after meal; titrate q2–3wk based on PO_4 levels.

W/P: [C, ?/−] No data in GI disease; not for peds.
CI: Bowel obstruction, fecal impaction, ileus.
DISP: Chew tabs 500, 750, 1,000 mg.
SE: N/V, graft occlusion, headache, ↓ BP.
NOTES: Chew tabs before swallowing; separate from meds that interact w/ antacids by 2 hr.

LEUPROLIDE (ELIGARD, LUPRON, LUPRON DEPOT, LUPRON DEPOT-PED, GENERIC)

USES: *Advanced PCa (all except Depot-Ped), endometriosis (*Lupron*), uterine fibroids (*Lupron*), & precocious puberty (*Lupron-Ped*).*
ACTIONS: LHRH agonist; paradoxically ↓ release of GnRH w/ ↓ LH from anterior pituitary; in men ↓ testosterone, in women ↓ estrogen.

DOSE:

Adults: *PCa: Lupron DEPOT*: 7.5 mg IM q28d or 22.5 mg IM q3mo or 30 mg IM q4mo or 45 mg IM q6mo. *Eligard:* 7.5 mg SQ q28d or 22.5 mg SQ q3mo or 30 mg SQ q4mo or 45 mg SQ 6 mo. *Endometriosis (Lupron DEPOT):* 3.75 mg IM qmo × 6 or 11.25 IM q3mo × 2. *Fibroids:* 3.75 mg IM qmo × 3 or 11.25 mg IM × 1.
Peds: *CPP (Lupron DEPOT- Ped):* 50 μg/kg/d SQ Inj; ↑ by 10 μg/kg/d until total downregulation achieved. *Lupron DEPOT:* ***<25 kg:*** 7.5 mg IM q4wk; ***>25–37.5 kg:*** 11.25 mg IM q4wk; ***>37.5 kg:*** 15 mg IM q4wk, ↑ by 3.75 mg q4wk until response.
W/P: [X, −] w/ Impending cord compression in PCa, ↑ QT w/ meds or pre-existing CV disease; postmarketing reports of seizures.
CI: AUB, implant in women/peds; pregnancy.
DISP: Inj 5 mg/mL; *Lupron DEPOT:* 3.75 mg (1 mo for fibroids, endometriosis); *Lupron DEPOT* for PCa: 7.5 mg (1 mo), 11.25 (3 mo), 22.5 (3 mo), 30 mg (4 mo), 45 mg (6 mo); *Eligard depot* for PCA: 7.5 (1 mo); 22.5 (3 mo), 30 (4 mo), 45 mg (6 mo); *Lupron DEPOT-Ped:* 7.5, 11.25, 15, 30 mg.
SE: Hot flashes, gynecomastia, N/V, alopecia, anorexia, dizziness, headache, insomnia, paresthesias, depression exacerbation, peripheral edema, & bone pain (transient "flare reaction" at 7–14 days after the 1st dose [LH/testosterone surge before suppression]); ↓ BMD w/ >6 mo use, bone loss possible, abnormal menses, hyperglycemia.
NOTES: Nonsteroidal antiandrogen (eg, bicalutamide) may block flare in men w/ PCa; Viadur 12 mo form unavailable to new patients.

LEVOFLOXACIN (LEVAQUIN, GENERIC)

WARNING: ↑ Risk Achilles tendon rupture and tendonitis, ↑ in pts >60 yr, on steroids or with organ transplant; avoid w/ myasthenia gravis, may ↑ muscle weakness.
USES: *SSSI, UTI, chronic bacterial prostatitis, acute pyelo, acute bacterial sinusitis, acute bacterial exacerbation of chronic bronchitis, community-acquired pneumonia, including multidrug-resistant *S. pneumoniae*, nosocomial pneumonia; Treat inhalational anthrax in adults & peds ≥6 mo.*
ACTIONS: Quinolone, ↓ DNA gyrase. *Spectrum:* Excellent gram(+) except MRSA & *E. faecium;* excellent gram(−) except *Stenotrophomonas maltophilia & Acinetobacter* sp; poor anaerobic.

DOSE:

Adults: ***≥18 yr:*** IV/PO: *Bronchitis:* 500 mg qd × 7 days. *Community-acquired pneumonia:* 500 mg qd × 7–14 days or 750 mg qd × days. *Sinusitis:* 500 mg qd × 10–14 days or 750 mg qd × days. *Prostatitis:* 500 mg qd × 28 days. *Uncomp SSSI:* 500 mg qd × 7–10 days. *Comp SSSI/nosocomial pneumonia:* 750 mg qd × 7–14 days. *Anthrax:* 500 mg qd × 60 days; *Uncomp*

UTI: 250 mg qd × 3 days. *Comp UTI/acute pyelo*: 250 mg qd × 10 days or 750 mg qd × 5 days. CrCl 10–19 mL/min: 500 mg then 250 mg q other day or 750 mg, then 500 mg q48h. *Hemodialysis:* 750 mg, then 500 mg q48h.
Peds: ≥***6 mo:*** *Anthrax >50 kg:* 500 mg q24h × 60 days, <50 kg: 8 mg/kg (250 mg/dose max.) q12h for 60 days ↓ w/ renal impairment avoid antacids w/ PO; oral soln 1 hr before, 2 hr after meals; *Community-acquired pneumonia:* ≥6 mo–≤4 yr: 8 mg/kg/dose q12h (max. 750 mg/d), 5–16 yr: 8 mg/kg/dose once daily (750 mg/d).
W/P: [C, −] w/ Cation-containing products (eg, antacids), w/ drugs that ↑ QT interval.
CI: Quinolone sensitivity.
DISP: Tabs 250, 500, 750 mg; premixed IV 250, 500, 750 mg, Inj 25 mg/mL; Leva-Pak 750 mg × 5 days.
SE: N/D, dizziness, rash, GI upset, photosensitivity, CNS stimulant w/ IV use, *C. difficile* enterocolitis; rare fatal hepatox, peripheral neuropathy risk.
NOTES: Use w/ steroids ↑ tendon risk; only for anthrax in peds.

LIDOCAINE; LIDOCAINE W/ EPINEPHRINE (ANESTACON TOPICAL, XYLOCAINE, XYLOCAINE VISCOUS, XYLOCAINE MPF, OTHERS)

USES: *Local anesthetic, epidural/caudal anesthesia, regional nerve blocks, topical on mucous membranes (mouth/pharynx/urethra).*
ACTIONS: Anesthetic; stabilizes neuronal membranes; inhibits ionic fluxes required for initiation and conduction.

DOSE:

Adults: *Local Inj anesthetic:* 4.5 mg/kg max. total dose or 300 mg; w/ epi 7 mg/kg or total 500 mg max. dose. *Oral:* 15 mL viscous swish and spit or *pharyngeal* gargle and swallow, do not use <3-hr intervals or >8 × in 24 hr. *Urethra:* Jelly 5–30 mL (200–300 mg) in men, 3–5 mL female urethra; 600 mg/24 h max.
Peds: *Topical:* Apply max. 3 mg/kg/ dose. *Local Inj anesthetic:* Max. 4.5 mg/kg.
W/P: [B, +] Epi-containing soln may interact w/ tricyclic antidepressants or MAOI and cause severe ↑ BP.
CI: Do not use lidocaine w/ epi on penis, digits, ears, or nose (vasoconstriction & necrosis).
DISP: *Inj local:* 0.5%, 1%, 1.5%, 2%, 4%, 10%, 20%; Inj w/ epi 0.5%/1:200,000, 1%/1:100,000, 2%/1:100,000; (MPF) 1%/1:200,000, 1.5%/1:200,000, 2%/1:200,000; cream 2%, 3%, 4%; lotion 30%, jelly 2%, gel 2%, 2.5%, 4%, 5%; oint 5%; liq 2.5%; soln 2, 4%; viscous 2% topical spray 9.6%.
SE: Dizziness, paresthesias, & seizures associated w/ tox.

LIDOCAINE/PRILOCAINE (EMLA, ORAQ IX)

USES: *Topical anesthetic for intact skin or genital mucous membranes*; adjunct to phlebotomy or dermal procedures.
ACTIONS: Amide local anesthetics.

DOSE:

Adults: *EMLA cream,* thick layer 2–2.5 g to intact skin over 20–25 cm^2 of skin surface, cover

w/ occlusive dressing (eg, Tegaderm) for at least 1 hr. *Anesthetic disc:* 1 g/10 cm^2 for at least 1 hr.
Peds: *Max. dose:* ***<3 mo or <5 kg:*** 1 g/10 cm^2 for 1 hr. ***3–12 mo & >5 kg:*** 2 g/20 cm^2 for 4 hr. ***1–6 yr & >10 kg:*** 10 g/100 cm^2 for 4 hr. ***7–12 yr & >20 kg:*** 20 g/200 cm^2 for 4 hr.
W/P: [B, +].
CI: Methemoglobinemia use on mucous membranes, broken skin, eyes; allergy to amide-type anesthetics.
DISP: Cream 2.5% lidocaine/2.5% prilocaine; anesthetic disc (1 g); periodontal gel 2.5/2.5%.
SE: Burning, stinging, methemoglobinemia.
NOTES: Longer contact time ↑ effect.

LIDOCAINE/TETRACAINE, PATCH (SYNERA) CREAM (PLIAGLIS)

USES: *Topical anesthesia for venipuncture and dermatologic procedures (*Synera*); dermatologic procedures (*Pliaglis*).*
ACTIONS: Combo amide and ester local anesthetic.

DOSE:
Adults & Peds: *Synera:* Apply patch 20–30 min before procedure.
Adults: *Pliaglis:* Apply cream 20–60 min before procedure, volume based on site surface (see label).
W/P: [B, ?/−] Use on intact skin only; avoid eyes; not for mucous membranes; do not use w/ Hx methemoglobinemia anaphylaxis reported; caution w/ Class I antiarrhythmic drugs; remove before MRI.
CI: Component sensitivity (PABA or local anesthetics).
DISP: *Synera* 70 mg lidocaine/70 mg tetracaine in 50 cm^2 patch; *Pliaglis* 70 mg lidocaine/70 mg tetracaine/g (7%/7%) cream 30, 60, 100 g tube.
SE: Erythema, blanching, and edema.

LINDANE (GENERIC)

WARNING: Only for pts intolerant/failed 1st-line Treat w/ safer agents. Seizures and deaths reported w/ repeated/prolonged use. Caution d/t increased risk of neurotox in infants, children, elderly, w/ other skin conditions, and if <50 kg. Instruct pts on proper use and inform that itching occurs after successful killing of scabies or lice.
USES: *Head lice, pubic "crab" lice, body lice, scabies.*
ACTIONS: Ectoparasiticide & ovicide.

DOSE:
Adults & Peds. *Cream or lotion:* Thin layer to dry skin after bathing, leave for 8–12 hr, rinse; also use on laundry. *Shampoo:* Apply 30 mL to dry hair, develop a lather w/ warm water for 4 min, comb out nits.
W/P: [C, −].
CI: Premature infants, uncontrolled seizure disorders, Norwegian scabies, open wounds.
DISP: Lotion 1%; shampoo 1%.
SE: Arrhythmias, seizures, local irritation, GI upset, ataxia, alopecia, N/V, aplastic anemia.

NOTES: Caution w/ overuse (may be absorbed); caution w/ hepatic in pts may repeat Treat in 7 days; try OTC 1st w/ pyrethrins (*Pronto*, *Rid*, others).

LINEZOLID (ZYVOX)

USES: *Infections caused by gram(+) bacteria (including VRE), pneumonia, skin infections.*
ACTIONS: Unique, binds ribosomal bacterial RNA; bactericidal for streptococci, bacteriostatic for enterococci & staphylococci. *Spectrum:* Excellent gram(+) including VRE & MRSA.

DOSE:

Adults: 600 mg IV or PO q12h.
Peds: Ä ≤*11 y:* 10 mg/kg IV or PO q8h (q12h in preterm neonates).
W/P: [C, ?/−].
CI: Concurrent MAOI use or w/in 2 wk, uncontrolled HTN, thyrotoxicosis, vasopressive agents, carcinoid tumor, SSRIs, tricyclics, w/ MAOI (may cause serotonin syndrome when used w/ these psych meds), avoid foods w/ tyramine & cough/cold products w/ pseudoephedrine; w/ ↓ BM.
DISP: Inj 200, 600 mg; tabs 600 mg; susp 100 mg/5 mL.
SE: Lactic acidosis, peripheral/optic neuropathy, HTN, N/diarrhea, headache, insomnia, GI upset, ↓ BM, tongue discoloration prolonged use C. diff infection.
NOTES: Check weekly CBC; not for gram(−) infection, ↑ deaths in catheter-related infections; MAOI activity.

LISINOPRIL (PRINIVIL, ZESTRIL, GENERIC)

WARNING: ACE inhibitor can cause fet al injury/death in 2nd/3rd tri; D/C w/ *pregnancy*.
USES: *HTN, CHF, prevent diabetic nephropathy & acute MI*
ACTIONS: ACE inhibitor.
DOSE: 5–40 mg/24 h PO daily–BID, CHF target 40 mg/d. *AMI:* 5 mg w/in 24 hr of MI, then 5 mg after 24 hr, 10 mg after 48 hr, then 10 mg/d; ↓ in renal insufficiency; use low dose, ↑ slowly in elderly.
W/P: [C (1st tri) D (2nd, 3rd tri), −] w/ Aortic stenosis/ cardiomyopathy.
CI: Pregnancy, ACE inhibitor sensitivity, idiopathic or hereditary angioedema.
DISP: Tabs 2.5, 5, 10, 20, 30, 40 mg.
SE: Dizziness, headache, cough, ↓ BP, angioedema, ↑ K^+, ↑ Cr, rare ↓ BM.
NOTES: To prevent DN, start when urinary microalbuminuria begins; check BUN, Cr, K^+, WBC.

LISINOPRIL/HYDROCHLOROTHIAZIDE (PRINZIDE, ZESTORETIC, GENERIC)

WARNING: ACE inhibitor can cause fet al injury/death in 2nd/3rd tri; D/C w/ pregnancy.
USES: *HTN.*
ACTIONS: ACE inhibitor w/ diuretic (HCTZ).
DOSE: Initial 10 mg lisinopril/12.5 mg HCTZ, titrate upward to effect; >80 mg/d lisinopril or >50 mg/day HCTZ are not recommended; ↓ in renal insufficiency; use low dose, ↑ slowly

in elderly.
W/P: [C 1st tri, D after, −] w/ Aortic stenosis/cardiomyopathy, bilateral RAS.
CI: Pregnancy, ACE inhibitor, idiopathic or hereditary angioedema, sensitivity (angioedema).
DISP: Tabs (mg lisinopril/mg HCTZ) 10/12.5, 20/12.5; *Zestoretic* also available as 20/25.
SE: Anaphylactoid reaction (rare), dizziness, headache, cough, fatigue, ↓ BP, angioedema, ↑ / ↓ K^+, ↑ Cr, rare ↓ BM/cholestatic jaundice.
NOTES: Use only when monotherapy fails; check BUN, Cr, K^+, WBC.

LOSARTAN (COZAAR, HYZAAR, GENERIC)

WARNING: Can cause fet al injury and death if used in 2nd & 3rd tri. D/C Treat if pregnancy detected.
USES: *HTN, DN, HTN w/ LVH.*
ACTIONS: Angiotensin II receptor antagonist.

DOSE:

Adults: 25–50 mg PO daily–BID, max. 100 mg; ↓ in elderly/hepatic impairment.
Peds: ***≥6 yr:*** *HTN:* Initial 0.7 mg/kg qd, ↑ to 50 mg/d PRN; 1.4 mg/kg/d or 100 mg/d max.
W/P: [C (1st tri, D 2nd, & 3rd tri), ?/−] w/ NSAIDs; w/ K^+-sparing diuretics, supl may cause ↑ K^+; w/ RAS, hepatic impairment.
CI: Pregnancy, component sensitivity.
DISP: Tabs 25, 50, 100 mg.
SE: ↓ BP in pts on diuretics; ↑ K^+; GI upset, facial/angioedema, dizziness, cough, weakness, ↓ renal function.
NOTES: w/ DM risk check glucose.

LULICONAZOLE (LUZU)

USES: *Tinea pedis, tinea cruris, tinea corporis.*
ACTIONS: Azole antifungal, inhibits ergosterol synthesis.
DOSE: Tinea pedis apply 1 ×/d for 2 wk; tinea corporis, tinea cruris apply 1 ×/d for 1 wk.
W/P: [C, ?/-].
CI: None.
DISP: Cream, 1%; 30/60 g.
SE: Site reaction, rare.

LYMPHOCYTE IMMUNE GLOBULIN [ANTITHYMOCYTE GLOBULIN, ATG] (ATGAM)

WARNING: Should only be used by physician experienced in immunosuppressive therapy or management of solid organ and/or BMT pts. Adequate lab and supportive resources must be readily available.
USES: *Allograft rejection in renal transplant pts; aplastic anemia if not candidates for BMT*, GVHD after BMT.
ACTIONS: ↓ Circulating antigen-reactive T lymphocytes; a human, & equine product.

DOSE:

Adults: *Prevent rejection:* 15 mg/kg/d IV × 14 days, then q other day × 7 days for total 21 doses in 28 days; initial w/in 24 hr before/after transplant. *Treat rejection:* Same but use 10–15 mg/kg/d; max. 21 doses in 28 days, qd 1st 14 days. *Aplastic anemia:* 10–20 mg/kg/d × 8–14 days, then q other day × 7 doses for total 21 doses in 28 days.
Peds: *Prevent renal allograft rejection:* 5–25 mg/kg/d IV; *aplastic anemia* 10–20 mg/kg/day IV 8–14 days then q other day for 7 more doses.
W/P: [C, ?/−] D/C if severe unremitting thrombocytopenia, leukopenia.
CI: Hx previous reaction or reaction to other equine γ-globulin prep, ↓ plt and WBC.
DISP: Inj 50 mg/mL.
SE: D/C w/ severe ↓ plt and WBC; rash, fever, chills, ↓ BP, headache, CP, edema, N/V/diarrhea, lightheadedness.
NOTES: Test dose: 0.1 mL 1:1,000 dilution in NS, a systemic reaction precludes use; give via central line; pretreat w/ antipyretic, antihistamine, and steroids; monitor WBC, plt; plt counts usually return to nl w/o D/C Treat 4 hr Inf.

MAGNESIUM HYDROXIDE (MILK OF MAGNESIA) [OTC]

USES: *Constipation*, hyperacidity, Mg^{2+} replacement.
ACTIONS: NS laxative.

DOSE:

Adults: *Antacid:* 5–15 mL (400 mg/5 mL) or 2–4 tabs (311 mg) PO PRN up to QID. *Laxative:* 30–60 mL (400 mg/5 mL) or 15–30 mL (800 mg/5 mL) or 8 tabs (311 mg) PO qhs or ÷ doses.
Peds: *Antacid and* <12 yr not OK. *Laxative:* <2 yr not OK. ***2–5 yr:*** 5–15 mL (400 mg/5 mL) PO qhs or ÷ doses. ***6–11 yr:*** 15–30 mL (400 mg/5 mL) or 7.5–15 mL (800 mg/5 mL) PO qhs or ÷ doses. ***3–5 yr:*** 2 (311 mg) tabs PO qhs or ÷ doses. ***6–11 yr:*** 4 (311 mg) tabs PO qhs or ÷ doses.
W/P: [B, +] w/ Neuromuscular disease or renal impairment.
CI: Component hypersens.
DISP: Chew tabs 311, 400 mg; liq 400, 800 mg/5 mL (OTC).
SE: Diarrhea, abdominal cramps.
NOTES: For occasional use in constipation, different forms may contain Al^{2+}.

MAGNESIUM OXIDE (MAG-OX 400, OTHERS) [OTC]

USES: *Replace low Mg^{2+} levels.*
ACTIONS: Mg^{2+} supl.
DOSE: 400–800 mg/d or ÷ w/ food in full glass of H_2O; ↓ w/ renal impairment.
W/P: [B, +] w/ Neuromuscular disease & renal impairment, w/ bisphosphonates, calcitriol, CCBs, neuromuscular blockers, tetracyclines, quinolones.
CI: Component hypersens.
DISP: Caps 140, 250, 500, 600 mg; tabs 400 mg (OTC).
SE: Diarrhea, N.

MAGNESIUM SULFATE (GENERIC)

USES: *Replace low Mg^{2+}; preeclampsia, eclampsia, & premature labor, cardiac arrest, AMI arrhythmias, cerebral edema, barium poisoning, seizures, pediatric acute nephritis*; refractory ↓ K^+ & ↓ Ca^{2+}.
ACTIONS: Mg^{2+} supl, bowel evacuation, ↓ acetylcholine in nerve terminals, ↓ rate of sinoatrial node firing.

DOSE:

Adults: 1 g q6h IM × 4 doses & PRN 1–2 g q3–6h IV then PRN to correct deficiency.
Peds & Neonates: 25–50 mg/kg/dose IV, repeat PRN; max. 2 g single dose.
W/P: [A/C (manufacturer specific), +] w/ Neuromuscular disease; interactions see Magnesium Oxide and aminoglycosides.
CI: Heart block, myocardial damage.
DISP: Premix Inj: 10, 20, 40, 80 mg/mL; Inj 125, 500 mg/mL; oral/topical powder 227, 454, 1,810, 2,720 g.
SE: CNS depression, diarrhea, flushing, heart block, ↓ BP, vasodilation.
NOTES: Different formulation may contain Al^{2+}, monitor Mg^{2+} levels.

MANNITOL, INTRAVENOUS (GENERIC)

USES: *Cerebral edema, ↑ IOP, renal impairment, poisonings.*
ACTIONS: Osmotic diuretic.
DOSE: *Test dose:* 0.2 g/kg/dose IV over 3–5 min; if no diuresis w/in 2 hr, D/C. *Oliguria:* 50–100 g IV over 90 min ↑ *IOP:* 0.25–2 g/kg IV over 30 min. *Cerebral edema:* 0.25–1.5 g/kg/dose IV q6–8h PRN, maintain serum osmolarity < 300–320 mOsm/kg.
W/P: [C, ?/M] w/ CHF or vol overload, w/ nephrotoxic drugs & lithium.
CI: Anuria, dehydration, heart failure, PE intracranial bleeding.
DISP: Inj 5%, 10%, 15%, 20%, 25%.
SE: May exacerbate CHF, N/V/diarrhea, ↓ / ↑ BP, ↑ HR.
NOTES: Monitor for vol depletion.

MEGESTROL ACETATE (MEGACE, MEGACE-ES)

USES: *Anorexia, cachexia, or an unexplained significant weight loss in patients with AIDS; palliative treatment of advanced carcinoma of the breast or endometrium.*
ACTIONS: Hormone; anti-leuteinizing; progesterone analog.
DOSE: *Appetite: Megace-ES* 625 mg/day (5 mL or 1 teaspoon/d). *Breast cancer*: 160 mg/d (40 mg QID); *Endometrial cancer*: 40–320 mg/d divided doses.
W/P: [D (tablet)/X (suspension), −] Thromboembolism; handle w/ care.
CI: Pregnancy.
DISP: Tabs 20, 40 mg; susp 40 mg/ mL, *Megace-ES* 125 mg/mL.
SE: DVT, edema, menstrual bleeding, photosensitivity, N/V/diarrhea, headache, mastodynia, ↑ Ca, ↑ glucose, insomnia, rash, ↓ BM, ↑ BP, CP, palpitations.
NOTES: Do not D/C abruptly; Megace-ES not equivalent to others mg/mg.

MELPHALAN [L-PAM] (ALKERAN, GENERIC)

WARNING: Administer under the supervision of a qualified physician experienced in the use of chemotherapy; severe BM depression, leukemogenic, & mutagenic hypersens (including anaphylaxis in ~2%).
USES: *Palliative treatment multiple myeloma and ovariant cancer*, breast & testicular cancer, melanoma; allogenic & ABMT (high dose), neuroblastoma, rhabdomyosarcoma.
ACTIONS: Alkylating agent, nitrogen mustard.

DOSE:

Adults: *Multiple myeloma:* 16 mg/ m^2 IV q2wk × 4 doses then at 4-wk intervals after tox resolves; w/ renal impairment ↓ IV dose 50% or 6 mg PO qd × 2–3 wk, then D/C up to 4 wk, follow counts then 2 mg qd. *Ovarian cancer:* 0.2 mg/kg qd × 5 days, repeat q4–5wk based on counts, ↓ in renal insufficiency.
W/P: [D, ?/−] w/ Cisplatin, digitalis, live vaccines extravasation, need central line.
CI: Allergy or resistance.
DISP: Tabs 2 mg; Inj 50 mg.
SE: N/V, secondary malignancy, AF, ↓ LVEF, ↓ BM, secondary leukemia, alopecia, dermatitis, stomatitis, pulm fibrosis; rare allergic reactions, thrombocytopenia.
NOTES: Take PO on empty stomach, false(+) direct Coombs test.

MEPERIDINE (DEMEROL, GENERIC) [C–II]

USES: *Mod–severe pain*, postoperative shivering, rigors from amphotericin B.
ACTIONS: Narcotic analgesic.

DOSE:

Adults: 50–150 mg PO or IV/IM/SQ q3–4h PRN.
Peds: 1–1.5 mg/kg/ dose PO or IM/SQ q3–4h PRN, up to 100 mg/dose; hepatic impairment, avoid in renal impairment, avoid use in elderly.
W/P: [C, −] risk for dependency, ↓ seizure threshold, adrenal insufficiency, head injury, ↑ ICP, hepatic impairment, not OK in sickle cell disease.
CI: w/ MAOIs.
DISP: Tabs 50, 100 mg; syrup/soln 50 mg/5 mL; Inj 25, 50, 75, 100 mg/mL.
SE: Resp/CNS depression, seizures, sedation, constipation, ↓ BP, rash N/V, biliary and urethral spasms, dyspnea.
NOTES: Analgesic effects potentiated w/ hydroxyzine; 75 mg IM = 10 mg morphine IM; not best in elderly; do not use oral for acute pain; not OK for repetitive use in ICU setting, naloxone does not reverse neurotox, used as analgesic, is not recommended, limit Tx to <48 hr.

MEROPENEM (MERREM, GENERIC)

USES: *Intra-abdominal infections, bacterial meningitis, skin infection.*
ACTIONS: Carbapenem; ↓ cell wall synth. *Spectrum:* Excellent gram(+) (except MRSA, methicillin-resistant *S. epidermidis* [MRSE] & *E. faecium*); excellent gram(−) including

extended-spectrum β-lactamase producers; good anaerobic.

DOSE:

Adults: *Abdominal infection:* 1–2 g IV q8h. *Skin infection:* 500 mg IV q8h.
Peds: ***>3 mo, <50 kg:*** *Abdominal infection:* 20 mg/kg IV q8h. *Skin infection:* 10 mg/kg IV q8h; ***Peds >50 kg.*** Use adult dose; max. 2 g IV q8h; ↓ in renal insufficiency (see package insert).
W/P: [B, ?/M] w/ Probenecid, valproic acid.
CI: β-Lactam anaphylaxis.
DISP: Inj 1 g, 500 mg.
SE: Less seizure potential than imipenem; *C. difficile* enterocolitis, diarrhea, ↓ plt.
NOTES: Overuse ↑ bacterial resistance.

MESNA (MESNEX [ORAL] , GENERIC [IV])

USES: *Prevent hemorrhagic cystitis d/t ifosfamide* or cyclophosphamide.
ACTIONS: Antidote, reacts w/ acrolein and other metabolites to form stable compounds (sodium 2-mercaptoethane sulfonate).
DOSE: Per protocol; dose as % of ifosfamide or cyclophosphamide dose. *IV bolus:* 20% (eg, 10–12 mg/kg) IV at 0, 4, & 8 hr; *IV Inf:* 20% prechemotherapy, 40% w/ chemotherapy for 12–24 hr; *Oral:* 100% ifosfamide dose given as 20% IV at hour 0 then 40% PO at hours 4 & 8; if PO dose vomited repeat or give dose IV; mix PO w/ juice.
W/P: [B; ?/−].
CI: Thiol sensitivity.
DISP: Inj 100 mg/mL; (*Mesnex*) tabs 400 mg.
SE: ↓ BP, ↓ plt, ↑ HR, ↑ RR allergic reactions, rash, headache, GI upset, taste perversion; false positive urinary ketones.
NOTES: Hydration helps ↓ hemorrhagic cystitis; higher dose for BMT; IV contains benzyl alcohol.

METHENAMINE HIPPURATE (HIPREX)

USES: *Suppress recurrent UTI long term; use only after infection cleared by antibiotics.*
ACTIONS: Converted to formaldehyde & ammonia in acidic urine; nonspecific bactericidal action.

DOSE:

Adults: 1 g PO BID.
Peds: ***6–12 yr:*** 0.5–1 g PO BID PO ÷ BID; w/ food, ascorbic acid w/ hydration.
W/P: [C, +] Large doses (8 g/d for 3–4 wk) have caused bladder irritation, painful/frequent micturition, albuminuria, and gross hematuria.
CI: Renal insufficiency, severe hepatic disease, severe dehydration w/ sulfonamides (may precipitate in urine).
DISP: Tabs 1 g.
SE: Rash, GI upset, dysuria, ↑ LFTs, super infection w/ prolonged use, *C. difficile*-associated diarrhea.

NOTES: Not indicated in peds <6 yr. Not for pts w/ indwelling catheters as dwell time in bladder required for action.

METHENAMINE COMBINATION PRODUCTS (HYOPHEN, URIBEL, UROGESIC BLUE, OTHERS)

(Note: This labeling has not been approved by the FDA)
USES: *Relief of local symptoms, such as inflammation, hypermotility, and pain, which accompany lower UTIs and symptoms caused by diagnostic procedures.*
ACTIONS: Based on individual components: *Methenamine* in acid urine releases formaldehyde (antiseptic); *phenyl salicylate* is a mild analgesic; *methylene blue/benzoic acid* are mild antiseptics; hyoscyamine is parasympatholytic (belladonna alkaloid) ↓ bladder spasm; *sodium phosphate monobasic* is an acidifier to maintain an acid pH for the degradation of methenamine.

DOSE:
Adults & Peds: ***>12 yr:*** 1 tab PO QID w/ liberal fluid intake.
W/P: [C, ?/−] Avoid w/ sulfonamides, narrow-angle glaucoma, pyloric/duodenal obst, bladder outlet obstruction, coronary artery spasm.
CI: Component hypersens.
DISP: Tabs and capsules (see representative products below).
- **HYOPHEN** (methenamine, benzoic acid, phenyl salicylate, methylene blue, hyoscyamine sulfate) tablet
- **PROSED** (methenamine, phenyl salicylate, methylene blue, benzoic acid, hyoscyamine) tablet
- **URIBEL** (methenamine, sodium phosphate monobasic monohydrate, phenyl salicylate, methylene blue, hyoscyamine sulfate) capsule
- **URIMAR-T, URIN D/S, UROGESIC BLUE, UTIRA-C** (methenamine, sodium phosphate monobasic, phenyl salicylate, methylene blue, hyoscyamine sulfate) tablet
- **USTELL** (methenamine, sodium phosphate monobasic, phenyl salicylate, methylene blue, and hyoscyamine sulfate) capsule.

SE: Rash, dry mouth, flushing, ↑ pulse, dizziness, blurred vision, urine/feces discoloration (blue/light green), voiding difficulty/retention.
NOTES: Take w/ plenty of fluid, can cause crystalluria; not rec in peds ≤6 yr; Not for pts w/ indwelling catheters as dwell time in bladder required for action; see also hyoscyamine and phenazopyridine listings.

METHOTREXATE (RHEUMATREX DOSE PACK, TREXALL, GENERIC)

WARNING: Administration only by experienced physician; do not use in women of child-bearing age unless absolutely necessary (teratogenic); impaired elimination w/ impaired renal function, ascites, pleural effusion; severe ↓ BM w/ NSAIDs; hepatotox, occasionally fatal; can induce life-threatening pneumonitis; diarrhea and ulcerative stomatitis require D/C; lymphoma risk; may cause tumor lysis syndrome; can cause severe skin reaction, opportunistic infections; w/ RT can ↑ tissue necrosis risk. Preservatives make this agent unsuitable for intrathecal IT or higher-dose use.

USES: *ALL, AML, leukemic meningitis, trophoblastic tumors (choriocarcinoma, hydatidiform mole), breast, lung, head, & neck, cancers, Burkitt's lymphoma, mycosis fungoides, osteosarcoma, Hodgkin disease & NHL, psoriasis; rheumatoid arthritis, JRA, SLE*, chronic disease.
ACTIONS: ↓ Dihydrofolate reductase-mediated prod of tetrahydrofolate, causes ↓ DNA synth.

DOSE:

Adults: *Cancer:* Per protocol. *Rheumatoid arthritis:* 7.5 mg/wk PO 1/wk or 2.5 mg q12h PO for 3 doses/wk. *Psoriasis:* 2.5–5 mg PO q12h × 3 d/wk or 10–25 mg PO/IM qwk. *Chronic:* 15–25 mg IM/SQ qwk, then 15 mg/wk.
Peds: JIA: 10 mg/m^2 PO/IM qwk, then 5–14 mg/m^2 × 1 or as 3 divided doses 12 hr apart; ↓ elderly, w/ renal/hepatic impairment.
W/P: [X, −] w/ Other nephro/hepatotoxic meds, multiple interactions, w/ seizure, profound ↓ BM other than cancer related.
CI: Severe renal/hepatic impairment, pregnancy/lactation.
DISP: Dose pack 2.5 mg in 8, 12, 16, 20, or 24 doses; tabs 2.5, 5, 7.5, 10, 15 mg; Inj 25 mg/mL; Inj powder 20 mg, 1 g.
SE: ↓ BM, N/V/diarrhea, anorexia, mucositis, hepatotox (transient & reversible; may progress to atrophy, necrosis, fibrosis, cirrhosis), rashes, dizziness, malaise, blurred vision, alopecia, photosensitivity, renal failure, pneumonitis; rare pulm fibrosis; chemical arachnoiditis & headache w/ IT delivery.
NOTES: Monitor CBC, LFTs, Cr, MTX levels & CXR; "high dose" >500 mg/m^2 requires leucovorin rescue to ↓ tox; w/ IT, use preservative-/alcohol-free soln; systemic levels: *Therapeutic:* >0.01 μmole; *Toxic:* >10 micromole over 24 hr.

METHYLENE BLUE (UROLENE BLUE, VARIOUS)

USES: *Methemoglobinemia, vasoplegic syndrome, ifosfamide-induced encephalopathy, cyanide poisoning, dye in therapeutics/diagnosis.*
ACTIONS: Low IV dose converts methemoglobin to hemoglobin; excreted, appears in urine as green/green-blue color; MAOI activity.
DOSE: 1–2 mg/kg or 25–50 mg/m^2 IV over 5–10 min, repeat q1h; direct instillation into fistulous tract.
W/P: [X, −] w/ Severe renal impairment w/ psych meds such as SSRI, SNRI, TCA (may cause serotonin syndrome), w/ G6PD deficiency.
CI: Intra spinal Inj, severe renal insufficiency.
DISP: 1, 10 mL Inj.
SE: *IV use:* N, abdominal, CP, sweating, fecal/urine discoloration, hemolytic anemia.
NOTES: Component of some oral medications; stains tissue blue, limits repeat use in surgical visualization.

METHYLPREDNISOLONE (DEPO-MEDROL, MEDROL, MEDROL DOSEPAK, SOLU-MEDROL, GENERIC) [SEE STEROIDS]

USES: *Steroid responsive conditions (endocrine, rheumatic, collagen, dermatologic, allergic,

ophthalmic, respiratory, hematologic, neoplastic, edematous, GI, CNS, others).*
ACTIONS: Glucocorticoid.

DOSE:
See Steroids Peds: *Status asthmaticus, anaphylactic shock:* 2 mg/kg IV/IO/IM (max. 60 mg). *Maint:* 0.5 mg/kg IV q6h or 1 mg/kg q12h to 120 mg/d.
W/P: [C, ?/M] May mask Infx, cataract w/ prolonged use; avoid vaccines.
CI: Fungal Infx, component allergy.
DISP: Oral (*Medrol*) 4, 8, 16, 32 mg, (*Medrol Dosepak*) 21 4-mg tabs taken over 6 days; Inj acetate (*Depo-Medrol*) 20, 40, 80 mg/mL; Inj succinate (*Solu-Medrol*) 40, 125, 500 mg, 1, 2 g.
SE: Fluid and electrolyte disturbances, muscle weakness/loss, ulcers, impairment wound healing, others (see label).
NOTES: Taper dose to avoid adrenal insufficiency.

METOCLOPRAMIDE (METOZOLV, REGLAN, GENERIC)

WARNING: Chronic use may cause tardive dyskinesia; D/C if Sxs develop; avoid prolonged use (> 2 wk).
USES: *Diabetic gastroparesis, symptomatic GERD; chemo & postop N/V, facilitate small bowel intubation & upper GI radiologic exam*, *GERD, diabetic gastroparesis *(Metozolv)* stimulate gut in prolonged postop ileus.*
ACTIONS: ↑ Upper GI motility; blocks dopamine in chemoreceptor trigger zone, sensitized tissues to ACH.

DOSE:

Adults: *Gastroparesis (Reglan):* 10 mg PO 30 min ac & hs for 2–8 wk PRN, or same dose IM/IV for 10 days, then PO. *Reflux:* 10–15 mg PO 30 min ac & hs. *Chemo antiemetic:* 1–2 mg/kg/dose IV 30 min before chemo, then q2h × 2 doses, then q3h × 3 doses. *Postop:* 10–20 mg IV/IM q4–6h PRN.
Adults & Peds: ***>14 yr:*** *Intestinal intubation:* 10 mg IV × 1 over 1–2 min.
Peds: *Reflux:* 0.1–0.2 mg/kg/dose PO 30 min ac & hs. *Chemo antiemetic:* 1–2 mg/kg/dose IV as adults. *Postop:* 0.25 mg/kg IV q6–8h PRN.
Peds: *Intestinal intubation:****6–14 yr:*** 2.5–5 mg IV × 1 over 1–2 min; ***<6 yr:*** Use 0.1 mg/kg IV × 1.
W/P: [B, M] Drugs w/ extrapyramidal ADRs, MAOIs, tricyclic antidepressants, sympathomimetics.
CI: w/ EPS meds, GI bleeding, pheochromocytoma, seizure disorders, GI obst.
DISP: Tabs 5, 10 mg; syrup 5 mg/5 mL; ODT *(Metozolv)* 5, 10 mg; Inj 5 mg/mL.
SE: Dystonic reactions common w/ high doses (Treat w/ IV diphenhydramine), fluid retention, restlessness, diarrhea, drowsiness.
NOTES: ↓ w/ Renal impairment/elderly; check baseline Cr.

METRONIDAZOLE (FLAGYL, FLAGYL ER, METROCREAM, METROGEL, METROLOTION)

WARNING: Carcinogenic in rats.
USES: *Bone/joint, endocarditis, intra-abdominal, meningitis, & skin infections; amebiasis & amebic liver abscess; trichomoniasis in pt and partner; bacterial vaginosis; PID; giardiasis; antibiotic-associated pseudomembranous colitis (*C. difficile*), eradicate *H. pylori* w/ combo Treat, rosacea, prophylactic in postop colorectal surgery.*
ACTIONS: Interferes w/ DNA synth. *Spectrum:* Excellent anaerobic, *C. difficile.*

DOSE:

Adults: *Anaerobic* infections: 500 mg IV q6–8h. *Trichomonas:* 250 mg PO TID for 7 days or 2 g PO × 1 (Treat partner). *C. difficile:* 500 mg PO or IV q8h for 7–10 days (PO preferred; IV only if pt NPO), if no response, change to PO vancomycin. *Vaginosis:* 1 applicator intravag qd or BID × 5 days, or 500 mg PO BID × 7 days or 750 mg PO qd × 7 days. *Acne rosacea/skin:* Apply BID.
Peds: *Anaerobic infections*: PO: 15–35 mg/kg/d ÷ q8h *IV*: 30 mg/kg IV/d ÷ q6H, 4 g/d max. ÷ dose; *Trichomonas:* 15–30 mg/kg/d PO ÷ q8h × 7 days. *C. difficile:* 30 mg/kg/d PO ÷ q6h × 10 days, max. 2 g/d; ↓ w/ severe hepatic/renal impairment.
W/P: [B, −] Avoid EtOH, w/ warfarin, CYP3A4 substrates, ↑ Li levels.
CI: 1st tri pregnancy.
DISP: Tabs 250, 500 mg; ER tabs 750 mg; caps 375 mg; IV 500 mg/100 mL; lotion 0.75%; gel 0.75, 1%; intravag gel 0.75% (5 g/applicator 37.5 mg in 70-g tube), cream 0.75, 1%.
SE: Disulfiram-like reaction; dizziness, headache, GI upset, anorexia, urine discoloration, flushing, met allic taste.
NOTES: For trichomoniasis, Treat pt's partner; no aerobic bacteria activity; use in combo w/ serious mixed infections; wait 24 hr after 1st dose to breast-feed or 48 hr if extended Treat, take ER on empty stomach.

MICAFUNGIN (MYCAMINE)

USES: *Candidemia, acute dissem and esophageal candidiasis, *Candida* peritonitis & abscesses; prophylaxis *Candida* infection w/ HSCT.*
ACTIONS: Echinocandin; ↓ fungal cell wall synth.
DOSE: *Candidemia, acute disseminated candidiasis, Candida peritonitis & abscesses:* 100 mg IV daily; *Esophageal candidiasis:* 150 mg IV daily; *Prophylaxis of Candida infection:* 50 mg IV daily over 1 hr.
W/P: [C, ?/−] w/ Sirolimus, nifedipine, itraconazole dosage adj may be necessary.
CI: Component or other echinocandin allergy.
DISP: Inj 50, 100 mg vials.
SE: N/V/diarrhea, headache, pyrexia, abdominal pain, ↓ K^+, ↓ plt, histamine Sxs (rash, pruritus, facial swelling, vasodilatation), anaphylaxis, anaphylactoid reaction, hemolysis, hemolytic anemia, ↑ LFTs, hepatotox, renal impairment.

MICONAZOLE (MONISTAT 1 COMBO, MONISTAT 3, MONISTAT 7 [OTC]) (MONISTAT-DERM)

USES: *Candidal infections, dermatomycoses (tinea pedis/ tinea cruris/tinea corporis/tinea versicolor/candidiasis).*
ACTIONS: Azole antifungal, alters fungal membrane permeability.
DOSE: *Intravag:* 100 mg supp or 2% cream intravag qhs × 7 days or 200 mg supp or 4% cream intravag qhs × 3 days. *Derm:* Apply BID, a.m./p.m. *Tinea versicolor:* Apply qd. Treat tinea pedis and tinea corporis for 1 mo and other infections for 2 wk.
Peds: ≥ ***12 yr:*** 100 mg supp or 2% cream intravag qhs × 7 days or 200 mg supp or 4% cream intravag qhs × 3 days. Not for OTC use in children <2 yr.
W/P: [C, ?] Azole sensitivity.
DISP: *Monistat-Derm:* (Prescription) Cream 2%; *Monistat 1 combo:* 2% cream w/ 1,200 mg supp, *Monistat 3:* Vag cream 4%, supp 200 mg; *Monistat 7:* cream 2%, supp 100 mg; lotion 2%; powder 2%; effervescent tab 2%, oint 2%, spray 2%; Vag supp 100, 200, 1,200 mg; Vag cream 2%, 4%; [OTC].
SE: Vag burning; on skin contact dermatitis, irritation, burning.
NOTES: May interfere w/ condom and diaphragm, do not use w/ tampons.

MICONAZOLE/ZINC OXIDE/PETROLATUM (VUSION)

USES: *Candidal diaper rash.*
ACTIONS: Combo antifungal.

DOSE:

Peds: ≥ ***4 wk:*** Apply at each diaper change × 7 days.
W/P: [C, ?].
CI: None.
DISP: Miconazole/zinc oxide/petrolatum oint 0.25/15/81.35%, 50-, 90-g tube.
SE: None.
NOTES: Keep diaper dry, not for prevention.

MINERAL OIL [OTC]

USES: *Constipation, bowel irrigation, fecal impaction.*
ACTIONS: Lubricant laxative.

DOSE:

Adults: *Constipation:* 15–45 mL PO/d PRN. *Fecal impaction or after barium:* 118 mL rectally × 1.
Peds: > ***6 yr:*** *Constipation:* 5–25 mL PO qd. ***2–12 yr:*** *Fecal impaction:* 59 mL rectally × 1.
W/P: [?, ?] w/ N/V, difficulty swallowing, bedridden pts; may ↓ absorption of vits A, D, E, K, warfarin.
CI: Colostomy/ileostomy, appendicitis, diverticulitis, ulcerative colitis.
DISP: All [OTC] liq, PO microemulsion 2.5 mL/5 mL, rectal enema 118 mL.
SE: Lipid pneumonia (aspiration of PO mineral oil), N/V, temporary anal incontinence.

NOTES: Take PO upright, do not use PO in peds <6 yr; no longer recommended as lubricant for surgical instruments (not water soluble).

MINERAL OIL/PRAMOXINE HCL/ZINC OXIDE (TUCKS OINTMENT [OTC])

USES: *Temporary relief of anorectal disorders (itching, etc.).*
ACTIONS: Topical anesthetic.

DOSE:
Adults & Peds: ≥***12 yr:*** Cleanse, rinse, & dry, apply externally or into anal canal w/ tip 5×/d × 7 days max.
W/P: [?, ?] Do not place into rectum.
CI: None.
DISP: Oint 1% 30-g tube.
SE: Local irritation.
NOTES: D/C w/ or if rectal bleeding occurs or if condition worsens or does not improve w/in 7 days.

MINOCYCLINE (DYNACIN, MINOCIN, SOLODYN, GENERIC)

USES: *Mod–severe nonnodular acne (*Solodyn*), anthrax, rickettsiae, skin infection, URI, UTI, nongonococcal urethritis, amebic dysentery, asymptomatic meningococcal carrier, *Mycobacterium marinum.**
ACTIONS: Tetracycline, bacteriostatic, ↓ protein synth.

DOSE:
Adults & Peds: >***12 yr:*** *Usual:* 200 mg, then 100 mg q12h or 100–200 mg IV or PO, then 50 mg QID. *Gonococcal urethritis, men:* 100 mg q12h × 5 days. *Syphilis:* Usual dose × 10–15 days. *Meningococcal carrier:* 100 mg q12h × 5 days. *M. marinum:* 100 mg q12h × 6–8 wk. *Uncomp urethral, endocervical, or rectal infection:* 100 mg q12h × 7 days minimum.
Adults & Peds: >***12 yr:*** *Acne:* (*Solodyn*) 1 mg/kg PO qd × 12 wk. > ***yr:*** 4 mg/kg initially then 2 mg/kg q12h w/ food to ↓ irritation, hydrate well, ↓ dose or extend interval w/ renal impairment.
W/P: [D, −] Associated w/ pseudomembranous colitis, w/ renal impairment, may ↓ OCP, or w/ warfarin may ↑ INR.
CI: Allergy, children <8 yr.
DISP: Tabs 50, 75, 100 mg; tabs ER (*Solodyn*) 45, 65, 90, 115, 135 mg, caps (*Minocin*) 50, 100 mg, susp 50 mg/mL.
SE: diarrhea, headache, fever, rash, joint pain, fatigue, dizziness, photosensitivity, hyperpigmentation, SLE syndrome, pseudotumor cerebri.
NOTES: Do not cut/crush/chew; keep away from children, tooth discoloration in <8 yr or w/ use last half of pregnancy.

MIRABEGRON (MYRBETRIQ)

USES: *Overactive bladder (OAB) with symptoms of urge urinary incontinence, urgency, and

urinary frequency. *
ACTIONS: β-3 adrenergic agonist; relaxes smooth muscle.
DOSE: Start 25 mg PO daily; ↑ to 50 mg daily after 8 wk PRN; 25 mg max. daily w/ severe renal or mod hepatic impairment; swallow whole, do not cut/chew.
W/P: [C, −] w/ Severe uncontrolled HTN; urinary retention w/ bladder outlet obstruction & antimuscarinic drugs; w/ drugs metabolized by CYP2D6 (eg, thioridazine, flecainide, propafenone); do not use w/ ESRD or severe hepatic impairment; monitor serum digoxin when starting both together.
CI: None.
DISP: Tabs ER 25, 50 mg.
SE: ↑ BP, headache, UTI, nasopharyngitis, N/diarrhea, constipation, abdominal pain, dizziness, tachycardia, URI, arthralgia, fatigue.

MITOMYCIN (GENERIC)

WARNING: Administer only by physician experienced in chemotherapy; myelosuppressive; can induce HUS w/ irreversible renal failure.
USES: *Stomach, pancreas*, breast, colon cancer; squamous cell carcinoma of the anus; NSCLC, head & neck, cervical; bladder cancer (intravesically).
ACTIONS: Alkylating agent; generates oxygen-free radicals w/ DNA strand breaks.
DOSE: (Per protocol) 20 mg/m^2 q6–8wk IV or 10 mg/m^2 combo w/ other myelosuppressive drugs q6–8wk. *Bladder cancer:* 20–40 mg in 40 mL NS via a urethral catheter once/wk; immediately postop if no evidence of extravasation × 1 to reduce recurrences following TURBT; ↓ in renal/hepatic impairment.
W/P: [D, −] w/ Cr >1.7 mg/dL/ ↑ cardiac tox w/ vinca alkaloids/doxorubicin.
CI: ↓ Plt, coagulation disorders, ↑ bleeding tendency, pregnancy.
DISP: Inj 5, 20, 40 mg.
SE: ↓ BM (persists for 3–8 wk, may be cumulative; minimize w/ lifetime dose <50–60 mg/m^2), N/V, anorexia, stomatitis, renal tox, microangiopathic hemolytic anemia w/ renal failure (HUS), veno-occlusive liver disease, interstitial pneumonia, alopecia, extrav reactions, contact dermatitis; CHF w/ doses >30 mg/m^2.

MITOTANE (LYSODREN)

WARNING: Administer only by physician experienced in chemotherapy; discontinue temporarily immediately following shock or severe trauma since adrenal suppression is its prime action. Exogenous steroids should be administered in such circumstances.
USES: *Inoperable adrenocortical carcinoma (functioning/nonfunctioning).
ACTIONS: Adrenal cytotoxic agent, suppresses cortisol production by inhibiting 11β-hydroxylase (ortho-para-DDD).
DOSE: 2–6 g/d in divided dose TID–QID; increase as tolerated to max. tolerated dose (generally 2–18 g/d); decrease dose with side effects; administer with glucocorticoid and if needed mineralocorticoid replacement.
W/P: [C/?]; increases warfarin metabolism.
CI: Hypersensitivity to compound.

DISP: Tablets 500 mg.
SE: Adrenal insufficiency, GI distress, depression, lethargy, somnolence, dizziness, vertigo, orthostasis.
NOTES: Neuropsychiatric testing with use >2 yr; higher doses of glucocorticoid required due to metabolism; treat until there is no clinical benefit.

MITOXANTRONE (GENERIC)

WARNING: Administer only by physician experienced in chemotherapy; except for acute leukemia, do not use w/ ANC count of <1,500 cells/mm^3; severe neutropenia can result in infection, follow CBC; cardiotoxic (CHF), secondary AML reported.
USES: *Combination for myelogenous, promyelocytic, monocytic, and erythroid acute leukemias, progressive relapsing MS; pain related to advanced hormone refractory prostate cancer. *
ACTIONS: Anthracenedione; DNA-intercalating agent; ↓ DNA synth by interacting w/ topoisomerase II.
DOSE: Per protocol; Cap 12–14 mg/m^2 short IV infusion every 21 days with steroids (such as prednisone 10 qd or 5 mg PO BID); ↓ dose w/ hepatic impairment, leukopenia, thrombocytopenia.
W/P: [D, −] Reports of secondary AML, w/ MS ↑ CV risk, do not treat MS pt w/ low LVEF.
CI: Pregnancy, sig ↓ in LVEF.
DISP: Inj 2 mg/mL.
SE: ↓ BM, N/V, stomatitis, alopecia (infrequent), cardiotox, urine discoloration, secretions & scleras may be blue-green.
NOTES: Maintain hydration; baseline CV evaluation w/ ECG & LVEF; cardiac monitoring prior to each dose; not for intrathecal use.

MORPHINE (AVINZA XR, ASTRAMORPH/PF, DURAMORPH, INFUMORPH, MS CONTIN, KADIAN SR, ORAMORPH SR, ROXANOL) [C-II]

WARNING: Do not crush/chew SR/CR forms; swallow whole or sprinkle on applesauce. 100 and 200 mg for opioid-tolerant pt only for mod–severe pain when pain control needed for an extended period and not PRN. Be aware of misuse, abuse, diversion. No alcoholic beverages while on therapy.
USES: *Treat severe pain*, AMI, acute pulmonary edema.
ACTIONS: Narcotic analgesic; SR/CR forms for chronic use.

DOSE:

Adults: *Short-term use PO:* 5–30 mg q4h PRN; *IV/IM:* 2.5–15 mg q2–6h; *Supp:* 10–30 mg q4h. SR formulations 15–60 mg q8–12h (do not chew/crush); use w/ caution; can be reversed w/ 0.4–2 mg IV naloxone.
Peds: ***>6 mo:*** 0.1–0.2 mg/kg/dose IM/IV q2–4h PRN; 0.15–0.2 mg/kg PO q3–4h PRN.
W/P: [C, +/−] Severe resp depression possible; w/ head injury; chewing delayed release forms can cause severe rapid release of morphine.
CI: (Many product specific) Severe asthma, resp depression, GI obst/ileus; *Oral soln:* CHF d/t

lung disease, head injury, arrhythmias, brain tumor, acute alcoholism, DTs, seizure disorders; *MS Contin and Kadian* CI include hypercarbia.
DISP: IR tabs 15, 30 mg; soln 10, 20, 100 mg/5 mL; supp 5, 10, 20, 30 mg; Inj 2, 4, 5, 8, 10, 15, 25, 50 mg/mL; *MS Contin CR* tabs 15, 30, 60, 100, 200 mg; *Oramorph SR* tabs 15, 30, 60, 100 mg; *Kadian SR caps* 10, 20, 30, 40, 50, 60, 70, 80, 100, 130, 150, 200 mg; *Avinza XR* caps 30, 60, 90, 120 mg; *Duramorph/Astramorph PF:* Inj 0.5, 1 mg/mL; *Infumorph* 10, 25 mg/mL.
SE: Narcotic SE (resp depression, sedation, constipation, N/V, pruritus, diaphoresis, urinary retention, biliary colic), granulomas w/ IT.
NOTES: May require scheduled dosing to relieve severe chronic pain.

MOXIFLOXACIN (AVELOX)

WARNING: ↑ Risk Achilles tendon rupture and tendonitis, ↑ in pts >60 yr, on steroids or with organ transplant; avoid w/ myasthenia gravis, may ↑ muscle weakness.
USES: *Acute sinusitis & bronchitis, skin/soft-tissue/intra-abdominal infections, conjunctivitis, community-acquired pneumonia* TB, anthrax, endocarditis.
ACTIONS: 4th-gen quinolone; ↓ DNA gyrase. *Spectrum:* Excellent gram(+) except MRSA & *E. faecium;* good gram(−) except *P. aeruginosa, Stenotrophomonas maltophilia, & Acinetobacter* sp; good anaerobic.
DOSE: 400 mg/d PO/IV daily; avoid cation products, antacids TID.
W/P: [C, −] Quinolone sensitivity; interactions w/ Mg^{2+}, Ca^{2+}, Al^{2+}, Fe^{2+}-containing products, & class IA & III antiarrhythmic agents.
CI: Quinolone/component sensitivity.
DISP: Tabs 400 mg, ABC Pak 5 tabs, Inj.
SE: Dizziness, N, QT prolongation, seizures, photosensitivity, peripheral neuropathy risk.

MUPIROCIN (BACTROBAN, BACTROBAN NASAL)

USES: *Impetigo (oint); skin lesion infect w/ *S. aureus* or *S. pyogenes*; eradicate MRSA in nasal carriers.*
ACTIONS: ↓ Bacterial protein synth.
DOSE: *Topical:* Apply small amount 3×/d × 5–14 days. *Nasal:* Apply 1/2 single-use tube BID in nostrils × 5 days.
W/P: [B, ?/M].
CI: Do not use w/ other nasal products.
DISP: Oint 2%; cream 2%; nasal oint 2% 1-g single-use tubes.
SE: Local irritation, rash.
NOTES: Pt to contact healthcare provider if no improvement in 3–5 days.

MYCOPHENOLATE MOFETIL (CELLCEPT, GENERIC)

WARNING: ↑ Risk of infections, lymphoma, other cancers, progressive multifocal leukoencephalopathy (PML); risk of pregnancy loss and malformation; female of child-bearing potential must use contraception.
USES: *Prevent organ rejection after transplant.*
ACTIONS: Cytostatic to lymphocytes.

DOSE:

Adults: 1 g PO BID, doses differ based on transplant.
Peds: *BSA 1.2–1.5 m²:* 750 mg PO BID. *BSA >1.5 m²:* 1 g PO BID; used w/ steroids & cyclosporine or tacrolimus; ↓ in renal insufficiency or neutropenia. *IV:* Infuse over >2 hr. *PO:* Take on empty stomach, do not open caps.
W/P: [D, −].
CI: Component allergy; IV use in polysorbate 80 allergy.
DISP: Caps 250, 500 mg; susp 200 mg/mL, Inj 500 mg.
SE: N/V/diarrhea, pain, fever, headache, infection, HTN, anemia, leukopenia, edema.
NOTES: *Cellcept & Myfortic* are not interchangeable.

NAFCILLIN (GENERIC)

USES: *Infections d/t susceptible strains of *Staphylococcus & Streptococcus.**
ACTIONS: Bactericidal; antistaphylococcal PCN; ↓ cell wall synth. *Spectrum:* Good gram(+) except MRSA & enterococcus, no gram(−), poor anaerobe.

DOSE:

Adults: 1–2 g IV q4–6h.
Peds: 50–200 mg/kg/d ÷ q4–6h.
W/P: [B, ?].
CI: PCN allergy, allergy to corn-related products.
DISP: Inj powder l, 2 g.
SE: Interstitial nephritis, N/diarrhea, fever, rash, allergic reaction.
NOTES: In setting of both hepatic & renal impairment, modification of dose may be necessary.

NALOXONE (GENERIC, EVZIO)

USES: *Opioid addiction (diagnosis) & OD.*
ACTIONS: Competitive opioid antagonist.

DOSE:

Adults: 0.4–2 mg IV, IM, or SQ q2–3 min; via endotracheal tube, dilute in 1–2 mL NS; may be given intranasal; total dose 10 mg max.; *Evzio:* 0.4 mg IM or sub-Q.
Peds: 0.01–0.1 mg/kg/dose IV, IM, or SQ; repeat IV q3min × 3 doses PRN; *Reverse narcotic effects:* 0.1 mg/kg q2min PRN; max. dose 2 mg; smaller doses (1–5 μg/kg may be used); cont Inf 2–160 μg/kg/h.
W/P: [C, ?], *Evzio* [B, ?/-], may precipitate withdrawal in addicts.
CI: Component hypersensitivity.
DISP: Inj 0.4, 1 mg/mL; *Evzio* 0.4 mg/0.4mL prefilled auto-injector, w/ electronic voice instructions.
SE: ↓ BP, ↑ BP, fever, tachycardia, VT, VF, irritability, agitation, coma, GI upset, pulm edema, tremor, piloerection, sweating.
NOTES: If no response after 10 mg, suspect nonnarcotic cause; w/ *Evzio* use in the field, seek

emergent care immediately; duration of action less than most opioids, may need repeat dosing; for by-stander use, administer in anterolateral thigh.

NAPROXEN (ALEVE [OTC] , ANAPROX, ANAPROX DS, EC-NAPROSYN, NAPRELAN, NAPROSYN, GENERIC)

WARNING: May ↑ risk of CV events & GI bleeding.
USES: *Arthritis & pain.*
ACTIONS: NSAID; ↓ prostaglandins.

DOSE:
Adults & Peds: ***>12 yr:*** 200–500 mg BID–TID to 1,500 mg/d max. ***>2 yr:*** *JRA* 5 mg/kg/dose BID; ↓ in hepatic impairment.
W/P: [C, (D 3rd tri), −].
CI: NSAID or ASA triad sensitivity, peptic ulcer, post-CABG pain, 3rd-tri pregnancy.
DISP: *Tabs:* 250, 375, 500 mg; *DR:* 375, 500, 750 mg; *CR:* 375, 550 mg; susp 25 mg/5 mL (*Aleve*) 200 mg multiple OTC forms.
SE: Dizziness, pruritus, GI upset, peptic ulcer, edema.
NOTES: Take w/ food to ↓ GI upset; 220 mg naproxen sodium = 200 mg naproxen base.

NEOMYCIN (NEO-FRADIN, GENERIC)

WARNING: Systemic absorption of oral route may cause neuro/oto/nephrotoxic; resp paralysis possible w/ any route of administration.
USES: *Hepatic coma, bowel prep.*
ACTIONS: Aminoglycoside, poorly absorbed PO; ↓ GI bacterial flora

DOSE:

Adults: 3–12 g/24 h PO in 3–4 ÷ doses; 12 g/d max.
Peds: 50–100 mg/kg/24 h PO in 3–4 ÷ doses.
W/P: [C, ?/−] Renal failure, neuromuscular disorders, hearing impairment.
CI: Intestinal obst.
DISP: Tabs 500 mg; *Neo-Fradin* PO soln 125 mg/5 mL.
SE: Hearing loss w/ long-term use; rash, N/V.
NOTES: Do not use parenterally (↑ tox); also topical forms.

NEOMYCIN-POLYMYXIN BLADDER IRRIGANT [NEOSPORIN GU IRRIGANT]

USES: *Short-term use (up to 10 days) as a continuous irrigant in the urinary bladder of abacteriuric patients to help prevent bacteriuria and gram-negative rod septicemia associated with the use of indwelling catheters.*
ACTIONS: Bactericidal; not for *Serratia* sp or streptococci.
DOSE: 1 mL irrigant in 1 L of 0.9% NaCl; cont bladder irrigation w/ 1 L of soln/24 h 10 days max.
W/P: [D].
CI: Component allergy; aminoglycoside allergy.

DISP: Soln neomycin sulfate 40 mg & polymyxin B 200,000 U/mL; amp 1, 20 mL.
SE: Rash, neomycin oto/nephrotoxic (rare).
NOTES: Potential for bacterial/fungal super-infection; not for Inj; use only 3-way catheter for irrigation.

NIFEDIPINE (ADALAT CC, AFEDITAB CR, PROCARDIA, PROCARDIA XL, GENERIC)

USES: *HTN*; tocolytic.
ACTIONS: Calcium channel blocker.

DOSE:

Adults: SR tabs 30–90 mg/d.
Peds: 0.25–0.5 mg/kg/24 h ÷ 3–4×/d.
W/P: [C, +] Heart block, aortic stenosis, cirrhosis.
CI: Component hypersensitivity.
DISP: Caps 10, 20 mg; SR/XL tabs 30, 60, 90 mg.
SE: Headache common on initial Treat; reflex tachycardia may occur w/ regular-release dosage forms; peripheral edema, ↓ BP, flushing, dizziness.
NOTES: Adalat CC & Procardia XL not interchangeable; used for medical expulsive therapy for ureterolithiasis; considered to be inferior to α-1 blockers such as tamsulosin.

NILUTAMIDE (NILANDRON)

WARNING: Interstitial pneumonitis possible; most cases in 1st 3 mo; check CXR before and during Treat.
USES: *Combo w/ surgical castration for metastatic PCa.*
ACTIONS: Nonsteroidal antiandrogen.
DOSE: 300 mg/d PO × 30 days, then 150 mg/d.
W/P: [Not used in females].
CI: Severe hepatic impairment, resp insufficiency.
DISP: Tabs 150 mg.
SE: Interstitial pneumonitis, hot flashes, ↓ libido, impotence, N/V/diarrhea, gynecomastia, hepatic dysfunction.
NOTES: May cause reaction when taken w/ EtOH, follow LFTs/CXR.

NITROFURANTOIN (FURADANTIN, MACROBID, MACRODANTIN, GENERIC)

USES: *Prophylaxis & Treat UTI.*
ACTIONS: Interferes w/ metabolism & cell wall synthesis. *Spectrum:* Some gram(+) & (−) bacteria; *Pseudomonas, Serratia,* & most *Proteus* resistant.

DOSE:

Adults: *Prophylaxis:* 50–100 mg/d PO. *Treat:* 50–100 mg PO QID × 7 days; *Macrobid* 100 mg PO BID × 7 days.

Peds: *Prophylaxis:* 1–2 mg/kg/d ÷ in 1–2 doses, max. 100 mg/d. *Treat:* 5–7 mg/kg/24 h in 4 ÷ doses (w/ food/milk/antacid).
W/P: [B, +/not OK if child < 1 mo] Avoid w/ CrCl <60 mL/min.
CI: Anuria, oliguria, or significant impairment of renal function (CrCl <60 mL/min), infants <1 mo, pregnancy at term; history of cholestatic jaundice/hepatic dysfunction associated with nitrofurantoin.
DISP: Caps 25, 50, 100 mg; (*Furadantin*) susp 25 mg/5 mL.
SE: GI effects, dyspnea, various acute/chronic pulm reactions, peripheral neuropathy, hemolytic anemia w/ G6PD deficiency, rare aplastic anemia.
NOTES: Macrocrystals (eg, *Macrodantin*) <nausea than other forms; not for comp UTI; may turn urine brown; ineffective for pyelonephritis or cystitis.

NORFLOXACIN (NOROXIN)

WARNING: ↑ Risk Achilles tendon rupture and tendonitis, ↑ in pts >60 yr, on steroids or with organ transplant; avoid w/ myasthenia gravis, may ↑ muscle weakness.
USES: *Comp & uncomp UTI, prostatitis due to *E. Coli,* gonorrhea*, infectious diarrhea, conjunctivitis.
ACTIONS: Quinolone, ↓ DNA gyrase, bactericidal. *Spectrum:* Broad gram(+) and (–) *E. faecalis, E. coli, K. pneumoniae, P. mirabilis, P. aeruginosa, S. epidermidis, S. saprophyticus.*
DOSE: *Uncomp UTI (E. coli, K. pneumoniae, P. mirabilis):* 400 mg PO BID × 3 days; other uncomp UTI Treat × 7–10 days. *Comp UTI:* 400 mg PO q12h for 10–21 days. *Gonorrhea:* 800 mg × 1 dose. *Prostatitis:* 400 mg PO BID × 28 days. *Gastroenteritis, traveler's diarrhea:* 400 mg PO BID × 1–3 days; take 1 hr ac or 2 hr pc.
Adults & Peds: ***>1 yr:*** Ophthal: 1 gtt each eye QID for 7 days; CrCl < 0 mL/min use 400 mg qd.
W/P: [C, −] Quinolone sensitivity, w/ some antiarrhythmics ↑ QT.
CI: Hx allergy or tendon problems due to quinolones.
DISP: Tabs 400 mg; ophthal 3 mg/mL.
SE: Photosensitivity, headache, dizziness, asthenia, GI upset, pseudomembranous colitis; ocular burning w/ ophthal, peripheral neuropathy risk w/ PO only.
NOTES: Interactions w/ antacids, theophylline, caffeine; good conc in the kidney & urine, poor blood levels; not for urosepsis; CDC suggests do not use for GC.

NYSTATIN (GENERIC)

USES: *Mucocutaneous *Candida* infections (oral, skin, vaginal).*
ACTIONS: Alters membrane permeability. *Spectrum:* Susceptible *Candida* sp.

DOSE:
Adults & Peds: *PO:* 400,000–600,000 U PO "swish & swallow" QID. *Vag:* 1 tab Vag hs × 2 wk. *Topical:* Apply BID–TID to area.
Peds Infants: 200,000 U PO q6h.
W/P: [B (C PO), +].
DISP: PO susp 100,000 U/ mL; PO tabs 500,000 U; troches 200,000 U; Vag tabs 100,000 U; topical cream/oint 100,000 U/g, powder 100,000 U/g.

SE: GI upset, SJS.
NOTES: Not absorbed through mucus membranes/intact skin, poorly absorbed through GI; not for systemic infections; see also triamcinolone/nystatin.

OFLOXACIN (FLOXIN)

WARNING: ↑ Risk Achilles tendon rupture and tendonitis, ↑ in pts >60 yr, on steroids or with organ transplant; avoid w/ myasthenia gravis, may ↑ muscle weakness.
USES: *Lower resp tract, skin, & skin structure, & UTI, prostatitis, uncomp gonorrhea, & *Chlamydia* infections.*
ACTIONS: Bactericidal; ↓ DNA gyrase. *Broad-spectrum gram(+) & (–): S. pneumoniae, S. aureus, S. pyogenes, H. influenzae, P. mirabilis, N. gonorrhoeae, C. trachomatis, E. coli.*

DOSE:

Adults: 200–400 mg PO BID or IV q12h. ↓ in renal impairment, take on empty stomach.
W/P: [C, −] ↓ Absorption w/ antacids, sucralfate, Al^{2+}, Ca^{2+}, Mg^{2+}, Fe^{2+}, Zn^{+} -containing drugs, Hx seizures.
CI: Quinolone allergy.
DISP: Tabs 200, 300, 400 mg; Inj 20, 40 mg/mL; ophthal & otic 0.3%.
SE: N/V/diarrhea, photosensitivity, insomnia, headache, local irritation, ↑ QTc interval, peripheral neuropathy risk.
NOTES: *Floxin* brand D/C.

ONDANSETRON (ZOFRAN, ZOFRAN ODT, GENERIC)

USES: *Prevent chemotherapy-associated & postop N/V.*
ACTIONS: Serotonin receptor (5-HT_3) antagonist.

DOSE:
Adults & Peds: *Chemotherapy:* 0.15 mg/kg/dose IV prior to chemotherapy, then 4 & 8 hr after 1st dose or 4–8 mg PO TID; 1st dose 30 min prior to chemotherapy & give on schedule, not PRN.
Adults: *Postoperation:* 4 mg IV immediately preanesthesia or postoperation.
Peds: *Postoperation:* ***<40 kg:*** 0.1 mg/kg. ***>40 kg:*** 4 mg IV; ↓ w/ hepatic impairment.
W/P: [B, +/−] Arrhythmia risk, may ↑ QT interval.
DISP: Tabs 4, 8, 24 mg, soln 4 mg/5 mL, Inj 2 mg/mL; *Zofran* ODT tabs 4, 8 mg.
SE: Diarrhea, headache, constipation, dizziness.
NOTES: ODT contains phenylalanine. No single IV dose > 6 mg.

ONDANSETRON, ORAL SOLUBLE FILM (ZUPLENZ)

USES: *Prevent chemotherapy/RT-associated & postop N/V.*
ACTIONS: Serotonin receptor (5-HT_3) antagonist.

DOSE:

Adults: *Highly emetogenic chemo:* 24 mg (8 mg film × 3) 30 min prechemo; *RT N& V:* 8 mg

film TID.
Adults & Peds: *>12 yr. Mod emetogenic chemo:* 8 mg film 30 min prechemo, then 8 mg in 8 hr; 8 mg film BID × 1–2 days after chemo.
Adults: *Postop: 16 mg (8 mg film × 2) 1 hr preop;* ↓ w/ hepatic impairment.
W/P: [B, +/−].
CI: w/ Apomorphine.
DISP: Oral soluble film 4, 8 mg.
SE: Headache, malaise/ fatigue, constipation, diarrhea.
NOTES: Use w/ dry hands, do not chew/swallow; place on tongue, dissolves in 4–20 s; peppermint flavored.

OSPEMIFENE (OSPHENA)

WARNING: ↑ Risk endometrial Ca; ↑ risk of CVA, DVT/PE.
USES: *Treatment of moderate–severe dyspareunia.*
ACTIONS: Estrogen agonist/antagonist.

DOSE:

Adults: 1 tab daily.
W/P: [X, −] Do not use w/ estrogens and estrogen agonists/antagonists, fluconazole & rifampin ↓ effect, ketoconazole ↑ effect, ↑ side effects w/ drugs that inhibit CYP3A4 and CYP2C9; highly protein bound, may be displaced by other highly bound drugs.
CI: Undiagnosed abnormal genital bleeding; known/suspected estrogen-sensitive cancer; pregnancy.
DISP: Tab 60 mg.
SE: DVT/PE, hemorrhagic or thrombotic stroke, arterial thromboembolic dz, hot flashes; vaginal discharge; hyperhidrosis; muscle cramps; metabolized by CYP3A4, CYP2C9, and CYP2C19.
NOTES: Do not use w/ severe liver disease.

OXACILLIN (GENERIC)

USES: *infections d/t susceptible *S. aureus, Streptococcus & other organisms.**
ACTIONS: Bactericidal; ↓ cell wall synth. *Spectrum:* Excellent gram(+), poor gram(−).

DOSE:

Adults: 250–500 mg (2 g severe) IM/ IV q4–6h.
Peds: 150–200 mg/kg/d IV ÷ q4–6h.
W/P: [B, M].
CI: PCN sensitivity.
DISP: Powder for Inj 500 mg, 1, 2, 10 g.
SE: GI upset, interstitial nephritis, blood dyscrasias, may ↓ OCP effectiveness.

OXYBUTYNIN (DITROPAN, DITROPAN XL, GENERIC)

USES: Relief of symptoms of bladder instability associated with voiding in patients with

uninhibited neurogenic or reflex neurogenic bladder (ie, urgency, frequency, urinary leakage, urge incontinence, dysuria). *Ditropan XL*: Overactive bladder with symptoms of urge urinary incontinence, urgency, and frequency; pediatric patients >6 yr with symptoms of detrusor overactivity associated w/ a neurologic condition (eg, spina bifida).
ACTIONS: Anticholinergic, relaxes bladder smooth muscle, ↑ bladder capacity.

DOSE:

Adults: 5 mg BID–TID, 5 mg 4×/d max. XL 5–10 mg/d, 30 mg/d max.
Peds: ***>5 yr:*** 5 mg PO BID–TID; 15 mg/d max.
Peds: ***1–5 yr:*** 0.2 mg/kg/dose 2–4×/d (syrup 5 mg/5 mL); 15 mg/d max.; ↓ in elderly; periodic drug holidays OK.
W/P: [B, ?].
CI: Narrow-angle glaucoma, myasthenia gravis, GI/GU obst, ulcerative colitis, megacolon.
DISP: Tabs 5 mg; XL tabs 5, 10, 15 mg; syrup 5 mg/5 mL.
SE: Anticholinergic (drowsiness, xerostomia, constipation, tachycardia), ↑ QT interval, memory impairment; ER form empty shell expelled in stool.
NOTES: See topical forms of oxybutynin.

OXYBUTYNIN, TOPICAL (GELNIQUE)

USES: *Overactive bladder with symptoms of urge urinary incontinence, urgency, and frequency.*
ACTIONS: Anticholinergic, relaxes bladder smooth muscle, ↑ bladder capacity.
DOSE: 1 g sachet qd to dry skin (abdominal/shoulders/thighs/upper arms).
W/P: [B, ?/−].
CI: Gastric or urinary retention; narrow-angle glaucoma.
DISP: Gel 10%, 1-g sachets (100 mg oxybutynin).
SE: Anticholinergic (lethargy, xerostomia, constipation, blurred vision, ↑ HR); rash, pruritus, redness, pain at site; UTI.
NOTES: Cover w/ clothing, skin-to-skin transfer can occur; gel is flammable; after applying wait 1 hr before showering.

OXYBUTYNIN TRANSDERMAL SYSTEM (OXYTROL, OXYTROL FOR WOMEN [OTC])

USES: *Overactive bladder with symptoms of urge urinary incontinence, urgency, and frequency.*
ACTIONS: Anticholinergic, muscarinic antagonist; relaxes bladder smooth muscle, ↑ bladder capacity.
DOSE: One 3.9 mg/d system apply 2×/wk (q3–4d) to abdomen, hip, or buttock.
W/P: [B, ?/−].
CI: GI/GU obst, untreated narrow-angle glaucoma.
DISP: 3.9 mg/d transdermal patch (Rx and OTC).
SE: Anticholinergic, itching/ redness at site.
NOTES: Do not apply to same site w/in 7 days.

OXYCODONE/ACETAMINOPHEN ER (XARTEMIS XR) [CII]

WARNING: Addiction risk, risk of resp depression. Accidental consumption, esp. peds, can be fatal. Use during PRG can cause neonatal opioid withdrawal. Contains acetaminophen, associated with liver failure, transplant and death.
USES: *Acute pain that requires opioids where alternatives are inadequate.*
ACTIONS: Opioid agonist and acetaminophen.
DOSE: 2 tabs q12h, w/o regard to food; do not crush/chew.
W/P: [C, -] Do not use before delivery; not equivalent to other combo products; caution: w/ other CNS depressants, MAOI, neuromusc blockers, elderly, debilitated, w/ hepatic impair; may ↑ ICP (check pupils); assoc w/ skin reactions; may ↓ BP; acetaminophen hepato tox >4,000 mg, avoid w/ other acetaminophen products; impairs mental/physical abilities; drugs that ↓ CYP3A4 may ↓ oxycodone clearance.
CI: Component hypersens; resp dep, severe asthma/hypercarbia, ileus.
DISP: Tabs oxycodone/acetaminophen: 7.5/325 mg.
SE: ↓ resp, ↓ BP, sedation, coma.

OXYCODONE (OXYCONTIN, ROXICODONE, GENERIC) [C-II]

WARNING: High abuse potential similar to morphine; controlled release only for extended chronic pain, not for PRN use; 60-, 80-, 160-mg tab only for opioid-tolerant pts; or single dose >40 mg or total daily dose of >80 mg can cause fatal respiratory depression if intolerant; do not crush, break, or chew.
USES: *Mod– severe pain, usually in combo w/ nonnarcotic analgesics.*
ACTIONS: Narcotic analgesic.

DOSE:

Adults: 5 mg PO q6h PRN (immediate release). *Mod–severe chronic pain:* 10–160 mg PO q12h (ER); can give ER q8h if effect does not last 12 hr.
Peds: ***6–12 yr:*** 1.25 mg PO q6h PRN. >***12 yr:*** 2.5 mg q6h PRN; ↓ w/ severe liver/renal disease, elderly; w/ food.
W/P: [B (D if prolonged use/near term), M].
CI: Allergy, resp depression, acute asthma, ileus w/ microsomal morphine.
DISP: CR Roxicodone tabs 15, 30 mg; ER (OxyContin) 10, 15, 20, 30, 40, 60, 80, 160 mg; liq 5 mg/5 mL; soln conc 20 mg/mL.
SE: ↓ BP, sedation, resp depression, dizziness, GI upset, constipation, risk of abuse.
NOTES: *OxyContin* for chronic cancer pain; do not crush/chew/cut ER product; sought after as drug of abuse; reformulated *OxyContin* is intended to prevent the opioid medication from being cut, broken, chewed, crushed, or dissolved to release more medication.

OXYCODONE/ACETAMINOPHEN (PERCOCET, TYLOX) [C-II]

WARNING: Acetaminophen has been associated with cases of acute liver failure, at times resulting in liver transplant and death. Most of the cases of liver injury are associated with the use of acetaminophen at doses that exceed 4,000 mg/d, and often involve more than 1 acetaminophen-containing product.

USES: *Mod– severe pain.*
ACTIONS: Narcotic analgesic.

DOSE:

Adults: 1–2 tabs/caps PO q4–6h PRN (acetaminophen max. dose 4 g/d).
Peds: Oxycodone 0.05–0.15 mg/kg/dose q4–6h PRN, 5 mg/dose max.
W/P: [C (D prolonged use or near term), M].
CI: Allergy, paralytic ileus, resp depression.
DISP: Percocet tabs, mg oxycodone/mg acetaminophen: 2.5/325, 5/325, 7.5/325, 10/325, 7.5/500, 10/650; Tylox caps 5 mg oxycodone, 500 mg acetaminophen; soln 5 mg oxycodone & 325 mg acetaminophen/5 mL.
SE: ↓ BP, sedation, dizziness, GI upset, constipation.
NOTES: See Acetaminophen note.

OXYCODONE/ASPIRIN (PERCODAN) [C-II]

USES: *Mod–severe pain.*
ACTIONS: Narcotic analgesic w/ NSAID.

DOSE:

Adults: 1–2 tabs/caps PO q4–6h PRN.
Peds: Oxycodone 0.05–0.15 mg/kg/dose q4–6h PRN, up to 5 mg/dose; ↓ in severe hepatic failure.
W/P: [D, −] w/ Peptic ulcer, CNS depression, elderly, Hx seizures.
CI: Component allergy, children (<16 yr) w/ viral infection (Reyes syndrome), resp depression, ileus, hemophilia.
DISP: *Generics:* 4.83 mg oxycodone hydrochloride, 0.38 mg oxycodone terephthalate, 325 mg aspirin; *Percodan* 4.83 mg oxycodone hydrochloride, 325 mg ASA.
SE: Sedation, dizziness, GI upset/ulcer, constipation, allergy.
NOTES: Monitor for possible drug abuse; max. 4 g aspirin/d.

OXYCODONE/IBUPROFEN (COMBUNOX) [C-II]

WARNING: May ↑ risk of serious CV events; CI in perioperative CABG pain; ↑ risk of GI events such as bleeding.
USES: *Short-term (not >7 days) management of acute mod–severe pain.*
ACTIONS: Narcotic w/ NSAID.
DOSE: 1 tab q6h PRN 4 tab max./24 h; 7 days max.
W/P: [C, −] w/ Impaired renal/hepatic function; COPD, CNS depression, avoid in pregnancy.
CI: Paralytic ileus, 3rd-tri pregnancy, allergy to ASA or NSAIDs, where opioids are CI.
DISP: Tabs 5 mg oxycodone/400 mg ibuprofen.
SE: N/V, somnolence, dizziness, sweating, flatulence, ↑ LFTs.
NOTES: Check renal function; abuse potential w/ oxycodone.

PACLITAXEL (ABRAXANE, TAXOL, GENERIC)

WARNING: Administration only by physician experienced in chemotherapy; fatal anaphylaxis and hypersens possible; severe myelosuppression possible.
USES: *Ovarian & breast cancer, Kaposi sarcoma, non-small cell lung cancer.*
ACTIONS: Mitotic spindle poison; promotes microtubule assembly & stabilization against depolymerization.
DOSE: Per protocols; use glass or polyolefin containers (eg, nitroglycerin tubing set); PVC sets leach plasticizer; ↓ in hepatic failure.
W/P: [D, −].
CI: Neutropenia ANC <1,500 cells/mm^3, <1,000 cells/mm^3 in w/ AIDS-related Karposi's syndrome; solid tumors, component allergy.
DISP: Inj 6 mg/mL, vial 5, 16.7, 25, 50 mL; (*Abraxane*) 100 mg/vial.
SE: ↓ BM, peripheral neuropathy, transient ileus, myalgia, ↓ HR, ↓ BP, mucositis, N/V/diarrhea, fever, rash, headache, phlebitis; hematologic tox schedule dependent; leukopenia dose limiting by 24-hr Inf; neurotox limited w/ short (1–3 hr) Inf; allergic reactions (dyspnea, ↓ BP, urticaria, rash).
NOTES: Maintain hydration; allergic reaction usually w/in 10 min of Inf; minimize w/ corticosteroid, antihistamine pretreatment.

PALONOSETRON (ALOXI)

USES: *Prevent acute & delayed N/V w/ emetogenic chemotherapy; prevent postoperative N/V up to 24 hr.*
ACTIONS: 5-HT3-receptor antagonist.

DOSE:

Adults: *Chemotherapy:* 0.25 mg IV 30 min prechemo; 0.5 mg PO 1 hr prechemo w/o regard to food. *Postoperative N/V:* 0.075 mg immediately before induction.
Peds: 1 mo–17yr 20 μg/kg (max. 1.5 mg) × 1 IV over 15 min, 30 min prechemo.
W/P: [B, ?] May ↑ QTc interval.
CI: Component allergy.
DISP: 0.05 mg/mL (1.5 & 5 mL vials); 0.5 mg caps.
SE: HA, constipation, dizziness, abdominal pain, anxiety.

PAMIDRONATE (GENERIC)

USES: *Hypercalcemia of malignancy, Paget disease, palliate symptomatic osteolytic mets of multiple myeloma and breast cancer.*
ACTIONS: Bisphosphonate; ↓ nl & abnormal bone resorption.
DOSE: *Hypercalcemia:* 60–90 mg IV over 2–24 hr or 90 mg IV over 24 hr if severe; may repeat in 7 days. *Paget disease:* 30 mg/d IV slow Inf over 4 hr × 3 days. *Osteolytic bone mets in myeloma*: 90 mg IV over 4 hr qmo. *Osteolytic bone mets breast cancer:* 90 mg IV over 2 hr q3–4wk; 90 mg/max. single dose.
W/P: [D, ?/−] Avoid invasive dental procedures w/ use.
CI: Bisphosphonate sensitivity.
DISP: Inj 30, 60, 90 mg.
SE: Fever, malaise, convulsions, Inj site reaction, uveitis, fluid overload, HTN, abdominal

pain, N/V, constipation, UTI, bone pain, ↓ K^+, ↓ Ca^{2+}, ↓ Mg^{2+}, hypophosphatemia; jaw osteonecrosis (mostly cancer pts; avoid dental work), renal tox.
NOTES: Perform dental exam pretherapy; follow Cr, hold dose if Cr ↑ by 0.5 mg/dL w/ nl baseline or by 1 mg/dL w/ abnormal baseline; restart when Cr returns w/in 10% of baseline; may ↑ atypical subtrochanteric femur fractures.

PAPAVERINE; PAPAVERINE/PHENTOLAMINE ("BIMIX"); PAPAVERINE/PHENTOLAMINE/PROSTAGLANDIN E_1 ("TRIMIX")

(Note: These medications are not FDA approved for this use. These medications are prepared by compounding pharmacies.)
USES: Erectile dysdunction.
ACTIONS: *Prostaglandin E_1*: Vasodilator, relaxes smooth muscle of corpus cavernosa; *papaverine:* smooth muscle relaxation w/ vasodilatation; *phentolamine* blocks α-adrenergic receptors, results in vasodilation.
DOSE: Based on formulation, typical starting volumes of 0.1–0.5 mL and titrated in the office; self-administered using insulin syringe with a 26–30G 1/2-inch needle through the lateral shaft of the mod penis into one corporeal body; erection should occur in a few minutes.
W/P: [n/a, n/a].
CI: No official information, probably similar to intracorporeal alprostadil: ↑ Priapism risk (especially sickle cell, myeloma, leukemia), penile deformities/urethral stricture/implants; men in whom sex inadvisable; component hypersensitivity.
DISP: Based on compounding pharmacy; reported concentrations: Papaverine 5–30 mg/mL; BiMix (papaverine 5.88–30 mg and phentolamine 1–4 mg); TriMix (papaverine 5–30 mg/mL, phentolamine 0.1–5 mg/mL, prostaglandin E_1 5–40 μg/mL).
SE: Penile pain, penile nodule formation, transient increases in LFTs, and hematoma priapism.
NOTES: Titrate dose in office.

PASIREOTIDE (SIGNIFOR)

USES: *Cushing disease where pituitary surgery not an option*
ACTIONS: Somatostatin analogue inhibitor ACTH secretion.

DOSE:

Adults: 0.6–0.9 mg SQ 2×/d; titrate on response/tolerability; hepatic impairment (Child-Pugh B): 0.3–0.6 mg SQ twice daily, (Child-Pugh C): avoid.
W/P: [C, −] w/ Risk for ↓ HR or ↑ QT; w/ drugs that ↓ HR, ↑ QT, cyclosporine, bromocriptine.
CI: None.
DISP: Inj single-dose 0.3, 0.6, 0.9 mg/mL.
SE: N/V/diarrhea, hyperglycemia, headache, abdominal pain, cholelithiasis, fatigue, DM, hypocortisolism, ↓ HR, QT prolongation, ↑ glucose, ↑ LFTs, ↓ pituitary hormones, Inj site reaction, edema, alopecia, asthenia, myalgia, arthralgia.
NOTES: Prior to and periodically (see label), check TSH/T_4 , HbA1c, LFTs, ECG, gallbladder

US.

PAZOPANIB (VOTRIENT)

WARNING: Severe and fatal hepatotoxicity has been observed in clinical trials. Monitor hepatic function and interrupt, reduce, or discontinue dosing.
USES: *Advanced RCC; metastatic soft-tissue sarcoma after chemotherapy.*
ACTIONS: Tyrosine kinase inhibitor.
DOSE: 800 mg PO once daily, ↓ to 200 mg daily if moderate hepatic impairment, not rec in severe hepatic disease (bili >3 × ULN).
W/P: [D, −] Avoid w/ CYP3A4 inducers/inhibitor and QTc prolonging drugs, all SSRI; follow thyroid function tests; risk of thrombotic microangiopathy (TMA), including thrombotic thrombocytopenic purpura (TTP) and HUS; simvastatin increases the risk of ALT elevations.
CI: Severe hepatic disease.
DISP: 200-mg tablet.
SE: ↑ BP, N/V/diarrhea, GI perf, anorexia, hair depigmentation, ↓ WBC, ↓ plt, ↑ bleeding, ↑ AST/ALT/bili, ↓ Na, CP, ↑ QTc; reversible posterior leukoencephalopathy syndrome; proteinuria (hold w/ >3 g protein/24 h).
NOTES: Hold for surgical procedures. Take 1 hr ac or 2 hr pc.

PEGFILGRASTIM (NEULASTA)

USES: *↓ Frequency of infection in pts w/ nonmyeloid malignancies receiving myelosuppressive anti-cancer drugs that cause febrile neutropenia.*
ACTIONS: Granulocyte and macrophage-stimulating factor.

DOSE:

Adults: 6 mg SQ × 1/chemotherapy cycle.
W/P: [C, M] w/ Sickle cell.
CI: Allergy to *E. coli*-derived proteins or filgrastim.
DISP: *Syringes:* 6 mg/0.6 mL.
SE: Splenic rupture, headache, fever, weakness, fatigue, dizziness, insomnia, edema, N/V/diarrhea, stomatitis, anorexia, constipation, taste perversion, dyspepsia, abdominal pain, granulocytopenia, neutropenic fever, ↑ LFTs & uric acid, arthralgia, myalgia, bone pain, ARDS, alopecia, worsen sickle cell disease.
NOTES: Never give between 14 days before & 24 hr after dose of cytotoxic chemotherapy.

PENCICLOVIR (DENAVIR)

USES: *Herpes simplex (herpes labialis/cold sores).*
ACTIONS: Competitive inhibitor of DNA polymerase.
DOSE: Apply at 1st sign of lesions, then q2h while awake × 4 days.
W/P: [B, ?/−].
CI: Allergy, previous reaction to famciclovir.
DISP: Cream 1%.

SE: Erythema, headache.
NOTES: Do not apply to mucous membranes.

PENICILLIN G, AQUEOUS (POTASSIUM OR SODIUM) (PFIZERPEN, PENTIDS)

USES: *Bacteremia, endocarditis, pericarditis, resp tract infections, meningitis, neurosyphilis, SSSI.*
ACTIONS: Bactericidal; ↓ cell wall synth. *Spectrum:* Most gram(+) (not staphylococci), streptococci, *N. meningitidis,* syphilis, clostridia, & anaerobes (not *Bacteroides*).

DOSE:

Adults: Based on indication range 0.6–24 MU/d in ÷ doses q4h.
Peds: *Newborns < wk:* 25,000–50,000 U/ kg/dose IV q12h. *Infants 1 wk–<1 mo:* 25,000–50,000 U/kg/dose IV q8h. *Children:* 100,000–400,000 U/kg/24h IV ÷ q4h; ↓ in renal impairment.
W/P: [B, M].
CI: Allergy.
DISP: Powder for Inj.
SE: Allergic reactions; interstitial nephritis, diarrhea, seizures.
NOTES: Contains 1.7 mEq of K^+/MU.

PENICILLIN V (PEN-VEE K, VEETIDS, OTHERS)

USES: Susceptible streptococcal infections, otitis media, URIs, skin/soft-tissue infections (PCN-sensitive staphylococci).
ACTIONS: Bactericidal; ↓ cell wall synth. *Spectrum:* Most gram(+), including streptococci.

DOSE:

Adults: 250–500 mg PO q6h, q8h, q12h.
Peds: 25–50 mg/kg/24 h PO in 3–4 ÷ dose above the age of 12 yr, dose can be standardized vs. Wt based; ↓ in renal impairment; take on empty stomach.
W/P: [B, M].
CI: Allergy.
DISP: Tabs 125, 250, 500 mg; susp 125, 250 mg/5 mL.
SE: GI upset, interstitial nephritis, anaphylaxis, convulsions.
NOTES: A well-tolerated oral PCN; 250 mg = 400,000 U of PCN G.

PENICILLIN G BENZATHINE (BICILLIN)

USES: *Single-dose regimen for streptococcal pharyngitis, rheumatic fever, glomerulonephritis prophylaxis, & syphilis.*
ACTIONS: Bactericidal; ↓ cell wall synth. *Spectrum:* See Penicillin G.

DOSE:

Adults: 1.2–2.4 MU deep IM Inj q2–4wk.

Peds: 50,000 U/kg/dose, 2.4 MU/dose max.; deep IM Inj q2–4 wk.
W/P: [B, M].
CI: Allergy.
DISP: Inj 300,000, 600,000 U/mL; Bicillin L-A benzathine salt only; Bicillin C-R combo of benzathine & procaine (300,000 U procaine w/ 300,000 U benzathine/mL or 900,000 U benzathine w/ 300,000 U procaine/2 mL).
SE: Inj site pain, acute interstitial nephritis, anaphylaxis.
NOTES: IM use only; sustained action, w/ levels up to 4 wk; drug of choice for noncongenital syphilis.

PENICILLIN G PROCAINE (WYCILLIN, OTHERS)

USES: *Infections of resp tract, skin/soft tissue, scarlet fever, syphilis.*
ACTIONS: Bactericidal; ↓ cell wall synth. *Spectrum:* PCN G-sensitive organisms that respond to low, persistent serum levels.

DOSE:

Adults: 0.6–4.8 MU/d in ÷ doses q12–24h; give probenecid at least 30 min prior to PCN to prolong action.
Peds: 25,000–50,000 U/kg/d IM ÷ daily–BID.
W/P: [B, M].
CI: Allergy.
DISP: Inj 300,000, 500,000, 600,000 U/mL.
SE: Pain at Inj site, interstitial nephritis, anaphylaxis.
NOTES: LA parenteral PCN; levels up to 15 hr.

PENTAZOCINE (TALWIN, TALWIN COMPOUND, TALWIN NX) [C-IV]

WARNING: Oral use only; severe and potentially lethal reactions from misuse by Inj.
USES: *Mod–severe pain.*
ACTIONS: Partial narcotic agonist–antagonist; combination with other pain relief agents (see Disp).

DOSE:

Adults: 30 mg IM or IV; 50–100 mg PO q3–4h PRN.
Peds: ***5–8 yr:*** 15 mg IM q4h PRN. ***9–14 yr:*** 30 mg IM q4h PRN; ↓ in renal/hepatic impairment.
W/P: [C (1st tri, D w/ prolonged use/high dose near term), +/−].
CI: Allergy, ↑ ICP (unless ventilated).
DISP: *Talwin Compound* tab 12.5 mg + 325 mg aspirin; *Talwin NX* 50 mg + 0.5 mg naloxone; *Talwin* Inj 30 mg/mL.
SE: Considerable dysphoria; drowsiness, GI upset, xerostomia, seizures.
NOTES: 30–60 mg IM = 10 mg of morphine IM; Talwin NX has naloxone to curb abuse by nonoral route.

PENTOSAN POLYSULFATE SODIUM (ELMIRON)

USES: *Relieve pain/discomfort w/ interstitial cystitis.*
ACTIONS: Bladder wall buffer.
DOSE: 100 mg PO TID; on empty stomach w/ H_2O 1 hr ac or 2 hr pc.
W/P: [B, ?/−].
CI: Hypersensitivity to pentosan or related compounds (LMWH, heparin).
DISP: Caps 100 mg.
SE: Alopecia, N/diarrhea, headache, ↑ LFTs, anticoagulant effects, ↓ plts, rectal bleed.
NOTES: Reassess after 3 mo; related to LMWH, heparin; role for hemorrhagic cystitis suggested.

PERMETHRIN (ELIMITE, NIX, GENERIC [OTC])

USES: *Treat lice/scabies.*
ACTIONS: Pediculicide.

DOSE:
Adults & Peds: ***>2 yr:*** *Lice:* Saturate hair & scalp; allow 10 min before rinsing. *Scabies:* Apply cream head to toe; leave for 8–14 hr, wash w/ H_2O.
W/P: [B, ?/−].
CI: Allergy >2 mo.
DISP: Topical lotion 1%; cream 5%.
SE: Local irritation.
NOTES: Sprays available (*Rid, A200, Nix*) to disinfect clothing, bedding, combs, & brushes; lotion not OK in peds <2 mo; may repeat after 7 days.

PHENAZOPYRIDINE (PYRIDIUM, GENERIC) (AZO, MANY OTHER OTC FORMS)

USES: *Relief of pain, burning, urgency, frequency, and other discomforts d/t irritation of the lower urinary tract mucosa caused by infection, trauma, surgery, endoscopic procedures, or the passage of sounds or catheters. *
ACTIONS: Anesthetic on urinary tract mucosa.

DOSE:

Adults: 100–200 mg PO TID; 2 days max. w/ antibiotics for UTI; ↓ w/ renal insufficiency.
W/P: [B, ?] Hepatic disease; methemoglobinemia w/ acute overdose.
CI: Renal failure, component hypersensitivity.
DISP: Tabs (*Pyridium, Rx*) 100, 200 mg; OTC Tabs 45, 95, 97.2, 97.5, 99.5 mg.
SE: GI disturbances, red-orange urine color (can stain clothing, contacts), yellow tinge to skin/sclera, rash, headache, dizziness, acute renal failure, methemoglobinemia, tinting of sclera/skin.
NOTES: Take w/ food, hydrate well. For peds phenazopyridine can be compounded with glycerin to form a suspension yielding a 10 mg/mL solution, the dose is 4 mg/kg/dose TID.

PHENYLEPHRINE, ORAL (SUDAFED, OTHERS [OTC])

WARNING: Not for use in peds <2 yr.
USES: *Nasal congestion.*
ACTIONS: α-Adrenergic agonist.

DOSE:

Adults: 10–20 mg PO q4h PRN, max. 60 mg/d.
Peds: 4–5 y: 2.5 mg q4h max. 6 doses/d; >6–12: 5 mg q4h, max. 30 mg/d ≥12: adult dosing.
W/P: [C, +/−] HTN, acute pancreatitis, hep, coronary disease, narrow-angle glaucoma, hyperthyroidism.
CI: MAOI w/in 14 days, narrow-angle glaucoma, severe ↑ BP or CAD, urinary retention.
DISP: Liq 7.5 mg/5 mL; drops: 1.25/0.8 mL, 2.5 mg/5 mL; tabs 5, 10 mg; chew tabs 10 mg; tabs once daily 10 mg; strips: 1.25, 2.5, 10 mg; many combo OTC products.
SE: Arrhythmias, HTN, headache, agitation, anxiety, tremor, palpitations; can be chemically processed into methamphetamine; products now sold behind pharmacy counter w/o prescription.
NOTES: 60 mg 4 times daily for 6 wk for retrograde ejaculation.

PIPERACILLIN/TAZOBACTAM (ZOSYN, GENERIC)

USES: *Infections of skin, bone, resp & urinary tract, abdominal, sepsis.*
ACTIONS: 4th-gen PCN plus β-lactamase inhibitor; bactericidal; ↓ cell wall synth. *Spectrum:* Good gram(+), excellent gram(−); anaerobes & β-lactamase producers.

DOSE:

Adults: 3.375–4.5 g IV q6h; ↓ in renal insufficiency.
W/P: [B, M].
CI: PCN or β-lactam sensitivity.
DISP: Frozen and powder for Inj: 2.25, 3.375, 4.5 g.
SE: Diarrhea, headache, insomnia, GI upset, serum sickness-like reaction, pseudomembranous colitis.
NOTES: Often used in combo w/ aminoglycoside.

PODOFILOX [PODOPHYLLIN] (PODOCON-25, CONDYLOX, CONDYLOX GEL 0.5%)

USES: *Topical Treat of benign growths (genital & perianal warts [condylomata acuminata]*, papillomas, fibromas).
ACTIONS: Direct antimitotic effect; exact mechanism unknown.
DOSE: *Condylox gel & Condylox:* Apply BID for 3 consecutive d/wk then hold for 4 days, may repeat 4 × 0.5 mL/d max.; *Podocon-25:* Use sparingly on the lesion, leave on for only 30–40 min for 1st application, then 1–4 hr on subsequent applications, thoroughly wash off; limit <5 mL or <10 cm^2/Treat.
W/P: [X, ?] Immunosuppression.
CI: DM, bleeding lesions.
DISP: *Podocon-25* (w/ benzoin) 15-mL bottles; *Condylox gel* 0.5% 35-g clear gel; *Condylox soln*

0.5% 35-g clear.
SE: Local reactions, sig absorption; anemias, tachycardia, paresthesias, GI upset, renal/hepatic damage.
NOTES: *Podocon-25* applied by the clinician; do not dispense directly to pt.

POLYETHYLENE GLYCOL [PEG] 3350 (MIRALAX [OTC])

USES: *Occasional constipation*, constipation/dysfunctional elimination syndrome in peds.
ACTIONS: Osmotic laxative.

DOSE:
Adult: 17-g powder (1 heaping tsp) in 8 oz (1 cup) of H_2O & drink; max. 14 d.
Peds: ***>6 mo:*** (Not FDA) 0.5–1.5 g/kg daily, max. dose 17 g/d.
W/P: [C, ?] Rule out bowel obst before use.
CI: GI obst, allergy to PEG.
DISP: Powder for reconstitution; bottle cap holds 17 g.
SE: Upset stomach, bloating, cramping, gas, severe diarrhea, hives.
NOTES: Can add to H_2O, juice, soda, coffee, or tea.

POTASSIUM CITRATE (UROCIT-K, GENERIC)

USES: *Alkalinize urine, prevention of urinary stones (uric acid, calcium stones if hypocitraturic).*
ACTIONS: Urinary alkalinizer.
DOSE: 30–60 mEq/d based on severity of hypocitraturia. Max. 100 mEq/d.
W/P: [A, +].
CI: Severe renal impairment, dehydration, ↑ K^+, peptic ulcer; w/ K^+-sparing diuretics, salt substitutes.
DISP: Tabs 5, 10, 15 mEq/d.
SE: GI upset, ↓ Ca^{2+}, ↑ K^+ (more likely with renal insufficiency); metabolic alkalosis.
NOTE: Maintain high fluid intake; gastrointestinal upset is the primary SE; treatment should be avoided when the urine pH is >6.5.

POTASSIUM SUPPLEMENTS (KAON, KAOCHLOR, K-LOR, SLOW-K, MICRO-K, KLORVESS, GENERIC)

USES: *Prevention or Treat of ↓ K^+* (eg, diuretic use).
ACTIONS: K^+ supl.

DOSE:

Adults: 20–100 mEq/d PO ÷ 1–4×/d; IV 10–20 mEq/h, max. 40 mEq/h & 150 mEq/d (monitor K^+ levels frequently and in presence of continuous ECG monitoring w/ high-dose IV).
Peds: Calculate K^+ deficit; 1–3 mEq/kg/d PO ÷ 1–4×/d; IV max. dose 0.5–1 mEq/kg/× 1–2 hr.
W/P: [A, +] Renal insufficiency, use w/ NSAIDs & ACE inhibitor.

CI: ↑ K^+.
DISP: PO forms see table at top of page, Inj.
SE: GI irritation; ↓ HR, ↑ K^+, heart block.
NOTES: Mix powder & liq w/ beverage (unsalted tomato juice, etc.); swallow SR tabs must be swallowed whole; follow monitor K^+; Cl^- salt OK w/ alkalosis; w/ acidosis use acetate, bicarbonate, citrate, or gluconate salt; do not administer IV K^+ undiluted.

Commonly Used Potassium Supplements

Brand Name	Salt	Form	mEq Potassium/ Dosing Unit
Glu-K	Gluconate	Tablet	2 mEq/tablet
Kaon elixir	Gluconate	Liquid	20 mEq/15 mL
Kaon-Cl 10	KCl	Tablet, SR	10 mEq/tablet
Kaon-Cl 20%	KCl	Liquid	40 mEq/15 mL
K-Dur 20	KCl	Tablet, SR	20 mEq/tablet
KayCiel	KCl	Liquid	20 mEq/15 mL
K-Lor	KCl	Powder	20 mEq/packet
K-lyte/Cl	KC /bicarbonate	Effervescent tablet	25 mEq/tablet
Klorvess	KCl/bicarbonate	Effervescent tablet	20 mEq/tablet
Klotrix	KCl	Tablet, SR	10 mEq/tablet
K-Lyte	Bicarbonate/citrate	Effervescent tablet	25 mEq/tablet
Klor-Con/EF	Bicarbonate/citrate	Effervescent tablet	25 mEq/tablet
K-Tab	KCl	Tablet, SR	10 mEq/tablet
Micro-K	KCl	Capsule, SR	8 mEq/capsule
Potassium Chloride 10%	KCl	Liquid	20 mEq/15 mL
Potassium Chloride 20%	KCl	Liquid	40 mEq/15 mL
Slow-K	KCl	Tablet, SR	8 mEq/tablet
Tri-K	Acetate/ bicarbonate and citrate	Liquid	45 mEq/15 mL
Twin-K	Citrate/gluconate	Liquid	20 mEq/5 mL

Based on data in and modified from Gomella LG, Haist S, Adams A, eds. *Clinicians' Pocket Drug Reference, 2015 Edition*. New York, NY: McGraw-Hill.

PRAMOXINE (ANUSOL OINTMENT, PROCTOFOAM-NS, OTHERS)

USES: *Relief of pain & itching from hemorrhoids, anorectal surgery*; topical for burns & dermatosis.
ACTIONS: Topical anesthetic.
DOSE: Apply freely to anal area 3–5 ×/d.
W/P: [C, ?].
DISP: [OTC] All 1%; foam (*ProctoFoam-NS*), cream, oint, lotion, gel, pads, spray.
SE: Contact dermatitis, mucosal thinning w/ chronic use.

PRAMOXINE/HYDROCORTISONE (PROCTOFOAM-HC)

USES: *Relief of pain & itching from hemorrhoids.*
ACTIONS: Topical anesthetic, anti-inflammatory.
DOSE: Apply freely to anal area TID–QID.
W/P: [C, ?/−].
DISP: *Cream:* Pramoxine 1% acetate 1/2.5/2.35%, *foam:* Pramoxine 1% hydrocortisone 1%; *lotion:* Pramoxine 1% hydrocortisone 1/2.5%; ointment pramoxine 1% & hydrocortisone 1/2.5%.
SE: Contact dermatitis, mucosal thinning w/ chronic use

PRAZOSIN (MINIPRESS, GENERIC)

USES: *HTN *
ACTIONS: Peripherally acting α-adrenergic blocker.

DOSE:

Adults: 1 mg PO TID; can ↑ to 20 mg/d max. PRN.
Peds: 0.05–0.1 mg/kg/d in 3 ÷ doses; max. 0.5 mg/kg/d.
W/P: [C, ?] Use w/ phosphodiesterase-5 (PDE5) inhibitor (eg, sildenafil) can cause ↓ BP.
CI: Component allergy, concurrent use of PDE5 inhibitor.
DISP: Caps 1, 2, 5 mg; tabs ER 2.5, 5 mg.
SE: Dizziness, edema, palpitations, fatigue, GI upset.
NOTES: Can cause orthostatic ↓ BP, take the 1st dose hs; tolerance develops to this effect; tachyphylaxis may result.

PREDNISOLONE (FLO-PRED, OMNIPRED, PEDIAPRED, GENERIC)

See Steroids pages 968, 969

PREDNISONE (GENERIC)

See Steroids pages 968, 969

PREGABALIN (LYRICA, GENERIC)

USES: *DM peripheral neuropathy pain; postherpetic neuralgia; fibromyalgia; adjunct w/ adult partial onset seizures
ACTIONS: Nerve transmission modulator, antinociceptive, antiseizure effect; mechanism uncertain; related to gabapentin.
DOSE: *Neuropathic pain:* 50 mg PO TID, ↑ to 300 mg/d w/in 1 wk based on response, 300 mg/d max. *Postherpetic neuralgia:* 75–150 mg BID or 50–100 mg TID; start 75 mg BID or 50 mg TID; ↑ to 300 mg/d w/in 1 wk PRN; if pain persists after 2–4 wk, ↑ to 600 mg/d. *Partial onset seizure:* Start 150 mg/d (75 mg BID or 50 mg TID) may ↑ to max. 600 mg/d; ↓ w/ CrCl <60; w/ or w/o food.
W/P: [C, −] w/ Sig renal impairment (see PI), w/ elderly & severe CHF avoid abrupt D/C.
CI: Hypersensitivity.
DISP: Caps 25, 50, 75, 100, 150, 200, 225, 300 mg; soln 20 mg/mL.
SE: Dizziness, drowsiness, xerostomia, edema, blurred vision, Wt gain, difficulty concentrating; suicidal ideation.
NOTES: w/ D/C, taper over at least 1 wk.

PROBENECID (PROBALAN, GENERIC)

USES: *Prevent gout & hyperuricemia; extends levels of PCNs & cephalosporins.*
ACTIONS: Uricosuric, renal tubular blocker of weak organic anions.

DOSE:

Adults: *Gout:* 250 mg BID × 1 wk, then 500 mg PO BID; can ↑ by 500 mg/mo up to 2–3 g/d.

Antibiotic effect: 1–2 g PO 30 min before dose.
Peds: ***>2 yr:*** 25 mg/kg, then 40 mg/kg/d PO QID.
W/P: [B, ?].
CI: Uric acid kidney stones, initiations during acute gout attack, coadministration of salicylates, age <2 yr, MDD, renal impairment.
DISP: Tabs 500 mg.
SE: Headache, GI upset, rash, pruritus, dizziness, blood dyscrasias.

PROPANTHELINE (PRO-BANTHINE, GENERIC)

USES: *Adjunctive therapy in the treatment of peptic ulcer *, symptomatic Treat small intestine hypermotility, spastic colon, ureteral spasm, bladder spasm, pylorospasm.
ACTIONS: Antimuscarinic.

DOSE:

Adults: 15 mg PO ac & 30 mg PO hs; ↓ in elderly.
Peds: 2–3 mg/kg/24 h PO ÷ 3–4×/d.
W/P: [C, ?].
CI: Glaucoma, severe ulcerative colitis, toxic megacolon, GI atony in elderly, myasthenia gravis, GI/GU obst.
DISP: 15 mg.
SE: Anticholinergic (eg, xerostomia, blurred vision).

PROPRANOLOL (INDERAL LA, INNOPRAN XL, GENERIC)

USES: *HTN, angina, MI, hyperthyroidism, essential tremor, hypertrophic subaortic stenosis, pheochromocytoma; prevents migraines & atrial arrhythmias*, thyrotoxicosis.
ACTIONS: β-Adrenergic receptor blocker, β_1, β_2; only β-blocker to block conversion of T_4 to T_3.

DOSE:

Adults: *Angina:* 80–320 mg/d PO ÷ 2–4×/d or 80–320 mg/d SR. *Arrhythmia*: 10–30 mg/dose PO q6–8h or 1 mg IV slowly, repeat q5min, 5 mg max. *HTN:* 40 mg PO BID or 60–80 mg/d SR, weekly to max. 640 mg/d. *Hypertrophic subaortic stenosis:* 20–40 mg PO 3–4×/d. *MI:* 180–240 mg PO ÷ 3–4×/d. *Migraine prophylaxis:* 80 mg/d ÷ 3–4×/d, ↑ weekly 160–240 mg/d ÷ 3–4 ×/d max.; wean if no response in 6 wk. *Pheochromocytoma:* 30–60 mg/d ÷ 3–4×/d. *Thyrotoxicosis:* 1–3 mg IV × 1; 10–40 mg PO q6h. *Tremor:* 40 mg PO BID, ↑ PRN 320 mg/d max. ***ECC 2010***. *SVT:* 0.5–1 mg IV given over 1 min; repeat PRN up to 0.1 mg/kg.
Peds: *Arrhythmia:* 0.5–1.0 mg/kg/d ÷ 3–4×/d, ↑ PRN q3–7d to 8 mg/kg max.; 0.01–0.1 mg/kg IV over 10 min, 1 mg max. infants, 3 mg max. children. *HTN:* 0.5–1.0 mg/kg ÷ 3–4×/day, PRN q3–7d to 8 mg/kg/d max.; ↓ in renal impairment.
W/P: [C (1st tri, D if 2nd or 3rd tri), +].
CI: Uncompensated CHF, cardiogenic shock, HR, heart block, PE, severe resp disease.
DISP: Tabs 10, 20, 40, 80 mg; SR caps 60, 80, 120, 160 mg; oral soln 4, 8, mg/ mL; Inj 1 mg/mL.

SE: ↓ HR, ↓ BP, fatigue, GI upset, erectile dysfunction.

PROTAMINE (GENERIC)

WARNING: Severe ↓ BP, CV collapse, noncardiogenic pulm edema, pulm vasoconstriction, and pulm HTN can occur; risk factors: high dose/ overdose, repeat doses, prior protamine use, current or use of prior protamine-containing product (eg, NPH or protamine zinc insulin, some β-blockers), fish allergy, prior vasectomy, severe LV dysfunction, abnormal pulm testing; weigh risk/benefit in pts w/ 1 or more risk factors; resuscitation equipment must be available.
USES: *Reverse heparin effect.*
ACTIONS: Neutralize heparin by forming a stable complex.
DOSE: Based on degree of heparin reversal; give IV slowly; 1 mg reverses ~100 U of heparin given in the preceding 30 min; 50 mg max.
W/P: [C, ?].
CI: Allergy.
DISP: Inj 10 mg/mL.
SE: Follow coagulation markers; anticoagulant effect if given w/o heparin; ↓ BP, ↓ HR, dyspnea, hemorrhage.
NOTES: Check aPTT ~15 min after use to assess response.

PROTHROMBIN COMPLEX CONCENTRATE, HUMAN (KCENTRA)

WARNING: Risk vit K antag reversal w/ a thromboembolic event, must be weighed against the risk of NOT reversing vitamin K antag; this risk is higher in those who have had a prior thromboembolic event. Fatal and non-fatal arterial and venous thromboembolic events have occurred. Monitor. May not be effective in pts w/ thromboembolic events in the prior 3 mo.
USES: *Urgent reversal of acquired coagulation factor deficiencies caused by vit K antagonists; only for acute major bleeding.*
ACTIONS: Reverse vit K antag coagulopathy; replaces Factor II, VII, IX, X & Protein C & S.
DOSE: Based on INR and wgt: INR 2–4, 25 U/kg, 2,500 U max.; INR 4–6, 35 U/kg, 3,500 U max.; INR >6, 50 U/kg, 5,000 U max.; 100 mg/kg max.; give w/ vit K.
W/P: [C, ?] Hypersensitivity reaction; arterial/venous thrombosis; risk of viral Infxn including variant CJD.
CI: Anaphylaxis/reactions to: heparin, albumin or coag factors (Protein C & S, antithrombin III); known HIT DIC.
DISP: Single vial, to reconstitute, see package; separate IV for inf.
SE: Thromboembolic events (stroke, DVT/PE); DIC; ↓ BP, HA, N/V, HA, arthralgias.
NOTES: INR should be <1.3 w/in 30 min; risk of transmitting variant CJD, viral Dz (human blood product), and other Infxn (Hep A, B & C, HIV, etc.).

PSEUDOEPHEDRINE (MANY OTC MONO AND COMBINATION BRANDS)

USES: *Decongestant*, retrograde ejaculation.
ACTIONS: Stimulates α-adrenergic receptors w/ vasoconstriction.

DOSE:

Adults: *IR:* 60 mg PO q4–6h PRN; *ER:* 120 mg PO q12h, 240 mg/d max.; *Retrograde ejaculation*: Up to 60 mg, PO QID for 2–14 days.
Peds: ***2–5 yr:*** 15 mg q4–6h, 60 mg/24 h max. ***6–12 yr:*** 30 mg q4–6h, 120 mg/24 h max.; ↓ w/ renal insufficiency.
W/P: [C, +] Not rec for use in peds <6 yr.
CI: Poorly controlled HTN or CAD, w/ MAOIs w/in 14 days, urinary retention.
DISP: Immediate release tabs 30, 60 mg; ER caplets 60, 120 mg; ER tabs 120, 240 mg; liq 15, 30 mg/5 mL; syrup 15, 30 mg/5mL; multiple combo OTC products.
SE: HTN, insomnia, tachycardia, arrhythmias, nervousness, tremor.
NOTES: Found in many OTC cough/cold preparations; OTC restricted distribution by state (illicit ingredient in methamphetamine production).

PYRAZINAMIDE (GENERIC)

USES: *Active TB in combo w/ other agents.*
ACTIONS: Bacteriostatic; unknown mechanism.

DOSE:

Adults: Dose varies based on Tx option chosen daily 1 × 2 wk–3 × wk; dosing based on lean body Wt; ↓ dose in renal/hepatic impairment.
Peds: 20–40 mg/kg/d PO ÷ daily–BID; ↓ W/ renal/hepatic impairment.
W/P: [C, +/−].
CI: Severe hepatic damage, acute gout.
DISP: Tabs 500 mg.
SE: Hepatotox, malaise, GI upset, arthralgia, myalgia, gout, photosensitivity.
NOTES: Use in combo w/ other anti-TB drugs; consult http://www.cdc.gov/tb/ for latest TB recommendations; dosage regimen differs for “directly observed” Treat.

PYRIDOXINE [VITAMIN B_6] (GENERIC)

USES: *Treat & prevention of vit B_6 deficiency* supplement when on INH, idiopathic hyperoxaluria.
ACTIONS: Vit B_6 supl.

DOSE:

Adults: *Deficiency:* 10–20 mg/d PO. *Drug-induced neuritis:* 100–200 mg/d; 25–100 mg/d prophylaxis.
Peds: 5–25 mg/d × 3 wk.
W/P: [A (C if doses exceed RDA), +].
CI: Component allergy tabs 25, 50, 100, 250, 500 mg, tab SR 500 mg; liquid 200 mg, 15 mg; Inj: 100 mg/mL; caps: 50, 250.

QUINAPRIL (ACCUPRIL, GENERIC)

WARNING: ACE inhibitor used during pregnancy can cause fet al injury & death.
USES: *HTN, CHF, DN, post-MI.*

ACTIONS: ACE inhibitor.
DOSE: 10–80 mg PO daily; ↓ in renal impairment.
W/P: [D, +] w/ RAS, vol depletion.
CI: ACE inhibitor sensitivity, angioedema, pregnancy.
DISP: Tabs 5, 10, 20, 40 mg.
SE: Dizziness, headache, ↓ BP, impaired renal function, angioedema, taste perversion, cough.

QUINUPRISTIN/DALFOPRISTIN (SYNERCID)

USES: *Vancomycin-resistant infections d/t *E. faecium* & other gram(+).*
ACTIONS: ↓ Ribosomal protein synth. *Spectrum:* Vancomycin-resistant *E. faecium,* methicillin-susceptible *S. aureus, S. pyogenes;* not against *E. faecalis.*

DOSE:
Adults & Peds: 7.5 mg/kg IV q12h (central line preferred); incompatible w/ NS or heparin; flush IV w/ dextrose; ↓ w/ hepatic failure.
W/P: [B, M] Multiple drug interactions w/ drugs metabolized by CYP3A4 (eg, cyclosporine).

RADIUM-223 DICHLORIDE (XOFIGO)

USES: *Castration-resistant prostate cancer, symptomatic bone metastases w/o visceral metastatic disease.*
ACTIONS: α-emitting radioactivity, forms complexes in bone in area of ↑ bone turnover.

DOSE:

Adults: *Men only:* 50 kBq/kg, Q 4 wk × 6 doses.
W/P: [X, -] not indicated in women.
CI: Preg.
DISP: Single vial, 1,000 kBq/mL or 6,000 kBq/vial.
SE: Anemia, ↓ lymphocytes, ↓ WBC, ↓ plts, ↓ neutrophils; N/V/D, edema.
NOTES: Slow IV infusion over 1 min; follow radiation safety and pharmaceutical quality control requirements; men should use condoms during Tx & to 6 mo post-Tx and female partners should use 1 method because of potential effects of radiation on sperm; less bone marrow toxicity than β-emitters such as strontium.

RALOXIFENE (EVISTA)

WARNING: Increased risk of venous thromboembolism and death from stroke.
USES: *Prevent osteoporosis, breast cancer prevention.*
ACTIONS: Partial antagonist of estrogen, behaves like estrogen.
DOSE: 60 mg/d.
W/P: [X, −].
CI: Thromboembolism, pregnancy.
DISP: Tabs 60 mg.
SE: CP, insomnia, rash, hot flashes, GI upset, hepatic dysfunction, leg cramps.

RAMIPRIL (ALTACE, GENERIC)

WARNING: ACE inhibitor used during pregnancy can cause fet al injury & death.
USES: *HTN, CHF, DN, post-MI.*
ACTIONS: ACE inhibitor.
DOSE: 1.25–20 mg/d PO ÷ daily–BID; ↓ in renal failure.
W/P: [C-1st tri/D-2nd & 3rd, +].
CI: ACE inhibitor-induced angioedema.
DISP: Caps 1.25, 2.5, 5, 10 mg.
SE: Cough, headache, dizziness, ↓ BP, renal impairment, angioedema.
NOTES: OK in combo w/ diuretics.

RASBURICASE (ELITEK)

WARNING: Anaphylaxis possible; do not use in G6PD deficiency and hemolysis; can cause methemoglobinemia; can interfere w/ uric acid assays; collect blood samples and store on ice.
USES: *Reduce ↑ uric acid d/t tumor lysis.*
ACTIONS: Catalyzes uric acid.

DOSE:
Adult & Peds: 0.20 mg/kg IV over 30 min, daily × 5; do not bolus, redosing-based uric acid levels.
W/P: [C, ?/−] Falsely ↓ uric acid values.
CI: Anaphylaxis, screen for G6PD deficiency to avoid hemolysis, methemoglobinemia.
DISP: 1.5, 7.5 mg powder Inj.
SE: Fever, neutropenia, GI upset, headache, rash.
NOTES: Place blood test tube for uric acid level on ice to stop enzymatic reaction; removed by dialysis; doses as low as 0.05 mg/kg have been used effectively in clinical trials.

RIFAMPIN (RIFADIN, RIMACTANE, GENERIC)

USES: *TB & Treat & prophylaxis of *N. meningitidis, H. influenzae,* or *S. aureus* carriers*; adjunct w/ severe *S. aureus.*
ACTIONS: ↓ DNA-dependent RNA polymerase.

DOSE:

Adults: *N. meningitidis* & *H. influenzae carrier:* 600 mg/d PO for 4 d. *TB:* 600 mg PO or IV daily or 2×/wk w/ combo regimen.
Peds: 10–20 mg/kg/dose PO or IV daily–BID; ↓ in hepatic failure.
W/P: [C, +] w/ Fosamprenavir, multiple drug interactions.
CI: Allergy, active *N. meningitidis* infection, w/ saquinavir/ritonavir.
DISP: Caps 150, 300 mg; Inj 600 mg.
SE: Red-orange–colored bodily fluids, ↑ LFTs, flushing, headache.
NOTES: Never use as single agent w/ active TB.

RISEDRONATE (ACTONEL, ACTONEL W/ CALCIUM, GENERIC)

USES: *Paget disease; Treat/prevention glucocorticoid-induced/postmenopausal osteoporosis, ↑ bone mass in osteoporotic men; w/ calcium only FDA approved for female osteoporosis.*

ACTIONS: Bisphosphonate; ↓ osteoclast-mediated bone resorption.
DOSE: *Paget disease:* 30 mg/d PO for 2 mo. *Osteoporosis Treat/prevention:* 5 mg daily or 35 mg qwk or 150 mg qmo; 30 min before 1st food/drink of the day; stay upright for at least 30 min after dose.
W/P: [C, ?/−] Ca^{2+} supls & antacids ↓ absorption; jaw osteonecrosis, avoid dental work.
CI: Component allergy, ↓ Ca^{2+}, esophageal abnormalities, unable to stand/sit for 30 min, CrCl < 30 mL/min.
DISP: Tabs 5, 30, 35, 150 mg; Risedronate 35 mg (4 tabs)/calcium carbonate 1,250 mg (24 tabs).
SE: Back pain, headache, abdominal pain, dyspepsia, arthralgia; flu-like Sxs, hypersensitivity (rash, etc.), esophagitis, bone pain, eye inflammation.
NOTES: Monitor LFTs, Ca^{2+}, PO^{3+}, K^{+}; may ↑ atypical subtrochanteric femur fractures.

RISEDRONATE, DELAYED RELEASE (ATELVIA)

USES: *Postmenopausal osteoporosis.*
ACTIONS: See Risedronate.
DOSE: One 35 mg tab 1 × wk; in a.m. following breakfast w/ 4-oz water; do not lie down for 30 min.
W/P: [C, ?/−] Ca^{2+} & Fe^{2+} supls/ antacids ↓ absorption; do not use w/ Actonel or CrCl < 30 mL/min; jaw osteonecrosis reported, avoid dental work; may ↑ subtrochanteric femur fractures; severe bone/ jt pain.
CI: Component allergy, ↓ Ca^{2+}, esophageal abnormalities, unable to stand/sit for 30 min.
DISP: DR Tabs 35 mg.
SE: Diarrhea, influenza, arthralgia, back/abdominal pain; rare hypersens, eye inflam.
NOTES: Correct ↓ Ca^{2+} before use; check Ca^{2+}.

RIVAROXABAN (XARELTO)

WARNING: May ↑ risk of spinal/epidural hematoma w/ paralysis & increase risk of stroke w/ premature D/C, monitor closely.
USES: *Prevention of DVT in knee/hip replacement surgery & prevention of stroke and systemic embolism in pts w/ nonvalvular Afib.*
ACTIONS: Factor Xa inhibitor.
DOSE: 10 mg PO qd × 35 d (hip) or 12 d (knee), stroke 20 mg daily; w or w/o food.
W/P: [C, −] w/ CYP3A4 inhibitor/inducers, other anticoagulants or plt inhibitor; avoid w/ CrCl < 30 mL/min or mod/severe hepatic impairment.
CI: Active bleeding; component hypersens.
DISP: Tabs 10 mg.
SE: Bleeding.
NOTES: See PI for information about timing of stopping or starting dosage in relation to other anticoagulants.

SARGRAMOSTIM [GM-CSF] (LEUKINE)

USES: *Myeloid recovery following BMT or chemotherapy.*
ACTIONS: Recombinant GF, activates mature granulocytes & macrophages.

DOSE:
Adults & Peds: 250 μg/m²/d IV cont until ANC >1,500 cells/m² for 3 consecutive days.
W/P: [C, ?/−] Li, corticosteroids.
CI: >10% blasts, allergy to yeast, concurrent chemotherapy/RT.
DISP: Inj 250, 500 μg.
SE: Bone pain, fever, ↑ BP, tachycardia, flushing, GI upset, myalgia.
NOTES: Rotate Inj sites; use acetaminophen PRN for pain.

SEVELAMER CARBONATE (RENVELA)

USES: *Control of serum phosphorus in patients with chronic kidney disease (CKD) on dialysis.*
ACTIONS: Intestinal phosphate binder.
DOSE: Start 0.8 or 1.6 g PO TID w/ meals; titrate 0.8 g/meal for target PO_4 3.5–5.5 mg/dL; switch g/g among sevelamer forms, titrate PRN.
W/P: [C, ?] w/ Swallow disorders, bowel problems, may ↓ absorption of vits D, E, K, ↓ ciprofloxacin & other medicine levels.
CI: Bowel obst.
DISP: Tab 800 mg, powder 0.8/2.4 g.
SE: N/V/diarrhea, dyspepsia, abdominal pain, flatulence, constipation.
NOTES: Separate other meds 1 hr before or 3 hr after.

SEVELAMER HYDROCHLORIDE (RENAGEL)

USES: *Control of serum phosphorus in patients with chronic kidney disease (CKD) on dialysis. *
ACTIONS: Binds intestinal PO_4.
DOSE: *Initial:* PO_4 >5.5 and <7.5 mg/dL: 800 mg PO TID; ≥7.5 mg/dL: 1,200–1,600 mg PO TID. *Switching from sevelamer carbonate:* per-g basis; titrate ↑/↓ 1 tab/meal 2-wk intervals PRN; take w/ food 2–4 caps PO TID w/ meals; adjust based on PO_4; max. 4 g/dose.
W/P: [C, ?] May ↓ absorption of vits D, E, K, ↓ ciprofloxacin & other medicine levels.
CI: ↓ PO_4, bowel obst.
DISP: Tab 400, 800 mg.
SE: N/V/diarrhea, dyspepsia, ↑ Ca^{2+}.
NOTES: Do not open/chew caps; separate other meds 1 hr before or 3 hr after; 800 mg sevelamer = 667 mg Ca acetate.

SILDENAFIL (VIAGRA, REVATIO)

USES: *Viagra:* *erectile dysfunction*; *Revatio:* *Pulm artery HTN (adult only).*
ACTIONS: ↓ Phosphodiesterase type 5 (PDE5) (responsible for cGMP breakdown); ↑ cGMP activity to relax smooth muscles & ↑ flow to corpus cavernosum and pulm vasculature;

possibly antiproliferative on pulm artery smooth muscle; onset 15–60 min, duration 4 hr.
DOSE: *Erectile dysfunction:* 25–100 mg PO 1 hr before sexual activity, max. 1/d; ↓ if >65 yr.
W/P: [B, ?] w/ CYP3A4 inhibitor, retinitis pigmentosa; hepatic/severe renal impairment; w/ sig hypo/hypertension.
CI: w/ Nitrates or if sex not advised; w/ protease inhibitor.
DISP: Tabs *Viagra:* 25, 50, 100 mg, tabs. *Revatio:* Tabs 20 mg; Inj 5–10 mg/vial.
SE: Headache; flushing; dizziness; blue haze visual change (reacts with PDE6 in retina), hearing loss, priapism.
NOTES: Cardiac events in the absence of nitrates debatable; postpone dose for 4 hr after taking α-adrenergic antagonist; transient global amnesia reports; report of ↑melanoma risk; avoid fatty food w/ dose; not for peds use.

SILODOSIN (RAPAFLO)

USES: *BPH*
ACTIONS: α-blockers of prostatic α_{1a}.
DOSE: 8 mg/d; 4 mg/d w/ CrCl 30–50 mL/min; take w/ food.
W/P: [B, ?] Not for use in females; do not use w/ other α-blockers or glycoprotein inhibitor (ie, cyclosporine); R/O PCa before use; intraoperative floppy iris syndrome possible w/ cataract surgery.
CI: Severe hepatic/renal impairment (CrCl <30 mL/min), w/ CYP3A4 inhibitor (eg, ketoconazole, clarithromycin, itraconazole, ritonavir).
DISP: Caps 4, 8 mg.
SE: Retrograde ejaculation, dizziness, diarrhea, syncope, somnolence, orthostatic ↓ BP, nasopharyngitis, nasal congestion, intraoperative floppy iris syndrome during contract surgery.
NOTES: Not for use as antihypertensive; no effect on QT interval.

SILVER NITRATE (GENERIC)

USES: *Removal of granulation tissue & warts; prophylaxis in burns*, control hemorrhagic cystitis.
ACTIONS: Caustic antiseptic & astringent.
DOSE:
Adults & Peds: Apply to moist surface 2–3 × wk for 2–3 wk or until effect; 0.5–1% solution instilled in bladder for up to 20 min (R/O reflux before, requires anesthesia.
W/P: [C, ?].
CI: Do not use on broken skin.
DISP: Topical impregnated applicator sticks, soln 0.5, 10, 25, 50%; topical ointment 10%.
SE: May stain tissue black, usually resolves; local irritation, methemoglobinemia.
NOTES: D/C if redness or irritation develops; no longer used in US for newborn prevention of gonococcus conjunctivitis

SILVER SULFADIAZINE (SILVADENE, GENERIC)

USES: *Prevention & Treat of infection in 2nd- & 3rd-degree burns.*
ACTIONS: Bactericidal.

DOSE:
Adults & Peds: Aseptically cover the area w/ 1/16-in coating BID.
W/P: [B unless near term, ?/−].
CI: Infants <2 mo, pregnancy near term.
DISP: Cream 1%.
SE: Itching, rash, skin discoloration, blood dyscrasias, hep, allergy.
NOTES: Systemic absorption w/ extensive application.

SIPULEUCEL-T (PROVENGE)

USES: *Asymptomatic/minimally symptomatic metastatic castrate-resistant PCa.*
ACTIONS: Autologous (pt specific) cellular immunotherapy.
DOSE: 3 doses over 1 mo @ 1-wk intervals; premed w/ acetaminophen & diphenhydramine.
W/P: [N/A, N/A] Confirm identity/expir date before Inf; acute transfusion reaction possible; not tested for transmissible disease.
CI: None.
DISP: 50 MU autologous CD54+ cells activated w/ PAP GM-CSF in 250 mL LR.
SE: Chills, fatigue, fever, back pain, N, joint ache, headache.
NOTES: Pt must undergo leukapheresis, w/ shipping and autologous cell processing at manufacturing facility before each Inf. Confirm/maintain testosterone <50 ng/mL.

SIROLIMUS [RAPAMYCIN] (RAPAMUNE)

WARNING: Use only by physicians experienced in immunosuppression; immunosuppression associated w/ lymphoma,↑ infection risk; do not use in lung transplant (fatal bronchial anastomotic dehiscence); do not use in liver transplant: ↑ risk hepatic artery thrombosis, graft failure, and mortality (w/ evidence of infection).
USES: *Prevent organ rejection in new renal Tx pts.*
ACTIONS: ↓ T-lymphocyte activation and proliferation.

DOSE:

Adults: ***>40 kg:*** 6 mg PO on day 1, then 2 mg/d PO.
Peds: ***<40 kg & ≥13 y:*** 3 mg/m^2 load, then 1 mg/ m^2/d (in H_2O/orange juice; no grapefruit juice w/ sirolimus); take 4 hr after cyclosporine; ↓ in hepatic impairment.
W/P: [C, ?/−] Impaired wound healing & angioedema; grapefruit juice, ketoconazole.
CI: Component allergy.
DISP: Soln 1 mg/mL, tab 0.5, 1, 2 mg.
SE: HTN, edema, CP, fever, headache, insomnia, acne, rash, ↑ cholesterol, GI upset, ↑/↓ K^+, infections, blood dyscrasias, arthralgia, tachycardia, renal impairment, graft loss & death in liver transplant (hepatic artery thrombosis), ascites.
NOTES: Levels: *Trough:* 4–20 ng/mL; varies w/ assay method and indication.

SODIUM BICARBONATE [$NAHCO_3$] (GENERIC)

USES: *Alkalinization of urine, RTA, metabolic acidosis, ↑ K^+, tricyclic antidepressants OD*, alkalize bladder urine to retrieve sperm in retrograde ejaculation.
ACTIONS: Alkalinizing agent.

DOSE:

Adults: ***ECC 2010:*** Cardiac arrest w/ good ventilation, hyperkalemia, OD of TCAs, ASA, cocaine, diphenhydramine: 1 mEq/kg IV bolus; repeat 1/2 dose q10min PRN. *Metabolic acidosis:* 2–5 mEq/kg IV over 8 hr & PRN based on acid–base status. ↑ K^+: 50 mEq IV over 5 min. *Alkalinize urine:* 4 g (48 mEq) PO, then 12–24 mEq q4h; adjust based on urine pH; 2 amp (100 mEq)/1 L D_5W at 100–250 mL/h IV, monitor urine pH & serum bicarbonate. *Chronic renal failure:* 1–3 mEq/kg/d. *Distal RTA:* 0.5–2 mEq/kg/d in 4–5 ÷ doses.
Peds: *Severe metabolic acidosis, hyperkalemia:* 1 mEq/kg IV slow bolus; 4.2% conc in infants <1 mo. *Chronic renal failure:* See Adult dosage. *Distal RTA:* 2–3 mEq/kg/d PO. *Proximal RTA:* 5–10 mEq/kg/d; titrate based on serum bicarbonate. *Urine alkalinization:* 84–840 mg/kg/d (1–10 mEq/kg/d) in ÷ doses; adjust based on urine pH.
W/P: [C, ?].
CI: Alkalosis, ↑ Na^+, severe pulm edema, ↓ Ca^{2+}.
DISP: Powder, tabs; 325 mg = 3.8 mEq; 650 mg = 7.6 mEq; Inj 1 mEq/1 mL, 4.2% (5 mEq/10 mL), 7.5% (8.92 mEq/ mL), 8.4% (10 mEq/10 mL) vial or amp.
SE: Belching, edema, flatulence, ↑ Na^+, metabolic alkalosis.
NOTES: 1 g neutralizes 12 mEq of acid; 50 mEq bicarbonate = 50 mEq Na; can make 3 amps in 1 L D_5W = D_5NS w/ 150 mEq bicarbonate.

SODIUM CITRATE/CITRIC ACID (ORACIT)

USES: *Chronic metabolic acidosis, alkalinize urine; dissolve uric acid & cysteine stones.*
ACTIONS: Urinary alkalinizer.

DOSE:

Adults: 10–30 mL in 1–3- oz H_2O pc & hs.

Peds: 5–15 mL in 1–3-oz H_2O pc & hs; best after meals.

W/P: [?, ?].
CI: Severe renal impairment, oliguria or azotemia, untreated Addison's disease, adynamia episodica hereditaria, acute dehydration, heat cramp, anuria, severe myocardial damage, and hyperkalemia.
DISP: 15- or 30-mL unit dose: 16 (473 mL) or 4 fl oz.
SE: Tetany, metabolic alkalosis, ↑ K^+, GI upset; avoid use of multiple 50-mL amps; can cause ↑ Na^+/hyperosmolality.
NOTES: 1 mL = 1 mEq Na & 1 mEq bicarbonate.

SODIUM PHOSPHATE (OSMOPREP, VISICOL)

WARNING: Acute phosphate nephropathy reported w/ permanent renal impairment risk; w/

↑ age, hypovolemia, bowel obstr or colitis, baseline kidney disease, w/ meds that affect renal perf/function (diuretics, ACE inhibitor, ARB, NSAIDs).
USES: *Bowel prep prior to colonoscopy in adults*, short-term constipation.
ACTIONS: Hyperosmotic laxative.
DOSE: 3 tabs PO w/ at least 8-oz clear liq q15min for 6 doses; then 2 additional tabs in 15 min, 3–5 hr prior to colonoscopy;3 tabs q15 min for 6 doses, then 2 additional tabs in 15 min.
W/P: [C, ?] Renal impairment, electrolyte disturbances.
CI: Megacolon, bowel obst.
DISP: Tabs 0.398, 1.102 g (32/bottle).
SE: ↑ QT, ↑ PO_4, ↓ calcium, diarrhea, flatulence, cramps, abdominal bloating/pain.
NOTES: Acute phosphate nephropathy is associated w/ calcium-phosphate crystal deposits in the renal tubules and may result in permanent renal dysfunction. Risk factors for acute phosphate nephropathy: Age >55 yr, hypovolemia, pre-existing renal impairment, bowel obstruction, or active colitis; w/ meds that may affect renal perfusion/function (eg, diuretics, ACE inhibitors, ARBs, and possibly NSAIDs).

SODIUM POLYSTYRENE SULFONATE (KAYEXALATE, KIONEX, GENERIC)

USES: *Treat of ↑ K^+*
ACTIONS: Na^+/K^+ ion-exchange resin.
DOSE:
Adults: 15–60 g PO or 30–50 g PR q6h based on serum K^+.
Peds: 1 g/kg/dose PO or PR q6h based on serum K^+.
W/P: [C, ?].
CI: Obstructive bowel disease; ↑ Na^+; neonates w/ ↓ gut motility.
DISP: Powder; susp 15 g/60 mL sorbitol.
SE: ↑ Na^+, ↓ K^+, GI upset, fecal impaction.
NOTES: Enema acts more quickly than PO; PO most effective, onset action >2 hr.

SOLIFENACIN (VESICARE)

USES: *Overactive bladder with symptoms of urge urinary incontinence, urgency, and urinary frequency. *
ACTIONS: Muscarinic antagonist, ↓ detrusor contractions.
DOSE: 5 mg PO daily, 10 mg/d max.; ↓ w/ renal/hepatic impairment.
W/P: [C,?/−] Bladder outlet obstruction or GI obst, ulcerative colitis, myasthenia gravis, renal/hepatic impairment, QT prolongation risk.
CI: Uncontrolled narrow-angle glaucoma, urinary/gastric retention.
DISP: Tabs 5, 10 mg.
SE: Constipation, xerostomia, dyspepsia, blurred vision, drowsiness.
NOTES: CYP3A4 substrate; azole antifungals ↑ levels; recent concern over cognitive effects.

SORAFENIB (NEXAVAR)

USES: *Advanced RCC, differentiated thyroid carcinoma, unresectable hepatocellular carcinoma, advanced thyroid carcinoma refractory to radioactive iodine.
ACTIONS: Tyrosine kinase inhibitor.

DOSE:

Adults: 400 mg PO BID on empty stomach.
W/P: [D, −] w/ Irinotecan, doxorubicin, warfarin; avoid conception (male and female); avoid inducers.
CI: Hypersensitivity; combo with carboplatin and paclitaxel in squamous cell lung cancer.
DISP: Tabs 200 mg.
SE: Hand–foot syndrome; treatment emergent hypertension; bleeding, ↑ INR, cardiac infarction/ischemia; ↑ pancreatic enzymes, hypophosphatemia, lymphopenia, anemia, fatigue, alopecia, pruritus, diarrhea, GI upset, headache, neuropathy.
NOTES: Monitor BP 1st 6 wk; may require ↓ dose (daily or q other day); impaired metabolism w/ Asian descent; may effect wound healing, D/C before major surgery.

SPIRONOLACTONE (ALDACTONE, GENERIC)

WARNING: Tumorigenic in animal studies; avoid unnecessary use.
USES: *Hyperaldosteronism, HTN, class III/IV CHF, ascites from cirrhosis.*
ACTIONS: Aldosterone antagonist; K^+-sparing diuretic.

DOSE:

Adults: *CHF* (NYHA class III–IV) 12.5–25 mg/d (w/ ACE and loop diuretic); *HTN* 25–50 mg/d; *Ascites:* 100–400 mg q a.m w/ 40–160 mg of furosemide, start w/ 100 mg/40 mg, wait at least 3 days before ↑ dose.
Peds: 1–3.3 mg/kg/24 h PO ÷ BID q12–24h, take w/ food.
W/P: [C, + (D/C w/ breast-feeding)].
CI: ↑ K^+, acute renal failure, anuria.
DISP: Tabs 25, 50, 100 mg.
SE: ↑ K^+ & gynecomastia, arrhythmia, sexual dysfunction, confusion, dizziness, diarrhea/N/V, abnormal menstruation.

STARCH, TOPICAL, RECTAL (TUCKS SUPPOSITORIES [OTC])

USES: *Temporary relief of anorectal disorders (itching, etc.)*.
ACTIONS: Topical protectant.

DOSE:
Adults & Peds: ***≥12 y:*** Cleanse, rinse, and dry, insert 1 supl rectally 6×/d × 7 d max.
W/P: [?, ?]
CI: None
DISP: Supp
SE: D/C w/ or if rectal bleeding occurs or if condition worsens or does not improve w/in 7 days.

STEROIDS, SYSTEMIC (SEE TABLE AT BOTTOM OF PAGE)

The following relates only to the commonly used systemic glucocorticoids.

USES: *Endocrine disorders (adrenal insufficiency), rheumatoid disorders, collagen–vascular diseases, derm diseases, allergic states, cerebral edema*, nephritis, nephrotic syndrome, immunosuppression for transplantation, ↑ Ca^{2+}, malignancies (breast, lymphomas), preop (pt who has been on steroids in past year, known hypoadrenalism, preop for adrenalectomy); Inj into joints/tissue.

ACTIONS: Glucocorticoid.

DOSE: Varies w/ use & institutional protocols.

- *Adrenal Insufficiency, acute:* ***Adults:*** *Hydrocortisone:* 100 mg IV; then 300 mg/d ÷ q8h for 48 hr then convert to 50 mg PO q8h × 6 doses, taper to 30–50 mg/d ÷ BID. ***Peds:*** *Hydrocortisone:* 1–2 mg/kg IV, then 150–250 mg/d ÷ q6h–q8h.
- *Adrenal Insufficiency, chronic (physiologic replacement):* May need mineralocorticoid supl such as Florinef. ***Adults:*** *Hydrocortisone:* 20 mg PO q a.m., 10 mg PO q p.m.; *cortisone:* 25–35 mg PO daily. *Dexamethasone:* 0.03–0.15 mg/kg/d or 0.6–0.75 mg/ m^2/d ÷ q6–12h PO, IM, IV. ***Peds:*** *Hydrocortisone:* 8–10 mg/m^2/d ÷ q8h; some may require up to 12 mg/m^2/d. *Hydrocortisone succinate:* 0.25–0.35 mg/kg/d IM.
- *Asthma, acute:* ***Adults:*** *Methylprednisolone* 40–80 mg/d in 1–2 ÷ dose PO/IV or *dexamethasone* 12 mg IV q6h. ***Peds:*** *Prednisolone* 1–2 mg/kg/d or *prednisone* 1–2 mg/kg/d ÷ daily–BID for up to 5 days; *methylprednisolone* 12 mg/kg/d IV ÷ BID; *dexamethasone* 0.1–0.3 mg/kg/d ÷ q6h.
- *Congenital adrenal hyperplasia:* ***Peds:*** Initial *hydrocortisone* 10–20 mg/m^2/d in 3 ÷ doses.
- *Extubation/airway edema:* ***Adults:*** *Dexamethasone:* 0.5–2 mg/kg/d IM/IV ÷ q6h (start 24 hr prior to extubation; continue × 4 more doses). ***Peds:*** *Dexamethasone:* 0.5–2 mg/kg/d ÷ q6h (start 24 hr before & cont for 4–6 doses after extubation).
- *Immunosuppressive/anti-inflammatory:* ***Adults & Older Peds:*** *Hydrocortisone:* 15–240 mg PO, IM, IV q12h. *Methylprednisolone:* 2–60 mg/d PO in 1–4 ÷ doses, taper to lowest effective dose. *Methylprednisolone Na succinate:* 10–80 mg/d IM or 10–40 mg/d IV. ***Adults:*** *Prednisone or prednisolone:* 5–60 mg/d PO ÷ daily–QID. ***Infants & Younger Children:*** *Hydrocortisone:* 2.5–10 mg/kg/d PO ÷ q6–8h; 1–5 mg/kg/d IM/IV ÷ BID–daily.
- *Nephrotic syndrome:* ***Peds:*** *Prednisolone or prednisone:* 2 mg/kg/d PO TID–QID until urine is protein-free for 5 days, use up to 28 days; for persistent proteinuria, 4 mg/kg/ dose PO q other day max., 120 mg/d for an additional 28 days; maint 2 mg/kg/dose q other day for 28 days; taper over 4–6 wk (max. 80 mg/d).
- *Septic shock (controversial):* ***Adults:*** *Hydrocortisone:* 50 mg IV q6h; max. 300 mg/d; some suggest 200 mg/d cont Inf. ***Peds:*** *Hydrocortisone:* 1–2 mg/kg/d intermittent or continuous Inf; may titrate up to 50 mg/kg/d.
- *Status asthmaticus:* ***Adults & Peds:*** *Hydrocortisone:* 1–2 mg/kg/dose IV q6h for 24 hr; then ↓ by 0.5–1 mg/kg q6h.
- *Rheumatic disease:* ***Adults:*** *Intra-articular: Hydrocortisone acetate:* 25–37.5 mg large jt, 10–25 mg small jt. *Methylprednisolone acetate:* 20–80 mg large jt, 4–10 mg small jt. *Intrabursal: Hydrocortisone acetate:* 25–37.5 mg. *Intraganglial: Hydrocortisone acetate:* 25–37.5 mg. *Tendon sheath: Hydrocortisone acetate:* 5–12.5 mg.

Commonly Used Systemic Steroids

	Relative Equivalent		Relative Mineralocorticoid	
Drug	Dose (mg)	Activity	Duration (hr)	Route
Betamethasone	0.75	0	36–72	PO, IM
Cortisone (Cortone)	25	2	8–12	PO, IM
Dexamethasone (Decadron)	0.75	0	36–72	PO, IV
Hydrocortisone (Solu-Cortef, Hydrocortone)	20	2	8–12	PO, IM, IV
Methylprednisolone acetate (Depo-Medrol)	4	0	36–72	PO, IM, IV
Methylprednisolone succinate (Solu-Medrol)	4	0	8–12	PO, IM, IV
Prednisone (Deltasone)	5	1	12–36	PO
Prednisolone (Delta-Cortef)	5	1	12–36	PO, IM, IV

Based on data in and modified from Gomella LG, Haist S, Adams A, eds. *Clinicians' Pocket Drug Reference, 2015 Edition*. New York, NY: McGraw–Hill.

- *Perioperative steroid coverage: Hydrocortisone:* 100 mg IV night before surgery, 1 hr preop, intraoperative, & 4, 8, & 12 hr postop; postop day No. 1 100 mg IV q6h; postop day No. 2 100 mg IV q8h; postop day No. 3 100 mg IV q12h; postop day No. 4 50 mg IV q12h; postop day No. 5 25 mg IV q12h; resume prior PO dosing if chronic use or D/C if only perioperative coverage required.
- *Cerebral edema: Dexamethasone:* 10 mg IV; then 4 mg IV q4–6h.

W/P: [C/D, ?].
CI: Active varicella infection, serious infection except TB, fungal infections.
DISP:
SE: ↑ Appetite, hyperglycemia, ↓ K^+, osteoporosis, nervousness, insomnia, "steroid psychosis," adrenal suppression.
NOTES: Hydrocortisone succinate for systemic, acetate for intra-articular; never abruptly D/C steroids, taper dose; also used for bacterial and TB meningitis.

STEROIDS, TOPICAL (SEE TABLE NEXT PAGE)

USES: *Steroid-responsive dermatoses (seborrheic/atopic dermatitis, neurodermatitis, anogenital pruritus, psoriasis).*
ACTIONS: Glucocorticoid; ↓ capillary permeability, stabilizes lysosomes to control inflammation; controls protein synthesis; ↓ migration of leukocytes, fibroblasts.
DOSE: Use lowest potency produce for shortest period for effect (see Table next page).
W/P: [C, +] Do not use occlusive dressings; high potency topical products not for rosacea, perioral dermatitis; not for use on face, groin, axillae; none for use in a diapered area.
CI: Component hypersens.
DISP: See Table on next page.

Commonly Used Topical Steroids

Agent	Common Trade Names Dosage/Strength	Potency	Apply
Alclometasone dipropionate	**Aclovate**, cream, oint 0.05%	Low	BID/TID
Amcinonide	Cream, lotion, oint 0.1%	High	BID/TID
Betamethasone			
Betamethasone valerate	Cream, lotion, oint 0.1%	Low	q day/BID
Betamethasone valerate	**Luxiq** foam 0.12%	Intermediate	q day/BID
Betamethasone dipropionate	Cream, lotion, oint 0.05%; aerosol 0.1%	High	q day/BID
Betamethasone dipropionate, augmented	**Diprolene** oint, lotion, gel 0.05% **Diprolene AF** cream 0.05%	Ultrahigh	q day/BID
Clobetasol propionate	**Temovate, Clobex, Cormax** cream, gel, oint, lotion, foam, aerosol, shampoo, sol, 0.05%	Ultrahigh	BID (2 wk max.)
Clocortolone pivalate	**Cloderm** cream 0.1%	Intermediate	q day–QID
Desonide	**DesOwen**, cream, oint, lotion 0.05%	Low	BID–QID
Desoximetasone			
Desoximetasone 0.05%	**Topicort** cream, gel 0.05%	Intermediate	q day–QID
Desoximetasone 0.25%	**Topicort** cream, gel 0.025%	High	q day–BID
Dexamethasone base	Aerosol 0.01% Cream 0.1%	Low	BID–QID
Diflorasone diacetate	**ApexiCon** cream, oint 0.05%	Ultrahigh	BID/QID
Fluocinolone			
Fluocinolone acetonide 0.01%	**Synalar** cream, soln 0.01% **Capex** shampoo 0.01%	Low	BID/TID
Fluocinolone acetonide 0.025%	**Synalar** oint, cream 0.025%	Intermediate	BID/TID
Fluocinonide 0.1%	**Vanos** cream 0.1%	High	qd/BID
Flurandrenolide	**Cordran** cream, oint 0.25% tape 4 mcg/cm^2	Intermediate	qd
Fluticasone propionate	**Cutivate** cream, lotion 0.05%, oint 0.005%	Intermediate	BID
Halobetasol	**Ultravate** cream, oint 0.05%	Very high	BID
Halcinonide	**Halog** cream oint 0.1%	High	qd/TID
Hydrocortisone			
Hydrocortisone	**Cortizone, Caldecort, Hycort, Hytone,** others aerosol 1%, cream 0.5, 1, 2.5%, gel 0.5%, oint 0.5, 1, 2.5%, lotion 0.5, 1, 2.5%, paste 0.5%, soln 1%	Low	TID/QID
Hydrocortisone acetate	Cream, oint 0.5, 1%	Low	TID/qid
Hydrocortisone butyrate	**Locoid** oint, cream, lotion soln 0.1%	Intermediate	BID/TID
Hydrocortisone valerate	Cream, oint 0.2%	Intermediate	BID/TID
Mometasone furoate	Elocon cream, oint, lotion, sol 0.1%	Intermediate	qd
Prednicarbate	Dermatop cream, oint 0.1%	Intermediate	BID
Triamcinolone			
Triamcinolone acetonide 0.025%	Cream, oint, lotion 0.025%	Low	TID/QID
Triamcinolone acetonide 0.1%	Cream, oint, lotion 0.1% **Kenalog Aerosol** 0.147 mg/g	Intermediate	TID/QID
Triamcinolone acetonide 0.5%	Cream, oint 0.5%	High	TID/QID

Based on data in and modified from Gomella LG, Haist S, Adams A, eds. *Clinicians' Pocket Drug Reference, 2015 Edition*. New York, NY: McGraw-Hill.

SE: Skin atrophy w/ chronic use; chronic administration or application over large area may cause adrenal suppression or hyperglycemia.

STREPTOMYCIN (GENERIC)

WARNING: Neuro/oto/renal toxicity possible; neuromuscular blockage w/ respiratory paralysis possible.
USES: *TB combo therapy, nontuberculous infections (eg, Pasteurella pestis [plague], Francisella tularensis [tularemia], others, see package insert).
ACTIONS: Aminoglycoside; ↓ protein synthesis.

DOSE:

Adults: *TB:* 15 mg/kg/d (up to 1 g), directly observed therapy (DOT) 2× wk 20–30 mg/kg/dose (max. 1.5 g), DOT 3 × wk 25–30 mg/kg/dose (max. 1 g).

Peds: 15 mg/kg/d; DOT 2 × wk 20–40 mg/kg/dose (max. 1 g); DOT 3 × wk 25–30 mg/kg/dose (max. 1 g);↓ w/ renal insufficiency, either IM or IV over 30–60 min.
W/P: [D, +]. CI: Pregnancy.
DISP: Injectable 400 mg/mL (1-g vial).
SE: ↑ Incidence of vestibular and auditory toxicity, ↑ neurotoxicity risk in patients w/ impaired renal function.
NOTES: Monitor levels: *Peak:* 20–30 μg/mL, *Trough:* <5 μg/mL; *Toxic peak:* >50, *Trough:* >10; IV over 30–60 min.

STRONTIUM-89 CHLORIDE (METASTRON)

USES: Bone pain in patients with osseous metastasis.
ACTIONS: Ca^{2+} analogue taken up by bone in areas of active osteogenesis with selective radiation of metastasis.
DOSE: 148 MBq (4 mCi) IV slowly, or 15–22 MBq/kg.
W/P: [D, −].
CI: Pregnancy.
DISP: Injectable.
SE: Platelets nadir about 12–16 wk after treatment.
NOTES: Administered by radiation oncology; caution with platelet counts <60,000 or WBC of <2,400.

SUCROFERRIC OXYHYDROXIDE (VELPHORO)

USES: *↓ phos in ESRD/CKD.*
ACTIONS: Binds phosphate.

DOSE:

Adults: Chew 500 mg TID w/ meals; may ↑ dose weekly to target phos <5.5 mg/dL; max. dose studied 3,000 mg/d.
W/P: [B, +] check Fe^{+2} w/ peritonitis during peritoneal dialysis, hepatic or GI disorders, post-GI surgery or Dz resulting in Fe^{+2} accumulation.
CI: None.
DISP: Tab 500 mg.
SE: D, discolored feces.
NOTES: DO NOT prescribe with levothyroxine or vit D; take alendronate or doxycycline 1 hr before.

SUNITINIB (SUTENT)

WARNING: Hepatotox that may be severe and/or result in fatal liver failure.
USES: *Advanced GI stromal tumor (GIST) refractory/intolerant of imatinib; advanced RCC; well-differentiated pancreatic neuroendocrine tumors unresectable, locally advanced, metastatic.*
ACTIONS: Tyrosine kinase inhibitor; VEGF inhibitor.

DOSE:

Adults: 50 mg PO daily × 4 wk, followed by 2 wk holiday = 1 cycle; ↓ to 37.5 mg w/ CYP3A4 inhibitor, to ↑ 87.5 mg or 62.5 mg/d w/ CYP3A4 inducers.
CI: None.
W/P: [D, −] Multiple interactions require dose modification (eg, St. John's wort); TEN and SJS reported.
DISP: Caps 12.5, 25, 50 mg.
SE: ↓ WBC & plt, bleeding, ↑ BP, ↓ ejection fraction, ↑ QT interval, pancreatitis, DVT, seizures, adrenal insufficiency, N/V/diarrhea, skin discoloration, oral ulcers, taste perversion, hypothyroidism.
NOTES: Monitor left ventricular ejection fraction, ECG, CBC/plts, chemistries (K^+/Mg^{2+}/phosphate), TFT & LFTs periodically; ↓ dose in 12.5-mg increments if not tolerated.

TACROLIMUS, EXTENDED RELEASE (ASTAGRAF XL)

WARNING: Only physicians experienced in immunosuppression should prescribe. ↑ Risk of malignancy; use in liver transplant not rec due to ↑mortality in female patients.
USES: *Px kidney transplant rejection w/ MMF and steroids, w/ or w/o basiliximab induction.*
ACTIONS: Calcineurin inhib/immunosuppressant.
DOSE: w/ basiliximab induct: 0.15 mg/kg/d (target level day 1–60: 5–17 ng/mL; Mo 3–12: 4–12 ng/mL w/o induct: Preop 0.1 mg/kg/d; postop 0.2 mg/kg/d (target level: Day 1–60: 6–20 ng/mL; Mo 3–12: 6–14 ng/mL; take daily q a.m; empty stomach; do not take w/ alcohol or grapefruit juice; take whole.
W/P: [C, −] not interchangeable w/ immediate release; follow glucose, Cr, K^+, can ↑ BP, can ↑ QT interval; do not use w/ sirolimus, CYP3A inhib/inducers; avoid live vaccines, monitor for red cell aplasia w/ Cyclosporine; avoid topical if <2 yr; Neuro & nephrotox, ↑ risk opportunistic Infxns; avoid grapefruit juice.
CI: Component allergy, castor oil allergy w/ IV form.
Disp: ER Caps 0.5, 1, 5 mg.
SE: N, D, constipation, edema, tremor, anemia.
NOTES: Monitor levels; African Americans may need ↑ dose; see tacrolimus immediate release.

TACROLIMUS, IMMEDIATE RELEASE (PROGRAF, GENERIC)

WARNING: ↑ Risk of infection and lymphoma. Only physicians experienced in immunosuppression should prescribe.
USES: *Prevent organ rejection (kidney/liver/heart).*
ACTIONS: Calcineurin inhibitor/immunosuppressant.

DOSE:

Adults: IV: 0.03–0.05 mg/kg/d in kidney and liver, 0.01 mg/kg/d in heart IV Inf.
Peds: IV: 0.03–0.05 mg/kg/d as cont Inf. *PO:* 0.15–0.2 mg/kg/d PO ÷ q12h.
Adults & Peds: *Eczema:* Take on empty stomach; ↓ w/ hepatic/renal impairment.
W/P: [C, −] w/ Cyclosporine; avoid topical if <2 yr; Neuro & nephrotoxic, ↑ risk

opportunistic infections; avoid grapefruit juice.
CI: Component allergy, castor oil allergy w/ IV form.
DISP: Caps 0.5, 1, 5 mg; Inj 5 mg/mL.
SE: HTN, edema, headache, insomnia, fever, pruritus, ↑/↓ K^+, hyperglycemia, GI upset, anemia, leukocytosis, tremors, paresthesias, pleural effusion, seizures, lymphoma, PRES, BK nephropathy, PML.
NOTES: Monitor levels; *Trough:* 5–12 ng/mL based on indication and time since transplant.

TADALAFIL (CIALIS)

USES: *Erectile dysfunction, BPH, alone or together.*
ACTIONS: PDE5 inhibitor, ↑ cyclic guanosine monophosphate (cGMP) & NO levels; relaxes smooth muscles, dilates cavernosal arteries; 15–120 min, duration 24–36 hr.

DOSE:

Adults: *PRN:* 10 mg PO before sexual activity (5–20 mg max. based on response) 1 dose/24 h. *Daily dosing:* 2.5 mg qd, may ↑ to 5 mg qd, *BPH*; 5 mg PO qd; w/o regard to meals; BPH therapy initiated with tadalafil and finasteride, tadalafil dose is 5 mg/d for up to 26 wk; ↓ w/ renal/hepatic insufficiency; 5 mg not more than once in every 72 hr w/ CrCl <30 mL/min/ESRD on dialysis.
W/P: [B, −] w/ α-Blockers (except tamsulosin); use w/ CYP3A4 inhibitor 2.5 mg/daily dose or 5 mg PRN dose; CrCl <0 mL/min, hemodialysis/severe hepatic impairment, do not use daily dosing.
CI: Nitrates.
DISP: Tabs 2.5, 5, 10, 20 mg.
SE: Headache, flushing, dyspepsia, back/limb pain, myalgia, nasal congestion, urticaria, SJS, dermatitis, visual field defect, nonarteritic anterior ischemic optic neuropathy (NIAON), sudden ↓/loss of hearing, tinnitus.
NOTES: Longest acting of class (36 hr); daily dosing may ↑ drug interactions; excessive EtOH may ↑ orthostasis; transient global amnesia reports; not recommended in combo with α-blocker for BPH.

TAMSULOSIN (FLOMAX, GENERIC)

USES: *BPH,* medical expulsive therapy for ureteral stones.
ACTIONS: Antagonist of prostatic α_1-receptors.

DOSE: 0.4 mg/d, may ↑ to 0.8 mg PO daily.
W/P: [B, ?] Floppy iris syndrome w/ cataract surgery.
DISP: Caps 0.4 mg.
SE: Headache, dizziness, syncope, somnolence, ↓ libido, GI upset, retrograde ejaculation, rhinitis, rash, angioedema, intraoperative floppy iris syndrome.
NOTES: Not for use as antihypertensive; do not open/crush/chew; approved for use w/ dutasteride for BPH; also available a combination (Jalyn); for patients with a ureteral stone <10 mm and well-controlled symptoms, a period of observation along with medical expulsive therapy should be considered with α_1-blockers, the preferred agent.

TEMSIROLIMUS (TORISEL)

USES: *Advanced RCC.*
ACTIONS: Multikinase inhibitor, ↓mTOR (mammalian target of rapamycin), ↓ hypoxic-induced factors, ↓ VEGF.
DOSE: 25 mg IV 30–60 min 1×/wk. Hold w/ ANC <1,000 cells/μL, plt <75,000 cells/μL, or NCI grade 3 tox. Resume when tox grade 2 or less, restart w/ dose ↓ 5 mg/wk not <15 mg/wk. w/ CYP3A4 inhibitor: ↓ 12.5 mg/wk. w/ CYP3A4 inducers ↑ 50 mg/wk.
W/P: [D, −] Avoid live vaccines, ↓ wound healing, avoid periop.
CI: Bili >1.5 × ULN.
DISP: Inj 25 mg/mL w/ 250 mL diluent.
SE: Rash, asthenia, mucositis, N, bowel perforation, angioedema, impaired wound healing; interstitial lung disease anorexia, edema, ↑ lipids, ↑ glucose, ↑ triglycerides, ↑ LFTs, ↑ Cr, ↓ WBC, ↓ HCT, ↓ plt, ↓ PO^4.
NOTES: Premedicate w/ antihistamine; check lipids, CBC, plt, Cr, glucose; w/ sunitinib dose-limiting tox likely; females use w/ contraception.

TERAZOSIN (HYTRIN, GENERIC)

USES: *BPH, HTN.*
ACTIONS: α_1-Blocker (blood vessel & bladder neck/prostate).
DOSE: Initial, 1 mg PO hs; ↑ 20 mg/d max.; may ↓ w/ diuretic or other BP medicine.
W/P: [C, ?] w/ β-Blocker, calcium channel blocker, ACE inhibitor; use w/ phosphodiesterase-5 (PDE5) inhibitor (eg, sildenafil) can cause ↓ BP, intra-op floppy iris syndrome w/ cataract surgery.
CI: Component sensitivity.
DISP: Tabs 1, 2, 5, 10 mg; caps 1, 2, 5, 10 mg angina.
SE: Angina, ↓ BP, & syncope following 1st dose or w/ PDE5 inhibitor; dizziness, weakness, nasal congestion, peripheral edema, palpitations, GI upset.
NOTES: Caution w/ 1st dose syncope; if for HTN, combine w/ thiazide diuretic.

TERBINAFINE (LAMISIL, LAMISIL AT, GENERIC [OTC])

USES: *Onychomycosis, athlete's foot, jock itch, ringworm*, cutaneous candidiasis, pityriasis versicolor.
ACTIONS: ↓ Squalene epoxidase resulting in fungal death.
DOSE: *PO:* 250 mg/d PO for 6–12 wk. *Topical:* Apply to area tinea pedis BID, tinea cruris & corporis daily–BID, tinea versicolor soln BID; ↓ PO in renal/hepatic impairment.
W/P: [B, −] PO ↑ effects of drug metabolism by CYP2D6, w/ liver/renal impairment.
CI: CrCl <50 mL/min, WBC <1,000/mm^3, severe liver disease.
DISP: Tabs 250 mg; oral granules 125 mg/pkt, 187.5 mg/ pkt *Lamisil AT* [OTC] cream, gel, soln 1%.
SE: Headache, DIV/N dizziness, rash, pruritus, alopecia, GI upset, taste perversion, neutropenia, retinal damage, SJS, ↑ LFTs.
NOTES: Effect may take months d/t need for new nail growth; topical not for nails; do not use occlusive dressings; PO follow CBC/LFTs.

TERCONAZOLE (TERAZOL 3, TERAZOL 7, GENERIC)

USES: *Vag fungal infections.*
ACTIONS: Topical triazole antifungal.
DOSE: 1 applicator-full or 1 supp intravag hs × 3–7 days.
W/P: [C, ?].
CI: Component allergy.
DISP: Vag cream (Terszol 7) 0.4, (Terszol 3), 0.8%, (Terszol 3) Vag supp 80 mg.
SE: Vulvar/Vag burning.
NOTES: Insert high into vagina.

TERIPARATIDE (FORTEO)

WARNING: ↑ Osteosarcoma risk in animals, therefore only use in patients for whom the potential benefits outweigh risks.
USES: *Severe/refractory osteoporosis.*
ACTIONS: PTH (recombinant).
DOSE: 20 µg SQ daily in thigh or abdomen.
W/P: [C, ?/−].
CI: w/ Paget disease, prior radiation, bone metastases, hypercalcemia, caution in urolithiasis.
DISP: 3-mL prefilled device (discard after 28 days).
SE: Orthostatic ↓ BP on administration, N/diarrhea, hypercalcemia; leg cramps.
NOTES: 2 yr max. use; osteosarcoma in animals.

TESTOSTERONE, IMPLANT (TESTOPEL) [C-III]

USES: *Male hypogonadism (congenital/acquired).*
ACTIONS: Testosterone replacement.
DOSE: 150–450 mg (2–6 pellets) SQ implant q3–6mo (implant two 75-mg pellets for each 25 mg testosterone required weekly; eg, for 75 mg/wk, implant 450 mg or 6 pellets.
W/P: [X, −] May cause polycythemia, worsening of BPH Sx, prostate cancer, edema may worsen CHF; may ↓ blood glucose and insulin requirements; venous thrombosis risk.
CI: PCa, male breast CA, PRG women.
DISP: 75 mg/implant (3.2 mm × 9 mm).
SE: Pain/inflammation at site, gynecomastia, excessive erections, oligospermia, hirsutism, male pattern baldness, acne, retention of sodium and electrolytes, suppression of clotting factors, polycythemia, N, jaundice, ↑ LFT/cholesterol, polycythemia, rare hepatocellular neoplasms and peliosis hepatitis, ↑/↓ libido, sleep apnea, ↑ PSA.
NOTES: Check levels and adjust PRN (300–1,000 ng/dL testosterone range); follow periodic LFT and CBC; typical site upper outer posterior gluteal region using sterile technique, local anesthesia, 4 mm stab wound and provided 16G insertion trocar.

TESTOSTERONE, NASAL GEL (NATESTO) [C-III]

WARNING: Virilization reported in children exposed to topical testosterone products. Children to avoid contact w/ unwashed or unclothed application sites.
USES: *Adult male hypogonadism (congenital/ acquired).*

ACTIONS: Testosterone replacement.
DOSE: 2 pumps each nostril (11 mg testosterone) in each nostril TID (total 33 mg/day); blow nose before use; avoid blowing for 1 hr after.
W/P: [X, −] Avoid with nasal pathology; monitor BPH Sx and for DVT; may cause azoospermia, edema, sleep apnea; not rec if <18 yr; venous thrombosis risk.
CI: Prostate cancer, male breast cancer, women.
DISP: metered-dose pump; 1 pump = 5.5 mg of testosterone.
SE: ↑ PSA, headache, rhinorrhea, epistaxis, nasal discomfort, nasopharyngitis, bronchitis, URI, sinusitis, nasal scab. 1 pump = 5.5 mg of testosterone.
NOTES: Previously known as *CompleoTRT*; may minimize exposure of testosterone to women or children; check testosterone, PSA, Hgb, LFTs, and lipids periodically.

TESTOSTERONE, TOPICAL (ANDROGEL 1%, ANDROGEL 1.62% ANDRODERM, AXIRON, FORTESTA, STRIANT, TESTIM, VOGELXO) [C-III]

WARNING: Virilization reported in children exposed to topical testosterone products. Children to avoid contact w/ unwashed or unclothed application sites.
USES: *Male hypogonadism (congenital/acquired).*
ACTIONS: Testosterone replacement; ↑ lean body mass, libido.
DOSE: All daily applications: *AndroGel 1%:* 50 mg (4 pumps); *AndroGel 1.62%:* 40.5 mg (2 pumps); apply to clean skin on upper body only. *Androderm:* Two 2.5-mg or one 5-mg patch daily. *Axiron:* 60 mg (1 pump = 30 mg each axilla) q a.m. *Fortesta:* 40 mg (4 pumps) on clean, dry thighs; adjust form 1–7 pumps based on blood test 2 hr after (days 14 and 35). *Striant:* 30-mg buccal tabs BID. *Testim:* One 5-g gel tube. *Vogelxo:* 50 mg (1 tube or packet or 4 pump actuations) daily at same time.
W/P: [X, −] May cause polycythemia, worsening of BPH Sx.
CI: PCa, male breast CA, women, venous thrombosis risk.
DISP: *AndroGel 1%: 12.5 mg/pump; AndroGel 1.62%: 20.25 mg/pump; Androderm:* 2.5-, 5-mg patches; *Axiron:* Metered-dose pump 30 mg/pump; *Fortesta:* Metered-dose gel pump 10 mg/pump*; Striant:* 30-mg buccal tab; *Vogelxo*:50 mg tube or packet, 12.5 mg/pump.
SE: Site reactions, acne, edema, Wt gain, gynecomastia, HTN, ↑ sleep apnea, prostate enlargement, ↑ PSA.
NOTES: PO agents (*methyltestosterone & oxandrolone*) associated w/ hepatic tumors; transdermal/mucosal/implant forms preferred; wash hands immediately after topical applications *AndroGel* forms not equivalent; check T levels and adjust PRN (300–1,000 ng/dL testosterone range).

TESTOSTERONE UNDECANOATE, INJECTABLE (AVEED)

WARNING: Pulmonary oil microembolism (POME) reactions (urge to cough, dyspnea, throat tightening, chest pain, dizziness, syncope) and episodes of anaphylaxis, including life-threatening reactions, have been reported after the administration; observe patients for 30 min after dosing.
USES: *Male hypogonadism (congenital/acquired).*
ACTIONS: Testosterone replacement; ↑ lean body mass, libido.

DOSE: 3 mL (750 mg) IM (gluteal) initially, at 4 wk, every 10 wk thereafter; observe for 30 min for POME or anaphylaxis.
W/P: [X, −] May worsen BPH Sx, azoospermia possible, edema with pre-existing cardiac/renal/hepatic Dz, sleep apnea with other risk factors, monitor PSA, hgb/Hct, lipids periodically; may reduce insulin requirements, monitor INR if on warfarin; w/ steroids may ↑ fluid retention; venous thrombosis risk.
CI: PCa, male breast cancer, women, component sensitivity.
DISP: 3-mL (750 mg) in castor oil and benzyl benzoate.
SE: Acne, injection site pain, ↑ PSA and estradiol, hypogonadism, fatigue, irritability, ↑ hemoglobin, insomnia, mood swings.
NOTES: Available only through a restricted program (Aveed REMS); other IM forms not commonly used; testosterone enanthate (*Delatestryl; Generic)* & testosterone cypionate (*Depo-Testosterone*) dosed q14–28d w/ variable serum levels.

TETRACYCLINE (GENERIC)

USES: *Broad-spectrum antibiotic.*
ACTIONS: Bacteriostatic; ↓ protein synth. *Spectrum:* gram(+): *Staphylococcus, Streptococcus.* gram(−): *H. pylori.* Atypicals: *Chlamydia, Rickettsia,* & *Mycoplasma.*

DOSE:

Adults: 250–500 mg PO BID–QID.
Peds: >***8 yr:*** 25–50 mg/kg/24 h PO q6–12h; ↓ w/ renal/hepatic impairment, w/o food preferred.
W/P: [D, −].
CI: PREGNANCY, children <8 yr.
DISP: Caps 100, 250, 500 mg; tabs 250, 500 mg; PO susp 250 mg/5 mL.
SE: Photosensitivity, GI upset, renal failure, pseudotumor cerebri, hepatic impairment.
NOTES: Can stain tooth enamel & depress bone formation in children; do not administer w/ antacids or milk products.

TICAGRELOR (BRILINTA)

WARNING: ↑ Bleeding risk; can be fatal; daily aspirin >100 mg may ↓ effectiveness; do not start w/ active bleeding, Hx intracranial bleed, planned CABG; if hypotensive and recent procedure, suspect bleeding; manage any bleed w/o D/C of ticagrelor.
USES: *↓ CV death and heart attack in ACS.*
ACTIONS: Oral antiplatelet; reversibly binding ADP receptor antagonist inhibitor.
DOSE: Initial 180 mg PO w/ ASA 325 mg, then 90 mg BID w/ ASA 75–100 mg/d.
W/P: [C, −] w/ Mod hepatic impairment; w/ strong CYP3A inhibitor or CYP3A inducers.
CI: Hx intracranial bleed, active pathologic bleeding, severe hepatic impairment.
DISP: Tabs 90 mg.
SE: Bleeding, SOB.
NOTES: REMS; D/C 5 days preop.

TICARCILLIN/POTASSIUM CLAVULANATE (TIMENTIN)

USES: *Infections of the skin, bone, resp & urinary tract, abdominal, sepsis.*
ACTIONS: Carboxy-PCN; bactericidal; ↓ cell wall synth; clavulanic acid blocks β-lactamase.
Spectrum: Good gram(+), not MRSA; good gram(−) & anaerobes.

DOSE:

Adults: 3.1 g IV q4–6h max. 24 g ticarcillin component/d.
Peds: ***Ä 60 kg:*** (if ≥60 kg, adult dose). 200–300 mg/kg/d IV ÷ q4–6h; ↓ in renal failure.
W/P: [B, +/−] PCN sensitivity.
DISP: Inj ticarcillin/clavulanate acid 3.1/0.1-g vial.
SE: Hemolytic anemia, false(+) proteinuria.
NOTES: Often used in combo w/ aminoglycosides; penetrates CNS w/ meningeal irritation.

TINIDAZOLE (TINDAMAX)

WARNING: Carcinogenicity has been seen in mice and rats treated chronically with metronidazole, another nitroimidazole agent.
USES: *Trichomoniasis, giardiasis and amebiasis: in patients aged 3 and older; bacterial vaginosis: in nonpregnant adult.*
ACTIONS: Nitroimidazole antimicrobial.

DOSE:

Adults: *Trichomoniasis, Giardiasis:* 2 g PO w/ food × 1. For trichomoniasis treat sexual partners; *Bacterial vaginosis*: Nonpregnant, adult women: 2 g daily for 2 days w/ food, or 1 g once daily for 5 days w/ food.
Peds: ***>3 yr:*** *Giardiasis*: 50 mg/kg (up to 2 g) × 1 w/ food; Amebiasis 50 mg/kg/d (up to 2 g per day) × 3 days w/ food; Amebic liver abscess same up to 5 days.
W/P: [C, OK 3 days after D/C] Seizures/nephropathy reported; vaginal candidiasis.
CI: Component allergy; 1st tri pregnancy, breast-feeding.
DISP: Tabs 250, 500 mg.
SE: Met allic/bitter taste, nausea, anorexia dyspepsia, weakness/fatigue, headache, dizziness.

TIOCONAZOLE (GENERIC [OTC])

USES: *Vaginal fungal infections.*
ACTIONS: Topical antifungal.
DOSE: 1 applicator-full intravag hs (single dose).
W/P: [C, ?].
CI: Component allergy.
DISP: Vag oint 6.5%.
SE: Local burning, itching, soreness, polyuria.
NOTES: Insert high into vagina; may damage condom or diaphragm.

TIOPRONIN (THIOLA)

USES: *Prevent cystine urolithiasis in patients with severe homozygous cystinuria with

urinary cystine >500 mg/d, who are resistant to conservative measures (high fluid intake, alkali and diet modification), or have adverse reactions to D-penicillamine.*
ACTIONS: Combines with cystine to increase solubility (α-mercaptopropionylglycine).

DOSE:
Adults & Peds: ***>9 yr:*** Encourage conservative hydration therapy with 3 L fluid/d (>2 L urine output) before initiating therapy. 800 mg/d initially (peds 15/mg/kg/d) divided TID, 1 hr ac or 2 hr pc; titrate based on urinary cysteine levels; typical adult dose 1,000 mg/d.
W/P: [D, −].
CI: Pregnancy, prior history of agranulocytosis or thrombocytopenia on Thiola.
DISP: Tablets 100 mg.
SE: Fever, rash, arthralgia, lymphadenopathy, hypogeusia, wrinkling and friable skin.
NOTES: Maintain urine pH 6.5–7.0 (potassium alkali supplements over sodium alkali due to reduced hypercalciuria risks); check urinary cysteine after 1 mo and then every 3 mo to adjust dose. Better tolerated than D-penicillamine.

TOBRAMYCIN (NEBCIN)

USES: *Serious gram(−) infections.*
ACTIONS: Aminoglycoside; ↓ protein synth. *Spectrum:* gram(−) bacteria (including *Pseudomonas*).

DOSE:

Adults: Conventional dosing: 1–2.5 mg/kg/dose IV q8–12h. *Once-daily dosing:* 5–7 mg/kg/dose q24h.
Peds: 2.5 mg/kg/dose IV q8h; ↓ w/ renal insufficiency.
W/P: [D, −].
CI: PREGNANCY; aminoglycoside sensitivity.
DISP: Inj 10, 40 mg/mL.
SE: Nephro/ototox.
NOTES: Follow CrCl & levels. Levels: *Peak:* 30 min after Inf; *Trough:* <0.5 hr before next dose; *Therapeutic Conventional: Peak:* 5–10 μg/mL, *Trough:* <2 μg/mL.

TOLTERODINE (DETROL, DETROL LA, GENERIC)

USES: *Overactive bladder with symptoms of urge urinary incontinence, urgency, and frequency.*
ACTIONS: Anticholinergic; muscarinic receptor antagonist.
DOSE: *Detrol:* 1–2 mg PO BID; *Detrol LA:* 2–4 mg/d.
W/P: [C, −] w/ CYP2D6 & 3A3/4 inhibitor; w/ QT prolongation.
CI: Urinary retention, gastric retention, or uncontrolled narrow-angle glaucoma.
DISP: Tabs 1, 2 mg; *Detrol LA* tabs 2, 4 mg.
SE: Xerostomia, blurred vision, headache, constipation.
NOTES: LA form may see “intact” ghost pill in stool.

TRAMADOL (RYBIX ODT, RYZOLT ER, ULTRAM, ULTRAM ER, GENERIC)

(C-IV)
USES: *Mod–severe pain.*
ACTIONS: Centrally acting synthetic opioid analgesic.

DOSE:

Adults: 50–100 mg PO q4–6h PRN, start 25 mg PO q a.m., ↑ q3d to 25 mg PO QID; ↑ 50 mg q3d, 400 mg/d max. (300 mg if >75 yr); ER 100–300 mg PO daily; Rybix ODT individualize ↑ 50 mg/d q3d to 200 mg/d or 50 mg QID; after titration 50–100 mg q4–6 PRN, 400 mg/d max.
Peds: (ER form not rec) 1–2 mg/kg q4–6h (max. dose 100 mg); ↓ w/ renal insufficiency.
W/P: [C, −] Suicide risk in addiction prone, w/ tranquilizers or antidepressants; ↑ seizures risk w/ MAOI; serotonin syndrome.
CI: Opioid dependency; w/ MAOIs; sensitivity to opioids, acute alcohol intoxication, hypnotics, centrally acting analgesics, or w/ psychotropic drugs.
DISP: Tabs 50 mg; ER 100, 200, 300 mg; Rybix ODT 50 mg.
SE: Dizziness, headache, somnolence, GI upset, resp depression, anaphylaxis.
NOTES: ↓ Seizure threshold; tolerance/dependence may develop; abuse potential d/t μ-opioid agonist activity; Avoid EtOH; do not cut, chew ODT tabs.

TRAMADOL/ACETAMINOPHEN (ULTRACET) (C-IV)

USES: *Short-term Treat acute pain (<5 days).*
ACTIONS: Centrally acting opioid analgesic w/ acetaminophen.
DOSE: 2 tabs PO q4–6h PRN; 8 tabs/d max. *Elderly/renal impairment:* Lowest possible dose; 2 tabs q12h max. if CrCl <30 mL/min.
W/P: [C, −] Seizures, hepatic/renal impairment, suicide risk in addiction prone, w/ tranquilizers or antidepressants.
CI: Acute intoxication, w/ ethanol, hypnotics, central-acting analgesics or psychotropic drugs, hepatic dysfunction.
DISP: Tab 37.5 mg tramadol/325 mg acetaminophen.
SE: SSRIs, TCAs, opioids, MAOIs ↑ risk of seizures; dizziness, somnolence, tremor, headache, N/V/diarrhea, constipation, xerostomia, liver tox, rash, pruritus, ↑ sweating, physical dependence.
NOTES: Avoid EtOH; abuse potential μ-opioid agonist activity (tramadol); see acetaminophen note.

TRIAMCINOLONE/NYSTATIN (GENERIC)

USES: *Cutaneous candidiasis.*
ACTIONS: Antifungal & anti-inflammatory.
DOSE: Apply lightly to area BID; max. 25 mg/d.
W/P: [C, ?].
CI: Varicella; systemic fungal infections.
DISP: Cream & oint: Triamcinolone 1 mg/g and 100,000 U nystatin/g.
SE: Local irritation, hypertrichosis, pigmentation changes.
NOTES: For short-term use (<7 days). See also nystatin.

TRIAMTERENE (DYRENIUM)

WARNING: Hyperkalemia can occur.
USES: *Edema associated w/ CHF, cirrhosis.*
ACTIONS: K^+-sparing diuretic.

DOSE:

Adults: 100–300 mg/24 h PO ÷ daily–BID.
Peds: *HTN:* 2–4 mg/kg/d in 1–2 ÷ doses; ↓ w/ renal/hepatic impairment.
W/P: [C (Expert opinion), ?].
CI: ↑ K^+, renal impairment; caution w/ other K^+-sparing diuretics.
DISP: Caps 50, 100 mg.
SE: ↓ K^+, ↓ BP, bradycardia, cough, headache.
NOTES: Do not use in hypercalciuria due to triamterene stone risk.

TRIETHYLENETHIOPHOS-PHORAMIDE (THIOTEPA)

USES: *Breast, ovarian cancers, lymphomas (infrequently used) preparative regimens for allogeneic & ABMT w/ high doses, intravesical for bladder cancer, intracavitary effusion control.*
ACTIONS: Polyfunctional alkylating agent.
DOSE: Per protocol typical 0.3–0.4 mg/kg IV q1–4 wk. *Effusions:* Intracavitary 0.6–0.8 mg/kg; 60 mg into the bladder & retained 2 hr q1–4wk; 900–125 mg/m^2 in ABMT regimens (highest dose w/o ABMT is 180 mg/m^2); ↓ in renal failure.
W/P: [D, −] w/ BM suppression, renal and hepatic impairment.
CI: Component allergy.
DISP: Inj 15 mg/vial.
SE: ↓ BM, N/V, dizziness, headache, allergy, paresthesias, alopecia.
NOTES: Intravesical use in bladder cancer infrequent today; due to critical US shortage in 2013 TEPADINA, a European product, was allowed to be distributed in the US.

TRIMETHOPRIM (PRIMSOL, GENERIC)

USES: *UTI d/t susceptible gram(+) & gram(−) organisms; Treat PCP w/ dapsone* suppression of UTI.
ACTIONS: ↓ Dihydrofolate reductase. *Spectrum:* Many gram(+) & (–) except *Bacteroides, Branhamella, Brucella, Chlamydia, Clostridium, Mycobacterium, Mycoplasma, Nocardia, Neisseria, Pseudomonas,* & *Treponema.*

DOSE:

Adults: 100 mg PO BID or 200 mg PO daily; PCP 15 mg/kg ÷ in 3 days w/ dapsone.
Peds: ≥***2 mo:*** 4–6 mg/kg/d in 2 ÷ doses; otitis media (≥6 mo): 10 mg/kg/d in 2 ÷ doses × 10 days; For prophylaxis: 2 mg/kg/day.
W/P: [C, +]. ↓ w/ renal failure.
CI: Megaloblastic anemia d/t folate deficiency.
DISP: Tabs 100 mg; (*Primsol*) PO soln 50 mg/5 mL.

SE: Rash, pruritus, megaloblastic anemia, hepatic impairment, blood dyscrasias.
NOTES: Take w/ plenty of H_2O.

TRIMETHOPRIM (TMP)/SULFAMETHOXAZOLE (SMX) [CO-TRIMOXAZOLE, TMP-SMX] (BACTRIM, BACTRIM DS, SEPTRA DS, GENERIC)

USES: *UTI Treat & prophylaxis, otitis media, sinusitis, bronchitis, prevent PCP pneumonia (w/ CD4 count <200 cells/mm^3).*
ACTIONS: SMX ↓ synth of dihydrofolic acid, TMP ↓ dihydrofolate reductase to impair protein synth. *Spectrum:* Includes *Shigella,* PCP, & *Nocardia* infections, *Mycoplasma, Enterobacter* sp, *Staphylococcus, Streptococcus,* & more.
DOSE: All doses based on TMP.
Adults: 1 DS tab PO BID or 8–20 mg/kg/24 h IV in 1–2 ÷ doses. *PCP:* 15–20 mg/kg/d IV or PO (TMP) in 4 ÷ doses. *Nocardia:* 10–15 mg/kg/d IV or PO (TMP) in 4 ÷ doses. PCP prophylaxis: 1 reg tab daily or DS tab 3 × wk. *UTI prophylaxis:* 1 PO BID.
Peds: 8–10 mg/kg/24 h PO ÷ in 2 doses or 3–4 doses IV; do not use in <2 mo.
W/P: [C (D if near term), -]. ↓ in renal failure; maintain hydration.
CI: Sulfonamide sensitivity, porphyria, megaloblastic anemia w/ folate deficiency, PRF, breast-feeding Inf <2 mo, sig hepatic impairment.
DISP: Regular tabs 80 mg TMP/400 mg SMX; DS tabs 160 mg TMP/800 mg SMX; PO susp 40 mg TMP/200 mg SMX/5 mL; Inj 80 mg TMP/400 mg SMX/5 mL.
SE: Allergic skin reactions, photosensitivity, GI upset, SJS, blood dyscrasias, hep.
NOTES: Synergistic combo, interacts w/ warfarin.

TRIPTORELIN (TRELSTAR 3.75, TRELSTAR 11.25, TRELSTAR 22.5)

USES: *Advanced prostate cancer.*
ACTIONS: LHRH analog; ↓ GNRH w/ cont dosing; transient ↑ in LH, FSH, testosterone, & estradiol 7–10 days after 1st dose; w/ chronic use (usually 2–4 wk), sustained ↓ LH & FSH w/ ↓ testicular & ovarian steroidogenesis similar to surgical castration.
DOSE: 3.75 mg IM q4wk; or 11.25 mg IM q12wk or 22.5 mg q24wk.
W/P: [X, N/A].
CI: Pregnancy, component hypersensitivity.
DISP: Inj Depot 3.75 mg; 11.25 mg; 22.5 mg.
SE: Dizziness, emotional lability, fatigue, headache, insomnia, HTN, diarrhea, vomiting, erectile dysfunction, retention, UTI, pruritus, anemia, Inj site pain, musculoskelet al pain, osteoporosis, allergic reactions.
NOTES: Check periodic testosterone levels & PSA.

TROSPIUM (SANCTURA, SANCTURA XR, GENERIC)

USES: *OAB w/ Sx of urge incontinence, urgency, frequency.*
ACTIONS: Muscarinic antagonist, ↓ bladder smooth muscle tone.
DOSE: 20 mg tab PO BID; 60 mg ER caps PO daily a.m., 1 hr ac or on empty stomach. ↓ w/ CrCl <30 mL/min and elderly.
W/P: [C, +/−] w/ EtOH use, in hot environments, ulcerative colitis, myasthenia gravis,

renal/hepatic impairment.
CI: Urinary/gastric retention, narrow-angle glaucoma.
DISP: Tab 20 mg; caps ER 60 mg.
SE: Dry mouth, constipation, headache, rash.

VALACYCLOVIR (VALTREX, GENERIC)

USES: *Herpes zoster; genital herpes; herpes labialis.*
ACTIONS: Prodrug of acyclovir; ↓ viral DNA replication. *Spectrum:* Herpes simplex I & II.
DOSE: *Zoster:* 1 g PO TID × 7 days. *Genital herpes (initial episode):* 1 g BID × 7–10 days, *(recurrent)* 500 mg PO BID × 3 days. *Herpes prophylaxis:* 500–1,000 mg/d. *Herpes labialis:* 2 g PO q12h × 1 day ↓ w/ renal failure.
W/P: [B, +] ↑ CNS effects in elderly.
DISP: Caplets 500, 1,000 mg; tab 500, 1,000 mg.
SE: Headache, GI upset, ↑ LFTs, dizziness, pruritus, photophobia.

VALRUBICIN (VALSTAR)

USES: *Intravesical therapy of BCG-refractory bladder CIS in patients for whom immediate cystectomy would be associated with unacceptable morbidity or mortality.*
ACTIONS: An anthracycline; alkylating agent.
DOSE: 800 mg intravesically 1 × wk for 6 wk (4 vials diluted in 55 mL NS, total volume of 75 mL).
W/P: [C, -] do not administer with perforated bladder.
CI: Hypersensitivity to anthracyclines or polyoxyl castor oil, UTI, bladder capacity <75 mL.
DISP: 5 mL single-use vials (200 mg/5mL).
SE: Frequency, dysuria, urgency, spasm, hematuria, pain, incontinence.
NOTES: monitor closely for disease recurrence or progression; if there is not a complete response of CIS to treatment after 3 mo or if CIS recurs, cystectomy must be reconsidered. Procedures for proper handling and disposal of anticancer drugs should be used. Spills should be cleaned up with undiluted chlorine bleach.

VANCOMYCIN (VANCOCIN, GENERIC)

USES: *Serious MRSA infections; enterococcal infections; PO Treat of *S. aureus* and *C. difficile* pseudomembranous colitis.*
ACTIONS: ↓ Cell wall synth. *Spectrum:* gram(+) bacteria & some anaerobes (includes MRSA, *Staphylococcus*, *Enterococcus*, *Streptococcus* sp, *C. difficile*).

DOSE:

Adults: 15–20 mg/kg IV q8–48h based on CrCl, 15–20 mg/kg/dose; *C. difficile:* 125–500 mg PO q6h × 7 days.
Peds: 40–60 mg/kg/d IV in ÷ doses q6–12 h; *C. difficile:* 40 mg/kg/d PO in ÷ 3–4 doses × 7–10 days.
W/P: [B oral + C Inj, -].
CI: Component allergy; avoid in Hx hearing loss.

DISP: Caps 125, 250 mg; powder for Inj.
SE: Oto/nephrotoxic, GI upset (PO).
NOTES: Not absorbed PO, effect in gut only; give IV slowly (over 1–3 hr) to prevent "red-man syndrome" (flushing of head/neck/upper torso); IV product used PO for colitis. *Levels: Trough:* <0.5 hr before next dose; *Therapeutic: Trough:* 10–20 μg/mL; *Trough:* 15–20 μg/mL. *Half-life:* 6–8 hr; peak monitoring is not rec (toxic >80 μg/mL).

VARDENAFIL (LEVITRA, STAXYN, GENERIC)

USES: *Erectile dysfunction.*
ACTIONS: PDE5 inhibitor, increases cGMP and NO levels; relaxes smooth muscles, dilates cavernosal arteries; onset 15–60 min, duration 2–8 hr.
DOSE: *Levitra* 10 mg PO 60 min before sexual activity; titrate; max. × 1 = 20 mg; 2.5 mg w/ CYP3A4 inhibitor; *Staxyn* 1 (10 mg ODT) 60 min before sex, max. 1×/d.
W/P: [B, −] w/ CV, hepatic, or renal disease or if sex activity not advisable; potentiate the hypotensive effects of nitrates, α-blockers, and antihypertensives.
CI: w/ Nitrates.
DISP: *Levitra* Tabs 2.5, 5, 10, 20 mg tabs; *Stayxn* 10 mg ODT (contains phenylalanine).
SE: ↑ QT interval ↓ BP, headache, dyspepsia, priapism, flushing, rhinitis, sinusitis, flu syndrome, sudden ↓/loss of hearing, tinnitus, NIAON.
NOTES: Do not use w/ type 1A or type 3 antiarrhythmics or w/ long QT syndrome; concomitant α-blockers may cause ↓ BP; transient global amnesia reports; place Staxyn on tongue to disintegrate w/o liquids; ODT not interchangeable to oral pill; gets higher levels.

VERAPAMIL (CALAN, COVERA HS, ISOPTIN, VERELAN, GENERIC)

USES: *Angina, HTN, PSVT, AF, atrial flutter*, migraine prophylaxis, hypertrophic cardiomyopathy, bipolar disease, Peyronie disease.
ACTIONS: Calcium channel blocker.

DOSE:

Adults: *Arrhythmias:* 2nd line for PSVT w/ narrow QRS complex & adequate BP 2.5–10 mg IV over 1–2 min; repeat 5–10 mg in 15–30 min PRN (30 mg max.). *Angina:* 80–120 mg PO TID, ↑ 480 mg/24 h max. *HTN:* 80–180 mg PO TID or SR tabs 120–240 mg PO daily to 240 mg BID.
Peds: ***<1 yr:*** 0.1–0.2 mg/kg IV over 2 min (may repeat in 30 min). ***1–16 yr:*** 0.1–0.3 mg/kg IV over 2 min (may repeat in 30 min); 5 mg max. *PO:* 3–4 mg/kg/d PO ÷ in 3 doses, max. 8 mg/kg/d up to 480 mg/d. ***>5 yr:*** 80 mg q6–8h; ↓ in renal/hepatic impairment.
W/P: [C, +] Amiodarone/β-blockers/flecainide can cause ↓ HR; statins, midazolam, tacrolimus, theophylline levels may be ↑; use w/ clonidine may cause severe ↓ HR w/ elderly pts.
CI: EF <30%, severe LV dysfunction, BP <90 mm Hg, SSS, 2nd-, 3rd-AV block AF/atrial flutter w/ bypass tract.
DISP: *Calan SR:* Caps 120, 180, 240 mg; *Verelan SR:* Caps 120, 180, 240, 360 mg; *Verelan PM*: Caps (ER) 100, 200, 300 mg; *Calan:* Tabs 80, 120 mg; *Isoptin SR* 24-hr 120, 180, 240 mg; Inj 2.5 mg/mL.
SE: Gingival hyperplasia, constipation, ↓ BP, bronchospasm, HR or conduction disturbances;

edema; ↓ BP and bradyarrhythmias taken w/ telithromycin.
NOTES: topical use reported in Peyronie disease.

VINBLASTINE (GENERIC)

WARNING: Chemotherapeutic agent; handle w/ caution; only individuals experienced in use of vinblastine should administer.
USES: *Hodgkin's disease, non-Hodgkin's malignant lymphomas, rhabdomyosarcoma, neuroblastoma, Wilms' tumor, acute leukemia.*
ACTIONS: ↓ Microtubule assembly.
DOSE: 0.1–0.5 mg/kg/wk (4–20 mg/m^2) (based on specific protocol); ↓ in hepatic failure.
W/P: [D, ?].
CI: Granulocytopenia, bacterial infection.
DISP: Inj 1 mg/mL in 10-mg vial.
SE: ↓ BM (especially leukopenia), N/V, constipation, neurotox, alopecia, rash, myalgia, tumor pain.
NOTES: Use can be fatal.

VINCRISTINE (MARQIBO, GENERIC)

WARNING: Chemotherapeutic agent; handle w/ caution; fatal if administered IT; IV only; administration by individuals experienced in use of vincristine only; severe w/ extrav.
USES: *ALL, breast & small-cell lung cancer, sarcoma (eg, Ewing tumor, rhabdomyosarcoma), Wilms tumor, Hodgkin disease & NHLs, neuroblastoma, multiple myeloma.*
ACTIONS: Promotes disassembly of mitotic spindle, causing metaphase arrest, vinca alkaloid.
DOSE: 0.4–1.4 mg/m^2 (single doses 2 mg/max.); ↓ in hepatic failure.
W/P: [D, −].
CI: Charcot–Marie–Tooth syndrome
DISP: Inj 1 mg/mL.
SE: Neurotox commonly dose limiting, jaw pain (trigeminal neuralgia), fever, fatigue, anorexia, constipation & paralytic ileus, bladder atony; no sig ↓ BM w/ standard doses; tissue necrosis w/ extrav; myelosuppression.

WARFARIN (COUMADIN, JANTOVEN, GENERIC)

WARNING: Can cause major/fatal bleeding. Monitor INR. Drugs, dietary changes, other factors affect INR. Instruct pts about bleeding risk.
USES: *Prophylaxis & Treat of PE & DVT, AF w/ embolization*, other postop indications.
ACTIONS: ↓ Vit K-dependent clotting factors in this order: VII-IX-X-II.

DOSE:

Adults: Titrate, INR 2.0–3.0 for most; mechanical valves INR is 2.5–3.5. *American College of Chest Physicians guidelines:* 5 mg initial, may use 7.5–10 mg; ↓ if pt elderly or w/ other bleeding risk factors; maint 2–10 mg/d PO, follow daily INR initial to adjust dosage.
Peds: 0.05–0.34 mg/kg/24 h PO or IV; follow PT/INR to adjust dosage; monitor vit K intake; ↓ w/ hepatic impairment/elderly.

W/P: [X, +].
CI: Bleeding, peptic ulcer, pregnancy.
DISP: Tabs 1, 2, 2.5, 3, 4, 5, 6, 7.5, 10 mg; Inj.
SE: Bleeding d/t over anticoagulation or injury & therapeutic INR; bleeding, alopecia, skin necrosis, purple toe syndrome.
NOTES: Monitor vit K intake (↓ effect); INR preferred test; to rapidly correct overanticoagulation: vit K, fresh-frozen plasma, or both. Caution pt on taking w/ other meds that can ↑ risk of bleed. *Common warfarin interactions: Potentiated by:* Acetaminophen, EtOH (w/ liver disease), amiodarone, cimetidine, ciprofloxacin, cotrimoxazole, erythromycin, fluconazole, flu vaccine, isoniazid, itraconazole, metronidazole, omeprazole, phenytoin, propranolol, quinidine, tetracycline. *Inhibited by:* Barbiturates, carbamazepine, chlordiazepoxide, cholestyramine, dicloxacillin, nafcillin, rifampin, sucralfate, high–vit K foods. Consider genotyping for VKORC1 & CYP2C9.

WITCH HAZEL (TUCKS PADS, OTHERS [OTC])

USES: After bowel movement, cleansing to decrease local irritation or relieve hemorrhoids; after anorectal surgery, episiotomy, Vag hygiene.
ACTIONS: Astringent; shrinks blood vessels locally.
DOSE: Apply PRN.
W/P: [?, ?] External use only.
CI: None.
SUPPLIED: Presoaked pads.
SE: Mild itching or burning.

ZOLEDRONIC ACID (RECLAST, ZOMETA, GENERIC)

USES: *Hypercalcemia of malignancy (HCM), ↓ skelet al-related events in community-acquired pneumonia, multiple myeloma, & metastatic bone lesions (*Zometa*)*; *prevent/Treat of postmenopausal osteoporosis, Paget disease, ↑ bone mass in men w/ osteoporosis, steroid-induced osteoporosis (*Reclast*).*
ACTIONS: Bisphosphonate; ↓ osteoclastic bone resorption.
DOSE: *Zometa HCM:* 4 mg IV over ≥15 min; may retreat in 7 days w/ adequate renal function. *Zometa bone lesions/myeloma:* 4 mg IV over >15 min, repeat q3–4wk PRN; extend w/ ↑ Cr. *Reclast Treat osteoporosis:* 5 mg IV annually. *Reclast:* Prevent postmenopausal osteoporosis 5 mg IV q2y. *Paget:* 5 mg IV × 1.
W/P: [D, ?/−] w/ Diuretics, aminoglycosides; ASA-sensitive asthmatics; avoid invasive dental procedures.
CI: Bisphosphonate allergy; hypocalcemia, angioedema, CrCl <35.
DISP: Vial 4 mg, 5 mg.
SE: Fever, flu-like syndrome, GI upset, insomnia, anemia; electrolyte abnormalities, bone, joint and muscle pain, AF, ONJ, atyp femur Fx.
NOTES: Requires vigorous prehydration; do not exceed rec doses/Inf duration to ↓ renal dysfunction; follow Cr; effect prolonged w/ Cr ↑; avoid oral surgery; dental exam recommended prior to Treat; ↓ dose w/ renal dysfunction; give Ca^{2+} and vit D supls; may ↑

atypical subtrochanteric femur fractures.

Cytochrome P-450 enzymes and common medication interactions

CYP1A2
Substrates: Acetaminophen, caffeine, cyclobenzaprine, clozapine, imipramine, mexiletine, naproxen, propranolol, theophylline
Inhibitors: Amiodarone, cimetidine, most fluoroquinolone antibiotics, fluvoxamine, verapamil
Inducers: Carbamazepine, charcoal-broiled foods, cruciferous vegetables, omeprazole, modafinil, tobacco smoking

CYP2C9
Substrates: Most NSAIDs (including COX-2), glipizide, irbesartan, losartan, phenytoin, tamoxifen, warfarin
Inhibitors: Amiodarone, fluconazole, isoniazid (INH), ketoconazole, metronidazole
Inducers: Aprepitant, barbiturates, rifampin

CYP2C19
Substrates: Amitriptyline, clopidogrel, cyclophosphamide, diazepam, lansoprazole, omeprazole, pantoprazole, phenytoin, rabeprazole
Inhibitors: Fluoxetine, fluvoxamine, isoniazid, ketoconazole, lansoprazole, omeprazole, ticlopidine
Inducers: Barbiturates, carbamazepine, prednisone, rifampin

CYP2D6
Substrates:
Antidepressants: Most tricyclic antidepressants, clomipramine, fluoxetine, paroxetine, venlafaxine
Antipsychotics: Aripiprazole, clozapine, haloperidol, risperidone, thioridazine
β-blockers: Carvedilol, metoprolol, propranolol, timolol
Opioids: Codeine, hydrocodone, oxycodone, tramadol
Others: Amphetamine, dextromethorphan, duloxetine, encainide, flecainide, mexiletine, ondansetron, propafenone, selegiline, tamoxifen
Inhibitors: Amiodarone, bupropion, cimetidine, clomipramine, doxepin, duloxetine, fluoxetine, haloperidol, methadone, paroxetine, quinidine, ritonavir
Inducers: Dexamethasone, rifampin

CYP3A
Substrates:
Anticholinergics: Darifenacin, oxybutynin, solifenacin, tolterodine
Benzodiazepines: Alprazolam, diazepam, midazolam, triazolam
Calcium channel blockers: Amlodipine, diltiazem, felodipine, nifedipine, nimodipine, nisoldipine, verapamil
Chemotherapy: Cyclophosphamide, erlotinib, ifosfamide, paclitaxel, tamoxifen, vinblastine, vincristine
HIV protease inhibitors: Atazanavir, indinavir, nelfinavir, ritonavir, saquinavir
HMG-CoA reductase inhibitors: Atorvastatin, lovastatin, simvastatin
Immunosuppressive agents: Cyclosporine, tacrolimus
Macrolide-type antibiotics: Clarithromycin, erythromycin, telithromycin, troleandomycin
Opioids: Alfentanil, cocaine, fentanyl, methadone, sufentanil
Steroids: Budesonide, cortisol, 17-β-estradiol, estrogens, progesterone, testosterone, prednisone
Others: Acetaminophen, amiodarone, carbamazepine, delavirdine, efavirenz, nevirapine, quinidine, repaglinide, sildenafil, tadalafil, trazodone, vardenafil
Inhibitors: Amiodarone, amprenavir, aprepitant, atazanavir, ciprofloxacin, cisapride, clarithromycin, diltiazem, erythromycin, fluconazole, fluvoxamine, grapefruit juice (in high ingestion), indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, norfloxacin, ritonavir, saquinavir, telithromycin, troleandomycin, verapamil, voriconazole
Inducers: Carbamazepine, efavirenz, glucocorticoids, modafinil, nevirapine, phenytoin, phenobarbital, rifabutin, rifapentine, rifampin, St. John's wort

Aging Male Survey (AMS)

(See also Section II: Aging Male Survey)

AMS Questionnaire

Which of the following symptoms apply to you at this time? Please mark the appropriate box for each symptom. For symptoms that do not apply, please mark "none."

Symptoms	Score =	None 1	Mild 2	Moderate 3	Severe 4	Extremely severe 5
1. **Decline in your feeling of general well-being** (general state of health, subjective feeling)		☐	☐	☐	☐	☐
2. **Joint pain and muscular ache** (lower back pain, joint pain, pain in a limb, general back ache)		☐	☐	☐	☐	☐
3. **Excessive sweating** (unexpected/sudden episodes of sweating, hot flushes independent of strain)		☐	☐	☐	☐	☐
4. **Sleep problems** (difficulty in falling asleep, difficulty in sleeping through, waking up early and feeling tired, poor sleep, sleeplessness)		☐	☐	☐	☐	☐
5. **Increased need for sleep, often feeling tired**		☐	☐	☐	☐	☐
6. **Irritability** (feeling aggressive, easily upset about little things, moody)		☐	☐	☐	☐	☐
7. **Nervousness** (inner tension, restlessness, feeling fidgety)		☐	☐	☐	☐	☐
8. **Anxiety** (feeling panicky)		☐	☐	☐	☐	☐
9. **Physical exhaustion/lacking vitality** (general decrease in performance, reduced activity, lacking interest in leisure activities, feeling of getting less done, of achieving less, of having to force oneself to undertake activities)		☐	☐	☐	☐	☐
10. **Decrease in muscular strength** (feeling of weakness)		☐	☐	☐	☐	☐
11. **Depressive mood** (feeling down, sad, on the verge of tears, lack of drive, mood swings, feeling nothing is of any use)		☐	☐	☐	☐	☐
12. **Feeling that you have passed your peak**		☐	☐	☐	☐	☐
13. **Feeling burnt out, having hit rock-bottom**		☐	☐	☐	☐	☐
14. **Decrease in beard growth**		☐	☐	☐	☐	☐
15. **Decrease in ability/frequency to perform sexually**		☐	☐	☐	☐	☐
16. **Decrease in the number of morning erections**		☐	☐	☐	☐	☐
17. **Decrease in sexual desire/libido** (lacking pleasure in sex, lacking desire for sexual intercourse)		☐	☐	☐	☐	☐

Have you got any other major symptoms? Yes ☐ No ☐

If Yes, please describe: _____

Thank you very much for your cooperation

Antibiotic Prophylaxis: AUA Guidelines

Patients undergoing urologic surgery should be considered for appropriate antibiotic prophylaxis. The American Urologic Association (AUA) has made the following recommendations to help with decisions regarding use of antimicrobial prophylaxis in urologic surgery based on upper or lower urinary tract surgery. The selection of agent and determination of appropriate dosing should always consider the patient's specific circumstances (allergy, etc.).
Key points in the AUA guidelines:

- The duration of surgical prophylaxis should extend throughout the period in which bacterial invasion is facilitated and/or is likely to establish an infection.
- Begin infusion of the 1st dose within 60 minutes of the incision (except 120 min for IV fluoroquinolones and vancomycin).
- Do not extend prophylaxis beyond 24 hr after a procedure except with prosthetic materials, if a urinary catheter is present prior to or is placed at the time of the procedure in patients with risk factors, or in the presence of documented bacteriuria.
- For surgical prophylaxis, all agents should be administered IV (except for oral medications for fluoroquinolones, trimethoprim–sulfamethoxazole, bowel preparation agents, and some agents given at catheter removal); in addition, intramuscular administration for antimicrobials for transrectal prostate biopsy is acceptable.
- With an existing infection, a therapeutic course of antimicrobials should be given in an attempt to sterilize the field or suppress the bacterial count. Prophylaxis can be omitted if urine culture shows no growth.
- Standard dosing regimens are noted. Dose adjustments based on body weight. Additional intraoperative doses are required intraoperatively if the procedure extends beyond 2 half-lives of the initial dose.
- Oral agents used for bowel preparation include erythromycin base: 1–2 g PO (variable), Metronidazole: 1–2 g PO (variable), Neomycin (for bowel preparation): 1–2 g PO (variable).
- Antimicrobial prophylaxis for genitourinary procedures solely to prevent infectious endocarditis is no longer recommended by the American Heart Association as the risk of adverse events exceeds the benefit.
- For patients with orthopedic considerations see Section II: "Joint Replacement, Urologic Considerations".

This version was updated on January 1, 2014 and this information and the tables below are based on data from "Urologic Surgery Antimicrobial Prophylaxis" https://www.auanet.org/education/guidelines/antimicrobial-prophylaxis.cfm (Accessed August 29, 2014). Please refer to this site for additional details.

PROPHYLAXIS FOR LOWER URINARY TRACT INSTRUMENTATION

Procedure (Organisms)[1]	Prophylaxis Indicated	Antimicrobial(s) of Choice[2]	Alternative Antimicrobial(s)[2]
Removal of external urinary catheter,[3,4] (GU tract)	Patients with risk factors[5,7]		*Aminoglycoside ± ampicillin:* Gentamicin: 5 mg/kg IV single dose Tobramycin: 5 mg/kg IV single dose Amikacin: 15 mg/kg IV single dose Ampicillin: 1–2 g IV (q6h) OR *1st gen. cephalosporin:* Cephalexin: 500 mg PO (q6h) Cephradine: 500 mg PO (q6h) Cefadroxil: 500 mg PO (q12h) Cefazolin: 1 g IV (q8h) OR *2nd gen. cephalosporin:* Cefaclor: 500 mg PO (q8h) Cefprozil: 500 mg PO (q12h) Cefuroxime: 500 mg PO (q12h) Cefoxitin: 1–2 g IV (q8h) OR *Amoxicillin/clavulanate:* 875 mg PO (q12h)
Cystography, urodynamic study or simple Cystourethroscopy (GU tract)	Patients with risk factors[5,7]	*Fluoroquinolones:* Levofloxacin: 500 mg PO single dose Ciprofloxacin: 500 mg PO (q12h) Ofloxacin: 400 mg PO (q12h) OR *TMP-SMX (Trimethoprim–sulfamethoxazole):* 1 double-strength tablet PO (q12h)	
Cystourethroscopy with manipulation[6] (GU tract)	All patients		
Prostate brachytherapy or cryotherapy (skin)	Uncertain	*1st gen. cephalosporin:* Cephalexin: 500 mg PO (q6h) Cephradine: 500 mg PO (q6h) Cefadroxil: 500 mg PO (q12h) Cefazolin: 1 g IV (q8h)	*Clindamycin:* 600 mg IV (q8h)
Transrectal prostate biopsy (intestine)	All patients	*Fluoroquinolones:* Levofloxacin: 500 mg PO single dose Ciprofloxacin: 500 mg PO (q12h) Ofloxacin: 400 mg PO (q12h) OR *1st gen. cephalosporin:* Cephalexin: 500 mg PO (q6h) Cephradine: 500 mg PO (q6h) Cefadroxil: 500 mg PO (q12h) Cefazolin: 1 g IV (q8h) OR *2nd gen. cephalosporin:* Cefaclor: 500 mg PO (q8h) Cefprozil: 500 mg PO (q12h) Cefuroxime: 500 mg PO (q12h) Cefoxitin: 1–2 g IV (q8h) OR *3rd gen. cephalosporin:* (oral agents not listed) Ceftizoxime: 1 g IV (q8h) Ceftazidime: 1 g IV (q12h) Ceftriaxone: 1–2 IV single dose Cefotaxime: 1 g IV (q8h)	*TMP-SMX (Trimethoprim–sulfamethoxazole):* 1 double-strength tablet PO (q12h) OR *Aminoglycoside* Gentamicin: 5 mg/kg IV single dose Tobramycin: 5 mg/kg IV single dose Amikacin: 15 mg/kg IV single dose OR *Aztreonam:* 1–2 g IV (q8h)

Key: gen. = generation; GU = genitourinary.

1. Organisms common to the GU tract: *E. coli, Proteus sp., Klebsiella sp., Enterococcus;* Intestine: *E. coli, Klebsiella sp., Enterobacter, Serratia sp., Proteus sp., Enterococcus,* and Anaerobes; Skin: *S. aureus, coagulase negative Staph. sp.,* Group A *Strep. sp.* Skin organisms: *S. aureus, coagulase negative Staph. sp.,* Group A *Strep. sp.* Intestinal organisms: *E. coli, Klebsiella sp., Enterobacter, Serratia sp, Serratia sp., Proteus sp., Enterococcus,* and anaerobes.
2. Order of agents is not indicative of preference.
3. If urine culture shows no growth prior to procedure, antimicrobial prophylaxis is not necessary.
4. Or full course of culture-directed antimicrobials for documented infection (treatment not prophylaxis).
5. Risk factors: Advanced age, anatomic anomalies of the urinary tract, poor nutritional status, smoking, chronic corticosteroid use, immunodeficiency, externalized catheters, colonized endogenous/exogenous material, distant coexistent infection, prolonged hospitalization.
6. Includes transurethral resection of bladder tumor and prostate, and any biopsy, resection, fulguration, foreign body removal, urethral dilation or urethrotomy, or ureteral instrumentation including catheterization or stent placement/removal.
7. If culture negative pre op, prophylaxis not necessary.

PROPHYLAXIS FOR UPPER URINARY TRACT INSTRUMENTATION

Procedure (Organisms)[1]	Prophylaxis Indicated	Antimicrobial(s) of Choice[2]	Alternative Antimicrobial(s)[2]
Shock-wave lithotripsy (GU tract)	If risk factors[3]	*Fluoroquinolones:* Levofloxacin: 500 mg PO single dose Ciprofloxacin: 500 mg PO (q12h) Ofloxacin: 400 mg PO (q12h) OR *TMP-SMX (Trimethoprim–sulfamethoxazole):* 1 double-strength tablet PO (q12h)	*Aminoglycoside ± ampicillin* 1st/2nd gen. cephalosporin Amoxicillin/clavulanate
Ureteroscopy (GU tract)	All patients		
Percutaneous renal surgery (GU tract and skin)	All patients	*1st gen. cephalosporin:* Cephalexin: 500 mg PO (q6h) Cephradine: 500 mg PO (q6h) Cefadroxil: 500 mg PO (q12h) Cefazolin: 1 g IV (q8h) OR *2nd gen. cephalosporin:* Cefaclor: 500 mg PO (q8h) Cefprozil: 500 mg PO (q12h) Cefuroxime: 500 mg PO (q12h) Cefoxitin: 1–2 g IV (q8h) OR *Aminoglycoside* Gentamicin: 5 mg/kg IV single dose Tobramycin: 5 mg/kg IV single dose Amikacin: 15 mg/kg IV single dose WITH *Metronidazole:* 1 g IV (q12h) OR *Clindamycin:* 600 mg IV (q8h)	*Ampicillin/sulbactam:* 1.5–3 g IV (q6h) OR *Fluoroquinolones:* Levofloxacin: 500 mg PO single dose Ciprofloxacin: 500 mg PO (q12h) Ofloxacin: 400 mg PO (q12h)
Vaginal surgery (GU tract, skin, and Group B *Strep.*)	All patients	*1st gen. cephalosporin:* Cephalexin: 500 mg PO (q6h) Cephradine: 500 mg PO (q6h) Cefadroxil: 500 mg PO (q12h) Cefazolin: 1 g IV (q8h) OR *2nd gen. cephalosporin:* Cefaclor: 500 mg PO (q8h) Cefprozil: 500 mg PO (q12h) Cefuroxime: 500 mg PO (q12h) Cefoxitin: 1–2 g IV (q8h) OR *Aminoglycoside:* Gentamicin: 5 mg/kg IV single dose Tobramycin: 5 mg/kg IV single dose Amikacin: 15 mg/kg IV single dose WITH *Metronidazole:* 1 g IV (q12h) OR *Clindamycin:* 600 mg IV (q8h)	*Ampicillin/sulbactam:* 1.5–3 g IV (q6h) OR *Fluoroquinolones:* Levofloxacin: 500 mg PO single dose Ciprofloxacin: 500 mg PO (q12h) Ofloxacin: 400 mg PO (q12h)
Involving entry into the urinary tract (GU tract and skin)	All patients		

Key: gen. = generation; GU = genitourinary.

1. Organisms common to the GU tract: *E. coli, Proteus sp., Klebsiella sp., Enterococcus;* Intestine: *E. coli, Klebsiella sp., Enterobacter, Serratia sp., Proteus sp., Enterococcus,* and Anaerobes; Skin: *S. aureus, coagulase negative Staph. sp.,* Group A *Strep. sp.* Skin organisms: *S. aureus, coagulase negative Staph. sp.,* Group A *Strep. sp.* Intestinal organisms: *E. coli, Klebsiella sp., Enterobacter, Serratia sp, Serratia sp., Proteus sp., Enterococcus.*
2. Order of agents is not indicative of preference.
3. Risk factors: Advanced age, anatomic anomalies of the urinary tract, poor nutritional status, smoking, chronic corticosteroid use, immunodeficiency, externalized catheters, colonized endogenous/exogenous material, distant coexistent infection, prolonged hospitalization.
4. For surgery involving colon, bowel preparation with oral neomycin plus either erythromycin base or metronidazole can be added to or substituted for systemic agents.

PROPHYLAXIS FOR UPPER URINARY TRACT INSTRUMENTATION (Continued)

Without entering urinary tract (skin)	Patients with risk factors[3]	*1st gen. cephalosporin (single dose):* Cephalexin: 500 mg PO Cephradine: 500 mg PO Cefadroxil: 500 mg PO Cefazolin: 1 g IV	*Clindamycin*: 600 mg IV single dose
Involving intestine[4] (GU tract, skin, and intestine)	All patients	*2nd gen. cephalosporin:* Cefaclor: 500 mg PO (q8h) Cefprozil: 500 mg PO (q12h) Cefuroxime: 500 mg PO (q12h) Cefoxitin: 1–2 g IV (q8h) OR *3rd gen. cephalosporin:* (oral agents not listed) Ceftizoxime: 1 g IV (q8h) Ceftazidime: 1 g IV (q12h) Ceftriaxone: 1–2 IV single dose Cefotaxime: 1 g IV (q8h) OR *Aminoglycoside:* Gentamicin: 5 mg/kg IV single dose Tobramycin: 5 mg/kg IV single dose Amikacin: 15 mg/kg IV single dose WITH *Metronidazole:* 1 g IV (q12h) OR *Clindamycin*: 600 mg IV (q8h)	*Ampicillin/sulbactam:* 1.5–3 g IV (q6h) OR *Ticarcillin/clavulanate:* 3.1 g IV (q6h) OR *Piperacillin/tazobactam:* 3.375 g IV (q6h) OR *Fluoroquinolones:* Levofloxacin: 500 mg PO single dose Ciprofloxacin: 500 mg PO (q12h) Ofloxacin: 400 mg PO (q12h)
Involving implanted prosthesis (GU tract and skin)	All patients	*Aminoglycoside:* Gentamicin: 5 mg/kg IV single dose Tobramycin: 5 mg/kg IV single dose Amikacin: 15 mg/kg IV single dose WITH *1st gen. cephalosporin*: Cephalexin: 500 mg PO (q6h) Cephradine: 500 mg PO (q6h) Cefadroxil: 500 mg PO (q12h) Cefazolin: 1 g IV (q8h) OR *2nd gen. cephalosporin:* Cefaclor: 500 mg PO (q8h) Cefprozil: 500 mg PO (q12h) Cefuroxime: 500 mg PO (q12h) Cefoxitin: 1–2 g IV (q8h) OR *Vancomycin*: 1 g IV (q12h)	*Ampicillin/sulbactam:* 1.5–3 g IV (q6h) OR *Ticarcillin/clavulanate:* 3.1 g IV (q6h) OR *Piperacillin/tazobactam:* 3.375 g IV (q6h)

Key: gen. = generation; GU = genitourinary.

1. Organisms common to the GU tract: *E. coli, Proteus sp., Klebsiella sp., Enterococcus;* Intestine: *E. coli, Klebsiella sp., Enterobacter, Serratia sp., Proteus sp., Enterococcus,* and Anaerobes; Skin: *S. aureus, coagulase negative Staph. sp.*, Group A *Strep. sp.* Intestinal organisms: *E. coli, Klebsiella sp., Enterobacter, Serratia sp, Serratia sp., Proteus sp., Enterococcus.*
2. Order of agents is not indicative of preference.
3. Risk factors: Advanced age, anatomic anomalies of the urinary tract, poor nutritional status, smoking, chronic corticosteroid use, immunodeficiency, externalized catheters, colonized endogenous/exogenous material, distant coexistent infection, prolonged hospitalization.
4. For surgery involving colon, bowel preparation with oral neomycin plus either erythromycin base or metronidazole can be added to or substituted for systemic agents.

Anticoagulation and Antiplatelet Therapy in Urologic Practice

The following is based on Anticoagulation and Antiplatelet Therapy in Urologic Practice: ICUD and AUA Review Paper. The American Urologic Association (AUA) and the International Consultation on Urological Disease (ICUD) collaborated on this review. http://www.auanet.org/common/pdf/education/clinical-guidance/Anticoagulation-Antiplatelet-Therapy.pdf (Accessed July 12, 2014)

Patients often have multiple comorbidities and require urologic surgical intervention. Conditions can include coronary arterial disease requiring percutaneous coronary artery intervention with angioplasty, bare metal coronary stents, drug eluting coronary stent, cardiac dysrhythmias (such as atrial fibrillation, others), valvular heart disease, deep venous thrombosis, and inferior vena cava filters. This table provides guidelines on the management of anticoagulation and antiplatelet (AP) therapy in urologic practice. These are only general guidelines with the most effective approach for an individual patient best determined by the patient's clinical conditions and in collaboration with a multidisciplinary medical team that may include internists, cardiologists, or neurologists where appropriate.

- Anticoagulant (AC)
  - Heparins
  - Warfarin
  - Novel oral anticoagulants (NOACs) include thrombin inhibitor, dabigatran, and the factor Xa inhibitors, rivaroxaban, and apixaban
- Oral Anti Platelet (AP)
  - AP medications: aspirin, clopidogrel, ticagrelor, ticlopine, dipyridamole

1. **Deep venous thrombosis and pulmonary embolism** are discussed in Section I: "Deep Venous Thrombosis and Pulmonary Embolus, Urologic Considerations" and Section II: "Deep Venous Thrombosis, Prophylaxis, AUA Guidelines."

2. **For patients on clopidogrel or aspirin for secondary stroke prevention:** continue aspirin through the perioperative period.

3. **Coronary artery stents:** Dual AP therapy should not be stopped before urologic surgery within 12 mo of drug eluding stent or within 3 mo of a bare metal stent. For urologic procedures outside of these limits discontinuation of the clopidogrel, prasugrel, or ticagrelor, and continuation of aspirin, is recommended if procedural bleeding risks are acceptable.

4. **Mechanical heart valves:** AC bridge therapy is recommended.

5. **Cardiac risk factors on low-dose aspirin monotherapy**: continue in perioperative period without increased risk of major bleeding.

6. **Low-dose aspirin without specific indication:** may be scheduled electively, discontinuing the aspirin until directed by the team.

7. **Patients on** NOACs **(apixaban, dabigatran, rivaroxaban), with nonvalvular atrial fibrillation should be risk stratified:**

- Minor bleeding risk: these agents do not have to be modified, similar to the management with warfarin or low-molecular-weight heparin.
- Urgent procedure: delay for 24–36 hr and obtain consultation.
- Emergency procedure: if bleeding risk increased, expert consultation and avoid spinal/epidural anesthesia.
- With operative loss of nephrons determine renal function post-op and adjust these agents.

8. **Atrial fibrillation in high-risk procedure**: stop warfarin 5 days before surgery; restart 12–24 hr post-op if bleeding risk acceptable.

9. **Higher risk of thromboembolic events (eg, mechanical valves) on warfarin**: bridging anticoagulation with unfractionated heparin or low-molecular-weight heparin. The NOACs apixaban, dabigatran, or rivaroxaban, would be stopped 2–5 days before elective surgery based on the bleeding risk of the procedure. Rivaroxaban may increase stroke risk if stopped; bridging with some other AC such as heparin is recommended.

10. **Prosthetic heart valves:** follow standard guidelines (ie, the American College of Cardiology, American Heart Association, etc.).

- **Low risk of thrombosis:** bileaflet mechanical AVR and no risk factors (eg, atrial fib, previous thromboembolism, left ventricular dysfunction, hypercoagulable conditions, older generation thrombogenic valves, mechanical tricuspid valves or more than one mechanical valve). Stop warfarin 48–72 hr pre-op and restarted within 24 hr post-op. Heparin is usually unnecessary. Check INR immediately pre-op to ensure that the INR is >1.5.
- **High risk of thrombosis:** (any mechanical mitral valve replacement or a mechanical aortic valve with any risk factor [see above for risk factors]) begin bridging when the INR <2 (usually 48 hr pre-op); dose adjust aPTT 2–3 times the control. Unfractionated heparin is stopped 4–6 hours pre-op and restarted post-op based on bleeding stability. Restart warfarin as soon as possible postoperatively; unfractionated heparin is continued until the INR is therapeutic for at least 48 hr.

11. **Bridging regimens:** As recommended by the American College of Chest Physicians:

- A high-dose (therapeutic-dose) heparin bridging (eg, LMW heparin: enoxaparin 1 mg/kg BID or 1.5 mg/kg daily, dalteparin 100 IU/kg BID or 200 IU/kg daily, tinzaparin 175 IU/kg daily, or IV unfractionated heparin to keep aPTT 1.5–2 times control).
- A low-dose (prophylactic-dose) heparin regimen (eg, enoxaparin 30 mg BID or 40 mg daily, dalteparin 5,000 IU daily, unfractionated heparin 5,000–7,500 IU BID).
- An intermediate-dose regimen (eg, enoxaparin 40 mg BID).

12. **ESWL:** oral ACs and APs agents should be stopped and or reversed. Coordinate with multidisciplinary team.

13. **Ureteroscopy:** can be performed with continuing oral ACs and APs agents.

14. **Percutaneous nephrostolithotomy (PCNL):** oral ACs and APs agents discontinued prior to PCNL and patients bridged where deemed necessary.

15. **Laser prostatectomy:** In appropriately selected patients can be safely accomplished with a therapeutic INR who has a significant risk of thrombosis without stopping oral ACs and APs agents.

16. **Standard electrosurgical TURP:** The use of oral ACs and APs agents in patients undergoing TURP is associated with an increased risk of bleeding. Anticoagulation should be carefully assessed and managed; alternative treatment of the bladder outlet may be preferable.

17. **Prostate biopsy:** safe on low-dose aspirin. With oral ACs small studies suggest this can be performed without significant major bleeding risk. Stopping APs agents before biopsy, when medical evaluation demonstrates a low risk of thromboembolic complications, is associated with a lower rate of minor complications.

18. **Perioperative continuation of aspirin:** this may be associated with a minor risk of increased bleeding, but the transfusion rate is not increased and the consequences of bleeding are minor. The exception is with transurethral resection of the prostate.

AUA Symptom Index/International Prostate Symptom Score (I-PSS)

(See also Section II: AUA (American Urologic Association) Symptom Index for BPH and International Prostate Symptom Score (IPSS))

American Urological Association (AUA) Symptom Index for BPH

	Not at all 0	Less than 1 time in 5 1	Less than half the time 2	About half the time 3	More than half the time 4	Almost always 5
1. INCOMPLETE EMPTYING Over the last month or so, how often have you had a sensation of not emptying your bladder completely after you finished urinating?	○ 0	○ 1	○ 2	○ 3	○ 4	○ 5
2. FREQUENCY During the last month or so, how often have you had to urinate again <2 hours after you finished urinating?	○ 0	○ 1	○ 2	○ 3	○ 4	○ 5
3. INTERMITTENCY During the last month or so, how often have you stopped and started again several times when you urinated?	○ 0	○ 1	○ 2	○ 3	○ 4	○ 5
4. URGENCY During the last month or so, how often have you found it difficult to postpone urination?	○ 0	○ 1	○ 2	○ 3	○ 4	○ 5
5. WEAK STREAM During the last month or so, how often have you had a weak urinary stream?	○ 0	○ 1	○ 2	○ 3	○ 4	○ 5
6. STRAINING During the last month or so, how often have you had to push or strain to begin urination?	○ 0	○ 1	○ 2	○ 3	○ 4	○ 5
7. SLEEPING During the last month, how many times did you most typically get up to urinate from the time you went to bed at night until the time you got up in the morning?	○ 0	○ 1	○ 2 (times at night)	○ 3	○ 4	○ 5

SCORE: (0-35) ☐

The **International Prostate Symptom Score (IPSS)** uses the same 7 questions as the AUA Symptom Index, but adds a "Disease Specific Quality of Life Question" (sometimes referred to as the "bother score") and scored on a scale from 0 to 6 points ("delighted" to "terrible").

If you were to spend the rest of your life with your urinary condition just the way it is now, how would you feel about that?

Delighted	Pleased	Mostly satisfied	Mixed	Mostly disappointed	Unhappy	Terrible
0 ○	1 ○	2 ○	3 ○	4 ○	5 ○	6 ○

Contrast Agents, Genitourinary

Contrast agents used in urology include intravascular (CT, excretory urography, vascular studies, etc.), gastrointestinal (oral contrast), body cavity (fistulogram and tube studies), uroradiological (cystogram, urethrogram, retrograde pyelography, etc.), and MRI contrast agents (gadolinium-based paramagnetic compounds). Commonly used intravascular and uroradiological agents are shown in the tables below. See also Section I: "Contrast Allergy and Reactions" and Section II: "Contrast Induced Nephropathy (CIN)" and "Nephrogenic Systemic Fibrosis/Fibrosing Dermatopathy (NSF/NFD)."

Key points:

- Intravascular contrast agents are classified as ionic or nonionic and high, low, or iso-osmolar relative to serum (290 mOsm/kg H_2O). High-osmolar contrast media (HOCM) are the oldest intravascular agents and ionize in solution (osmolality typically >1,000). Low-osmolar contrast media (LOCM) and iso-osmolar contrast media (IOCM) are nonionic compounds (no ionization in solution). The toxicity of contrast agents generally decreases as osmolality approaches that of serum. Typical osmolality (in mOsm/kg H_2O) is as follows: HOCM > 1,000, LOCM ~ 400–800, and IOCM 290.
- Uroradiologic contrast agents are not injected into the circulation so that issues relating to potential toxicity are almost nonexistent.
- MRI contrast agents: Nephrogenic systemic fibrosis (NSF) is associated with the administration of intravenous gadolinium. The primary risk factor is renal insufficiency (dialysis patient or with a GFR < 30).

Intravascular Contrast Agents

Agents sorted by osmolarity from highest to lowest and represent commonly used agents in the United States.

Product	Chemical Structure	Anion	Cation	Osmolality (mOsm/kg H_2O)
MD-76™ (Covidien)	Ionic	Diatrizoate	Meglumine Sodium	1,551
Conray™ Covidien)	Ionic	Iothalamate	Meglumine	1,400

INTERNATIONAL INDEX OF ERECTILE FUNCTION (IIEF)

Patient Questionnaire

These questions ask about the effects that your erection problems have had on your sex life over the last four weeks. Please try to answer the questions as honestly and as clearly as you are able. Your answers will help your doctor to choose the most effective treatment suited to your condition. In answering the questions, the following definitions apply:

- **sexual activity** includes intercourse, caressing, foreplay, and masturbation
- **sexual intercourse** is defined as sexual penetration of your partner
- **sexual stimulation** includes situation such as foreplay, erotic pictures etc.
- **ejaculation** is the ejection of semen from the penis (or the feeling of this)
- **orgasm** is the fulfilment or climax following sexual stimulation or intercourse

	Over the past 4 weeks:	*Please check **one** box only*
☐ Q1	**How often were you able to get an erection during sexual activity?**	0 No sexual activity 1 Almost never or never 2 A few times (less than half the time) 3 Sometimes (about half the time) 4 Most times (more than half the time) 5 Almost always or always
☐ Q2	**When you had erections with sexual stimulation, how often were your erections hard enough for penetration?**	0 No sexual activity 1 Almost never or never 2 A few times (less than half the time) 3 Sometimes (about half the time) 4 Most times (more than half the time) 5 Almost always or always
☐ Q3	**When you attempted intercourse, how often were you able to penetrate (enter) your partner?**	0 Did not attempt intercourse 1 Almost never or never 2 A few times (less than half the time) 3 Sometimes (about half the time) 4 Most times (more than half the time) 5 Almost always or always
☐ Q4	**During sexual intercourse, how often were you able to maintain your erection after you had penetrated (entered) your partner?**	0 Did not attempt intercourse 1 Almost never or never 2 A few times (less than half the time) 3 Sometimes (about half the time) 4 Most times (more than half the time) 5 Almost always or always
☐ Q5	**During sexual intercourse, how difficult was it to maintain your erection to completion of intercourse?**	0 Did not attempt intercourse 1 Extremely difficult 2 Very difficult 3 Difficult 4 Slightly difficult 5 Not difficult
☐ Q6	**How many times have you attempted sexual intercourse?**	0 No attempts 1 One to two attempts 2 Three to four attempts 3 Five to six attempts 4 Seven to ten attempts 5 Eleven or more attempts
☐ Q7	**When you attempted sexual intercourse, how often was it satisfactory for you?**	0 Did not attempt intercourse 1 Almost never or never 2 A few times (less than half the time) 3 Sometimes (about half the time) 4 Most times (more than half the time) 5 Almost always or always
☐ Q8	**How much have you enjoyed sexual intercourse?**	0 No intercourse 1 No enjoyment at all 2 Not very enjoyable 3 Fairly enjoyable 4 Highly enjoyable 5 Very highly enjoyable
☐ Q9	**When you had sexual stimulation or intercourse, how often did you ejaculate?**	0 No sexual stimulation or intercourse 1 Almost never or never 2 A few times (less than half the time) 3 Sometimes (about half the time) 4 Most times (more than half the time) 5 Almost always or always

(Continued on next page)

☐ Q10	**When you had sexual stimulation or intercourse, how often did you have the feeling of orgasm or climax?**	1 Almost never or never 2 A few times (less than half the time) 3 Sometimes (about half the time) 4 Most times (more than half the time) 5 Almost always or always
☐ Q11	**How often have you felt sexual desire?**	1 Almost never or never 2 A few times (less than half the time) 3 Sometimes (about half the time) 4 Most times (more than half the time) 5 Almost always or always
☐ Q12	**How would you rate your level of sexual desire?**	1 Very low or none at all 2 Low 3 Moderate 4 High 5 Very high
☐ Q13	**How satisfied have you been with your overall sex life?**	1 Very dissatisfied 2 Moderately dissatisfied 3 Equally satisfied and dissatisfied 4 Moderately satisfied 5 Very satisfied
☐ Q14	**How satisfied have you been with your sexual relationship with your partner?**	1 Very dissatisfied 2 Moderately dissatisfied 3 Equally satisfied & dissatisfied 4 Moderately satisfied 5 Very satisfied
☐ Q15	**How do you rate your confidence that you could get and keep an erection?**	1 Very low 2 Low 3 Moderate 4 High 5 Very high

Total Score _____

Interpretation of IEEF

IIEF Domains	Maximum Score
A. Erectile Function (Questions 1, 2, 3, 4, 5, 15)	30
B. Orgasmic Function (Questions 9, 10)	10
C. Sexual Desire (Questions 11, 12)	10
D. Intercourse Satisfaction (Questions 6, 7, 8)	15
E. Overall Satisfaction (Questions 13, 14)	10

A score of 0–5 is awarded to each of the 15 questions that examine the 4 main domains of male sexual function: erectile function, orgasmic function, sexual desire, and intercourse satisfaction.

Analysis of the questionnaire should, therefore, be viewed as an adjunct to, rather than a substitute for, a detailed sexual history and examination. The following guidelines are typical based on the IIEF scores and are based on the recommendations of the British Association of Urologic Surgeons:

1. Low IIEF scores (<14 out of 30) in Domain A (Erectile Function) may be considered for a trial course of therapy with Sildenafil unless contraindicated. Specialist referral is indicated if this is unsuccessful.
2. Patients demonstrating primary orgasmic or ejaculatory dysfunction (Domain B) should be referred for specialist investigation.
3. Patients with reduced sexual desire (Domain C) require testing of blood levels of androgen and prolactin.
4. Psychosexual counselling should be considered if low scores are recorded in Domains D and E but there is only a moderately lowered score (14 to 25) in Domain A.

Based on data from Rosen R, Riley A, Wagner G, et al. The International Index of Erectile Function (IIEF): A multidimensional scale for assessment of erectile dysfunction. *Urology*. 1997;49:822–830 and the British Association of Urologic Surgeons http://www.baus.org.uk/Resources/BAUS/Documents/PDF%20Documents/Patient%20information/iief.pdf.

Male Sexual Health Questionnaire (MSHQ) Short Form

MSHQ is a 25 question self-administered questionnaire for assessing key domains of sexual function and satisfaction in aging men with urogenital health concerns. (Rosen RC, Catania J, Pollack L. Male Sexual Health Questionnaire (MSHQ): Scale development and psychometric validation. *Urology.* 2004;64(4):777–782.)

A modified form, known as the MSHQ Short Form is commonly used for assessing ejaculatory dysfunction (also called the MSHQ-EjD). See also Section II: Male Sexual Health Questionnaire (MSHQ) and the MSHQ short form

In the past month:						
Ejaculatory Function						
1. How often have you been able to ejaculate or "cum" when having sexual activity?	All the time (5)	Most of the time (4)	About half the time (3)	Less than half the time (2)	None of the time/could not ejaculate (1)	
2. How would you rate the strength or force of your ejaculation?	As strong as it always was (5)	A little less strong than it used to be (4)	Somewhat less strong than it used to be (3)	Much less strong than it used to be (2)	Very much less strong than it used to be (1)	Could not ejaculate (0)
3. How would you rate the amount or volume of semen or fluid when you ejaculate?	As much as it always was (5)	A little less than it used to be (4)	Somewhat less than it used to be (3)	Much less than it used to be (2)	Very much less than it used to be (1)	Could not ejaculate (0)
Bother/Satisfaction						
4. If you have had any ejaculation difficulties or have been unable to ejaculate, have you been bothered by this?	No problem with ejaculation (0)	Not at all bothered (1)	A little bothered (2)	Moderately bothered (3)	Very bothered (4)	Extremely bothered (5)

Rosen RC, Catania JA, Althof SE, et al. Development and validation of four-item version of male sexual health questionnaire to assess ejaculatory dysfunction. *Urology*. 2007;69(5):805–809, with permission.

National Institutes of Health (NIH) Chronic Prostatitis Symptom Index (CPSI)

(See also Section II: National Institutes of Health (NIH) Chronic Prostatitis Symptom Index. Form is to be filled out by patient.)

Pain or Discomfort

1. In the last week, have you experienced any pain or discomfort in the following areas?

		Yes	No
a.	Area between rectum and testicles (perineum)	❑1	❑0
b.	Testicles	❑1	❑0
c.	Tip of the penis (not related to urination)	❑1	❑0
d.	Below your waist, in your pubic or bladder area	❑1	❑0

2. In the last week, have you experienced:

		Yes	No
a.	Pain or burning during urination?	❑1	❑0
b.	Pain discomfort during or after sexual climax (ejaculation)?	❑1	❑0

3. How often have you had pain or discomfort in any of these areas over the last week?

❑0 Never
❑1 Rarely
❑2 Sometimes
❑3 Often
❑4 Usually
❑5 Always

4. Which number best describes your AVERAGE pain or discomfort on the days that you had it, over the last week?

❑ ❑ ❑ ❑ ❑ ❑ ❑ ❑ ❑ ❑ ❑
0 1 2 3 4 5 6 7 8 9 10
NO PAIN — PAIN AS BAD AS YOU CAN IMAGINE

Urination

5. How often have you had a sensation of not emptying your bladder completely after you finished urinating, over the last week?

❑0 Not at all
❑1 Less than 1 time in 5
❑2 Less than half the time
❑3 About half the time
❑4 More than half the time
❑5 Almost always

6. How often have you had to urinate again less than two hours after you finished urinating, over the last week?

❑0 Not at all
❑1 Less than 1 time in 5
❑2 Less than half the time
❑3 About half the time
❑4 More than half the time
❑5 Almost always

Impact of Symptoms

7. How much have your symptoms kept you from doing the kinds of things you would usually do, over the last week?

❑0 None
❑1 Only a little
❑2 Some
❑3 A lot

8. How much did you think about your symptoms, over the last weeks?

❑0 None
❑1 Only a little
❑2 Some
❑3 A lot

Quality of Life

9. If you were to spend the rest of your life with your symptoms just the way they have been during the last week, how would you feel about that?

❑0 Delighted
❑1 Pleased
❑2 Mostly satisfied
❑3 Mixed (about equally satisfied and dissatisfied)
❑4 Mostly dissatisfied
❑5 Unhappy
❑6 Terrible

Scoring the NIH-Chronic Prostatitis Symptom Index Domains

Pain: Total of items 1a, 1b, 1c, 1d, 2a, 2b, 3, and 4 = _____

Urinary Symptoms: Total of items 5 and 6 = _____

Quality of Life Impact: Total of items 7, 8, and 9 = _____

Litwin MS, McNaughton-Collins M, Fowler FJ Jr, et al. The National Institutes of Health chronic prostatitis symptom index: Development and validation of a new outcome measure. *J Urol*. 1999;162(2):369–375, with permission.

Prostate Cancer Screening Guidelines

Screening for prostate cancer is highly controversial. This table summarizes some of the major US and international medical groups recommendations in this area.

Organization (Year)	Recommendation
American Cancer Society (ACS) (2010)	1. No routine screening; after informed discussion of risk and benefits for those who wish to be screened 2. No screening with <10-yr life expectancy 3. Screen with PSA, w/ or w/o DRE, at age 50 with >10 yr life expectancy; if PSA >2.5 ng/mL, screen yearly, otherwise screen every 2 yr 4. Beginning screening discussions at age 40–45 if at high risk of developing prostate cancer (eg, black men, or with a first-degree relative with prostate cancer diagnosed before age 65). 5. Biopsy referral threshold is 4 ng/mL. With PSA 2.5–4 ng/mL, encourage individualized decision making and assessment (http://deb.uthscsa.edu/URORiskCalc/Pages/uroriskcalc.jsp), which can include age, race, family history, DRE, previous biopsy results, and use of 5 α-reductase inhibitors.
American College of Physicians (2013)	1. Inform men age 50–69 about limited benefits and harms; screen only if patient wants it 2. Do not screen <age 50 if average risk, over 69, or <10–15-yr life expectancy
American Urological Association (2013)	1. No screening under 40; not recommended if average risk 40–54; individualize if high risk[c] 2. Shared decision making for men age 55–69 3. No screening over age 75 or any man <10–15-yr life expectancy some men over age 70 in excellent health might benefit from screening. 4. Reduce the harms of screening, a screening interval of 2 yr or more may be preferred. 5. Lack of evidence for using any tests (eg, PSA derivatives, PSA kinetics, PSA molecular markers, urinary markers, imaging, or risk calculators) other than PSA for triggering a biopsy referral. No specific threshold for biopsy referral.
Australian Cancer Council (2011)	1. Does not support population-based screening 2. Recommends a patient-centered approach that individualizes the decision
Canadian Task Force on Preventive Health Care (2006; 2014 Update pending)	1. Recommends against screening for prostate cancer with PSA or TRUS 2. Insufficient evidence to recommend for or against screening with DRE
European Society for Medical Oncology (ESMO) (2013)	1. Recommends against population-based screening; favors individualized shared decision making 2. There is inconsistent evidence screening men <50 and 70–75 yr of age; evidence that the harms of screening outweigh the benefits for men over age 75.
National Comprehensive Cancer Network (NCCN) (2014)	1. Informed discussion with all 2. Baseline DRE and PSA age 45; if PSA <1 repeat age 50; if PSA >1, repeat every 1–2 yr 3. Age 50–70 with normal DRE and PSA <3, repeat every 1–2 yr 4. Use caution screening if > age 70 and only if very healthy; few > age 75 benefit from screening
United Kingdom National Screening Committee (2010)	1. Does not recommend screening for prostate cancer
United States Preventive Services Task Force (USPSTF) (2012)	1. No role in any man unless symptoms (grade D) 2. Men requesting screening be supported in making an informed decision.

All PSA values are ng/mL

[a]African American or have a 1st-degree relative diagnosed with PCa at <65 yr of age.

[b]Several 1st-degree relatives diagnosed with PCa at <65 yr of age.

[c]Positive family history or African American race.

SEXUAL HEALTH INVENTORY FOR MEN
IIEF-5

Patient's Study ID Number_____

Date of evaluation_____

PATIENT INSTRUCTIONS

Sexual health is an important part of an individual's overall physical and emotional well-being. Erectile dysfunction is one type of very common sexual complaint. There are many different treatment options for erectile dysfunction. This questionnaire is designed to help you and your physician identify if you may be experiencing erectile dysfunction and to potentially discuss treatment options.

Each question has several responses from which you are asked to choose the one that best describes your own situation. Please be sure that you select at least one but only one response by circling the number that best fits your answer.

Over the past six months:

How do you rate your confidence that you could get and keep an erection?		Very low 1	Low 2	Moderate 3	High 4	Very high 5
When you had erections with sexual stimulation, how often were your erections hard enough for penetration?	No sexual activity 0	Almost never/never 1	A few times (musch less than half the time) 2	Sometimes (about half the time) 3	Most times (much more than half the time) 4	Almost always/ always 5
During sexual intercourse, how often were you able to maintain your erection after you had penertrated (entered) your partner?	Did not attempt intercourse 0	Almost never/never 1	A few times (musch less than half the time) 2	Sometimes (about half the time) 3	Most times (much more than half the time) 4	Almost always/ always 5
During sexual intercourse, how difficult was it to maintain your erection to completion of intercourse?	Did not attempt intercourse 0	Extremely difficult 1	Very difficult 2	Difficult 3	Slightly difficult 4	Not difficult 5
When you attempted sexual intercourse, how often was it satisfactory for you?	Did not attempt intercourse 0	Almost never/never 1	A few times (musch less than half the time) 2	Sometimes (about half the time) 3	Most times (much more than half the time) 4	Almost always/ always 5

Score_____

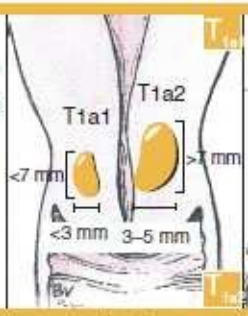
If your score is 21 or less, you show signs of erectile dysfunction, and your doctor can suggest treatment options that can improve your condition.

Sexual Health Inventory for Men. An abridged 5-item version of the 15-item International Index of Erectile Function (IIEF-5) was developed to diagnose the presence and severity of erectile dysfunction (ED). Reprinted with permission from Rosen RC, Cappelleri JC, Smith MD, Lipsky J, Peña BM. Development and evaluation of an abridged, 5-item version of the International Index of Erectile Function (IIEF-5) as a diagnostic tool for erectile dysfunction. *Int J Impot Res*. 1999;11:319–326.

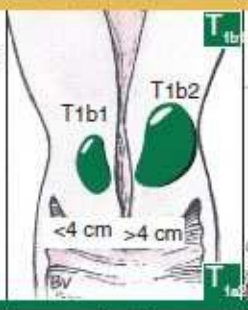
TNM Classification: Cervix Cancer

DEFINITION OF TNM

T1
Cervical carcinoma confined to uterus
(T1a) Invasive carcinoma diagnosed only by microscopy. Stromal invasion with a maximum depth of 5 mm measured from the base of the epithelium and a horizontal spread of ≤7 mm. Vascular space involvement, venous or lymphatic, does not affect classification.
(T1a1) Measured stromal invasion ≤3 mm in depth and ≤7 mm in horizontal spread
(T1a2) Measured stromal invasion >3 mm and not >5 mm with a horizontal spread ≤7 mm

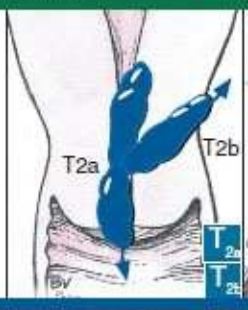


T1b
Clinically visible lesion confined to the cervix or microscopic lesion greater than T1a/IA2
(T1b1) Clinically visible lesion ≤4 cm in greatest dimension
(T1b2) Clinically visible lesion >4 cm in greatest dimension



N0
No regional lymph node metastasis

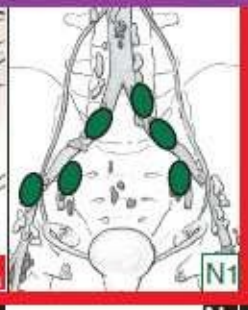
T2
Cervical carcinoma invades beyond uterus but not to pelvic wall or to lower third of vagina
(T2a) Tumor without parametrial invasion
(T2a1) Clinically visible lesion ≤4 cm in greatest dimension
(T2a2) Clinically visible lesion >4 cm in greatest dimension
(T2b) Tumor with parametrial invasion



T3
Tumor extends to pelvic wall and/or involves lower third of vagina, and/or causes hydronephrosis or nonfunctioning kidney
(T3a) Tumor involves lower third of vagina, no extension to pelvic wall
(T3b) Tumor extends to pelvic wall and/or causes hydronephrosis or nonfunctioning kidney

N1
Regional lymph node metastasis

T4
Tumor invades mucosa of bladder or rectum, and/or extends beyond true pelvis (bullous edema is not sufficient to classify a tumor as T4)



M0
No distant metastasis

M1
Distant metastasis (including peritoneal spread, involvement of supraclavicular, mediastinal, or paraaortic lymph nodes, lung, liver, or bone)

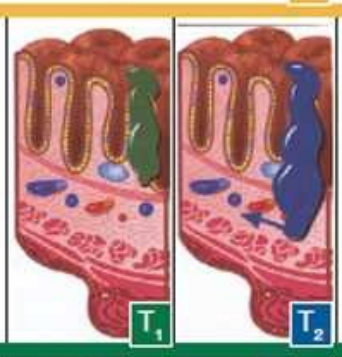
TNM Classification: Colon Cancer

DEFINITION OF TNM

T1
Tumor invades submucosa

T2
Tumor invades muscularis propria

N0
No regional lymph node metastasis



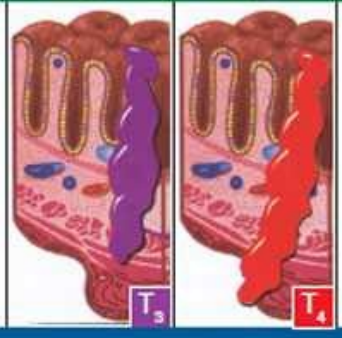
STAGE GROUPINGS

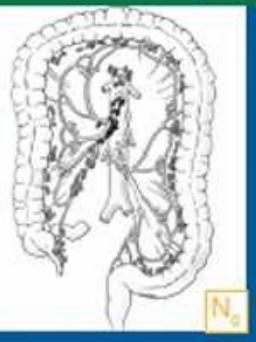
Stage I
T1 N0 M0
T2 N0 M0

T3
Tumor invades through the muscularis propria into pericolorectal tissues

T4
Tumor directly invades other organs or structures, and/or perforates visceral peritoneum

N0
No regional lymph node metastasis





Stage IIA
T3 N0 M0

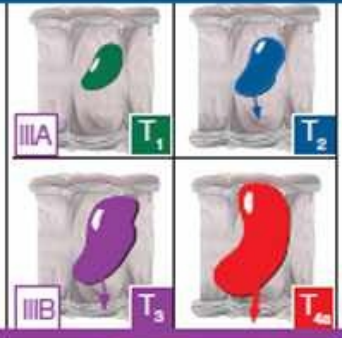
Stage IIB
T4a N0 M0

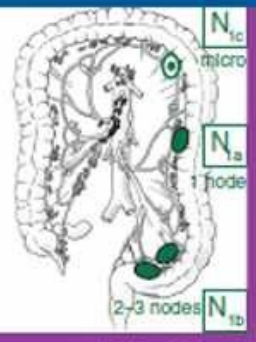
Stage IIC
*T4b N0 M0

*not shown

T4a
Tumor penetrates to the surface of the visceral peritoneum**

N1a
Metastasis in 1 regional lymph node
N1b
Metastasis in 2–3 regional lymph nodes
N1c
Tumor deposit(s) in the subserosa, mesentery, or nonperitonealized pericolic or perirectal tissues without regional nodal metastasis





Stage IIIA
T1–T2 N1–N1c M0
T1 N2a M0

Stage IIIB
T3–T4a N1 N1c M0
*T2 T3 N2a M0
*T1 T2 N2b M0

*not shown

T4b
Tumor directly invades or is adherent to other organs or structures **,***

N2
Metastasis in 4 or more regional lymph nodes
N2a
Metastasis in 4–6 regional lymph nodes
N2b
Metastasis in 7 or more regional lymph nodes

Stage IIIC
T4a N2a
T3–T4a N2b
T4b N1–N2

M1
Distant metastasis
M1a
Metastasis confined to 1 organ or site (eg, liver, lung, ovary, nonregional node)
M1b
Metastases in more than 1 organ/site or the peritoneum

Stage IVA
Any T Any N M1a

Stage IVB
Any T Any N M1b

**Note: Direct invasion in T4 includes invasion of other organs or other segments of the colorectum as a result of direct extension through the serosa, as confirmed on microscopic examination (eg, invasion of the sigmoid colon by a carcinoma of the cecum) or, for cancers in a retroperitoneal or subperitoneal location, direct invasion of other organs or structures by virtue of extension beyond the muscularis propria (ie, respectively, a tumor on the posterior wall of the descending colon invading the left kidney or lateral abdominal wall; or a mid or distal rectal cancer with invasion of prostate, seminal vesicles, cervix, or vagina).
***Note: Tumor that is adherent to other organs or structures, grossly, is classified cT4b. However, if no tumor is present in the adhesion, microscopically, the classification should be pT1–4a depending on the anatomical depth of wall invasion. The V and L classifications should be used to identify the presence or absence of vascular or lymphatic invasion, whereas the PN site-specific factor should be used for perineural invasion.

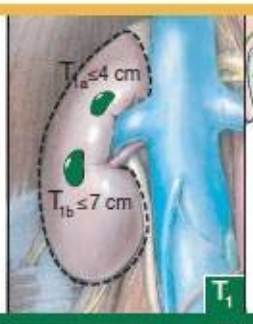
From Rubin P, Hansen JT, eds. *TNM Staging Atlas with Oncoanatomy*. 2nd ed. Philadelphia: Lippincott Williams & Wilkins; 2012, 327.

TNM Classification: Kidney Cancer

DEFINITION OF TNM

T1
Tumor ≤7 cm in greatest dimension, limited to the kidney
(T1a) Tumor ≤4 cm in greatest dimension, limited to the kidney
(T1b) Tumor >4 cm but not >7 cm in greatest dimension, limited to the kidney

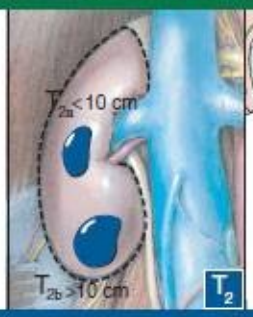
N0
No regional lymph node metastasis



I

T2
Tumor >7 cm in greatest dimension, limited to the kidney
(T2a) Tumor >7 cm but ≤10 cm in greatest dimension, limited to the kidney
(T2b) Tumor >10 cm, limited to the kidney

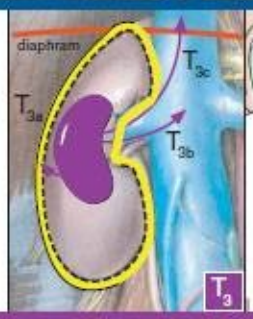
N0
No regional lymph node metastasis



II

T3
Tumor extends into major veins or perinephric tissues but not into the ipsilateral adrenal gland and not beyond Gerota's fascia
(T3a) Tumor grossly extends into the renal vein or its segmental (muscle containing) branches, or tumor invades perirenal and/or renal sinus fat but not beyond Gerota's fascia
(T3b) Tumor grossly extends into the vena cava below the diaphragm
(T3c) Tumor grossly extends into the vena cava above the diaphragm or invades the wall of the vena cava

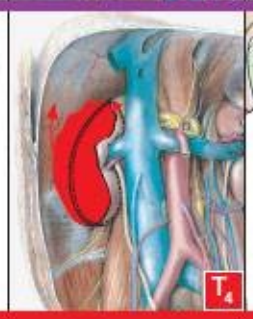
N1
Metastasis in a single regional lymph node



III

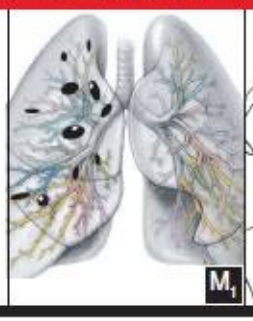
T4
Tumor invades beyond Gerota's fascia (including contiguous extension into the ipsilateral adrenal gland)

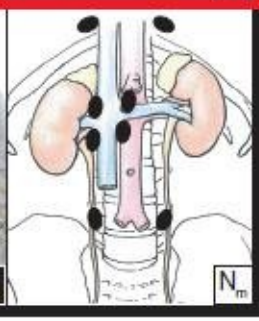
M0
No distant metastasis



IV

M1
Distant metastasis





IV

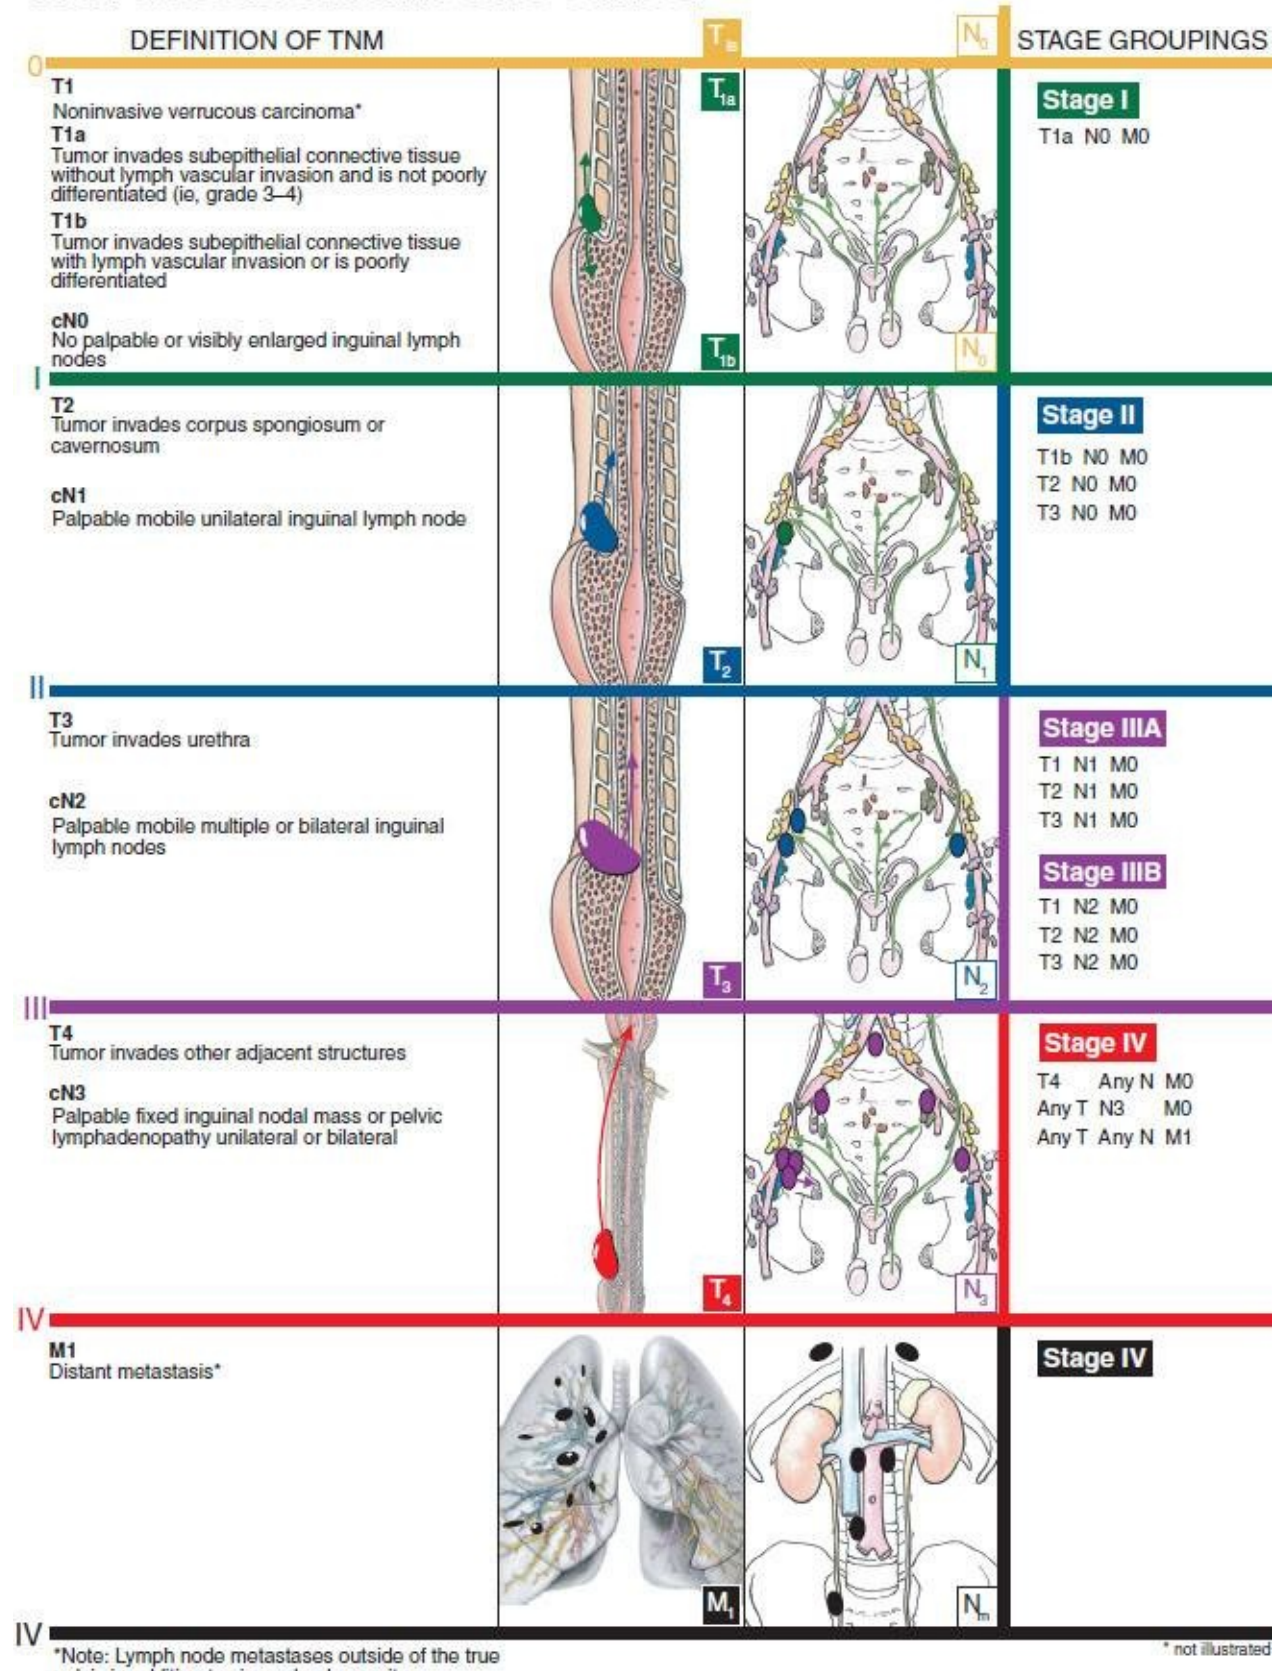
TNM Classification: Penis Cancer



From Rubin P, Hansen JT, eds. *TNM Staging Atlas with Oncoanatomy*. 2nd ed. Philadelphia: Lippincott Williams & Wilkins; 2012, 437.

TNM Classification: Prostate Cancer

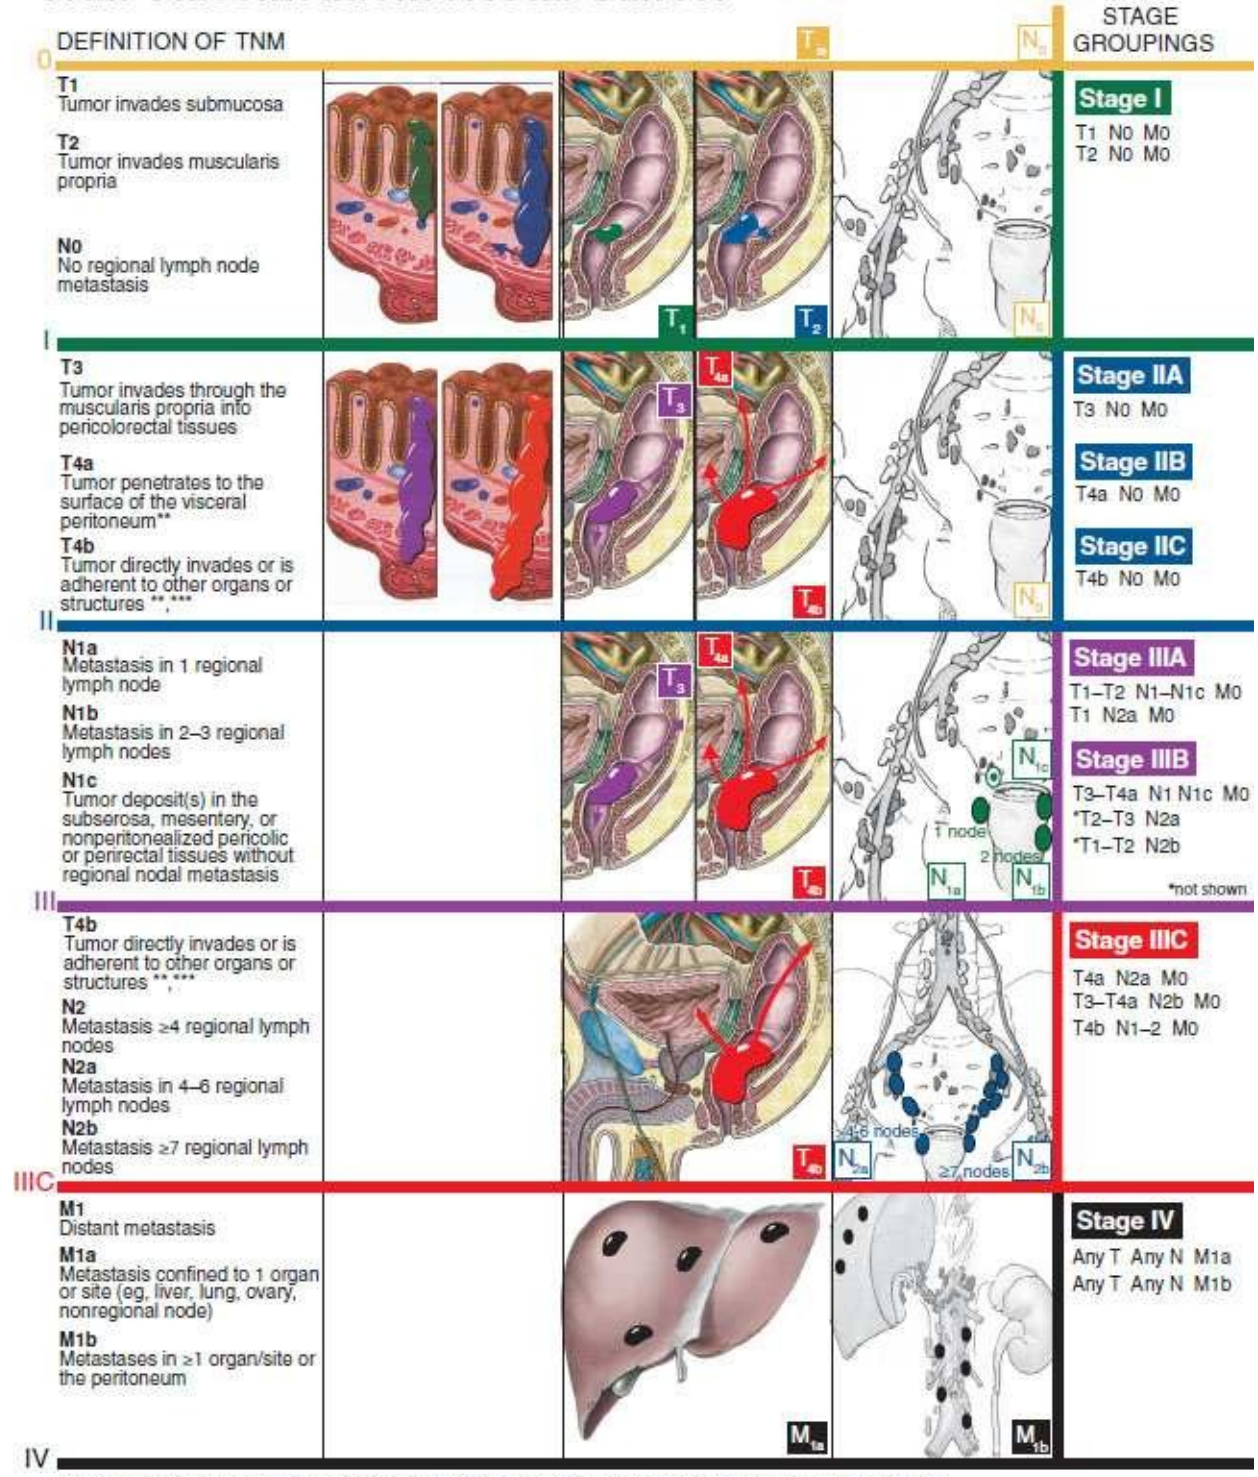
Note: Prostate cancer can be staged clinically (eg: cT1b) or pathologically (eg: pT2b). Pathologic and clinical staging are similar except that there is no pathological T1 stage.

DEFINITION OF TNM	PSA		GLEASON	STAGE GROUPINGS
T1 Clinically inapparent tumor neither palpable nor visible by imaging (T1a) Tumor incidental histologic finding in 5% or less of tissue resected (T1b) Tumor incidental histologic finding in more than 5% of tissue resected (T1c) Tumor identified by needle biopsy (eg, because of elevated PSA) **N0** No regional lymph node metastasis **G1** - Well differentiated (Gleason 2–4)	<10			**Stage I** T1a–c N0 M0 G1 T2a N0 M0 G1 T1–2a N0 M0 GX
T2 Tumor confined within prostate* (T2a) Tumor involves one-half of one lobe or less (T2b) Tumor involves more than one-half of one lobe but not both lobes (T2c) Tumor involves both lobes **G2** Moderately differentiated (moderate anaplasia Gleason 5–6) **G3–4** Poorly differentiated/undifferentiated (marked anaplasia Gleason 7–10)	<20			**Stage IIA** T1a N0 M0 G2, 3–4 T1b N0 M0 Any G T1c N0 M0 Any G T2a N0 M0 Any G T2b N0 M0 Any G **Stage IIB** T2c N0 M0 Any G T1-2 N0 M0 Any G
T3 Tumor extends through the prostate capsule** (T3a) Extracapsular extension (unilateral or bilateral) (T3b) Tumor invades seminal vesicle(s) **N0** No regional lymph node metastasis	>20			**Stage III** T3 N0 M0 Any G
T4 Tumor is fixed or invades adjacent structures other than seminal vesicles such as external sphincter, rectum, bladder, levator muscles, and/or pelvic wall **N0** No regional lymph node metastasis **N1** Metastasis in regional lymph node(s) **M0** No distant metastasis	any			**Stage IV** T4 N0 M0 Any G Any T N1 M0 Any G Any T Any N M1 Any G
M1 Distant metastasis (M1a) Nonregional lymph node(s) (M1b) Bone(s) (M1c) Other site(s) with or without bone disease *Note: when more than 1 site of metastasis is present, the most advanced category is used. pM1c is most advanced.	any			**Stage IV**

*Note: Tumor found in 1 or both lobes by needle biopsy, but not palpable or reliably visible by imaging, is classified as T1c.
**Note: Invasion into the prostatic apex or into (but not beyond) the prostatic capsule is classified not as T3 but as T2.

From Rubin P, Hansen JT, eds. *TNM Staging Atlas with Oncoanatomy*. 2nd ed. Philadelphia: Lippincott Williams & Wilkins; 2012, 425.

TNM Classification: Rectal Cancer



**Note: Direct invasion in T4 includes invasion of other organs or other segments of the colorectum as a result of direct extension through the serosa, as confirmed on microscopic examination (for example, invasion of the sigmoid colon by a carcinoma of the cecum) or, for cancers in a retroperitoneal or subperitoneal location, direct invasion of other organs or structures by virtue of extension beyond the muscularis propria (ie, respectively, a tumor on the posterior wall of the descending colon invading the left kidney or lateral abdominal wall; or a mid or distal rectal cancer with invasion of prostate, seminal vesicles, cervix, or vagina).

***Note: Tumor that is adherent to other organs or structures, grossly, is classified cT4b. However, if no tumor is present in the adhesion, microscopically, the classification should be pT1–4a depending on the anatomical depth of wall invasion. The V and L classifications should be used to identify the presence or absence of vascular or lymphatic invasion whereas the PN site-specific factor should be used for perineural invasion.

URORADIOLOGY SIGNS (See also Section II: "Uroradiology Signs")

Sign (Typical Modality)	Description	Diagnosis
Arterial cut-off sign (CT or MR w/contrast)	Abrupt termination of contrast material within the renal artery	Renal artery obstruction from thrombosis, embolus or dissection from trauma
Ball-on-Tee, Lobster Claw, signet ring (XR, retrograde urography)	Patterns of renal papillary excavation; signet ring occurs when the necrotic papillary tip remains in the pelvis and then it is filled with contrast material (acts as the "stone" for the ring)	Papillary necrosis (nonsteroidal anti-inflammatory drugs [NSAIDs], sickle cell anemia, analgesic nephropathy, Infection-TB, and diabetes mellitus)
Balloon on a string (XR)	High exit point of ureter from a dilated renal pelvis (can be seen with hydronephrotic rim sign, crescent sign, or on its own)	Ureteropelvic junction obstruction
Bear's paw (CT)	Dilated multiloculated appearing renal calyces with contracted renal pelvis (in setting of obstructing stone)	Diffuse xanthogranulomatous pyelonephritis
Bullet on a Bodkin (XR, CT)	Encasement of the ureter; dilated ureter (the bullet) on top of the smaller encased ureter (the bodkin)	Metastatic disease, extension from an adjacent tumor, lymphoma, or retroperitoneal fibrosis
Cobra head sign (XR)	Dilatation of the distal ureter that is surrounded by a thin lucent line	Orthotopic ureteroceles
Cobweb (CT)	Exaggerated appearance of perirenal septa	Multiple disease processes but commonly seen in acute ureteral obstruction from stones
Coiled catheter sign (XR)	Related to goblet sign: Dilated ureteral segment provides a space for catheter to coil within	Urothelial carcinoma
Comet sign (CT)	Focal density with adjacent, tapering, noncalcified "tail"	Phlebolith
Concentric ring sign—aka Target sign (MR, best T1 weighted)	Rings of hyper and hypointensity within a hematoma (inner bright ring signifies hemoglobin degradation)	Renal hematoma present for greater than 3 wk
Corkscrew ureter (XR)	Healing stages of tuberculosis involving the ureter	Late ureteral tuberculosis
Crescent sign (CT w/contrast)	Concentrated contrast material in collecting tubules, parallel to a dilated calyx	Prolonged, incomplete obstruction of collecting system. (Typically indicates that renal function is still recoverable upon relief of the obstruction)
Dromedary hump (any modality)	A pseudomass appearing in the left kidney, that is drained by a normal collecting system element	Normal variant of kidney is molded by the adjacent spleen creating a protrusion that can be mistakenly identified as a mass
Drooping lily sign (XR)	Dilated upper moiety ureter in a duplicated system that places downward and/or lateral pressure on the functional lower moiety	Completely duplicated system with an obstructed upper moiety

Angio, angiography; CT, computed tomography; MR, magnetic resonance imaging; XR, plain x-ray; IVP or retrograde pyelogram.

Sign (Typical Modality)	Description	Diagnosis
Faceless kidney (any modality)	Normal renal parenchyma, lacking central renal sinus structures (duplicated system) OR any edema that eliminates the typical appearance of the kidney	Renal duplication (slice in between duplicated systems); edema obliterating normal kidney appearance can signify any inflammatory condition or infiltrative condition such as lymphoma or renal cell carcinoma
Fragmented staghorn (XR)	Disrupted densities following the outline of the renal pelvis; usually associated with renal enlargement	Pyonephrosis or Xanthogranulomatous pyelonephritis
Goblet sign (Retrograde XR)	Ureteral dilatation below an intraluminal filling defect; usually a chronic process	Urothelial cell carcinoma; less likely metastatic disease or endometriosis
Growing calculus sign (XR)	Apparent enlargement of medullary calcifications contained in ectatic tubules pre- and postcontrast administration	Medullary nephrocalcinosis caused by medullary sponge kidney
Horseshoe	Kidneys joined by a lower pole isthmus that crosses anterior to the aorta, just inferior to the Inferior mesenteric artery	Most common congenital fusion abnormality of the kidney (Horseshoe kidney)
Hydronephrotic rim sign (CT or MR w/contrast)	Variable enhancement of residual but atrophic renal parenchyma surrounding dilated renal pelvis and calyces (inner margin of rim is concave toward hilum, can also have enhancement of cortical columns)	Chronic hydronephrosis
Keyhole sign (US)	Thick bladder wall and dilated posterior urethra	Posterior urethral valves
Kidney sweat (US, CT, MR)	Extracapsular hypoechoic rim of fluid around kidney (perirenal edema)	Renal failure
Loop-to-loop colon	Transverse colon extends lateral to abdominal wall, descending colon then courses medially to fill renal fossa creating a loop of colon	Renal agenesis
Lying down (pancake) adrenal gland	Typical shape of adrenal gland is dependent on kidney; when kidney absent, the adrenal gland (when present) can assume a flattened appearance	Renal agenesis
Maiden waist deformity (XR)	Medial deviation of bilateral ureters; ureters are drawn toward each other in the lumbosacral region	Retroperitoneal fibrosis
Mulberry (XR)	Density in the urinary system with less developed spikes (mamillated appearance)	Calcium oxalate dihydrate stone
Pear sign (XR, CT)	Symmetric compression of the bladder	Pelvic fluid (hematoma, lymphocele, urinoma, abscess), pelvic lipomatosis, vascular dilatation from aneurysms or collateral vessels, lymph node enlargement or psoas hypertrophy
Phantom calyx sign (XR)	No identifiable collecting system element where one should be seen	Inflammation (tuberculosis, acute pyelonephritis), neoplasm, stricture from trauma and/or stone passage, ischemia, congenital anomaly, renal contusion or technical error of underfilling

Angio, angiography; CT, computed tomography; MR, magnetic resonance imaging; XR, plain x-ray; IVP or retrograde pyelogram.

Sign (Typical Modality)	Description	Diagnosis
Pie-in-the-sky sign (XR)	High position of contrast opacified bladder in pelvis	Pelvic hematoma from pelvic trauma; high suspicion of urethral injury
Pipestem ureter	Ureter is straight and rigid	Ureteral tuberculosis
Putty kidney	Calcifications outlining the entire, or close to the entire kidney	Genitourinary tuberculosis (end-stage finding in kidney)
Reverse rim sign (CT or MR w/contrast)	Hypoattenuating renal cortex with medullary enhancement	Disruption of cortical blood flow with development of cortical necrosis. Can be caused by shock, intravascular hemolysis, toxins, and rejection in transplanted kidney
Rim sign of vascular compromise (CT or MR w/contrast)	Rim of subcapsular enhancement	Renal artery obstruction from thrombosis, embolus or dissection from trauma (most commonly). Renal vein thrombosis and acute tubular necrosis (less commonly)
Sawtooth ureter	Dilatation and ragged irregularity of the ureter	Early ureteral tuberculosis
Soft-tissue rim sign (CT)	Focal density with surrounding edema of ureteral wall	Ureteral stone; usually impacted; may be absent with stones >4 mm or when at UVJ. Can help distinguish stone from phlebolith as it is uncommon for phlebolith to have soft tissue rim
Spaghetti sign (XR, CT)	Linear filling defect within the bladder	Gross hematuria; this sign implies blood has come from above the bladder (ureter acts as a mold for the blood clot)
Spoked wheel pattern (US, CT, MR)	Peripheral "rim" vessel branching into centripetal "spoke" vessels within a mass; can have a central area of decreased perfusion (central scar)	Renal cell carcinoma; oncocytoma
Spotted nephrogram (CT or MR w/contrast, renal angio)	Patchy irregular enhancement of the renal parenchyma	Small vessel occlusion, caused by scleroderma, hypertensive nephrosclerosis, or periarteritis nodosa
Staghorn (XR)	Branching radiopaque densities following the outline of the renal pelvis	Renal calculus that fills the entire renal collecting system, forming a cast of the renal pelvis
Stipple sign (XR)	Contrast material trapped between the papillary projections of urothelial cell carcinoma	Urothelial cell carcinoma, best seen in large papillary bladder tumors
String of pearls (Angio)	Arteries with thickened ridges, alternating with wall thinning and aneurysm formation	Fibromuscular dysplasia
Thimble bladder	Thick wall of calcification in the bladder that reduces its capacity	Tuberculosis of the bladder
Threads and streaks sign (Angio, CT, MR)	Linear string/thread-like vessels supplying the intravascular tumor in the affected vasculature	Vascularized tumor thrombus extending into the renal vein or IVC
Toy jacks (XR)	Spiked density in the urinary system	Calcium oxalate dihydrate stone
Tramline or railroad track calcifications	Thin rims of dystrophic calcifications on both sides of renal cortex	Renal cortical necrosis (most commonly). Glomerulonephritis, hyperoxaluria, Alport syndrome (less common)

Angio, angiography; CT, computed tomography; MR, magnetic resonance imaging; XR, plain x-ray; IVP or retrograde pyelogram.

Based on select data from Dyer RB, Chen MY, Zagoria RJ. Classic signs in uroradiology. *Radiographics.* 2004;24:S247–S280.

Voiding Diary

(See also Section II: "Voiding Diary (Frequency Volume Chart (FVC])." This form is meant to be completed by the patient.)

This voiding diary records your amount of fluid intake, amount you void and if there is any leakage of urine. It should be completed for an entire 24-hr period. For the most useful results, it should be done over 2 or 3 separate 24-hr periods. You must measure and complete this form every time you void or experience urinary leakage. Please bring these voiding diary records to your next Urology office visit. Copy additional pages if needed.

How to complete this form:

1. Begin the record with your first morning void after you wake up for the day.
2. Measure all fluid intake and the amount voided in mL or ounces. Ladies can measure the amount of urine by placing a plastic bowl or collection container that we can provide to you on the toilet seat. Men can void into a suitable collection jar or other container.
3. If you experience sudden leakage of urine, note the activity you were doing at the time of leakage (laughing, coughing, sneezing, lifting, etc.).
4. If you experience urinary leakage, use the following scale to estimate the amount of urine that you leaked:

    1 = Dampness
    2 = Wet underwear or pad
    3 = Soaked through or emptied bladder

5. Indicate by **Yes/No** if when you leaked you had an urge to void. FVC

Your Name: ______________________________ **Date:** ____________________________

Your Physician's Name: ____

Time (AM or PM)	**Fluid Intake** (Type and amount in ounces or mL)	**Amount Voided** (In ounces or mL)	**Leak Volume** (See above for estimate)	**Did you have an urge with leakage?** (Yes/No)	**Physical activity at time of leakage**
