- Zhao, H.X., D.C. Yang, C.R. Woese and M.P. Bryant. 1993b. Assignment of fatty acid-beta-oxidizing syntrophic bacteria to *Syntrophomonadaceae* fam. nov. on the basis of 16S ribosomal RNA sequence analyses. Int. J. Syst. Bacteriol. 43: 278–286.

Family X. *Veillonellaceae* Rogosa 1971b, 232^{AL}

FRED A. RAINEY

Veil.lo.nel.la'ce.ae. N.L. fem. n. *Veillonella* type genus of the family; *-aceae* ending to denote family; N.L. fem. pl. n. *Veillonellaceae* the *Veillonella* family.

The family *Veillonellaceae* can be described on the basis of phylogenetic analyses of 16S rRNA gene sequences (Figure 199); the family contains the genera *Veillonella* (type genus), *Acetonema*, *Acidaminococcus*, *Allisonella*, *Anaeroarcus*, *Anaeroglobus*, *Anaeromusa*, *Anaerosinus*, *Anaerovibrio*, *Centipeda*, *Dendrosporobacter*, *Dialister*, *Megasphaera*, *Mitsuokella*, *Pectinatus*, *Pelosinus*, *Phascolarctobacterium*, *Propionispira*, *Propionispora*, *Quinella*, *Schwartzia*, *Selenomonas*, *Sporomusa*, *Sporotalea*, *Succiniclasticum*, *Succinispira*, *Thermosinus* and *Zymophilus*. The genera *Pelosinus* and *Sporotalea* were proposed after finalization of the content of this volume and are not described here (see Boga et al. (2007); Shelobolina et al. (2007)).

Members of the family are Gram-stain-negative, morphologically diverse and include short rods, curved rods, pleomorphic rods, cocci and vibrioid forms. All species are obligate anaerobes.

Type genus: Veillonella Prévot 1933, 118^{AL}.

Taxonomic comments

The family *Veillonellaceae* was described by Rogosa (1971b) to accommodate the genera *Veillonella*, *Acidaminococcus* and

Megasphaera. The genera *Veillonella* and *Acidaminococcus* had previously been placed in the family *Neisseriaceae* (Prévot, 1933; Rogosa, 1969). The family description was very specific and based on the characteristics of the three genera assigned to it (Rogosa, 1971b). These properties included coccoid morphology, lack of endospores, nonmotile, chemo-organotrophy and parasites of homothermic animals (Rogosa, 1971b). As new genera have been described and shown by phylogenetic analysis to fall within the radiation of the three genera that had been assigned to the family *Veillonellaceae* the characteristics and thus the description of the family broadened so that many of the family characteristics defined by Rogosa (1971b) were no longer applicable. The emended family description given above is broad to include the diverse characteristics of the organisms of the family *Veillonellaceae*. More specific details of the characteristics of the members of the family *Veillonellaceae* are found in the chapters describing these taxa in this volume.

Genus I. *Veillonella* Prévot 1933, 118^{AL} emend. Mays, Holdeman, Moore, Rogosa and Johnson 1982, 35

JEAN-PHILIPPE CARLIER

Veil.lo.nel'la. N.L. dim. suff. *-ella*; N.L. fem. n. *Veillonella* named after Adrien Veillon, the French microbiologist who isolated the type species.

Cocci, 0.3–0.5 µm in diameter; cells are usually arranged in pairs, masses, or short chains. Stains **Gram negative**. Nonmotile, nonsporeforming. **Anaerobic**. Optimum temperature, 30–37°C. Optimum pH, 6.5–8.0. Oxidase negative. **Nitrate is reduced**. Some species produce an atypical catalase lacking porphyrin. **Gas is produced by most strains. Pyruvate, lactate, malate, fumarate, and oxaloacetate are fermented. Carbohydrates and polyols are not fermented by most strains.** Major metabolic end products in trypticase-glucose-yeast extract (TGY, see below) broth are **acetic and propionic acids**. In addition, **CO₂ and H₂** are produced from lactate (Rogosa, 1964). Resident of oral cavity, genito-urinary, respiratory, and intestinal tracts of humans and animals, but can also cause severe human infections such as bacteremia, endocarditis, osteomyelitis, and prosthetic joint infection.

DNA G+C content (mol%): 36–43 (*T_m*) or 40–44 (Bd).

Type species: Veillonella parvula (Veillon and Zuber 1898) Prévot 1933, 119^{AL} (*Staphylococcus parvulus* Veillon and Zuber 1898, 542).

Further descriptive information

The genus *Veillonella* is represented by 10 species.

Morphology and ultrastructure. They are small, nonmotile, nonsporeforming organisms. Ultrastructure of thin sections viewed by electron microscopy reveal typical Gram-negative surface layers consisting of an outer membrane composed of two dense layers 3 nm wide separated by a less dense layer of

2 nm, a thin peptidoglycan layer, and a cytoplasmic membrane (Figure 200). By negative staining, the outer membrane appears extremely convoluted, whereas the peptidoglycan layer tightly follows the periphery of the protoplasm (Bladen and Mergenhagen, 1964).

Colonial characteristics. Colonies on blood agar are 1–3 mm in diameter and appear smooth, opaque, and grayish-white. Nonhemolytic. *Veillonella*, unlike *Acidaminococcus*, *Anaeroglobus*, and *Megasphaera*, exhibits a pink to red fluorescence on brain heart infusion agar (BHI) containing either sheep or horse blood (Brazier and Riley, 1988). Fluorescence appears under UV light at 366 nm and fades rapidly after 5–10 min of exposure to air. However, the reaction depends upon the medium and varies among the species. The fluorescent pigment is a porphyrin.

Nutrition and metabolism. The species of *Veillonella* are not clearly distinguished by their phenotypic characteristics. Most species, except *Veillonella criceti* and an unidentified phylogenetically related strain (Marchandin et al., 2005), are unable to ferment carbohydrates or amino acids (Rogosa, 1964). Some strains require putrescine or cadaverine (Rogosa and Bishop, 1964a). H₂S is produced from cysteine, cystine, glutathione, thiosulfate, thiocyanate, and thioglycolate (Rogosa and Bishop, 1964b). Indole is not produced; gelatin is not liquefied. Lactate enhances the growth with accompanying production of acetic and propionic acids, CO₂, and H₂. Rogosa and Bishop (1964b)

reported that succinate is metabolized by resting cells, whereas the organisms cannot grow with succinate as an energy source in basal medium. However, most strains of *Veillonella* species ferment succinate naturally present within TGY broth. In addition, when succinate is added to trypticase-yeast extract broth, it is metabolized to propionate. In fact, succinate is co-metabolized with lactate, and the decarboxylation energy is mainly used for nongrowth purposes (Samuelov et al., 1990).

About 34% of strains are catalase positive, and 99% of strains are susceptible to kanamycin and colistin special-potency antibiotic disks (Jousimies-Somer et al., 1999). Resistance to colistin has been observed for *Veillonella montpellierensis*, the type strain of *Veillonella ratti* (Jumas-Bilak et al., 2004), and an unidentified phylogenetically related strain (Marchandin et al., 2005).

Major metabolic end products from TGY broth are acetic and propionic acids, which are produced in approximately equal quantities.

Fatty acid composition. Major cellular fatty acids are C^{13:0} and C^{17:1} ω⁸. Minor cellular fatty acids include C^{11:0}, C^{12:0}, C^{14:0}, C^{15:0}, C^{16:1} ω^{9c}, C^{16:0}, C^{17:0}, C^{18:1} ω^{9c}, C^{18:0}. Other compounds are present in trace amounts (Table 201).

Genetics. *Veillonella* species can be differentiated by DNA-DNA hybridization (Mays et al., 1982), 16S rRNA gene sequence comparison (Figure 201), and restricted fragment-length polymorphism (RFLP) analysis of 16S rRNA genes (Sato et al., 1997). However, the utility of the last two methods is limited by the low level of sequence variation among some *Veillonella*

^aFatty acid nomenclature: unsaturated fatty acids, the position of the double bond can be located by counting from the methyl (ω) end of the carbon chain; OH, hydroxylated fatty acids; *cis*, *trans* isomers are indicated by the suffix *c* and *t*, respectively.

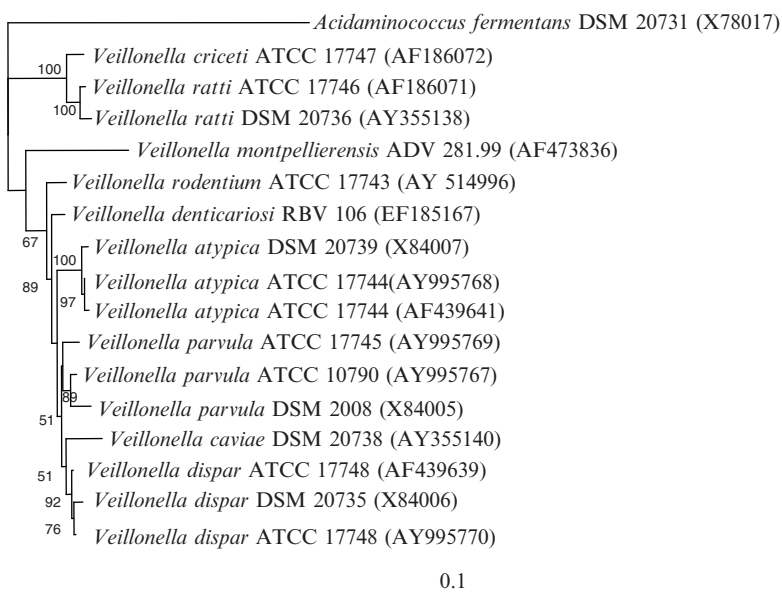

FIGURE 201. Phylogeny of *Veillonella* species. The phylogenetic relationships of all sequences of type strains of the genus *Veillonella* available from public databases are shown above. The sequence of *Acidaminococcus fermentans* DSM 20731 was used as an outgroup. Bar = 10% difference in 16S rRNA gene sequences. The neighbor-joining method was used for tree construction. One hundred bootstrap trees were generated, and bootstrap confidence levels are shown as percentages on the nodes.

species and the frequent intrachromosomal heterogeneity between copies of the 16S rRNA genes in human isolates (Marchandin et al., 2003c). Four 16S ribosomal operons are present in reference strains of *Veillonella parvula*, *Veillonella dispar*, *Veillonella atypica*, and 27 clinical isolates. The variability observed between these operons is higher than that between the 16S rRNA gene sequences of *Veillonella parvula* and *Veillonella dispar*. Thus, 16S rDNA-based methods may be not suitable for the identification of these species. A similar situation occurs within the type strains of *Veillonella ratti* and *Veillonella criceti* which form a very tight phylogenetic group. Thus, analyses of 16S rRNA gene sequences can not identify species within this group (Marchandin et al., 2005). The limitations of 16S rRNA gene sequence analyses within *Veillonella* and related genera caused by the variability of the 16S rRNA operons have been reviewed in detail (Marchandin and Jumas-Bilak, 2006). The 70 kDa heat-shock protein gene (*dnaK*) is suggested to be an effective alternative for discriminating between species because of its higher interspecies variability.

The G + C values for the DNA are 36–43 mol%; the majority clustering around 39 mol% when tested by the thermal denaturation method (Mays et al., 1982).

Genomic structure. The genome of *Veillonella* species consists of one circular chromosome of 2.15 Mb (Marchandin et al., 2003a).

Plasmids and bacteriophages. Plasmids have been found in about 50% of the human oral strains. Their molecular sizes range from 1.1 to 28 MDa (Arai et al., 1984). Mays et al. (1982) have suggested that the fructose fermentation by some strains of *Veillonella criceti* may be associated with the presence of a plasmid.

A temperate bacteriophage specific for genus *Veillonella* has been reported (Shimizu, 1968). In addition, 25 virulent phages were isolated from washings of the oral cavity of 200 individuals (Hiroki et al., 1976; Totsuka, 1976). These phages were classified into two major groups on the basis of their morphology and serological characteristics. Seven phages infected strain ATCC 17743, now classified as *Veillonella rodentium*. The lipopolysaccharide of *Veillonella rodentium* ATCC 17743 acts as receptor for one of the bacteriophages (Totsuka, 1988; Totsuka and Ono, 1989).

Antibiotic susceptibility. *Veillonella* species are considered susceptible to ampicillin (0.12–4 µg/ml), amoxicillin/clavulanic acid (0.06–2 µg/ml), piperacillin/tazobactam (0.12–32 µg/ml), cefoxitin (0.12–8 µg/ml), cefotetan (0.12–2 µg/ml), ceftriaxone (0.12–8 µg/ml), imipenem (0.06–1 µg/ml), meropenem (0.06–0.12 µg/ml), clindamycin (0.06–0.12 µg/ml), bacitracin (1–4 units/ml), and metronidazole (0.5–4 µg/ml) and are resistant to ramoplanin (512 µg/ml), trimethoprim/sulfamethoxazole (8–256 µg/ml), and vancomycin (32–256 µg/ml) (Finegold et al., 2004; Roberts et al., 2006).

In the first edition of *Bergey's Manual of Systematic Bacteriology* (Rogosa, 1984b), veillonellae are considered susceptible to penicillin G. However, based on the National Committee for Clinical Laboratory Standards (NCCLS, now called Clinical and Laboratory Standards Institute) recommendations (National Committee for Clinical Laboratory Standards, 2003), most strains should be considered resistant. Several studies have

shown that a large population of *Veillonella* species is penicillin resistant with MIC over 2 µg/ml (the breakpoint for susceptibility according to NCCLS criteria). Resistance to amoxicillin and penicillin has also been reported for *Veillonella dispar* and *Veillonella parvula* (Ready et al., 2004). In another study on 40 clinical strains tested by agar dilution method, 80% were found resistant to penicillin (Reig et al., 1997). The strains for which penicillin MICs were >8 µg/ml were also less susceptible to ampicillin and cefoxitin (MIC >0.25 µg/ml and >1 µg/ml, respectively). The mechanism involved in high levels of penicillin resistance in *Veillonella* remains to be elucidated. Although occasional strains of *Veillonella parvula* produce β-lactamase (Valdes et al., 1982), the main resistance mechanism of veillonellae may be due to alterations in a penicillin-binding protein (Theron et al., 2003).

Antibiotic resistance genes. Tetracycline resistance (Tcr) genes are present within about 10–12.5% of *Veillonella* species isolated from the oral cavity (Lancaster et al., 2005, 2003; Ready et al., 2006). Five different Tc^r genes have been detected: *tetA*, *tetL*, *tetM*, *tetO*, and *tetS*. The most common is *tetM*, followed by *tetS*. Some strains harbor two Tc^r genes (Ready et al., 2006). The *tetM* gene is located on a Tn916-like element.

A nitroimidazole resistance gene (*nimE*) is present in a metronidazole-susceptible *Veillonella* species (Marchandin et al., 2004). This gene is probably located on a low copy number plasmid which can explain the susceptibility observed.

Pathogenicity. Veillonellae are commensals in the oropharynx, gastrointestinal tract, and uro-genital tract of humans and animals. Of the ten recognized species, only *Veillonella parvula*, *Veillonella dispar*, *Veillonella atypica*, *Veillonella denticariosi*, and *Veillonella montpellierensis* have been isolated from humans. However, a strain genetically closely related to the *Veillonella criceti*–*Veillonella ratti* group has been isolated from a human clinical specimen (Marchandin et al., 2005). Veillonellae are implicated in several systemic diseases such as meningitis (Bhatti and Frank, 2000), bone infections (Isner-Horobeti et al., 2006; Singh and Yu, 1992), prosthetic joint infections (Marchandin et al., 2001; Zaninetti-Schaerer et al., 2004), endocarditis (Boo et al., 2005; Houston et al., 1997; Rovey et al., 2005), bacteremia (Liu et al., 1998), and in various infections in children (Brook, 1996).

Pathogenicity in animals is unknown.

Virulence factors. Mergenhagen et al. (1961) established that a phenol-water extract of *Veillonella* cells exhibited biological and immunological activities characteristic of endotoxins and that this water-soluble material was composed mainly of lipid and polysaccharide. The lipid moiety accounting for approximately two-thirds of the complex contains glucosamine, tridecanoic acid, 3-hydroxytridecanoic acid and 3-hydroxypentadecanoic acid. (Hewett et al., 1971; Tortorello and Delwiche, 1984). Tridecanoic acid and 3-hydroxytridecanoic acid represent about 50% of the total lipopolysaccharide fatty acids (Bishop et al., 1971). The polysaccharide moiety contains 2-keto-3-deoxyoctonic acid (KDO), glyceromannoheptose, galactose, rhamnose, glucose, and glucosamine. (Hewett et al., 1971; Hofstad and Kristoffersen, 1970). However, other hexoamines may be present (Hewett et al., 1971). The *Veillonella* LPS is highly endotoxic. Sveen showed that *Veillonella* LPS induces

skin inflammation and the Schwartzman phenomenon in rabbits (Sveen, 1977). Moreover, phenol-water extracted lipopolysaccharide is lethal at nanogram levels for mice, chick embryos, pyrogenic in rabbits, and gelated *Limulus* amoebocyte lysate. The endotoxin activity of *Veillonella* LPS is comparable to that from *Fusobacterium* and *Salmonella enteritidis* (Sveen et al., 1977). LPS from both *Veillonella parvula* and *Veillonella atypica* reduce microbial activity of human neutrophils but do not affect monocyte function (Focà et al., 1990).

Ecology. Veillonellae colonize the human mouth within the three first months of life (Kononen et al., 1992). The colonization is not dependent on the presence of erupted teeth (Kononen et al., 1999). The organisms persist in the oral flora, and *Veillonella* species remain the dominant anaerobic bacteria in the saliva of elderly edentulous persons (Sato et al., 1993). Dental plaque, buccal mucosa, and the tongue are the main ecological niches of *Veillonella* species.

During the plaque development, the dominant strains of *Veillonella* change in their phenotypic and genotypic characteristics (Palmer et al., 2006). Within the oral cavity, *Veillonella* species form coaggregates with many other bacteria (Hughes et al., 1988). Coaggregation promotes formation of mixed-species bacterial colonies between veillonellae and other oral bacteria. Both the rapid succession within the *Veillonella* population and coaggregation are important processes in establishment of a stable oral ecosystem (Hughes et al., 1988; Palmer et al., 2006).

Enrichment and isolation procedures

Veillonellae can be isolated by streaking samples onto Columbia or Wilkins-Chalgren sheep-blood agar and incubating at 37°C for 2 d. Lactate agar medium containing vancomycin (7.5 µg/ml) favors isolation. Strict anaerobic conditions are required for growth.

Maintenance procedures

Strains may be maintained in trypticase-glucose-yeast extract (TGY) medium (Carlier et al., 2002) under anaerobic conditions as described above. Cultures of veillonellae will usually survive for no longer than 1 week without subcultivation. Strains in the exponential growth stage in BHI or TGY broth can be stored at -80°C or in liquid nitrogen. Cells suspended in skim milk can be successfully lyophilized.

Differentiation of the genus *Veillonella* from closely related taxa

The differentiation of the genus *Veillonella* from other genera of anaerobic Gram-negative cocci can be done primarily on the basis of poor growth with gas formation on the usual media (except for *Veillonella denticariosi* which does not produce gas), nitrate reduction, and lactate fermentation. Other characteristics are given in Table 201 of the chapter describing the genus *Anaeroglobus*.

Upon routine laboratory examination, *Veillonella* is frequently misidentified as *Dialister*, a tiny Gram-negative rod. Nevertheless, a positive nitrate reaction and production of large amounts of propionic acid are the key features differentiating *Veillonella* species from most *Dialister* species which are negative for these tests. Although *Dialister propionificiens* produces

small amounts of propionic acid, it does not reduce nitrate to nitrite. Upon misinterpretation of the Gram reaction, *Parvimonas micra*, which is a very small anaerobic Gram-positive coccus, can also be misidentified as *Veillonella*. *Parvimonas micra* does not produce propionic acid and does not reduce nitrate.

Taxonomic comments

The type species of the genus *Veillonella* was first isolated by Veillon and Zuber in 1898 and designated *Staphylococcus parvulus*. Prévot (1933) further described these bacteria and proposed the genus *Veillonella*, with two species, *Veillonella parvula* and *Veillonella alcalescens*. He placed the new genus in the family *Neisseriaceae*. Based on serological reactions, Rogosa (1965) divided veillonellae into seven distinct subspecies, which were subsequently shown to be species by DNA-DNA hybridization (Mays et al., 1982; Rogosa, 1984b). In 1971, the genus *Veillonella* was excluded from the family *Neisseriaceae* and transferred into the new family *Veillonellaceae* (Rogosa, 1971b). Subsequently, it was proposed to include the genus *Veillonella* in a new family "*Acidaminococcaceae*" (Garrity and Holt, 2001). The family "*Acidaminococcaceae*" was created to include members of the *Firmicutes* or low G + C Gram-positive bacteria that possessed a Gram-negative type of cell wall. *Acidaminococcus* was selected as the type genus. However, the placement of the genus *Veillonella* (Prévot, 1933) in the family "*Acidaminococcaceae*" is not in accordance with the Rules 23a and 56a of the International Code of Nomenclature of Bacteria (1990 Revision) (Lapage et al., 1992). Moreover, the name *Veillonellaceae* has priority over "*Acidaminococcaceae*". Therefore, in the current volume, the family "*Acidaminococcaceae*" is not used, and the family *Veillonellaceae* is retained.

Today, the identification of *Veillonella* at the species level remains difficult. Because of the lack of phenotypic criteria, the commonly used biochemical tests are useless. Serological tests (Rogosa, 1965) are no longer available. DNA-DNA hybridization (Mays et al., 1982), which seems to be a good method, is laborious, difficult to interpret and therefore not well-suited for routine identification. Molecular genetic methods, such as RFLP analysis and 16S rRNA sequencing, are valuable means to distinguish some species (Kolenbrander, 2006). However, these methods, though helpful, are not absolute. There is doubt as to whether *Veillonella parvula* and *Veillonella dispar* (Marchandin et al., 2003c; Palmer et al., 2006) as well as *Veillonella criceti* and *Veillonella rattii* (Marchandin et al., 2005) are truly separate species. Alternative molecular markers to 16S rRNA, such as other housekeeping genes, could clarify these interspecies relationships. For instance, three highly conserved genes, *rpoB*, *dnaK*, and *gyrB*, had greater discriminatory power than the 16S rRNA gene in differentiating between *Veillonella* strains. Of these, the *rpoB* gene showed the highest level of interspecies but the lowest intraspecies diversity (Byun et al., 2006). Thus, multilocus Sequencing Typing (MLST) of highly conserved genes could be an attractive method to differentiate *Veillonella* species (Stackebrandt et al., 2002).

Acknowledgements

I would like to thank H el ene Marchandin for her critical reading of this chapter and providing the transmission electron micrographs and Jean Euz eby for his advice on etymology.

List of species of the genus *Veillonella*

1. ***Veillonella parvula*** (Veillon and Zuber 1898) Prévot 1933, 119^{AL}. (*Staphylococcus parvulus* Veillon and Zuber 1898, 542) par'vu.la. L. fem. dim. adj. *parvula* very small.
The characteristics are as described for the genus. Some strains of *Veillonella parvula* can grow aerobically in static culture on lactate (Kolenbrander, 2006). The type strain of *Veillonella parvula* subsp. *parvula* ATCC 10790 has been found to have 74% homology with type strain of *Veillonella alcalescens* subsp. *alcalescens* ATCC 17745 and, therefore, they were considered as synonyms (Mays et al., 1982). *Veillonella parvula* has priority.
Antigenic properties: serogroup VI (*Veillonella parvula* subsp. *parvula*); serogroup IV (*Veillonella alcalescens* subsp. *alcalescens*) (Rogosa, 1965).
Pathogenicity: *Veillonella parvula* has been associated with osteomyelitis, prosthetic valve endocarditis, and bacteremia. Two fatal cases of *Veillonella parvula* bacteremia have been reported (Liu et al., 1998). Isolated from oral cavity and intestinal tract of humans and rodents.
DNA G+C content (mol%): 37–40, mean 38 (T_m) and 41 (Bd).
Type strain: ATCC 10790, ATCC 17742, CCUG 5123, DSM 2008, JCM 12972, KCTC 5019, NCTC 11810, VPI 11221, Prévot Te 3, ATCC 17745, VPI 11224.
GenBank accession number (16S rRNA gene): AY995767, X84005 (*Veillonella parvula* subsp. *parvula*); AY995769 (*Veillonella parvula* subsp. *alcalescens*).
2. ***Veillonella atypica*** (Rogosa 1965) Mays, Holdeman, Moore, Rogosa and Johnson 1982, 35^{VP} (*Veillonella parvula* subsp. *atypica* Rogosa 1965, 707) a.ty'pi.ca. Gr. pref. *a* not; L. adj. *typicus -a -um* typical; N.L. fem. adj. *atypica* not typical.
The characteristics are as described for the genus.
Antigenic properties: Serogroups V and VI (Rogosa, 1965).
Pathogenicity: not reported; isolated from human saliva.
DNA G+C content (mol%): 36–40, mean 39 (T_m).
Type strain: ATCC 17744, DSM 20739, NCTC 11830, VPI 11220 (strain KON).
GenBank accession number (16S rRNA gene): AF439641, AY995768, X84007.
3. ***Veillonella caviae*** Mays, Holdeman, Moore, Rogosa and Johnson 1982, 35^{VP} ca.vi'a.e. N.L. gen. n. *caviae* of *Cavia*, the zoological genus name of the guinea pig.
The characteristics are as described for the genus.
Antigenic properties: Serogroup VIII (Rogosa, 1984b).
Pathogenicity: not reported; isolated from guinea pig mouth.
DNA G+C content (mol%): 37–39, mean 39 (T_m).
Type strain: ATCC 33540, DSM 20738, NCTC 12021, VPI 12140, Rogosa strain PV1.
GenBank accession number (16S rRNA gene): AY355140.
4. ***Veillonella criceti*** (Rogosa 1965) Mays, Holdeman, Moore, Rogosa and Johnson 1982, 35^{VP} (*Veillonella alcalescens* subsp. *criceti* Rogosa 1965, 708) cri.ce'ti. N.L. gen. n. *criceti* of *Cricetus*, the zoological genus name of the hamster.
The characteristics are as described for the genus. Nine out of ten strains fermented fructose (Rogosa, 1984b). A human clinical isolate phylogenetically closely related to *Veillonella criceti* and fermenting fructose has been reported (Marchandin et al., 2005).
Antigenic properties: Serogroup I (Rogosa, 1965).
Pathogenicity: not reported; isolated from hamster mouth.
DNA G+C content (mol%): 38–40, mean 39 (T_m).
Type strain: ATCC 17747, DSM 20734, VPI 11226, NCTC 12020, Rogosa strain HV1.
GenBank accession number (16S rRNA gene): AF186072.
5. ***Veillonella denticariosi*** Byun, Carlier, Jacques, Marchandin and Hunter 2007, 2847^{VP} den.ti.cari.o'si. L. n. *dens dentis* tooth; L. adj. *cariosus* rotten, decayed; N.L. gen. n. *denticariosi* of a decayed tooth.
Does not produce gas from TGY broth. Other characteristics are as described for the genus. Can be differentiated from other species of the genus *Veillonella* by 16S DNA and *dnaK* sequencing.
Pathogenicity: Isolated from human carious dentin.
DNA G+C content (mol%): unknown.
Type strain: RBV 106, CIP 109448, CCUG 54362, DSM 19009.
GenBank accession number (16S rRNA gene): EF185167.
6. ***Veillonella dispar*** (Rogosa 1965) Mays, Holdeman, Moore, Rogosa and Johnson 1982, 35^{VP} (*Veillonella alcalescens* subsp. *dispar* Rogosa 1965, 708) dis'par. L. fem. adj. *dispar* dissimilar, different.
The characteristics are as described for the genus.
Antigenic properties: Serogroup VII (Rogosa, 1965).
Pathogenicity: *Veillonella dispar* has been associated with prosthetic valve endocarditis and prosthetic joint infections. Isolated from mouth and respiratory tract of humans.
DNA G+C content (mol%): 38–40, mean 39 (T_m) and 42 (Bd).
Type strain: ATCC 17748, DSM 20735, NCTC 11831, VPI 11223, Rogosa strain ERN.
GenBank accession number (16S rRNA gene): AF439639, AY995770, X84006.
7. ***Veillonella montpellierensis*** Jumas-Bilak, Carlier, Jean-Pierre, Teyssier, Gay, Campos and Marchandin 2004, 1315^{VP} mont.pel.li.er.en'sis. N.L. fem. adj. *montpellierensis* pertaining to Montpellier, where the type strain and two other strains were isolated.
The characteristics are as described for the genus. Cells are coccoid (0.3–0.5 mm in diameter) and occur singly, in pairs, or in short chains. Colonies on Columbia blood agar are 1–3 mm in diameter and appear smooth, opaque, and grayish-white. Can be differentiated from other species of the genus *Veillonella* by 16S DNA and *dnaK* gene sequencing.
Pathogenicity: *Veillonella montpellierensis* has been isolated from the gastric fluid of a newborn and from the amniotic fluid of 2 women. Association with endocarditis has been reported (Roverly et al., 2005).

DNA G+C content (mol%): unknown.

Type strain: ADV 281.99, CCUG 48299, CIP 107992, DSM 17217.

GenBank accession number (16S rRNA gene): AF473836.

8. *Veillonella ratti* (Rogosa 1965) Mays, Holdeman, Moore, Rogosa and Johnson 1982, 35^{VP} (*Veillonella alcalescens* subsp. *ratti* Rogosa 1965, 708)

rat'ti. N.L. gen. n. *ratti* of *Rattus*, the zoological genus name of the rat.

The characteristics are as described for the genus.

Antigenic properties: Serogroup III (Rogosa, 1965).

Pathogenicity: not reported; isolated from rat mouth.

DNA G+C content (mol%): 41–43, mean 42 (T_m) and 44 (Bd).

Type strain: ATCC 17746, DSM 20736, VPI 11225, NCTC 12019, Rogosa strain RV-12X.

GenBank accession number (16S rRNA gene): AF186071, AY355138.

9. *Veillonella rogosae* Arif, Do, Byun, Sheehy, Clarke, Gilbert and Beighton 2007, 584^{VP}

rog.o.sae. N.L. gen. n. *rogosae* of Rogosa, named in honor of the American microbiologist Morrison Rogosa.

The characteristics are as described for the genus. Using the rapid ID 32A system, alkaline phosphatase and pyroglutamic acid arylamidase activities are detected. Can be differentiated from other species of the genus *Veillonella* by 16S rRNA and *rpoB* sequencing.

Pathogenicity: not reported. Found in supra-gingival plaque of caries-free children.

DNA G+C content (mol%): unknown.

Type strain: 100CF, CCUG 54233.

GenBank accession number (16S rRNA gene): EF108443.

10. *Veillonella rodentium* (Rogosa 1965) Mays, Holdeman, Moore, Rogosa and Johnson 1982, 35^{VP} (*Veillonella parvula* subsp. *rodentium* Rogosa 1965, 707)

ro.den'ti.um. N.L. pl. gen. n. *rodentium* (from L. part. adj. *rodens-entis* gnawing), of rodents.

The characteristics are as described for the genus.

Antigenic properties: Serogroup II (Rogosa, 1965).

Pathogenicity: not reported; isolated from hamster mouth.

DNA G+C content (mol%): 42–43, mean 43 (T_m) and 44.4 (Bd).

Type strain: ATCC 17743, DSM 20737, VPI 11222, NCTC 12018, Rogosa strain HV 19.

GenBank accession number (16S rRNA gene): AY514996.

Genus II. *Acetonema* Kane and Breznak 1992, 191^{VP} (Effective publication: Kane and Breznak 1991, 97.)

FRED A. RAINEY

A.ce.to.ne' ma. L. n. *acetum* vinegar; Gr. neut n. *nema* thread; N. L. neut. n. *Acetonema* vinegar-forming thread.

Thin, straight rods, 0.3–0.4 µm in diameter and 6–60 µm in length. Motile by means of peritrichous flagella. **Gram-negative cell wall**. Gram-negative staining. Lipopolysaccharide present. Heat resistant, dipicolinic acid containing **endospores are formed**. Catalase-positive, oxidase-negative. **Strict anaerobe**. **Facultative chemolithotroph**. Mesophiles. **Ferments H₂ + CO₂ to acetate**. Sugars and organic acids are fermented to acetate, propionate, butyrate, succinate, and H₂ and CO₂ depending on the substrate. Do not respire anaerobically with nitrate or sulfate. Cytochromes not detected. Isolated from gut contents of the termite *Pterotermes occidentis*.

DNA G+C content (mol%): 55.1 (Bd).

Type species: *Acetonema longum* Kane and Breznak 1992, 191^{VP} (Effective publication: Kane and Breznak 1991, 97.).

Further descriptive information

The genus *Acetonema* contains the single species *Acetonema longum* the description of which is based on the characterization of a single strain APO-1^T (Kane and Breznak, 1991). Cells of this species stain Gram-negative, and transmission electron microscopy of thin sections shows the presence of a distinct inner cytoplasm and outer membrane as found in Gram-negative bacteria. The Gram-negative nature of the cell wall was confirmed using the polymyxin B test as described by Wiegel and Quandt (1982). In addition, a significant amount of lipopolysaccharide is determined in the cell lipid fraction. The endospores formed by this organism are spherical and terminal and swell the sporangium. Viable cells can be recovered from cultures that have been heat treated (80°C, 10 min). The length of the cells varies with phase of growth as well as substrate. Cells grown on H₂:CO₂

are 20 µm long during the exponential phase of growth and decrease in length by at least 50% at the end of the exponential phase. At the end of the exponential phase, 75% of the cells have formed endospores; these sporulating cells are all ≤12 µm long. Cells growing on organic substrates are generally longer (up to 60 µm) and form fewer endospores than cells grown on H₂:CO₂.

Growth of strain APO-1^T is stimulated by the addition of trypticase and yeast extract, but rumen fluid had little effect on growth. Cells grow in the temperature range 19–40°C and the pH range 6.4–8.6. With H₂:CO₂ as the growth substrate, maximum growth rates were obtained at 30–33°C and pH 7.8. The pH of the culture drops to 6.7 during growth. Doubling times vary with growth substrate–H₂:CO₂ (36 h), glucose (8 h), rhamnose (15 h), and fumarate (40 h). When grown on H₂:CO₂, only acetate is produced, but on organic substrates a number of major end products are detected. On glucose, the major products of fermentation are acetate, butyrate, CO₂, and H₂. Fermentation of fructose, mannose, mannitol, oxaloacetate, pyruvate, and ribose yields butyrate and acetate as the main acidic end products. The major product of rhamnose fermentation is 1, 2-propanediol while that of fumarate dissimilation is propionate. Substrates used as energy sources by strain APO-1^T include: H₂:CO₂, glucose, fructose, mannose, rhamnose, ribose, mannitol, pyruvate, oxaloacetate, and fumarate. Poor growth is observed on citrate, propanol, ethylene glycol, and 3,4,5-trimethylbenzoate. No growth is observed on the following substrates: melibiose, raffinose, maltose, cellobiose, arabinose, galactose, lactose, xylose, sucrose, trehalose, starch, L-fucose, formate, lactate, malate, D-gluconate, acetate, oxalate,

succinate, gallate, syringate, caffeate, 3-hydroxybenzoate, benzoate, pyrogallol, methanol, ethanol, glycerol, adonitol, sorbitol, erythritol, butanol, isobutanol, dulcitol, pectin, xanthine, dextrin, betaine, salicin, esculin, *N,N*-dimethylglycine, and casamino acids.

Enrichment, isolation, and growth conditions

Acetonema longum was isolated from homogenates of the hind gut contents of the termite *Pterotermes occidentis*. The homogenates were prepared under anaerobic conditions using buffered salts solution (Breznak and Switzer, 1986). Serially diluted homogenates were inoculated into anaerobic AC-K1 or AC-K2 medium with a H₂:CO₂ headspace (Kane and Breznak, 1991). Isolates were obtained from tubes of AC-K2 showing bacterial growth, gas consumption, and acetate production using the roll tube technique in which AC-K2 medium was solidified with 2% agar. Strains were routinely cultured in AC-K1 medium. From the initial enrichment studies using AC-K2 and a H₂:CO₂ headspace, three strains were obtained and strain APO-1^T was further characterized. AC-K3 was used to culture strain APO-1^T for growth and nutrition studies (Kane and Breznak, 1991). For the determination of growth on non-gaseous substrates, tubes were filled completely with liquid medium without a headspace. A 100% N₂ atmosphere was used in the headspace for studies of the fermentation of organic substrates using AC-K3 buffered with 3-(*N*-morpholino)propanesulfonic acid rather than the NaHCO₃ buffering system.

Taxonomic comments

When this genus was described in 1991 (Kane and Breznak, 1991) there were a limited number of 16S rRNA gene sequences

available for comparison. However, the comparison to available sequences showed it to represent a distinct lineage that fell within the radiation of the species of the genera *Sporomusa*, *Selenomonas*, and *Megasphaera* and had highest similarity to *Sporomusa termitida* and *Sporomusa paucivorans*. Since then, a number of new genera have been described in this group and *Acetonema longum* now clusters with species of the genera *Pelosinus*, *Sporotalea*, *Propionispora*, *Anaerosinus*, *Dendrosporobacter*, and *Sporomusa* (see Figure 199). The 16S rRNA gene sequence similarities between *Acetonema longum* and these related taxa are in the range 90–92.5%. The genera *Pelosinus* and *Sporotalea* were proposed after finalization of the content of this volume and are not described here (see Shelobolina et al., 2007; Boga et al., 2007). The genus *Acetonema* is a member of the family *Veillonellaceae*.

Differentiation of the genus *Acetonema*

Acetonema longum can be differentiated from related taxa on the basis of a number of characteristics (Table 202). These include cell morphology, spore formation, flagellation, temperature optimum for growth, substrate utilization, end products of fermentation, and mol% G+C content of DNA. A number of characteristics are shared with only some related genera. Morphologically *Acetonema* is similar to *Sporotalea* and *Dendrosporobacter* in forming straight rods although the length of the rods of the latter two genera is much shorter. *Acetonema* can be differentiated from *Anaerosinus*, which does not have flagella or form endospores. The two characteristics that distinguish *Acetonema* from all of the related genera are its abilities to grow on H₂:CO₂ and produce butyrate as the major end product of glucose fermentation.

TABLE 202. Differentiation of *Acetonema* from related genera

List of species of the genus *Acetonema*

1. ***Acetonema longum*** Kane and Breznak 1992, 191^{VP} (Effective publication: Kane and Breznak 1991, 97.)

lon'gum. L. neut. adj. *longum* long in shape.

Forms thin straight cells with rounded ends. Cells are 6–60 µm in length and 0.3–0.4 µm in diameter. Motile by means of peritrichous flagella. Endospores are spherical, terminal, and swell the sporangium. Subsurface colonies are 1–2 mm in diameter, circular with uneven edges and opaque, slightly brown in color when grown in 2% agar on H₂:CO₂. Strict anaerobe. Catalase-positive, oxidase-negative. Obtains energy from H₂:CO₂ by acetogenesis. Growth occurs on glucose, fructose, mannose, ribose, rhamnose, mannitol, pyruvate, and oxaloacetate, which are fermented to butyrate

and acetate. H₂, CO₂, and propionate are formed from glucose fermentation; H₂, CO₂, succinate and 1,2-propanediol are formed from rhamnose fermentation. Acetate is the sole acid end product from the fermentation of ethylene glycol and 3,4,5-trimethoxybenzoate. The pH range for growth is 6.4–8.6 with an optimum at 7.8. The temperature range for growth is 19–40 °C with an optimum in the range 30–33 °C. Trypticase or yeast extract is required for good growth. Isolated from the gut contents of the termite *Pterotermes occidentis* (Walker) (Kalotermitidae).

DNA G+C content (mol%): 55.1 (Bd).

Type strain: APO-1, DSM 6540, ATCC 51454.

GenBank accession number (16S rRNA gene): AJ010964.

Genus III. ***Acidaminococcus*** Rogosa 1969, 765^{AL} emend. Cook, Rainey, Chen, Stackebrandt and Russell 1994a, 577

JAMES B. RUSSELL

A.cid.a.min.o.coc'cus. L. n. *acidum* acid; N.L. neut. n. *amino* amino; Gr. n. *kokkos* a grain, berry; N.L. masc. n. *Acidaminococcus* the amino acid coccus.

Cells coccoid, 0.6–1.0 µm in diameter, often occurring as oval or kidney-shaped diplococci. Nonspore-forming. **Gram-stain-negative**. Nonmotile; flagella are not present. The cellwall contains **meso-diaminopimelic acid**; whole cells contain galactose, glucose, and ribose. Menaquinones and ubiquinones are absent. **Anaerobic**; no growth on the surface of agar media incubated in the air. Optimal growth at 30–37 °C and pH 7.0. Oxidase and catalase-negative. **Chemo-organotrophic**: D- and L-Glutamate, *trans*-aconitate, and citrate are the known energy sources. Other amino acids, pyruvate, lactate, fumarate, malate, and succinate are not used as energy sources. Approximately 40% of the strains catabolize glucose, from which little acid is produced. On complex media, ammonia, CO₂, acetate, butyrate, and hydrogen are produced, but propionate and valerate have not been detected. Glutamate is fermented to about 1.0 CO₂, 1.0 ammonia, 1.2 acetate, 0.4 butyrate, and up to 10 kPa H₂; citrate and *trans*-aconitate are fermented to about 2.0 CO₂, 1.8 acetate, 0.1 butyrate, and 90 kPa H₂. Nutritional requirements are complex. Isolated from the intestinal tract of the pig and humans. Has also been isolated from cattle rumen, but not usually a predominant ruminal bacterium.

DNA G+C content (mol%): 54.7–57.4.

Type species: ***Acidaminococcus fermentans*** Rogosa 1969, 765^{AL} emend. Cook, Rainey, Chen, Stackebrandt and Russell 1994a, 577.

Further descriptive information

An outer cell-wall membrane is demonstrable in thin sections by electron microscopy. Lipopolysaccharide (endotoxin) is present, and a Shwartzman reaction occurs in rabbits.

Optimal growth is obtained on media containing 0.1 M sodium glutamate, 0.5% yeast extract, 20 mM potassium phosphate (pH 7.4), VRB salts (Rogosa, 1969), and 20 mM thioglycollate as a reducing agent under N₂ at 37 °C. On liquid media, cell densities up to OD₆₀₀ = 3.0 are reached. In freshly prepared semisolid media (0.2% agar) in 16 × 160 mm sealed tubes under air, growth starts at the site of inoculation with a syringe and spreads over the entire medium except about 5 mm below the

surface. H₂ up to 50 kPa does not inhibit growth. On agar plates under an anoxic atmosphere consisting of 95 kPa N₂ and 5 kPa H₂, after 48 h at 37 °C colonies, are obtained which are 1–2 mm in diameter, round, entire, slightly raised, and whitish gray or nearly transparent. The plating efficiency is very low.

Growth on citrate is less efficient (OD₆₀₀ ≤ 1.5) than on *trans*-aconitate and glutamate. After transfer from glutamate to citrate medium, growth may not commence for as long as one week. Growth on glutamate requires ≥ 5 mM Na⁺, whereas for the tricarboxylates > 0.1 mM Na⁺ is necessary (Cook et al., 1994a; Härtel and Buckel, 1996; Wohlfahrt and Buckel, 1985).

Growth is poor or absent at 25 and 45 °C. Cells do not survive 60 °C for 30 min. Growth occurs at initial pH values between 6.2 and 7.5, although best growth occurs at a neutral reaction. Final pH values in media initially at pH 7.5 range ~ 6.1–6.7.

Nutritional requirements are multiple. Tryptophan, glutamate, valine, and arginine are required by all strains. Cysteine and histidine are required by 93% of strains, tyrosine by 75%, phenylalanine and serine by 50%. Glycine is sometimes stimulatory. Alanine, leucine, isoleucine, proline, threonine, methionine, lysine, and aspartate are not required for growth. In amino acid containing media, vitamin B₁₂, pyridoxal, pantothenate, and biotin are indispensable for growth; *p*-aminobenzoic acid is essential or highly stimulatory. Exogenous putrescine, folic acid, folinic acid, thiamine, niacin, and riboflavin are not required. On glutamate/yeast extract medium, growth is completely inhibited by avidin (100 µg/ml). Pyruvate is utilized by some strains.

Polyols including adonitol, dulcitol, erythritol, glycerol, inositol, mannitol, and sorbitol are not attacked. Amygdalin, arabinose, fructose, galactose, insulin, maltose, mannose, melezitose, α-methyl-D-glucoside, α-methyl-D-mannoside, raffinose, salicin, sorbose, sucrose, trehalose, xylose, erythrose, and esculin are not attacked. Ambiguous, extremely weak, or negative reactions occur with cellobiose, fucose, lactose, melibiose, rhamnose, and ribose. The type strain does not ferment glucose. Reference strains fermenting glucose weakly include ATCC 25086 (strain VR7) and ATCC 25087 (strain VR11).

Ammonia is produced. Gelatin is generally not liquefied, although slow and partial liquefaction may sometimes occur. H₂S is produced by some strains. Indole is generally not produced. Oxidase and catalase-negative. The benzidine test for porphyrin is negative. Nitrate is not reduced. Sulfophthalein indicators are not reduced.

Resistant to vancomycin (7.5 µg/ml), kanamycin (100 µg/ml), and streptomycin (100 µg/ml). Sensitive to ampicillin (20 µg/ml), chloramphenicol (25 µg/ml), colistin (10 µg/ml), erythromycin (2 µg/ml), neomycin (20 µg/ml), spectinomycin (20 µg/ml), and tetracycline (6 µg/ml). Cultures grown on and *trans*-aconitate were resistant to the ionophore, monensin, but those grown on citrate were sensitive (Cook and Russell, 1994).

Enrichment and isolation procedures

Acidaminococcus strains have been isolated from intestinal tracts of pig and humans, in relatively large numbers from 25% of normal human feces, from a closed abdominal abscess, and from a putrid lung abscess as part of mixed anaerobic and facultative flora (Sugihara et al., 1974). They may be widespread in the intestinal tracts of various homothermic animals. In a study of the isolation of *Acidaminococcus* from human feces, Sugihara et al. (1974) found that the highest recovery was obtained from dilutions of the fecal samples when kanamycin-vancomycin blood agar, neomycin blood agar, or nonantibiotic-containing blood agar were used. More recently, *Acidaminococcus fermentans* strain AO, which is "virtually identical to the type strain" was isolated from the rumen, but it is not normally a predominant ruminal bacterium (Cook et al., 1994a). The ability of *Acid-*

aminococcus fermentans to convert *trans*-aconitate to acetate may prevent tricarballylate accumulation and grass tetany (magnesium deficiency) in ruminants (Cook et al., 1994b).

Maintenance procedures

Cells suspended in skim milk may be lyophilized successfully.

Biochemical comments

Organisms of the order *Clostridiales* use two different pathways of glutamate fermentation which lead to identical products (Braune et al., 1999; Buckel, 1980): The methylaspartate pathway, which involves coenzyme B₁₂, is found in the genus *Clostridium* and in enterobacteria. *Acidaminococcus fermentans*, *Peptostreptococcus asaccharolyticus*, *Fusobacterium nucleatum*, and *Clostridium symbiosum* ferment glutamate via the (*R*)-2-hydroxyglutarate pathway, in which following unusual enzymes are involved: 2-hydroxyglutarate dehydrogenase, glutamate CoA-transferase, 2-hydroxyglutaryl-CoA dehydratase, and glutacetyl-CoA decarboxylase, a biotin containing Na⁺ pump. All genes encoding these enzymes from *Acidaminococcus fermentans* have been cloned and sequenced. Deduced proteins with the highest sequence identities have been found in other *Clostridiales* (e.g., *Veillonella*) and in the archaeon *Archaeoglobus fulgidus* (Braune et al., 1999; Hans et al., 1999). There is no serological cross-reaction between strains of *Acidaminococcus* and either *Veillonella* serovars or *Peptostreptococcus asaccharolyticus* (formerly called *Peptococcus aerogenes*). The newly proposed family "*Acidaminococcaceae*" also contains organisms which ferment glutamate to propionate instead of butyrate, e.g., *Selemononas acidaminophila*.

List of species of the genus *Acidaminococcus*

1. ***Acidaminococcus fermentans*** Rogosa 1969, 765^{AL} emend. Cook, Rainey, Chen, Stackebrandt and Russell 1994a, 577

fer.men'tans. L. part. adj. *fermentans* fermenting.
Description is the same as for the genus.

DNA G+C content (mol%): 54.7–57.4 (*T_m*).

Type strain: VR4, ATCC 25085, CCUG 9996, CIP 106432, DSM 20731.

GenBank accession number (16S rRNA gene): X65935, X78017.

Genus IV. ***Allisonella*** Garner, Flint and Russell 2003, 373^{VP} (Effective publication: Garner, Flint and Russell 2002, 504.)

FRED A. RAINEY

Al.li.son.ella. N.L. dim. suff. *-ella*; N.L. fem. n. *Allisonella* named after the American microbiologist Milton J. Allison, a prominent rumen microbiologist who isolated *Oxalobacter formigenes*, a ruminal bacterium that decarboxylates oxalate.

Cells are **ovoid shaped, nonmotile**, and form diploids or chains. **Spores not observed**. Cells stain **Gram-negative**. Resistant to ionophore and monensin. **Catalase-, oxidase-, and indole-negative**. Nonfermentative, facultative anaerobic, and chemoheterotrophic. Utilizes histidine as sole energy source. Produces histamine and CO₂ as end products from histidine. Growth occurs in medium containing yeast extract, butyrate, and histidine. On the basis of 16S rRNA gene sequence comparisons, the genus *Allisonella* is a member of the family *Veillonellaceae*.

DNA G+C content (mol%): 45–48 (HPLC).

Type species: ***Allisonella histaminiformans*** Garner, Flint and Russell 2003, 373^{VP} (Effective publication: Garner, Flint and Russell 2002, 504.).

Enrichment and isolation procedures

Allisonella histaminiformans was isolated in a study looking at the component of a mixed rumen bacterial population that could convert histidine to histamine (Garner et al., 2002). Rumen contents from cows on three different diets were studied. Rumen bacteria capable of converting histidine to histamine were detected in cows fed 3.4 kg of grain and 9.8 kg of grain. The highest numbers of bacteria that utilized histidine as a sole energy source were found in the cow fed 9.8 kg of grain. When enriched in MRS medium, histamine-producing bacteria can be detected but are not selectively enriched, and a number of colony morphologies are observed on plating. MRS enrichments

showing histamine production are transferred to carbonate medium with added histidine (50 mM). A variety of colonies are also produced when these carbonate medium cultures are streaked on agar containing histidine. Not all of these colonies are histamine producers and only the small translucent colonies are capable of histamine production when transferred to carbonate broth plus histidine. *Allisonella histaminiformans* can be easily isolated from the rumen of cattle fed grain, but it cannot be detected in the grain itself or in cattle fed hay. Also, *Allisonella histaminiformans* can be isolated at lower numbers from bovine feces and the cecum of a horse.

Taxonomic comments

The genus *Allisonella* was described on the basis of its phenotypic, chemotaxonomic, and phylogenetic characteristics. *Allisonella histaminiformans* is considered to be the first histamine-producing

bacterium that can only utilize histidine as a sole energy source. The fatty acid profile is dominated by unsaturated C_{16:1} and C_{18:1} species as well as C_{14:0} and was shown to differ from the profiles of the classical rumen bacteria *Megasphaera elsdenii* and *Selenomonas ruminantium*. Comparison of the 16S rRNA gene sequence of *Allisonella histaminiformans* with those of other members of the Firmicutes lineage shows the genus *Allisonella* falls within the radiation of the species of the genera *Dialister*, *Anaeroglobus*, *Megasphaera*, and *Veillonella* (see Figure 199). The clustering of these genera is supported by a bootstrap value of 99%. The highest 16S rRNA gene sequence similarities are found between *Allisonella histaminiformans* and species of the genus *Dialister* (*Dialister pneumosintes*, 94.7%; *Dialister invisus*, 93.5%; *Dialister propionicifaciens*, 93.1%; *Dialister microaerophilus*, 91.4%). The 16S rRNA gene sequence similarity to other genera of this cluster is lower and in the range 88.0–90.3%.

List of species of the genus *Allisonella*

1. ***Allisonella histaminiformans*** Garner, Flint and Russell 2003, 373^{VP} (Effective publication: Garner, Flint and Russell 2002, 504.)

his.ta.min.i.for.mans. N.L. neut. n. *histaminum* histamine; L. part. adj. *formans* forming; N.L. part. adj. *histaminiformans* histamine-forming.

Cells are ovoid shaped, nonmotile and occur in diploids or chains. Cells are 1.0–8.0 μm in length and 0.4–0.8 μm in diameter. Spores are not observed. Stains Gram-negative. Highly resistant to ionophore and monensin. Facultative anaerobe, chemoheterotroph, utilizes histidine producing histamine and CO₂ as end products. Cellular yield is 1.5 mg of protein per

mmol of histidine. Growth occurs in medium containing yeast extract, butyrate, and histidine. Volatile fatty acids are not produced and butyric acid is required for growth. Lysine is utilized, but lysine alone does not support growth. Does not utilize carbohydrates or organic acids. Optimum temperature for growth is 39°C with a doubling time of 110 min. Cellular fatty acid profiles are dominated by C_{14:0}, C_{16:1}, and C_{18:1}. C_{16:0} saturated fatty acids account for less than 5% of the total. The type strain was isolated from dairy cow rumen content.

DNA G+C content (mol%): 46.8 (HPLC).

Type strain: MR2, ATCC BAA-610, DSM 15230.

GenBank accession number (16S rRNA gene): AF548373.

Genus V. *Anaeroarcus* Strömpl, Tindall, Jarvis, Lünsdorf, Moore and Hippe 1999, 1870^{VP}

CARSTEN STRÖMPL AND HEINRICH LÜNSDORF

An.ae.ro.ar'cus. Gr. pref. *an* not; Gr. n. *aer* air, anaero not (living) in air; L. masc. n. *arcus* a bow, arc; N.L. masc. n. *Anaeroarcus* a bow not living in air.

Cells are **curved** or spiral-shaped **rods**, motile and **Gram-stain-negative**. **Endospores are not formed**. Obligately **anaerobic chemo-organotroph**. A limited range of organic acids, amino acids, carbohydrates, and alcohols are fermented mainly to acetate, propionate, succinate, and propanol. Yeast extract, Casamino acids, peptone, and Biotrypticase support growth. The modified **naphthoquinone** "Lipid F", with octa- and nonaprenologues (ratio 4:1) as the predominating isoprenologues, and *b*-type **cytochromes** are present. Ferric iron, but not sulfate or nitrate, is reduced. **Mesophilic**.

DNA G+C content (mol%): ~48.

Type species: ***Anaeroarcus burkinensis*** (Outtara, Traore and Garcia 1992) Strömpl, Tindall, Jarvis, Lünsdorf, Moore and Hippe 1999, 1870^{VP} (*Anaerovibrio burkinabensis* Outtara, Traore and Garcia 1992, 395).

Further descriptive information

Phosphatidyl ethanolamine and phosphatidyl serine are the major polar lipids, together with an unidentified, probably atypical glycolipid. Major fatty acids are C_{11:0 iso}, C_{15:1}, C_{17:1}, and

C_{13:0 iso 3OH}. Minor variations in sequence primary structure and length were observed in particular in helix 6 of the 16S rRNA gene, indicating multiple gene copies.

Enrichment and isolation procedures

The sole strain characterized has been isolated from waterlogged, iron-rich rice field soils by use of a basal medium (Outtara et al., 1992) and standard anaerobic techniques. Pure cultures have been obtained by repeated application of the roll tube method (Hungate, 1969).

Maintenance and storage

Active cultures can be maintained in the laboratory by frequent transfer in PY broth supplemented with lactate (0.25%) or DSM medium 575. Lyophilized cultures (Hippe, 1991) have been viable after 12 years of storage.

Taxonomic comments

When Outtara et al. (1992) characterized an isolate from anoxic rice field soils, they compared their strain among others with

the type species of *Anaerovibrio*, *Anaerovibrio lipolytica*, and found sufficient similarities to describe their isolate as a new species of *Anaerovibrio*, *Anaerovibrio burkinabensis*. Strömpl et al. (1999) re-evaluated the species of *Anaerovibrio* and concluded that the differences in 16S rRNA gene sequence, chemical composition, and metabolic traits between the two species *Anaerovibrio lipolyticus* and *Anaerovibrio burkinabensis* justified the assignment of *Anaerovibrio burkinabensis* to a new genus and combination, *Anaeroarcus burkinensis* (corrig.).

The genera *Anaeroarcus* (with the single species, *Anaerovibrio burkinensis*) and *Anaeromusa* (with *Anaerovibrio acidaminophila* Baena et al., 1999) are very closely related. 16S rRNA gene sequence similarity values indicate a relationship at genus level. The two organisms share, among other features, very similar pH ranges and optima, growth temperatures, DNA base ratios, and fermentation profiles. One major difference observed so far lies in the inability of *Anaeromusa* to utilize carbohydrates (Table 203). This bacterium has also not been tested for its ability to reduce ferric iron, nor has its lipid composition or its lipoquinone compo-

sition been determined. *Anaeromusa* possesses several (up to 16), lateral flagella mainly emerging from the concave side of the cell. Re-examination of the type strain of *Anaeroarcus burkinensis* (Figure 202) confirmed the observation reported by Outtara et al. (1992), that this species normally possesses a single, subpolar flagellum. If future analyses support the view that the two genera should be merged in one genus, the name *Anaeromusa* would have priority.

Further comments

Gu et al. (2004) reported on 16S rRNA gene clone sequences (cluster TCE33, GenBank accession number AF349762) from trichloroethene and *cis*-1,2-dichloroethene degrading enrichments which may be related both to *Anaeroarcus* and *Anaeromusa* at generic level. The enrichments had initially been supplied with lactate as an energy source, but the function of these uncultivated organisms in the final, dechlorinating culture remained unclear. Similar 16S rDNA sequences were obtained from a chlorobenzene degrading reactor (GenBank accession nos AJ488080 and AJ488092).

FIGURE 202. Transmission electron micrograph of an individual cell of *Anaeroarcus burkinensis* B₄B₀^T, unfixed and shadow-casted with Pt/C-coating (see Golyshina et al., 2000). The slightly vibrioid-shaped cell shows the outer membrane as a flattened contour of the darker cell body, caused by cytoplasmic shrinkage during preparation. A single flagellum of about 8 μm in length is inserted subpolarly as it can be recognized from the flagellum insertion (see inset, lower left). Cell width is 0.70–0.98 μm and cell length ranges from 2.3–2.9 μm.

TABLE 203. Characteristics differentiating the genera *Anaeroarcus* and *Anaeromusa*

Characteristic	<i>Anaeroarcus</i> ^a	<i>Anaeromusa</i> ^b
Flagella	Subpolar, single	Up to 16, predominantly on the concave side of the cell
Substrates utilized	Citrate, fumarate, malate, lactate, pyruvate, dihydroxyacetone, fructose, 1,2-propanediol, aspartate, glutamate. Slight degradation of glycerol; glycerol 3-phosphate degraded in the presence of yeast extract	Lactate, pyruvate, aspartate, glutamate
Fermentation products	Acetate and propionate from all substrates; succinate from fumarate, malate and aspartate; H ₂ (traces), 1,3-propanediol from glycerol; propanol from 1,2-propanediol; traces of lactate from sugars	Acetate and propionate from all substrates; succinate from aspartate
Ferric iron reduction	+	ND ^c
Cytochromes	<i>b</i>	<i>b, c</i>
16S rDNA sequence similarity (%)	99.5

List of species of the genus *Anaeroarcus*

1. **Anaeroarcus burkinensis** (Outtara, Traore and Garcia 1992) Strömpl, Tindall, Jarvis, Lünsdorf, Moore and Hippe 1999, 1870^{VP} (*Anaerovibrio burkinabensis* Outtara, Traore and Garcia 1992, 395)

bur.kin.en'sis. N.L. adj. *burkinensis* pertaining to Burkina Faso, the place from which the organism was isolated.

Strictly anaerobic chemo-organotroph. Substrates used as energy sources are citrate, fumarate, malate, lactate, pyruvate, dihydroxyacetone, fructose, 1,2-propanediol, aspartate, glutamate. Slight degradation of glycerol; glycerol 3-phos-

phate degraded in the presence of yeast extract. Acetate and propionate are the main fermentation products; succinate formed from malate, fumarate, and aspartate, propanol from 1,2-propanediol, and 1,3-propanediol from glycerol. Vitamins required for growth, NaCl not required. The pH range for growth is 5.3–8.4 with the optimum around 6.8. The temperature range is 13–43°C with the optimum around 35°C.

DNA G+C content (mol%): 48.5 ± 0.4 (HPLC).

Type strain: B₄B₀, ATCC 51455, CIP 105409, DSM 6283.

GenBank accession number (16S rRNA gene): AJ010961.

Genus VI. **Anaeroglobus** Carlier, Marchandin, Jumas-Bilak, Lorin, Henry, Carriere and Jean-Pierre 2002, 986^{VP}

JEAN-PHILIPPE CARLIER

An.ae.ro. glo'bus. Gr. pref. *an* not; Gr. n. *aer* air; N.L. *anaero* not (living) in air; L. masc. n. *globus* sphere; N.L. masc. n. *Anaeroglobus* a sphere not living in air.

Anaerobic, Gram-stain-negative cocci, 0.5–1.1 µm in diameter, nonmotile, endospores not formed. Cells are coccoid to ellipsoidal and found in pairs or short chains. Most of the usual carbohydrates are not fermented. **No gas is produced** in glucose agar deeps. **Catalase and nitrate reduction tests are negative**. The metabolic end products are acetic, propionic, isobutyric, butyric, and isovaleric acids. Occurs in gastrointestinal tract and presumably in oral cavity of man.

DNA G+C content (mol%): 51.8 (T_m).

Type species: **Anaeroglobus geminatus** Carlier, Marchandin, Jumas-Bilak, Lorin, Henry, Carriere and Jean-Pierre 2002, 986^{VP}.

Further descriptive information

The cells are coccoid to ellipsoidal. Individual cells are about 0.5–1.1 µm in diameter (Figure 203). Ultrastructural examination reveals distinct inner and outer membranes of 3.6 and 4.9 nm in width, respectively. The membranes are separated by approximately 24 nm (Marchandin, 2001). The nonpigmented and nonhemolytic colonies formed on blood agar after 2 d incubation are small, circular, convex, and translucent with a smooth surface. *Anaeroglobus geminatus* is unreactive in most conventional biochemical tests. Indole is not produced. Gelatin and milk are not modified and lactate is not fermented. Acid is

produced from galactose and mannose. Acid is not produced from esculin, arabinose, cellobiose, fructose, glucose, glycerol, inositol, lactose, maltose, mannitol, melezitose, melibiose, raffinose, rhamnose, ribose, salicin, sorbitol, starch, sucrose, trehalose, and xylose. Esculin and starch are not hydrolyzed. The type strain has been tested for enzymic activity using the Rapid ID32A kit (API bioMérieux), and a positive reaction was obtained for the β-glucosidase test (API code 0010 0000 00). The strain is resistant to 5 µg vancomycin discs, but is susceptible to 1 mg kanamycin, 10 µg colistin, 4 µg metronidazole, and bile discs. The major metabolic end products are acetic, propionic, isobutyric, butyric, and isovaleric acids. Lactic and succinic acids are not produced. The 16S rRNA gene sequence analysis reveals that *Anaeroglobus* belongs to the family *Veillonellaceae* (Carlier et al., 2002) which includes all members of the *Sporomusa* sub-branch of the class *Clostridia* of the phylum *Firmicutes* (Garrity and Holt, 2001). The closest phylogenetic neighbors of *Anaeroglobus* are *Megasphaera cerevisiae*, *Megasphaera elsdenii*, *Veillonella parvula*, and *Acidaminococcus fermentans* with sequence identities of 91, 87, 87, and 84%, respectively. In addition, several sequences (AF287783, AF287784, AF287785 (Paster et al., 2001) and AF481223 (Munson et al., 2002) which have been deposited in the public databases as oral clones of

FIGURE 203. Transmission electron micrographs of *Anaeroglobus geminatus* AIP 313.00^T. (top) General morphology after negative staining and (bottom) cell wall and membranes after ultrathin sectioning.

Megasphaera species exhibit high similarity values (93–99%) with the sequence of *Anaeroglobus geminatus*. However, these sequences were obtained from cloning and sequencing of 16S

rRNA genes from oral flora without cultures, and thus the phenotypic characteristics of these micro-organisms are unknown.

Genomic mapping with the endonuclease I-CeuI revealed that *Anaeroglobus geminatus* possesses a genome of about 1800 kb with four *rrn* operons. This genomic structure is similar to those of *Veillonella* species and *Dialister pneumosintes*, which are 2191 kb and 1445 kb carrying 4 and 5 *rrn* copies, respectively. In contrast, the chromosome of *Megasphaera elsdenii* is 2878 kb in size and contains seven *rrn* copies (Marchandin, 2001).

Enrichment and isolation procedures

Anaeroglobus can be isolated by streaking samples onto Columbia or Wilkins-Chalgren sheep-blood agar and incubating at 37°C for 2 d. Strict anaerobic conditions are required for growth of *Anaeroglobus*, and good growth can be obtained in an anaerobic jar containing either an Anaerogen System (Oxoid Unipath) or a mixture of 5% H₂, 5% CO₂ and 90% N₂ (by vol.).

Maintenance procedures

The strain may be maintained in trypticase-glucose-yeast extract (TGY) medium (Carlier et al., 2002) under anaerobic conditions as described above. Under these conditions, cultures of *A. geminatus* will usually survive for no longer than 1 week without subcultivation. The organism may not survive freeze-drying procedures, but can be preserved in liquid nitrogen for several years.

Differentiation from closely related taxa

The differentiation of *Anaeroglobus* from other closely related anaerobic Gram-stain-negative cocci can be done primarily on the basis of poor growth on the usual media and absence of gas. Other characteristics are given in Table 204.

Taxonomic comments

The anaerobic Gram-stain-negative cocci were originally classified in a single family, the *Veillonellaceae* (Rogosa, 1984a), belonging to the *Sporomusa* sub-branch of the class *Clostridia* of the phylum *Firmicutes*. Three genera were included into this family: *Veillonella*, the type genus of the family, *Acidaminococcus*, and *Megasphaera*. In the first volume of this edition of *Bergey's Manual of Systematic Bacteriology* (Garrity and Holt, 2001), all members of the *Sporomusa* sub-branch were grouped in the family “*Acidaminococcaceae*”, and the family *Veillonellaceae* was not recognized. However, *Veillonellaceae* has priority over “*Acidaminococcaceae*”, so this error was corrected in the revised road map of this volume (Ludwig et al., this volume). Phylogenetically, *Anaeroglobus* and the closely related oral clones identified by Paster et al. (2001) fall within the family *Veillonellaceae* and branch together with the *Dialister* and *Megasphaera* genera (Figure 204). The *Anaeroglobus–Dialister–Megasphaera* group forms a cluster that is distinct from *Veillonella* and *Acidaminococcus*. In this subgroup, *Megasphaera cerevisiae* and the new species *Megasphaera micronuciformis* group together and form a separate branch from *Anaeroglobus* and related clones. On the other hand, *Dialister pneumosintes* and *Megasphaera elsdenii* individually are more deeply branched. However, in a larger tree comprising 41 representative sequences of the *Sporomusa* sub-branch, *Megasphaera elsdenii* clustered with *Megasphaera micronuciformis*, whereas *Anaeroglobus geminatus* and *Megasphaera cerevisiae* represented two distinct lineages (Marchandin et al., 2003b). Thus, the relationship between each species of *Megasphaera* and *Anaeroglobus geminatus* remains questionable.

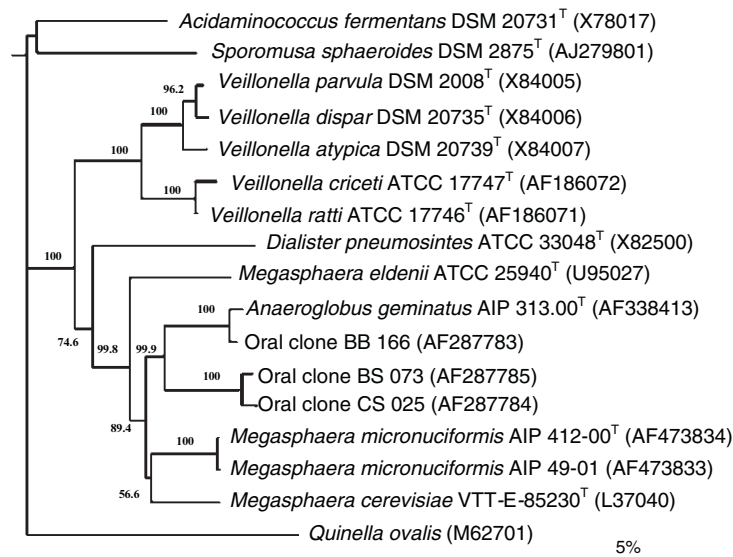

FIGURE 204. Phylogenetic relationships of *Anaeroglobus geminatus* and other closely related genera, inferred from 16S rRNA gene sequence analysis. The sequence of *Quinella ovalis* was used as an outgroup. Numbers at the nodes represent bootstrap percentage values from 1000 resampled datasets. Accession numbers are given in parentheses. The bar represents a 5% sequence difference.

List of species of the genus *Anaeroglobus*

1. ***Anaeroglobus geminatus*** Carlier, Marchandin, Jumas-Bilak, Lorin, Henry, Carriere and Jean-Pierre 2002, 986^{VP}

ge.min'at.us. L. adj. masc. *geminatus* paired, double, referring to twin cells of this organism.

The characteristics are as described for the genus. Isolated from human intestinal tract.

DNA G+C content (mol%): 51.8 % (T_m).

Type strain: AIP 313.00, CIP 106856, CCUG 44773.

GenBank accession number (16S rRNA gene): AF338413.

Genus VII. *Anaeromusa* Baena, Fardeau, Woo, Ollivier, Labat and Patel, 1999, 973^{VP}

CARSTEN STRÖMPL

An.ae.ro'mu.sa. L. v. Gr. pref. *an* not; Gr. n. *aer* air; N.L. n. *musa* a banana; N.L. fem. n. *Anaeromusa* an anaerobic banana.

Cells are **curved Gram-stain-negative rods**, usually single or in pairs. Motile by means of lateral flagella. **Nonspore-former**. Obligately **anaerobic chemo-organotroph**. A limited range of amino acids are fermented mainly to acetate and propionate. Sulfate, thiosulfate, and nitrate are not reduced. Mesophilic.

DNA G+C content (mol%): ~48.

Type species: ***Anaeromusa acidaminophila*** (Nanninga, Drent and Gottschal 1987) Baena, Fardeau, Woo, Ollivier, Labat and Patel, 1999, 973^{VP} (*Selenomonas acidaminophila* Nanninga, Drent and Gottschal 1987, 156).

Further descriptive information

Nanninga et al. (1987) studied the amino acid metabolism of the type strain, DKglu16. A distinguishing feature of this strain is the formation of propionate from the fermentation of glutamate. The arrangement of the flagella is somewhat intermediate between *Pectinatus* and *Selenomonas*; it is neither comb-like nor tufted.

Enrichment and isolation procedures

The type strain was isolated from a glutamate plus aspartate-limited chemostat culture which was inoculated with a sample

from an anaerobic purification plant of a potato starch producing factory. Similar organisms have been enriched, but not obtained in pure culture, in several types of dehalogenating reactors (Gu et al., (2004), accession numbers AF349762, AJ488080 and AJ488092).

Maintenance and storage

DSM medium 339 or the medium of Nanninga et al. (1985) may be used for routine culturing of the strain. Lyophilization is recommended for long term storage (Hippe, 1991).

Taxonomic comments

Nanninga et al. (1987) effectively described "*Selenomonas acidaminophila*" based on similarities in cell shape, temperature range and optimum, and fermentation products as a new member of the genus *Selenomonas*, but never validated their description. Baena et al. (1999), studying the 16S rRNA gene sequence-derived phylogenetic relationships of some amino acid-utilizing anaerobes, then renamed and validly described this strain as *Anaeromusa acidaminophila*. This genus is closely related to the genus *Anaeroarcus*.

List of species of the genus *Anaeromusa*

1. ***Anaeromusa acidaminophila*** (Nanninga, Drent and Gottschal 1987) Baena, Fardeau, Woo, Ollivier, Labat and Patel, 1999, 973^{VP} (*Selenomonas acidaminophila* Nanninga, Drent and Gottschal 1987, 156)

a.ci.dam.in.o'phi.la. N.L. neut. n. *acidum* acid; N.L. neut. n. *aminum* amine; Gr. adj. *philos* loving; N.L. part. adj. *acidamino-philus* amino acid-loving.

Cell size is approximately $0.3\text{--}0.5 \times 0.7\text{--}1.8\mu\text{m}$, with rounded ends. Cells are motile by means of several lateral flagella emerging mainly from the concave side of the cell. Glutamate, aspartate, lactate, and pyruvate are utilized as

energy substrates. Acetate and propionate are the main fermentation products; succinate is formed from aspartate. Growth occurs in mineral medium with a reducing agent. Indole is not formed; gelatin is hydrolyzed, but urea and esculin are not. Catalase-negative. Cells contain cytochromes *b* and *c*. No requirement for sodium. The temperature range is from 25–46°C, with the optimum around 38°C. The pH range is from 5.0–8.5, optimum 6.8–7.2.

DNA G+C content (mol%): 48.0 ± 1 (T_m).

Type strain: DKglu16, ATCC 43704, DSM 3853.

GenBank accession number (16S rRNA gene): AF071415.

Genus VIII. ***Anaerosinus*** Strömpl, Tindall, Jarvis, Lünsdorf, Moore and Hippe 1999, 1870^{VP}

CARSTEN STRÖMPL AND HANS HIPPE

An.ae.ro.si'nus. Gr. pref. *an* not; Gr. n. *aer* air; *anaero* not (living) in air; L. masc. n. *sinus* bend; N. L. masc. n. *Anaerosinus* a curved organism not living in air.

Cells are curved rods or spirals exhibiting a **Gram-stain-negative cell wall**. Motile, but motility may be lost in culture. **Endospores are not formed**. **Obligately anaerobic**. **Chemo-organotrophic**. Catalase-negative. **Cytochrome *b*** and the modified **naphthoquinone**, "lipid F", with octa- and nonaprenologues (ratio 1:2) as the predominating isoprenologues, are present. **Mesophilic**. Phosphatidyl serine and phosphatidyl ethanolamine are the **major polar lipids**. Major fatty acids are $C_{15:1}$, $C_{15:0}$, $C_{17:1}$, and $C_{17:0}$, and, of the hydroxy fatty acids, $C_{11:0\ 3OH}$, $C_{12:0\ 3OH}$, and $C_{13:0\ 3OH}$ dominate.

DNA G+C content (mol%): ~35.

Type species: ***Anaerosinus glycerini*** (Schauder and Schink 1996) Strömpl, Tindall, Jarvis, Lünsdorf, Moore and Hippe 1999, 1870^{VP} (*Anaerovibrio glycerini* Schauder and Schink 1996, 625).

Further descriptive information

Anaerosinus glycerini was originally described and thereafter validly published as *Anaerovibrio glycerini* (Schauder and Schink, 1989, 1996). The allocation of strain LG4 to the genus *Anaerovibrio* was based on common properties, including production of propionate as fermentation product, a similar DNA G+C content, a slight lipolytic activity (degradation of diolein), and the lack of spore formation.

Phylogenetic data derived from 16S rRNA gene sequence analyses confirmed that strain LG4 clustered with the *Sporomusa-Pectinatus-Selenomonas* phyletic group. The sequence similarity between strain LG4 and *Anaerovibrio lipolyticus* was, however, remote and therefore justified the creation of a new genus, *Anaerosinus*, for strain LG4 (Strömpl et al., 1999).

Anaerosinus glycerini proved to be the predominant glycerol degrader in anoxic sediments; 10^8 cells per ml were found in various freshwater sediment samples (Schauder and Schink, 1989). In contrast to batch culture, enrichment in continuous culture at low dilution rates, a method which favors bacteria with high substrate affinities, allowed the development and isolation of this highly specialized glycerol degrader. Besides glycerol, the glycerol residue of diolein and perhaps other glycerolesters is used as

FIGURE 205. Phase-contrast micrograph of cells of *Anaerosinus glycerini* strain LGS4^T in the late exponential phase of growth ($\times 2000$). Note the dark granular inclusion bodies in the cells and the tapering cell tips (courtesy of B. Schink, University of Konstanz, Germany).

sole source of carbon and energy. *Anaerosinus glycerini* grows in mineral medium without vitamins. Yeast extract increases the cell yield by about 40% but does not support growth itself. The metabolic pathway of glycerol fermentation and energy metabolism in *Anaerosinus glycerini* appear to be basically understood. It has been assumed that glycerol is activated to glycerophosphate (consumes 1 ATP) which is converted to pyruvate via glycerol-aldehyde phosphate, phosphoglycerate, and phosphoenolpyruvate (yields 2 ATP). Pyruvate then is converted to propionate via the methylmalonyl-CoA pathway, yielding further ATP by electron transport phosphorylation in fumarate reduction with electrons derived from glycerophosphate dehydrogenation. However, enzyme studies show no or only poor activities of some enzymes involved. Cell-free extracts convert succinate to propionate. Cytochrome *b* in the cell fraction is reduced by glycerophosphate or glycerol in the presence of ATP and reoxidized by fumarate (Schauder and Schink, 1989).

Enrichment and isolation procedures

Anaerosinus glycerini was isolated from a continuous culture inoculated with black freshwater sediments and anoxic sewage sludge with glycerol as the sole source of carbon and energy (Schauder and Schink, 1989).

Maintenance and storage

Anaerosinus may be maintained in PY-broth with 0.5% glycerol (Holdeman et al., 1977). Freezing in liquid nitrogen or lyophilization is recommended for long-term storage (Hippe, 1991).

Further comments

Strain SB90 (Chin et al., 1999) exhibits almost 95% 16S rDNA sequence similarity to strain LG4, but it does not belong to the genus *Anaerosinus* due to its ability to ferment sugars to acetate and propionate. Furthermore, it was reported to stain Gram-positive.

List of species of *Anaerosinus*

1. ***Anaerosinus glycerini*** (Schauder and Schink 1996) Strömpl, Tindall, Jarvis, Lünsdorf, Moore and Hippe 1999, 1870^{VP} (*Anaerovibrio glycerini* Schauder and Schink 1989, 477)

gly.ce.ri'ni. N.L. neut. n. *glycerinum* glycerol, *glycerini* of glycerol, referring to utilization of glycerol as sole substrate.

Cell size is approximately $0.5 \times 2\text{--}10\ \mu\text{m}$. Cells exhibit slightly pointed ends (Figure 205). Colonies on agar are small, cone-shaped, and yellow to orange with a slightly rough surface. Growth occurs between 10 and 42°C but optimally at 30°C to 37°C. Optimal pH is 6.5–7.5, with limits at pH 5.0

and 8.5. The type strain grows equally well in the absence and presence of 2% NaCl. Sulfate, sulfite, thiosulfate, sulfur, and nitrate are not reduced. Molecular nitrogen is not fixed. No vitamins required for growth. Glycerol and diolefin used as sole source of carbon and energy. Propionate is the only organic fermentation product. Hydrogen is formed from glycerol. Indole is not formed; gelatin and urea are not hydrolyzed.

DNA G+C content (mol%): 35.0 (HPLC).

Type strain: LGS4, ATCC 51177, CIP 105408, DSM 5192.

GenBank accession number (16S rRNA gene): AJ010960.

Genus IX: *Anaerovibrio* Hungate 1966, 80^{AL}

CARSTEN STRÖMPL AND GRAEME N. JARVIS

An.aer.o.vib'rio. Gr. pref. *an* not; Gr. n. *aer* air; *anaero* not (living) in air; L. v. *vibrio* to move rapidly to and fro, vibrate; N.L. masc. n. *vibrio* that which vibrates; N.L. masc. n. *Anaerovibrio* vibrio not living in air.

Slightly curved rods usually $0.5\ \mu\text{m} \times 1.2\text{--}3.6\ \mu\text{m}$. Capsules not formed. **Nonspore-forming**. No resting stage known. **Gram-stain-negative**. **Motile with a single polar flagellum**. Obligately **anaerobic**. **Chemo-organotrophic**; no scavenging system for oxygen is present. Growth occurs at 38°C, but not at 20°C, 30°C, or 50°C. Optimum pH for growth, 6.3; no growth occurs below pH 5.9 or above 7.0. **Lipolytic**. A limited range of sugars can be utilized as a carbon source. Glycerol is fermented mainly to propionate. Fermentation products from growth on DL-lactate, ribose, and fructose are acetate, propionate, CO₂, and traces of H₂ and succinate. Peptides, triacylglycerol, and phospholipids also support growth. An organic nitrogen source and vitamins (folic acid, pantothenate and pyridoxal-HCl) are required.

DNA G+C content (mol%): 44.0 ± 0.3 (HPLC).

Type species: ***Anaerovibrio lipolyticus*** corrig. Hungate 1966, 80^{AL}.

Further descriptive information

Large inserts occurring at the 5' end in the helix 6 region (Neefs et al., 1991) of the 16S rRNA gene lead to multiple 16S rRNA genes of different length and/or sequence. 16S rRNA data indicate that the genus falls within the radius of the *Veillonellaceae*, but specifically within a lineage including species of the genera *Selenomonas*, *Schwartzia*, *Centipeda*, *Mitsuokella*, *Pecti-*

natus, and *Zymophilus* (Strömpl et al., 1999). Closest 16S rRNA gene sequence similarity (92–93%) is with the species *Selenomonas ruminantium* subsp. *ruminantium*, *Mitsuokella multacida*, and *Schwartzia succinovorans* (Strömpl et al., 1999). Phylogenetic and chemotaxonomic analyses have indicated that this genus is restricted to only one species, *Anaerovibrio lipolyticus* (corrig.) (Strömpl et al., 1999). There are no other described species in this genus.

The morphology of the slightly curved, Gram-stain-negative cells alters with age. Young cells are generally $0.5\ \mu\text{m} \times 1.2\text{--}1.8\ \mu\text{m}$ in liquid media, but with age become more difficult to stain, develop a central granule, and are generally longer ($3.0\text{--}3.6\ \mu\text{m}$). With further ageing, the cells seem to disintegrate leaving only a granular mass (Hobson and Mann, 1961). Although noncapsulated, a large amount of slime formation is noted during active growth (Hobson and Mann, 1961).

The cell-wall peptidoglycan contains no lipoproteins, but its major polyamines are spermidine and cadaverine; the latter is a common peptidoglycan constituent for members of the *Sporomusa*–*Pectinatus*–*Selenomonas* phyletic group (Hamana et al., 2002; Hirao et al., 2000). These compounds are covalently linked to the peptidoglycan and are essential for both cell surface integrity and normal cell growth (Hirao et al., 2000).

The respiratory lipoquinones of *Anaerovibrio* are primarily represented by the compound "lipid F" with the predominant form being the "lipid F" with eight isoprenologues. Interestingly, "lipid F" is now thought to be a modified naphthoquinone with an isoprenoid side chain (Strömpl et al., 1999). No evidence exists for the presence of ubiquinones or menaquinones.

The polar lipids phosphatidyl serine and phosphatidyl ethanolamine predominate, with the principal fatty acids being C_{15:0}, C_{15:1}, C_{17:0}, and C_{17:1} (Strömpl et al., 1999; van Golde et al., 1975; Verkley et al., 1975). A third constituent, an atypical glycolipid, has also been reported (Strömpl et al., 1999). The majority of fatty acids present are straight chained, even and odd numbered, and saturated and unsaturated. No iso-branched fatty acids occur. The main 3-OH fatty acids present are C_{13:0 3OH} and C_{15:0 3OH} (Strömpl et al., 1999).

Initial isolations of *Anaerovibrio* employed linseed oil as the carbon source with 30–40% (v/v) rumen fluid (Hobson and Mann, 1961). Although it was later established that good growth could be achieved in a glycerol-based medium supplemented with yeast extract and trypticase, data also indicated that growth (albeit poorer) was also possible if glycerol was omitted and yeast extract and trypticase alone were employed (Prins et al., 1975).

Substrates utilized for growth include glycerol, ribose, DL-lactate, trypticase, triglycerides, and phospholipids (Prins et al., 1975). Strains do not utilize the long chain fatty acids resulting from lipid hydrolysis for growth, and their growth is not adversely affected by their presence (Henderson, 1973a; Hobson and Mann, 1961). Hydrogen sulfide is produced, a weak urease activity occurs, and both esterase and lipase activity are present. Neither gelatin nor esculin is hydrolyzed, nitrate is not reduced, and the indole test is negative (Counotte, 1981; Hobson and Mann, 1961).

Fermentation products from glycerol are propionate, succinate, and traces of H₂ and L-lactate, whereas fermentation of ribose, fructose, and DL-lactate produce acetate, propionate, CO₂, traces of succinate and H₂, and traces of L-lactate (when sugars are fermented) (Hobson and Summers, 1967; Prins et al., 1975). The formation of propionate from DL-lactate occurs via succinate using the dicarboxylic (succinate-propionate) pathway (Gottschalk, 1986; Prins et al., 1975). Glycerol is fermented via glycerol kinase in a manner similar to that of the propionic acid bacteria (de Vries et al., 1974). *Anaerovibrio* is also capable of reducing fumarate to succinate via the presence of a membrane-bound fumarate reductase (Henderson, 1980). This enzyme is considered to be markedly different in properties from that of other bacterial fumarate reducers in the rumen (Asanuma and Hino, 2000).

Lipolytic activity is due to a constitutive enzyme which is associated with extracellular membranous structures known as "blebs" (Henderson and Hodgkiss, 1973). Much information has been published on the properties and purification of the lipase (Henderson, 1970, 1971, 1968; Hobson and Summers, 1966, 1967; Prins et al., 1975).

Ecology

Anaerovibrio has only been found in the rumens of sheep and cattle. Its ability to hydrolyze lipids and utilize lactate probably indicates its key role in this ecosystem. It has been isolated from sheep fed a linseed cake meal (Hobson and Mann, 1961) and

from cattle during transition from forage to concentrate feeding (Slyter et al., 1976) at levels of at least 10⁸/ml of rumen contents. Lower levels (0.5–1.6 × 10⁷/ml) have been found in sheep and cows fed hay at maintenance levels (Prins et al., 1975). The relative sensitivity of *Anaerovibrio* to low pH values is probably indicative of only a modest role in ruminal lactate fermentation, and there is some contention over its importance in ruminal lipolysis (Harfoot and Hazlewood, 1997; Prins et al., 1975).

Enrichment and isolation procedures

Rumen contents are serially diluted in a specialized linseed oil-agar medium such as Medium 13 of Hobson and Mann (1961)* in roll tubes using the Hungate technique (1966). Clearing zones will develop around colonies positive for lipolysis. Final purification occurs in an agar medium in which the linseed oil is replaced by glycerol (0.2%) as the substrate. Henderson (1973b) suggested the use of trilaurin agar medium (TAM). This non-rumen fluid based agar contained trilaurin as the lipid source as well as yeast extract and casein hydrolysate. The benefits were noted as being a more rapid colony formation and more defined zones of clearing around bacterial colonies.

Maintenance procedures

Stock cultures of *Anaerovibrio* can be maintained in the medium of Henderson (1971) or in PY-broth (Holdeman et al., 1977) supplemented with 0.5% (v/v) glycerol with biweekly transfers. Long-term storage of cultures of this genus is best achieved by lyophilization using common procedures employed for obligate anaerobes (Hippe, 1991).

Differentiation of the genus *Anaerovibrio* from other closely related genera

Anaerovibrio can be differentiated from other genera within the *Veillonellaceae* based on chemotaxonomic, 16S rRNA gene sequence analysis, cell morphology, narrow range of growth substrates, and lipolytic ability. Species of the genus *Selenomonas* are generally nonlipolytic, have different substrate ranges, and/or have low 16S rRNA gene sequence similarity values compared to *Anaerovibrio*. The single polar flagellum and narrow substrate range differentiate *Anaerovibrio* from members of the genera *Zymophilus* and *Pectinatus*. A recently described rumen organism *Schwartzia succinovorans* (van Gylswyk et al., 1997), while having similar mol% G+C content, has a different substrate range and 16S rRNA gene sequence from that of *Anaerovibrio*.

Taxonomic comments

The taxonomic relationship of *Anaerovibrio* to other genera of anaerobic Gram-stain-negative bacteria has recently been

* Medium 13 of Hobson and Mann (1961) contains (per liter): mineral solution A (KH₂PO₄, 3.0g; (NH₄)₂SO₄, 6.0g; NaCl, 6.0g; MgSO₄, 0.6g; CaCl₂, 0.6g; distilled water, 1000 ml), 150 ml; mineral solution B (K₂HPO₄, 3.0g; distilled water, 1000 ml), 150 ml; rumen fluid (clarified through cheesecloth and centrifuged at 62,000 × g for 10 minutes), 400 ml; distilled water, 290 ml; resazurin (0.1% (w/v) aqueous solution), 1 ml; 1.0 ml NaHCO₃, 4.0g; 1.0 ml cysteine-HCl, 0.5g; linseed oil (50% (v/v) emulsion in sterile rumen fluid), 20.0 ml; and 20 g agar. The minerals, rumen fluid, water, and resazurin are autoclaved together at 120°C for 15 min. The NaHCO₃ and cysteine-HCl are added aseptically from filter-sterilized solutions, and the linseed oil from a sterile emulsion. The medium is shaken immediately after the linseed oil addition to facilitate oil-agar emulsion forming on setting, and it is kept at 50°C until just prior to inoculation.

resolved (Strömpl et al., 1999). There is only one member of this genus, *Anaerovibrio lipolyticus* (Hungate, 1966; Strömpl et al., 1999). According to rule 65 of the Bacteriological Code

(1990 Revision, Lapage et al., 1992), the name *Anaerovibrio lipolytica* Hungate (1966) was corrected to *Anaerovibrio lipolyticus* (corrig.) (Strömpl et al., 1999).

List of species of the genus *Anaerovibrio*

1. *Anaerovibrio lipolyticus* corrig. Hungate 1966, 80^{Al}

li.po.ly'ti.cus. Gr. n. *lipos* fat; Gr. adj. *lutikos* dissolving; N.L. adj. *lipolyticus* fat-dissolving.

The description is as given for the genus. Minute brownish colonies develop in 5–7 d in linseed oil agar and produce zones of clearing in agar where the triacylglycerols have been hydrolyzed. In glycerol agar, the colonies are lens-shaped, mucoid, whitish discs. Glycerol, fructose, ribose, and DL-lactate can be utilized as carbon sources. Resistant to ionic

phoric antibiotics such as monensin or lasalocid, and fungal mycotoxins of the trichothecene group (Dennis et al., 1981; Westlake et al., 1987). Found in the rumen of sheep and cattle.

DNA G+C content (mol%): 44.0 ± 0.3 (HPLC).

Type strain: ATCC 33276, CIP 105407, DSM 3074, 5S, VPI 7553.

GenBank accession number (16S rRNA gene): AB034191, AJ010959.

Genus X. *Centipeda* Lai, Males, Dougherty, Berthold and Listgarten 1983, 631^{VP}

ALANNA M. SMALL AND FRED A. RAINEY

Cen.ti'pe.da. L. fem. n. *centipede* a centipede.

Gram-stain-negative, nonspore-forming, serpentine, and rod-shaped with three or more curves. The cells are **motile** by means of flagella, which are inserted in a spiral path along the cell body. The movement of the cells occurs by flexion of the entire cell and rotation around its long axis. **Anaerobic**, chemo-organotrophic. Saccharoclastic. Propionic acid is a major end product of growth; acetic acid, succinic acid, and lactic acid are also produced from carbohydrate fermentation.

DNA G+C content (mol%): 51.4–53.6 (T_m).

Type species: *Centipeda periodontii* Lai, Males, Dougherty, Berthold and Listgarten 1983, 631^{VP}.

Further descriptive information

Cells of *Centipeda periodontii* are slightly serpentine, long, and rod-shaped with three or more curves with bluntly tapered ends. The degree of cell curvature is variable among strains and is lessened after repeated passage in culture. The cell diameter is 0.65 µm, and the cell length ranges from 4 to 17 µm or longer in older cultures. Gram-stain-negative. The cells occur singly or occasionally in chains. The occasional budding of the cells gives rise to branched forms. Multiple sets of flagellar bundles are present on each side of the cell with the number of bundles increasing with cell length. The bundles begin alternately from the concave areas along the curved cell body. Higher magnifications of negatively stained cells show a spiral path of insertion of the individual flagella from which the bundles are formed. This flagellar pattern is distinct from the one-sided patterns of *Selenomonas* and *Pectinatus* species.

Cells are actively motile in broth cultures 24 h after incubation. The cell's movement is described as flexion of the entire cell in a snakelike motion with rotation around the long axis of the cell body and occasional tumbling is observed. Before the cells are able to change direction they exhibit a twitching motion in which the cells are nearly stationary, then the flagellar bundles on the cells fully extend and rotate erratically. After 5-d growth in liquid media few cells are motile, and cytoplasmic granules are visible when cells are examined by dark-field microscopy.

Cells stain Gram negative. Typical brain-like surface contour, similar to descriptions of other Gram-stain-negative bacteria, is found in negatively stained preparations of cell surfaces. A typical Gram-negative cell-wall structure is seen on cellular cross-sections. The outer and inner membranes consist of two electron-dense layers separated by an electron-lucent layer. The outer membrane has an irregular, undulating profile, whereas the cytoplasmic membrane is relatively smooth and in direct contact with the moderately electron-dense peptidoglycan layer. Nucleoid areas are dispersed throughout the cytoplasm, which contains rod-shaped, electron-dense inclusions. Specialized regions of the peripheral cytoplasm approximately 30 × 130–220 nm occur along the inner membrane.

During initial isolation on blood agar, strains form flat, transparent colonies approximately 2 mm in diameter with irregular borders. After subculturing, the colonies are gray, transparent, and flat or thinly raised with finely granular surfaces. The colonies grow quickly and, after only 3 d of incubation, the entire surface of a plate is covered. In liquid culture, growth in tubes is turbid forming dense, white, sediment, which may be 2–3 cm deep after 24 h.

Cultures grown on complex media (e.g., blood agar and Todd–Hewitt broth) are strict anaerobes and produce no growth aerobically or in atmospheres containing increased concentrations of CO₂. The temperature range for growth is 32°C and 37°C; the optimum growth temperature is 35°C. Growth is not enhanced by bile, but fermentable carbohydrates enhance growth in liquid cultures. Acid without gas is produced from the fermentation of carbohydrates. All strains ferment fructose, galactose, glucose, lactose, maltose, mannitol, melibiose, farinose, sorbitol, and sucrose. Fermentation of adonitol, cellobiose, mannose, melezitose, rhamnose, salicin, trehalose, and xylose is variable among strains. The final pH after growth in peptone-yeast extract broth containing 1% glucose is 4.2–5.0.

Centipeda periodontii strains produce 1.2 and 2.2 meq of propionic acid per 100 ml of peptone-yeast extract broth and peptone-yeast extract-glucose broth, respectively; smaller amounts

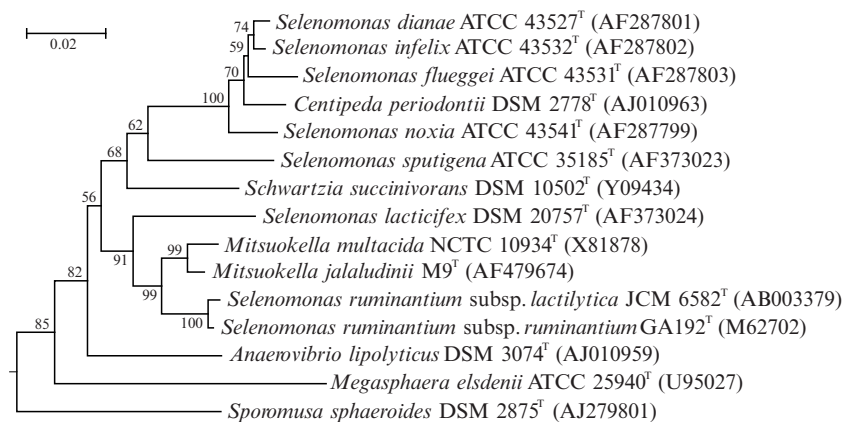

FIGURE 206. 16S rRNA gene sequence based phylogeny showing the position of the genus *Centipeda* within the radiation of the species of the genus *Selenomonas* and related genera. The tree was reconstructed from distance matrices using the neighbor-joining method. The species *Selenomonas lipolytica* was not included owing to availability of only a short (~250-nucleotide) 16S rRNA gene sequence. The scale bar represents 2 inferred nucleotide changes per 100 nucleotides.

of succinic acid and lactic acid are also produced. Lactate may be converted to succinate. Propionate is not produced from the threonine. The pathogenicity of *Centipeda periodontii* has not been determined.

The lipopolysaccharide of *Centipeda periodontii* is composed of hexose (21.7%), hexosamine (9.1%), fatty acid (10.3%), protein (0.5%), phosphorous (2.5%), 2-keto-3-deoxyoctonate (4.3%), and heptose (2.3%) (Kokeguchi et al., 1990).

Enrichment and isolation procedures

Strains of *Centipeda* species can be isolated from subgingival debris dispersed and diluted in prerduced dispersion media, plated on trypticase-soy agar containing 5% sheep blood (BBL) and incubated at 35°C under anaerobic conditions for 5–7 d. The atmosphere of the anaerobic chamber in which the plates are incubated is N₂:CO₂:H₂ (80:10:10). Strains can subsequently be cultivated on blood agar plates.

Maintenance procedures

Active cultures can be maintained on blood agar and subcultured weekly. Strains can be grown on blood agar and pieces of the agar can be placed in Socransky complex broth supplemented with 5% DMSO and stored in liquid nitrogen. Strains can be lyophilized in brain heart infusion supplemented medium containing 12% sucrose. Strains can be grown in Todd–Hewitt broth (BBL) for inocula or large volume cultures.

Procedures and methods for characterization tests

Members of this genus can be characterized according to the general methods outlined in the Virginia Polytechnic

Institute Anaerobic Laboratory Manual (Holdeman and Moore, 1972).

Taxonomic comments

The characteristics of the genus *Centipeda* and the single species *Centipeda periodontii* are based on the study of nine strains (Lai et al., 1983). The cells have a centipede-like appearance due to the numerous sets of flagellar bundles found on both sides of the cells, and this is considered the main differentiating characteristic of this genus from related genera, namely, *Selenomonas*. The first phylogenetic study of *Centipeda periodontii* placed it close to the genus *Selenomonas* (Sawada et al., 1999). Phylogenetic analysis based on the current 16S rRNA gene sequence database shows the genus *Centipeda* falls within the radiation of the genera *Selenomonas*, *Schwartzia*, *Anaerovibrio*, and *Mitsuokella* (Figure 206). It shares 96.1–97.8% 16S rRNA gene sequence similarity with a cluster of *Selenomonas* species, namely, *Selenomonas diana*, *Selenomonas flueggei*, *Selenomonas infelix*, and *Selenomonas noxia* that is supported by a bootstrap value of 100%. Interestingly *Centipeda periodontii* shares only 91% 16S rRNA gene sequence similarity with *Selenomonas sputigena*—the type species of the genus *Selenomonas*—which does not cluster with the majority of the *Selenomonas* species. Considering the lack of relationship between *Selenomonas sputigena* and the *Selenomonas* species closely related to *Centipeda periodontii*, it could be considered that the *Selenomonas* species *Selenomonas diana*, *Selenomonas flueggei*, *Selenomonas infelix*, and *Selenomonas noxia* are in fact species of the genus *Centipeda*. A 16S rRNA gene sequence based PCR assay has been developed for the detection of *Centipeda periodontii* and for differentiating it from *Selenomonas sputigena* (Sawada et al., 2000).

List of species of the genus *Centipeda*

1. ***Centipeda periodontii*** Lai, Males, Dougherty, Berthold and Listgarten 1983, 631^{VP}

peri.o.don'ti.i. Gr. prop. *peri* around; Gr. masc. n. *odon* tooth; N.L. neut. n. *periodontium* periodontium; N.L. gen. n. *periodontii* of the periodontium.

Cells are Gram-stain-negative, slightly serpentine, long, and rod-shaped with bluntly tapered ends. The cell diam-

eter is 0.65 μm, and the cell length ranges from 4 to >17 μm. Multiple sets of flagellar bundles are present on each side of the cell. Actively motile with occasional tumbling. Older cultures lack motility, and cytoplasmic granules are visible. Nucleoid areas. Cytoplasm contains rod-shaped, electron-dense inclusions. Colonies on isolation on blood agar are flat, transparent, and approximately 2 mm in diameter with

irregular borders. Subcultured colonies are gray, transparent, and flat or thinly raised with finely granular surfaces. Growth on complex media. Strict anaerobes. Growth occurs between 32°C and 37°C; the optimum temperature is 35°C. Fructose, galactose, glucose, lactose, maltose, mannitol, melibiose, farinose, sorbitol, and sucrose are fermented by all strains. Fermentation of adonitol, cellobiose, mannose, melezitose, rhamnose, salicin, trehalose, and xylose is variable among strains. Amygdalin, arabinose, dulcitol, esculin, glycogen, inositol, inulin, sorbose, and starch are not fermented. Starch is not hydrolyzed; esculin hydrolysis varies among strains. Arginine is not utilized. The major

end product of growth on peptone-yeast extract broth and peptone-yeast extract-glucose broth is propionic acid; succinic acid and lactic acid are also produced. Catalase, oxidase, urease, H₂S, and indole are not produced. Nitrate is reduced, and *o*-nitrophenyl-β-(D)-galactopyranoside is utilized. Propionate is not produced from threonine, and gelatin is not liquefied. No hemolysis occurs on sheep blood agar. Isolated from human periodontal lesions.

DNA G+C content (mol%): 51.4–53.6 (T_m).

Type strain: LL2383, ATCC 35019, CCUG 44586, CIP 105322, DSM 2778.

GenBank accession number (16S rRNA gene): AJ010963.

Genus XI. *Dendrosporobacter* Strömpl, Tindall, Lünsdorf, Wong, Moore and Hippe 2000, 105^{VP}

CARSTEN STRÖMPL

Den.dro.spo.ro.bac'ter. Gr. n. *dendro* tree; Gr. n. *spora* seed, spore; N.L. masc. n. *bacter* equivalent of Gr. neut. dim. n. *bakterion* rod, staff; N.L. masc. n. *Dendrosporobacter* a spore-bearing rod from a tree.

Cells are straight rods with **Gram-stain-negative** cell walls. Cells occur singly or in pairs and often show unequal division. Motile by one to three lateral flagella. Cell size is 0.4–0.6 × 1.2–2.7 μm. **Spores** are round and terminal or oval and central, and swell the cell. **Obligately anaerobic. Mesophilic** with optimal growth occurring at 25–30°C. Catalase and oxidase-negative. **Chemorganotrophic**. Major products in Peptone/Yeast extract (PY) broth with 0.5% (w/v) fructose are acetate, propionate, propanol, and hydrogen. The modified **naphthoquinone** “lipid F”, with octa- and nonaprenologues (ratio approx. 1:1) as the predominant isoprenologues, is present, but **no cytochromes**. Predominant polar lipids are phosphatidyl ethanolamine, phosphatidyl serine, and an unidentified glycolipid, together with a number of minor phospholipids and unidentified components. 3-Hydroxy fatty acids

(C_{11:0} 3OH, C_{12:0} 3OH, and C_{13:0} 3OH) are present, approximately half of which are not esterified. The predominant non-hydroxylated fatty acids are C_{11:0}, C_{15:1}, C_{15:0} and C_{17:1}.

DNA G+C content (mol%): 48.5 (HPLC) or 52–54 (T_m).

Type species: ***Dendrosporobacter quercicolus*** (Stankewich, Cosenza and Shigo 1971) Strömpl, Tindall, Lünsdorf, Wong, Moore and Hippe 2000, 105^{VP} (*Clostridium querciculum* Stankewich, Cosenza and Shigo 1971, 302).

Further descriptive information

Lipoquinones are present at relatively low concentrations. Multiple heterogeneous copies of the 16S rRNA gene may be present. Cadaverine is the main polyamid in cell-wall peptidoglycan; minor polyamids are spermidine and putrescine (Hamana et al., 2002).

Enrichment and isolation procedures

Dendrosporobacter has been isolated from the ooze of discolored oak tree tissue. This organism has been isolated only once and has not been detected from other habitats in culture-independent studies suggesting a high specialization of this fastidious anaerobe.

Maintenance procedures

Dendrosporobacter may be maintained in PY-fructose broth (Holdeman et al., 1977). Long-term storage by lyophilization (Hippe, 1991) is successfully applied at the DSMZ.

Taxonomic comments

Stankewich et al. (1971) assigned their isolate to the genus *Clostridium*, although it possesses some characteristics which are not typical for the genus (Cato et al., 1986). Besides its restricted physiological activities, it exhibits a Gram-stain-negative cell wall and an unusually high G+C content of the DNA. The 16S rRNA sequence (M59110) published by Woese grouped this species remote from the type species, *Clostridium butyricum*. Consequently, Collins et al. (1986) created their “clostridial cluster IX” exclusively for *Clostridium querciculum* during their phylogenetic analysis of *Clostridium sensu lato*. It became apparent that *Clostridium querciculum* is related to the genera in the *Veillonellaceae* and not to the typical *Clostridium*. The additional chemotaxonomic data obtained by Strömpl et al. (2000) led them to recognize a new genus and combination for *Clostridium querciculum*, as *Dendrosporobacter quercicolus*. The next closest relatives by 16S rRNA gene sequence similarity are the genera *Anaerostipes* and *Propionispora*. *Propionispora arboris*, isolated from wetwoods of living trees, shows very different metabolic properties, a significantly lower G+C content of the DNA, and possesses cytochromes.

List of species of the genus *Dendrosporobacter*

1. ***Dendrosporobacter quercicolus*** (Stankewich, Cosenza and Shigo 1971) Strömpl, Tindall, Lünsdorf, Wong, Moore and Hippe 2000, 105^{VP} (*Clostridium querciculum* Stankewich, Cosenza and Shigo 1971, 302^{AL})
quer.ci'co.lus. L. n. *quercus* oak, L. masc. adj. *quercicolus* associated with oak.

The species description is identical with that of the genus with the following additions.

Surface colonies on blood agar plates are irregular, raised, gray, and dull, with a lobate or rhizoid margin. Gelatin, esculin, and starch are not hydrolyzed. Lipase and lecithinase are not produced. Indole is not produced. Nitrate is not reduced. Acid is formed from fructose, but not from glucose, amygdalin, cellobiose, glycogen, lactose, maltose, ribose, starch, sucrose, trehalose, and xylose. Weak

fermentation of glycerol, inositol, and ribose may occur in trypticase-yeast extract broth. The type strain is susceptible to chloramphenicol, clindamycin, erythromycin, and tetracycline but resistant to penicillin G. Culture supernatants are nontoxic to mice.

DNA G+C content (mol%): 48.5 (HPLC) or 52–54 (T_m).

Type strain: ATCC 25974, DSM 1736.

GenBank accession number (16S rRNA gene): M59110, AJ010962.

Genus XII. *Dialister* (ex Bergey, Harrison, Breed, Hammer and Huntoon 1923)

Moore and Moore 1994, 191^{VP} emend. Downes, Munson and Wade 2003, 1939 emend. Jumas-Bilak, Jean-Pierre, Carlier, Teyssier, Bernard, Gay, Campos, Morio and Marchandin 2005, 2478

WILLIAM G. WADE

Dialis'ter. The etymology, and therefore the gender, of the genus name is unknown. Downes et al. (2003) proposed that the gender of the genus name be assigned as masculine, as allowed under Rule 65(3) of the Bacteriological Code.

Cells are **obligately anaerobic** or **microaerophilic**, nonmotile, nonspore-forming, **nonfermentative**, small Gram-stain-negative **coccobacilli** (0.2–0.4 × 0.3–0.7 μm). Growth in broth media is only slightly turbid at best. Esculin and urea are not hydrolyzed; indole and catalase are not produced. There is no growth in 20% bile. **Metabolic end products are variable amounts of acetate, lactate, and propionate**. The major cellular constituents of the type species *Dialister pneumosintes*, *Dialister microaerophilus*, and *Dialister propionificiens* include the fatty acids $C_{18:1\ 09c}$, $C_{16:0}$, $C_{18:0}$, and $C_{16:1\ 07c}$, but have not been determined for *Dialister invisus*.

DNA G+C content (mol%): 35–46; type species, 35.

Type species: ***Dialister pneumosintes*** (Olitsky and Gates 1921) (ex Bergey, Harrison, Breed, Hammer and Huntoon 1923, Moore and Moore 1994, 191^{VP} emend. Downes, Munson and Wade 2003, 1940 emend. Jumas-Bilak, Jean-Pierre, Carlier, Teyssier, Bernard, Gay, Campos, Morio and Marchandin 2005, 2477 (*Bacterium pneumosintes* Olitsky and Gates 1921, 727; *Bacteroides pneumosintes* Holdeman and Moore 1970, 33).

Further descriptive information

Dialister species are found in the oral cavity of humans. They have been isolated from healthy subjects and from a variety of oral infections. They have also been isolated from clinical specimens including blood cultures and abscesses at various body sites including the brain, infected cysts, and wound infections.

All species are predominantly unreactive in conventional biochemical physiological tests, but some useful differential characteristics are given in Table 205.

Enrichment and isolation procedures

Dialister species grow slowly and form small colonies (<0.5 mm in diameter) on solid media even after extended incubation, but are able to grow on standard blood agar base media supplemented with 5% horse or sheep blood. Growth in peptone/yeast extract broth is poor, showing faint turbidity at best, although this may be partly due to the small size and consequent lack of light refraction of the organisms. Supplementation of broth media with carbohydrates does not improve growth.

Maintenance procedures

Strains can be maintained on blood agar incubated anaerobically at 37°C and subcultured weekly. Lyophilization of cultures in the early stationary phase of growth is recommended for long term storage of most strains. Strains can also be stored at –70°C in Brain heart Infusion broth supplemented with 10% glycerol.

Procedures for testing special characters

The general methods described for the characterization of anaerobes in the VPI Anaerobe Laboratory Manual (Holdeman et al., 1977) and the Wadsworth-KTL Anaerobic Laboratory

Manual (Jousimies-Somer et al., 2002) are suitable for the study of members of this genus. The RapidID 32A anaerobe identification kit (bioMérieux) is of limited value for the identification of members of this genus because two species, *Dialister invisus* and *Dialister propionificiens*, give uniformly negative results in each of the constituent tests (Jumas-Bilak et al., 2005).

Differentiation of the genus *Dialister* from closely related taxa

The genera most closely related to *Dialister* are *Veillonella*, *Anaeroglobus*, and *Megasphaera*. *Veillonella* species resemble *Dialister* in being Gram-stain-negative anaerobic cocci. It is difficult to reliably distinguish members of the two genera on the basis of cellular or colonial morphology, although *Veillonella* species exhibit faster and relatively more luxuriant growth on solid media. *Anaeroglobus geminatus* produces acid from galactose and mannose while all species of *Dialister*, *Megasphaera*, and *Veillonella* do not.

The most reliable way to distinguish *Dialister* from related genera is 16S rRNA gene sequence analysis (Downes et al., 2003; Jumas-Bilak et al., 2005; Willems and Collins, 1995a). 16S rRNA comparisons also allow the differentiation of *Dialister* species, as does comparative analysis of *dnaK* sequences (Jumas-Bilak et al., 2005).

Taxonomic comments

Dialister belongs to a group of genera, sometimes referred to as the *Sporomusa* sub-branch, within the predominantly Gram-stain-positive phylum *Firmicutes*, that have true Gram-negative cell walls (Figure 207). Designated Cluster IX in the clostridial classification described by Collins et al. (1994), this group contains a number of genera in addition to those mentioned above including *Sporomusa*, *Selenomonas*, and *Acidaminococcus*.

Dialister species vary considerably in the mol% G+C content of their DNAs, from 35% for the type species *Dialister pneumosintes* to 46% for *Dialister invisus*, an unusually wide range for members of the same genus. However, Jumas-Bilak et al. (2005) have shown that the species also vary markedly in their genome size with *Dialister invisus* having a genome of 1.9 Mb, almost 50% larger than that of *Dialister pneumosintes* at 1.34 Mb. It would appear then, that a large scale horizontal transfer event or deletion has occurred during the evolution of this genus, resulting in chromosomes of differing G+C content.

Acknowledgements

Julia Downes is thanked for her contribution to the data reported in this chapter and for numerous helpful discussions.

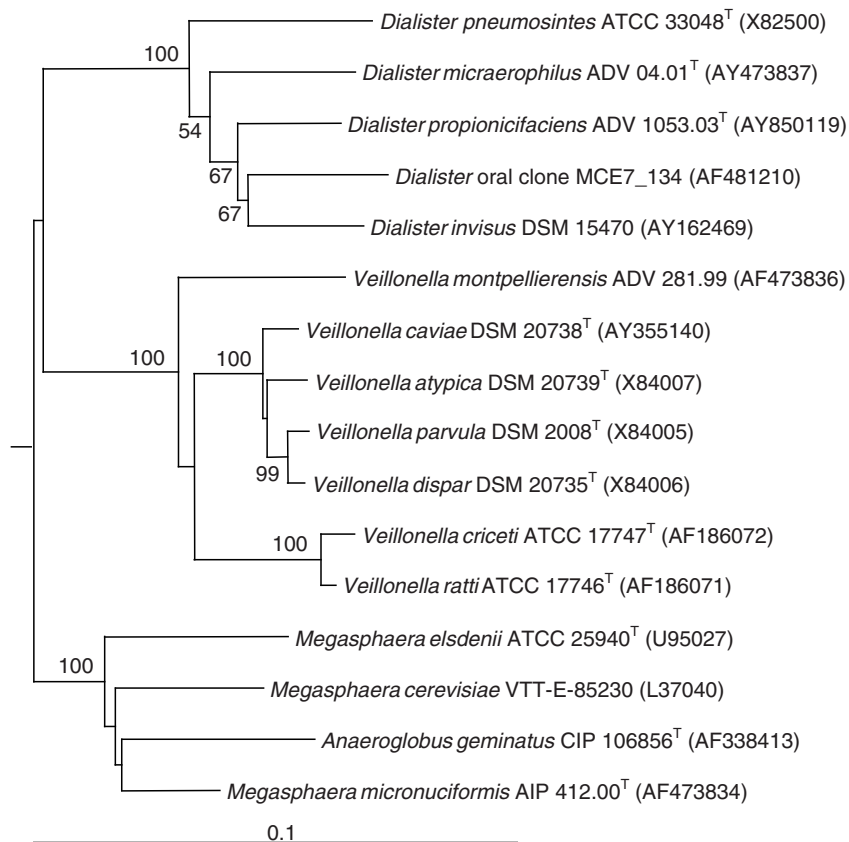

FIGURE 207. Phylogenetic tree based on 16S rRNA gene sequence comparisons over 1296 aligned bases showing relationship between *Dialister* species and related taxa. Tree was constructed using the neighbor-joining method following distance analysis of aligned sequences. Numbers represent bootstrap values for each branch based on data for 100 trees.

List of species of the genus *Dialister*

1. ***Dialister pneumosintes*** (Olitsky and Gates 1921) (*ex* Bergey, Harrison, Breed, Hammer, Huntoon 1923) Moore and Moore 1994, 191^{VP} emend. Downes, Munson and Wade 2003, 1940 emend. Jumas-Bilak, Jean-Pierre, Carlier, Teyssier, Bernard, Gay, Campos, Morio and Marchandin 2005, 2477 (*Bacterium pneumosintes* Olitsky and Gates 1921, 727; *Bacteroides pneumosintes* Holdeman and Moore 1970, 33)
 pneu.mo.sint'es. Gr. n. *pneuma* air; Gr. n. *sintes* a spoiler, thief; N.L. adj. *pneumosintes* breath destroying.
 Cells of the type strain are 0.2–0.4 × 0.3–0.6 µm, arranged singly, in pairs, or in very short chains. Deep agar colonies are punctiform, granular, and white with no evidence of gas production. Surface colonies on blood agar are punctiform, circular, entire, convex, clear, transparent, shiny, and smooth. Growth in broth exhibits faint turbidity at best. Equivalent growth at 30 and 37°C; no growth at 25 or 45°C. Isolated from the nasopharynx and mouth in healthy individuals and from clinical specimens from periodontitis, endodontic infections, blood, respiratory tract, and brain abscesses. No DNase or phosphatase detected. Pathogenic for rabbits when injected intratracheally.
DNA G+C content (mol%): 35 (HPLC).
Type strain: ATCC 33048, CCUG 21025, CIP 107041, DSM 11619, JCM 10004.
GenBank accession number (16S rRNA gene): X82500.
2. ***Dialister invisus*** Downes, Munson and Wade 2003, 1939^{VP}
 in.vis'us. L. adj. *invisus* unseen, referring to the lack of turbidity of broth cultures of this organism.
 Description is based on six strains isolated from the human oral cavity. Cells are obligately anaerobic, nonmotile, Gram-stain-negative, small or ovoid cocci (0.3–0.4 × 0.3–0.6 µm) occurring singly, in pairs, short chains, and small clumps. After 7 d incubation on FAA plates (Fastidious Anaerobe Agar, LabM, Bury, UK), colonies are 0.5–0.7 mm in diameter, circular, entire, and either translucent and umbonate or transparent and low convex with a narrow marginal, translucent fringe. Growth in broth media produces only a slight turbidity and is not visibly stimulated by the addition of 1% carbohydrates. Cells are asaccharolytic and only trace amounts of acetate and propionate are detected as end products of metabolism in PYG (peptone yeast extract glucose broth). Esculin, arginine, and urea are not hydrolyzed. Indole and catalase are not produced. There is no growth in 20% bile. Isolated from the human oral cavity in patients with endodontic and periodontal infections.
DNA G+C content (mol%): 45 (HPLC).
Type strain: E7.25, CCUG 47026, DSM 15470.
GenBank accession number (16S rRNA gene): AY162469.
3. ***Dialister microaerophilus*** Jumas-Bilak, Jean-Pierre, Carlier, Teyssier, Bernard, Gay, Campos, Morio and Marchandin 2005, 2476^{VP}
 mic.aer'o.phi.lus. Gr. adj. *mikros* small; Gr. n. *aer*, air; N.L. adj. *philus* from Gr. adj. *philos* loving; N.L. masc. adj. *microaerophilus* slightly air-loving, referring to the ability of the species to grow in microaerophilic conditions.
 Cells are Gram-stain-negative, nonmotile, nonspore-forming, coccoid to coccobacillary (0.2–0.4 × 0.3–0.6 µm) occurring singly, in pairs or in clumps. After prolonged incubation, on Columbia blood agar, colonies are less than 0.5 mm in diameter, circular, convex, and translucent. Growth occurs under anaerobic and microaerophilic conditions. Members of this species are unreactive in most conventional tests, and metabolic end products are not produced in any significant quantities. Isolated from human clinical samples.
DNA G+C content (mol%) of the type strain: 36 (HPLC).
Type strain: ADV04.01, AIP 25.04, CIP 108278, CCUG 48837.
GenBank accession number (16S rRNA gene): AF473837.
4. ***Dialister propionicifaciens*** Jumas-Bilak, Jean-Pierre, Carlier, Teyssier, Bernard, Gay, Campos, Morio and Marchandin 2005, 2477^{VP}
 pro.pi.o'ni.ci.fa.ci'ens. N.L. n. *acidum propionicum* propionic acid; L. v. *facio ere* to produce; N.L. part. adj. *propionicifaciens* propionic acid-producing.
 Cells are Gram-stain-negative, nonmotile, nonspore-forming, coccoid to coccobacillary (0.2–0.4 × 0.3–0.6 µm) occurring singly, in pairs, or in clumps. After prolonged incubation, on Columbia blood agar, colonies are less than 0.5 mm in diameter, circular, convex, and translucent. Growth occurs under anaerobic and microaerophilic conditions. Members of this species are unreactive in most conventional tests. Small amounts of acetic, propionic, and lactic acids are produced as end products of metabolism. Propionate is produced when growth medium is supplemented with sodium succinate. Isolated from human clinical samples.
DNA G+C content (mol%): not determined because of the poor growth of the organism.
Type strain: ADV 1053.03, AIP 26.04, CIP 108336, CCUG 49291.
GenBank accession number (16S rRNA gene): AY850119.

Genus XIII. ***Megasphaera*** Rogosa 1971a, 187^{AL} emend. Engelmann and Weiss 1985; emend. Marchandin, Jumas-Bilak, Gay, Teyssier, Jean-Pierre, Siméon de Buochberg, Carrière and Carlier 2003b, 552

HÉLÈNE MARCHANDIN, RIIKKA JUVONEN AND AULI HAIKARA

Me.ga.sphae'ra. Gr. adj. *megas* big; Gr. n. *sphaera* a sphere; N.L. fem. n. *Megasphaera* big sphere.

Anaerobic. Gram-stain-negative cocci, 0.4–2.0 µm or more in diameter. Nonmotile. Endospores not formed. Glucose, fructose, and lactate may or may not be fermented. Gas may or may

not be produced. Gelatin or milk is not hydrolysed and nitrate is not reduced. Pyruvate but not succinate is utilized. Common metabolic end products of all five species described are acetic,

propionic, butyric, and valeric acid. Found in the rumen of cattle and sheep, in the feces and intestine of man, in human clinical samples, and in spoiled bottled beer.

DNA G+C content (mol%): 42.4–46.4 (T_m), 53.6 (Bd).

Type species: Megasphaera elsdenii (Gutierrez, Davis, Lindahl and Warwick 1959) Rogosa 1971a, 187^{AL} (*Peptostreptococcus elsdenii* Gutierrez, Davis, Lindahl and Warwick 1959, 20; organism LC Elsdén and Lewis 1953, 183; rumen organism LC Elsdén, Volcani, Gilchrist and Lewis 1956, 686).

Further descriptive information

All strictly anaerobic, Gram-stain-negative cocci were originally classified in a single family, the *Veillonellaceae*, including the genera *Veillonella*, *Acidaminococcus*, and *Megasphaera* (Rogosa, 1971b, 1984a). An additional genus, i.e., the genus *Anaeroglobus*, was subsequently characterized within this family (Carlier et al., 2002). According to phylogenetic taxonomy, these four genera, despite the presence of a cell envelope typical for Gram-stain-negative bacteria, belong to the *Sporomusa* sub-branch of the *Clostridium* subphylum (Schleifer et al., 1990; Stackebrandt et al., 1985) of the *Firmicutes* (Carlier et al., 2002). Further phylogenetic analyses have supported the relationships among the species of genera belonging to the *Sporomusa* sub-branch (Both et al., 1992; Willems and Collins, 1995a; Marchandin et al., 2003b). More recently, in *Bergey's Manual of Systematic Bacteriology*, all members of the *Sporomusa* sub-branch have been grouped in the family *Veillonellaceae* (Figure 6; Ludwig et al., 2009). The genus *Megasphaera* created by Rogosa (1971a) presently includes five species: *Megasphaera elsdenii* (the type species), *Megasphaera cerevisiae*, *Megasphaera micronuciformis*, *Megasphaera paucivorans*, and *Megasphaera sueciensis*. Based on the 16S rRNA gene sequence analysis, the similarity between *Megasphaera elsdenii* and *Megasphaera cerevisiae* was 92%. *Megasphaera micronuciformis* displayed 94.5% and 93.8% 16S rRNA gene sequence identity with *Megasphaera cerevisiae* and *Megasphaera elsdenii*, respectively (Marchandin et al., 2003b). *Megasphaera sueciensis* and *Megasphaera paucivorans* shared almost identical sequences and showed 93.9%, 93.2% and 89.8% sequence identity with *Megasphaera cerevisiae*, *Megasphaera micronuciformis* and *Megasphaera elsdenii*, respectively (Juvonen and Suihko, 2006). The nearest other species (having similarities with the type strain *Megasphaera elsdenii* ATCC 25940^T) are *Anaeroglobus geminatus* (92.4%), *Allisonella histaminiformans* (88.9%), and two *Dialister* species,

Dialister pneumosintes and *Dialister invisus* (88–89%). Doyle et al. (1995) have first demonstrated the phylogenetic position of *Megasphaera cerevisiae* as a sister taxon of *Megasphaera elsdenii* by determining the nucleotide sequence of the small subunit 16S rRNA of the bacterium. The phylogenetic tree (obtained by applying the neighbor-joining method and parsimony analyses) also showed the relationship between *Megasphaera cerevisiae* and organisms of the *Sporomusa* group (Doyle et al., 1995). Marchandin et al. (2003b) conducted a general phylogenetic analysis of the *Sporomusa* sub-branch based on 16S rRNA gene sequences and showed that members of the genus *Megasphaera* grouped together with *Anaeroglobus geminatus* and then with members of the genus *Dialister*. However, an absolute branching order in the *Megasphaera*–*Anaeroglobus* group still remains uncertain owing to the low bootstrap values obtained for the corresponding nodes (Juvonen and Suihko, 2006; Marchandin et al., 2003b).

The species of the genus *Megasphaera* can be differentiated from each other based on cell size with the exception of *Megasphaera sueciensis* and *Megasphaera paucivorans*. *Megasphaera elsdenii* cells are the largest, up to 2.4–2.6 µm in diameter, occurring in pairs or occasionally in chains of 8–20 cells (Figure 208) (Elsden et al., 1956; Rogosa, 1971b). Extremely long chains are formed in the rumen (Gutierrez et al., 1959). In stained preparations, the adjacent sides of pairs of cells tend to be flattened and *Megasphaera elsdenii* cells were 1.2–1.8 × 1.7 µm (Elsden et al., 1956). *Megasphaera cerevisiae* cells are spherical or slightly oval, 1.3–2.1 µm in diameter, occur singly, in pairs, or occasionally in short chains (Figure 209 and Figure 210) (Engelmann and Weiss, 1985; Juvonen and Suihko, 2006). In fixed or stained preparations, the cell diameter is 1.0–1.2 µm (Haikara and Lounatmaa, 1987). The ultrastructure of the cell surface of the *Megasphaera cerevisiae* brewery isolates and *Megasphaera elsdenii* is very uniform (Haikara and Lounatmaa, 1987). The cells of *Megasphaera sueciensis* and *Megasphaera paucivorans* are on mean smaller than those of *Megasphaera cerevisiae* and occur mostly in pairs. Stationary phase cells of *Megasphaera paucivorans* may form clumps and chains of 20–25 diplococci (Juvonen and Suihko, 2006). *Megasphaera micronuciformis* is the smallest representative of the genus *Megasphaera* and consists of coccoid cells showing a convoluted surface after negative staining. *Megasphaera micronuciformis* cells are usually single and their diameter varies from 0.4 to 0.6 µm (Figure 211) (Marchandin

et al., 2003b). Electron microscopy of ultrathin sections reveals that the *Megasphaera* species, despite their phylogenetic affiliation to the Gram-stain-positive bacteria, possess a triple-layered cell wall typical of Gram-stain-negative bacteria with an outer cell-wall membrane (Engelmann and Weiss, 1985; Marchandin et al., 2003b; Rogosa, 1971a).

The cellular fatty acids of *Megasphaera cerevisiae* and *Megasphaera elsdenii* have been investigated, and shown to be almost identical (Helander and Haikara, 1995; Johnston and Goldfine, 1982). The main fatty acid components are C_{12:0}, C_{16:0}, C_{16:1}, C_{18:1}, C_{17 cyclo}, C_{19 cyclo}, C_{12:0 3OH}, and C_{14:0 3OH}. Alk-1-enyl chains instead of acyl chains are detected to a considerable extent (14 % of total fatty acids); alk-1-enyl chains are indicative of plasmalo-

gen lipids (1-alkenyl-2-acyl glycerolipids), which are confined to strict anaerobes. *Megasphaera elsdenii* is particularly rich in the plasmalogen forms of phosphatidylethanolamine and phosphatidylserine, which together represent approximately 50% of the total phospholipid (Kaufman et al., 1990; Kaufman et al., 1988; van Golde et al., 1973). This plasmalogen content is not affected by growth temperature (Johnston and Goldfine, 1982) but can dramatically decrease when the interval between serial subcultures is prolonged to 3–6 weeks (Kaufman et al., 1988). The cellular fatty acids of the three other *Megasphaera* species are unknown.

The cell-wall peptidoglycan of *Megasphaera cerevisiae* as well as that of *Megasphaera elsdenii* is of the *meso*-diaminopimelic acid

direct type and contains putrescine residues (Engelmann and Weiss, 1985). No information is available concerning the cell surface protein pattern and the lipopolysaccharide (LPS) composition of the genus *Megasphaera*.

Several growth media have been used for culturing *Megasphaera elsdenii* including the semi-defined medium described by Scott and Dehority (1965) (Cheng et al., 1988; Forsberg, 1978) and the medium described by Van Golde et al. (1973) (Johnston and Goldfine, 1982). However, the most commonly used media for cultivation and isolation of *Megasphaera elsdenii* strains are peptone-yeast extract (PY) media (Holdeman et al., 1977) supplemented with lactate (PYL) or glucose (PYG) (1% w/v, final concentration), lactate-based growth media (ATCC medium 566), and the Reinforced Clostridial Medium (ATCC medium 1053) (Kaufman et al., 1988). Moreover, Sugihara et al. showed that *Megasphaera elsdenii* can be recovered on *Bifidobacterium* selective agar or Eugonagar with maltose and on media containing neomycin (*Veillonella* agar with neomycin, egg yolk agar with neomycin, or blood agar with neomycin) (Sugihara et al., 1974). Owing to the inability of *Megasphaera cerevisiae* to utilize glucose, replacement of glucose with fructose or lactate in peptone-yeast extract medium (PYF*, PYL) is necessary for maximal growth (Engelmann and Weiss, 1985). *Megasphaera micronuciformis* can grow on Columbia sheep blood agar (Marchandin et al., 2003b) as well as in trypticase/glucose/yeast extract (TGY) medium (Carrier et al., 2002). Excellent growth of *Megasphaera paucivorans* and *Megasphaera sueciensis* (4+ on a scale from 0 to 4+) is obtained in PY supplemented with pyruvate or gluconate (1%, v/v, final concentration). PYG and PYF support moderate to good (1+ or 2+) growth (Juvonen and Suihko, 2006). Because the *Megasphaera* species are strict anaerobes, anaerobic cultivation conditions are required (see *Pectinatus*). *Megasphaera elsdenii* colonies on yeast extract peptone agar supplemented with sodium lactate are round, smooth, slightly raised, and have a glistening, mucoid appearance. At 48 h, the colonies were 0.2–1.0 mm in diameter and older colonies were as large as 3–4 mm. Deep colonies are lenticular, 1–4 mm in diameter, and tan with soft butyrous texture (Gutiérrez et al., 1959; Rogosa, 1971a). Colonies of *Megasphaera cerevisiae* on PYL or PYF are whitish, smooth, opaque, flat, shiny, and 2–5 mm in diameter (Engelmann and Weiss, 1985; Weiss et al., 1979). Colonies of *Megasphaera micronuciformis* appeared on Columbia sheep blood agar after 2–3 d incubation at 37°C and are circular, convex, shiny, and translucent with a smooth surface. The colonies are approximately 0.5–1.0 mm in diameter, nonpigmented and nonhemolytic (Marchandin et al., 2003b). Colonies of *Megasphaera paucivorans* and *Megasphaera sueciensis* after 7 d incubation have a diameter of 1–1.5 mm and 0.5–0.8 mm, respectively, and are circular, convex, glossy and opaque with entire margins and yellowish color. The optimum growth temperature for the brewery-related *Megasphaera* species is around 30°C (28–37°C) (Engelmann and Weiss, 1985; Haikara and Lounatmaa, 1987; Juvonen and Suihko, 2006), whereas for *Megasphaera elsdenii* it is 37–40°C (25–40°C) (Rogosa, 1971a). A few *Megasphaera elsdenii* strains can grow at 45°C, but no culture can be obtained at 50°C. Moreover, *Megasphaera elsdenii* does not grow at room temperature, whereas the brewery isolates can

grow at 15°C. A selective medium is designed for the detection of *Megasphaera cerevisiae* (see *Enrichment and isolation procedures*, below) that also supports the growth of the two other brewery-related *Megasphaera* species (Juvonen and Suihko, 2006).

Effect of pH on the growth rates of *Megasphaera elsdenii* showed that it grew over a pH range of 4.6–7.8 with an optimum pH for growth about 6.05 (Therion et al., 1982). *Megasphaera elsdenii* is therefore considered as relatively acid-tolerant. In comparison to acid-intolerant species, this acid tolerance could be attributed to a larger amount of H⁺-ATPase at neutral pH and to a higher capacity to enhance the amount of H⁺-ATPase at low pH (Miwa et al., 1997). *Megasphaera cerevisiae* is sensitive to the normal low pH of beer. Increase of pH from 4.1 to 4.7 accelerates growth, and no growth occurs in beer of pH 4.0–4.1 (Haikara, 1984; Haikara and Lounatmaa, 1987; Seidel et al., 1979). Acid tolerance of *Megasphaera paucivorans* and *Megasphaera sueciensis* is unknown but the bottled beers spoiled by these organisms had a pH of 4.3–4.9 (Juvonen and Suihko, 2006).

In addition to low pH, alcohol is the important factor inhibiting the growth of *Megasphaera cerevisiae* in beer. Beer with low alcohol content (<2.25% w/v) is more prone to spoilage by *Megasphaera cerevisiae* than beers with higher alcohol content (Haikara, 1984; Haikara and Lounatmaa, 1987). The growth of *Megasphaera cerevisiae* is restricted in commercial beer with an alcohol content of 3.5% (w/v) and is totally prevented by an alcohol content above 4.3% (w/v) (Back, 1981; Haikara, 1991; Seidel et al., 1979). *Megasphaera sueciensis* has hitherto only been found in low-alcohol beer (2.2%, w/v) whereas *Megasphaera paucivorans* has spoiled beer with an alcohol content of 3.9% (w/v) (Juvonen and Suihko, 2006). *Megasphaera cerevisiae* is rather tolerant to hop bitter substances of beer (Back, 1981; Kirchner et al., 1980; Seidel et al., 1979), and due to its sensitivity to alcohol and low pH, the respective contaminations are much more uncommon than those caused by *Pectinatus* species.

Utilization of different carbon sources by the five *Megasphaera* species is presented in Table 206. *Megasphaera elsdenii* possesses a fermentative type of metabolism and can use both carbohydrates and organic acids. Good growth and gas production are observed with lactate, glucose, and fructose. Growth and fermentation are variable with maltose, sorbitol, and mannitol. No growth and no fermentation occur with arabinose, cellobiose, dextrin, galactose, glycerol, inulin, lactose, mannose, raffinose, rhamnose, salicin, starch, sucrose, trehalose, or xylose. Due to the different metabolic pathways involved, the composition of the fermentation end products is variable depending on the energy source present in the medium. Products from lactate fermentation are acetate, propionate, C4 straight- and branched-chain fatty acids, valerate, little or no caproate and formate according to the strain tested, a large quantity of CO₂, and small amounts of H₂ (Marounek et al., 1989). C4 straight- and branched-chain volatile fatty acids produced by *Megasphaera elsdenii* are butyric, isobutyric, iso-valeric, and 2-methylbutyric acids (Allison, 1978). Glucose is fermented producing different end products. First observations reported by Elsden et al. (1956) and then by Rogosa (1971a, 1984a) indicated that propionate was produced from glucose and that caproate was the most copious product from glucose fermentation (about 60% or more of the total). Several further studies showed that butyrate was the main fermentation product

*PYF consists of (per liter): fructose, 5 g; peptone, 5 g; tryptone, 5 g; yeast extract, 10 g; Na₂HPO₄, 2 g; Tween 80, 1 ml; cysteine-HCl, 0.5 g; pH 7.0.

TABLE 206. Utilization of different carbon sources by *Megasphaera* species^{a,b}

Carbon source	<i>M. elsdenii</i>	<i>M. cerevisiae</i>	<i>M. cerevisiae</i>	<i>M. cerevisiae</i>	<i>M. micronuciformis</i>	<i>M. paucivorans</i>	<i>M. sueciensis</i>
	ATCC 25940 ^T	DSM 20462 ^T	DSM 20461	VTT E-84195, VTT E-85230	AIP 412.00 ^T	VTT E-032341 ^T , VTT E-042576	VTT E-97791 ^T
Arabinose	-	+	-	+	-	-	-
Fructose	+	+	+	+	-	-	-
Glucose	+	-	-	-	-	-	-
Mannitol	+	-	-	-	-	-	-
Maltose	+	-	-	-	-	-	-
Sucrose	+	-	-	-	-	ND	ND
Lactate	+	+	+	+	-	-	-
Gluconate	+	+	ND	ND	-	+	+
None	(+)	(+)	(+)	(+)	ND	(+)	(+)

^a+, pH ≤5.5 or enhanced growth in comparison to medium w/o the added carbon source; (+), pH 5.5–6.0 or slight growth; -, no additional growth or pH decrease caused by the carbon source; ND, not determined.

^bTest results (except for the strains in parentheses): none of the strains used adonitol, esculin, D-cellobiose, dulcitol, erythritol, glycerol (AIP 412.00^T), i-inositol, inulin, lactose, α-D-melibiose, melezitose (AIP 412.00^T), N-acetylglucosamine, raffinose, rhamnose, D-ribose, D-salicin, sorbitol (VTT E-97791^T, VTT E-032341^T), succinate, trehalose (VTT E-97791^T, VTT E-032341^T), D-xylose or xylitol. All strains used pyruvate (data compiled from Haikara, 1991; Marchandin et al., 2003b; Juvonen and Suihko, 2006).

and that no production of propionate from glucose is observed (Forsberg, 1978; Marounek et al., 1989). This latter observation was further attributed to the lack of lactate racemase synthesis by strains fermenting glucose (Hino and Kuroda, 1993). Indeed, lactate racemase synthesis is induced by lactate and the metabolism from D-lactate to propionate is suppressed when *Megasphaera elsdenii* is fermenting glucose (Hino and Kuroda, 1993). Finally, products from glucose differed from those from lactate by formate and caproate production, a lesser production of valerate, little or no production of acetate (according to the strain tested), no production of propionate, and the major metabolic end product being butyric acid (Marounek et al., 1989). Succinate, fumarate, and malate are not attacked. Many studies on the different transport mechanisms and metabolic pathways in *Megasphaera elsdenii* showed that (i) lactate is fermented and propionate is produced via the acrylate pathway, and lactate transport across the membrane appears to occur by active transport that is not dependent on Na⁺ or K⁺ (Martin, 1994), (ii) glucose and fructose uptake involve an inducible phosphoenolpyruvate phosphotransferase (PEP-PTS) system (Dills et al., 1981), and (iii) maltose metabolism involves inducible maltose phosphorylase and maltase (Martin and Wani, 2000). Based on its metabolic characteristics, particularly its capacity to ferment 74–97% of ruminal lactate, *Megasphaera elsdenii* is considered as a probiotic micro-organism useful in reducing acidosis due to lactic acid accumulation in cattle introduced to a high grain diet (Counotte et al., 1981; Ouwerkerk et al., 2002). The carbohydrate spectrum of *Megasphaera cerevisiae* is very narrow compared with that of *Megasphaera elsdenii*. The isolates do not utilize glucose or maltose, but like *Megasphaera elsdenii*, they can grow in sugar-free medium, although growth is very poor (Engelmann and Weiss, 1985; Weiss et al., 1979). With respect to the fermentation of carbohydrates, *Megasphaera cerevisiae* strains form a highly uniform group. Like *Pectinatus*, they can utilize lactate. Metabolic end products are acetic, propionic, iso- and *n*-butyric, iso- and *n*-valeric, and caproic acids (Engelmann and Weiss, 1985; Haikara, 1985; Weiss et al., 1979). Depending on the carbon source used, the predominant end product is butyrate, valerate or caproate. Of the carbon sources tested, *Megasphaera paucivorans* and *Megasphaera sueciensis* only

utilize the organic acids gluconate and pyruvate. Gluconate is mainly fermented to acetate and *n*-butyrate whereas degradation of pyruvate additionally leads to the synthesis of propionate (Juvonen, unpublished data). The major metabolite produced by *Megasphaera paucivorans* and *Megasphaera sueciensis* in autoclaved PYF is iso-valerate but acetate, propionate, iso- and *n*-butyrate, iso- and *n*-valerate and caproate are also formed. Propionate production by *Megasphaera paucivorans* is, however, minor or negligible. In beer, the main metabolic product of both *Megasphaera cerevisiae* and *Megasphaera paucivorans* is *n*-butyric acid (Haikara and Lounatmaa, 1987; Juvonen and Suihko, 2006). The organic acids produced by *Megasphaera sueciensis* in beer have not been determined. All the *Megasphaera* species with the exception of *Megasphaera micronuciformis* produce H₂S (Engelmann and Weiss, 1985; Juvonen and Suihko, 2006; Weiss et al., 1979). Owing to the mixture of various fatty acids and H₂S, the flavor of contaminated beer is particularly unpleasant. *Megasphaera micronuciformis* does not produce gas or ferment any of the carbohydrates tested, and acid is not produced from arabinose, cellobiose, fructose, galactose, glucose, glycerol, inositol, lactose, maltose, mannitol, mannose, melezitose, melibiose, raffinose, rhamnose, ribose, salicin, sorbitol, starch, sucrose, trehalose, or xylose. Its major metabolic end products are acetic, propionic, butyric, iso-valeric, and 2-phenyl-lactic acids (Marchandin et al., 2003b).

The five *Megasphaera* species are catalase and indole-negative and do not hydrolyze urea, arginine, esculin, milk or gelatin. They do not reduce nitrate (Gutierrez et al., 1959; Juvonen and Suihko, 2006; Marchandin et al., 2003b; Weiss et al., 1979), but *Megasphaera elsdenii* can metabolize nitrite (Cheng et al., 1988). Voges–Proskauer reaction (production of acetoin) is negative or weakly positive (Juvonen and Suihko, 2006). *Megasphaera elsdenii* and *Megasphaera cerevisiae* are known to be also benzidine negative. Resistance pattern of the type strains of the five *Megasphaera* species to vancomycin (5 µg) and colistin (10 µg) differ. *Megasphaera paucivorans* and *Megasphaera sueciensis* are resistant to vancomycin and colistin, *Megasphaera micronuciformis* is sensitive to both of these antibiotics whereas *Megasphaera cerevisiae* and *Megasphaera elsdenii* are resistant to vancomycin but sensitive to colistin (Juvonen and Suihko, 2006).

The *Megasphaera* species can be differentiated from each other based on the G+C content of their DNA with the exception of *Megasphaera cerevisiae* and *Megasphaera sueciensis*. The G+C content of the DNA of *Megasphaera elsdenii* is 53.6 mol% (Bd) and that of *Megasphaera cerevisiae* is 42.4–44.8 mol% (T_m) (Engelmann and Weiss, 1985), indicating that there is no close genomic relationship between them. The G+C content of the DNA of *Megasphaera micronuciformis*, *Megasphaera paucivorans* and *Megasphaera sueciensis* is 46.4, 40.5 and 43.1 mol% (T_m), respectively (Juvonen and Suihko, 2006; Marchandin et al., 2003b). According to DNA–DNA hybridization results, 12 *Megasphaera cerevisiae* strains belong to a single genospecies, the similarity being 72–100%, whereas a low degree of similarity, i.e., 22–38% exists between *Megasphaera cerevisiae* strains and *Megasphaera elsdenii* (Engelmann and Weiss, 1985). The DNA–DNA hybridization has confirmed that *Megasphaera sueciensis* and *Megasphaera paucivorans* (41.0 %) are not related to each other or to (respectively) *Megasphaera micronuciformis*^T (28.9 % and 17.1 %), *Megasphaera elsdenii*^T (7.2 % and 23.6 %) or *Megasphaera cerevisiae*^T (22.0 % and 3.1 %) at species level (Stackebrandt and Goebel, 1994; Wayne et al., 1987). The characteristics useful for differentiating the species belonging to the genus *Megasphaera* (except the different carbon sources utilized which are summarized in Table 206) are given in Table 207.

Based on the 16S rRNA gene sequences, real-time *Taq* nuclease PCR assays have been developed to enumerate *Megasphaera elsdenii* in the complex rumen microbial system (Ouwerkerk et al., 2002). The combined primer and probe set used are not specific for *Megasphaera elsdenii* since they also recognize *Megasphaera cerevisiae*. However, since *Megasphaera cerevisiae* was never isolated from the rumen, the assay was considered to be specific for *Megasphaera elsdenii* in the rumen fluid (Ouwerkerk et al., 2002). Specific primers based on the 16S rRNA gene sequence have been designed for early detection of *Megasphaera cerevisiae*

in beer by PCR technique (Doyle et al., 1995; Juvonen et al., 2003; Sakamoto et al., 1997; Satokari et al., 1998), and commercial ready-to-use kits for the analysis of this species in brewery samples are also available (Braune and Eidtmann, 2003; Homann et al., 2002).

Automated ribotyping with *EcoRI*, *PstI*, and *PvuII* has been used for the characterization of 13 *Megasphaera cerevisiae* strains (Suihko and Haikara, 2001). Using a combination of these enzymes, the strains could be divided into six ribotypes. Ribotyping with *EcoRI* also distinguished between *Megasphaera sueciensis* and *Megasphaera paucivorans* strains although their 16S rRNA gene sequences are nearly identical (Juvonen and Suihko, 2006; Suihko and Haikara, 2001). Serological characteristics of *Megasphaera cerevisiae* have been studied by producing peptidoglycan-specific and bacterial surface-reactive Mabs and by producing antibodies against the 40–50 kDa surface protein (Hakalehto, 2000; Ziola et al., 1999, 2000).

Megasphaera elsdenii was shown to be resistant to monensin (growth in the presence of 10 µM), an ionophore antibiotic used as antimicrobial feed additive in cattle diets (Callaway et al., 1999). This observation is in agreement with the negative Gram staining and the presence of an outer membrane in *Megasphaera elsdenii* and contrasts with the phylogenetic placement of *Megasphaera elsdenii* in the low G+C Gram-positive bacteria (*Firmicutes*). Indeed, Gram-stain-negative ruminal bacteria with an outer membrane were shown to be more resistant to monensin than were Gram-stain-positive species (Callaway et al., 1999). Further studies on antimicrobial susceptibility patterns of *Megasphaera elsdenii* revealed that a great strain-to-strain variability can be observed (Marounek et al., 1989; Piriz et al., 1992) and that some strains displayed resistance to several antimicrobial cattle feed additives (Nagaraja and Taylor, 1987). In particular, tetracycline-resistant *Megasphaera elsdenii* strains harboring *tet* genes were isolated from cecal contents and tissues

TABLE 207. Characteristics differentiating the species of the genus *Megasphaera*^{a,b}

^bTaxa (reference): *Megasphaera elsdenii* (Juvonen and Suihko, 2006; Rogosa, 1984a); *Megasphaera cerevisiae* (Engelmann and Weiss, 1985; Juvonen and Suihko, 2006); *Megasphaera micronuciformis* (Juvonen and Suihko, 2006; Marchandin et al., 2003b), *Megasphaera paucivorans* and *Megasphaera sueciensis* (Juvonen and Suihko, 2006).

^cParentheses indicate that production is not constant. Major products are underlined.

of pigs (Stanton and Humphrey, 2003). *Megasphaera elsdenii* was therefore considered to play a role not only in the preservation and dissemination of antibiotic resistance in the intestinal tract but also in the evolution of resistance. *Megasphaera elsdenii* has been detected in intestinal contents and feces of cattle, sheep (Elsden et al., 1956; Gutierrez et al., 1959), and pigs (Giesecke et al., 1970). *Megasphaera elsdenii* is considered one of the most important micro-organisms in the rumen (Marounek et al., 1989) where it can play a major role in preventing or controlling acidosis by removing lactic acid through catabolic action (Stewart and Bryant, 1988). Human isolates were from normal feces (Sugihara et al., 1974; Werner, 1973), from fecal samples of adults and children suffering from gastrointestinal disorders (Haralambie, 1983), from conjunctiva (Thiel and Schumacher, 1994), from gastric and amniotic fluid samples (Marchandin, unpublished data) and from a putrid lung abscess as part of mixed flora (Sugihara et al., 1974). More rarely, *Megasphaera elsdenii* is associated with disease and was implicated in a case of human endocarditis (Brancaccio and Legendre, 1979) and in foot rot lesions in goats (Duran et al., 1990). The natural habitats of the *Megasphaera* species remain unknown. Most of the *Megasphaera cerevisiae* strains and both of the *Megasphaera paucivorans* and the *Megasphaera sueciensis* strain described and characterized have been isolated from spoiled, unpasteurized beer. The sporadic occurrence of *Megasphaera cerevisiae* in pitching yeast and in brewery environment has also been reported (Haikara, 1989, 1991; Seidel, 1985). The *Megasphaera micronuciformis* currently reported are of human origin and were isolated from a liver abscess, pus samples (Marchandin et al., 2003b), sinus and throat (Marchandin, unpublished data). “*Candidatus Megasphaera micronuciformis*” oral clone BU057 (GenBank accession no. AF385566) was described from human purified crevicular cells (Paster et al., unpublished data; Marchandin et al., 2003b). Moreover, *Megasphaera* genomospecies C1, which displayed 99.4% of 16S rRNA gene sequence identity with the type strain of *Megasphaera micronuciformis* and could therefore be considered as “*Candidatus Megasphaera micronuciformis*” oral clone C3MLM013 (GenBank accession no. AY278622), was recovered from the human mouth in microflora associated with dental caries (Wade and Munson, unpublished data).

Enrichment and isolation procedures

Strictly anaerobic conditions are required for growth of the *Megasphaera* species. For example, *Megasphaera elsdenii* and *Megasphaera micronuciformis* grew well in anaerobic conditions obtained in an anaerobic jar with Anaerogen System (Oxoid). Many agar media and broths (see description above) containing fermentable sugars or lactate can be used for cultivation and isolation of *Megasphaera elsdenii*. No enrichment method and no specific selective medium exist for growth of *Megasphaera elsdenii*, however, Sugihara et al. obtained high recovery of *Megasphaera elsdenii* on several media containing neomycin (Sugihara et al., 1974). In any cultivation medium, fructose or lactate (instead of glucose) is required for *Megasphaera cerevisiae* whereas pyruvate or gluconate (1 %, v/v, final concentration) is required for good growth of *Megasphaera paucivorans* and *Megasphaera sueciensis* (Juvonen and Suihko, 2006). In the quality control of beer, an enrichment method is used (Anonymous, 2001). In this method concentrated culture medium is added to the headspace of the bottle immediately after filling

and capping. Development of turbidity is monitored for three to four weeks and the presence of *Megasphaera* is confirmed microscopically and by smell (H_2S , fatty acids).

A selective medium (SMMP) for enrichment of *Megasphaera* and *Pectinatus* in beer has been developed (the recipe is given in the chapter on *Pectinatus*). The change in medium color from purple to yellow indicates the presence of *Megasphaera* bacteria (Anonymous, 1998; Juvonen and Suihko, 2006).

Maintenance procedures

Megasphaera elsdenii cultures can be maintained in lactate-based media at 4°C in anaerobic conditions if they are routinely transferred each week or at least fortnightly (Furtado et al., 1994; Rogosa, 1971a). They can also be frozen at -70°C with either dimethylsulfoxide (10 % v/v, final concentration) (Stanton and Humphrey, 2003) or 30% glycerol. *Megasphaera elsdenii* may not tolerate a number of freeze-drying procedures but survives in liquid nitrogen. *Megasphaera micronuciformis* and *Megasphaera elsdenii* can also be frozen at -80°C on glass beads. See the chapter on *Pectinatus* for maintenance of *Megasphaera cerevisiae*.

Differentiation of the genus *Megasphaera* from other closely related taxa

The genus *Megasphaera* can be differentiated from the three other genera of anaerobic Gram-stain-negative cocci of the family Veillonellaceae, i.e., the genera *Veillonella*, *Acidaminococcus*, and *Anaeroglobus*, on the basis of major metabolic end products, physiological tests, DNA G+C content and 16S rRNA gene sequence. The characteristics useful in differentiating the genus *Megasphaera* from these other genera are given in Table 208.

Taxonomic comments

The genus *Megasphaera* was created by Rogosa in (1971a) to reclassify *Peptostreptococcus elsdenii* (Gutierrez et al., 1959), formerly known as Organism LC (Elsden et al., 1956). This organism showed many features uncharacteristic of peptostreptococci, particularly its Gram-stain-negative stain and the outer membrane observed in electron microscopy. Rogosa included the *Megasphaera* genus and its type species *Megasphaera elsdenii*, together with the genera *Veillonella* and *Acidaminococcus*, in a novel family, the *Veillonellaceae* (Rogosa, 1971b). Phylogenetic analysis revealed that this family belongs to the *Sporomusa* sub-branch of the Gram-stain-positive bacteria, corresponding to clostridial cluster IX of Collins et al. (1994), and the family *Veillonellaceae* was enlarged to include most of these and related genera (Ludwig et al., this volume). In 1979, Weiss et al. isolated anaerobic Gram-stain-negative cocci from beer (Weiss et al., 1979). On the basis of differential characteristics of the genera *Veillonella*, *Acidaminococcus*, and *Megasphaera*, the beer isolates could be assigned to the genus *Megasphaera* (Weiss et al., 1979). Based on G+C content of the DNA and low similarity in DNA-DNA hybridization with *Megasphaera elsdenii* and *Veillonella parvula*, the beer isolates were assigned to a new species, *Megasphaera cerevisiae* (Engelmann and Weiss, 1985). The third species of the genus *Megasphaera*, *Megasphaera micronuciformis*, has been characterized from human clinical specimens on the basis of cell size, biochemical tests (particularly its metabolic end products), G+C content of the DNA, and 16S rRNA gene sequence (Marchandin et al., 2003b). Two novel *Megasphaera*

TABLE 208. Characteristics useful in differentiating the genus *Megasphaera* from other genera of anaerobic Gram-stain-negative cocci belonging to the family *Veillonellaceae*^{a,b}

Characteristic	<i>Megasphaera</i>	<i>Acidaminococcus</i>	<i>Anaeroglobus</i>	<i>Veillonella</i>
Cell size (µm)	0.4–0.6 × 1.3–2.6	0.6–1	0.5–1.1	0.3–0.5

^aFor symbols, see standard footnote of Table 207.

^bAdapted from Carlier et al., (2002). Data for *Megasphaera elsdenii*, *Acidaminococcus*, and *Veillonella* were taken from Rogosa, (1984a). Data for *Megasphaera cerevisiae* are given by Engelmann and Weiss, (1985). Data for *Megasphaera micronuciformis* were from Marchandin et al., (2003b). Data for *Megasphaera paucivorans* and *Megasphaera sueciensis* are from Juvonen and Suihko (2006).

species have been isolated from spoiled bottled beers. Based on cell size, physiological tests, volatile fatty acid profiles, DNA–DNA hybridization, 16S rRNA gene sequence and G+C content of the DNA, *Megasphaera paucivorans* and *Megasphaera sueciensis* were described. In contrast to *Megasphaera elsdenii* and *Megasphaera cerevisiae*, *Megasphaera micronuciformis*, *Megasphaera sueciensis* and *Megasphaera paucivorans* are negative in most of the conventional biochemical and physiological tests. The characteristics useful in differentiating between the five *Megasphaera* species are shown in Table 208. Besides automated ribotyping with *EcoRI* is a useful technique to identify and differentiate the five *Megasphaera* species (Juvonen and Suihko, 2006). Moreover, *Megasphaera micronuciformis* differs from *Megasphaera elsdenii* at the genomic level (Marchandin and Jumas-Bilak, 2006). A genomic organization study of *Megasphaera micronuciformis* reveals a genome of about 1800 kb showing four *rrn* operons whereas the genome of *Megasphaera elsdenii* is about 2600 kb and comprises seven *rrn* operons (Marchandin et al., 2003b). The ability to produce volatile

fatty acids containing 4–6 carbon atoms is a distinctive characteristic of the five species of *Megasphaera*. Biodiversity in the genus *Megasphaera* still seems to be underestimated. Culture-independent DNA-based methods used to study vaginal microbial flora in five adult healthy women by Zhou et al. (2004) revealed numerous identical uncultured *Megasphaera* species clones (GenBank accession nos from AY271931 to AY271953) that could represent a potential novel species. On another hand, Fredricks et al. (2005) demonstrated an association between potential novel *Megasphaera* species and bacterial vaginosis.

List of species of the genus *Megasphaera*

- Megasphaera elsdenii*** (Gutierrez, Davis, Lindahl and Warwick 1959) Rogosa 1971a, 187^{AL} (*Peptostreptococcus elsdenii* Gutierrez, Davis, Lindahl and Warwick 1959, 20; organism LC Elsdén and Lewis 1953, 183; rumen organism LC Elsdén, Volcani, Gilchrist and Lewis 1956, 686)

els.de'ni.i. N.L. gen. n. *elsdenii* of Elsdén; named after S.R. Elsdén who first isolated the organism.

Cocci 2.0 µm or more in diameter, in pairs or occasionally in chains. Nonsporulating. Gram-stain-negative. Nonmotile. Anaerobic. Colonies in yeast extract peptone agar supplemented with sodium lactate are round, smooth, slightly raised, and have a glistening, mucoid appearance. At 48 h, the colonies are 0.2–1.0 mm in diameter with older colonies 3–4 mm. Growth occurs from 25 to 40°C but generally not at 45°C. Catalase and indole-negative. Gelatin is not liquefied. Nitrate is not reduced. H₂S is produced. Chemorganotrophic. Gas is produced. Lactate is fermented with the production of acetic, propionic, butyric, iso-butyric, iso-valeric, 2-methylbutyric, and valeric acids, little or no caproic and formic acids, a large quantity of CO₂, and small amounts

of H₂. Products from glucose fermentation are different from those from lactate: butyrate is the most copious product, some formate and caproate are produced, less valerate is formed, little or no acetate is produced, and propionate is not produced. Pyruvate is utilized, but succinate, fumarate, and malate are not attacked. Nutritional requirements are complex. Found in the rumen of cattle and sheep and in the feces and intestine of man and pigs.

DNA G+C content (mol%): 53.1–54.1 (Bd).

Type strain: ATCC 25940, CCUG 6199, CIP 106852, DSM 20460, JCM 1772, LC1, NCBI 8927.

GenBank accession number (16S rRNA gene): U95027.

- Megasphaera cerevisiae*** Engelmann and Weiss 1986, 355^{VP} (Effective publication: Engelmann and Weiss 1985, 290.)

ce.re. vi' si. ae. L. n. *cerevisia* beer; L. gen. n. *cerevisiae* of beer.

Slightly elongated cocci, 1.3–2.1 µm in diameter, occurring singly, in pairs, and occasionally in short chains. Gram-stain-negative. Nonsporulating. Nonmotile. Strictly anaerobic. Colonies on PYL or PYF agar are whitish, smooth and flat, 2–3 mm in diameter. Growth occurs between 15 and 37°C,

but not at 40°C. Catalase and benzidine test negative. H₂S is produced. Nitrate is not reduced to nitrite. Indole is not produced. Gas, acetic, propionic, iso- and *n*-butyric, iso- and *n*-valeric, and caproic acid are produced. Utilization of carbon sources is shown in Table 206. Cell-wall peptidoglycan is of the *m*-Dpm-direct type. The peptide subunit contains one putrescine residue covalently bound to the α -carbonyl group of the glutamic acid. Habitat unknown. Strains of this species mainly isolated from spoiled beer.

DNA G+C content (mol%): 42.4–44.8 (T_m).

Type strain: PAT 1, ATCC 43254, DSM 20462, JCM 6130.

GenBank accession number (16S rRNA gene): L37040.

3. **Megasphaera micronuciformis** Marchandin, Jumas-Bilak, Gay, Teyssier, Jean-Pierre, Siméon de Buochberg, Carrière and Carlier 2003b, 552^{VP}

mic.ro.nu.ci.for'mis. Gr. adj. *micro* small; L. fem. gen. n. *nucis* a nut; L. adj. suff. *-formis* is shaped like; N.L. fem. adj. *micronuciformis* small walnut-shaped (referring to the morphology of bacterial cells and cell surface).

Cells are Gram-stain-negative, coccoid, usually single, 0.4–0.6 mm in diameter, nonmotile. Endospores are not formed. Strictly anaerobic. Colonies appear on Columbia sheep blood agar after 2–3 d incubation at 37°C and are circular, convex, shiny, and translucent with a smooth surface. Colonies are approximately 0.5–1.0 mm in diameter, non-pigmented and non-hemolytic. Non-fermentative and non-proteolytic (gelatin and milk negative). Gas is not produced. Nitrate is not reduced, and indole and catalase are not produced. Desulfoviridin may be produced. Metabolic end products are acetic, propionic, butyric, iso-valeric, and 2-phenylacetic acids. Valeric acid and trace amounts of isobutyric acid may be produced. Utilization of carbon sources is shown in Table 206. Differentiated from other *Megasphaera* species by size, DNA G+C content, metabolic end products, and 16S rRNA gene sequence. Habitat is unknown.

DNA G+C content (mol%): 46.4 (T_m).

Type strain: AIP 412.00, CCUG 45952, CIP 107280.

GenBank accession number (16S rRNA gene): AF473834.

4. **Megasphaera paucivorans** Juvonen and Suihko 2006, 700^{VP}

pau.ci.vo'rans. L. adj. *paucus* few, little, L. part. adj. *vorans* devouring; N.L. part. adj. *paucivorans* devouring a few substrates.

Gram-stain-negative, non-spore-forming and nonmotile cocci with a mean size of 1.5 μ m \times 1.2 μ m, and mainly arranged in pairs. Stationary phase cells may form cell clumps and chains of 20–25 diplococci. Strictly anaerobic. Moderate to good growth (2+ or 3+ on a scale of 0 to 4+) is obtained in autoclaved PYF, PYG, MRS and SMMP media. Growth in SMMP is accompanied by color change from violet to yellow. Poor growth in PY medium (1+), but the addition of 1 % (v/v) pyruvate or gluconate results in heavily turbid suspension (4+). Colonies on PYF plates appear after 3 d at 30°C and after 7 d are yellowish, circular, convex, glossy and opaque with entire margins and a diameter of 1–1.5 mm. Grows at 15–37°C, with an optimum at around 30°C, but not at 10°C or 45°C. Major volatile fatty acids produced in beer are butyric and iso-valeric acid. H₂S and minor amounts of propionic, isobutyric, valeric and caproic acid are also formed. Other phenotypic properties and the characteristics differentiating the species from the other *Megasphaera* species are presented in Table 206 and Table 207. The type strain was isolated from spoiled Italian beer.

DNA G+C content (mol%): 46.4 (T_m).

Type strain: VTT E-032341^T, DSM 16981^T.

GenBank accession number (16S rRNA gene): DQ223730.

5. **Megasphaera sueciensis** Juvonen and Suihko 2006, 700^{VP}

sue.ci.en' sis. N.L. fem. adj. *sueciensis* pertaining to Sweden.

Strictly anaerobic, Gram-stain-negative, non-spore-forming and nonmotile cocci, mainly arranged in pairs and occasionally in short chains. Mean cell size is 1.2 μ m \times 1.0 μ m. Moderate growth (2+ on a scale of 0 to 4+) is obtained in autoclaved PYF, PYG, MRS and SMMP media at 30°C. The addition of 1 % (v/v) pyruvate or gluconate to the PY medium markedly stimulates the growth. Colonies on PYF and PYG plates appear after 4 d at 30°C and after 7 d are slightly yellowish, glossy, convex, opaque, smooth and circular with entire edges and a diameter of 0.5–0.8 mm. Grows at 15–37°C, with an optimum at around 30°C, but not at 10°C or 45°C. Other physiological properties and characteristics differentiating this species from the other *Megasphaera* species are shown in Table 206 and Table 207. The type strain was isolated from spoiled Swedish beer.

DNA G+C content (mol%): 43.1 (T_m).

Type strain: VTT E-97791, DSM 17042.

GenBank accession number (16S rRNA gene): DQ223729.

Genus XIV. **Mitsuokella** Shah and Collins 1983, 439^{VP}

ANNE WILLEMS AND MATTHEW D. COLLINS

Mit.su.o.ke'l'a. N.L. fem. n. *Mitsuokella* named after Tomotari Mitsuoka, the Japanese bacteriologist who first described the organism.

Gram-stain-negative, obligately anaerobic, non-spore-forming, nonmotile rods. Stout rods of regular shape with rounded ends. **Fermentative metabolism.** Growth is enhanced by glucose or other fermentable carbohydrates. **Major end products from glucose fermentation are acetate, lactate and succinate.** No copious gas formation from glucose. Gelatinase and catalase absent; amylase present. Indole-negative. Nitrate is reduced to nitrite.

DNA G+C composition is 55.9–58.2 mol% (T_m). On the basis of 16S rRNA gene sequences, *Mitsuokella* belongs to the

Sporomusa branch of the *Clostridium* subphylum of the *Firmicutes* where it is closely related to *Selenomonas ruminantium* (Lan et al., 2002b; Willems and Collins, 1995b).

Type species: ***Mitsuokella multacida*** corrig. (Mitsuoka, Terada, Watanabe and Uchida 1974) Shah and Collins 1983, 439^{VP} (Effective publication: Shah and Collins 1982, 493.).

Further descriptive information

Phylogenetic treatment. The 16S rRNA gene sequences of *Mitsuokella multacida* and *Mitsuokella jalaludinii* share 98.7% similar-

^cNo information available for *Mitsuokella jalaludinii*.

tity. According to the 16S rRNA phylogenetic analysis presented in the roadmap to this volume (Figure 6), the genus *Mitsuokella* is a member of the family *Veillonellaceae*, order *Clostridiales*, class *Clostridia* in the phylum *Firmicutes*. This family contains several other Gram-stain-negative genera (e.g., *Sporomusa*, *Selenomonas*, *Veillonella*). Closest phylogenetic relative is *Selenomonas ruminantium* with approximately 96% 16S rDNA sequence similarity (Willems and Collins, 1995b). Despite this relatively close relatedness, *Selenomonas* differs from *Mitsuokella* in a number of phenotypic and chemotaxonomic features (Table 209).

Cell morphology. Cells of *Mitsuokella multacida* are nonmotile, large, regular rods, 0.8–1.5 µm wide by 3.0–20 µm long, with rounded ends (Shah and Collins, 1982). Cells of *Mitsuokella jalaludinii* are smaller: 0.6–0.8 µm by 1.2–2.4 µm. Cells occur singly, in short chains or irregular groups (Holdeman et al., 1986; Lan et al., 2002b).

Cell-wall composition. Cell-wall murein of *Mitsuokella multacida* is of the A1γ type (Schleifer and Kandler, 1972) containing meso-diaminopimelic acid as the dibasic amino acid (Shah et al., 1983).

Colonial characteristics. After 2–3 d of incubation at 37°C, colonies of *Mitsuokella multacida* on blood agar plates are circular, 3–8 mm in diameter, convex with an irregular surface and edge and are grayish-white in color. Some strains are slightly hemolytic (Shah and Collins, 1982). Colonies of *Mitsuokella jalaludinii* were circular with regular margins, grayish-white, convex with smooth surface and 1–4 mm in diameter after 2 d at 39°C on PYG agar (Lan et al., 2002b).

Nutrition and growth conditions. A strictly anaerobic atmosphere is required, e.g., of nitrogen, CO₂ (10%) and hydrogen (20%). Optimum growth temperature is 37°C and 42°C for *Mitsuokella multacida* and *Mitsuokella jalaludinii*, respectively. There is usually no growth of *Mitsuokella multacida* at 45°C, however, *Mitsuokella jalaludinii* is capable of growth at 45°C and at 47°C. For both species growth is markedly enhanced by the presence of glucose or another fermentable carbohydrate (Shah and Collins, 1982) but not by bile (Lan et al., 2002b). The final pH in glucose broth is 4.1–4.3 for *Mitsuokella multacida* (Shah and Collins, 1982) and 3.8–4.0 for *Mitsuokella jalaludinii* (Lan et al., 2002b).

Metabolism and metabolic pathways. *Mitsuokella* has a fermentative metabolism, using a variety of carbohydrates. Major end products from glucose fermentation are acetic and lactic acid with small amounts of succinic acid for *Mitsuokella*

multacida (Mitsuoka et al., 1974; Shah et al., 1983) and lactic and succinic acid with some acetic acid for *Mitsuokella jalaludinii* (Lan et al., 2002b). Additional biochemical characteristics are listed in Table 210.

Chemotaxonomic data. No chemotaxonomic data are available for *Mitsuokella jalaludinii*. The data in this section only characterize *Mitsuokella multacida*. Fatty acids consist of non-hydroxylated (ca. 80%) and 3-hydroxy (ca. 20%) types. The non-hydroxylated fatty acids are predominantly straight-chain and monounsaturated types with C_{16:1} constituting the major compound, C_{12:0} and C_{16:0} also present in substantial amounts and C_{14:0} present in smaller amounts. The major 3-hydroxy fatty acid is 3-OH-C_{14:0}. Small amounts of branched-chain fatty acids are also present (Shah et al., 1983).

Menaquinones and ubiquinones are not present (Shah et al., 1983). Sphingolipids are absent (Miyagawa et al., 1978). Polar lipids comprise major amounts of phosphatidylethanolamine and an unidentified amino-containing phospholipid that does not contain sugar residues. Small amounts of four other unidentified components are also present. Some strains possess diphosphatidylglycerol (Shah et al., 1983). *Mitsuokella multacida* does not contain polyamines (Hamana et al., 1995).

Plasmids. Some strains of *Mitsuokella multacida* contain plasmids (size 11.7 kb) (Flint and Stewart, 1987).

Antibiotic sensitivity. Antibiotic resistance data for both species are listed in Table 210. *Mitsuokella multacida* strains vary in their resistance to tetracycline (Flint and Stewart, 1987). Several *Mitsuokella multacida* strains contain tetracycline resistance genes: TetQ was identified in one strain (Leng et al., 1997) and TetW, representing a new class of tetracycline resistance determinants, has been identified in both porcine and bovine strains (Barbosa et al., 1999).

Ecology. *Mitsuokella* species are strict anaerobes that inhabit the intestinal tract of humans and livestock animals. The acids they produce may be used by acid utilizing bacteria to form butyrate. *Mitsuokella multacida* belongs to the normal anaerobic rumen and colon microflora and has been isolated from feces of humans and domestic animals (Al Jassim, 2003; Mitsuoka et al., 1974; Sirotek et al., 2003; Tsukahara et al., 2002). *Mitsuokella jalaludinii* was originally reported from the rumen of cattle in Malaysia (Lan et al., 2002b) and has also been recovered from the equine gastro-intestinal tract (Al Jassim et al., 2005). Both species have a strong phytase activity; this enzyme catalyzes the release of phosphate from phytate, the predominant

^bBoth species hydrolyse starch and esculin and reduce nitrate to nitrite. All strains produce acid from glucose, mannose, fructose, galactose, L-arabinose, D-xylose, sucrose, maltose, lactose, salicin, melibiose and raffinose. No acid is produced from adonitol, dulcitol, inulin, meso-erythritol, α-methyl mannoside or α-methyl glucoside. Neither species produces gelatinase, indole, H₂S or catalase and grows at 20°C. Both species are resistant to neomycin and sensitive to 0.005% crystal violet.

^cResult only reported for the type strain (Lan et al., 2002b).

^dVariable according to Holdeman et al. (1977).

^eThe type strain is negative according to Lan et al. (2002b).

^fPositive according to Holdeman et al. (1986).

^gWeak or negative response according to Holdeman et al. (1986).

^hNegative according to Holdeman et al. (1986).

form of phosphorous in seeds, cereals and legumes (Lan et al., 2002a; Yanke et al., 1998). The phytase of *Mitsuokella multacida* is located in the outer membrane (D'Silva et al., 2000). *Mitsuokella multacida* strains from the rabbit caecum were mucinolytic (Sirotek et al., 2003).

The role of the microflora in the development of cancers of the colon remains unclear. In a study of the effects of intestinal microflora on the development of colonic neoplasm induced by 1,2-dimethylhydrazine in mice, the incidence of colonic adenoma in mice mono-associated with *Mitsuokella multacida* was less (68%) than in germ-free mice (74%), but higher than in conventionalized mice (58%). The adenoma in germ-free mice was smaller than in conventionalized mice, suggesting that micro-organisms may have two different effects: on the one hand they may inhibit incidence of

adenoma, but on the other hand, they may promote tumour growth (Horie et al., 1999).

Genetic characteristics. In *Mitsuokella multacida* two GATC-specific DNA methyltransferases and *Sau3AI* isoschizomeric restriction endonucleases were partially characterized (Piknova et al., 2005).

Isolation procedures

The strains used for the original description of *Bacteroides multacidus* (Mitsuoka et al., 1974) were isolated by plating out fecal material, emulsified in an anaerobic buffer solution, on modified Eggerth-Gagnon (EG) agar, glucose blood liver agar and neomycin brilliant green taurocholate blood agar (Mitsuoka et al., 1964, 1965). Plates were incubated for 3 d at 37°C under an atmosphere of 100% CO₂ and strains were checked for purity

and routinely maintained on EG agar (Mitsuoka et al., 1974). The more recently isolated *Mitsuokella jalaludinii* was obtained from rumen fluid by serial dilution and inoculation into roll-tubes of modified phytase-screening (MPS) agar using Hungate anaerobic techniques (Lan et al., 2002b).

Maintenance procedures

Cultures can be maintained on blood agar plates by twice-weekly subculture in an atmosphere of nitrogen plus 10% CO₂ and 20% H₂ at 37°C (Shah et al., 1983). According to the original description of *Bacteroides multiacidus* (Mitsuoka et al., 1974), strains can be maintained on slants of EG agar H₂CO₃-CO₂ buffer and stored at 4°C for up to 3 months. For long term preservation strains can be lyophilized using standard procedures.

Differentiation of the genus *Mitsuokella* from other Gram-stain-negative, anaerobic, non-spore-forming, saccharolytic bacilli

On phenotypic grounds, *Mitsuokella* was previously regarded as a member of the genus *Bacteroides* (Mitsuoka et al., 1974). It can be differentiated from *Bacteroides* and *Prevotella*, the two saccharolytic genera of the *Bacteroidaceae*, by its higher G+C content, the production of lactic acid in addition to acetate and succinate as end products from glucose fermentation. The absence of respiratory menaquinones, and a distinctive fatty acid composition have only been reported for *Mitsuokella multacida* (Table 209). Features for the differentiation of *Mitsuokella* from *Selenomonas*, its closest phylogenetic neighbor, and other Gram-stain-negative, anaerobic, non-spore-forming bacilli with a similar G+C content are given in Table 209.

In a system using oligonucleotide primers targeting the 16S rRNA gene to monitor species in the rumen ecosystem by real-time PCR, one primer-set was used to amplify both *Mitsuokella multacida* and *Selenomonas ruminantium*. It was not possible to design primers with a sufficiently high melting temperature to distinguish both species in the experimental set-up used (Tajima et al., 2001), although on the basis of the level of sequence similarity between both species (approx. 96%) it should be possible to select species-specific primers.

Taxonomic comments

Bacteroides multiacidus was originally proposed to accommodate a group of Gram-stain-negative, strictly anaerobic, saccharolytic, large rods isolated from the feces of humans and pigs (Mitsuoka et al., 1974). Subsequently several chemotaxonomic and biochemical studies provided strong evidence to exclude

Bacteroides multiacidus from the genus *Bacteroides* because of differences in cell-wall peptidoglycan structure, fatty acid and lipid composition, DNA base composition, fermentation end products and dehydrogenase activities (Miyagawa et al., 1978, 1979; Shah et al., 1983). Because these characteristics indicated that *Bacteroides multiacidus* was unlike any other existing Gram-stain-negative anaerobic bacillus, a new genus, *Mitsuokella*, was proposed with one species, *Mitsuokella multiacidus* (Shah and Collins, 1982), later corrected to *Mitsuokella multacida* (Euzéby, 1998). Sequencing of the 16S rRNA gene of the type strain of *Mitsuokella multacida* confirmed its separateness from the genus *Bacteroides* and placed it in the *Sporomusa* cluster of the *Clostridium* subphylum, close to *Selenomonas ruminantium* (Willems and Collins, 1995b).

A second species, *Mitsuokella dentalis*, which was described for isolates from human dental root canals (Haapasalo et al., 1986a), differs from *Mitsuokella multacida* in its fermentation end products, carbohydrate fermentation patterns, starch hydrolysis, resistance to bile and fatty acid composition (Haapasalo et al., 1986b; Shah and Collins, 1982). On the basis of its 16S rRNA gene sequence, *Mitsuokella dentalis* belongs to the genus *Prevotella* in the *Bacteroides-Flavobacterium* phylum of the Gram-stain-negative bacteria. Since it is distinct from the other *Prevotella* species, it was transferred to this genus as *Prevotella dentalis* comb. nov. Its is highly related (99.8% 16S rDNA sequence similarity (Willems and Collins, 1995b) to *Hallella seregens*, a group of Gram-stain-negative, anaerobic, rod-shaped bacteria from the gingival crevices of humans with gingivitis or periodontitis (Moore and Moore, 1994). Phenotypically, both species are very similar, with the only reported difference being the fermentation of trehalose and the hydrolysis of starch by *Hallella seregens* and not by *Prevotella dentalis*. DNA-DNA hybridizations should establish whether *Hallella seregens* represents a separate *Prevotella* species or is a later subjective synonym of *Prevotella dentalis* (Willems and Collins, 1995b).

Mitsuokella jalaludinii, created for strains from cattle in Malaysia, is genetically highly related to *Mitsuokella multacida*: a DNA-DNA hybridization value of 63.8% was reported between both type strains (Lan et al., 2002b). However, the species can be distinguished by the ability of *Mitsuokella jalaludinii* to grow at 47°C, to produce acid from glycerol but not from melezitose or D-tagatose and to resist kanamycin (100 µg/ml) but not brilliant green (0.001%).

Genus XV. *Pectinatus* Lee, Mabee and Jangaard 1978, 582^{AL} emend. Juvonen and Suihko 2006, 700

AULI HAIKARA AND RIIKKA JUVONEN

Pec.ti.na'tus. L. part. adj. *pectinatus* combed; N.L. masc. n. *Pectinatus* combed (bacteria).

Slightly curved rods, 0.4–0.9 µm in diameter and 2–50 µm or more in length, with rounded ends. They occur singly, in pairs, and only rarely in short chains. In old cultures, very elongated cells with a helical shape can be found and round cell forms are also observed. Gram-stain-negative. According to the cell envelope structure, intermediates between Gram-stain-positive and Gram-stain-negative bacteria. Cadaverine or putrescine is found in the cell-wall peptidoglycan. **Motile**, young cells form an “X” shape during movement whereas old cells have characteristically slow snakelike movements. **Flagella emanate from only one side of the cell body**. The organisms are **obligately anaerobic, non-spore-forming mesophiles**. They are cytochrome oxidase-negative and do not produce indole, liquefy gelatin, reduce nitrate, or hydrolyze arginine. Urease and catalase may or may not be produced. The main metabolic products from glucose are **propionic and acetic acid**. **Hydrogen sulfide and acetoin are also produced and succinic and lactic acids may be produced**. Originally isolated from **spoiled, packaged beer**. The habitat outside the brewery is not defined.

DNA G+C content (mol%): 38–41.

Type species: ***Pectinatus cerevisiiphilus*** Lee, Mabee and Jangaard 1978, 582^{AL} emend. Schleifer, Leuteritz, Weiss, Ludwig, Kirchhof and Seidel-Rüfer 1990, 25.

Further descriptive information

The genus *Pectinatus* was originally suggested to belong to the family *Bacteroidaceae* (Lee et al., 1978). The phylogenetic position of *Pectinatus* has established during recent years when the 16S rRNA, 23S rRNA and the ATPase β-subunit gene sequences, the 16S–23S rRNA intergenic spacer regions, and/or DNA–DNA hybridization have been used as markers (Both et al., 1992; Juvonen and Suihko, 2006; Klugbauer et al., 1992; Ludwig et al., 1992; Motoyama and Ogata, 2000a; Sawada et al., 1999; Schleifer et al., 1990; Willems and Collins, 1995a). The genus *Pectinatus*, along with *Selenomonas*, *Megasphaera*, *Sporomusa*, *Veillonella*, and *Zymophilus*, has been placed to the *Sporomusa* sub-branch of the *Clostridium* sub-phylum of Gram-stain-positive bacteria (Collins et al., 1994; Schleifer et al., 1990; Willems and Collins, 1995a). The cell envelope composition of *Pectinatus* has further supported its new taxonomic position (Helander et al., 1983; Helander et al., 1992; Schleifer et al., 1990; Strömpl et al., 1999). More recently, all members of the *Sporomusa* sub-branch have been grouped in the family *Veillonellaceae* of the class *Clostridia* of the phylum *Firmicutes* (Garrity and Holt, 2001). The genus *Pectinatus* currently comprises three validly named species, *Pectinatus cerevisiiphilus* (Lee et al., 1978; Schleifer et al.,

1990), *Pectinatus frisingensis* (Schleifer et al., 1990) and *Pectinatus haikarae* (Juvonen and Suihko, 2006). Based on the 16S rRNA gene sequence analysis, the similarity between *Pectinatus frisingensis*^T and *Pectinatus haikarae*^T is 93.6%. *Pectinatus cerevisiiphilus*^T has 95.6% and 94.3% sequence identity to *Pectinatus haikarae*^T and *Pectinatus frisingensis*^T, respectively. Based on the sequence similarity calculations of Willems and Collins (1995a) on fourteen species of the *Sporomusa* sub-branch the nearest species with *Pectinatus frisingensis* and *Pectinatus cerevisiiphilus* were three *Selenomonas* species (88–89%), *Zymophilus paucivorans* (88%), *Clostridium quercicolum* (87–88%), *Sporomusa paucivorans* (86–88%), *Veillonella parvula* (86–87%) and *Megasphaera elsdenii* (86%). The phylogenetic study of Motoyama and Ogata (2000a) on anaerobic beer spoilage bacteria showed that the 16S–23S rDNA intergenic spacer regions of *Pectinatus frisingensis* and *Pectinatus cerevisiiphilus*, *Zymophilus raffinosivorans* and *Zymophilus paucivorans* and *Selenomonas lactificifex* were of two molecular sizes (long and short). The dendrogram of the short spacer region corresponded with that of the 16S rRNA gene sequence (Schleifer et al., 1990). On the contrary, the order of the tRNA genes in the long spacer region and the DNA sequences of the long spacer region indicated that *Pectinatus* was more closely related to the *Selenomonas lactificifex* than to the *Zymophilus* species, which according to the authors better reflects the phylogenetic positions of the species. Notably, the order of the alanine tRNA/isoleucine tRNA genes in the long spacer regions of *Pectinatus* and *Selenomonas lactificifex* was the reverse of what has previously been reported for other bacteria (Gürtler and Stanisich, 1996).

Pectinatus cells typically appear as curved rods (Figure 212). Very elongated cells up to 50 µm or more with helical shape can be found in old cultures (Haikara, 1991; Juvonen and Suihko, 2006). Ultrastructure of several *Pectinatus cerevisiiphilus* and *Pectinatus frisingensis* strains has been characterized. The unique comb-like flagellar arrangement of *Pectinatus cerevisiiphilus* observed by Lee et al. (1978) using scanning electron microscopy has been confirmed by other workers in negatively stained preparations (Back et al., 1979; Haikara et al., 1981b; Kirchner et al., 1980). The cell envelope structure seen in such sections has revealed a multilayered cell wall typical of Gram-stain-negative bacteria (Lee et al., 1978). The peptidoglycan layer is very thick (30 nm), almost filling the periplasmic space of the cell envelope (Haikara et al., 1981a, 1981b). The freeze-fracture technique has demonstrated that the cell envelope structure in different strains is similar (Haikara et al., 1981a, 1981b). The thick peptidoglycan layer and the invaginations of

FIGURE 212. Electron micrograph of *Pectinatus frisingensis* illustrates flagella on one side of the cell body. Bar = 1 μm . (Reprinted with permission from Haikara, A. 1991. The genera *Pectinatus* and *Megasphaera*. In Balows, Trüper, Dworkin, Harder and Schleifer (Editors). The Prokaryotes, 2nd edn, Vol. II, Springer-Verlag, New York, pp. 1993–2004.)

the cytoplasmic membrane are typical features of Gram-stain-positive bacteria whereas the presence of an outer membrane is typical of Gram-stain-negative bacteria (Figure 213). The outer membrane of *Pectinatus*, however, is exceptional since it lacks the permeability barrier function normally assigned to the outer membrane of Gram-stain-negative (e.g., the enteric) bacteria (Helander et al., 1994). The cellular fatty acid composition is similar in type strains of *Pectinatus cerevisiiphilus* and *Pectinatus frisingensis*. The fatty acids are heavily dominated by odd-numbered fatty acids, $\text{C}_{11:0}$, $\text{C}_{15:0}$, $\text{C}_{17:1}$, $\text{C}_{18:0 \text{ cyclo}}$, and $\text{C}_{13:0 \text{ 3OH}}$, which are the main fatty acids detected in both species (Helander and Haikara, 1995). Alk-1-enyl chains with chain lengths of 15–18 are also found, indicating the presence of plasmalogens common in strict anaerobic bacteria. In addition to the major hydroxy acid component (*R*)13:0(3OH), both *Pectinatus* species are shown to contain, in minor amounts, five 3-hydroxy acids with chain lengths of 11–15 carbons. These include the unsaturated acid $\text{C}_{13:1 \text{ 3OH}}$, the occurrence of which is limited to *Pectinatus*. As discussed by Helander and Haikara (1995) and Strömpl et al. (1999), because fatty acid $\text{C}_{13:0 \text{ 3OH}}$ is not in the

MIDI database utilized for fatty acid-based identification of anaerobic bacteria, this fatty acid has been erroneously identified as $\text{C}_{14:0}$ dimethylacetal (DMA) in several bacterial genera, including *Pectinatus* (Moore et al., 1994).

Pectinatus possesses directly cross-linked *meso*-diaminopimelic acid-containing peptidoglycan, with covalently linked diamine (cadaverine or, rarely, putrescine) in the peptide subunit of the peptidoglycan (Schleifer et al., 1990). With the aid of monoclonal antibodies isolated on the basis of their binding to *Pectinatus cerevisiiphilus* peptidoglycan, Ziola et al. (1999) found a peptidoglycan structure that they suggested was common to several species of anaerobic beer spoilage bacteria, including *Pectinatus frisingensis*, *Selenomonas lactificex*, *Zymophilus paucivorans* and *Zymophilus raffinosivorans*.

The cell surface lipopolysaccharides (LPS) of the type strains *Pectinatus cerevisiiphilus* ATCC 29359 and *Pectinatus frisingensis* ATCC 33332 have been characterized in detail. Several exceptional properties are assigned to *Pectinatus* LPS, including the production of at least two distinct types of LPS by one strain (Helander et al., 1992), the presence of the phosphorylated disaccharide $\alpha\text{-D-Glc}_N\text{-(1'-4)-Kdo}$ (3-deoxy-D-manno-oct-2-ulopyranosonic acid) in the LPS core (Helander et al., 1993), the resistance of the lipid A-polysaccharide linkage to acid (Helander et al., 1994) and the predominance of furanosidic 6-deoxyhexose in the O-specific chains (Senchenkova et al., 1995). The lipid A backbone of *Pectinatus cerevisiiphilus* and *Pectinatus frisingensis* is composed of the common bisphosphorylated $\beta\text{1'-6}$ -linked glucosamine (GlcN) disaccharide, with almost quantitative substitution of the ester-linked phosphate by 4-amino-4-deoxyarabinose (Helander et al., 1994). The glycosidically linked phosphate of *Pectinatus* also carries minor amounts of this aminopentose, analogous to the structure found in *Klebsiella pneumoniae* O3 lipid A (Helander et al., 1996). The fatty acids in *Pectinatus* lipid A comprise two amide-linked and two ester-linked $\text{C}_{13:0 \text{ 3OH}}$. The hydroxyl groups of the fatty acids linked to the nonreducing GlcN carry the fatty acid $\text{C}_{11:0}$ or, to a small extent, $\text{C}_{13:0}$ in acyloxyacyl linkage. Whereas $\text{C}_{13:0 \text{ 3OH}}$ is the main hydroxy acid in *Pectinatus*, the minor 3-hydroxy acids are also most probably constituents of the lipid A, although their position has not been determined. Complete structures of the core oligosaccharides in *Pectinatus* LPS are not known, but each strain presumably elaborates two structurally distinct cores, only one of which carries polymeric O-specific chains; these two LPS populations can be separated from each other during processing of initial phenol/chloroform/petroleum ether extracts (Helander et al., 1992). The O-specific chain of *Pectinatus cerevisiiphilus* is composed of repeating disaccharides of 1 \rightarrow 2 linked $\alpha\text{-D}$ -fucopyranose and $\alpha\text{-D}$ -glucopyranose, whereas the repeating unit of *Pectinatus frisingensis* O-specific chain is a branched tetrasaccharide consisting of a single sugar type, the rare 6-deoxy-L-altrofuranoose (Senchenkova et al., 1995). It is worthy of note that the O-specific chains of *Pectinatus frisingensis* and *Pectinatus cerevisiiphilus* are highly labile towards acid, whereas the normally acid-labile lipid A-core linkage is exceptionally stable. The reason for the latter property is unknown at present, but the presence of acid-stable linking sugars such as 2-octulosonic acid has been excluded in their LPS (Helander et al., 1994). The LPS of both species exhibit the biological potency of classical endotoxins (Helander et al., 1984).

FIGURE 213. Electron micrograph of thin section of *Pectinatus frisingensis*. The cell envelope structure, the cytoplasmic membrane (CM), the thick peptidoglycan layer (PC), the outer membrane (OM) with numerous vesicles (V) are around the cytoplasm (C). Inside the cytoplasm invaginations (I) of the CM and the mesosomes (M), most likely artefacts of preparation for electron microscopy are seen. Bar = 0.1 μm . (Reprinted with permission from Haikara, A., Enari, T.-M. and Lounatmaa, K. (1981a). Proceedings of the 18th Congress, European Brewery Convention, Copenhagen, pp. 229–240.)

The most commonly used media for the cultivation and isolation of *Pectinatus* strains are de Man–Rogosa–Sharpe (MRS) lactobacilli broth or agar, modified MRS medium (Schleifer et al., 1990), thioglycollate medium with 1% glucose and 1.5% agar (Lee, 1984), and peptone-yeast extract-fructose (PYF) medium (the recipe given in *Megasphaera* chapter, above) (Engelmann and Weiss, 1985). Colonies of *Pectinatus* species on these agars are circular, entire, low convex to pulvinate or pyramidal, beige to white or grayish in color, glistening, and opaque (Haikara et al., 1981b; Juvonen and Suihko, 2006; Schleifer et al., 1990). Back et al. (1979) have reported a rough colony produced by one strain. A selective medium for the isolation and differentiation of *Pectinatus* and *Megasphaera* from other brewery organisms has been developed by Lee (1994) (see *Enrichment and isolation procedures*).

The acid tolerance of *Pectinatus cerevisiiphilus* and *Pectinatus frisingensis* in beer has been studied in growth media and beer. The strains of these species grow well in the pH range 4.5–8.5 (Back et al., 1979; Haikara et al., 1981b) the optimum being 6.0–7.0 (Kirchner et al., 1980; Takahashi, 1983). In beer some retardation of growth has been measured at pH 4.0–4.1 (Haikara, 1984; Kirchner et al., 1980; Seidel et al., 1979). According to Tholozan et al. (1997), *Pectinatus frisingensis* copes better with low pH and is able to grow over a wider pH range than *Pectinatus cerevisiiphilus*; for the latter, pH 6.2 is optimal for growth and biomass production, whereas for the former, pH of approximately 4.9 is optimal at glucose concentrations below 20 mM.

In the utilization of carbon sources, *Pectinatus cerevisiiphilus* and *Pectinatus haikarae* more closely resemble each other than *Pectinatus frisingensis* but clear differences between the species still exist (Haikara, 1991; Juvonen and Suihko, 2006; Schleifer et al., 1990) (Table 211). *Pectinatus cerevisiiphilus* can be distinguished from the other two species by its inability to ferment inositol. *Pectinatus frisingensis* utilizes *N*-acetylglucosamine and cellobiose but not melibiose or xylose whereas for the *Pecti-*

natus cerevisiiphilus and *Pectinatus haikarae* the situation is the reverse. *Pectinatus haikarae*, on the other hand, can be easily differentiated from the other two species by its positive catalase reaction. Furthermore, it is able to ferment lactose and does not grow at +37°C. In contrast to other brewery contaminants, most *Pectinatus* strains are incapable of utilizing maltose, the main carbohydrate of wort. On the other hand, they can utilize lactate. The major metabolic end products of the *Pectinatus* species from glucose or fructose are propionic and acetic acids and acetoin. *Pectinatus cerevisiiphilus* and *Pectinatus frisingensis* also produce succinic and lactic acid from glucose (Back et al., 1979; Haikara et al., 1981b; Juvonen and Suihko, 2006; Lee et al., 1978; Tholozan et al., 1994). The most abundant acid produced is propionic acid; more than 1000 mg/l has been detected in contaminated beer. Similar to the propionibacteria, *Pectinatus frisingensis* and *Pectinatus cerevisiiphilus* have been shown to use the succinate pathway for the production of propionic acid (Haikara et al., 1981a, 1981b; Tholozan et al., 1994). This observation further supports the assignment of *Pectinatus* to the family Veillonellaceae instead of Bacteroidaceae, as the *Bacteroides* species are known to use the acrylate pathway for propionate synthesis. A very specific feature of the metabolism of *Pectinatus* bacteria is the production of organic sulfur compounds (Haikara et al., 1981a). In addition to H₂S detected by Lee et al. (1980), production of methyl mercaptan and dimethyltrisulfide has been observed.

According to DNA–DNA hybridization, the 16S rRNA and 23S rRNA gene sequences, and the 16S rRNA–23S rDNA intergenic spacer regions, *Pectinatus cerevisiiphilus* and *Pectinatus frisingensis* can be genotypically distinguished (Haikara, 1989; Motoyama and Ogata, 2000a; Schleifer et al., 1990; Willems and Collins, 1995a). Nearly complete 16S rRNA gene sequence of *Pectinatus haikarae* has been determined which can be used to differentiate it from the other *Pectinatus* species (Juvonen and Suihko, 2006). PCR has been applied to the identification and

^cCombined data for eleven, fourteen and four *Pectinatus cerevisiophilus*, *Pectinatus frisingensis* and *Pectinatus haikarae*, respectively. All strains are positive for acid production from adonitol, L-arabinose, DL-erythritol, D-fructose, D-galactose, D-glucose, glycerol, mannose, D-ribose and utilization of DL-lactate. All strains are negative for acid production from glycogen, inulin and melezitose, for the utilization of succinate and for the production of oxidase, desulfovibrin and indole, and for the hydrolysis of arginine and gelatin and for the reduction of nitrate.

detection of *Pectinatus* by using species-specific, genus-specific and group-specific primers (Juvonen et al., 2003, 2008; Motoyama and Ogata, 2000b; Sakamoto et al., 1997; Satokari et al., 1997; Satokari et al., 1998). The ribotyping fingerprinting technique has been used for the characterization and identification of *Pectinatus* species (Juvonen and Suihko, 2006; Motoyama et al., 1998; Suihko and Haikara, 2001). Motoyama et al. (1998) employed three different restriction enzymes (i.e., *EcoRI*, *HindIII*, and *BamHI*) for ribotyping *Pectinatus cerevisiophilus* and *Pectinatus frisingensis* strains. By using a combination of all these enzymes, all 34 *Pectinatus frisingensis* strains fell into one of 17 ribotypes. Five *Pectinatus cerevisiophilus* strains were defined as one of three types with single enzymes, the composite ribotypes not showing greater definition. Suihko and Haikara (2001) used the *EcoRI* enzyme for the characterization of 24 *Pectinatus frisingensis* and eight *Pectinatus cerevisiophilus* strains. *Pectinatus frisingensis* strains were divided into nine different ribotypes and *Pectinatus cerevisiophilus* strains into five, allowing identification below the species level. Ribotyping with *EcoRI* divided the Finnish and German isolates of *Pectinatus haikarae* into separate ribotypes that could also be clearly distinguished from the ribotypes of *Pectinatus frisingensis* and *Pectinatus cerevisiophilus* strains (Juvonen and Suihko, 2006; Suihko and Haikara, 2001).

The immunological characteristics of *Pectinatus frisingensis* and *Pectinatus cerevisiophilus* have been studied using polyclonal and monoclonal antibodies for purposes of detection, sub-grouping and identification (Gares et al., 1993; Haikara, 1983; Hakalehto, 2000; Hakalehto and Finne, 1990; Hakalehto et al., 1984; Ziola et al., 1999).

Unlike most bacterial species with a Gram-negative outer membrane structure, *Pectinatus frisingensis* and *Pectinatus cerevisiophilus* have been found to be sensitive to cationic agents such as polymyxin B and nisin and to antibacterial agents with fairly large molecular mass such as bacitracin (Chihib et al., 1999; Helander et al., 1994). The sensitivity of *Pectinatus* can be related to an abnormal outer membrane which does not form an effective barrier and might have cracks permitting the entry of various compounds (Haikara et al., 1981b; Lee et al., 1978). In disc tests, *Pectinatus haikarae* and *Pectinatus frisingensis* are resistant to 5 µg vancomycin, whereas *Pectinatus cerevisiophilus* is sensitive (Juvonen and Suihko, 2006).

The original source of *Pectinatus*, i.e., its habitat outside the brewery is not known. It has been speculated that *Pectinatus* bacteria have been carried to breweries with the various plant materials utilized (cereals, rice, corn, hops) because the lipopolysaccharide of *Pectinatus cerevisiophilus* contains O-chains with D-6-deoxyhexose that is often found in plant-associated bacteria (Helander, 2003; Helander et al., 1992; Senchenkova et al., 1995). Most of the strains described and characterized

have been isolated exclusively from spoiled, unpasteurized packaged beer. *Pectinatus* has sporadically been found in lubrication oil mixed with beer, in drainage and water pipe systems, in the air of the filling hall, in the filling machine, on the floor of the filling hall, in condensed water on the ceiling, in chain lubricants and in the steeping water before milling (Back et al., 1988; Dürr, 1983; Haikara, 1991; Haukeli, 1980; Juvonen and Suihko, 2006; Lee et al., 1980; Soberka and Warzecha, 1986; Suihko and Haikara, 2001). It is obvious that *Pectinatus*, despite its anaerobic nature, can survive in aerosols in the filling hall and be transferred via air into beer. Catalase activity of *Pectinatus haikarae* may help the survival of this species in aerobic conditions. In fact, two of the four characterized strains were isolated from the air of a brewery bottling hall (Juvonen and Suihko, 2006).

The growth of *Pectinatus frisingensis* and *Pectinatus cerevisiiphilus* in beer is dependent on the combined effects of several factors such as pH, alcohol and oxygen content, and hop bitter substances. In addition to the tolerance of *Pectinatus* bacteria towards acid and hops, they are also rather alcohol-tolerant, growing in beer with an alcohol content of 3.7–4.4% w/v although the growth is slower than in low-alcohol beer (< 2.25% w/v) (Haikara, 1984). Alcohol content exceeding 5.2% w/v prevents growth (Haikara et al., 1981b; Haukeli, 1980; Kirchner et al., 1980; Seidel et al., 1979). In culture medium, ethanol concentrations of 6.0–7.8% w/v (1.3–1.7M) totally inhibit the growth of *Pectinatus frisingensis* and *Pectinatus cerevisiiphilus*, the former appearing less sensitive (Tholozan et al., 1997; Tholozan et al., 1996; Watier et al., 1996). The oxygen content of beer is the most decisive factor regarding its susceptibility to spoilage by *Pectinatus frisingensis* and *Pectinatus cerevisiiphilus*. The dissolved oxygen content as well as the volume of air in the headspace has decreased considerably in recent years due to advances in filling technology resulting in improved chemical stability of beer, but, on the other hand, facilitating the growth of strictly anaerobic bacteria such as *Pectinatus* and *Megasphaera* in unpasteurized beer. Factors affecting the growth of *Pectinatus haikarae* in beer have not been studied but all the spoilage incidents from which detailed information is available concern low-alcohol beer (Juvonen and Suihko, 2006; Juvonen unpublished data).

Enrichment and isolation procedures

As mentioned above, many agar media and broths containing fermentable sugars can be used for the cultivation and isolation of *Pectinatus* strains. Lee (1994) developed a "Selective Medium Megasphaera, Pectinatus" (SMMP)* for the isolation and differentiation of *Pectinatus* and *Megasphaera* species from other brewery organisms. The SMMP medium is beer-based, contains 1% lactate (v/v, final concentration) as a sole carbon source and is supplemented with reducing agents, various nutrients, 20 ppm actidione (cycloheximide) to inhibit yeasts, and 5 ppm crystal violet and 25 ppm sodium fusidate to inhibit Gram-stain-

positive bacteria. Enterobacteria are suppressed by alcohol and hop compounds present in beer, and hence appropriate levels of ethanol must be incorporated into SMMP when nonalcoholic beer is assayed (Lee, 1994).

The maintenance of strictly anaerobic conditions is important for the cultivation of *Pectinatus* bacteria. The anaerobic glove box and the GasPak system provide optimal growth conditions (Back et al., 1979; Haikara et al., 1981a, 1981b; Kirchner et al., 1980; Lee et al., 1978). Using reduced media and special reducing agents can enhance growth. In quality control of beer, forcing tests and enrichment are practical methods (Anonymous, 2001). In these methods, the development of turbidity of beer without or with added liquid medium, such as concentrated MRS broth, is followed at 27–30°C for 2–6 weeks and the presence of *Pectinatus* is confirmed microscopically (motile) and by smell (H₂S).

Maintenance procedures

Working cultures of *Pectinatus* can be maintained by subculturing (30°C, 2–3 d) at least every 2 weeks in PYF broth (0.5% peptone, 0.5% tryptone, 1% yeast extract, 0.5% fructose, 0.2% Na₂HPO₄, 0.1% Tween 80, and 0.05% cysteine hydrochloride added as a reducing agent). After incubation, the cultures are stored at 4°C in anaerobic jars. The working cultures can also be maintained in 5% dimethylsulfoxide in plastic screw-cap ampoules frozen at –70°C. For long-term preservation, conventional freeze-drying methods using 20% skim milk as protective agent as well as freezing in drinking straws in a –150°C deep freezer or in liquid nitrogen at –196°C using 5% dimethylsulfoxide as protective agent have been used. The polypropylene straws are packed after filling (0.1 ml) into 2-ml plastic screw-cap ampoules (e.g., Nunc) and placed directly into liquid nitrogen (Suihko and Haikara, 1990).

Differentiation of the genus *Pectinatus* from other closely related taxa

The anaerobic, Gram-stain-negative rod-shaped bacteria originating from beer or the brewery environment belong to the genera *Pectinatus*, *Zymophilus*, *Zymomonas* and *Selenomonas*. *Pectinatus* can be differentiated from these other genera on the basis of its major metabolic end products. *Pectinatus* species produce propionic and acetic acid, H₂S, and acetoin; *Zymomonas* species produce acetaldehyde in addition to H₂S and the brewery *Selenomonas* species produce lactic acid. The differential characteristics of the brewery-related species belonging to the *Veillonellaceae* are given in Table 211.

Taxonomic comments

Pectinatus does not belong to the family *Bacteroidaceae*, as initially suggested by Lee et al. (1978), since the genus *Bacteroides* and related genera represent a distinct phylum within the phylogenetic tree of bacteria (Woese, 1987). According to *Bergey's Manual of Systematic Bacteriology* (Garrity and Holt, 2001; Ludwig et al., 2009), *Pectinatus* species, despite their negative Gram stain, belong to the class *Clostridia* of the phylum *Firmicutes* in the family *Veillonellaceae*. Cellular ultrastructure as well as several chemotaxonomic markers further support the inclusion of *Pectinatus* species into this family. At present three validly named *Pectinatus* species have been described. Very soon after the description of *Pectinatus cerevisiiphilus*

*Yeast extract, 75 g; Bacto-peptone, 75 g; DL-lactic acid, sodium salt (60% syrup), 75 ml; sodium thioglycollate, 0.75 g; L-cysteine-HCl, 0.75 g; K₂HPO₄·3H₂O, 7.5 g; KH₂PO₄, 7.5 g; NaCl, 7.5 g; (NH₄)₂ HPO₄, 7.5 g; NaC₂H₃O₂·3H₂O, 7.5 g; H₂O, 728.5 ml. B1 selective stock solution: sodium fusidate (Sigma or equivalent), 0.75 g; cycloheximide (Upjohn or equivalent), 0.60 g; crystal violet (Sigma or equivalent), 0.075–0.15 g; absolute ethanol, 100 ml.

(Lee et al., 1978), another strain (VTT E-79100, later *Pectinatus frisingensis* ATCC 33332^T) was isolated and identified as the same species on the basis of its physiological and biochemical characteristics (Haikara et al., 1981b). However, this strain as well as many other new isolates, when compared to *Pectinatus cerevisiiphilus*, showed clear-cut differences in serological characteristics, cell surface-protein patterns and DNA–DNA hybridization (Haikara, 1983; Haikara, 1989; Hakalehto and Finne, 1990; Hakalehto et al., 1984). Finally, Schleifer et al. (1990) described the new species, *Pectinatus frisingensis*, using the 16S rRNA gene sequence analysis and confirmatory physiological tests. They also emended the description of *Pectinatus cerevisiiphilus*. In 1987, a *Pectinatus* strain DSM 20764 (= VTT E-97914) which was phenotypically similar to *Pectinatus cerevisiiphilus* but exhibited less than 20% DNA similarity with *Pectinatus frisingensis* and *Pectinatus cerevisiiphilus* was deposited

from spoiled German beer to the DSMZ. Further genetic analyses performed on this and similar strains from spoiled beer or from the air of a brewery bottling hall (Sakamoto et al., 1997; Suihko and Haikara, 2001) supported their inclusion into a new species. In 2006, a novel species, *Pectinatus haikarae*, was described based on the sequence of the 16S rRNA gene sequence and unique biochemical and physiological properties. In addition, the description of the genus *Pectinatus* was emended (Juvonen and Suihko, 2006).

Haikara, A. and I. Helander. 2002. *Pectinatus*, *Megasphaera*, and *Zymophilus*. In Dworkin (Editor), *The Prokaryotes: An Evolving Electronic Database for the Microbiological Community*, 3rd Ed. (release 3.5), Springer Verlag, New York. ISBN 0-387-14254-1.

List of species of the genus *Pectinatus*

1. ***Pectinatus cerevisiiphilus*** Lee, Mabee and Jangaard 1978, 582^{AL} emend. Schleifer, Leuteritz, Weiss, Ludwig, Kirchhof and Seidel-Rüfer 1990, 25

ce.re.vi.si.i'phi.us. L. n. *cerevisia* beer; Gr. adj. *philos* loving N.L. adj. *cerevisiiphilus* beer-loving (bacteria).

The strains of this species form slightly curved rods that are 0.4–0.9 µm in diameter and 2–30 µm in length. They occur singly, in pairs, and only rarely in short chains. The occurrence of longer, helical filaments is characteristic for older cells. The cells are usually motile. Flagella emanate on only one side of the cell (comb-like). Cells stain Gram-stain-negative and do not form endospores. Colonies are circular, entire, beige to white, glistening, and opaque. Obligately anaerobic mesophiles with the optimum temperature for growth of 30–32°C. Glucose is fermented to acetic and propionic acid. Organic sulfur compounds produced. Catalase and cytochrome-oxidase-negative. Cadaverine and putrescine are found as characteristic components of the cell-wall peptidoglycan type, directly cross-linked *meso*-diaminopimelic acid. Lipid F is also found as a characteristic cellular compound. Strains of this species have been isolated from spoiled beer. The physiological characteristics useful for differentiating *Pectinatus cerevisiiphilus* from other species of the genus *Pectinatus* are given in Table 211.

DNA G+C content (mol%): 38–41 (T_m).

Type strain: ATCC 29359, DSM 20467, HAMBI 1348.

GenBank accession number (16S rRNA gene): AF373026.

2. ***Pectinatus frisingensis*** Schleifer, Leuteritz, Weiss, Ludwig, Kirchhof and Seidel-Rüfer 1990, 25^{VP}

fri.sin.gen'sis. L. adj. *frisingensis*, of Frisinga, the Latin name of Freising, the German town where the organism was isolated.

The phenotypic characteristics of *Pectinatus frisingensis* are similar to those described for *Pectinatus cerevisiiphilus* except that it ferments cellobiose, inositol, and *N*-acetylglucosamine but not xylose and melibiose. *Pectinatus frisingensis* can also

be distinguished from *Pectinatus cerevisiiphilus* serologically, by cell-surface-protein patterns, lipopolysaccharide O-chain composition, DNA–DNA hybridization (similarity value 16%), and 16S rRNA gene sequencing. The physiological characteristics useful for differentiating *Pectinatus frisingensis* from other species of the genus *Pectinatus* are given in Table 211. Isolated from beer and brewery environment, the type strain is isolated in 1978 from Finnish beer.

DNA G+C content (mol%): 38–41 (T_m).

Type strain: VTT E-79100, ATCC 33332, DSM 6306, HAMBI 1347.

GenBank accession number (16S rRNA gene): AF373027.

3. ***Pectinatus haikarae*** Juvonen and Suihko 2006, 701^{VP}

Pectinatus haikarae (hai.ka'rae. N.L. gen. fem. n. *haikarae* of Haikara, named after Auli Haikara for her many contributions to the characterization and detection of *Pectinatus* species).

Cells are 0.6–0.8 µm by 3–50 µm or more in size but otherwise resemble morphologically *Pectinatus cerevisiiphilus*. Growth occurs at 15–30°C, but not at 10°C or 37°C. The optimum temperature lies between 20 and 30°C. Good growth (3+ or 4+ on a scale of 0 to 4+) in PYF, PYG, SMMP and MRS media after 1–2 d at 30°C. Weak growth also observed on supplemented Brucella Blood agar and PY medium. Colonies on PYF and PYG plates after 3 d at 30°C are from convex to pyramidal, glossy, opaque, cream to gray in color, and circular with entire margins and a diameter of 0.5–2.5 mm. Major products of fructose fermentation are propionic and acetic acids. Acetoin and H₂S are also produced. Differential characteristics compared to closely related anaerobic Gram-stain-negative rod-shaped bacteria isolated from breweries are shown in Table 211.

Isolated from spoiled German and Finnish beer and from the air of a brewery bottling hall in Finland.

DNA G+C content (mol%): 38.8 (T_m).

Type strain: VTT E-88329^T, DSM 16980^T.

GenBank accession number (16S rRNA gene): DQ223731.

Genus XVI. **Phascolarctobacterium** Del Dot, Osawa and Stackebrandt 1994, 182^{VP}
(Effective publication: Del Dot, Osawa and Stackebrandt 1993, 383.)

ERKO STACKEBRANDT AND RO OSAWA

Phas.co.larc'to.bac.te'ri.um. Genus name *Phascolarctos* Koala; Gr. neut. dim. n. *bakterion* rod; N.L. neut. n. *Phascolarctobacterium* bacterium of Koalas.

Pleomorphic rods, $0.5 \times 2.0 \mu\text{m}$ to $0.5 \times 5\text{--}20 \mu\text{m}$. Pleomorphism is medium dependent; in the presence of succinate small rods are transformed into elongated and fragmented rods with multiple branches. Gram-stain-negative, nonmotile, nonspore-forming chemo-organotroph. **Propionic acid is the main end product of succinate fermentation.** Growth inhibited by fumarate. Growth of satellite colonies around colonies of succinate-producing *Escherichia coli* cells. **Obligately anaerobic.** Growth most rapid at 30–37°C. Phylogenetically a member of the family Veillonellaceae, phylum Firmicutes. So far *Succiniclasticum ruminis* is the closest phylogenetic neighbor.

DNA G+C content (mol%): 41.4–42.3 (T_m).

Type species: Phascolarctobacterium faecium Del Dot, Osawa and Stackebrandt 1994, 182^{VP} (Effective publication: Del Dot, Osawa and Stackebrandt 1993, 383.).

Further descriptive information

On Wilkins–Chalgren Anaerobe agar (WCA), *Phascolarctobacterium* strains showed satellite growth around colonies of strains of *Escherichia coli* but not around colonies of strains of *Streptococcus bovis* (Figure 214). Enhanced growth of highly pleomorphic cells was due to the presence of succinic acid produced by *Escherichia coli* (Osawa et al., 1992) (Figure 215). Although a maximum growth response of *Phascolarctobacterium faecium* strains to succinate was reached at 50–100 mmol/l, growth was completely inhibited at 200 mmol or above. Fumarate has a strong inhibitory effect on growth. Active production of propionic acid from succinate-supplemented broth also suggests that AK strains are capable of using the succinate-propionate pathway, which is employed by most propionate-producing organisms including *Propionibacterium* spp., *Selenomonas ruminantium*, and *Veillonella alcalescens* (de Vries et al., 1973; Hilpert and Dimroth, 1984).

Phylogenetic studies by 16S rDNA (Del Dot et al., 1993) revealed that the organism is related to members of cluster IX of clostridia (Collins et al., 1994). While the original description indicated *Acidaminococcus fermentans* as the nearest neighbor (92.8% similarity), recent expansion of the 16S rDNA database also shows *Succiniclasticum ruminis* (van Gylswyk, 1995) and *Succinispira mobilis* (Janssen and O'Farrell, 1999) to be similarly closely related (93.3% similarity) (Figure 216).

Enrichment and isolation procedures

Enrichment of *Phascolarctobacterium* can be accomplished by emulsifying freshly voided feces in 0.25-strength Ringer solution. Serial 10-fold dilutions are plated onto Wilkins–Chalgren Anaerobe (WCA) agar (Oxoid) supplemented with sodium succinate (20 mmol/l). Dilutions are incubated anaerobically at 37°C for 5 d in an atmosphere of CO₂/H₂/N₂ (10:10:80, by volume), using a Bio-Bag (Becton Dickinson Co., Cockeysville, MD, USA) onto which cultures of *Escherichia coli* are stamped separately with the tip of a sterile cotton swab. Small transparent colonies grow predominantly on the plates inoculated with higher dilutions (10⁻⁵ and 10⁻⁶) of koala feces adjacent to colonies of *Escherichia coli*.

Maintenance procedures

Phascolarctobacterium faecium is maintained anaerobically on WCA plate medium supplemented with sodium succinate (20 mmol/l).

Differentiation of *Phascolarctobacterium* from other taxa

The distant 16S rDNA sequence similarity determined for *Phascolarctobacterium faecium* and its closest phylogenetic neighbors (<94%) makes determination of this sequence the most straightforward approach to identification (see Figure 216 for accession numbers). Table 212 lists characteristics features that can be used to differentiate cells from those of phylogenetically related genera. Cluster IX of clostridia contains a broad spectrum of Gram-negatively and Gram-positively staining genera, none of which closely matches the description of *Phascolarctobacterium faecium*.

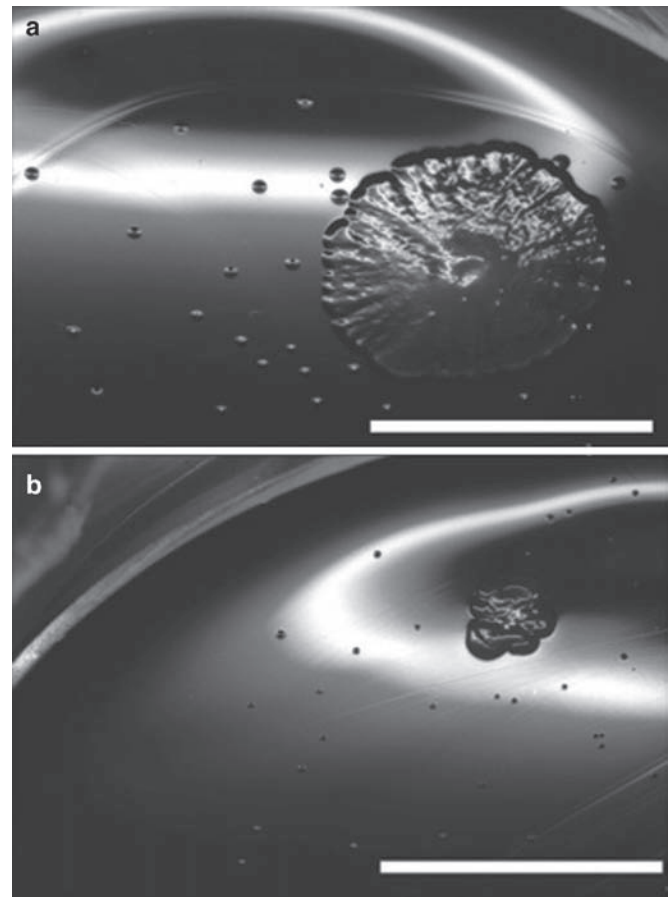

FIGURE 214. Stimulated growth of *Phascolarctobacterium* AK strain near a colony of *Escherichia coli* on WCA with 5% defibrinated horse blood. Colonies of *Phascolarctobacterium faecium* strain ACM 3679^T around a colony of *Escherichia coli* (a) and a colony of *Streptococcus bovis* (b).

FIGURE 215. Photomicrographs of cells of *Phascolarctobacterium faecium* strain ACM 3679^T from 3-d-old surface colonies on WCA with 5% defibrinated horse blood (a) and WCA supplemented with succinate (20 mmol/l) (b). Bars = 10 µm.

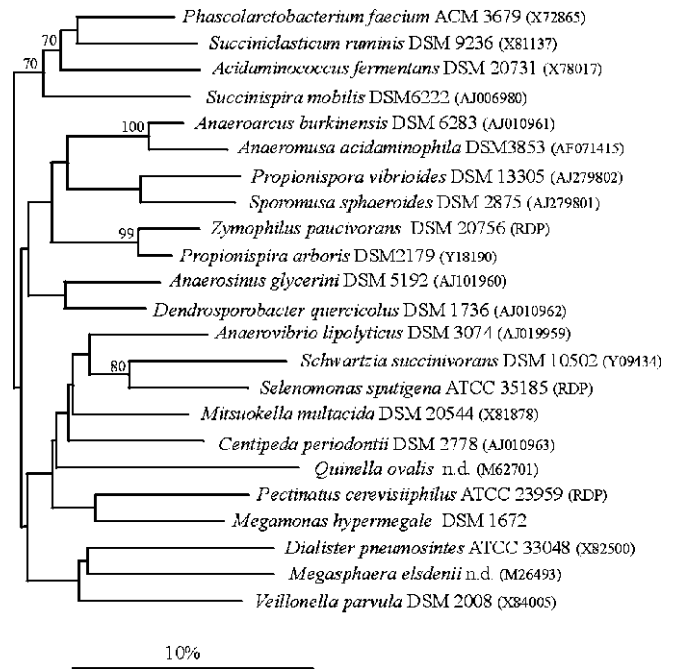

FIGURE 216. Phylogenetic position of *Phascolarctobacterium faecium* to some related bacteria of the *Sporomusa* subbranch as defined by the taxonomic browser of NCIB (<http://www.ncib.nlm.nih.gov>). The dendrogram was constructed by the neighbor-joining analysis of 16S rDNA sequences. Bar represents 10% sequence divergence.

TABLE 212. Differentiation of *Phascolarctobacterium* from phylogenetic neighboring genera

Characteristics	<i>Phascolarctobacterium</i>	<i>Succiniclasticum</i>	<i>Acidaminococcus</i>	<i>Succinispira</i>
Morphology	Rods, pleomorphic, branching	Short rods	Coccus, diplococci	Curved rods, spiral
Motility	-	-	-	+
DNA G+C content (mol%)	41–42	52	56	36
Major fermentation end products	Propionate ^a	Propionate, CO ₂	Acetate, butyrate, CO ₂	Formate, acetate, propionate, malate, CO ₂ , H ₂
Ability to ferment carbohydrates	-	-	-	-
Peptides, amino acids as main energy source	-	-	+	-

^a Production of CO₂ has not been reported by Del Dot et al. (1993).

List of species of the genus *Phascolarctobacterium*

1. ***Phascolarctobacterium faecium*** Del Dot, Osawa and Stackebrandt 1994, 182^{VP} (Effective publication: Del Dot, Osawa and Stackebrandt 1993, 383.)

fae'ci.um N.L. gen. pl. n. *faecium* of feces, isolated from the feces of koala.

The characteristics are the same as those described for the genus. Colonies grown on succinate are transparent, convex, smooth, 0.5 mm in diameter. Nonhemolytic on blood agar with 5% defibrinated horse blood. Cells grown in Wilkins-Chalgren medium and peptone/yeast-extract medium have uniform

small rods ($0.5 \times 2.0 \mu\text{m}$), while pleomorphic nocardoid forms ($0.5 \times 5\text{--}20 \mu\text{m}$) develop in the presence of succinate. Grows in 20% bile. Catalase-negative, nitrate reduction negative. No production of indole, urease, alkaline phosphatase, or pyroglutamic acid arylamidase. No acid from fructose, glucose, or mannose. Kanamycin and colistin sensitive, vancomycin-resistant.

Isolated from feces of Koala.

DNA G+C content (mol%): 41.4–42.3 (T_m).

Type strain: ACM 3679, DSM 14760.

GenBank accession number (16S rRNA gene): X72865.

Genus XVII. ***Propionispira*** Schink, Thompson and Zeikus 1983, 673^{VP}
(Effective publication: Schink, Thompson and Zeikus 1982, 2778.)

BERNHARD SCHINK

Pro.pi.o.ni.spi'ra. N.L. n. *acidum propionicum* propionic acid; L. fem. n. *spira* a coil; N.L. fem. n. *Propionispira* a propionic acid forming coil.

Curved to helical rods, $1 \mu\text{m} \times 5\text{--}9 \mu\text{m}$. Spore formation not observed. Stains Gram-negative. **Motile by means of one terminally inserted flagellum. Strictly anaerobic, fermentative metabolism.** Optimum temperature 30–35°C. Chemo-organotrophic, using a wide variety of compounds as energy sources including lactate, glucose, lactose, sorbitol, xylose, and amygdalin. Fermentation end products are propionic acid, acetic acid, and carbon dioxide. Ethanol and succinate are formed under special conditions. Fumarate is reduced to succinate or propionate; sulfate and nitrate not reduced. Cytochrome *b* and nitrogenase are present; catalase is absent. Occurs in anoxic wetwoods in softwood trees such as cottonwood, poplar, or willows. The type strain was isolated from wetwood of a mature cottonwood tree located in Columbus, WI, USA.

DNA G+C content (mol%): 36.7 ± 1 (T_m).

Type species: ***Propionispira arboris*** Schink, Thompson and Zeikus 1983, 673^{VP} (Effective publication: Schink, Thompson and Zeikus 1982, 2778.).

Further descriptive information

Propionispira arboris clusters with Gram-positive bacteria of the low G + C group within the family *Veillonellaceae*, in the order *Clostridiales* (Stackebrandt et al., 1999). According to the 16S rRNA phylogenetic analysis presented in the roadmap to this volume (Figure 6), the genus *Propionispira* is a member of the family *Veillonellaceae*, order *Clostridiales*, class *Clostridia* in the phylum *Firmicutes*.

Propionispira arboris stains Gram-negative, but belongs to the Gram-positive bacteria on the basis of 16S rRNA sequence analysis (Stackebrandt et al., 1999). Cells are coiled to curved rods and are motile by means of terminally inserted flagella. The temperature range for growth is 4–46°C with an optimum temperature at 30–35°C for the type strain. The pH range for growth is 4.5–8.0 with an optimum of 6.0–6.5.

Propionispira arboris ferments arabinose, cellobiose, galactose, glucose, lactose, mannose, mannitol, raffinose, galacturonate, sorbitol, sucrose, glycerol, lactate, and amygdalin. Inositol, maltose, melibiose, melizitose, rhamnose, trehalose, arabinogalactan, cellulose, pectin, polygalacturonic acid, starch, xylan,

citrate, pyruvate, tartrate, esculin, salicin, Casamino acids, gelatin, and tryptone are not fermented.

Growth with glucose is substantially faster in complex media than with ammonium chloride or N_2 as nitrogen source. The cell yield on any carbon substrate tested is highest in complex medium and lowest if N_2 is the sole source of nitrogen.

Propionispira arboris is so far the only representative among the strictly anaerobic propionic-acid-forming bacteria that is able to fix molecular nitrogen. Addition of ammonium chloride to cultures inhibits nitrogenase activity. After growth in the presence of bound nitrogen, no nitrogenase activity is detectable.

The main products of carbohydrate fermentation are propionate, acetate, and CO_2 . Ethanol and succinate are formed in trace quantities only when glucose is fermented. Ethanol is a more significant product of xylose metabolism, and succinate is a major end product when fumarate is added to glucose medium. H_2 , lactate, and other soluble and gaseous compounds were not detected as fermentation products. Sugars are degraded through the Embden–Meyerhof pathway; propionic acid is formed via the methylmalonyl-CoA pathway (Thompson and Zeikus, 1988).

Enrichment and isolation procedures

Propionispira arboris can be isolated selectively with glucose or other carbohydrates as the carbon and energy source and N_2 as the sole source of nitrogen in reduced media under strictly anoxic conditions. Wetwoods of softwood trees appear to be a natural source of this bacterium. Enrichments are incubated at 30°C. After 1–2 transfers, typical coil-shaped cells will dominate and can be selectively purified under anoxic conditions on agar plates or in agar shake dilution series.

Maintenance procedures

Pure cultures may be stored anoxically in liquid medium at 4°C in the dark. Stock cultures should be transferred every 1–2 months. For long-term preservation, a dense cell suspension of *Propionispira arboris* may be suspended in anoxic medium containing glycerol or dimethyl sulfoxide, sealed in sterile glass capillaries, and stored in liquid nitrogen.

Differentiation of the genus *Propionispira* from other genera

The genus *Propionispira* is distinguished from other fermentative bacteria by its phylogenetic position, its unusual cell shape, and its capacity to ferment carbohydrates exclusively to propionate, acetate, and CO₂, and to fix molecular nitrogen in purely

synthetic mineral media. With these properties, *Propionispira* differs substantially from organisms of similar morphology and metabolic capacities such as *Pectinatus* (which cannot fix N₂), from the classical club-shaped propionic acid bacteria, and from most members of the *Bacteroidetes*.

List of species of the genus *Propionispira*

1. ***Propionispira arboris*** Schink, Thompson and Zeikus 1983, 673^{VP} (Effective publication: Schink, Thompson and Zeikus 1982, 2778.)

ar' bo.ris. L. masc. n. *arbor* tree; gen. *arboris* of a tree, referring to the occurrence of this bacterium in wetwood.

The description is as for the genus. Isolated with glucose as only electron donor and N₂ as only nitrogen source. Occurs in anoxic wetwoods of cottonwood trees.

DNA G+C content (mol%): 36.7 ± 1 (T_m).

Type strain: 12B4, ATCC 33732, DSM 2179.

GenBank accession number (16S rRNA gene): Y18190.

Genus XVIII. ***Propionispira*** Biebl, Schwab-Hanisch, Spröer and Lünsdorf 2001, 793^{VP} (Effective publication: Biebl, Schwab-Hanisch, Spröer and Lünsdorf 2000, 246.)

HANNO BIEBL

Pro.pi.on.i.spo'ra. N.L. n. *acidum propionicum* propionic acid; Gr. n. *spora* a seed; N.L. fem. n. *Propionispira* a propionic-acid-forming, spore-forming organism.

Curved or spiral-shaped rods. Motile by a **tuft of flagellae inserted at the concave side** of the cell (Figure 217). Forms round, terminally located **endospores**. **Gram-stain-negative**. Chemo-organotrophic and anaerobic. **Ferments sugars and sugar alcohols to propionic acid, acetic acid, and CO₂**. Requires yeast extract.

DNA G+C content (mol%): 42.3–48.7.

Type species: ***Propionispira vibrioides*** Biebl, Schwab-Hanisch, Spröer and Lünsdorf 2001, 793^{VP} (Effective publication: Biebl, Schwab-Hanisch, Spröer and Lünsdorf 2000, 246.).

Further descriptive information

Colonies and centrifuge pellets appear slightly pink from unknown pigments. The number of fermentable sugars and sugar alcohols is limited (see list of species); pyruvate and lactic acid are not used. In addition to propionic and acetic acid, some hydrogen is also produced to balance redox differences between substrate and cell mass. Cultures tolerate exposure to air.

Enrichment and isolation procedures

A common enrichment procedure cannot be given for the genus because the two existing strains were obtained in very different manners.

Maintenance procedures

Both species can be maintained in the anaerobically prepared medium of Biebl et al. (2000) containing erythritol or fructose as substrate. Long-term storage can take place in 10% glycerol at -70°C or by freeze-drying.

Differentiation from other related genera

Propionispira is distinguished from most of the other Gram-stain-negative anaerobic genera by its unique morphology (see generic definition) which is shared with *Selenomonas* and *Sporomusa* (Biebl et al., 2000; Kingsley and Hoeniger, 1973; Möller et al., 1984). It differs from *Selenomonas* by forming spores and from *Sporomusa* by not being acetogenic. *Dendrosporobacter* and *Acetonema*, which are also anaerobic Gram-stain-negative spore-formers, are straight rods and exhibit peritrichous flagellation; *Acetonema* performs an acetogenic type of fermentation.

Taxonomic comments

16S rRNA gene sequences indicate some relationship to *Dendrosporobacter quercicolus* (93% similarity) and to *Sporomusa* species (91%). Other members of the *Sporomusa*–*Pectinatus*–*Selenomonas* group are relatively close to these species (88–90%).

FIGURE 217. *Propionispira vibrioides*. Platinum-carbon shadow-cast preparation of a non-sporing cell showing six flagella inserted at the concave

List of species of the genus *Propionispora*

1. ***Propionispora vibrioides*** Biebl, Schwab-Hanisch, Spröer and Lünsdorf 2001, 793^{VP} (Effective publication: Biebl, Schwab-Hanisch, Spröer and Lünsdorf 2000, 246.)
vi.brio.i'des. N.L. masc. n. *vibrio* that which vibrates, a generic name; Gr. n. *eidōs* shape; N.L. adj. *vibrioides* vibrio-shaped.
Cell shape, flagella insertion, and spore characteristics as in the genus description. Cell size $0.6 \times 2.2\text{--}6\mu\text{m}$. Cells only slightly swollen during sporulation. Growth and fermentation substrates are polyols such as erythritol, xylitol, mannitol, sorbitol; fructose is also fermented, but not glucose, xylose, or glycerol. Biotin allows weak growth in synthetic medium, but does not entirely replace yeast extract. Good growth between 30 and 40°C, optimum at 37°C; pH range 5.0–8.5, optimum at 7.5.
The existing strain was isolated from an enrichment culture for anaerobic degradation of erythritol using composted fatty material as an inoculum.
DNA G+C content (mol%): 48.7 (HPLC).
Type strain: FKBS1, DSM 13305.
GenBank accession number (16S rRNA gene): AJ279802.
2. ***Propionispora hippei*** Abou-Zeid, Biebl, Spröer and Müller 2004, 953^{VP}
hip'pe.i. N.L. n. *hippei* in honor of Hans-H. Hippe, a German microbiologist and anaerobe specialist.
Cell shape, structure, and size as for *Propionispora vibrioides*. Spore-forming cells distinctly swollen. Fermented substrates as listed for *Propionispora vibrioides*, but glucose and glycerol are used in addition. The temperature range for growth is between 20 and 50°C with an optimum at 40°C; the pH ranges between 5.0 and 8.2 with an optimum at 7.0.
The existing strain was isolated from an enrichment culture for anaerobic degradation of polypropylene adipate using sewage from a German treatment plant as inoculum. The strain is able to depolymerize the polyester to 1,3-propanediol and adipic acid, but cannot attack these products. DNA–DNA hybridization with *Propionispora vibrioides* FKBS1 is 47%.
DNA G+C content (mol%): 42.3 (HPLC).
Type strain: KS, ATCC BAA-665, DSM 15287.
GenBank accession number (16S rRNA gene): AJ508927, AJ508928.

Genus XIX. ***Quinella*** Krumholz, Bryant, Brulla, Vicini, Clark and Bryant 1993, 295^{VP}

LEE R. KRUMHOLZ, WOLFGANG BUCKEL, GREGORY M. COOK AND JAMES B. RUSSELL

Quin.el'la. N.L. fem. n. *Quinella* named for the pioneering ruminologist, J.I. Quin, who described the organism in some detail (Quin, 1943).

Cells are **Gram-stain-negative** and **oval shaped**. Size is $3\text{--}4 \times 5\text{--}8\mu\text{m}$ in size but can be considerably smaller in the rumen if crowding occurs. **Tumbling motility** with linear tufts of flagella on one side of the cells. **Endospores are not formed**. **Heterotrophic** and **mesophilic**. Reproduces by binary fission, and it usually occurs as singles and pairs. A small number of **carbohydrates are fermented** mainly to lactate, acetate, propionate, and CO₂. Contains a glycogen-like reserve material.

DNA G+C content (mol%): unknown.

Type species: ***Quinella ovalis*** Krumholz, Bryant, Brulla, Vicini, Clark and Bryant 1993, 295^{VP}.

Further descriptive information

This genus has not been axenically cultivated and therefore this description is based on studies with highly purified cell suspensions obtained through differential centrifugation (Wicken and Howard, 1967). Small-subunit rRNA sequence information has shown that the closest cultivated relatives of *Quinella* are members of the genus *Selenomonas*, including rumen strains of *Selenomonas ruminantium* and oral strains of *Selenomonas gingivalis*. However, the evolutionary distance separating these organisms is too large to justify placing them in the same genus.

In addition to being observed in rumens of sheep fed molasses (Vicini et al., 1987) and in rumens of llamas (Orpin, 1972), cloned rRNA genes from members of the genus *Quinella* have been retrieved from rumens of a yak as well as a gaur (*Bos frontalis*). The cell density observed in the rumen is strongly influenced by the amount of fermentable sugars (e.g., glucose or sucrose) in the animal's diet (Brough et al., 1970; Orpin, 1972; Quin, 1943; Vicini et al., 1987), with numbers ranging from $10^5\text{--}10^8$ cells/ml in hay-fed sheep to 10^{11} cells/ml in sheep fed mainly molasses (Vicini et al., 1987).

Photomicrographs that represent the morphology have been published (Quin, 1943; Vicini et al., 1987; Wicken and Howard, 1967). The cell wall contains a distinct outer membrane as well as muramic and *m*-diaminopimelic acids (Wicken and Howard, 1967).

When sugars do not limit growth, lactic acid is produced as the major fermentation product. However when present in the rumen of molasses-fed sheep, when sugars are limiting and growth is slow, acetate, propionate, and CO₂ are the major fermentation products (Vicini et al., 1987). Under these conditions, no lactate is detectable at any time during the 24-h feeding cycle.

List of species of the genus *Quinella*

1. ***Quinella ovalis*** Krumholz, Bryant, Brulla, Vicini, Clark and Bryant 1993, 295^{VP}
o.val'is. L. fem. adj. *ovalis* egg-shaped.
Cells are oval and are about $3\text{--}4\mu\text{m} \times 5\text{--}8\mu\text{m}$ in size but can be considerably smaller in the rumen if crowding occurs (Vicini et al., 1987). Highly enriched and partially purified cell

suspensions ferment glucose, fructose, sucrose, and mannitol and slowly metabolize maltose. Polysaccharides, amino acids, proteins, lactate, melibiose, mannose, glucosamine, galactose, rhamnose, cellobiose, lactose, glucuronic acid, xylose, arabinose, and soluble starch are not fermented or are fermented at extremely low rates (Brough et al., 1970; Orpin, 1972).

Rapid growth occurs at 37–39°C, and slow growth occurs at 44°C. No growth occurs at 25 or 50°C (Orpin, 1972). It grows in the rumen at pH values at least as low as 6.0. The higher pH limit is not known.

Species have been obtained from the rumen of molasses-fed sheep.

DNA G+C content (mol%): unknown.

Type strain: the species has not been axenically cultivated, and therefore this description is the type of the species (in accordance with Rule 18f of the *International Code of Nomenclature of Bacteria*).

GenBank accession number (16S rRNA gene): M62701.

Acknowledgements

Marvin Bryant's love of anaerobic bacteria, his insistence on taxonomic classification, and his hard work are responsible for this description.

Genus XX. *Schwartzia* van Gylswyk, Hippe and Rainey 1997, 158^{VP}

FRED A. RAINEY

Schwartzia. L. fem. n. *Schwartzia* named in memory of Helen M. Schwartz, a South African rumen physiologist who had a keen interest in rumen microbiology.

Gram-stain-negative, curved rods, motile by lateral flagella. **Non-spore-forming. Anaerobic.**

Asaccharolytic and do not ferment amino acids or peptides. Ferments succinic acid with the production of propionic acid. Non-proteolytic, catalase-negative, urease-negative. Nitrate is not reduced. **Mesophilic.**

DNA G+C content (mol%): 46 (UV).

Type species: *Schwartzia succinivorans* van Gylswyk, Hippe and Rainey 1997, 158^{VP}.

Further descriptive information

The description of the genus *Schwartzia* and the single species *Schwartzia succinivorans* is based on the properties of four strains S1-1^T (DSM 10502^T), strain S2-3 (DSM 10503), strain S3-2 (DSM 10504), and strain S4-2 (DSM 10505). The cells stain Gram-negative, are slightly curved to curved rods that have tapered ends. The strains are motile by means of flagella, which can be single or in tufts and are found in the middle of the concave side of the cells. The cells vary in width (0.35–0.6 µm) and length (1.6–3.3 µm). S-shaped cells can be up to 5 µm long. Long filaments greater than 30 µm might be undivided cells. Colonies on the surface of agar slopes (40% rumen fluid, 0.2% yeast extract, 1% succinate, and 1.5% agar) are 0.25 mm in diameter, colorless, round, raised, and smooth edged after 24 h of incubation. Subsurface colonies are 0.1 mm in diameter and round discs. After 48 h of incubation, surface colonies are 5 mm in diameter while subsurface colonies are 0.3 mm wide.

Substrate utilization is limited to succinate for all of the four strains tested. Succinate is fermented to propionic acid. These strains failed to ferment galactose, glucose, fructose, mannose, arabinose, xylose, cellobiose, maltose, sucrose, glycerol, mannitol, the sodium salts of DL-lactic and pyruvic acids, the disodium salts of oxalic, malic, malonic, methylmalonic, fumaric, oxaloacetic, and glutaric acids, and the trisodium salts of citric, *trans*-aconitic, and tricarballic acids. Growth is not supported by amino acids and peptides even when digests of casein are added to the medium. Rumen fluid and yeast extract are required to obtain good growth on succinate. A reducing agent is not required to obtain good growth if the medium is prepared under anaerobic conditions. If air is added to the headspace, growth is not good if the medium has not been reduced using

a reducing agent. No growth is obtained for the four strains at 22°C. Different amounts of growth are observed for each of the four strains when incubated 45°C.

Enrichment and isolation procedures

The basal medium used for the isolation of *Schwartzia* contains (per liter) 0.225 g of K₂HPO₄, 0.225 g of KH₂PO₄, 0.45 g of NaCl, 0.45 g of (NH₄)₂SO₄, 0.045 g of CaCl₂ (anhydrous), 0.09 g of MgSO₄·7H₂O, 6.36 g of NaHCO₃, 0.25 g of cysteine hydrochloride·H₂O, 0.25 g of Na₂S (hydrated), 0.005 g of indigo carmine, and 400 ml of clarified rumen fluid. This basal medium with 2% agar added is preincubated at 39°C for one week after which 0.5% succinate, NaHCO₃ and reducing agent are added before sterilization. Samples of the rumen ingesta are diluted to 10⁻⁷, and 0.5-ml aliquots are injected into sterile CO₂-purged roll bottles to which 2.5 ml of the molten preincubated and sterilized succinate agar is added. After 5 d incubation, large colonies are selected and their growth on succinate further tested on basal medium containing 40% clarified rumen fluid and 0.5% yeast extract with or without 1% succinate. Microscopic examination of the cultures allows for selection of cells with curved rod morphologies.

Taxonomic comments

The genus *Schwartzia* was described on the basis of its phenotypic, chemotaxonomic, and phylogenetic properties. Based on 16S rRNA gene sequence comparisons, strain S1-1^T was shown to fall within the radiation of the Gram-stain-negative bacteria of the genera *Selenomonas*, *Pectinatus*, and *Zymophilus* and represents a distinct lineage with no strong affiliation to any previously described genus (van Gylswyk et al., 1997). Comparison of the 16S rRNA gene sequence of strain S1-1^T with the currently available database confirms this original finding (see Figure 206). 16S rRNA gene sequence similarities are in the range 90.6–92.4% to species of the genera *Selenomonas*, *Mitsuokella*, and *Centipeda*. *Schwartzia succinivorans* falls outside the cluster comprising most species of the genus *Selenomonas*, and its relationship to any of the species/genera clusters is not supported by bootstrap analysis. The genus *Schwartzia* can be differentiated from related genera by its utilization of a limited range of substrates; the majority of species of related genera can utilize

a wide range of substrates. The only other Gram-stain-negative anaerobe that is limited to succinate as a fermentable carbon source is *Succiniclasticum ruminis*, but this taxon is phylogenetically unrelated to strain S1-1^T (see *Succiniclasticum* chapter, below). In the original description of the genus *Schwartzia* the

case was made that it had a different fatty acid pattern than species of related genera. These data need to be redetermined with all strains grown under the same conditions to further evaluate this claim. Differences in mol% G+C content of the DNA have also been considered to be a differentiating characteristic.

List of species of the genus *Schwartzia*

1. *Schwartzia succinivorans* van Gylswyk, Hippe and Rainey 1997, 158^{VP}

suc.cin.i.vo'rans. L. neut. n. *succinicum* amber; N.L. neut. n. *acidum succinum* succinic acid; L. part. *vorans* devouring; L. part. adj. *succinivorans* succinic acid-devouring.

Cells are curved motile rods with one or more flagella emanating from the concave side in the middle of the cell. Flagella occur in tufts if more than one is present. Cells are 1.6–3.3 µm in length and 0.35–0.6 µm in diameter. S-shaped cells and helical filaments up to 30 µm long occur. Colonies on succinate agar are colorless, slightly raised, and have multiple lobes and smooth edges. Colonies are up to 5 mm in diameter after 48 h growth. The optimum temperature for growth is 39°C, and no growth occurs at 22°C and lim-

ited growth at 45°C. Succinate is fermented to propionate. Rumen fluid and yeast extract are required for good growth. Glycerol, lactate, pyruvate, oxalate, malate, malonate, methylmalonate, fumarate, oxalacetate, glutarate, citrate, aconitate, tricarballoylate, and amino acids and peptides present in acid or enzymic hydrolysates of casein are not utilized. Catalase, urease, sulfide production, nitrate reduction, and gelatin liquefaction negative. The major cellular fatty acids are: C_{15:0} aldehyde, C_{16:1} cis7, C_{12:0}, C_{14:0}, C_{15:0}, and C_{16:0}. Branched-chain fatty acids are absent. Type strain was isolated from rumen ingesta of cows on pasture.

DNA G+C content (mol%): 46.0 (UV).

Type strain: S1-1, DSM 10502.

GenBank accession number (16S rRNA gene): Y09434.

Genus XXI. *Selenomonas* Von Prowazek 1913, 36^{AL}

YOGESH S. SHOUCHE, ABHIJIT S. DIGHE, DHIRAJ P. DHOTRE, MILIND S. PATOLE AND DILIP R. RANADE

Se.le.no.mo'nas. Gr. n. *selene* the moon; Gr. n. *monas* a unit, monad; N.L. fem. n. *Selenomonas* moon (-shaped) monad.

Curved to helical rods, usually 0.9–1.1 × 3.0–6.0 µm. The ends are usually tapered and rounded to give short kidney- to crescent-shaped or **vibrioid cells**. Long cells and chains of cells are often helical. Capsules are not formed. Resting stages are not known. Gram-stain-negative. **Motile with active tumbling; flagella (up to 16) are arranged linearly as a tuft near the center of the concave side in the area of cell fission. Strictly anaerobic.** Optimum temperature 35–40°C; maximum 45°C; minimum 20–30°C. Chemoorganotrophic, **having a fermentative type of metabolism. Carbohydrates and lactate can serve as fermentable substrates. Fermentation of glucose chiefly yields acetate, propionate, CO₂, and/or lactate.** Small amounts of H₂ and succinate may be produced. Catalase negative.

DNA G+C content (mol%): 40–61.

Type species: *Selenomonas sputigena* (Flügge 1886) Boskamp 1922, 70^{AL}. (*Spirillum sputigenum* Flügge 1886, 387).

Further descriptive information

This description is based in part upon the chapter in the first edition of the *Systematics* by Bryant (1984). Cells show varying morphology; typically they are vibrioid to helical to crescent shape. They occur singly, in pairs, and short chains and may occur in clumps, especially in *Selenomonas sputigena* (Kingsley and Hoeniger, 1973). The cells are usually 1 µm × 2.0–4.0 µm long, however, some could be larger, 2.0–3.0 × 5–10 µm (Prins, 1971). The ultrastructure and flagella have been studied extensively for *Selenomonas sputigena*, *Selenomonas Palpitans*, and *Selenomonas ruminantium*. The flagella are present as a tuft arranged linearly near the center of the concave side of the organism.

The number can vary from 4–5 (*Selenomonas lipolytica*) to 22 (*Selenomonas palpitans*). A typical flagellum is 17 nm thick and 7 µm long, with a center to center distance between adjacent flagella of 68 nm.

Much information has been published on the cell envelope, membrane structure, and lipid chemistry of *Selenomonas ruminantium* (see Takatsuka and Kamio, 2004 for further references). Under the electron microscope, the *Selenomonas ruminantium* outer membrane is wrinkled and has several irregular blebs. These are formed at several sites where the membrane is pinched off, forming vesicles of various sizes. The cell wall is not as complex as that seen in the *Proteobacteria*, and the addition of very low concentrations of lysozyme leads to rapid cell lysis. *Selenomonas ruminantium* does not have Braun lipoprotein which has an important role in the maintenance of the structural integrity of proteobacterial outer membranes (Kamio and Takahashi, 1980). Instead, *Selenomonas ruminantium* has cadaverine, which is covalently linked to the peptidoglycan and is an essential component for cell division (Kamio et al., 1981b). The major phospholipids of both outer and inner membranes from *Selenomonas* are phosphatidyl ethanolamine, ethanolamine plasmalogens, and glyceryl ether type ethanolamines, while phosphatidyl glycerol or cardiolipins are absent in both membranes. Types of phosphatidyl ethanolamine plasmalogen present in outer and inner membranes are quite different. One of the important lipid fractions present in *Selenomonas* membranes is 2-keto-3-deoxyoctulosonic acid-lipid A (Kamio and Takahashi, 1980). This lipid has phosphorus, 2-keto-3-deoxyoctulosonic acid and 3-OH fatty acid but no detectable levels of glycerol.

The outer membrane from both glucose- and lactate-grown cells contain two major peptidoglycan-associated proteins with apparent molecular masses of 42,000 and 40,000. The amount of each protein varies considerably, depending upon the culture conditions. These are novel lysine decarboxylases that are responsible for synthesis of cadaverin (Takatsuka and Kamio, 2004). A regulatory protein "P22" is found to be associated with lysine decarboxylase, and it is a stimulatory factor for the degradation of the enzyme. Lipopolysaccharides from cell envelopes of *Selenomonas* also play a role as the virulence factors in human periodontal diseases (Kumada et al., 1997).

Selenomonas species show wide variation in colony morphology. Colonies typically are visible after 48–60 h of growth. *Selenomonas ruminantium* var. *bryanti* produces glassy, round, lenticular, translucent water-droplet-like colonies, which become opaque and larger as they grow, becoming 6 mm in diameter after 5–6 d. *Selenomonas ruminantium* strains are strongly iodophilic and accumulate reserve carbohydrate granules in the cytoplasm on addition of fermentable sugars to growth media. *Selenomonas noxia* colonies on rabbit blood agar after 48 h are minute to 0.5 mm in diameter, circular, entire, low convex to flat, transparent, smooth, shiny, and colorless to yellowish. *Selenomonas fluggei* colonies are 0.5–1.0 mm in diameter, circular, entire to spreading, opaque, white, shiny, and smooth. They sometimes form a spreading growth over the entire plate. *Selenomonas infelix* colonies are 0.5–1.0 mm, circular, entire, pulvinate, translucent, shiny, and smooth. It may also produce a spreading growth. *Selenomonas diana* colonies are minute, entire, circular, shiny, smooth, and gray to white. *Selenomonas artemidis* colonies are minute to 0.5 mm in diameter, circular, entire, low convex, translucent, smooth, shiny, and colorless. *Selenomonas sputigena* colonies on blood-agar media are generally 0.5–1.2 mm in diameter, smooth, convex, and gray to gray-yellow in color. *Selenomonas lipolytica* colonies on PYG agar are light brown, spherical, 2 mm in diameter, opaque, and convex with defined borders. Fully grown colonies possess elevated darker pointed centers.

Selenomonas species except *Selenomonas lipolytica* require volatile fatty acids, such as *n*-valerate, for growth when glucose is the energy source (Kanegasaki and Takahashi, 1967). CO₂ is required for growth on lactate or glycerol but not on glucose in complex media containing trypticase and yeast extract. Strains of *Selenomonas ruminantium* require L-aspartate, CO₂, *p*-aminobenzoic acid, and biotin for growth in a lactate-salts medium, and aspartate can be replaced by malate or fumarate (Evans and Martin, 1997). Medium containing small amounts of dithiothreitol is reported to be better for the growth of *Selenomonas*. *Selenomonas ruminantium* cannot grow on aspartate, fumarate, or malate in the absence of lactate, but it can grow on all three organic acids in the presence of extracellular hydrogen gas (Martin, 1998). Sulfide can be the sole source of sulfur (Linehan et al., 1978).

Much information has been published on *Selenomonas* metabolism and metabolic pathways – see Ricke et al. (1996) for further references. *Selenomonas* cannot degrade complex polysaccharides but can metabolize simpler carbohydrates released from the initial hydrolysis of these polymers. Selenomonads have multiple routes for carbon flow during carbohydrate catabolism and ATP generation. Most *Selenomonas* species, like *Selenomonas ruminantium*, *Selenomonas sputigena*, and *Selenomo-*

nas lipolytica utilize glucose by the Embden–Meyerhof–Parnas glycolytic pathway (EMP) and produce acids, such as acetate, lactate, propionate, and succinate (Melville et al., 1988). *Selenomonas ruminantium* ferments glucose to lactate, acetate, propionate, and CO₂. The amounts and proportions of these end products depend upon the growth and nutritional conditions. In batch culture, with glucose as the carbon source, the cells first produce DL-lactate. Some strains of *Selenomonas* can utilize lactate and produce acetate and propionate (Nisbet and Martin, 1994).

The pathways for these transformations are complex. Glucose is first catabolized to phosphoenolpyruvate, which is converted to either pyruvate or oxaloacetate. Pyruvate is either reduced to L-lactate or oxidatively decarboxylated to acetyl coenzyme A and CO₂. Acetyl-CoA is converted to acetate and CoA by acetate thiokinase with formation of ATP (Melville et al., 1988). Oxaloacetate is converted to succinate that is either excreted or decarboxylated to propionate. Enzymes such as pyruvate kinase, acetate thiokinase, PEP carboxykinase, fumarate reductase, and methylmalonyl-CoA decarboxylase are involved in energy conservation in *Selenomonas ruminantium* (Melville et al., 1988). Strains of *Selenomonas ruminantium* can ferment xylose and xylo-oligosaccharides, and they possess xylosidase and arabinosidase that are induced by these sugars (Cotta and Whitehead, 1998). Different *Selenomonas* strains have the ability to produce trace amounts of hydrogen gas. *Selenomonas ruminantium* accumulates intracellular polysaccharide as an energy reserve during starvation (Russell, 1998).

Selenomonas can utilize ammonia, protein, and amino acids as a nitrogen source for protein synthesis. Selenomonads can use urea as a source of nitrogen, and most *Selenomonas* species produce urease (Smith et al., 1981). *Selenomonas* strains are known to utilize glutamate dehydrogenase, glutamine synthetase–glutamate synthase pathways for ammonia assimilation (Smith et al., 1981).

The phylogenetic structure of the genus has been studied using 16S rRNA gene sequences, and the genus was found to be phylogenetically coherent with interspecies similarity levels of 90–99% (Figure 218). *Selenomonas diana*, *Selenomonas infelix*, *Selenomonas fluggei*, *Selenomonas noxia*, and *Selenomonas artemidis* form a tight cluster with sequence similarities in the range of 96–99%. *Selenomonas sputigena* and *Selenomonas ruminantium* have a mean sequence similarity of 94% with members of this cluster. DNA hybridization has been used to delineate oral species of *Selenomonas* which have a narrow range of G + C content of their DNA (53–58 mol%).

Selenomonas ruminantium contains several plasmids, ranging in size from 1.4 kb to >30 kb. At least seven of these have been sequenced (Al-Khaldi et al., 1999; Sprincova et al., 2005). Two phages, one temperate and one lysogenic, have been reported from this organism (Cheong and Brooker, 1998; Lockington et al., 1988).

The antigenicity of *Selenomonas* has not been studied in detail for either identification or classification. Monoclonal antibodies against *Selenomonas ruminantium* have been used for ELISA detection (Broker and Stokes, 1990). Antisera against the 42 kDa heat modifiable protein from cell envelopes of *Selenomonas ruminantium* cross-react with other *Selenomonas* species (Kalmokoff et al., 2000). This antigen forms a regularly ordered array in the outer membrane and is very similar to outer-membrane proteins in certain *Proteobacteria*.

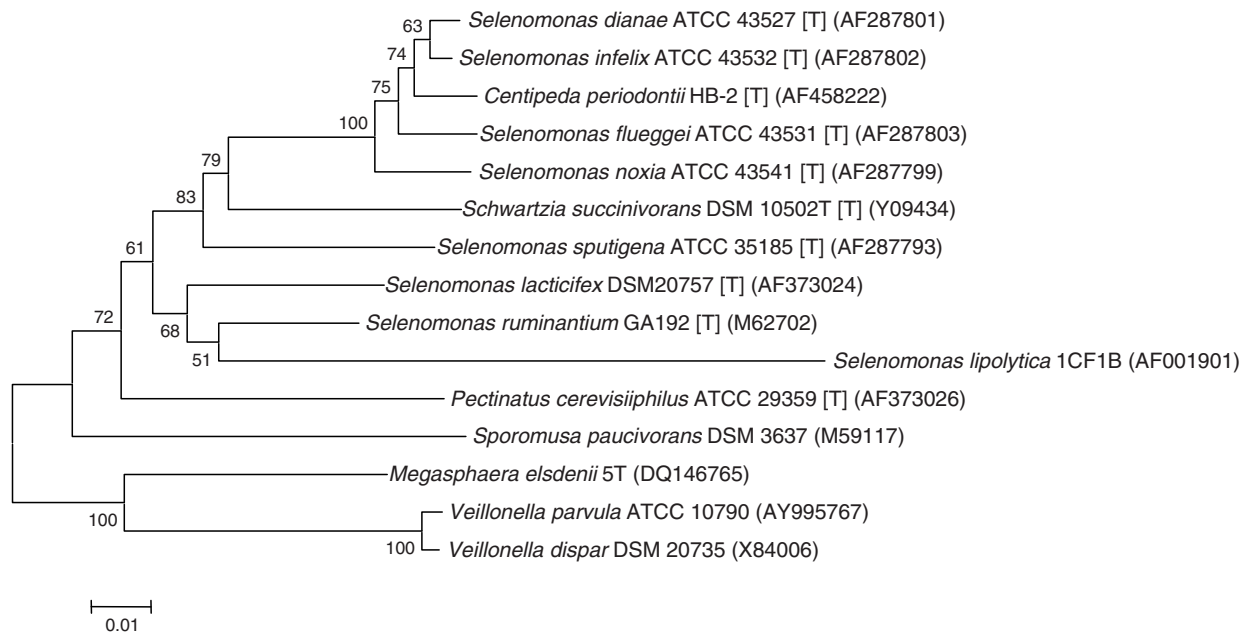

FIGURE 218. Rooted phylogenetic relationships of members of the genus *Selenomonas* and related species based on 16S rRNA gene sequences. The topology was inferred by MEGA3.1 using neighbor-joining method with Kimura 2-parameter as a model of nucleotide substitution with 1000 bootstrap replicates. Tree was rooted using *Veillonella* as an outgroup. Bootstrap values are shown at each internal node. Accession numbers are shown after each species name in parentheses. Scale bar represents substitutions per site.

Most *Selenomonas* species are sensitive to various antibiotics that act against protein and cell-wall biosynthesis. *Selenomonas sputigena* is resistant to penicillin G (Walker et al., 1985), while *Selenomonas lipolytica* is resistant to erythromycin (Dighe et al., 1998).

McCarthy et al. (1981) reported the first isolation of *Selenomonas sputigena* from blood culture of a patient with septicemia. Clones representing 16S rRNA gene sequences from *Selenomonas* have since been found associated with endodontic infections, dental caries, and in subgingival plaques (Munson et al., 2004; Paster et al., 2001; Rolph et al., 2001).

Selenomonads are believed to be one of the first bacteria observed by Antonie van Leeuwenhoek in gingival scrapings from the human mouth (Dobell, 1960, as quoted by Bryant, 1984), and selenomonads are considered as part of the normal indigenous microflora of human gingival crevices. The type species *Selenomonas sputigena* was isolated from the human oral cavity by Flügee (1886) as quoted by Bryant, 1984). Originally named *Spirillum sputigenum*, the generic name *Selenomonas* was suggested by Von Prowazek (1913), as quoted by Bryant, 1984), and *Spirillum sputigenum* was renamed as *Selenomonas sputigena* by Boskamp (1922). Although its function in the oral cavity is not readily understood, its saccharolytic activity presumably plays some role. The selenomonads are often more abundant in individuals with clinically detectable gingivitis or periodontal disease. The pure lipopolysaccharide from selenomonads possesses endotoxin properties in mice (Kurimoto et al., 1986). Some occurrences of *Selenomonas sputigena* and other selenomonads in human septicemia also have been reported (McCarthy and Carlson, 1981; Pomeroy et al., 1987).

Selenomonas ruminantium is a very common species in the rumens of cows and sheep, and many strains of the species are described (Bryant, 1956; Hobson and Mann, 1961; Prins, 1971).

Animal feed containing rapidly fermentable carbohydrates such as grains leads to more rapid growth of selenomonads in the rumen than feed low in rapidly fermentable carbohydrates, such as straw or silage (Caldwell and Bryant, 1966). These bacteria are also responsible for glycerol fermentation in the sheep and cattle rumen (Bryant, 1956; Hobson and Mann, 1961). Only a few species of ruminal bacteria ferment lactate. The lactate-fermenting strain of *Selenomonas ruminantium* is designated *Selenomonas ruminantium* subsp. *lactilytica* (Bryant, 1956). Animal bloat resulting from feed high in grain is associated with lower ruminal pHs, increased lactate formation, and substantial increases in the number of selenomonads.

Selenomonads are also present in swine intestine. Approximately 21% of the total bacteria isolated from the cecal contents of healthy swine are strains of *Selenomonas ruminantium* (Robinson et al., 1981). These organisms are also found in swine feces (Salanitro et al., 1977). Presumably, like in the rumen, a functional role for selenomonads in the swine intestine involves fermentation of soluble sugars. The dominance of *Selenomonas ruminantium* strains in the swine intestine may be related to the availability of lactate.

Selenomonads are also found in the cecum of a number of small rodents. About 5% of the total bacterial isolates from rat cecal contents are selenomonads (Ogimoto, 1972). Morphologically typical selenomonads have been observed in cecal contents of squirrels. As many as 10^9 – 10^{10} cells per gram of cecal contents were isolated from cecal contents of the ground squirrel, *Citellus tridecemlineatus* (Barnes and Burton, 1970). Selenomonads are also reported in the cecum of guinea pigs (Kingsley and Hoegner, 1973; Robinow, 1954). Simons reported the presence of "*Selenomonas palpitanis*" from the cecum and feces of guinea pigs. The electron micrographs of this isolate reveal that it differs in

some respects in cell morphology from *Selenomonas ruminantium* (Kingsley and Hoeniger, 1973). However, in the absence of a pure culture, the existence of this species is questionable.

Other environments from which selenomonads have been isolated include river water (Leifson, 1960) and ditch water from a bog habitat (Harborth and H. H. Hanert, 1982). A chemostat culture developed with anaerobic sewage sludge possessed selenomonads (Nanninga et al., 1987). *Selenomonas lipolytica*, which possesses lipolytic activity, was isolated from a ditch in an oil mill (Dighe et al., 1998). All these studies suggest that selenomonads are present in many naturally anaerobic habitats.

Isolation

Selenomonads are obligately anaerobic bacteria. The exclusion of oxygen at every stage of isolation, transfer, and preservation is an essential prerequisite. The principles of anaerobic techniques described by Hungate (1969) and subsequently modified by Miller and Wolin (1974) are employed.

The nutritional requirements of selenomonads are simple. These bacteria grow well in medium containing glucose, ammonia, minerals, vitamins, and sulfide. Addition of *n*-valeric acid and trypticase enhances growth. An O₂-free atmosphere of N₂ or CO₂ or mixture of both of these gases is essential for isolation and growth of these bacteria. Media like PYG (Holdeman et al., 1977), MPB (Kingsley and Hoeniger, 1973), and OA-1 (Dighe et al., 1998) are useful in isolation of selenomonads. Hespell et al. (1992) suggest a modified selective medium (SS) for isolation of *Selenomonas ruminantium*. Tiwari et al. (1969) used SS medium for isolation of ruminal selenomonads. The medium is selective because of the acidic pH (6.0) and presence of mannitol as the sole carbohydrate. This medium allows growth of selenomonads and inhibits growth of many other ruminal bacteria that are unable to use mannitol. Isolation with glycerol or lactate allows preferential growth of *Selenomonas ruminantium* subsp. *lactilytica*. MacDonald and Madlener (1957) recommend the use of complex medium containing sodium lauryl sulfate (0.01%) or sodium oleate (0.15%) and sheep serum (10%). These additions suppress the growth of many micro-organisms present in gingival scrapings without affecting selenomonad growth. The complex media such as brain heart infusion agar are used for such isolations.

The OA-1 medium described by Dighe et al. (1998) seems to be a good choice for enrichment and isolation of lipid-degrading selenomonads. The medium has less protein and more edible oil. Anaerobic lipolytic bacteria therefore get better opportunity to grow in this medium.

Maintenance procedures

Cultures of *Selenomonas* can be preserved for long periods in liquid nitrogen and for 18 months in medium with 6% (w/v) glycerol at -20°C. For some strains, storage by lyophilization under anaerobic conditions is possible.

Differentiation of the genus *Selenomonas* from closely related taxa

Two major characteristics of the genus *Selenomonas*, flagellar arrangement and production of propionate from glucose fermentation are useful in differentiating the genus from many other genera of anaerobic, curved, motile, Gram-stain-negative, nonsporulating rods. *Selenomonas* possess a tuft of flagella

arranged in a closely spaced linear fashion near the middle of the concave side of the cell. Propionate is the major end product of glucose fermentation. It differs from the genus *Pectinatus* in that the latter has linearly arranged flagella that may be placed all along one side of the cell. *Selenomonas* species do not grow at 15°C, whereas *Pectinatus* grows between 15 and 40°C. *Selenomonas* species usually ferment esculin, lactose, raffinose and sucrose, whereas *Pectinatus* strains do not. Also, the mol% G+C of the DNA of *Selenomonas* is 54–61, in contrast to a value of ~40 for *Pectinatus*. The only species that has mol% G+C of the DNA similar to *Pectinatus* is *Selenomonas lipolytica*. The two genera also have markedly different cellular fatty acid profiles; C₁₂ fatty acids are absent in *Pectinatus*, and the ratios of other fatty acids are also very different in the two genera.

Miscellaneous comments

In the 16S rRNA gene sequence based phylogenetic analyses, two single species genera, *Centipeda* (Lai et al., 1983) and *Schwartzia* (van Gylswyk et al., 1997) also fall within the radiation that includes species of *Selenomonas* (Figure 218). However, these species are defined as separate genera based on low levels of DNA hybridization with members of *Selenomonas* and on other morphological and chemotaxonomic characters.

Similarly, *Selenomonas acidaminovorans* was found to be distantly placed from other members of the genus with low level of sequence similarity. In the phylogenetic analysis it formed an independent line of descent. This, together with its thermophilic nature and other metabolic properties, led to the creation of the new genus *Thermanaerovibrio*, and it is now called *Thermanaerovibrio acidaminovorans* (Baena et al., 1999).

Taxonomic comments

Current phylogenetic analyses of 16S rRNA genes of *Selenomonas* suggest that it is a member of the family *Veillonellaceae* (Ludwig et al., 2009). The detailed comparative studies of *Selenomonas sputigena* and *Selenomonas ruminantium* by Kingsley and Hoeniger (1973) indicate that these bacteria should not be placed in *Spirillum* or *Aquaspirillum* (MacDonald et al., 1959).

Differentiation of the species of the genus *Selenomonas*

Some differential features of the species of *Selenomonas* are indicated in Table 213.

Acknowledgements

This chapter is based in part on the genus *Selenomonas* chapter of the first edition of *Bergey's Manual of Systematic Bacteriology*, authored by the late Dr M.P. Bryant. The authors recognize his contributions to this manuscript. The authors also wish to acknowledge Dr M.V. Deshpande, National Chemical Laboratory, Pune, India for careful reading of the manuscript and constructive criticism.

List of species of the genus *Selenomonas*

1. ***Selenomonas sputigena*** (Flügge 1886) Boskamp 1922, 70^{AL} (*Spirillum sputigenum* Flügge 1886, 387)

spu.ti'ge.na. L. n. *sputum* spit, sputum; L. v. *gigno* to produce; N.L. fem. adj. *sputigena* sputum-produced.

Colonies on anaerobic blood agar are generally smooth, convex, grayish yellow in color, sometimes mottled, and sometimes with a more opaque center. Usually the diameter is less than 0.5 mm. Sometimes the colonies are smooth, granular, flat, grayish, and translucent with an irregular border, and up to 2 mm in diameter.

In Brewer's thioglycolate broth (Difco), growth occurs as heavy floccules and coarse granulates (MacDonald et al., 1953). In MPB broth (Kingsley and Hoeniger, 1973) growth is turbid, often with a granular sediment.

Selenomonas sputigena is a strong fermenter of certain carbohydrates. Its ability to utilize amino acids or many other potential energy sources has not been determined. It does not usually produce H₂S from cysteine, suggesting that it does not degrade cysteine.

Glucose is fermented with production of propionate and acetate (Loesche et al., 1965), and may produce some lactate and small amounts of succinate. No clear cut evidence on the ability of the strain to produce H₂ is reported.

Selenomonas sputigena appears not to be pathogenic for mice or guinea pigs. Intravenous injection into rabbits has caused some symptoms and even death in some cases but not in others (MacDonald et al., 1959). Although *Selenomonas sputigena* is found in the human gingival crevice, its relationship to the etiology of periodontal disease has not been established.

DNA G+C content (mol%): 61 (Bd).

Type strain: VPI 10068, ATCC 35185, CCUG 44933, DSM 20758, VPI D19B-28.

GenBank accession number (16S rRNA gene): AF287793, AF373026.

2. ***Selenomonas artemidis*** Moore, Johnson and Moore 1987, 279^{VP}

ar.te'mi.dis Gr. gen. n. *aretimidos* of Artemis, goddess of the moon. N.L. gen n. *artemidis* of Artemis, referring to crescent shape of the cells.

Colonies on blood agar plate after 48 h are minute to 0.5 mm, circular, entire, low convex, translucent, smooth, shiny, and colorless. Abundant growth with slight turbidity and granular to nonflaky sediment in PYG cultures, whereas slight growth is seen in PY broth. Acetate and propionate are produced in PY as well as PYG media. No ammonia is detected in either medium, but a small amount is detected in chopped meat cultures. Threonine is not converted to propionate and lactate is not utilized.

DNA G+C content (mol%): 56-59 (T_m).

Type strain: ATCC 43528, JCM 8543, VPI D22B-14.

GenBank accession number (16S rRNA gene): not reported.

3. ***Selenomonas diana*** Moore, Johnson and Moore 1987, 279^{VP}

di.a'nae. L. gen. n. *diana* of Diana, goddess of the moon, referring to crescent shape of the cells.

Colonies on rabbit blood agar plate are minute, circular, entire, convex to flat and slightly spreading, transparent, shiny, smooth, and gray-white. Strains produce excellent growth in PYG broth and granular to flaky sediments and good growth in PY broth. Acetate, propionate, pyruvate, and lactate are produced in PYG medium; acetate and propionate are produced in PY medium. No ammonia is detected in either medium, but moderate amounts are detected in chopped meat cultures. Threonine is not converted to propionate and neither lactate nor pyruvate is utilized.

DNA G+C content (mol%): 53-59 (T_m).

Type strain: ATCC 43527, JCM 8542.

GenBank accession number (16S rRNA gene): AF287801.

4. ***Selenomonas flueggei*** Moore, Johnson and Moore 1987, 274^{VP}

fluegge'i. N.L. gen. n. *flueggei* of Flügge, an early German bacteriologist.

Colonies on rabbit blood agar plate after 48 h are 0.5-1 mm in diameter, circular, entire to spreading, opaque, white, smooth, and shiny. Sometimes growth spreads over entire plate. Moderate turbidity is produced in PY broth and abundant growth with smooth sediment and clear broth is seen in PYG cultures. Acetate, lactate, and propionate are

produced in both PY and PYG media, although molar ratios in each medium could be different. No H₂ is produced. In PYG medium, fermentation products are acetate and propionate, whereas in PY medium the products are acetate, propionate, and lactate. Moderate ammonia is produced in chopped meat cultures but none in PY or PYG cultures. Threonine is not converted to propionate, and lactate is not utilized.

DNA G+C content (mol%): 54–60 (T_m).

Type strain: ATCC 43531, JCM 8544.

GenBank accession number (16S rRNA gene): AF287803.

5. **Selenomonas infelix** Moore, Johnson and Moore 1987, 277^{VP}

in.fe'lix. L. adj. *infelix* causing harm, unlucky.

Colonies on rabbit blood agar plate after 48 h are 0.5–1 mm in diameter, circular, entire, pulvinate, translucent, shiny, smooth, and white. Sometimes growth spreads as a thin film over entire plate. Moderate turbidity is produced in PY broth and abundant growth with turbidity and smooth sediment in PYG broth. Acetate and propionate are produced in PY and PYG broths with different proportions. Threonine is not converted to propionate, and lactate is not utilized. Slight ammonia production is detected in these as well as in chopped meat cultures.

DNA G+C content (mol%): 56–58 (T_m).

Type strain: ATCC 43532, JCM 8545.

GenBank accession number (16S rRNA gene): AF287802.

6. **Selenomonas lactificex** Schleifer, Leuteritz, Weiss, Ludwig, Kirchhof and Seidel-Rüfer 1990, 26^{VP}

lac.ti'ci.fex. N.L. n. *acidum lacticum* lactic acid; L. suff. *fex* a maker; N.L. n. *lactificex* a maker of lactic acid.

Colonies on modified MRS medium are smooth, opaque, circular, yellowish, and 2–3 mm in diameter after 72 h at 30°C. Glucose is fermented to acetic, lactic, and propionic acids. It is distinguished from other lactic acid-producing species by lower G + C content and its inability to utilize mannitol and dulcitol.

DNA G+C content (mol%): 51–52 (T_m).

Type strain: VB4b, ATCC 49690, DSM 20757.

GenBank accession number (16S rRNA gene): AF373024.

7. **Selenomonas lipolytica** Dighe, Shouche and Ranade 1998, 790^{VP}

li.po.ly'ti.ca. Gr. n. *lipos* fat; Gr. adj. *lutikos* dissolving; N.L. fem. adj. *lipolytica* fat-dissolving.

Acetate and propionate are the only volatile fatty acids produced after fermentation of glucose, with propionate as the major end product. The strain has strong and true lipolytic activity, with degradation zones on tributyrin, triolein, and groundnut oil in qualitative plate clearance assays. The strain utilizes glycerol but not lactate. Does not require *n*-valerate for growth in glucose.

DNA G+C content (mol%): 40 (T_m).

Type strain: CF1B, MCMB 505.

GenBank accession number (16S rRNA gene): AF001901.

8. **Selenomonas noxia** Moore, Johnson and Moore 1987, 273^{VP}
no'xia L. fem. adj. *noxia* harmful.

Colonies on rabbit blood agar plates appear after 48 h and are minute to 0.5 mm in diameter, circular, entire, low con-

vex to flat, transparent, smooth, shiny, and colorless to yellowish. Strains produce slight turbidity in Peptone Yeast extract broth but abundant growth in PYG with smooth sediment. Growth in PYG medium produces acetate and propionate and in PY medium acetate, propionate, and lactate. Pyruvate and lactate are not utilized. Trace to abundant H₂ production is observed.

DNA G+C content (mol%): 56–58 (T_m).

Type strain: ATCC 43541, JCM 8546, VPI D9B-5.

GenBank accession number (16S rRNA gene): AF287799.

9. **Selenomonas ruminantium** (Certes 1889) Wenyon 1926, 311^{AL} (*Ancyromonas ruminantium* Certes 1889, 70)

ru.mi.nan'ti.um. N.L. pl. gen. n. *ruminantium* of ruminants.

On RGCA-medium roll tubes, colonies are entire, slightly convex, translucent, lightly tan, and 2–4 mm in diameter after incubation for 3 d at 37°C; deep colonies are thin and lenticular. Growth in liquid medium is heavily turbid, often with some lightly flocculent sediments (Bryant, 1956).

All strains of the species so far studied can utilize glucose as the energy source, ammonia as the nitrogen source, and sulfide as the sulfur source. They grow very well in a chemically defined media containing these three components along with B-vitamins, *n*-valerate, and minerals (Linehan et al., 1978). Some strains require only biotin among the B-vitamins, and some strains do not require *n*-valerate. Some strains can utilize amino acids such as aspartate, histidine, serine, or cysteine as sole nitrogen sources. Cysteine can also serve as a sole sulfur source. A few strains contain urease and can utilize urea as a sole nitrogen source (John et al., 1974; Robinson et al., 1981). *Selenomonas ruminantium* subsp. *lactilytica* strains, which require *n*-valerate when grown on glucose, do not require it for growth on lactate but have added requirements for aspartate and *p*-aminobenzoate (Kanegasaki and Takahashi, 1967; Linehan et al., 1978). Nitrate is reduced to ammonia in a few strains and thus serves as a sole nitrogen source (John et al., 1974), but other strains reduce nitrate only to nitrite or do not reduce nitrate at all.

Propionate, acetate, CO₂, and lactate (L- and sometimes a mixture of D- and L-; Scheifinger et al., 1975) are major end products of glucose fermentation while small amounts of H₂ are also produced. The amount of lactate produced as compared to propionate and acetate depends on the strain, the amount of glucose in the medium and, in chemostat cultures, the growth rate (Scheifinger et al., 1975). Strains may also produce some succinate. The amount of H₂ produced is more in presence of H₂-utilizing methane-producing bacteria (Scheifinger et al., 1975).

DNA G+C content (mol%): 54 (Bd).

Type strain: ATCC 12561, DSM 2150, NADL GA-192, JCM 6583.

GenBank accession number (16S rRNA gene): M62702.

- 9a. **Selenomonas ruminantium subsp. ruminantium** Bryant 1974, 425^{AL}

The description is as for the species. Differs from the subspecies *lactilytica* by being unable to ferment lactate and glycerol.

DNA G+C content (mol%): 54 (Bd).

Type strain: ATCC 12561, DSM 2150.

GenBank accession number (16S rRNA gene): M62702.

- 9b. **Selenomonas ruminantium subsp. lactilytica** (Hungate 1966) Bryant 1956, 165^{AL}. (*Selenomonas lactilytica* Hungate 1966, 68)

lac.ti.ly'ti.ca. L. n. *lac*, *lactis* milk; Gr. adj. *lutikos* dissolving; N.L. adj. *lactilytica* milk (lactate) dissolving.

This subspecies possesses the same characteristics as the species except that lactate and glycerol are fermented. Lactate is fermented with the production of propionate,

acetate, and CO₂ (Bryant, 1956). Glycerol is fermented mainly to propionate with small amounts of lactate, succinate, and acetate (Hobson and Mann, 1961).

"O" antisera from sheep strains have been found to react with a bovine strain of the same subspecies but not with a bovine strain of the subspecies *ruminantium*, suggesting that the two subspecies may differ in "O" antigens (Hobson et al., 1962).

Type strain: ATCC 19205, DSM 2872, JCM 6582.

Other organisms

The following organisms either have no available strains or have not been obtained in pure culture.

1. "**Selenomonas ruminantium subsp. bryanti**" Prins 1971, 825 bry.an'ti. N.L. gen. n. *bryanti* of Bryant.

This subspecies possesses characteristics similar to subspecies *ruminantium* except that the cells in pure culture are larger, measuring 2.0–3.0–5.0–10.0 μm. H₂S is not produced from cysteine, and arabinose, xylose, galactose, lactose, and dulcitol are not fermented.

This subspecies was isolated using anaerobic rumen-fluid agar medium containing minerals similar to those of RGCA medium and deep agar tubes rather than roll tubes. The rumen fluid source material was differentially centrifuged to enrich the large selenomonads before culture (Prins, 1971).

No type strain has been designated and none of the originally described strains are now available.

2. "**Selenomonas palpitans**" Simons 1920, 50 pal'pi.tans. L. part. adj. *palpitans* trembling.

Simons (1920) first observed an organism similar to *Selenomonas* in the cecum of guinea pigs and it was later named *Selenomonas palpitans* (Boskamp, 1922; Simons, 1920). It has not been obtained in pure culture, however, and in a study of the cytology of the organism from guinea pig cecal contents, Kinglsey and Hoeniger (1973) found that the flagella of the tuft were bunched together in a single area rather than forming a line of insertions as is the case in *Selenomonas*. The further taxonomic status of this organism must be delayed until it is isolated in pure culture.

Genus XXII. **Sporomusa** Möller, Ossmer, Howard, Gottschalk and Hippe 1985, 224^{VP} (Effective publication: Möller, Ossmer, Howard, Gottschalk and Hippe 1984, 394.)

HAROLD L. DRAKE AND ANITA S. GÖSSNER

Spo.ro.mu'sa. Gr. fem. n. *spora* a spore; N.L. fem. n. *musa* a banana; N.L. fem. n. *Sporomusa* spore-bearing banana.

Mesophilic, **acetogenic**, **anaerobic**. Cells are **banana shaped**, flagellated on the concave side of the cell, and form **endospores** that tend to be subterminal (Figure 219). Gram-stain-negative or weakly Gram-stain-positive. Growth can occur under both **chemo-organotrophic** and **chemolithoautotrophic** conditions.

DNA G+C content (mol%): 42.0–48.6.

Type species: **Sporomusa sphaeroides** Möller, Ossmer, Howard, Gottschalk and Hippe 1985, 224^{VP} (Effective publication: Möller, Ossmer, Howard, Gottschalk and Hippe 1984, 395.)

Further descriptive information

An overview of the general characteristics of the nine different species of the genus *Sporomusa* are presented in Table 214. Species of *Sporomusa* have been obtained from a variety of habitats, including silage (Möller et al., 1984), the termite gut (Boga et al., 2003; Breznak et al., 1988), freshwater sediments (Dehning et al., 1990; Möller et al., 1984), aerated soil (Kuhner et al., 1997), and roots of the estuarine plant black needlerush (*Juncus roemerianus*) (Gössner et al., 2006b). This diverse habitat range illustrates the versatility of this spore-forming genus.

The main physiological feature that unites all species of the genus *Sporomusa* is their utilization of the acetyl-CoA "Wood-Ljungdahl" pathway (Wood and Ljungdahl, 1991) as an energy-conserving, terminal electron-accepting process (Figure 220). Reductant derived from the oxidation of a large

variety of substrates is funneled toward the reductive synthesis of acetate from CO₂. The pathway also assimilates CO₂ and thus provides sporomusal species with a mechanism for autotrophic fixation of carbon. Lithotrophy occurs via the utilization of H₂. Membranous *b*-type cytochrome(s) is typical of the genus *Sporomusa* (note: some sporomusal species have not been analyzed for cytochromes), and it is likely that energy conservation occurs via the electron transport mediated translocation of protons and the synthesis of ATP by membranous ATPases (Müller et al., 2004).

There are 21 bacterial genera in which species of acetogens have been isolated (Drake et al., 2004). *Sporomusa* is functionally a monophyletic genus in regard to the ability of all nine sporomusal species to engage the acetyl-CoA pathway. *Acetobacterium* and *Moorella* are other examples of monophyletic acetogenic genera. However, certain genera that contain acetogens also contain species that lack the acetyl-CoA pathway (e.g., *Clostridium* and *Ruminococcus*).

H₂-CO₂, formate, methanol, lactate, pyruvate, and betaine are commonly utilized substrates of sporomusal species (Table 214). Several sporomusal species have the capacity to utilize methoxyl groups of aromatic compounds and to tolerate and consume (i.e., reduce) small amounts of O₂; these properties are shared with other acetogens in other genera (Drake et al., 2004). Certain sporomusal species (e.g., *Sporomusa*

FIGURE 219. Electron micrographs of (a) *Sporomusa sphaeroides* DSM 10669. Bar = 0.5 μm. (From Kuhner et al., 1997; used with permission.) and (b) *Sporomusa rhizae* DSM 16652. Bar = 1.0 μm. (From Gössner et al., 2006b; used with permission.) Abbreviation: SP, spore.

FIGURE 220. Acetyl-CoA “Wood–Ljungdahl” pathway. Abbreviations: THF, tetrahydrofolate; CoA, coenzyme A; ATP, adenosine triphosphate; e⁻, reducing equivalent. A corrinoid enzyme mediates a transfer of the methyl unit of methyl-THF prior to the formation of acetyl-CoA. See Drake et al. (2004), for details.

acidovorans and *Sporomusa malonica*) conserve energy via the decarboxylation of dicarboxylic acids (Dehning et al., 1989). For example, the change in Gibb’s free energy from the decarboxylation of succinate to propionate is approximately -20 kJ per mol reaction, and this small amount of available energy is adequate for the growth of certain sporomusal species. The subterminal endospores typical of the genus can also be observed as free spores. One type strain (*Sporomusa paucivorans*) does not form spores. Certain species require yeast extract or a source of amino acids for growth (together with a supplemental substrate).

^aAbbreviations: +, positive; -, negative; NR, not reported.

^bProduces acetate from succinate; other species form propionate as the major succinate-derived product.

Enrichment and isolation procedures

Nine species of *Sporomusa* have been isolated to date, but a selective procedure that is specific for the enrichment of *Sporomusa* has not been reported. H₂-CO₂, methanol, betaine, dimethylglycine, and glutarate have been used in primary enrichments. Mesophilic, anoxic, near pH neutral conditions, and a source of CO₂, can be regarded as essential. For cultivation medium, see following section.

Maintenance procedures

Species of *Sporomusa* are anaerobes and must therefore be cultivated under anoxic conditions. Near pH neutral media used for the cultivation of *Sporomusa* contain minerals, trace elements, vitamins, reducing agent (e.g., sodium sulfide, cysteine, dithi-

onite, or dithiothreitol), and a source of CO₂ (e.g., bicarbonate and/or CO₂ in the gas phase); yeast extract or Casamino acids can enhance growth and are required for certain strains of *Sporomusa*. ATCC Medium 1425 [http://www.lgcpromochem-atcc.com] and DSMZ Medium 311 [http://www.dsmz.de/] are examples of *Sporomusa* media. A more detailed statement on media and cultivation methods for acetogens can be found in Drake et al., (2004).

Species of *Sporomusa* are stable to long term storage conditions under both lyophilized and liquid conditions. This stability is likely due to the durability of sporomusal endospores. For example, endospores of *Sporomusa acidovorans* survive 20 min at 80°C (Ollivier et al., 1985), and endospores of *Sporomusa rhizae* can be revived after 1 year of storage under oxic, aqueous conditions (Gössner et al. 2006).

List of species of the genus *Sporomusa*

1. ***Sporomusa sphaeroides*** Möller, Ossmer, Howard, Gottschalk and Hippe 1985, 224^{VP} (Effective publication: Möller, Ossmer, Howard, Gottschalk and Hippe 1984, 395.)

sphae.roi'des. Gr. fem. adj. *sphaeroides* spherical, referring to the shape of the endospore.

Cells are Gram-stain-negative, spore-forming, motile, curved rods, 2–4 × 0.5–0.8 μm. Growth-supportive substrates include H₂-CO₂, pyruvate, lactate, alcohols, glycerol, serine, ethyleneglycol, betaine, and other *N*-methyl compounds. Yeast extract is not required for growth. Acetate is the main reduced end product; traces of ethanol are also produced. Methylamines are formed from *N*-methyl compounds. Cultures demethylate the osmolytes dimethylsulfoniopropionate and glycine-betaine to methylthiopropionate and dimethylglycine, respectively, however, only the demethylation of glycine-betaine supports growth (Jansen and Hansen, 2001). Catalase-positive. Nitrate, sulfate, thiosulfate, and sulfite are not utilized as terminal electron acceptors. Growth is optimum at pH 6.5 (range 5.7–8.7) and 34°C (range 15–45°C). Contains membranous *b*-type cytochrome(s); might also contain a *c*-type cytochrome. The type strain (which is also the type species of the genus) was isolated from river mud; primary enrichment was on betaine (Möller et al., 1984).

DNA G+C content (mol%): 46.7.

Type strain: E, ATCC 35900, DSM 2875.

GenBank accession number (16S rRNA gene): AJ279801.

2. ***Sporomusa acidovorans*** Ollivier, Cord-Ruwisch, Lombardo and Garcia 1990, 105^{VP} (Effective publication: Ollivier, Cord-Ruwisch, Lombardo and Garcia 1985, 310.)

a.ci.do'vo.rans. L. neut. n. *acidum* acid; L. v. *vor*o to devour; N.L. part. adj. *acidovorans* acid devouring.

Cells are Gram-stain-negative, spore-forming, motile, curved rods, 2–8 × 0.7–1 μm. Growth-supportive substrates include H₂-CO₂, organic acids (e.g., fumarate and oxaloacetate), methanol, glycerol, fructose, and ribose. Yeast extract is required for growth. Acetate is the sole reduced end product. Decarboxylates succinate to propionate (Dehning et al., 1989). Nitrate, sulfate, and sulfite are not utilized as terminal electron acceptors. Growth is optimum at pH 6.5 (range 5.4–7.5) and 35°C (range 20–40°C). Type strain was isolated from a distillation

wastewater bioreactor; primary enrichment was on methanol (Ollivier et al., 1985).

DNA G+C content (mol%): 42.

Type strain: Mol, ATCC 49682, DSM 3132.

GenBank accession number (16S rRNA gene): AJ279798.

3. ***Sporomusa aerivorans*** Boga, Ludwig and Brune 2003, 1403^{VP}

ae.ri.vo'rans. L. n. *aer* air; L. pres. part. *vorans* digesting, devouring; N.L. pres. part. *aerivorans* devouring air (O₂), referring to the organism's ability to reduce O₂.

Cells are Gram-stain-variable, spore-forming, motile, curved rods, 1.3–7.0 × 0.6–0.7 μm. Growth supportive substrates include H₂-CO₂, formate, methanol, ethanol, lactate, pyruvate, mannitol, citrate, and methoxylated aromatic compounds. Yeast extract or Casamino acids are required for growth. Acetate is the main reduced end product. Tolerates and reduces small amounts of O₂; catalase-positive. Nitrate and sulfate are not utilized as terminal electron acceptors. Growth is optimum at pH 7 (range 6.2–8.2) and 30°C (range 19–35°C). Contains membranous *b*-type cytochrome(s). Type strain was isolated from the soil-feeding termite *Thoracotermes macrothorax*; primary enrichment was on H₂-CO₂ and lactate (Boga et al., 2003).

DNA G+C content (mol%): not reported.

Type strain: TmA03, ATCC BAA-625, DSM 13326.

GenBank accession number (16S rRNA gene): AJ506191.

4. ***Sporomusa malonica*** Dehning, Stieb and Schink 1990, 321^{VP} (Effective publication: Dehning, Stieb and Schink 1989, 425.)

ma.lo'ni.ca. N.L. n. *acidum malonicum* malonic acid; N.L. fem. adj. *malonica* referring to organism's ability to metabolize malonic acid.

Cells are Gram-stain-negative, spore-forming, motile, curved rods, 2.6–4.8 × 0.7 μm. Growth-supportive substrates include H₂-CO₂ and numerous organic compounds, including formate, pyruvate, alcohols, dicarboxylic acids, fructose, and trimethoxycinnamate. Yeast extract is required for growth. Acetate is the reduced end product when H₂-CO₂, formate, methanol, fructose, pyruvate, or the *O*-methyl groups of trimethoxycinnamate are metabolized. Alcohols

yield acetate and the respective fatty acids, and crotonate and 3-hydroxybutyrate yield acetate and butyrate. Dicarboxylic acids (e.g., malonate and succinate) are decarboxylated to the respective fatty acids. Growth is optimal at pH 7.3 (range 6.0–8.5) and 30°C (range 15–38°C). Contains membranous *b*-type cytochrome(s). Type strain was isolated from freshwater sediment; primary enrichment was on glutarate (Dehning et al., 1989).

DNA G+C content (mol%): 44.1.

Type strain: WoG12, ATCC 49684, DSM 5090.

GenBank accession number (16S rRNA gene): AJ279799.

5. **Sporomusa ovata** Möller, Ossmer, Howard, Gottschalk and Hippe 1985, 224^{VP} (Effective publication: Möller, Ossmer, Howard, Gottschalk and Hippe 1984, 395.)

o.va'ta. L. fem. adj. *ovata* egg shaped, referring to the shape of the endospore.

Cells are Gram-stain-negative, spore-forming, motile, curved rods, 1–5 × 0.7–1.0 µm. Growth-supportive substrates include H₂-CO₂, pyruvate, lactate, alcohols, fructose, betaine, dimethylglycine, and sarcosine. Yeast extract is not required for growth. Acetate is the main reduced end product; traces of ethanol are also produced. Methylamines are formed from *N*-methyl compounds. Reductively dechlorinates tetrachloroethylene to trichloroethylene (Terzenbach and Blaut, 1994). Cultures demethylate the osmolytes dimethylsulfoniopropionate and glycine-betaine to methylthiopropionate and dimethylglycine, respectively, however, only the demethylation of glycine-betaine supports growth (Jansen and Hansen, 2001). Catalase-positive. Nitrate and sulfate are not utilized as terminal electron acceptors. Growth is optimum at pH 6.3 (range 5.0–8.1) and 34°C (range 15–43°C). Contains membranous *b*-type cytochrome(s); might also contain a *c*-type cytochrome. Type strain was isolated from sugar beet leaf silage; primary enrichment was on dimethylglycine (Möller et al., 1984).

DNA G+C content (mol%): 42.2.

Type strain: H1, ATCC 35899, DSM 2662, HAMBI 2226.

GenBank accession number (16S rRNA gene): AJ279800.

6. **Sporomusa paucivorans** Hermann, Popoff and Sebald 1987, 97^{VP}

pau.ci.vo'rans. L. n. *pauca* a few; L. v. *voro* to devour; N.L. part. adj. *paucivorans* referring to the relatively small substrate range of the organism.

Cells are Gram-stain-negative, motile, slightly curved rods, 2–3 × 0.4–0.7 µm. This is the only species of *Sporomusa* that has not been observed to form spores. H₂-CO₂, formate, methanol, pyruvate, serine, betaine, alcohols, and ethylene glycol support growth. Yeast extract is required for growth. Acetate is the sole reduced end product. Oxidation of alcohols yields the corresponding fatty acids. Nitrate, sulfate, thiosulfate, and sulfite are not utilized as terminal electron acceptors. Grows syntrophically with *Methanobacterium formicicum* on alcohols. The type strain was isolated from lake sediment; primary enrichment was on methanol (Hermann et al., 1987).

DNA G+C content (mol%): 47.1.

Type strain: X, DSM 3697.

GenBank accession number (16S rRNA gene): not available for type strain. (M59117 is the number given by author for strain DSM 3637.)

7. **Sporomusa rhizae** Gössner, Küsel, Schulz, Trenz, Acker, Lovell and Drake 2006a, 1460^{VP} (Effective publication: Gössner, Küsel, Schulz, Trenz, Acker, Lovell and Drake 2006, 1217.)

rhi'zae. N.L. gen. fem. n. *rhizae* (from Gr. fem. n. *rhiza* root) of the root; to indicate a spore-forming banana (per epithet of *Sporomusa*) from roots (the origin of the type strain).

Cells are weakly Gram-stain-positive, spore-forming, motile, curved rods. Cells mean 3.5 × 0.8 µm. Growth supportive substrates include H₂-CO₂, formate, lactate, vanillate, syringate, citrate, *N*-acetylglucosamine, and betaine. Acetate is the primary reduced end product; traces of butyrate, iso-butyrate, and propionate are also formed. Tolerates and reduces small amounts of O₂; spores withstand oxic aqueous conditions for 1 year. Peroxidase and NADH oxidase-positive. Growth is optimum at pH 7.5 (range 5.5–9.0) and 35°C (range 15–40°C). Contains membranous *b*-type cytochrome(s). Grows by trophic interaction with the aerotolerant fermentative anaerobe *Clostridium intestinale* RC (fortuitously co-isolated with the type strain). The type strain was isolated from a root homogenate prepared from the black needlerush *Juncus roemerianus* obtained from a pristine salt marsh; primary enrichment was on H₂-CO₂ (Gössner et al., 2006b).

DNA G+C content (mol%): not reported.

Type strain: RS, ATCC BAA-1028, DSM 16652.

GenBank accession number (16S rRNA gene): AM158322.

8. **Sporomusa silvacetica** Kuhner, Frank, Griesshammer, Schmittroth, Acker, Gössner and Drake 1997, 357^{VP}

sil.va.ce'ti.ca. L. n. *silva* forest; L. fem. adj. *acetica* pertaining to vinegar, acetic acid; N.L. fem. adj. *silvacetica* a forest organism producing acetic acid.

Cells are weakly Gram-stain-positive, spore-forming, motile, slightly curved rods. Mean cell dimensions are 3.5 × 0.7 µm. Growth-supportive substrates include H₂-CO₂, formate, methanol, pyruvate, vanillate, ferulate, fructose, betaine, fumarate, 2,3-butanediol, ethanol, lactate, and glycerol. Yeast extract and sodium are not required for growth. With most substrates, acetate is the main reduced end product. Traces of methane are produced under certain conditions. Nitrate and sulfate are not utilized as terminal electron acceptors. Tolerates and reduces small amounts of O₂ (Drake et al., 2002; Karnholz et al., 2002). Fumarate is dismutated to acetate and succinate. The acrylate side chain of ferulate is reduced. Growth is optimum at pH 7.2 (range 5.9–7.7) and 30°C (range 10–35°C). Contains membranous *b*-type cytochrome(s); might also contain a cytoplasmic *c*-type cytochrome. The type strain was isolated from forest soil; primary enrichment was on H₂-CO₂ (Kuhner et al., 1997). Strain DR5, phylogenetically closely related to the type strain, was isolated from flooded rice paddy soil and enriched on trimethoxybenzoate (Rosencrantz et al., 1999).

DNA G+C content (mol%): 42.7.

Type strain: DG-1, ATCC 700346, DSM 10669.

GenBank accession number (16S rRNA gene): Y09976.

9. **Sporomusa termitida** Breznak, Switzer and Seitz 1990, 212^{VP} (Effective publication: Breznak, Switzer and Seitz 1988, 287.)

ter.mi'ti.da. L. n. *tarmes*, *tarmit* (L.L. var. *termes*, *termit*) worm that eats wood; N.L. adj. *termitida* referring to termites, from whose intestinal tract the type strain was isolated.

Cells of *Sporomusa termitida* are Gram-stain-negative, spore-forming, motile, straight to slightly curved rods, 2–8 × 0.5–0.8 µm. Substrates include H₂-CO₂, CO, formate, methanol, ethanol, betaine, sarcosine, lactate, pyruvate, oxaloacetate, citrate, malonate, succinate, mannitol, and trimethoxybenzoate. Yeast extract or Casamino acids is required for growth. Acetate is the main reduced end product. Catalase-positive. Decarboxylates succinate to propionate. Nitrate and sulfate are not utilized as termi-

nal electron acceptors. Growth is optimal at pH 7.2 (no growth at 6.2 or 8.1) and 30°C (range 19–37°C). Contains membranous *b*-type cytochrome(s). The type strain was isolated from the gut of the wood-feeding termite *Nasutitermes nigriceps*; primary enrichment was on H₂-CO₂ (Breznak et al., 1988).

DNA G+C content (mol%): 48.6.

Type strain: JSN-2, ATCC 49683, DSM 4440.

GenBank accession number (16S rRNA gene): M61920.

Genus XXIII. *Succiniclasticum* van Gylswyk 1995, 298^{VP}

FRED A. RAINEY

Suc.cin.i.clas'ti.cum. N.L. n. *acidum succinicum* succinic acid; Gr. adj. *klastos* broken; N.L. adj. *clasticum* breaking; N.L. neut. n. *Succiniclasticum* breaking or splitting succinic acid.

Gram-stain-negative. Anaerobic. Nonmotile. Non-spore-forming, rod-shaped, branching cells. Mesophilic. Ferments succinate to propionate. Other carbohydrates, amino acids, or mono-, di-, and other tricarboxylic acids are not fermented. Non-protolytic, catalase- and urease-negative. Nitrate not reduced.

DNA G+C content (mol%): 52.0 (UV).

Type species: *Succiniclasticum ruminis* van Gylswyk 1995, 299^{VP}.

Further descriptive information

The description of the genus *Succiniclasticum* and the single species *Succiniclasticum ruminis* is based on the properties of a single strain SE10^T (DSM 9236^T). The cells are short, Gram-stain-negative, nonmotile rods and do not produce spores. Cells are up to 1.8 µm in length and 0.3–0.5 µm in diameter. Thicker rods tend to have rounded ends, while the narrower ones often have tapered ends and can be slightly curved. Cells form large clumps in liquid culture or in the liquid of agar slants.

On succinate agar, the colonies grow up to 5 mm in diameter, are practically colorless, convex, irregularly round with smooth edges and slightly opaque with a glistening appearance. Colonies are lens-shaped discs when growing below the agar surface.

Of the substrates tested, succinate is the only one fermented by strain SE10^T. Growth is slower with 40 mM succinate and 10 mM fumarate than with succinate alone although the same maximum optical density can be obtained. Increasing the amount of fumarate to 40 mM greatly reduces the amount of growth. The omission of either rumen fluid or yeast extract, results in very little growth. Increasing the amount of succinate in the culture medium reduces the growth rate but results in an increase in final biomass. Succinate is decarboxylated to produce propionate with no other end products detected although it is assumed that CO₂ is released. Growth in medium without CO₂ and NaHCO₃ is less than when these are available and the medium is highly buffered. A reducing agent is not required to obtain good growth if the medium is prepared under anaerobic conditions. If air is added to the headspace, growth is not good if the medium has not been reduced using a reducing agent.

Enrichment and isolation procedures

All media are prepared under strictly anoxic conditions and the head space gas has O₂-free CO₂. The basal medium used for the isolation of *Succiniclasticum* contains (per liter) 0.225 g of K₂HPO₄, 0.225 g of KH₂PO₄, 0.45 g of NaCl, 0.45 g of (NH₄)₂SO₄,

0.045 g of CaCl₂ (anhydrous), 0.09 g of MgSO₄·7H₂O, 6.36 g of NaHCO₃, 0.25 g of cysteine hydrochloride-H₂O, 0.25 g of Na₂S (hydrated), 0.005 g of indigo carmine, and 400 ml of clarified rumen fluid. Diluent contains the same ingredients except that rumen fluid and sulfide are omitted and the concentration of cysteine is increased to 0.5 g/l. For enrichment cultures, basal media with 20 mM succinate is used. Samples of whole rumen ingesta (obtained from lactating, rumen-fistulated cows) are serially diluted and an aliquot of the 10⁸ dilution added to 5 ml of enrichment medium and incubated at 39°C. After 1–4 d of incubation, aliquots of the enrichment culture are diluted and added to roll bottles containing succinate agar. Colonies that have grown after 10 d incubation are restreaked and their growth in liquid succinate medium tested.

Taxonomic comments

The description of the genus *Succiniclasticum* is based on its phylogenetic position as well as its inability to utilize substrates other than succinate. Comparisons based on 16S rRNA gene sequences show strain SE10^T to group in a cluster with the species *Phascolarctobacterium*, *Acidaminococcus*, and *Succinispira* (see family Veillonellaceae tree Figure 199). The similarities of the 16S rRNA gene sequences of the species of these genera to that of strain SE10^T are in the range 89.4–91.9%. The highest similarity is between the 16S rRNA gene sequences of strain SE10^T and *Phascolarctobacterium faecium*. The cluster comprising *Succiniclasticum ruminis*, *Phascolarctobacterium faecium*, *Acidaminococcus fermentans* and *Succinispira mobilis* is supported by a 99% bootstrap value. In addition to the low 16S rRNA gene sequence similarities between strain SE10^T and these related taxa differences in cell shape, mol% G+C content of the DNA and substrate utilization patterns differentiate *Succiniclasticum ruminis* from related taxa. *Succiniclasticum ruminis* forms short rods with limited branching while the cells of *Phascolarctobacterium faecium* are pleomorphic, *Acidaminococcus fermentans* are cocci, and *Succinispira mobilis* are curved rods. The mol% G+C of the DNA of *Succiniclasticum ruminis* is 52 compared to 41–42 for *Phascolarctobacterium faecium*, 56 for *Acidaminococcus fermentans*, and 36 for *Succinispira mobilis*. *Succiniclasticum ruminis* and *Succinispira mobilis* but not *Acidaminococcus fermentans* utilize succinate, and in *Phascolarctobacterium faecium* succinate only stimulates growth. In addition, amino acids support growth of *Acidaminococcus fermentans* and *Succinispira mobilis* but not *Succiniclasticum ruminis*; this characteristic was not determined for *Phascolarctobacterium faecium*.

List of species of the genus *Succiniclasticum*1. *Succiniclasticum ruminis* van Gylswyk 1995, 299^{VP}

ru'mi.nis. L. neut. gen. n. *ruminis* of the rumen.

Cells are short, Gram-stain-negative, nonmotile rods. Spores are not produced. Cells are up to 1.8 µm in length and 0.3–0.5 µm in diameter. Colonies are up to 5 mm in diameter on succinate agar slopes; irregularly round with smooth edges, convex, practically colorless, and slightly opaque with a glistening appearance. Subsurface colonies are lens-shaped discs. The maximum optical density is obtained at 39°C, with half as much growth at 45°C and no growth at 22°C. Succinate is the only substrate tested that is fermented. Rumen fluid and yeast extract are required for good growth. The end product of growth on succinate is propionate. Glucose, galactose, mannose, rhamnose, fructose, xylose, arabinose, maltose, cellobiose, lactose, sucrose,

trehalose, mannitol, glycerol, aspartic acid, the sodium salts of DL-lactic and pyruvic acids, the disodium salts of oxalic, malonic, oxaloacetic, malic, fumaric, glutaric, and methylmalonic acids, the trisodium salts of citric and *trans*-aconitic acids, and yeast extract (which contains amino acids) do not support growth. Prolonged incubation (9 d) with fumarate, malate, aspartate, citrate, or *trans*-aconitate does not induce utilization. Tween 80 has no effect on growth. Non-protolytic, does not liquefy gelatin or hydrolyze casein, H₂S is not produced. Catalase and urease are negative. Nitrate is not reduced. Type strain was isolated from rumen ingesta of a dairy cow.

DNA G+C content (mol%): 52.0 (UV).

Type strain: SE10, DSM 9236.

GenBank accession number (16S rRNA gene): X81137.

Genus XXIV. *Succinispira* Janssen and O'Farrell 1999, 1012^{VP}

PETER H. JANSSEN

Suc.ci.ni.spi'ra. L. n. *succinum* amber; N.L. n. *acidum succinicum* succinic acid (derived from amber); Gr. n. *spira* coil, spiral; N.L. fem. n. *Succinispira* succinate (utilizing) spiral (shaped bacterium).

Curved rods, 0.5 µm in diameter and 2–10 µm long. Longer cells can be spirals of up to 3 or 4 turns with an amplitude of 1.5–2.0 µm, and a wavelength of 3–4 µm. Gram-stain-negative. Aminopeptidase-negative. Cell-wall structure appears to be of a Gram-negative type with an outer membrane. **Highly motile** with laterally inserted flagella. Cytochromes are not formed. **No endospores**. Strict anaerobe; media containing a suitable reductant are required for growth. Chemo-organotrophic metabolism. **Organic and amino acids are fermented**, while carbohydrates and alcohols are not. **Formate, acetate, propionate, malate, CO₂, and H₂ are the fermentation end products**, depending on the substrate. Sulfate, sulfur, thiosulfate, nitrate, and fumarate are not used as terminal electron acceptors.

DNA G+C content (mol%): 36.

Type species: *Succinispira mobilis* Janssen and O'Farrell 1999, 1012^{VP}.

Enrichment and isolation procedures

Janssen (1990) enriched a mixed culture using an anaerobic freshwater medium with sulfide and cysteine as reductants and glycolate and yeast extract as growth substrates. *Succinispira mobilis* was isolated from this mixed culture after transferring it to a similar medium with citrate and yeast extract (Janssen, 1991). A pure culture of *Succinispira mobilis* was obtained from the mixed culture using agar deep culture under anaerobic conditions to

yield well-separated colonies, which were then removed from the agar using sterile, drawn out glass Pasteur pipettes. Pure cultures grew in the citrate-yeast extract medium within 24 h of inoculation after incubation at 34°C. Media containing a suitable reductant are required for growth. At this time, there is no known selective medium for *Succinispira* strains. There are a number of physiologically similar anaerobes, some within the family *Veillonellaceae*, and others with as-yet unknown phylogenetic affiliations, making selective enrichment difficult.

Maintenance procedures

Cultures of *Succinispira* can be stored for at least one year at 4°C in anaerobic media in sealed bottles or tubes either completely filled or under a nitrogen plus carbon dioxide headspace. Lyophilized cultures have been stored for a number of years without loss of viability.

Taxonomic comments

The genus is represented by only one isolate from a pond receiving effluent from an anaerobic solids digester. This means that the assignment of characteristics to the generic and specific descriptions is somewhat arbitrary. To date, no closely related 16S rRNA genes have been reported in the published literature, and so no information on the distribution of members of this genus is available.

List of species of the genus *Succinispira*1. *Succinispira mobilis* Janssen and O'Farrell 1999, 1012^{VP}

mo'bi.lis. L. adj. *mobilis* movable, motile.

The cells of this species are curved rods, 0.5 µm in diameter and 2–10 µm long. Longer cells can be spirals of up to 3 or 4 turns with an amplitude of 1.5–2.0 µm, and a wavelength of 3–4 µm. The cells are highly motile with 4 laterally inserted flagella. Cytochromes are not formed. Colonies in agar-deep cultures are white and lens shaped. Liquid cultures grow with

a uniform turbidity. The species displays a chemo-organotrophic metabolism and probably uses a decarboxylase-driven transmembrane sodium gradient for part of its ATP synthesis. Pyruvate, citrate, oxaloacetate, malate, succinate, fumarate, glutamate, and aspartate are fermented, while carbohydrates and alcohols are not. Formate, acetate, propionate, malate, CO₂, and H₂ are the fermentation end products, depending on the substrate. Hydrogenase activity is present. Sulfate, sul-

fur, thiosulfate, nitrate, and fumarate are not used as terminal electron acceptors. No esculin hydrolysis, urea hydrolysis, indole formation from L-tryptophan, or sulfide formation from L-cysteine. Growth factors are required and can be supplied by the addition of yeast extract. The range of pH for growth is 6.7–8.5, with an optimum of 7.4–7.7. The optimum

growth temperature is 37°C. No growth is possible at 40°C. NaCl at 0.2 g/l is sufficient for growth. Growth is possible at 19 g NaCl per liter, but not at 24 g/l.

DNA G+C content (mol %): 36 (T_m).

Type strain: 19gly1 (= DSM 6222).

GenBank accession number (16S rRNA gene): AJ006980.

Genus XXV. **Thermosinus** Sokolova, González, Kostrikina, Chernyh, Slepova, Bonch-Osmolovskaya and Robb 2004, 2357^{VP}

TATYANA G. SOKOLOVA

Ther.mo.sin'us. Gr. adj. *thermos* hot; L. masc. n. *sinus* bend; N.L. masc. n. *Thermosinus* thermophilic curved rod.

Cells are **motile, curved rods** that do not form spores. Cell wall is **Gram-negative type**. Divides by binary transverse fission. **Obligate anaerobe**. **Thermophilic** neutrophile that ferments carbohydrates. **Grows chemolithotrophically on CO with the formation of equimolar amounts of H₂ and CO₂**. Found in terrestrial hot springs.

DNA G+C content (mol %): 51.7.

Type species: **Thermosinus carboxydivorans** Sokolova, González, Kostrikina, Chernyh, Slepova, Bonch-Osmolovskaya and Robb 2004, 2358^{VP}.

Further descriptive information

Cells are curved rods of about 0.5 µm by 2.6–3 µm. Motile by means of lateral flagella. Thermophilic; it grows in the temperature range 40–68°C, with optimum growth at 60°C. Neutrophilic; it grows in the pH range 6.5–7.6, with optimum growth at pH 6.8–7.0. Grows on glucose, sucrose, lactose, arabinose, maltose, fructose, xylose, and pyruvate, but not on cellobiose, galactose, peptone, yeast extract, lactate, acetate, formate, ethanol, methanol, or sodium citrate. During glucose fermentation, acetate, H₂, and CO₂ are produced. Grows chemolithotrophically on CO with the formation of equimolar amounts of H₂ and CO₂. During growth on CO, sucrose or lactose, ferric iron is reduced. Reduces selenite to elemental selenium during growth on CO. Neither ferric iron nor selenite cause a significant shift in the ratio of H₂ and CO₂ produced. Elemental sulfur, thiosulfate, sulfate, and nitrate do not stimulate growth during growth on CO and are not reduced. However, thiosulfate enhances the growth rate and cell yield during growth on glucose, sucrose, or lactose; in this case, the fermentation products are acetate, H₂S, and CO₂. Lactate, acetate, formate, and H₂ are not utilized, either in the absence or presence of ferric iron, thiosulfate, sulfate, sulfite, elemental sulfur, or nitrate. Growth is completely inhibited by penicillin, ampicillin, streptomycin, kanamycin, and neomycin.

Enrichment and isolation procedures

The only representative of the genus *Thermosinus*, *Thermosinus carboxydivorans* Nor1^T, was isolated from a sample

of mud and water from a small hot pool in a wooded part of Norris Basin at Yellowstone National Park. The sample temperature and pH were 50°C and 7.5, respectively. The enrichment medium was prepared anaerobically and contained yeast extract (0.5 g/l) and ferric citrate or amorphous ferric oxide under a 100% CO atmosphere (Sokolova et al., 2004). After incubation at 60°C, growth of curved rod-shaped cells was observed accompanied by ferrous iron formation and CO oxidation to equimolar amounts of CO₂ and H₂. After several passages by serial 10-fold dilutions, the culture was transferred to a similar medium without ferric citrate or amorphous ferric oxide. After several passages by serial 10-fold dilutions in this new medium, colonies were obtained on the same medium solidified with 5% agar in roll-tubes under 100% CO (Sokolova et al., 2004). A pure culture was isolated from a single colony.

Maintenance procedures

The type strain is maintained on medium supplemented with ferric citrate under 100% CO (Sokolova et al., 2004). Liquid cultures may be stored at 4°C for 8–10 months without loss of viability. Good recovery is also obtained following vacuum drying by the DSMZ, Braunschweig, Germany.

Taxonomic comments

On the basis of 16S rRNA sequence analyses and the Gram-negative nature of the cell wall, the genus *Thermosinus* was originally placed within the so-called *Sporomusa–Selenomonas* group (Sokolova et al., 2004). Currently, members of this group have been reclassified in the family *Veillonellaceae*, which was created within the class *Clostridia* to contain species possessing Gram-negative cell-wall structures but phylogenetically related to *Firmicutes* (see Ludwig et al., 2009). Within this family, the closest relatives of *Thermosinus* are *Propionispora hippei* and *Propionispora vibrioides* (91% 16S rRNA gene sequence similarity). *Thermosinus* is the only genus within this family that has been shown to oxidize CO.

List of species of the genus *Thermosinus*

1. **Thermosinus carboxydivorans** Sokolova, González, Kostrikina, Chernyh, Slepova, Bonch-Osmolovskaya and Robb 2004, 2358^{VP}

car.bo.xy.di.vo'rans. N.L. n. *carboxydum* carbon monoxide; L. part. adj. *vorans* devouring, digesting; N.L. part. adj. *carboxydivorans* digesting carbon monoxide.

Has the characteristics of the genus. Grows chemolithotrophically on CO with the formation of equimolar amounts of H₂ and CO₂. The type strain was isolated from a hot pool with neutral pH at Norris Basin, Yellowstone National Park, USA.

DNA G+C content (mol %): 51.7±1 (T_m).

Type strain: Nor1, DSM 14886, VKM B-2281.

GenBank accession number (16S rRNA gene): AY519200.

Genus XXVI. *Zymophilus* Schleifer, Leuteritz, Weiss, Ludwig, Kirchhof and Seidel-Rüfer 1990, 26^{VP}

KARL-HEINZ SCHLEIFER

Zy.mo'phi.us. Gr. n. *zyme* leaven, yeast; Gr. adj. *philos* lover; N.L. masc. n. *Zymophilus* yeast-lover.

Slightly curved, helical, or crescent-shaped **rods** (0.7–1.0 × 3–30 µm) with rounded ends, occurring singly, in pairs, or in short chains. Gram-stain-negative. Motile. Mobility can be lost after several subcultivations. Nonspore-forming. **Strictly anaerobic**. Chemo-organotrophic, fermentative metabolism. **Glucose is fermented to acetic and propionic acids. Acetoin is not produced.** Occur in pitching yeast or brewery waste. The peptidoglycan type is directly cross-linked *meso*-diaminopimelic acid (variation A1γ; Schleifer and Kandler, 1972). Diamines cadaverine and rarely putrescine are found as characteristic components of peptidoglycan. Lipid F is found as characteristic cellular compound. Phylogenetically a member of the family *Veillonellaceae* (low G+C Gram-stain-positives with a Gram-negative cell-wall type). The closest phylogenetic neighbors are *Pectinatus*, *Megasphaera*, and *Selenomonas*.

DNA G+C content (mol%): 38–41 (T_m).

Type species: Zymomonas raffinosivorans Schleifer, Leuteritz, Weiss, Ludwig, Kirchhof and Seidel-Rüfer 1990, 26^{VP}.

Further taxonomic information

Phylogenetic analysis of 16S rDNA indicates that *Zymophilus paucivorans* is equally related to *Pectinatus cerevisiophilus*, *Pectinatus frisingensis*, and *Selenomonas lactificex* with 88% similarity (Willems and Collins, 1995a). An unrooted phylogenetic tree of members of the family *Veillonellaceae* based on 16S rRNA gene sequences is shown in Figure 199. There is a very close phylogenetic relationship between *Zymophilus paucivorans* and *Propionispira arboris*. The latter organism is an obligately anaerobic, Gram-stain-negative bacterium with a G+C content (36–37 mol%) similar to that of members of the genus *Zymophilus*. It forms long spiral filaments and can fix nitrogen. It ferments lactate and a variety of saccharides to propionate, acetate, and CO₂ as major end products. It has been isolated from alkaline wetwoods of poplar trees as described by Schink et al. (1982). Based on their close phylogenetic relatedness and their similar fermentation products, the two genera may be combined in one genus.

Comparative DNA sequence analysis of long 16S–23S intergenic spacer regions showed that two *Zymophilus* species are more closely related to each other (77% similarity) than to *Pectinatus* spp. and *Selenomonas lactificex* (40.3%; Motoyama and Ogata, 2000a). A comparison of the shorter 16S–23S intergenic spacer regions indicates an even higher relationship among the two *Zymophilus* species (96.7% similarity) and a slightly closer relationship to *Selenomonas lactificex* (45%) than to the *Pectinatus* spp. (39.3%; Motoyama and Ogata, 2000a). *Zymophilus raffinosivorans* and *Selenomonas lactificex* as well as the *Pectinatus* spp. contained two tRNA genes (alanine, isoleucine) within the longer spacer, whereas *Zymophilus paucivorans* contained only the alanine tRNA gene (Motoyama and Ogata, 2000a).

Strictly anaerobic Gram-stain-negative rods were isolated from pitching yeast and brewery waste and described as a new genus comprising the two species *Zymophilus raffinosivorans* and *Zymophilus paucivorans* (Schleifer et al., 1990).

Isolation, cultivation, and maintenance procedures

Strictly anaerobic conditions are required for the isolation and cultivation of *Zymophilus* species. Modified MRS (de Man–Rogosa–Sharpe) and MRS medium at 30°C have been used (Schleifer et al., 1990; Ziola et al., 1999). Working cultures can be maintained by subculturing (30°C, 2–3 d) in peptone yeast extract fructose broth (0.5% peptone, 0.5% tryptone, 1% yeast extract, 0.5% fructose, 0.2% Na₂HPO₄, 0.15 Tween 80, and 0.05% cysteine hydrochloride). After incubation, the cultures should be stored at 4°C in anaerobic jars. However, the cultures should be stored in the refrigerator no longer than 14 d because the cultures are no longer viable after four weeks of storage (Haikara, 1991; Seidel-Rüfer, 1990).

For long-term preservation, conventional freeze-drying methods using 20% skim milk as a protective agent and freezing in drinking straws in a –150°C deep freezer or in liquid nitrogen at –196°C using 5% dimethyl sulfoxide as a protective agent have been used (Suihko and Haikara, 1990).

Differentiation of the genus *Zymophilus* from other anaerobic, Gram-stain-negative, rod-shaped bacteria

Zymophilus morphologically resembles other anaerobic, Gram-stain-negative, rod-shaped bacteria isolated from breweries. Most of them were initially classified as *Pectinatus*. However, detailed chemotaxonomic and molecular taxonomic studies have indicated that these bacteria can be divided into three genera: *Pectinatus*, *Selenomonas*, and *Zymophilus* (Schleifer et al., 1990). They also differ in terms of their beer spoilage ability. Strains of *Pectinatus* are typical beer spoilage organisms, whereas *Selenomonas* and *Zymophilus* grow poorly in beer (Haikara, 1989, 1991). The G+C contents of the DNAs of *Pectinatus* and *Zymophilus* species are rather similar (38–41 mol%), whereas that of *Selenomonas lactificex* is significantly higher (51–52 mol%; Schleifer et al., 1990). All of them contain the directly cross-linked *meso*-diaminopimelic acid peptidoglycan type as well as cadaverine (or, rarely, putrescine) as typical substituents of the α-carboxyl group of D-glutamic acid in the peptidoglycan (Schleifer et al., 1990). Such a peptidoglycan type containing diamine-substituted glutamic acid was also found in strains of *Megasphaera*, other *Selenomonas* species, and *Sporomusa* (Engelmann and Weiss, 1985; Kamio et al., 1981a). Neither menaquinones nor ubiquinones were detected. However, as in *Megasphaera*, *Pectinatus*, *Selenomonas*, and *Sporomusa*, lipid F (Stackebrandt et al., 1985) was also detected in *Zymophilus*.

Zymophilus and *Pectinatus* species produce acetic and propionic acids as major fermentation products from glucose, but, in contrast to *Pectinatus* species, *Zymophilus* species are not able to produce acetoin. The major fermentation product of *Selenomonas lactificex* is lactic acid. *Zymophilus* species can also be distinguished from *Pectinatus* species by their ability to ferment maltose and sucrose. Major differences between *Zymophilus* and other similar genera are summarized in Table 215.

TABLE 215. Characteristics differentiating *Zymophilus* from other related taxa^a

Characteristic	<i>Zymophilus</i>	<i>Pectinatus</i>	<i>Propionispira</i>	<i>Selenomonas</i>
Acetoin production	-	+	ND	ND
<i>Acid produced from:</i>				
Maltose	+	-	ND	+
Sucrose	+	-	ND	+
Lactic acid as major fermentation product	-	-	-	- or +
DNA G+C content (mol%)	38–41	38–41	36–37	48–58
Nitrogen fixation	ND	ND	+	ND

^aSymbols: +, >85% positive; -, 0–15% positive; ND, not determined.

Differentiation of the species of the genus *Zymophilus*

The two species are morphologically quite different. Cells of *Zymophilus paucivorans* are curved, helical, or crescent-shaped, motile, Gram-stain-negative rods with rounded ends. Motility can disappear in some strains after several subcultivations. They are 0.8–1.0 × 5–30 μm and occur singly, in pairs, or in short chains. Colonies on modified MRS agar medium are circular, smooth, opaque, slightly yellow, and 1–2 mm in diameter after 3 d at 30 °C.

Zymophilus raffinosivorans cells are straight to slightly curved, motile Gram-stain-negative rods (0.7–0.9 × 3–15 μm in size)

TABLE 216. Characteristics differentiating *Zymophilus raffinosivorans* and *Zymophilus paucivorans*^a

Characteristic	<i>Z. raffinosivorans</i>	<i>Z. paucivorans</i>
<i>Acid produced from:</i>		
Dulcitol	+	-
Inositol	+	-
Lactose	+	-
Melibiose	+	-
Raffinose	+	-
Rhamnose	+	-
Xylitol	+	-
Xylose	+	-

^aSymbols: +, >85% positive; -, 0–15% positive.

with rounded ends. They occur predominantly singly and sometimes in pairs or short chains. Colonies on modified MRS agar resemble those of *Zymophilus paucivorans*.

The two species also differ in the utilization of carbohydrates (Table 216). In contrast to *Zymophilus paucivorans*, *Zymophilus raffinosivorans* can utilize the following carbohydrates: dulcitol, inositol, lactose, melibiose, *N*-acetylglucosamine, raffinose, and xylose. All strains of the two species produced acid from cellobiose, fructose, glucose, maltose, mannitol, mannose, ribose, and sucrose. None of the strains utilized glycogen, inulin, melizitose, or trehalose.

List of species of the genus *Zymophilus*

1. *Zymophilus raffinosivorans* Schleifer, Leuteritz, Weiss, Ludwig, Kirchhof and Seidel-Rüfer 1990, 26^{VP}

raf.fi.no.si'vo.rans. N.L. n. *raffinosum* raffinose; L. v. vorare to eat; N.L. part. adj. *raffinosivorans* raffinose- devouring.

The description is based on ten strains isolated from pitching yeast and four strains isolated from brewery waste.

Straight to slightly curved rods, 0.7–0.9 × 3–15 μm, with rounded ends. Occur predominantly singly or sometimes in pairs or short chains. Gram-stain-negative. Endospores not formed. Motile. Colonies on modified MRS agar medium are circular, smooth, opaque, slightly yellow, and 1–2 mm in diameter after 3 d at 30 °C. Optimum temperature for growth is 30 °C. Strictly anaerobic. Fermentative metabolism. Glucose is fermented to acetic and propionic acids. Acid is produced from arabinose, cellobiose, dulcitol, fructose, galactose, glucose, lactose, maltose, mannitol, mannose, sorbitol, sucrose, xylitol, and xylose. Most of the strains produce acid from adonitol, inositol, melibiose, raffinose, rhamnose, and salicin. No acid is produced from inulin, glycogen, melezitose, starch (with one exception), and trehalose.

The peptidoglycan type is directly cross-linked *meso*-diaminopimelic acid. Cadaverine and, rarely, putrescine are linked to the α-carboxyl group of D-glutamic acid in the peptidoglycan. Lipid F is also found as a characteristic compound.

DNA G+C content (mol%): 38–41 (T_m).

Type strain: SH2, ATCC 49691, DSM 20765.

GenBank accession number (16S rRNA gene): DQ217599.

2. *Zymophilus paucivorans* Schleifer, Leuteritz, Weiss, Ludwig, Kirchhof and Seidel-Rüfer 1990, 27^{VP}

pau.ci'vo.rans. L. adj. *paucus* little; L. v. vorare to eat; N.L. adj. *paucivorans* utilizing relatively few carbohydrates.

The description is based on four strains that were isolated from pitching yeast.

Curved or helically shaped rods, 0.8–1.0 × 5–30 μm, with rounded ends. Occur singly, in pairs, or in short chains. Gram-stain-negative. Endospores not formed. Motile. In two of the strains, motility disappeared after several subcultivations. Colonies on modified MRS agar medium are circular, smooth, slightly yellow, and 1–2 mm in diameter after 3 d at 30 °C. Strictly anaerobic. Fermentative metabolism. Glucose is fermented to acetic and propionic acids and trace amounts of lactic acid. Acid is produced from cellobiose, fructose, glucose, maltose, mannitol, mannose, ribose, and sucrose. Most strains produce acid from arabinose. One strain produced acid from adonitol, glycerol (weak), rhamnose, and xylitol. No acid was produced from amygdalin, dulcitol, erythritol, glycogen, inositol, inulin, melezitose, melibiose, raffinose, starch, trehalose, and xylose. Same peptidoglycan type and substitution as *Zymophilus raffinosivorans*. Lipid F is present.

DNA G+C content (mol%): 39–41 (T_m).

Type strain: AA1, ATCC 49689, DSM 20756.

GenBank accession number (16S rRNA gene): AF373025.

Family XI. Incertae Sedis

Previously assigned to the “*Peptostreptococaceae*” by Garrity et al. (2005), subsequent analyses suggest that these genera, while closely related to each other, are not closely related to *Peptostrep-*

tococcus or a member of any other previously described family. Until their taxonomic status has been clarified, they are classified within a family *incertae sedis*.

Genus I. *Anaerococcus* Ezaki, Kawamura, Li, Li, Zhao and Shu 2001b, 1526^{VP}

TAKAYUKI EZAKI AND KIYOFUMI OHKUSU

An.ae.ro.coc'cus. Gr. prep. *an* without; Gr. n. *aer* air; Gr. masc. n. *kokkos* berry, coccus; N.L. masc. n. *Anaerococcus* anaerobic coccus.

Cocci, occurring in pairs, tetrads, irregular masses or chains. Gram-stain-positive. Nonmotile. Nonsporeforming. Strictly anaerobic. Metabolize peptones and amino acids; the major metabolic end products are butyric acid, lactic acid and small amounts of propionic and succinic acids. Most species are able to ferment several carbohydrates, but are weakly fermentative. Glucose, fructose, sucrose and lactose are major sugars fermented. Most species do not produce indole. The position 1, position 3, and interpeptide bridge of peptidoglycan are gly-

cine or alanine, L-lysine, and D-glutamic acid or D-aspartic acid. Major cellular fatty acid are C_{18:1}, C_{16:1}, C₁₈, and C₁₆ (Ezaki et al., 1983; O'Leary and Wilkinson, 1988). Members of the genus are typically isolated from the human vagina and various purulent secretions.

DNA G+C content (mol%): 30–35.

Type species: *Anaerococcus prevotii* (Foubert and Douglas 1948) Ezaki, Kawamura, Li, Li, Zhao and Shu 2001b, 1526^{VP}.

List of species of the genus *Anaerococcus*

1. *Anaerococcus prevotii* (Foubert and Douglas 1948) Ezaki, Kawamura, Li, Li, Zhao and Shu 2001b, 1526^{VP} (*Peptostreptococcus prevotii* Foubert and Douglas 1948, Ezaki, Yamamoto, Ninomiya, Suzuki and Yabuuchi 1983, 693; *Peptococcus prevotii* Foubert and Douglas 1948, Douglas, 1957, 477^{AL}; *Micrococcus prevotii* Foubert and Douglas 1948, 31) pre.vo'ti.i. N.L. gen. n. *prevotii* of Prévot, named after A.R. Prévot, a French microbiologist.

The characteristics are as described for the genus and as listed in Table 188, with the following additional information. Endospores not formed. Cells are 0.6–0.9 µm in diameter and found in pairs and irregular masses. Negative for indole, alkaline phosphatase and coagulase. Some strains produce urease. Most strains ferment glucose and mannose. Acid is also produced from raffinose, ribose and mannose but not from lactose, cellobiose, maltose, sucrose or xylose. The major metabolic end product from peptone-yeast-glucose medium is butyric acid. Position 1, position 3, and the interpeptide bridge of the peptidoglycan are glycine, L-lysine, and D-glutamic acid, respectively. Descriptions of the major saccharolytic and proteolytic enzymes are given by Murdoch (1988). Differential characteristics from other members of the genus and closely related species of the genus *Peptoniphilus* are given in Table 188. Often isolated from human clinical specimens such as vaginal discharges and ovarian, peritoneal and sacral abscesses.

DNA G+C content (mol%): 29–33 (T_m).

Type strain: ATCC 9321, CCUG 41932, CIP 105881, DSM 20548, JCM 6508, NCTC 11806.

GenBank accession number (16S rRNA gene): D14139.

2. *Anaerococcus hydrogenalis* (Ezaki, Liu, Hashimoto and Yabuuchi 1990) Ezaki, Kawamura, Li, Li, Zhao and Shu 2001b, 1526^{VP} (*Peptostreptococcus hydrogenalis* Ezaki, Liu, Hashimoto and Yabuuchi 1990, 306)

hyd.ro.ge.na'lis. Chem. term *hydrogen*; L. suff. *-alis* pertaining to; N.L. masc. adj. *hydrogenalis* pertaining to hydrogen, because this organism produces hydrogen.

The characteristics are as described for the genus and as listed in Table 188, with the following additional information. Cells are 0.6–0.9 µm in diameter and occur in pairs, chains, and irregular masses. Endospores are not formed. Produces abundant H₂ from peptone-yeast-glucose medium. Indole-positive. Some strains produce urease and alkaline phosphatase. Acid is produced from glucose, lactose, raffinose and mannose. Negative for arginine dihydrolase, and coagulase. The major metabolic end product from PYG is butyric acid. Position 1, position 3, and the interpeptide bridge of peptidoglycan are alanine, L-lysine, and D-glutamic acid, respectively. Descriptions of major saccharolytic and proteolytic enzymes are given by Murdoch (1988). Differential characteristics from other members of the genus are given in Table 188. The organism is isolated from vaginal discharges and ovarian abscesses.

DNA G+C content (mol%): 30–34 (method not known).

Type strain: ATCC 49630, DSM 7454, JCM 7635, GIFU 7662.

GenBank accession number (16S rRNA gene): D14140.

3. *Anaerococcus lactolyticus* (Li, Hashimoto, Adnan, Miura, Yamamoto and Ezaki 1992) Ezaki, Kawamura, Li, Li, Zhao and Shu 2001b, 1527^{VP} (*Peptostreptococcus lactolyticus* Li, Hashimoto, Adnan, Miura, Yamamoto and Ezaki 1992, 604) lac.to.ly'ti.cus. L. n. *lac*, *lactis* milk; Gr. adj. *lutikos* dissolving; N.L. adj. *lactolyticus* milk-dissolving.

The characteristics are as described for the genus and as listed in Table 188, with the following additional information. Cells occur in short chains or irregular masses. Endospores are not formed. Strains produce urease, β-galactosidase, and

alkaline phosphatase but not indole or coagulase. Strong acid is produced from glucose, lactose and mannose. Raffinose and ribose are not fermented. The major metabolic end products from PYG is butyric, lactic and acetic acid. Position 1, position 3, and interpeptide bridge of peptidoglycan are glycine, L-lysine, and D-glutamic acid, respectively. Peptones and oligopeptides are used as major energy sources. Leucine arylamidase (AMD), alanine AMD, histidine AMD, glycine AMD, pyrrolidone AMD are present. Differential characteristics from other butyrate producing members of the genus are given in Table 188. Isolated from vaginal discharges and ovarian abscesses.

DNA G+C content (mol%): 30–34 (method not known).

Type strain: ATCC 51172, CIP 103725, DSM 7456, JCM 8140, GIFU 8586.

GenBank accession number (16S rRNA gene): D14154.

4. **Anaerococcus octavius** (Murdoch, Collins, Willems, Hardie, Young and Magee 1997) Ezaki, Kawamura, Li, Li, Zhao and Shu 2001b, 1527^{VP} (*Peptostreptococcus octavius* Murdoch, Collins, Willems, Hardie, Young and Magee 1997, 785)

oc.ta'vi.us. L. adj. *octavius* eight, referring to the fact that the organism was previously assigned to Hare group VIII.

The characteristics are as described for the genus and as listed in Table 188, with the following additional information. Cells occur in short chains or irregular masses. Endospores are not formed. Indole, urease, alkaline phosphatase, arginine dihydrolase and coagulase are negative. Glucose, ribose and mannose are fermented. Lactose and raffinose are not fermented. The major metabolic end products from PYG are butyric acid and caproic acid. Position 1, position 3, and interpeptide bridge of the peptidoglycan are alanine, L-lysine, and D-aspartic acid. Descriptions of major saccharolytic and proteolytic enzymes are given by Murdoch (1988). Differential characteristics from other members of the genus are given in Table 188. Isolated from vaginal discharges and ovarian abscesses. The type strain was isolated from a human nasal cavity. Often isolated from skin, vagina and nasal cavity.

DNA G+C content (mol%): 26–31 (method not known).

Type strain: Vavey 1, DSM 11663, NCTC 9810.

GenBank accession number (16S rRNA gene): Y07841.

5. **Anaerococcus tetradius** (Ezaki, Yamamoto, Ninomiya, Suzuki and Yabuuchi 1983) Ezaki, Kawamura, Li, Li, Zhao and Shu 2001b, 1526^{VP} (*Peptostreptococcus tetradius* Ezaki, Yamamoto, Ninomiya, Suzuki and Yabuuchi 1983, 696)

te.tra'di.us. Gr. n. *tetradion* group of four; N.L. adj. *tetradius* occurring in groups of four.

The characteristics are as described for the genus and as listed in Table 188, with the following additional information. Cells are 0.6–1.0 µm in diameter and found in tetrads, pairs, and irregular masses. Endospores not formed. Urease-positive. Negative for indole, alkaline phosphatase, arginine dihydrolase and coagulase. Glucose and mannose are fermented. Acid is not produced from lactose, raffinose, ribose, cellulose, maltose, sucrose, or xylose. The major metabolic end product from peptone-yeast-glucose medium is butyric acid and lactic acid. Position 1, position 3, and the interpeptide bridge of peptidoglycan are glycine, L-lysine, and D-glutamic acid, respectively. Descriptions of major saccharolytic and proteolytic enzymes are given by Murdoch (1988). Differential characteristics from other members of the genus and closely related species of the genus *Peptoniphilus* are given in Table 188. Isolated from vaginal discharges and ovarian abscesses.

DNA G+C content (mol%): 30–32 (*Tm*).

Type strain: ATCC 35098, CCM 3634, CCUG 17637, CIP 103927, DSM 2951, GIFU 7672, JCM 1964, LMG 14264.

GenBank accession number (16S rRNA gene): D14142.

6. **Anaerococcus vaginalis** (Li et al., 1992). Ezaki, Kawamura, Li, Li, Zhao and Shu 2001b, 1527^{VP}. (*Peptostreptococcus vaginalis* Li, Hashimoto, Adnan, Miura, Yamamoto and Ezaki 1992, 604)

va.gi.na'lis. L. adj. *vaginalis* of the vagina.

The characteristics are as described for the genus and as listed in Table 188, with the following additional information. Cells are 0.7–0.9 µm in diameter and occur in short chains or irregular masses. Produces arginine dihydrolase. Some strains are positive for indole and alkaline phosphatase. Coagulase and urease are negative. Major metabolic end products from PYG are butyric and acetic acid. Position 1, position 3, and the interpeptide bridge of peptidoglycan are alanine, L-lysine, and D-glutamic acid, respectively. Weak acid is produced from glucose and maltose but not from lactose cellobiose, sucrose, arabinose, ribose, mannitol, trehalose, sorbitol, and raffinose. Peptones and oligopeptides are used as major energy sources. Leucine arylamidase (AMD), alanine AMD, histidine AMD, and glycine AMD are present. Differential characteristics from other members of the genus are given in Table 188. Isolated from vaginal discharges and ovarian abscesses.

DNA G+C content (mol%): 28–30 (method not known).

Type strain: ATCC 51170, CIP 103621, DSM 7457, GIFU 12669, JCM 8138.

GenBank accession number (16S rRNA gene): D14146.

Genus II. *Finegoldia* Murdoch and Shah 2000, 1415^{VP} (Effective publication: Murdoch and Shah 1999, 556.)

TAKAYUKI EZAKI

Fine.gol'dia. N.L. fem. n. *Finegoldia* named after Sydney M. Finegold, an American microbiologist.

Non-spore-forming, obligately anaerobic, Gram-stain-positive cocci. Cells may occur in pairs, tetrads, and irregular masses and are 0.7–1.5 µm in diameter. Carbohydrates are not fermented. Indole is negative. The optimum temperature for growth is 37°C. Metabolize peptone and amino

acids to acetic acid. Alkaline phosphatase test is variable among strains. Found in vagina, oral cavity, and various abscess-forming human specimens. Differential characteristics from closely related genera are given in Table 187 and Table 217.

Peptidoglycan diamino acid is lysine and interpeptide bridge is D-aspartic acid.

Major cellular fatty acids are C_{18:1}, C_{16:1}, C₁₈, and C₁₆ (Ezaki et al., 1983; O'Leary and Wilkinson, 1988), 1988).

Type species: Finegoldia magna (Prévot 1933) Murdoch and Shah 2000, 1415^{VP} (Effective publication: Murdoch and Shah 1999, 557.) (*Diplococcus magnus* Prévot 1933, 140; *Peptococcus magnus* Holdeman and Moore 1972; *Peptostreptococcus magnus* Ezaki, Yamamoto, Ninomiya, Suzuki and Yobucchi 1983, 696).

List of species of the genus *Finegoldia*

1. ***Finegoldia magna*** (Prévot 1933) Murdoch and Shah 2000, 1415^{VP} (Effective publication: Murdoch and Shah 1999, 557.) (*Diplococcus magnus* Prévot 1933, 140; *Peptococcus magnus* Holdeman and Moore 1972; *Peptostreptococcus magnus* Ezaki, Yamamoto, Ninomiya, Suzuki and Yobucchi 1983, 696)

Mag'na. L. adj. *magna* large.

The species description is same to the genus description. Differential characteristics from closely related genera are given in Table 187 and Table 217.

DNA G+C content (mol%): 32–34 (*T_m*).

Type strain: ATCC 15794, CCUG 17636, DSM 20470, GIFU 7629, NCTC 11804.

GenBank accession number (16S rRNA gene): AF542227, D14149.

Genus III. ***Gallicola*** Ezaki, Kawamura, Li, Li, Zhao and Shu 2001a, 1527^{VP}

TAKAYUKI EZAKI

Ga.li'co.la. L. n. *gallus* rooster/chicken; L. masc. suff. *-cola* inhabitant; N.L.masc. n. *Gallicola* inhabitant of chickens, referring to the isolation of the type species from chicken feces.

Non-spore-forming, obligately anaerobic, Gram-stain-positive cocci. Cells may occur in pairs and as irregular masses. Carbohydrates are not fermented. Indole is negative. The optimum temperature for growth is 37°C. Metabolize peptone and amino acids to acetic and butyric acid. Found in chicken feces.

Peptidoglycan diamino acid is ornithine and the interpeptide bridge is D-aspartic acid.

Major cellular fatty acids are C_{18:1}, C_{16:1}, C₁₈, and C₁₆ (Ezaki et al., 1983; O'Leary and Wilkinson, 1988).

DNA G+C content (mol%): 32–34.

Type species: Gallicola barnesae (Scheifer-Ullrich and Andreesen 1985) Ezaki, Kawamura, Li, Li, Zhao and Shu 2001a, 1527^{VP} (*Peptostreptococcus barnesae* Scheifer-Ullrich and Andreesen 1985, 30).

List of species of the genus *Gallicola*

1. ***Gallicola barnesae*** (Scheifer-Ullrich and Andreesen 1985) Ezaki, Kawamura, Li, Li, Zhao and Shu 2001a, 1527^{VP} (*Peptostreptococcus barnesae* Scheifer-Ullrich and Andreesen 1985, 30) *barnesae*. N.L. gen. n. *barnesae* of Barnes named after E.M. Barnes, a microbiologist.

Description of the type species is same to the genus description.

Isolated from chicken feces. Negative for the production of indole, urease, alkaline phosphatase, arginine dihydrolase, and coagulase. A full description is given by Scheifer-Ullrich and Andreesen (1985). Glucose, lactose, raffinose,

ribose, and mannose are not fermented. Occasional strains produce weak indole. The metabolic end products from PYG medium are acetic and butyric acids. Descriptions of major saccharolytic and proteolytic enzymes are given by Murdoch (1988). Differential characteristics from closely related genera are given in Table 187 and Table 217.

Major cellular fatty acids are C_{18:1}, C_{16:1}, C₁₈, and C₁₆ (Ezaki et al., 1983; O'Leary and Wilkinson, 1988).

DNA G+C content (mol%): 32–34.

Type strain: HKB-5, ATCC 49795, DSM 3244.

GenBank accession number (16S rRNA gene): AB038361.

Genus IV. ***Helcococcus*** Collins, Facklam, Rodrigues and Ruoff 1993, 427^{VP}

KATHRYN L. RUOFF

Hel.co.coc'cus. Gr. masc. n. *helkos* wound; Gr. masc. n. *kokkos* berry, sphere; N.L. masc. n. *Helcococcus* a sphere found in wounds.

Gram-stain-positive cocci that are **catalase-negative** and **non-motile**. Cells are arranged in **irregular groups, pairs or short chains**. Helcococci form **small pinpoint non-hemolytic colonies** on blood agar after 24 hours of incubation at 35–37°C. **Facultative anaerobes that produce acid, but not gas from glucose. No**

hydrolysis of urea, hippurate or gelatin. Arginine dihydrolase is not produced. Nitrate is not reduced.

DNA G+C content (mol%): 29–30 mol% (*T_m*).

Type species: Helcococcus kunzii Collins, Facklam, Rodrigues and Ruoff 1993, 427^{VP}.

TABLE 217. Characteristics differentiating *Finegoldia*, *Gallicola*, and *Parvimonas* species^a

Characteristic	<i>Finegoldia magna</i>	<i>Gallicola barnesae</i>	<i>Parvimonas micra</i>
16S rRNA GenBank accession number	D14149	AB038361	D14143
DNA G+C content (mol%)	32–34	32–34	27–28
Major product from PYG	Acetate	Acetate, butyrate	Acetate
Cell size (µm)	0.7–1.5	0.7–1.2	0.3–0.6
Peptidoglycan (position 3, bridge)	Lys, Gly	Orn, D-Asp	Lys, D-Asp
<i>Production of:</i>			
Alkaline phosphatase	d	–	+
Indole	–	w	–
<i>Production of saccharolytic and proteolytic enzymes:</i>			
ArgA	+	–	+
HisA	d	–	+
LeuA	+	–	+
ProA	–	–	+
PyrA	+	–	+

^aSymbols: +, >85% positive; d d, different among strains; –, 0–15% positive; w, weak reaction; ND, not determined. ArgA, arginine arylamidase (AMD); ProA, proline AMD; PheA, phenylalanine AMD; LeuA, leucine AMD; PyrA, pyroglutamyl AMD; HisA, histidine AMD.

Further descriptive information

Helcococcus strains form Gram-stain-positive coccoid cells that are typically arranged in groups, pairs or short chains. Stavri and coworkers (2002) described a Pronase-, heat- and mutanolysin-sensitive hemagglutinin-lectin in *Helcococcus kunzii* cells with specificity for *N*-acetylglucosamine and lactose. The absence of fimbriae and fibrillae on the surface of *Helcococcus kunzii* cells suggested that the lectin is associated with peptidoglycan or the cell membrane.

Helcococci produce tiny colonies on blood agar and may be difficult to culture on non-blood-containing media. Growth of *Helcococcus kunzii* on brain heart infusion media is stimulated by the addition of 1% horse serum or 0.1% Tween 80, suggesting that this species is lipophilic (Collins et al., 1993). A strain of *Helcococcus ovis* exhibited satelliting growth around *Staphylococcus aureus* colonies on initial isolation, but adapted to independent growth after repeated subculture onto Columbia agar containing 7% sheep blood incubated in a candle jar (Collins et al., 1999a). Incubation of cultures in the ambient atmosphere appears to be sufficient for routine culture of helcococci after initial isolation. Strains of *Helcococcus kunzii* grow equally well on brucella agar with 5% horse blood when incubated in an atmosphere containing 5% CO₂, an anaerobic atmosphere, or the ambient atmosphere (Collins et al., 1993).

Helcococci are fairly inactive metabolically when tested on conventional media or with commercially available identification kits. Glucose and a small number of other carbohydrates are acidified and few enzymic activities are detected. Helcococci are Voges–Proskauer-negative. Growth is variable in serum-supplemented brain heart infusion broth containing 6.5% NaCl.

Analysis of the 16S rRNA gene sequence of *Helcococcus kunzii* (GenBank accession no. X69837) revealed only a remote relationship between *Helcococcus* and other low-G+C content Gram-stain-positive bacteria with similar phenotypic characteristics (Collins et al., 1993). *Helcococcus ovis* and *Helcococcus kunzii* 16S rRNA gene sequences display 96% similarity (Collins et al., 1999a).

Although different methods have been employed, all *Helcococcus* strains tested have exhibited susceptibility to vancomycin. *Helcococcus kunzii* strains are susceptible to penicillin (Caliendo et al., 1995; Chagla et al., 1998; Peel et al., 1997). Chagla and associates (1998) reported that 8 of the 9 *Helcococcus kunzii* strains in their collection were resistant to erythromycin and all were susceptible to clindamycin.

Helcococcus kunzii is isolated from human clinical material, often in mixed cultures of wounds (Caliendo et al., 1995), but the bacterium has been recovered as the sole isolate from an infected sebaceous cyst (Peel et al., 1997) and a breast abscess (Chagla et al., 1998). Lomholt and Killian (2000) did not detect the virulence factor immunoglobulin A1 protease in the single strain of *Helcococcus kunzii* included in their survey of this factor in various Gram-stain-positive bacteria. *Helcococcus ovis* has been recovered from postmortem specimens of an adult male sheep and from the milk of a sheep with subclinical mastitis. As with most reports of *Helcococcus kunzii* isolation, other bacteria were also present in cultures yielding *Helcococcus ovis* (Collins et al., 1999a). Although more information is needed concerning the clinical significance of *Helcococcus ovis*, *Helcococcus kunzii* appears to function as an opportunistic pathogen.

In a study by Haas and colleagues (1997) *Helcococcus kunzii* was recovered from swabs of the intact skin of the feet of both diabetic and non-diabetic podiatry patients, and from both the foot and hand skin of a healthy volunteer. These observations suggest that *Helcococcus kunzii* is part of normal human skin flora. The *Helcococcus kunzii* lectin described by Stavri and coworkers (2002) is hypothesized to play a role in the adhesion and colonization activities of this bacterium.

Species of the genus *Helcococcus* may not be included in the databases of commercially available identification products. The profile produced by most strains of *Helcococcus kunzii* examined with the API 20S Strep system (bioMérieux Vitek) was 4100413, corresponding to a doubtful identification of *Aerococcus viridans* (Chagla et al., 1998; Collins et al., 1993). The *Helcococcus kunzii* profile observed with this system corresponds to positive reac-

tions for pyrrolidonyl arylamidase, esculin hydrolysis, and acidification of lactose, trehalose, starch and glycogen.

Enrichment and isolation procedures

Helcococcus can be recovered from clinical specimens on blood agar media incubated at 35–37°C in a CO₂-enriched (5%) atmosphere. In specimens yielding mixed bacterial growth, the tiny colonies of *Helcococcus* strains may be overgrown by other more vigorously growing bacteria (e.g., staphylococci, *Enterobacteriaceae* strains). The selective agar plate medium described by Haas and associates (1997) may be employed to facilitate isolation of *Helcococcus kunzii*. The medium consists of brain heart infusion broth (37 g), agar (15 g), and Tween 80 (1 ml) added to 990 ml of distilled water. After autoclaving and tempering the medium to 50°C, 10 ml of a filter-sterilized aqueous solution containing novobiocin (1 mg/ml) and colistin (750 µg/ml) are added. The selective medium supports good growth of *Helcococcus kunzii*, but inhibits the growth of a number of Gram-stain-positive and Gram-stain-negative bacteria that might be encountered in clinical specimens containing mixed flora.

Maintenance procedures

After initial isolation from clinical specimens, *Helcococcus* strains can be routinely cultured on blood agar media at 35–37°C in the ambient atmosphere or an aerobic atmosphere with 5% CO₂. Long term storage of isolates can be accomplished by suspending growth from blood agar plates in a few ml of horse or other animal blood and freezing suspensions at –70°C. For retrieval of isolates, portions of the frozen suspensions are thawed, streaked onto blood agar and incubated at 35–37°C either in the ambient atmosphere or in an atmosphere containing 5% CO₂.

Procedures for testing special characteristics

The lipophilic nature of *Helcococcus kunzii* can be demonstrated by enhancement of growth in brain heart infusion or Todd–Hewitt broth supplemented with 0.1% Tween 80 (Chagla et al., 1998; Collins et al., 1993). Chagla and coworkers (1998) advocated use of the heart infusion broth-based media described by Facklam and Elliott (1995) for studying acidification of carbohydrates by *Helcococcus kunzii*. These authors noted that although isolates grew well in these media, acidification as indicated by a color change in the bromocresol purple indicator occurred only when the media were supplemented with 0.1% Tween 80.

Differentiation of the genus *Helcococcus* from other genera

The genera *Helcococcus* and *Aerococcus* share some phenotypic characteristics (catalase-negative Gram-stain-positive cocci arranged in clusters or groups) even though they are not closely related (see Table 187). *Helcococcus kunzii* and *Aerococcus viridans* are both pyrrolidonyl arylamidase-positive and leucine aminopeptidase-negative. These organisms can be differentiated on the basis of colony size and hemolysis (*Aerococcus viridans* forms alpha-hemolytic colonies that are larger than the tiny non-hemolytic colonies of *Helcococcus kunzii*) and preferred incubation conditions (*Aerococcus viridans* prefers aerobic conditions but *Helcococcus kunzii* grows equally well aerobically or anaerobically; Collins et al., 1993).

The pyrrolidonyl arylamidase-positive species *Aerococcus sanguicola* is leucine aminopeptidase and hippurate hydrolysis-positive in contrast to *Helcococcus kunzii* (Lawson et al., 2001b).

Helcococcus kunzii can be differentiated from the pyrrolidonyl arylamidase-positive, leucine aminopeptidase-negative genera *Globicatella* and *Dolosicoccus* on the basis of chain formation by cells of these organisms (Ruoff, 2002).

Both *Helcococcus ovis* and *Aerococcus urinae* are pyrrolidonyl arylamidase-negative and leucine aminopeptidase-positive, but *Aerococcus urinae* and other pyrrolidonyl arylamidase-negative *Aerococcus* species (*Aerococcus urinaehominis*, *Aerococcus christensenii*) hydrolyze hippurate, while both *Helcococcus* species are negative for this activity (Aguirre and Collins, 1992; Christensen et al., 1991; Collins et al., 1999b; Lawson et al., 2001a). *Helcococcus ovis* cells are arranged singly and in pairs or short chains, in contrast to the pairs, tetrads and groups of cells exhibited by *Aerococcus* species.

The tiny non-hemolytic colonies formed by *Helcococcus ovis* may help to distinguish this species from strains of streptococci that are pyrrolidonyl arylamidase-negative and leucine aminopeptidase-positive.

Positive results for both pyrrolidonyl arylamidase and leucine aminopeptidase or resistance to vancomycin will help to differentiate *Helcococcus* strains from many other currently described genera of catalase-negative Gram-stain-positive cocci (Ruoff, 2002).

Taxonomic comments

Although the genus *Helcococcus* bears phenotypic similarities with members of the lactic acid bacteria, its proposed phylogenetic relationship with these organisms diverges at the taxonomic class level. The genus *Helcococcus* is currently included within the clostridial branch of Gram-stain-positive bacteria with low G+C content and is classified within a family *incertae sedis* with a number of other genera formerly classified in the family *Peptostreptococcaceae*.

List of species of the genus *Helcococcus*

1. *Helcococcus kunzii* Collins, Facklam, Rodrigues and Ruoff 1993, 427^{VP}

kunzi.i. N.L. gen. n. *kunzii* of Kunz named after Lawrence J. Kunz, an American bacteriologist.

Gram-stain-positive cocci arranged in pairs and groups. Cells are nonmotile and non-pigmented. Non-hemolytic colonies formed on blood agar. No growth on bile esculin agar; growth may or may not occur in serum-supplemented 6.5% NaCl. Catalase-negative and facultatively anaerobic.

Lipophilic; growth stimulated by supplementation of non-blood containing media with 1% horse serum or 0.1% Tween 80. Acid but not gas produced from glucose and some other carbohydrates. The major end products of glucose metabolism are lactate and acetate. Acid is produced from lactose and trehalose, and by some strains from glycogen. No acid production from arabinose, inulin, raffinose, ribose, or sorbitol. Hippurate, urea and gelatin are not hydrolyzed. Esculin is hydrolyzed in the API 20Strep system, but not

in conventional test media. Arginine is not deaminated. Pyrrolidonyl arylamidase is produced. Pyrazinamidase is produced by some strains. No production of alkaline phosphatase, α -galactosidase, β -galactosidase, β -glucuronidase or leucine aminopeptidase. Voges–Proskauer-negative. Nitrate not reduced. Vancomycin-susceptible.

Isolated from human sources (wounds, abscesses, intact skin). Habitat thought to be human skin.

DNA G+C content (mol%): 30 (T_m , Collins et al., 1993).

Type strain: NCFB 2900 (IFO 15552; ATCC 51366).

GenBank accession number (16S rRNA gene): X69837.

2. **Helcococcus ovis** Collins, Falsen, Foster, Monasterio, Dominguez and Fernandez-Garazabal 1999a, 1432^{VP}
o'vis. L. gen. n. *ovis* of a sheep.

Gram-stain-positive cocci arranged singly, in pairs and short chains. Cells are nonmotile and non-pigmented. Non-hemolytic colonies formed on blood agar. Catalase-negative and facultatively anaerobic. Acid but not gas produced from glucose. Acid may or may not be produced from cyclodex-

trin, glycogen and maltose. No acid production from D-arabitol, L-arabinose, inulin, lactose, mannitol, melezitose, melibiose, methyl β -D-glucopyranoside, pullulan, raffinose, ribose, sorbitol starch, sucrose, tagatose or D-xylose. Esculin, hippurate, urea, and gelatin are not hydrolyzed. Arginine is not deaminated. Alkaline phosphatase, acid phosphatase, β -glucuronidase and leucine aminopeptidase are produced. No production of pyrrolidonyl arylamidase, alanyl-phenylalanine-proline arylamidase, glycyL-tryptophan arylamidase, chymotrypsin, esterase C4, ester lipase C8, α -fucosidase, α -galactosidase, β -glucosidase, valine arylamidase, lipase C14, α -mannosidase, β -mannosidase, trypsin and N-acetyl- β -glucosaminidase. Variable production of cystine arylamidase, β -galactosidase and phosphoamidase. Voges–Proskauer-negative. Nitrate not reduced. Vancomycin-susceptible.

Isolated from sheep. Habitat unknown.

DNA G+C content (mol%): 29 (T_m ; Collins et al., 1999a).

Type strain: CCUG 37441 (CIP 106312; ATCC BAA-59).

GenBank accession number (16S rRNA gene): Y16279.

Genus V. **Parvimonas** Tindall and Euzéby 2006, 2712^{VP}

THE EDITORIAL BOARD

Par.vi.mo'nas. L. adj. *parvus* little, small; Gr. fem n. *monas* a unit, monad; N.L. fem. n. *Parvimonas* a small monad.

Nonsporeforming, obligately **anaerobic** Gram-stain-positive **cocci**. Cells may occur in pairs, chains, and masses and are 0.3–0.7 μ m in diameter. **Carbohydrates are not fermented**. Indole is negative. Alkaline phosphatase is positive. The optimum temperature for growth is 37°C. Metabolize peptone and amino acids to acetic acid. Found in oral cavity and various human abscesses.

Peptidoglycan diamino acid is **lysine** and the interpeptide bridge is **glycine**. Major cellular fatty acids are C_{18:1}, C₁₆, C₁₈, and C_{16:1}.

DNA G+C content (mol%): 27–28.

Type species: **Parvimonas micra** (Prévot 1933) Tindall and Euzéby 2006, 2712^{VP} (*Streptococcus micros* Prévot 1933, 195; *Peptostreptococcus micros* Smith 1957, 537; *Micromonas micros* Murdoch and Shah 2000, 1415).

Further descriptive information

This description of *Parvimonas* is based upon Ezaki et al. (1983) and Murdoch and Shah (1999). *Parvimonas* does not ferment carbohydrates, and fructose, glucose, lactose, mannose, raffinose, ribose, and sucrose are not metabolized. Likewise, the enzymes β -galactosidase, β -glucuronidase, and α -glucosidase are not produced. Instead, peptones and amino acids are fermented, with acetate being the major acid formed. Arylamidases for arginine, histidine, leucine, phenylalanine, proline, pyroglutamate, serine and tyrosine are found in most if not all

strains. Catalase, coagulase, urease and arginine dihydrolase are not produced. Nitrate is not reduced to nitrite, and gelatin is not liquified. See Table 187 and Table 217 for differential characteristics with related genera.

Colonies form on blood agar plates vary in size from 1–2 mm in diameter after 5 d. They are circular, entire, white or gray, glistening and domed. They are frequently surrounded by a yellow-brown halo of discolored agar, up to 2 mm wide. Colonies are β -hemolytic.

Major cellular fatty acids are C_{18:1}, C_{16:1}, C₁₈, and C₁₆ (Ezaki et al., 1983; Wells and Field, 1976).

This organism is part of the normal flora of the human mouth and probably the gastrointestinal and female genitourinary tracts. Sometimes it is isolated from pathological specimens.

Taxonomic comments

Originally described as *Streptococcus micros* (Prévot, 1933), this species was transferred to *Peptostreptococcus* by Smith (1957). Upon sequencing of the 16S rRNA gene, it was discovered to be a representative of new genus (Li et al., 1994; Song et al., 2003). Originally, it was reclassified into a novel genus, *Micromonas*, by Murdoch and Shah (1999). However, this name was illegitimate because it was also in use within botany (*Micromonas* Manton and Parke 1960). Hence, *Parvimonas* was proposed to replace *Micromonas* (Tindall and Euzéby, 2006).

List of species of the genus *Parvimonas*

1. **Parvimonas micra** (Prévot 1933) Tindall and Euzéby 2006, 2712^{VP} (*Streptococcus micros* Prévot 1933, 195; *Peptostreptococcus micros* Smith 1957, 537; *Micromonas micros* Murdoch and Shah 2000, 1415)

mi'cra. Gr. adj. *micros* -ê-on small, little; N.L. fem. adj. *micra* small, little.

The species description is the same as the genus description.

DNA G+C content (mol%): 27–28 (T_m).

Type strain: ATCC 33270, CCUG 17638 A, CIP 105294, DSM 20468, GIFU 7824, NCTC 11808, VPI 5464.

GenBank accession number (16S rRNA gene): AF542231, AY323523.

Note: The name *Micromonas* Murdoch and Shah 2000 is illegitimate because of precedence of a microalga *Micromonas* I. Manton and M. Parke (Eukaryota; Viridiplantae; Chlorophyta; Prasinophyceae; Mamiellales; Mamiellaceae; *Micromonas*, *Micromonas pusilla*). See: Principle 2 and Rule 51b(4) of the Bacteriological Code (Lapage et al., 1992).

Genus VI. *Peptoniphilus* Ezaki, Kawamura, Li, Li, Zhao and Shu 2001a, 1524^{VP}

TAKAYUKI EZAKI AND YOSHIKI KAWAMURA

Pep.to.ni.phil'us. N.L. neut. n. *peptonum* peptone; Gr. adj. *philos* liking, friendly to; N.L. masc. n. *Peptoniphilus* friend of peptone, referring to the use of peptone as a major energy source).

Non-spore-forming, obligately anaerobic, Gram-stain-positive, cocci. Cells may occur in pairs, short chains, tetrads, or small masses. Nonmotile. Optimal growth temperature is 37°C. The major metabolic end product from peptone yeast extract glucose (PYG) medium is butyric acid. Carbohydrates are not fermented. Use peptones and oligopeptide as major energy source. The position 1, position 3, and interpeptide bridge of peptidoglycan are alanine, L-ornithine, and D-glutamic acid (Li et al., 1992; Schleifer and Nimmermann, 1973; Weiss, 1981).

Major cellular fatty acid: C_{18:1}, C₁₆, C₁₈, and C_{16:1} (Ezaki et al., 1983; O'Leary and Wilkinson, 1988).

DNA G+C content (mol%): 25–34 (Ezaki, 1982).

Type species: *Peptoniphilus asaccharolyticus* (Distaso 1912) Ezaki, Kawamura, Li, Li, Zhao and Shu 2001a, 1525 (*Peptococcus asaccharolyticus* Distaso 1912, Douglas 1957; *Peptostreptococcus asaccharolyticus* Ezaki, Yamamoto, Ninomiya, Suzuki and Yabuuchi 1983, 690).

List of species of the genus *Peptoniphilus*

1. *Peptoniphilus asaccharolyticus* (Distaso 1912) Ezaki, Kawamura, Li, Li, Zhao and Shu 2001a, 1525^{VP} (*Peptococcus asaccharolyticus* Distaso 1912, Douglas 1957; *Peptostreptococcus asaccharolyticus* Ezaki, Yamamoto, Ninomiya, Suzuki and Yabuuchi 1983, 690)

a.sac.cha.ro.ly'ti.us. Gr. pref. *a* not; Gr. n. *sachhar* sugar; Gr. adj. *lutikos* able to loosen; N.L. adj. *asaccharolyticus* not digesting sugar.

Obligately anaerobic, Gram-stain-positive cocci that appear in pairs, chains, and irregular masses.

Cells are 0.5–1.6 µm in diameter. Often isolated from various human clinical specimens such as vaginal discharges and ovarian and peritoneal abscesses. Most strains produce indole. Negative for urease, alkaline phosphatase, arginine dihydrolase, and coagulase. Does not produce acid from carbohydrates.

Major metabolic end product from PYG is butyric acid. Carbohydrates are not fermented. Use peptones and oligopeptide as major energy source. The position 1, position 3, and interpeptide bridge of peptidoglycan are alanine, L-ornithine, and D-glutamic acid. Production of major saccharolytic and proteolytic enzymes (Murdoch et al., 1988) and differential characteristics are summarized in Table 188.

The cell-wall peptidoglycan (position 1, position 3, and interpeptide bridge): alanine, ornithine, D-glutamate.

DNA G+C content (mol%): 31–32.

Type strain: ATCC 14963, CCUG 9988, CIP 74.17, DSM 20463, GIFU 7656, NCTC 11461.

GenBank accession number (16S rRNA gene): AF542228, D14138.

2. *Peptoniphilus harei* (Murdoch, Collins, Willems, Hardie, Young and Magee 1997) Ezaki, Kawamura, Li, Li, Zhao and Shu (2001a) 1526^{VP} (*Peptostreptococcus harei* Murdoch, Collins, Willems, Hardie, Young and Magee 1997, 783)

Ha're.i. N.L. gen. n. *harei* of R. Hare, a British microbiologist.

Obligately anaerobic, Gram-stain-positive cocci that appear in pairs and irregular masses. Cell size varies considerably (diameter, 0.5–1.5 µm).

The type strain was isolated from pus of a human sacral ulcer. Indole and catalase production are variable among strains. Negative for urease, arginine dihydrolase, alkaline phosphatase, and coagulase. Carbohydrates are not fermented. Use peptones and oligopeptide as major energy source. Major metabolic end product from PYG is butyric acid. Production of major saccharolytic and proteolytic enzymes (Murdoch et al., 1988) and differential characteristics are summarized in Table 188.

The position 1, position 3, and interpeptide bridge of peptidoglycan are alanine, L-ornithine, and D-glutamic acid.

DNA G+C content (mol%): 25.

Type strain: CIP 105325, DSM 10020, NCTC 13076, SBH 093.

GenBank accession number (16S rRNA gene): Y07839.

3. *Peptoniphilus indolicus* (Christiansen 1934) Ezaki, Kawamura, Li, Li, Zhao and Shu 2001a, 1525^{VP} (*Micrococcus indolicus* Christiansen 1934, 366; *Peptococcus indolicus* Høi Sorensen 1975, 221; *Peptostreptococcus indolicus* Ezaki, Yamamoto, Ninomiya, Suzuki and Yabuuchi 1983, 692)

in.do'li.us. Chem. term *indole*; L. suff. *-icus* related to; N.L. n. *indolicus* related to indole, referring to the ability of the organism to produce indole.

Obligately anaerobic, Gram-stain-positive cocci that appear in pairs, chains, and irregular masses.

Isolated from summer mastitis of cattle. Occasionally isolated from human clinical specimen. Most strains are coagulase, alkaline phosphatase, and indole-positive. Negative for urease and

arginine dihydrolase. No sugars are fermented. Use peptones and oligopeptide as major energy source. Major metabolic end product from PYG is butyric acid. Production of major saccharolytic and proteolytic enzymes (Murdoch et al., 1988) and differential characteristics are summarized in Table 188.

The position 1, position 3, and interpeptide bridge of peptidoglycan are alanine, L-ornithine, and D-glutamic acid.

DNA G+C content (mol%): 32–34.

Type strain: ATCC 29427, CCM 5987, CCUG 17639, DSM 20464, NCTC 11088.

GenBank accession number (16S rRNA gene): AY153430, D14147.

4. **Peptoniphilus ivorii** (Murdoch, Collins, Willems, Hardie, Young and Magee 1997) Ezaki, Kawamura, Li, Li, Zhao and Shu 2001a, 1526^{VP} (*Peptostreptococcus ivorii* Murdoch, Collins, Willems, Hardie, Young and Magee 1997, 785)

i.vo'ri.i. N.L. gen. n. *ivorii* of Ivor, a British microbiologist who first isolated the organism.

Obligately anaerobic, Gram-stain-positive cocci that appear in pairs and irregular masses.

The type strain was isolated from a human leg ulcer. Negative for urease, arginine dihydrolase, alkaline phosphatase, and coagulase. Carbohydrates are not fermented. Use peptones and oligopeptide as major energy source. Major metabolic end product from PYG is butyric acid. Production of major saccharolytic and proteolytic enzymes (Murdoch et al., 1988) and differential characteristics are summarized in Table 188.

The position 1, position 3, and interpeptide bridge of peptidoglycan are alanine, L-ornithine, and D-glutamic acid

DNA G+C content (mol%): 29%.

Type strain: CIP 105325, DSM 10022, NCTC 13078, SBH 093.

GenBank accession number (16S rRNA gene): Y07840.

5. **Peptoniphilus lacrimalis** (Li, Hashimoto, Adnan, Miura, Yamamoto and Ezaki 1992) Ezaki, Kawamura, Li, Li, Zhao and Shu 2001a, 1526^{VP} (*Peptostreptococcus lacrimalis* Li, Hashimoto, Adnan, Miura, Yamamoto and Ezaki 1992, 604)

la.cri.ma'lis. L. fem. n. *lacrima* a tear; N.L. adj. *lacrimalis* referring to the lacrimal gland, where the organism was isolated.

Obligately anaerobic, Gram-stain-positive cocci that appear in short chains and irregular masses.

Isolated from abscess of human lachrymal gland. Occasionally from otorrhea and abscesses from other areas of the human body. Negative for indole, urease, arginine dihydrolase, alkaline phosphatase, and coagulase. Carbohydrates are not fermented. Use peptones and oligopeptide as major energy source. Major metabolic end product from PYG is butyric acid. The following arylamidases (AMD) are strong: leucine AMD, alanine AMD, histidine AMD, glycine AMD, and phenylalanine AMD. The differential characteristics are summarized in Table 188.

The position 1, position 3, and interpeptide bridge of peptidoglycan are alanine, L-ornithine, and D-glutamic acid.

DNA G+C content (mol%): 30–34%.

Type strain: ATCC 51171, CCUG 31350, CIP 103724, DSM 7455, JCM 8139, GIFU 7667, NCTC 13149.

GenBank accession number (16S rDNA): AF542230, D14141.

Genus VII. **Sedimentibacter** Breitenstein, Wiegel, Haertig, Weiss, Andreesen and Lechner 2002, 806^{VP}

UTE LECHNER

Se.di.men.ti.bac'ter. N.L. masc. n. *sedimentum* sediment; N.L. n. *bacter* masc. equivalent of Gr. neut. dim. n. *bakterion* rod or staff; N.L. masc. n. *Sedimentibacter* rod from sediment, referring to its origin.

Slightly curved rod-shaped cells found singly or in chains, 0.35 × 7 μm, oval spores formed from terminal swollen sporangia. Gram-stain-positive or -negative. Motile by means of **peritrichous flagella**. Strict anaerobe. Growth between 12 and 41 °C with optimal growth at 33–37 °C. pH optimum 7–8.2. Growth requires yeast extract and is supported by the **fermentation of pyruvate or of amino acids in a Stickland-type reaction**. **H₂ not produced**. **Carbohydrates not fermented**. **Purines including uric acid, adenine, hypoxanthine, guanine, and xanthine are not utilized**. Catalase and urease are absent. The **cell-wall type is A1α** (L-lysine, direct). Menaquinones are not present. The genus represents a separate line of descent within the *Peptostreptococcaceae* according to 16S rRNA gene sequence analysis.

DNA G+C content (mol%): 34–35.5.

Type species: **Sedimentibacter hydroxybenzoicus** (Zhang, Mandelco and Wiegel 1994) Breitenstein, Wiegel, Haertig, Weiss, Andreesen and Lechner 2002, 806^{VP} (*Clostridium hydroxybenzoicum* Zhang, Mandelco and Wiegel 1994, 218).

Further descriptive information

Based on 16S rRNA gene sequences, the genus *Sedimentibacter* forms a distinct line of descent within a cluster of genera previously assigned to the family *Peptostreptococcaceae* and additional

bacteria formerly belonging to the cluster XII-clostridia including *Clostridium purinolyticum*, *Clostridium acidurici*, *Clostridium hastiforme*, and *Tissierella praeacuta* (Collins et al., 1994; Garrity et al., 2005) and the recently described genus *Soehngenia* (Parshina et al., 2003) (Figure 221). In phylogenetic trees prepared for this volume, it appears as a neighboring lineage to Family XI *Incertae Sedis*, and it was retained within that group until the taxonomic ambiguities are resolved. Sequence identities are highest (87–89%) with rod-shaped bacteria in this phylogenetic branch (*Clostridium purinolyticum*, *Clostridium acidurici*, *Sporan-aerobacter acetigenis*, *Soehngenia saccharolytica*, *Tissierella praeacuta*, *Clostridium hastiforme*, and *Fusibacter paucivorans*). 16S rRNA genes of coccoid members of the Family XI *Incertae Sedis* (*Hel-cococcus kunzii*, *Anaerococcus prevotii*, *Peptoniphilus asaccharolyticus*, *Finegoldia magna*, *Gallicola barnesae*, *Parvimonas micra* and *Pepto-streptococcus anaerobius*) are less similar (82–86% identity) and form a distinctly different phylogenetic branch (Figure 221). Morphologically the cells of *Sedimentibacter* are rod-shaped, peritrichously flagellated, and form spores. These features are common in the above-mentioned cluster XII-associated group, with the exception of *Tissierella*, where spore formation was not detected (Farrow et al., 1995). However, evidence was recently provided that the type strains of *Tissierella praeacuta* and of the

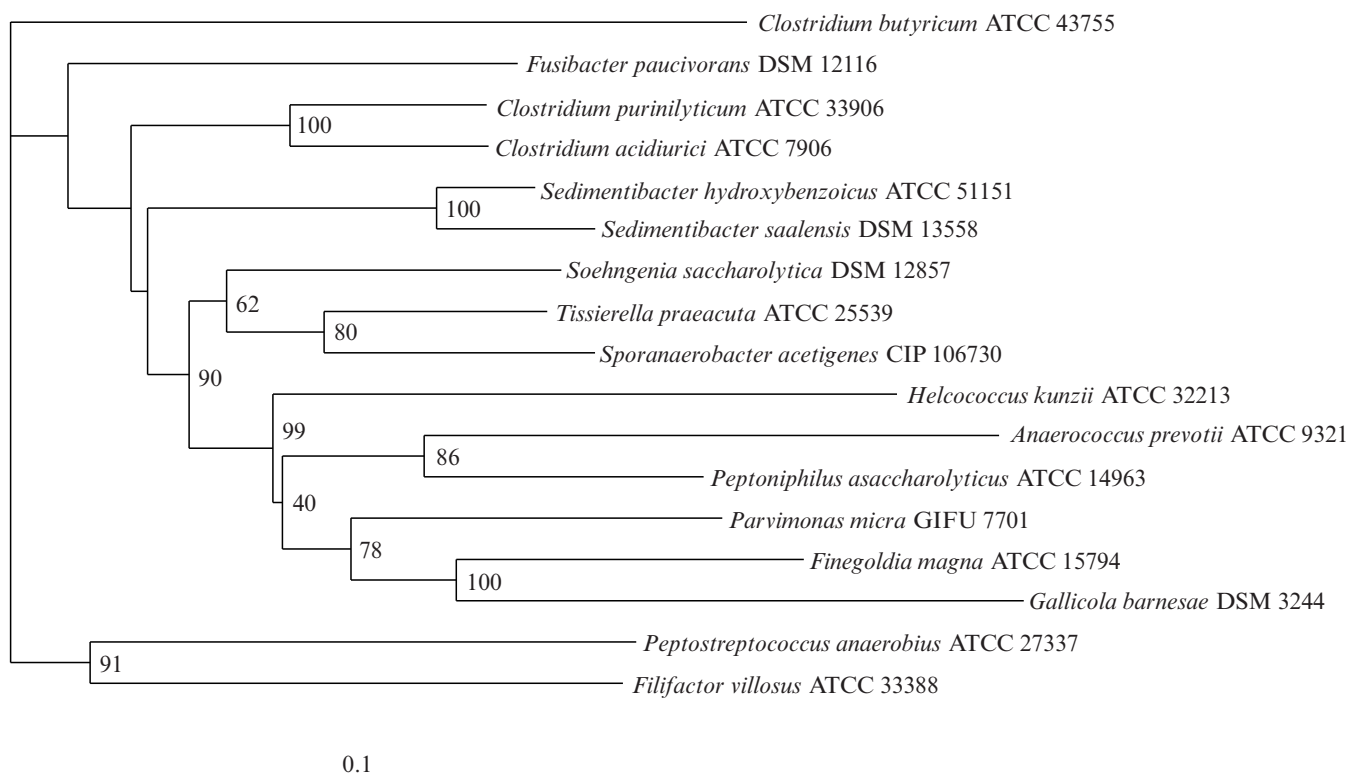

FIGURE 221. Phylogenetic neighbor-joining dendrogram showing the relationships of *Sedimentibacter* species with representatives of the family *Peptostreptococcaceae* and clostridia formerly assigned to cluster XII (Collins et al., 1994). Percentage bootstrap values are based on 500 replicates and are indicated at the branching points. Bar = 0.1 nucleotide substitutions per site. *Clostridium butyricum* was used as the outgroup.

spore-forming *Clostridium hastiforme* are members of the same species (Bae et al., 2004) and that *Tissierella praeacuta* contains sporulation genes (Onyenwoke et al., 2004; Jürgen Wiegler, personal communication). Cells of *Sedimentibacter* have pointed ends. Cells stain Gram-stain-negative or Gram-stain-positive, but exhibit the typical cell-wall structure of Gram-stain-positive organisms. The cell-wall type is A1 α (L-lysine, direct) in contrast to most genera within the *Peptostreptococcaceae* which often contain interpeptide bridges of dicarboxylic amino acids or glycine. *Tissierella praeacuta* and *Clostridium purinolyticum* contain meso-diaminopimelic acid (meso-DAP) or D-ornithine instead of L-lysine (Table 218). The dominant lipid fatty acids are C_{14:0}, C_{16:0}, and dimethyl acetals (for more details see footnote of Table 219). Methyl branched fatty acids as observed for *Peptostreptococcus anaerobius* and *Tissierella praeacuta* are not present.

White, disc-shaped colonies (0.5–2 mm in diameter) are formed in minimal medium with 10 mM pyruvate and 0.05% yeast extract solidified with 1% agar. The bacteria can be grown in an anaerobic minimal medium containing (per liter): (NH₄)HCO₃, 0.45 g; CaCl₂·2H₂O, 0.12 g; MgSO₄·6H₂O, 0.13 g; 1 ml trace element solution SL-10 (25% HCl, 10 ml; FeCl₂·4H₂O, 1.5 g; ZnCl₂, 70 mg; MnCl₂·4H₂O, 100 mg; H₃BO₃, 6 mg; CoCl₂·6H₂O, 190 mg; CuCl₂·2H₂O, 2 mg; NiCl₂·6H₂O, 24 mg; Na₂MoO₄·2H₂O, 36 mg; bidistilled water to 1000 ml); 1 ml selenite and tungstate solution (0.5 g NaOH, 3 mg Na₂SeO₃·5H₂O; 4 mg Na₂WO₄·2H₂O, bidistilled water to 1000 ml); resazurin, 1 mg; yeast extract, 3 g. After boiling and gassing with N₂/CO₂ (80:20), the pH is adjusted to 7.3 by the addition of NaHCO₃

(ca. 3.8 g) under continuous stirring. After autoclaving, the following compounds are added from anaerobic stock solutions: phosphate buffer (pH 7.3), 10 mM; glycine, 10 mM; arginine, 10 mM; Na₂S, 1 mM; Ti (III) citrate, 0.15 mM; vitamin solution, 1 ml/l, containing the following vitamins (in mg/l): L-lipoic acid, 5; D-(+)biotin, 2; folic acid, 2; riboflavin, 5; thiamine, 5; nicotinamide, 5; cyanocobalamin, 5; *p*-aminobenzoic acid, 5; pyridoxine, 10; pantothenic acid, 5; 1,4-naphthoquinone, 10.

Growth of the strictly anaerobic bacterium in minimal medium depends on yeast extract (at least 0.01%, optimum growth at 1.5% w/v for the type species). Carbohydrates are not fermented. Pyruvate is fermented to acetate and butyrate. Electrons produced during oxidative metabolism were probably transferred to acetate to form butyrate as described for *Clostridium acetireducens* (Girbal et al., 1997). Hydrogen is not formed either from pyruvate or yeast extract, in contrast to *Soehngenia* or *Sporanaerobacter* species. *Sedimentibacter* ferments the amino acids glycine and L-lysine to acetate and acetate plus butyrate, respectively. In the presence of both amino acids, an increased amount of acetate is formed at the expense of butyrate indicating that glycine functions as the electron acceptor in a Stickland-type reaction (Andreesen et al., 1989). Arginine alone does not support growth in contrast to many clostridia, which can use the energy-providing arginine deiminase pathway (Andreesen et al., 1989). The addition of arginine to glycine leads to an increase in growth and acetate formation. Arginine is converted to ornithine (Zhang et al., 1994) which probably serves as electron donor for the reduction of glycine to acetate (Andreesen et al.,

TABLE 218. Comparison of *Sedimentibacter* with some Gram-stain-positive, rod-shaped bacteria from the family *Peptostreptococcaceae*, former clostridial cluster XII (Collins et al., 1994), and *Clostridiales* Family *Incerta Sedis* XI (Ludwig et al., 2009)^a

^bThe following characteristics tested positive for both strains: fermentation of pyruvate, glycine, lysine, and arginine plus glycine and the formation of H₂S in SIM medium. Both contained the peptidoglycan type A1α, L-Lys direct and the cellular fatty acids C_{14:0}⁺, C_{16:0}⁺, C_{16:1 07c}⁺, C_{9c}⁺, C_{18:1 07c}⁺ and the dimethylacetals C_{16:0} and C_{18:0}⁺. The following characteristics were negative for both strains: catalase, gelatin and esculin hydrolysis, nitrate reduction, fermentation of carbohydrates (cellobiose, maltose, arabinose, glucose, mannose, xylose, trehalose, and sorbitol) and purines (uric acid, hypoxanthine, xanthine, guanine, and adenine), and production of H₂. The following characteristics tested negative for one or both strains: lipase reaction, hydrolysis of starch, lecithinase activity, acid formation from fructose, ribose, and glycogen (JW/Z-1^T), urease activity, and acid formation from mannitol, lactose, sucrose, salicin, glycerol, melizitose, raffinose, and rhamnose (ZF2^T).

^cData from strain JW/Z-1^T (Zhang et al., 1994).

^dData from strain ZF2^T (Breitenstein et al., 2002).

^eCells of both strains were slightly curved rods motile by peritrichous flagella.

1989). *Clostridium purinolyticum*, *Clostridium acidurici*, *Gallicola barnesae*, *Peptoniphilus asaccharilyticus*, and *Anaerococcus prevotii* are able to use purines as growth substrates (Andreesen, 1994), whereas *Sedimentibacter* does not ferment any purines tested (uric acid, hypoxanthine, xanthine, guanine, and adenine). Sodium ions stimulate growth in sodium-deficient medium and monensin inhibits growth and amino acid utilization suggesting that *Sedimentibacter* utilizes a sodium-proton antiport and a sodium-amino acid symport (Zhang et al., 1994). The reversible decarboxylation of 4-hydroxy- and 3,4-dihydroxybenzoate to phenol and catechol, respectively, is a characteristic feature of *Sedimentibacter hydroxybenzoicus* (Zhang and Wiegel, 1990; Zhang et al., 1994). The products are not further metabolized. The respective enzymes, 4-hydroxy- and 3,4-dihydroxybenzoate decarboxylases, were purified and characterized (He and Wiegel, 1995, 1996). They differ from known decarboxylases in that they are neither biotin, pyridoxal-5'-phosphate, nor thiamine diphosphate dependent. The gene of 4-hydroxybenzoate decarboxylase is the first characterized representative of a novel gene family which is distributed within *Bacteria* and *Archaea* (Huang et al., 1999). The physiological and ecological meaning of these reactions is not yet clear. Originally it was assumed that *Sedimentibacter hydroxybenzoicus* catalyzed the carboxylation of phenol in an enrichment culture which degraded 2,4-dichlorophenol via phenol (Zhang and Wiegel, 1990). However, the equilibrium of the reversible decarboxylation reaction is on the side of phenol (Zhang and Wiegel, 1994). In contrast to *Sedimentibacter hydroxybenzoicus*, *Sedimentibacter saalensis* neither decarboxylates 4-hydroxy- and 3,4-dihydroxybenzoate nor carboxylates phenol and catechol.

Sedimentibacter occurs in methanogenic freshwater sediments from which the strains *Sedimentibacter hydroxybenzoicus* JW/Z-1^T and *Sedimentibacter saalensis* ZF2^T were both isolated during attempts to enrich chlorophenol-dechlorinating communities. Another bacterium, strain BRS2, is related to *Sedimentibacter* on the basis of its 16S rDNA sequence (94% identity; GenBank accession number AY221992). It was isolated from a vinyl chloride-dechlorinating enrichment culture (Frank Löffler, personal communication) further indicating that the genus grows well under conditions used to enrich for reductively dechlorinating bacteria, but in no case was reductive dechlorination observed.

Isolation procedure

Sedimentibacter hydroxybenzoicus was obtained from a sediment which exhibited sequential degradation of 2,4-dichlorophenol via 4-chlorophenol and phenol to CH₄ and CO₂ (Zhang and Wiegel, 1990). Enrichment and isolation was achieved by feeding a phenol-degrading enrichment culture with 4-hydroxybenzoate which led to an increase of its decarboxylation from less than 1 mM per 24 h to over 100 mM of hydroxybenzoate per 24 h with a subsequent degradation to carbon dioxide, hydrogen, and acetate. Although *Sedimentibacter hydroxybenzoicus* does not metabolize phenol or hydroxybenzoate itself, the enrichment of this bacterium probably occurred due to the subsequent production of acetate by other members in the mixed culture. Acetate stimulates growth of *Sedimentibacter hydroxybenzoicus*. Final isolation occurred on yeast extract containing mineral media using dilution rows in anaerobic agar-shake-roll tubes inoculated with pasteurized enrichment samples (Zhang and Wiegel, 1990; J. Wiegel, personal communication).

Sedimentibacter saalensis was obtained from an anaerobic, 2,4,6-trichlorophenol-dehalogenating, mixed culture enriched from freshwater sediment by isolation of a single colony from agar-shake dilution series, which contained 10 mM pyruvate, 0.01% yeast extract, and 100 µM 2,4,6-trichlorophenol (Breitenstein et al., 2002). Further purification was achieved by consecutive serial dilutions in agar shakes containing 25 mM pyruvate and 0.05% yeast extract.

Maintenance procedures

Cultures can be maintained on either liquid medium (see above) or solidified by 1% agar. Cultures grow in liquid medium without shaking. Liquid cultures or colonies in agar shake tubes were observed to survive at 4°C for several months. Liquid cultures grown to the late exponential phase can be dispensed into 2 ml aliquots of N₂/CO₂ (80:20)-gassed Hungate tubes and mixed with 0.6 ml of anaerobic glycerol (87% v/v gassed with N₂, autoclaved and reduced with 1 mM Na₂S). Following incubation at 30°C for 2 h, cultures are frozen in liquid nitrogen and stored at –80°C. *Sedimentibacter* can also be lyophilized and is provided by DSMZ and ATCC in this form.

Characteristics for *Sedimentibacter* are listed in Table 219. All methods for analyzes of these properties are presented in Zhang and Wiegel (1990), Zhang et al. (1994), or Breitenstein et al. (2002).

Differentiation of the genus *Sedimentibacter* from other genera

Sedimentibacter can be distinguished from other rod-shaped members of the Family XI *Incertae Sedis* and the purinolytic

clostridia *Clostridium acidivorici* and *Clostridium purinolyticum* by a combination of properties such as the inability to ferment carbohydrates and purines and by the formation of acetate plus butyrate, but not hydrogen, from amino acids, pyruvate, or yeast extract (Table 218). So far, the observed type of cell-wall cross-linking A1 α (L-lysine, direct) of *Sedimentibacter* has not been described for the other genera mentioned. In addition, its phylogeny based on 16S rRNA sequence places it in a relatively deep branching lineage within the Family XI *Incertae Sedis*.

Taxonomic comments

Sedimentibacter hydroxybenzoicus JW/Z-1^T was originally assigned to the clostridia (Zhang et al., 1994), however, the

polyphyletic character of the genus *Clostridium* is now well established (Collins et al., 1994). Based on the 16S rRNA sequences of *Sedimentibacter hydroxybenzoicus* JW/Z-1^T and *Sedimentibacter saalensis* ZF2^T, which are 94% identical and show an affiliation to clostridial cluster XII and the *Peptostreptococcaceae*, the new genus *Sedimentibacter* was proposed and characterized by morphological, physiological, and chemotaxonomic studies.

Differentiation of the species of the genus *Sedimentibacter*

Differential characteristics of the species of *Sedimentibacter* are indicated in Table 219.

List of species of the genus *Sedimentibacter*

1. ***Sedimentibacter hydroxybenzoicus*** (Zhang, Mandelco and Wiegel 1994) Breitenstein, Wiegel, Haertig, Weiss, Andreesen and Lechner 2002, 806^{VP} (*Clostridium hydroxybenzoicum* Zhang, Mandelco and Wiegel 1994, 218)
 hy.drox.y.ben.zo'i.cus. Gr. n. *hydor* water; Gr. n. *oxys* acid; Ger. and Fr. n. *benzoin* frankincense of Java; Ger. n. *Benzoessäure* resin obtained from the tree *Styrax benzoin*; N.L. adj. *hydroxybenzoicus* pertaining to the organic acid hydroxybenzoic acid, referring to the characteristic feature of this organism, the reversible decarboxylation of 4-hydroxybenzoate and 3,4-dihydroxybenzoate.
 Morphological, cultural and biochemical characteristics are the same as described for the genus (Table 218). Other characteristics are described in Table 219.
 Originally isolated from a methanogenic sediment from a freshwater pond of the Cherokee Trailer Park, Athens, GA (USA)
DNA G+C content (mol%): 35.5 (HPLC).
Type strain: JW/Z-1, ATCC 51151, DSM 7310.
GenBank accession number (16S rRNA gene): L11305.
2. ***Sedimentibacter saalensis*** Breitenstein, Wiegel, Haertig, Weiss, Andreesen and Lechner 2002, 806^{VP}
 saa.len'sis. N.L. adj. *saalensis* referring to the German River Saale, from which the organism was isolated.
 Morphological, cultural and biochemical characteristics are essentially the same as described for the genus (Table 218) with some deviations and further properties given in Table 219. Striking differences from *Sedimentibacter hydroxybenzoicus* are the inability of *Sedimentibacter saalensis* to decarboxylate hydroxybenzoates and to form indole and the frequent occurrence of long filaments (up to 130 μ m with only a few or no septations in *Sedimentibacter saalensis* cultures). The filaments contain nucleoids every 4–6 μ m as indicated by staining with 4',6-diamidino-2-phenylindole (DAPI).
 Originally isolated from freshwater sediment of the River Saale, Germany.
DNA G+C content (mol%): 34 (HPLC).
Type strain: ZF2, ATCC BAA-283, DSM 13558.
GenBank accession number (16S rRNA gene): AJ404680.

Genus VIII. **Soehngenia** Parshina, Kleerebezem, Sanz, Lettinga, Nozhevnikova, Kostrikina, Lysenko and Stams 2003, 1796^{VP}

SOFIYA N. PARSHINA AND ALFONS J. M. STAMS

Soehn.ge'ni.a. N.L. fem. n. *Soehngenia* named in honor of Nicolas L. Soehngen, founder and first head (1911–1937) of the Laboratory of Microbiology of Wageningen University, The Netherlands, where this strain was isolated and described.

Rod-shaped cells, 0.5–0.7 \times 2–11 μ m (Figure 222). **Gram-stain-positive**. In the early exponential phase of growth, cells are slightly motile by means of peritrichous flagella (Figure 223); older cells lose their motility. Colonies are rhizoid, resemble a snowflake, dark, and creamy. Rare terminal and subterminal spore formation. **Mesophilic**. Anaerobic, but **aerotolerant**; it can grow with 50% air in the gas phase. Fixes molecular nitrogen. **Chemo-organotrophic**. Saccharolytic and weakly proteolytic. Growth substrates are a wide range of carbohydrates and some other carbon sources, including yeast extract, cysteine, and serine. Isolated from a laboratory anaerobic digester sludge with benzaldehyde as the substrate.

DNA G+C content (mol%): 43.0 (T_m).

Type species: ***Soehngenia saccharolytica*** Parshina, Kleerebezem, Sanz, Lettinga, Nozhevnikova, Kostrikina, Lysenko and Stams 2003, 1797^{VP}.

Further descriptive information

Because only one species in the genus has been described, the description of the genus is the same as that for the species.

Enrichment and isolation procedures

A stable enrichment culture was initiated from methanogenic granular sludge from a laboratory-scale UASB reactor treating

FIGURE 222. Electron micrograph of a thin section of a cell of *Soehngenia saccharolytica* strain BOR-Y^T. Bar = 1 μ m.

benzaldehyde as the sole substrate. The reactor treating benzaldehyde was itself inoculated with granular sludge from an industrial UASB reactor treating potato starch wastewater. The presence of yeast extract (routinely 0.2g/l) was required to obtain a stable enrichment. A pure culture was isolated upon repeated serial dilutions in liquid medium with 5–15 mM benzaldehyde and yeast extract.

Maintenance procedures

The type strain is maintained in the bicarbonate-phosphate buffered medium supplemented with 1.0g/l yeast extract and 10mmol/l benzaldehyde (Parshina et al., 2003; Parshina et al., 2000). Cultures can be lyophilized. In medium supplemented

FIGURE 223. Electron micrograph of a negatively stained whole cell of *Soehngenia saccharolytica* strain BOR-Y^T showing the flagella. Bar = 1 μ m.

with carbohydrates, cells lyse rapidly in the stationary phase of growth.

Differentiation of the genus *Soehngenia* from other genera

Table 220 lists characteristics differentiating *Soehngenia* from phylogenetically related genera. *Soehngenia* does not grow on creatine and creatinine like *Tissierella creatinini* and *Tissierella praeacuta*.

Tissierella creatinophila and *Clostridium hastiforme* do not grow on carbohydrates. *Soehngenia saccharolytica* does not grow on for-

mate, but it grows on fructose; *Clostridium ultunense* does not grow on fructose, but utilizes formate.

Strain *Soehngenia saccharolytica* has a high G+C content (43 mol%), which distinguishes it from species of the other related genera (28–32 mol%). DNA–DNA hybridization of *Soehngenia saccharolytica* BOR-Y with *Clostridium ultunense* BS and *Tissierella creatinini* DSM 9508, performed by method of De Ley (1970), revealed reassociation values of 9 and 13%, respectively.

Taxonomic comments

Based on detailed phylogenetic analyses of 16S rRNA gene sequences, *Soehngenia* is a deep branch of a clade currently assigned to Family XI *Incertae Sedis* that includes many genera formerly classified within the family *Peptostreptococcaceae* (Ludwig et al., 2009). This clade includes the genus *Tissierella*, with which it possesses the highest sequence similarity, as well as *Parvimonas*, *Anaerococcus*, *Helcococcus*, *Finegoldia*, *Gallicola*, *Peptoniphilus*, *Sporanaerobacter*, *Tepidimicrobium*, and *Sedimentibacter*.

List of species of the genus *Soehngenia*

1. *Soehngenia saccharolytica* Parshina, Kleerebezem, Sanz, Lettinga, Nozhevnikova, Kostrikina, Lysenko and Stams 2003, 1797^{VP}

sac.cha.ro.ly'ti.ca. Gr. n. *sakkaros* sugar; Gr. adj. *lutikos* loosening, dissolving; N.L. fem. adj. *saccharolytica* sugar-dissolving.

Colonies on agar are rhizoid, resemble a snow-flake, and are dark and creamy.

Rod-shaped cells are straight or slightly thickened at the middle and 0.5–0.7 µm × 2–11 µm; they occur singly, in pairs, or in chains. Chains of cells are formed in the stationary growth phase. Terminal or subterminal spores are formed occasionally on pyruvate or in nitrogen-free medium. Anaerobic with fermentative metabolism. Aerotolerant. Able to grow with 50% air. Fixes molecular nitrogen. Sulfite and thiosulfate are weakly used as electron acceptors. Sulfate, dithionite, disulfite, sulfur, and nitrate are not reduced. Benzaldehyde is dismutated to benzoate and benzylalcohol. Catalase-negative. Produces

indole and does not liquefy gelatin. Substrates used as carbon and energy sources include yeast extract, glucose, fructose, sucrose, xylose, arabinose, rhamnose, mannose, ribose, maltose, cellobiose, galactose, melibiose, lactose, cellulose, xylan, mannitol, pyruvate, malate, starch, cysteine, and serine. Vitamins are required for optimal growth. Moderate growth occurs in mineral medium supplemented with 0.2 g/l yeast extract. Abundant growth occurs in the mineral medium with 2 g/l yeast extract plus 10 mmol/l glucose or some other carbohydrates. In the medium supplemented with carbohydrates, cells lyse rapidly in the stationary phase of growth.

Growth temperature range is 15–40°C. The optimum temperature is 30–37°C. The growth pH range 6.0–7.5, and the optimum is around 7.0.

Habitat: anaerobic digester sludge.

DNA G+C content (mol%): 43.0 (T_m).

Type strain: BOR-Y, ATCC BAA-502, DSM 12858.

GenBank accession number (16S rRNA gene): AY353956.

Genus IX. *Sporanaerobacter* Hernandez-Eugenio, Fardeau, Cayol, Patel, Thomas, Macarie, Garcia and Ollivier 2002, 1221^{VP}

GUADALUPE HERNANDEZ-EUGENIO, MARIE-LAURE FARDEAU, JEAN-LOUIS GARCIA AND BERNARD OLLIVIER

Spor.an.a.e.ro.bac'ter. Gr. fem. n. *spora* spore; Gr. pref. *an* not; Gr. n. *aer* air; *anaero* not (living) in air; N.L. n. *bacter* masc. equivalent of Gr. neut. dim. n. *bakterion* rod, staff; N.L. masc. n. *Sporanaerobacter* a spore-forming anaerobic rod.

Cells are strictly anaerobic **rods**, occurring singly or in pairs and motile by a few laterally inserted flagella. Spherical, terminal, oval **spores** which swell the sporangium appear in the cells. **Gram-positive type** cell wall. Mesophilic and moderately thermophilic, growing at up to 50°C. Neutrophilic. **Heterotrophic**. Yeast extract is required for growth on sugars. **Ferments peptides and amino acids** in the presence of yeast extract. Glucose is fermented to acetate, H₂, and CO₂ as the major end products of metabolism. Performs the Stickland reaction using isoleucine as electron donor and glycine or serine as electron acceptors. **Uses elemental sulfur** but not sulfate, thiosulfate, sulfite, nitrate, or nitrite as an electron acceptor.

DNA G+C content (mol%): 32.2 (HPLC).

Type species: *Sporanaerobacter acetigenes* Hernandez-Eugenio, Fardeau, Cayol, Patel, Thomas, Macarie, Garcia and Ollivier 2002, 1221^{VP}.

Further descriptive information

Sporanaerobacter cells are 0.4–0.5 µm in width and 3–5 µm in length and occur singly or in pairs (Figure 224). Cells are

motile by a few laterally inserted flagella. In media appropriate for spore induction, spherical, terminal, oval spores which swell the sporangium appear in the cells. Electron microscopy of sections of cells exhibits a 33 nm thick stratified Gram-stain-positive type cell wall, composed of three dense layers (two thick layers and a thinner middle layer) separated by two light spaces. *Sporanaerobacter* cells grow at temperatures ranging from 25 to 50°C, with an optimum at 40°C, and in the presence of NaCl concentrations ranging from 0 to 4% NaCl, with optimum growth in the absence of NaCl. The optimum pH for growth is around 7.5 and growth occurs between pH 5.5 and 8.5.

Yeast extract is required for growth on sugars. Gelatin and casein are not used as energy sources, but peptone, bio-Trypcase and Trypticase soy are fermented. Small amounts of the following amino acids (around 1 mM) are used as energy sources in the presence of yeast extract (2 g/l): DL-histidine, L-isoleucine, DL-leucine, L-methionine, L-phenylalanine, DL-tryptophan, and DL-valine. In the presence of elemental sulfur as a terminal electron acceptor, the oxidation of the latter amino acids increases significantly (mean 2–3 mM). Lysine (1.7 mM) is only oxidized

FIGURE 224. Photomicrograph of *Sporanaerobacter acetigenes*. Bar = 10 μ m.

in the presence of elemental sulfur. Arginine (4.6 mM) is fermented, and the use of arginine is not improved in the presence of elemental sulfur. Valine is oxidized to isobutyrate, leucine to isovalerate, isoleucine to methyl-2-butyrate, phenylalanine to phenyl acetate, lysine to acetate, and histidine to acetate together with an unidentified product. Glycine and serine may serve as electron acceptors for oxidizing isoleucine. Peptone is fermented into acetate, hydrogen, and carbon dioxide as the major end products of metabolism. Traces of isobutyrate and isovalerate are also detected. Pyruvate is converted to acetate, H_2 , and CO_2 . *Sporanaerobacter* cells can utilize D-glucose, D-ribose, and fumarate, but not D-arabinose, D-fructose, D-galactose, maltose, D- and L-xylose, acetate, propionate, butyrate, valerate, ethanol, n-butanol, n-propanol, malate, and succinate. Acetate is the only fatty acid produced from glucose metabolism. No H_2 is detected from glucose metabolism in the presence of elemental sulfur as the electron acceptor.

Enrichment and isolation procedures

The Hungate technique (Hungate, 1969) is used to isolate *Sporanaerobacter* relatives. *Sporanaerobacter acetigenes* was isolated from an upflow anaerobic sludge blanket (UASB) reactor in Mexico. Enrichments were performed in 120 ml serum bottles using the following basal medium (BM) containing (per liter of distilled water): 1 g NH_4Cl , 3 g K_2HPO_4 , 3 g KH_2PO_4 , 0.2 g $MgCl_2 \cdot 6H_2O$, 0.1 g $CaCl_2 \cdot 2H_2O$, 0.1 g KCl, 0.6 g NaCl, 0.5 g cysteine-HCl, 1 mg resazurin and 10 ml trace mineral element solution (Balch et al., 1979). The pH was adjusted to 7.4 with 10 M KOH. The medium was boiled under a stream of O_2 -free N_2 gas and cooled to room temperature. Five ml aliquots were dispensed into Hungate tubes and 20 ml in serum bottles, under a stream of N_2 - CO_2 (80:20, v/v) gas and the sealed vessels were autoclaved for 45 min at 110°C. Prior to inoculation, $Na_2S \cdot 9H_2O$ and $NaHCO_3$ were injected from sterile stock solutions to final concentrations of 0.04 and 0.2% (w/v), respectively. Peptone (5 g/l) and elemental sulfur (20 mM) were added to basal medium as electron donor and acceptor, respectively. The serum bottle was inoculated with 4 ml of

sludge, corresponding to 10% (v/v) of the final liquid volume (40 ml). After inoculation, the serum bottle atmosphere was changed to H_2 at a final pressure of 2.026×10^5 Pa. The bottles were incubated at 35°C in a controlled temperature room for 2–3 weeks. Isolation was performed in the same medium with N_2 instead of H_2 in the gas phase. Four enrichment series were performed before isolation.

Enrichment cultures were incubated at 35°C for 2–3 weeks. Growth was regarded as positive on the basis of H_2S production. Colonies, 2–3 mm in diameter, appeared after 2 d of incubation at 37°C in roll tubes containing peptone-rich agar medium. Single colonies were picked using the techniques developed by Hungate (1969) and the process of serial dilution in roll tubes was repeated at least twice in order to purify the cultures.

Maintenance procedures

Stock cultures can be maintained on medium described by Hernandez-Eugenio et al. (2002) by monthly transfers. Liquid cultures retained viability after several weeks storage at 4°C, or when lyophilized, or after storage at $-80^\circ C$ in the basal medium containing 20% glycerol (v/v). Viability is best maintained from mid-exponential phase cultures.

Differentiation of the genus *Sporanaerobacter* from other genera

The genus *Sporanaerobacter* represented by only one species, *Sporanaerobacter acetigenes*, is an anaerobic spore-forming micro-organism of the domain *Bacteria* that grows heterotrophically on carbohydrates, peptones, and amino acids. A mixture of volatile fatty acids, including acetate, isovalerate, and isobutyrate, together with H_2 and CO_2 , are produced from peptone fermentation, but acetate is the only fatty acid produced from glucose metabolism. In this respect, this bacterium is an acetogen. Its inability to use H_2 as the electron donor and CO_2 as the electron acceptor to produce acetate indicates that it is not a homoacetogenic bacterium (Ljungdahl et al., 1989). Analysis of the 16S rRNA gene sequence of this isolate indicates that it is a member of the order *Clostridiales*, cluster XII (Figure 225), as defined by Collins et al. (1994). This cluster comprises *Clostridium* species (e.g., *Clostridium hastiforme*, *Clostridium acidurici*, *Clostridium purinilyticum*, and *Clostridium ultunense*), *Sedimentibacter* species (e.g., *Sedimentibacter saalensis* and *Sedimentibacter hydroxybenzoicus*), *Tissierella* species, *Soehngenia saccharolytica*, *Eubacterium angustum*, and the recently described thermophilic anaerobes isolated from extreme environments which include *Thermohalobacter berrensensis*, *Caloranaerobacter azorensis*, and *Garciella nitratreducens* (Cayol et al., 2000; Miranda-Tello et al., 2003; Wery et al., 2001). In the current volume, many members of this cluster, including *Sporanaerobacter*, are classified within Family XI *Incertae Sedis*. Interestingly, this cluster includes acetogenic bacteria (e.g., *Clostridium acidurici*, *Clostridium purinilyticum*, and *Eubacterium angustum*) that produce acetate, ammonium, and CO_2 from purines but, in contrast to *Sporanaerobacter*, these micro-organisms are described as asaccharolytic (Beuscher and Andreesen, 1984; Ljungdahl et al., 1989). Similarly, close relatives of *Sporanaerobacter acetigenes*, *Clostridium hastiforme*, *Tissierella praeacuta*, and *Sedimentibacter* species are also unable to use sugars (Breitenstein et al., 2002; Cato et al., 1986; Farrow et al., 1995; Hippe et al., 1992). *Sporanaerobacter acetigenes* is a moderately thermophilic

FIGURE 225. Phylogenetic tree based on 16S rRNA gene sequence comparison and obtained by a neighbor-joining algorithm (PHYLIP package), indicating the position of *Sporanaerobacter acetigenes* among members of the former cluster XII of the *Clostridiales*. *Paenibacillus kribbensis* was used as outgroup. Scale bar represents 5 substitutions per hundred nucleotides.

micro-organism but, unlike *Thermohalobacter berrensis* which was isolated from a solar saltern, *Garciella nitratreducens* which was isolated from an oilfield separator, and *Caloranaerobacter azorensis* which was isolated from a deep-sea hydrothermal, it does not grow at temperatures higher than 50°C (Cayol et al., 2000; Miranda-Tello et al., 2003; Wery et al., 2001). *Sporanaerobacter acetigenes* differs from *Clostridium ultunense* (Schnurer et al., 1996) in its ability to reduce elemental sulfur and in the range of sugars and amino acids used. In contrast to *Sporanaerobacter acetigenes*, *Clostridium ultunense* produces formate as well as acetate from glucose fermentation. Finally the DNA G+C content of *Soehngenia saccharolytica* (42 mol%) (Parshina et al., 2003) is higher than that of *Sporanaerobacter acetigenes* (32.2 mol%).

Sporanaerobacter acetigenes facultatively uses elemental sulfur as a terminal electron acceptor, producing sulfide. The ability to use inorganic sulfur-containing compounds (e.g., thiosulfate and/or elemental sulfur) has been reported for several members of the *Clostridiales*. They include species of *Thermoanaerobacter* and *Thermoanaerobacterium* described as using thiosulfate as an electron acceptor (Fardeau et al., 1994; Fardeau et al., 1993; Fardeau et al., 1997; Faudon et al., 1995; Lee et al., 1993; Schink and Zeikus, 1983). *Thermoanaerobacterium* species reduce thiosulfate to elemental sulfur, whereas *Thermoanaerobacter* spe-

cies reduce both thiosulfate and elemental sulfur to sulfide. Other fermentative bacteria also belonging to the *Clostridiales* that have the ability to reduce thiosulfate and/or elemental sulfur to sulfide have been isolated successfully, particularly from oilfield environments (Fardeau et al., 1993; Magot et al., 1997; Ravot et al., 1999; Ravot et al., 1997) but also from freshwater sediments (Hermann et al., 1987). None of these micro-organisms are phylogenetically closely related to *Sporanaerobacter acetigenes*. These results also suggest that thiosulfate and/or sulfur reduction might be a quite widespread metabolic trait within members of the order *Clostridiales*, which gives them a metabolic advantage through their ability to oxidize amino acids, as reported already for other micro-organisms belonging to this order (Fardeau et al., 1997; Faudon et al., 1995; Magot et al., 1997).

Taxonomic comments

Sporanaerobacter is a recently defined genus consisting of one species (*Sporanaerobacter acetigenes*). Phenotypic, genotypic, and phylogenetic characteristics clearly place it within Family XI *Incertae Sedis* of the *Clostridiales*. However, further analysis of this strain, as well as the isolation and characterization of more species which are representative of this genus, are required to confirm the taxonomic position of this genus.

List of species of the genus *Sporanaerobacter*

1. ***Sporanaerobacter acetigenes*** Hernandez-Eugenio, Fardeau, Cayol, Patel, Thomas, Macarie, Garcia and Ollivier 2002, 1221^{VP}

a.ce.ti.ge'nes. L. n. *acetum* vinegar, acetic acid; Gr. v. *gennaio* produce; N.L. adj. *acetigenes* producing acetate.

In addition to the properties listed in the genus description (Hernandez-Eugenio et al., 2002), the following properties are reported. Cells are $0.4\text{--}0.5 \times 3\text{--}5\ \mu\text{m}$. Electron microscopy of sections of cells reveals a 33-nm-thick, layered Gram-positive type cell wall, composed of three dense layers (two thick layers and a middle thinner layer) separated by two light spaces. Grows at temperatures ranging from 25 to 50°C, with optimum growth at 40°C. Grows in the presence of NaCl at concentrations ranging from 0 to 4% NaCl, with optimum growth in the absence of NaCl. The optimum pH for growth is around 7.5 and growth occurs between pH 5.5 and 8.5.

Heterotrophic. Gelatin and casein are not used as energy sources, but peptone, bio-Trypcase and Trypticase soy are fermented. The following amino acids are used as energy sources in the presence of yeast extract (2g/l): arginine, histidine, isoleucine, leucine, methionine, phenylalanine, tryptophan, and valine. In the presence of elemental sulfur as a terminal electron acceptor, the use of the amino acids cited above, with the exception of arginine, is improved. Lysine is only oxidized in the pres-

ence of elemental sulfur. Valine is oxidized to isobutyrate, leucine to isovalerate, isoleucine to methyl-2-butyrate, phenylalanine to phenyl acetate, lysine to acetate, and histidine to acetate and an unidentified compound. Peptone is fermented to acetate as the major end product of metabolism. Traces of isobutyrate and isovalerate are also detected. Pyruvate is converted to acetate, H_2 , and CO_2 . Utilizes D-glucose, D-ribose, and fumarate, but not D-arabinose, D-fructose, D-galactose, maltose, D- or L-xylose, acetate, propionate, butyrate, valerate, ethanol, *n*-butanol, *n*-propanol, malate or succinate. Acetate is the only fatty acid produced from glucose metabolism. Adverse effects on animals and humans are not known. Because of its ability to degrade amino acids and peptides, the possibility of harmful effects cannot be excluded. Cautious handling and autoclaving of cultures before disposal is recommended. Isolated from a UASB reactor in Mexico.

DNA G+C content (mol%): 32.2 (HPLC).

Type strain: Lup 33, CIP 106730, DSM 13106.

GenBank accession number (16S rRNA gene): AF358114.

Genus X. *Tissierella* Collins and Shah 1986, 463^{VP}, emend. Farrow, Lawson, Hippe, Gauglitz and Collins 1995, 439, emend. Bae, Park, Chang, Rhee and Park 2004, 948

HAROUN N. SHAH AND JOHN V. HOOKEY

Tis.si.er.el.la. N.L. dim. ending *-ella*; N.L. fem. dim. n. *Tissierella* named after Henry Tissier, who first described the organism that was originally isolated from the feces of an infant.

Rod-shaped nonsporulating cells, $2\text{--}8 \times 0.6\text{--}1.1\ \mu\text{m}$. Gram-stain-positive or -negative. Cells are either nonmotile, or motile via peritrichous flagella that occur singly, in pairs, or in short chains. **Obligately anaerobic**. Colonies are distinct, flat or low convex, white to gray and grow optimally at 37°C. **Weakly or non-fermentative**. **Creatine or creatinine are required for growth** and typically produce acetate, ammonia, and CO_2 . Predominant metabolic end products in peptone-yeast extract-glucose broth are acetic, butyric, and isovaleric acids. Nonhydroxylated and 3-hydroxylated long-chain

fatty acids that are straight-chained saturated and *iso*-methyl branched chain types. *meso*-Diaminopimelic acid or D-ornithine are present in the cell-wall peptidoglycan. **Respiratory menaquinones are absent**. Isolated from various infected sites in humans, human feces, and environmental sources. The 16S rRNA gene sequence similarity between the species varies from ~95 to 89%.

DNA G+C content (mol%): 28–32.

Type species: *Tissierella praeacuta* (Tissier 1908) Collins and Shah 1986, 463^{VP}.

List of species of the genus *Tissierella*

1. *Tissierella praeacuta* (Tissier 1908) Collins and Shah 1986, 463^{VP} (*Bacteroides praeacutus* Tissier 1908, 193)

prae.cu.ta. L. fem. adj. *praeacuta* sharpened to a point, sharpened.

Although well characterized, it has variously been assigned to diverse genera as *Bacteroides* (Moore and Holdeman, 1973), *Coccobacillus* (Tissier, 1908), *Fusibacterium* (Hoffman, 1957), and *Zuberella* (Prévot, 1933).

Cells ($2\text{--}8 \times 0.6\text{--}0.9\ \mu\text{m}$) are motile via peritrichous flagella that occur singly or in pairs. Gram-stain-positive. On blood agar, colonies are small, circular, low convex, smooth, and gray in color. Optimum temperature for growth is 37°C. Nitrate reduction, hippurate hydrolysis, and gelatin liquefaction are variable. Urease and indole are not produced. Esculin is not hydrolyzed and H_2S is produced in SIM (Difco) broth. 6-Phosphogluconate dehydrogenase is present, whereas the dehydrogenases (glucose-6-phosphate, glutamate, and malate) are not. Nonhydroxylated and 3-hydroxylated long-

chain fatty acids (which are straight-chained, saturated, and *iso*-methyl branched chain types) and 3-methyltetradecanoic (*iso*-C_{15:0}) acid predominate. *meso*-Diaminopimelic acid is present (Hammann and Werner, 1981), and 2-keto-3-deoxyoctulosonic acid or heptose are absent (Hofstad, 1974) in the cell-wall peptidoglycan. Menaquinones are absent.

Isolated from feces of infants and adults, gangrenous lesions, lung abscesses, and blood.

The previously proposed species *Clostridium hastiforme* and *Tissierella praeacuta* appear to be similar (Bae et al., 2004). The 16S rDNA sequence similarity to "*Clostridium hastiforme*" is 95.2%. There has been considerable progress made in recent years in establishing the phylogenetic relationships within the genus *Bacteroides* and related taxa (Paster et al., 1994). A comparative analysis demonstrated that *Tissierella praeacuta* was a member of the *Clostridium* subphylum of the Gram-positive bacteria (Farrow et al., 1995), and a polyphasic taxonomic study later concluded that the type strains

were similar (Bae et al., 2004). The description of the type strain is that of the species, except gelatin is hydrolyzed and nitrate reduced.

DNA G+C content (mol%): 28.0 (T_m).

Type strain: ATCC 25539, CCUG 27825, LMG 8203, NCTC 703038, NCTC 11158.

GenBank accession number (16S rRNA gene): X80833.

2. **Tissierella creatinini** Farrow, Lawson, Hippe, Gauglitz and Collins 1995, 439^{VP}

cre.a.ti.ni'ni. N.L. gen. n. *creatinini* of creatinine.

Cells are rod-shaped, $3.5 \times 1.0 \mu\text{m}$ in size, and occur mostly singly or in pairs. Nonmotile and non-sporeforming. Gram-stain-positive and surrounded by a slime capsule. Growth occurs at 20–39°C, and the optimum pH is 8.3. Sodium chloride and sodium bicarbonate are required for good growth. Creatinine and related nitrogen-containing compounds, with the notable exception of creatine, are metabolized. Biochemical tests for gelatin hydrolysis, production of lipase, lecithinase, indole and urease, reduction of nitrate, and hemolysis are negative. Unsaturated fatty acids ($C_{18:1\ c11/12}$) predominate, with minor amounts of straight-chained saturated, methyl-branched, and 3-hydroxylated long-chain fatty acids. Unlike the cell wall of *Tissierella praeacuta*, which is based on meso-diaminopimelic acid, that of strain BN11 contains D-ornithine as the dibasic amino acid. The cell-wall murein is type A4 β (with interpeptide bridge composed of L-ornithine with D-glutamic acid). Respiratory menaquinones are not produced. Shares 90.6% and 90.1% 16S rDNA sequence similarity to *Tissierella praeacuta* and “*Clostridium hastiforme*,”

respectively. Isolated from a sugar-refinery wastewater pond.

DNA G+C content (mol%): 32.0 (T_m)

Type strain: BN11, CIP 104584, DSM 9508.

GenBank accession number (16S rRNA gene): X75909.

3. **Tissierella creatinophila** Harms, Schleicher, Collins and Andreesen 1998, 991^{VP}

cre.at.in.o'phil.la. Gr. adj. *kreatinos* creatine, referring to meat; Gr. adj. *philos* loving; N.L. fem. adj. *creatinophila* creatine-loving.

Rod-shaped, $2-6 \times 0.7-1.1 \mu\text{m}$, motile via peritrichous flagella. Gram-stain-negative, either single cells or in chains. Non-sporeforming and non-fermentative. Colonies on PYG (peptone yeast glucose) agar are white to gray, small, circular, flat with a rough surface.

Unlike *Tissierella creatinini*, there is no growth on nitrogenous compounds other than creatinine and creatine. Degrades creatinine via creatine, sarcosine, and glycine to produce acetate, monomethylamine, ammonia, and CO₂. Creatine aminohydrolase is highly significant in medical diagnostics since the rate of creatinine clearance is an indicator of renal function (Siedel et al., 1988). Nitrate, sulfur and sulfate are not reduced. Cell-wall chemistry is unknown. No respiratory menaquinones. This species shares 95% 16S rDNA sequence similarity to other members of the genus *Tissierella*. Isolated from anaerobic human sewage sludge plant. Pathogenicity is unknown.

DNA G+C content (mol%): 30.0 (HPLC).

Type strain: KRE 4, DSM 6911.

GenBank accession number (16S rRNA gene): X80227.

Family XII. Incertae Sedis

Members of this group were previously assigned to the “*Peptostreptococcaceae*” or *Clostridiaceae* by Garrity et al. (2005). Subsequent analyses suggest that these genera are not closely related to either group or any other previously described family. For that reason, they are assigned to their own family *incertae sedis*.

Genus I. **Acidaminobacter** Stams and Hansen 1985, 223^{VP} (Effective publication: Stams and Hansen 1984, 335.)

THEO A. HANSEN

A.cid.a.min.o.bac'ter. L. n. *acidum* acid; N.L. neut. n. *aminum* amine; N.L. n. *bacter* the masc. equivalent of Gr. neut. n. *baktron* a staff or rod; N.L. masc. n. *Acidaminobacter* the amino acid rod.

Rod-shaped bacteria with pointed ends; Gram-stain-negative. Endospores not formed. **Chemo-organotrophic fermentative metabolism. Strictly anaerobic.** Amino acids are major energy sources. Acetate is the major fermentation product. Lactate, succinate, butyrate, and ethanol not formed. Growth on many substrates stimulated by or dependent on the presence of hydrogen-utilizing bacteria or archaea. Mesophilic.

DNA G+C content (mol%): 48.1 (T_m).

Type species: **Acidaminobacter hydrogenoformans** Stams and Hansen 1985, 223^{VP} (Effective publication: Stams and Hansen 1984, 336.).

Further descriptive information

When it was first described, *Acidaminobacter* was unique because its growth on several amino acids was shown to be stimulated by or dependent on the presence of hydrogen-utilizing bacteria or archaea (such as sulfate reducers or methanogens). Growth on alanine, for instance, was only possible if the reducing equivalents (hydrogen and possibly formate as well) were consumed by a syntrophic partner (Stams and Hansen, 1984). The thermodynamically difficult step is the conversion of the amino acid to the corresponding keto acid with the formation of hydrogen; even with the assumption of a high ratio of the concentration of the amino acid over the keto acid, only at hydrogen concentrations in the order of 1–10 Pa does the free energy change become negative.

α -Amino acid \rightarrow α -Keto acid + H₂ + NH₄⁺ standard free energy change approximately +55–60 kJ

In pure culture, *Acidaminobacter hydrogenoformans* fermented 1 mol of glutamate to approximately 2 mol of acetate, 1 mol of bicarbonate, 1 mol of NH₄⁺, and 1 mol of H₂ via a route with 3-methylaspartate as an intermediate. In mixed cultures with a hydrogenotrophic partner, the fermentation yielded less acetate and up to 0.47 mol of propionate per mol of glutamate; most likely, propionate formation occurred via 2-oxoglutarate and succinyl-CoA with the concomitant production of 2 H₂.

Positive effects of hydrogenotrophic anaerobes on fermentations of amino acids have since been described for a number of mesophilic bacteria including *Clostridium sporogenes* (Wildenauer and Winter, 1986; Winter et al., 1987), *Eubacterium acidaminophilum* (Zindel et al., 1988), *Aminobacterium* spp. (Baena et al., 2000, 1998), *Aminomonas paucivorans* (Baena et al., 1999a), and some thermophiles, e.g., *Gelria glutamica* (Plugge et al., 2002).

Enrichment and isolation procedures

Acidaminobacter has been obtained by direct anaerobic isolation from black surface mud of the Ems-Dollard estuary at the border between the Netherlands and Germany. Roll tubes with glutamate medium were used (Stams and Hansen, 1984). Strain glu 65 was the most numerous glutamate-fermenting bacterium.

Maintenance procedures

DSMZ medium 292 containing glycine or another suitable energy source can be used for routine cultivation. For long-term preservation, the organism can be stored in ampoules in medium supplemented with 8% glycerol under liquid nitrogen or at –80°C.

Differentiation of the genus *Acidaminobacter* from other genera

Strictly anaerobic, mesophilic, nonsporeforming, rod-shaped bacteria that mainly ferment amino acids (often dependent on or stimulated by hydrogenotrophic anaerobes) are found in the genera *Acidaminobacter* (Stams and Hansen, 1984), *Eubacterium* (Zindel et al., 1988), *Aminobacterium* (Baena et al., 2000, 1998), and *Aminomonas* (Baena et al., 1999a); see Table 221. Among these taxa, on the basis of 16S rRNA gene sequence comparisons, only *Acidaminobacter* (Meijer et al., 1999) and *Eubacterium acidaminophilum* (Baena et al., 1999b) are members of cluster XI of the *Clostridium* subphylum of the *Firmicutes* (low G+C Gram-positives) (Collins et al., 1994).

Taxonomic comments

The phylogenetic position of *Acidaminobacter* in cluster XI of the *Clostridium* subphylum is such that it is clearly a separate genus (Meijer et al., 1999). Both phenotypically and phylogenetically, the differences with other members of cluster XI are rather large. *Acidaminobacter* shares several characteristics with *Eubacterium acidaminophilum*, but it is not its closest relative (Baena et al., 1999b). *Eubacterium acidaminophilum* does not group with the type species of *Eubacterium*, *Eubacterium limosum*, which is a member of cluster XV (Collins et al., 1994). Other species, *Clostridium halophilum* and *Clostridium litorale*, which group with *Acidaminobacter* have considerable phenotypic differences with *Acidaminobacter* (Fendrich et al., 1990; Table 221). For these reasons it has been placed in a family *incertae sedis* in the current volume along with *Fusibacter* and *Guggenheimella*.

List of species of the genus *Acidaminobacter*

1. ***Acidaminobacter hydrogenoformans*** Stams and Hansen 1985, 223^{VP} (Effective publication: Stams and Hansen 1984, 336.)

hydro.ge.no.form'ans. N.L. n. *hydrogenium* hydrogen; L. part. adj. *formans* forming; N.L. adj. *hydrogenoformans* hydrogen-forming.

Characteristics are as described for the genus, with the following additional features. Rod-shaped cells, 0.5–0.6 × 1.5–3.7 μm, with pointed ends, singly or in pairs. Glutamate, histidine, cysteine, serine, glycine, adenine, pyruvate, and citrate fermented in pure culture. Acetate is the major fermentation product. In mixed cultures with hydrogen-utilizing sulfate-reducing bacteria (e.g., *Desulfovibrio*) or hydrogen-

utilizing archaea (e.g., *Methanospirillum*), several other amino acids and malate utilized as well. Branched-chain fatty acids formed from branched-chain amino acids. Propionate, in addition to acetate, formed from glutamate and histidine; lower pH limit for growth on glutamate is 6.7. Lactate, ethanol, succinate, glucose, fructose, and aspartate are not utilized. Sulfate and nitrate not reduced. Sulfide required. Indole formed. No catalase; no cytochromes. Temperature range for growth is 15–42°C, optimum 30°C.

DNA G+C content (mol%): 48.1 (*T_m*).

Type strain: glu 65, CIP 106102, DSM 2784.

GenBank accession number (16S rRNA gene): AF016691.

Genus II. ***Fusibacter*** Ravot, Magot, Fardeau, Patel, Thomas, Garcia and Ollivier 1999, 1145^{VP}

GILLES RAVOT, JEAN-LOUIS GARCIA, MICHEL MAGOT AND BERNARD OLLIVIER

Fu.si.bac'ter. L. n. *fusus* a spindle; N.L. n. *bacter* masc. equivalent of Gr. neut. dim. n. *bakterion* rod; N.L. masc. n. *Fusibacter* a small spindle-shaped rod.

Spindle-shaped rods with cells that are 1 × 2–5 μm, and occurring singly or in pairs. **Motile by one to four peritrichous flagella.** Spores are not formed. Gram-stain-positive. Chemo-organotrophic and **obligately anaerobic.** Requires yeast extract for growth. Oxidizes a few carbohydrates to butyrate, acetate, CO₂, and H₂. Uses thiosulfate and sulfur as electron acceptors during glucose fermentation with production of H₂S. **Mesophilic, neutrophilic, and halotolerant.**

DNA G+C content (mol%): 43 (HPLC).

Type species: ***Fusibacter paucivorans*** Ravot, Magot, Fardeau, Patel, Thomas, Garcia and Ollivier 1999, 1145^{VP}

Further descriptive information

Fusibacter paucivorans, isolated from an oil reservoir water, reduces thiosulfate to sulfide. The use of thiosulfate as an electron acceptor causes a shift in the flow of electrons, favoring H₂S production as already reported for *Thermoanaerobacter* species (Fardeau et al., 1996). In *Fusibacter paucivorans*, this results in channeling of the electrons away from butyrate to acetate, thereby increasing its concentration with concomitant increases in H₂S production (Table 222). Thiosulfate reduction is a common physiological trait exhibited by many fermentative mesophilic, thermophilic, and hyperthermo-

TABLE 222. Fermentation of glucose in the presence and absence of thiosulfate by *Fusibacter paucivorans*

Culture conditions ^a	Amount of substrate used (mM)	Amount of end products formed (mM)					Ratio of acetate produced/sugar consumed
		Acetate	Butyrate	CO ₂ ^b	H ₂ ^b	H ₂ S

Glucose + thiosulfate	9.9	12.2	3.0	20.4	7.1	11.5	1.23

^aSodium thiosulfate was added at a final concentration of 20 mM.^bMillimolar equivalents.**FIGURE 226.** (a) Phase-contrast micrograph of *Fusibacter paucivorans*. Bar = 10 μm. (b) Electron micrograph of a negatively stained culture of *Fusibacter paucivorans* showing one or two peritrichous flagella. Bar = 2 μm. (Reprinted with permission from Ravot et al., 1999. *Int. J. Syst. Bacteriol.* 49: 1141–1147.)

philic micro-organisms of the domain *Bacteria* also originating from oilfield ecosystems (Fardeau et al., 1993, 1997; Jeanthon et al., 1995; Magot et al., 1994, 1997a, 1997b; Ravot et al., 1995a, 1997, 1995b). Significant amounts of thiosulfate have been detected in oilfield facilities where it is thought to increase biocorrosion (Crolet and Magot, 1996; Magot et al., 1994), but the ecological significance of thiosulfate reduction in oil reservoirs is so far unknown.

Enrichment and isolation procedures

Fusibacter paucivorans was isolated from a reservoir water sample from an offshore oil-producing well (Emeraude oil-field) in Congo, central Africa. The *in situ* temperature was 35–40°C and the concentration of sodium chloride was 40 g/l (total salinity, 53 g/l). A one-liter sample was collected at the well head as described by Bernard et al. (1992), and culture broths were immediately inoculated. Enrichments were at 30°C without agitation by inoculating directly a 2-ml sample from the reservoir water into a basal medium containing (per liter of distilled water) 1 g NH₄Cl, 0.3 g K₂HPO₄, 0.3 g KH₂PO₄, 3 g MgCl₂ · 6H₂O, 0.1 g CaCl₂ · 2H₂O, 40 g NaCl, 1 g KCl, 0.5 g cysteine-HCl, 0.5 g CH₃COONa, 1 g yeast extract (Difco Laboratories), 1 g bio-Trypticase (bioMérieux), 10 ml of the trace element solution of Balch et al. (1979), and 0.1 mg resazurin.

The pH was adjusted to 7.3 with 10 M KOH. The medium was boiled under a stream of O₂-free N₂ gas and cooled to room temperature. Five- or twenty-milliliter aliquots were dispensed into Hungate tubes or serum bottles, respectively, under a stream of N₂/CO₂ (4:1, v/v), and the vessels were sealed and autoclaved for 45 min at 110°C. Prior to inoculation, Na₂S · 9H₂O, NaHCO₃, and sodium thiosulfate were injected from sterile anaerobic stock solutions, to final concentrations of 0.04% (w/v), 0.2%, and 20 mM, respectively. The final pH was 7.2. The strain was purified by repeated isolation on Petri dishes containing the same medium solidified with 1.6% (w/v) agar as already reported (Magot et al., 1997a, 1997b; Ravot et al., 1997). Incubation was performed in an anaerobic glove box at 30°C.

Differentiation of the genus *Fusibacter* from other genera

Fusibacter paucivorans is an anaerobic, nonsporulating, spindle-shaped mesophilic flagellated rod (Figure 226) which possesses a Gram-positive cell-wall ultrastructure and reduces thiosulfate and sulfur to sulfide. Phylogenetic analysis of 16S rRNA indicates that it is a member of the *Clostridium* phylum and belongs to cluster XI, which includes *Clostridium* spp. (Collins et al., 1994) together with members of genera *Acidaminobacter*, *Tindallia*, *Alka-*

^dData from Fendrich et al. (1990).

liphilus, and *Caminicella* (Alain et al., 2002; Kevbrin et al., 1998; Stams and Hansen, 1984; Takai et al., 2001). This cluster is taxonomically heterogeneous, containing non-spore-forming species such as *Acidaminobacter hydrogenoformans* and *Tindallia magadiensis*. The closest phylogenetic relatives of *Fusibacter paucivorans* are *Acidaminobacter hydrogenoformans* (92% similarity; Stams and Hansen, 1984) followed by *Clostridium halophilum* (90% similarity; Fendrich et al., 1990) and *Alkaliphilus transvaalensis* (mean similarity of 89%; Kevbrin et al., 1998). In the analyses performed for this volume, *Fusibacter* is classified in a family *incertae sedis* with *Acidaminobacter* and *Guggenheimella*. In addition to the significant phylogenetic difference (mean of 10%), the following genotypic and phenotypic traits distinguish *Fusibacter paucivorans* from its three nearest taxonomically validated phylogenetic neighbors (Table 223): (i) In contrast

to *Clostridium halophilum* and *Acidaminobacter transvaalensis*, *Fusibacter paucivorans* failed to produce spores; (ii) the G+C content of DNA from *Fusibacter paucivorans* is 43 mol% whereas that of *Clostridium halophilum* and *Acidaminobacter transvaalensis* DNA is 27 and 36.4 mol%, respectively; (iii) the substrate range of *Fusibacter paucivorans* differed markedly from that of *Acidaminobacter hydrogenoformans* and *Acidaminobacter transvaalensis*, both micro-organisms being unable to ferment sugars; (iv) the end products of carbohydrate fermentation are different from that of *Clostridium halophilum*; in contrast to *Fusibacter paucivorans*, ethanol and lactate are produced by *Clostridium halophilum*.

List of species of the genus *Fusibacter*

1. *Fusibacter paucivorans* Ravot, Magot, Fardeau, Patel, Thomas, Garcia and Ollivier 1999, 1145^{VP}

pau.ci.vo'rans. L. adj. *paucus* few; L. v. *voro* to devour; N.L. part. adj. *paucivorans* intended to mean a bacterium that utilizes few substrates.

Cells are spindle-shaped rods (1 × 2–5 µm), occur singly or in pairs, and possess one to four peritrichous flagella. Cells stain Gram-positive.

Round colonies (diameter, 1 mm) are present after 8 d incubation at 37°C.

Chemo-organotrophic and obligately anaerobic member of the domain *Bacteria*. Utilizes D-cellobiose, fructose, glucose, D-mannitol, and D-ribose but not arabinose, dulcitol, galactose, lactose, maltose, mannose, melibiose, raffinose, rhamnose, sorbitol, sorbose, sucrose, trehalose, xylose, cel-lulose, starch, formate, acetate, butyrate, lactate, propi-

onate, methanol, bio-Trypticase, Casamino acids, or gelatin. Requires yeast extract for growth. The end products of glucose fermentation are butyrate, acetate, CO₂, and H₂. Uses thiosulfate and sulfur as electron acceptors during glucose fermentation. H₂S is produced from thiosulfate and sulfur reduction.

The optimum temperature for growth is 37°C; temperature range between 20 and 45°C. The optimum pH is 7.3; growth occurs between pH 5.7 and pH 8.0. Halotolerant; the optimum sodium chloride concentration for growth is between 0 and 3% (w/v); growth occurs at NaCl concentrations ranging between 0 and 10%.

Isolated from an oil-producing well.

DNA G+C content (mol%): 43 (HPLC).

Type strain: SEBR 4211, DSM 12116.

GenBank accession number (16S rRNA gene): AF050099.

Genus III. **Guggenheimella** Wyss, Dewhirst, Paster, Thurnheer and Luginbühl 2005, 669^{VP}

THE EDITORIAL BOARD

Gug.gen.heim.el'la. L. dim. suff. *-ella*; N.L. fem. n. *Guggenheimella* after the Swiss microbiologist Bernhard Guggenheim.

Short to coccoid, non-spore-forming rods. Gram-stain-positive. Nonmotile. **Obligately anaerobic.** Assacharolytic. Cell wall contains the diamino acid ornithine.

DNA G+C content (mol%): 44.4.

Type species: Guggenheimella bovis Wyss, Dewhirst, Paster, Thurnheer and Luginbühl 2005, 669^{VP}.

Further descriptive information

Phylogenetic analysis of the 16S rRNA gene sequence places the genus within the class *Clostridia* and phylum *Firmicutes*. Its closest relative is *Tindallia magadiensis*. The major fatty acids are C_{16:0} (33%), C_{18:1cis9} (24%), C_{18:2cis9'12} (22%), and C_{18:0} (16%). The cell-wall murein is type A4β containing L-Orn-D-Asp.

Complex components (yeast extract, peptone, and serum) are required for growth.

The two reported strains (OMZ 913^T and OMZ 915) were isolated from diseased tissue surgically removed from the hooves of heifers with dermatitis digitalis in Switzerland—the only known habitat. Isolation was accomplished by dilution

in OMIZ-Pat medium containing (per liter) 10 ml heat-inactivated human serum, 1 mg rifampin, 100 mg fosfomycin, 5 mg polymyxin, and 30 mg nalidixic acid. Stocks cultures are maintained by the addition of glycerol (15% v/v) to well grown liquid cultures and stored frozen at -80°C or in liquid nitrogen.

Differentiation of the genus *Guggenheimella* from other closely related genera

Unlike its relatives (*Eubacterium brachy*, *Eubacterium limosum*, *Eubacterium nodatum*, *Eubacterium saphenum*, *Eubacterium sulci*, *Mogibacterium timidum*, and *Tindallia magadiensis*), *Guggenheimella* has higher mol% G+C and displays chymotrypsin-like activity. It is more fastidious than *Tindallia magadiensis* (which does not require yeast extract, peptone, and serum) and less fastidious than *Eubacterium saphenum* (which does require L-lysine, instead of L-arginine, and fetal bovine serum). There is also a difference in fatty acid production between *Guggenheimella* (butyrate and minor amounts of isovalerate, isobutyrate, propionate and acetate) and *Tindallia magadiensis* (mainly acetate, propionate, and isovalerate).

List of species of the genus *Guggenheimella*1. ***Guggenheimella bovis*** Wyss, Dewhirst, Paster, Thurnheer and Luginbühl 2005, 669^{VP}

bo'vis. L. gen. n. *bovis* of the cow, referring to the source of isolation.

Cells are short rods ($0.4 \times 0.5\text{--}1.5\ \mu\text{m}$) that grow into shiny, white opaque colonies (0.5 mm in diameter) on OMIZ-Pat agar or Columbia blood agar in Gas-Pak jars after 7–10 d at 37°C , or as a suspension in OMIZ-Pat liquid, with turbidity visible within 3 d and marked change in phenol red indicator to violet.

Growth occurs at mesophilic temperatures (but not at 25 or 45°C) and pH 6.5–9.0, with the optimum being pH 7.5–8.0. API ZYM detects acid and alkaline phosphatases, C4 and C8 esterases, leucine arylamidase, chymotrypsin, and naphthol phosphohydrolase, but not trypsin, α - and

β -galactosidases, α - and β -glucosidases, lipase C14, cystyl arylamidase, valine arylamidase, β -glucuronidase, *N*-acetyl- β -glucosaminidase, α -mannosidase, and α -fucosidase. Growth is not affected by D-arabinose, L-arabinose, D-cellobiose, D-fructose, D-fucose, L-fucose, D-galactose, D-galacturonic acid, D-glucose, D-glucuronic acid, glycogen, D-lactose, D-maltose, D-mannitol, D-mannose, D-melibiose, L-rhamnose, D-ribose, L-sorbose, starch, D-sucrose, D-trehalose, D-xylose, and L-xylose. Growth in OMIZ-Pat is resistant to fosfomycin (100 mg/l), rifampin (1 mg/l), polymyxin (5 mg/l), and nalidixic acid (30 mg/l) alone or in combination.

For all other characteristics, refer to the genus description.

DNA G+C content (mol%): 44.4 (HPLC).

Type strain: OMZ 913, CIP 108087, DSM 15657.

GenBank accession number (16S rRNA gene): AY272039.

Family XIII. Incertae Sedis

Previously assigned to the “*Eubacteriaceae*” by Garrity et al. (2005), subsequent analyses suggest that these genera, while closely related to each other, are not closely related to

Eubacterium or a member of any other previously described family. For that reason, they are assigned to their own family *incertae sedis*.

Genus I. *Anaerovorax* Matthies, Evers, Ludwig and Schink 2000, 1593^{VP}

BERNHARD SCHINK

An.a.e.ro.vo'rax. Gr. suff. *an* non; Gr. n. *aer* air; L. adj. *vorax* voracious; N.L. masc. n. *Anaerovorax* an anaerobic voracious bacterium.

Strictly anaerobic chemoorganotrophic bacteria of fermentative metabolism, nonphotosynthetic; inorganic electron acceptors not used. Typical cell-wall structure of Gram-positive bacteria without an outer membrane but Gram-negative staining. Non-sporeforming.

Chemoorganotrophic, fermentative type of metabolism, using preferentially amino acid derivatives as substrate. Media containing a reductant are necessary for growth. Catalase negative. Isolated from anoxic freshwater or marine sediments.

DNA G+C content (mol%): 29.6 ± 1.0.

Type species: *Anaerovorax odorimutans* Matthies, Evers, Ludwig and Schink 2000, 1593^{VP}.

Further descriptive information

The only described species so far, *Anaerovorax odorimutans*, was isolated as a strictly anaerobic bacterium growing with the biogenic amine putrescine (1,4-diaminobutane) as the only source of carbon and energy. Such primary amines are formed during oxygen-limited decomposition of organic matter rich in protein. Clostridia, pseudomonads, lactic acid bacteria, and some enterobacteria produce biogenic amines, e.g., putrescine or cadaverine (1,5-diaminopentane), by decarboxylation of ornithine or lysine (Andreesen et al., 1989; Geornaras et al., 1995; Madigan et al., 1997). These putrid-smelling and often toxic compounds (“ptomaines”) are also released in food, e.g., in ripening cheese (Stratton et al., 1991; Ten Brink et al., 1990).

In pure culture, the isolated strains of *Anaerovorax odorimutans* ferment putrescine to acetate, butyrate, and hydrogen (Matthies et al., 2000, 1989) according to the following equation: $10 \text{ putrescine}^{2+} + 26\text{H}_2\text{O} \rightarrow 6 \text{ acetate}^- + 7 \text{ butyrate}^- + 20\text{NH}_4^+ + 16\text{H}_2 + 13\text{H}^+$.

In co-culture with a hydrogen-scavenging methanogenic partner such as *Methanospirillum hungatei*, the fermentation balance was shifted to more acetate production, according to: $2 \text{ putrescine}^{2+} + \text{HCO}_3^- + 3\text{H}_2\text{O} \rightarrow 2 \text{ acetate}^- + \text{butyrate}^- + \text{CH}_4 + 4\text{NH}_4^+ + 2\text{H}^+$. A similar shift was obtained with *Acetobacterium woodii* as partner. Excess accumulation of hydrogen gas inhibited growth.

In addition to putrescine, only 4-aminobutyrate and 4-hydroxybutyrate were used as substrates and fermented to analogous product mixtures. No other substrates were utilized. The pathway of putrescine degradation as analyzed by enzyme measurements in cell-free extracts includes deamination and oxidation to 4-aminobutyrate and 4-hydroxybutyrate, activation and dehydration to vinylacetyl CoA, isomerization to crotonyl CoA, and subsequent dismutation to acetate and butyrate.

The cell-wall architecture is typical of Gram-positive bacteria. Spore formation was not observed, either in defined medium or in specific sporulation media.

Enrichment and isolation procedures

The only described species so far, *Anaerovorax odorimutans*, was isolated from anaerobic enrichment cultures with putrescine (1,4-diaminobutane) as the only source of carbon and energy. The type strain, strain NorPut1^T, was isolated from an anoxic brackish sediment (Norsminde fjord, Aarhus, Denmark); other similar isolates (strains FrPut1, MaPut1) were obtained from anoxic freshwater or marine sediments. These strains did not differ substantially in their metabolism and showed high tolerance toward the salt content of the medium. The comparably high growth optimum of 37°C indicates that this bacterium has its real habitat in intestinal tracts of warm-blooded animals where primary amines formed from incomplete degradation of amino acids may be common substrates.

Anaerovorax odorimutans strain NorPut1^T was cultivated with 10 mM putrescine in a sulfide-reduced, bicarbonate-buffered mineral medium which contained trace element solution SL10, selenite tungstate solution (Widdel et al., 1983), and 7-vitamin solution (Widdel and Pfennig, 1981) under a N₂/CO₂ (90%/10%) atmosphere. Details of cultivation and physiological characterization are given in the original description (Matthies et al., 1989). The salt content of the medium was adapted to the salinity of the source of isolation, i.e., freshwater, brackish, or saltwater medium. Since the produced hydrogen gas can be inhibitory to growth, sufficient headspace (at least equal to the medium volume) has to be provided in the culture bottles.

Maintenance procedures

Cultures are maintained either by repeated transfer at intervals of 2–3 months or by freezing in liquid nitrogen using techniques common for strictly anaerobic bacteria. No information exists about survival upon lyophilization.

Differentiation of the genus *Anaerovorax* from other genera

As indicated by morphological and physiological characteristics and corroborated by phylogenetic analysis of 16S rDNA sequences, strain NorPut1^T is a member of the phylum of the Gram-positive bacteria with a low DNA G+C content. Its closest relative among the bacteria is the not yet validly published species “*Clostridium aminobutyricum*” (Collins et al., 1994; Hardman and Stadtman, 1960), with 94.6% overall 16S rRNA sequence similarity. A moderate relationship of this pair and several *Eubacterium* species is indicated by similarity values of 90.5% and lower. Based upon analyses of the currently available 16S rRNA sequence data set, these organisms represent a monophyletic group (Family XIII *Incertae Sedis* in this volume). The separation into two subclusters was supported

by the majority of the various phylogenetic analyses. Strain NorPut1^T clusters with “*Clostridium aminobutyricum*”, *Eubacterium brachy*, *Eubacterium infirmum*, *Eubacterium saphenum*, and *Eubacterium timidum* (Cheeseman et al., 1996). The second subcluster comprises *Eubacterium nodatum*, *Eubacterium tardum*, *Eubacterium minutum* and an unnamed isolate, C2 (Attwood et al., 1998; Cheeseman et al., 1996). Strain NorPut1^T was separated and described as a new genus *Anaerovorax* because the relationship to the *Eubacterium* species is

only moderate and the current genus *Eubacterium* combines a phylogenetically diverse collection of species. “*Clostridium aminobutyricum*” could perhaps be added later to the genus *Anaerovorax* as a renamed species, *Anaerovorax aminobutyricus*. Its sequence similarity to *Anaerovorax odorimutans* is just at the borderline to allow assignment to the same genus (around 95% sequence similarity as suggested by Ludwig et al. (1998). Other *Eubacterium* species are more distinct and have to be grouped as a separate genus.

List of species of the genus *Anaerovorax*

1. *Anaerovorax odorimutans* Matthies, Evers, Ludwig and Schink 2000, 1593^{VP}

o.do.ri.mu'tans. L. masc. n. *odor* smell, odor; L. v. *mutare* to change, *mutans* changing; L. adj. *odorimutans* odor-changing, referring to the degradation of the odorous compound putrescine to form another odorous one, butyric acid.

Slightly curved rods, 0.7–0.8 × 1.9–2.7 μm, motile by 3–5 flagella inserted on the concave side of the cell; typical cell wall of Gram-positive bacteria without an outer membrane but it stains Gram-negative, and it is nonsporeforming.

Chemoorganotrophic, fermentative metabolism; external electron acceptors are not used. Contains no cytochromes. Putrescine, 4-aminobutyrate, and 4-hydroxybutyrate are the only substrates utilized. No growth with more than 30 differ-

ent substrates such as sugars, organic acids, alcohols, amino acids, or other amines tested. Products of putrescine fermentation were acetate, butyrate, NH₄⁺, and H₂; 4-aminobutyrate was fermented to acetate, butyrate, and NH₄⁺; 4-hydroxybutyrate to acetate and butyrate.

Growth in freshwater and saltwater media up to 2% NaCl and 0.3% MgCl₂ · 6H₂O (w/v), pH 7.2–7.6. Reducing agents such as sulfide required. Growth possible at 15–45 °C with an optimum at 37 °C; no growth at 12 or 50 °C. Habitat: anoxic freshwater, marine, or brackish water sediment. Isolated from anoxic brackish water sediment.

DNA G+C content (mol%): 29.6 ± 1.0 (HPLC).

Type strain: NorPut1, ATCC BAA-160, DSM 5092.

GenBank accession number (16S rRNA gene): AJ251215.

Genus II. *Mogibacterium* Nakazawa, Sato, Poco, Hashimura, Ideka, Kalfas, Sundqvist and Hoshino 2000, 686^{VP}

THE EDITORIAL BOARD

Mogi.bac.te'ri.um. Gr. n. *mogios* effort; Gr. dim. n. *bakterion* a small rod; N.L. neut. n. *Mogibacterium* a difficult-to-culture, rod-shaped bacterium.

Gram-positive rods, cells are 0.2–0.8 × 1.0–3.1 μm, occurring as single cells, in short chains or in clumps. No spores are formed. Non-motile. **Strictly anaerobic and asaccharolytic**. Very poor growth in broth medium. Colonies on brain heart infusion agar (BHI)-blood agar plates are minute (<1 mm in diameter), circular, convex and translucent even after prolonged incubation in an anaerobic glove box (7–10 d). No haemolysis occurs around colonies on BHI-blood agar plates. Catalase-negative. **Metabolic end product in peptone/yeast extract/glucose medium is phenylacetate**. Members of the genus *Mogibacterium* can be distinguished from each other by 16S rRNA sequences and DNA–DNA homology values.

DNA G+C content (mol%): 41–50.

Type species: *Mogibacterium pumilum* Nakazawa, Sato, Poco, Hashimura, Ideka, Kalfas, Sundqvist and Hoshino 2000, 686^{VP}.

Further descriptive information

Mogibacterium currently contains five species. Four species, *Mogibacterium diversum*, *Mogibacterium neglectum*, *Mogibacterium pumilum* and *Mogibacterium vesicum* were originally placed in the genus *Mogibacterium* (Nakazawa et al., 2002, 2000). *Mogibacterium timidum* (originally described as *Eubacterium timidum* by

Holdeman et al., 1980) was transferred from *Eubacterium* to *Mogibacterium* by Nakazawa et al. (2000).

Sources and clinical significance. Strains of *Mogibacterium* were from human oral cavities. *Mogibacterium diversum* (three strains studied) was isolated from human tongue plaque. *Mogibacterium neglectum* (two strains) was isolated from necrotic dental pulp. *Mogibacterium pumilum* (two strains) was isolated from an infected root canal and from a periodontal pocket. *Mogibacterium vesicum* (one strain) was isolated from a periodontal pocket. No information is given on the distribution or incidence of these four species in human mouths (Nakazawa et al., 2002). Isolates of *Mogibacterium timidum* (67 strains) were from areas associated with periodontitis (Holdeman et al., 1980). The only available antimicrobial susceptibility data were given by Holdeman et al. (1980) for 30 strains of *Mogibacterium timidum*.

Colony and cell morphology. Strains are rod-shaped organisms occurring as single cells, in short chains or in clumps. Electron micrographs of ultra-thin sections of the type strains of *Mogibacterium diversum*, *Mogibacterium neglectum*, *Mogibacterium pumilum*, and *Mogibacterium vesicum* reveal a cell wall typical of Gram-positive bacteria, containing a plasma

membrane layer, a thin peptidoglycan layer in the middle and a thicker outer layer. No pili- or flagella-like structures were found in the type strains of *Mogibacterium diversum* and *Mogibacterium neglectum*. All of the organisms form tiny, non-haemolytic colonies on BHI-blood agar plates. According to Holdeman et al. (1977) blood agar plates were prepared by adding 5 ml of defibrinated rabbit's blood to 100 ml of supplemented BHI agar; however, sheep and horse blood have also been used. The colonies are 0.3–0.6 mm in diameter, and even after prolonged incubation the colonies are less than 1 mm in diameter. The temperature of incubation is 37°C.

Phenotypic analysis. *Mogibacterium* strains do not ferment glucose or other carbohydrates and are inert in most biochemical tests (using the methods described by Holdeman et al., 1977). The following tests were negative: aesculin, arginine and starch hydrolysis, nitrate reduction, gelatin liquefaction and ammonia, catalase, indole and urease production. They produce phenylacetate (<10 mM) as a metabolic end product in peptone/yeast extract (PY) and PYG broth (as assayed by gas chromatography). Enzyme profiles of *Mogibacterium* type strains of the species have been determined by Rapid ID 32A Kit (API bioMérieux), according to the manufacturer's instructions, except for incubation under strictly anaerobic conditions. Results revealed an API Code 0000020000 for *Mogibacterium pumilum*, *Mogibacterium timidum* and *Mogibacterium vesicum*, which includes a positive reaction for the proline arylamidase test, and API Code 0000000000 for *Mogibacterium diversum* and *Mogibacterium neglectum* (Nakazawa et al., 2002).

Strains of *Mogibacterium diversum*, *Mogibacterium neglectum*, *Mogibacterium pumilum*, and *Mogibacterium vesicum* do not utilize adonitol, amygdalin, arabinose, cellobiose, erythritol, aesculin, fructose, galactose, glucose, glycogen, inositol, lactose, maltose,

mannitol, mannose, melezitose, melibiose, rhamnose, ribose, salicin, sorbitol, starch, sucrose, trehalose or xylose.

In whole-cell protein profiles examined using SDS-PAGE, each type strain showed typical protein profiles. There were no major bands in common, indicating great heterogeneity in the whole-cell protein components. Western immunoblotting reactions with rabbit antisera showed that antigens from the type strains of *Mogibacterium* species were recognized by their respective antiserum.

Genotypic analysis. The G+C content of the type strains of each species ranges from 41–50 (HPLC). DNA–DNA relatedness between the type strains of the species of *Mogibacterium* is 16–39%. Relatedness of *Mogibacterium* to three species of *Eubacterium* (also asaccharolytic, anaerobic, Gram-positive rods) namely *Eubacterium brachy*, *Eubacterium nodatum*, and *Eubacterium saphenum* is negligible (1–3%).

Phylogenetic analysis. The 16S rRNA similarity between type strains of species of *Mogibacterium* is 99–100% with the exception of *Mogibacterium diversum*, which joins the *Mogibacterium* cluster at 90% similarity (Nakazawa et al., 2002). The closest relatives tested by Nakazawa et al. (2002) were *Eubacterium* species (79–87% similarity).

Enrichment, isolation and maintenance procedures

Holdeman et al. (1980) describe their isolation procedures using supplemented brain heart infusion agar and supplemented chopped meat broth agar. Cultures may be stored at –70°C suspended in 10% skim milk or lyophilized.

Differentiation of the genus *Mogibacterium* from other genera

Table 224 gives the characteristics for differentiation of *Mogibacterium* from phenotypically related species (asaccha-

TABLE 224. Differential characteristics for *Mogibacterium* and phenotypically related genera^a

rolytic, anaerobic, Gram-positive rods). The closest relative by 16S rRNA gene sequencing is *Anaerovorax* (Ludwig et al., 2009), which can be differentiated from *Mogibacterium* because it is fermentative and has a DNA G+C content of about 30 mol% (Matthies et al., 2000). *Mogibacterium* species could only be differentiated from each other by DNA–DNA hybridization and 16S rRNA gene sequences (Nakazawa et al., 2002).

List of species of the genus *Mogibacterium*

1. ***Mogibacterium pumilum*** Nakazawa, Sato, Poco, Hashimura, Ideka, Kalfas, Sundqvist and Hoshino 2000, 686^{VP}

pu.mi'lum. L. adj. *pumilum* small or tiny, referring to the tiny colonies formed by this organism.

Cell and colony morphology, phenotypic characteristics and genotypic and phylogenetic analyses are given in the genus description. Individual cells are 0.2–0.3 × 1.0 μm and occur singly, in short chains or in clumps. Strains produce approximately 3 mM phenylacetate as the sole metabolic end product in PY and PYG broth.

DNA G+C content (mol%): 45–46 (HPLC).

Type strain: D2-18, ATCC 700696.

GenBank accession number (16S rRNA gene): AB021701.

2. ***Mogibacterium diversum*** Nakazawa, Poco, Sato, Ikeda, Kalfas, Sundqvist and Hoshino 2002, 121^{VP}

di.ver'sum. L. adj. *diversum* diverse, referring to its low level of rRNA gene sequence similarity to the other *Mogibacterium* species.

Cell and colony morphology, phenotypic characteristics and genotypic and phylogenetic analyses are given in the genus description. Individual cells are 0.2–0.3 × 1.0 μm and occur singly, in short chains or in clumps. Strains produce approximately 2 mM phenylacetate as the sole metabolic end product in PY and PYG broth.

DNA G+C content (mol%): 42 (HPLC).

Type strain: HM-7, ATCC 700923, JCM 11205.

GenBank accession number (16S rRNA gene): AB037874.

3. ***Mogibacterium neglectum*** Nakazawa, Poco, Sato, Ikeda, Kalfas, Sundqvist and Hoshino 2002, 121^{VP}

neg.lect'um. L. adj. *neglectum* neglected, referring to the poor growth and tiny colonies that caused this organism to be neglected for a long time.

Cell and colony morphology, phenotypic characteristics and genotypic and phylogenetic analyses are given in the genus description. Individual cells are 0.2–0.3 × 1.5 μm and occur singly or in clumps. Strains produce approximately 2 mM phenylacetate as the sole metabolic end product in PY and PYG broth.

DNA G+C content (mol%): 41–42 (HPLC).

Type strain: P9a-h, ATCC 700924, JCM 11204.

GenBank accession number (16S rRNA gene): AB037875.

4. ***Mogibacterium timidum*** Nakazawa, Sato, Poco, Hashimura, Ideka, Kalfas, Sundqvist and Hoshino 2000, 686^{VP} (*Eubacterium timidum* Holdeman, Cato, Burmeister and Moore 1980, 164)

ti'mi.dum. L. neut. adj. *timidum* fearful, timid, referring to the slight or slow growth in clumps.

Cells from PYG broth are 0.8–1.6 × 1.6–3.1 μm. Cells are arranged singly and often in clumps. Only 1 of 6 strains of this species tested by Holdeman et al. (1980) grew on BHI-blood agar. Colonies were <1 mm in diameter. Optimum temperature for growth is 37°C.

Sixty-seven *Mogibacterium timidum* strains isolated by Holdeman, et al. (1980) were from subgingival and supragingival samples. It was detected in 42% of the subgingival samples and made up 3–57% of the cultivable flora in specimens from which it was isolated. It was isolated from 19% of the supragingival samples examined and represented 3–13% of the flora. Samples were taken from patients with periodontitis. The type strain was isolated from a subgingival area. Downes et al. (2001) isolated 13 strains of *Mogibacterium timidum*, 11 of which were isolated from odontogenic infections and two from peri-implantitis.

Partial description of the phenotypic characteristics is given in the genus description. In addition Holdeman et al. (1980) reported that 67 strains tested produced no acid from amygdalin, arabinose, cellobiose, erythritol, esculin, fructose, glucose, glycogen, inositol, lactose, maltose, mannitol, mannose, melezitose, melibiose, raffinose, rhamnose, ribose, salicin, sorbitol, starch, sucrose, trehalose, or xylose. In addition, the type strain and five other strains tested did not ferment adonitol, dextrin, dulcitol, galactose, glycerol, inulin, pectin or sorbose. All strains tested by Holdeman et al. (1980) produced trace amounts of acetate, formate or sorbate as the metabolic end product in PY and PYG broth. Thirteen strains isolated by Downes et al. (2001) produced phenylacetate and trace amounts of acetate.

Thirty strains of *Mogibacterium timidum* tested by Holdeman et al. (1980) were susceptible to chloramphenicol, clindamycin, and erythromycin. Two were resistant to 2 U/ml of penicillin G and 8 were resistant to 6 μg/ml of tetracycline.

Genotypic and phylogenetic analyses are given in the genus description. The strains isolated by Downes et al. (2001) were identified by 16S rRNA gene sequencing.

DNA G+C content (mol%): 50 (HPLC).

Type strain: VPI D1B-22, ATCC 33093.

GenBank accession number (16S rRNA gene): Z36296.

5. **Mogibacterium vescum** Nakazawa, Sato, Poco, Hashimura, Ideka, Kalfas, Sundqvist and Hoshino 2000, 686^{VP}

ves'cum. L. adj. *vescum* weak, referring to the poor growth of this organism.

Cell and colony morphology, phenotypic characteristics and genotypic and phylogenetic analyses are given in the genus description. Individual cells are 0.2–0.3 × 1.5 µm and occur singly, in short chains or in clumps. Strains produce approximately 4 mM phenylacetate as the sole metabolic end product in PY and PYG broth.

Downes et al. (2001) isolated six strains from oral infections that were identified as *Mogibacterium vescum* by 16S rDNA.

DNA G+C content (mol%): 46 (HPLC).

Type strain: D5-2, ATCC 700697.

GenBank accession number (16S rRNA gene): AB021702.

Other organisms

Saito et al. (2006) described a possible novel species of *Mogibacterium* designated “uncultured clone AF_H06” (GenBank accession no. AY821870). This clone clustered with the five species of *Mogibacterium*. It was identified in a study to investigate the bacterial diversity of seven infected root canals by the analysis of 16S rDNA clone libraries. This broad-based cultivation-free approach has enabled detection of bacteria when culture generates negative results.

Family XIV. Incertae Sedis

Previously assigned to the “*Syntrophomonadaceae*” by Garrity et al. (2005), subsequent analyses suggest that this genus is not closely related to *Syntrophomonas* or a member of any other pre-

viously described family. For that reason, it is assigned to its own family *incertae sedis*.

Genus I. *Anaerobranca* Engle, Li, Woese and Wiegel 1995, 459^{VP}

JUERGEN WIEGEL

An.ae.ro.bran'ca. Gr. pref. *an* not; Gr. n. *aer* air; N.L. fem. n. *branca* claw, paw, the root of the En. word branch, an arm-like part diverging from a main axis; N.L. n. *Anaerobranca* referring to the branched cell shape of the obligately anaerobic bacterium.

Gram-positive type cell-wall ultrastructure but, depending on the species, cells stain **Gram-positive or -negative**. The cell wall is either thick (*Anaerobranca horikoshii*) or thin. To date, the genus contains only **thermophilic** species growing in the range 30–67°C (no growth at 70°C) and pH 10.3 at 60°C. As indicated by the genus name, all three species exhibit the occurrence of truly branched cells with no septa; up to 10 % of the cells in a culture are branched, depending on strain, growth stage, and conditions. General physiology is **organo-heterotrophic** (proteolytic and glucoytic), but all species also can reduce Fe(III) to Fe(II) with magnetite formation, selenite to elemental selenium (red precipitate) and selenide (Se²⁻), elemental sulfur to sulfide, and thiosulfate to sulfide. Some of the species can reduce (dissimilatory) fumarate to succinate. Proteinaceous compounds are the preferred substrates. The presence of thiosulfate stimulates the slow utilization of selected carbohydrates by functioning as an efficient electron acceptor. Spore formation not observed, but sporulation genes are present.

The genus *Anaerobranca* belongs to the phylum *Firmicutes* (low G+C Gram-positive bacteria) in the order *Clostridiales* within the class *Clostridia*. *Anaerobranca* was placed in Family VIII *Syntrophomonadaceae* as genus VI by Garrity et al. (2005). Despite the indication by the family name, but similar to situations of other genera within this family, none of the *Anaerobranca* strains isolated so far are known to be syntrophic. The most closely related taxa are relatively distant (Figure 227), with *Alkalibacter saccharofermentans* being the closest relative. BLAST searches identify many *Paenibacillus* and some *Brevibacillus* species as close relatives, all belonging to a different class of the *Firmicutes*. However, this is misleading due to short branch lengths of these taxa as depicted in the phylogenetic tree; only two species of *Paenibacillus* and *Brevibacillus* were included as representatives of the cluster. In addition, the tree includes *Syntrophomonas wolfei* subsp. *wolfei* (the type species of the family *Syntrophomonadaceae*), some thermophilic species of this family, and a few other taxa indicated by the BLAST search as close relatives e.g., *Clostridium tyrobutyricum*. *Clostridium butyricum* is included as a reference because it is the type species of the genus *Clostridium* and the type genus of the class *Clostridiales*. If more taxa in the close vicinity of *Anaerobranca* are isolated in the future, it is possible that they and *Anaerobranca*, as well as other nonsyntrophic taxa, will be placed in novel families. In light of these ambiguities, this genus is assigned to Family XIV *incertae sedis* in the current volume.

DNA G+C content (mol%): 30–34.

Type species: *Anaerobranca horikoshii* Engle, Li, Woese and Wiegel 1995, 459^{VP}.

Further descriptive information

The biogeography of the species appears to be restricted since species were only isolated from specific geothermally heated environments on the North American and African continents. For example, *Anaerobranca horikoshii* could only be isolated from a very restricted area of Yellowstone National Park but not from other areas of the park.

Three species have been validly published. Differentiating properties for the species are given in Table 225. All species require a growth factor from yeast extract (unidentified) which could not be substituted by vitamin supplementation. Late exponential growth phase cells tend to be pleomorphic including the appearance of round autoplast-like cells and irregular chains with cells of various lengths. This phenotype is frequently observed among alkalithermophilic aerobic and anaerobic thermophiles and was first described among anaerobic thermophiles for the neutrophilic thermophile, *Thermoanaerobacter ethanolicus* (Wiegel and Ljungdahl, 1981). This property is probably due to the inability to maintain an intact rigid cell-wall structure, possibly due to expression of lysogenic enzyme(s), a remnant from the sporulation process, although sporulation has not been observed in *Thermoanaerobacter ethanolicus* JW200 or in the strains of *Anaerobranca* described here (unpublished results).

All strains of *Anaerobranca* belong to the extremophile group of alkalithermophiles, thus they are thermophiles (i.e., optimum growth temperature at or above 50°C) and alkaliphiles (i.e., optimum at around pH^{20°C} of 9.0–9.5 or at pH^{60°C} around 8.5; see Wiegel, (1998), for comments on pH measurements and proposed form of reporting pH data for alkaline or acidic media incubated at elevated temperatures). Thus, these strains have to cope with the energetic problems caused by two extremes, i.e., problems caused by elevated temperatures and problems caused by alkaline pH values in the growth medium. Elevated temperatures cause problems that include membranes that become more permeable for protons, making it more difficult for the cells to maintain the necessary membrane energization. Problems arising from alkaline pH values in the growth medium include that, in contrast to the Mitchel theory, the internal pH is kept more acidic than the outside media pH, so that cells have a reversed intracellular/extracellular pH gradient. (Krulwich et al., (1990) and literature cited therein; Speelmans et al., 1995; Prowe et al., 1996).

TABLE 225. General characteristics to differentiate the three known species of the genus *Anaerobranca*^{a,b}

Characteristic	<i>A. californiensis</i>	<i>A. gottschalkii</i>	<i>A. horikoshii</i>
Habitat	Hot springs of Paoha Island in Mono Lake (CA, USA)	Hot inlet of Lake Bogoria (Kenya)	Hot springs at Old Faithful Hotel (Yellowstone National Park, USA)
Cell size (µm)	0.26–0.3 × 2.4–5	0.3–0.5 × 3–5	0.5–0.65 × 8–22
Gram reaction	Negative at all phases	Negative at all phases	Positive at all phases
Cell wall	Gram-positive type, but thin	Gram-positive type, but thin	Gram-positive type, typical thickness
Growth temperature (optimum) (°C)	45–67 (58)	30–65 (50–55)	30–66 (55–58)
pH range (optimum)	pH ^{20°C} 8.6–10.4 (9.0–9.5)	pH ^{20°C} 6.0–10.5 (9.5)	pH ^{60°C} 6.5–10.3 (8.5)
NaCl range (optimum) (% w/v)	0–6 (1–2.5)	0–4 (1), at pH 9.0, 50°C	ND
Main metabolism	Proteolytic and glycolytic	Glycolytic and proteolytic	Proteolytic (no carbohydrate utilization)
Na ₂ S ₂ O ₄ as electron acceptor (=> S ²⁻)	Yes	Yes	No
Fumarate as electron acceptor (=> succinate)	No	ND	Yes
Cellulose hydrolysis	No	Yes	No
G+C (mol%) content of DNA	30	30	32–34 (various strains)

^aData were obtained from Gorlenko et al., (2004) (*Anaerobranca californiensis*), Prowe et al. (2001) (*Anaerobranca gottschalkii*) and Engle et al. (1995) (*Anaerobranca horikoshii*). All three species have rod-shaped, motile, peritrichously flagellated cells, sometimes showing branching. All are obligate anaerobes and can reduce selenite to selenide.

List of species of the genus *Anaerobranca*1. *Anaerobranca horikoshii* Engle, Li, Woese and Wiegel 1995, 459^{VP}

hor.i.kosh'i.i. N.L. gen. n. *horikoshii* of Horikoshi, in honor of Koki Horikoshi, a pioneer in the study of the microbiology of alkaliphilic bacteria.

Description is mainly based on characterization of strain JW/YL-138^T (from a pH 6.7 and 92°C pool) and JW/YL-268 (from a pH 5.8 and 50°C pool) in Engle et al. (1995).

Cells are usually rod-shaped, 0.5–0.65 µm in diameter and 8–22 µm in length; peritrichously flagellated, but usually showing only tumbling motility. Between about 0.5–10% of the cells in a culture (pending on the strain and culture conditions) form one to three branches without septation. With continued subculturing over the years, the occurrence of branched cells in a culture has decreased. Cells stain Gram-positive during exponential growth phase. Spores have not been observed, although major sporulation specific genes have been detected in the type strain (Onyenwoke et al., 2004). Colonies in agar-shake-roll tubes are lens shaped and of whitish color; surface colonies are more or less circular (entire) and slightly convex.

Habitats: Using casein as growth substrate, *Anaerobranca horikoshii* has only been isolated from the geothermally heated area behind the Old Faithful Hotel in Yellowstone National park, but could not be isolated from other hot springs within Yellowstone National Park or other hot springs in New Zealand, Italy, and Japan. However, strains were isolated from mixed water-sediment samples of hot springs with either slightly alkaline pH (8.7) or slightly acidic pH (5.8) and with water temperature 50–92°C. The nine isolated strains differ slightly in size, marginal growth data, substrate utilization, and the protein band pattern (slight variations) on SDS gels. Minimum pH^{25°C} for growth for most strains is between 6.7 (no growth) and 7.0 (growth) and the maximum is between pH 9.4 (growth) and 10.3 (no growth), with the pH^{25°C} optimum for growth around 8.5–8.7. The temperature optimum is around 55–58°C. The minimal growth temperature was between 34°C (for one strain 30°C) (no growth) and 37°C (34°C) (growth) and the upper temperature range between 64°C (growth) and 66°C (no growth). These marginal data classify the bacterium as a facultative alkaliphile and a moderate thermophile. At optimal conditions (57°C, pH^{20°C} 9.0) the shortest observed doubling times were 36–70 min depending on the strain.

Anaerobranca horikoshii isolates are obligate anaerobes, however, non-growing cells are insensitive to exposure to oxygen (up to 25 h exposure to air tested) at 25 and 60°C. Strain JW/YL-138 and JW/YL-268 (others not tested) cannot utilize carbohydrates (glucose, sucrose, fructose, galactose, maltose, cellobiose, lactose, xylose, ribose, rhamnose, raffinose, arabinose, starch, or pectin), the alcohols mannitol, xylitol, methanol, or ethanol, or the acids acetate, lactate, and formate. Filter-sterilized pyruvate is a weak substrate (in contrast to the original description). Fermentation products from yeast extract are acetate, CO₂, and H₂ in an approximate ratio of 1:1:1. Selenite, thiosulfate, and sulfur can serve as electron acceptors. While growing on yeast extract, fumarate (12 mM) is stoichiometrically reduced to succinate by all except one strain. Interestingly, in the absence of fumarate, 3 mM succinate inhibits growth completely. Dissimilatory sulfate reduction has not been observed.

All strains are peptidolytic (since isolated on casein) and contain metalloproteases (EDTA sensitive) as their main proteases. Peptone and tryptone can substitute for the requirement of yeast extract supplement (0.2% w/v is sufficient). The variation in enzyme activities tested with API-test strips are given in the original species description (Engle et al., 1995). Differences were noted depending on whether or not the cells were incubated aerobically or anaerobically. A pullulanase type I was isolated based on analogies to the gene sequence from *Anaerobranca gottschalkii* genome sequence (Bertoldo et al., 2004). The profile of fatty acid from lipids is shown in Table 226.

DNA G+C content (mol%): 34 for the type strain; 33 for all other strains (HPLC).

Type strain: JW/YL-138, ATCC 700319, DSM9786.

GenBank accession number (16S rRNA gene): U21809.

2. *Anaerobranca californiensis* Gorlenko, Tsapin, Namsaraev, Teal, Tourova, Engler, Mielke and Neilson 2004, 742^{VP}

ca.li.for.ni.en'sis. N.L. fem. adj. *californiensis* referring to California, the location of the hot spring from which the microorganism was isolated.

The description is based on Gorlenko et al. (2004).

Cells are rod-shaped, 0.26–0.3 µm in diameter and 2.4–5 µm in length. Branching cells and longer cells are observed within the culture as well as retarded peritrichous flagellation leading to motility in the early to mid exponential growth phase. Division occurs via binary fission. Spores have not been observed. Colony morphology on agar plates incubated in anaerobic jars is circular, entire, convex, and of a whitish color.

The growth ranges for pH^{25°C} were between 8.6 and 10.4 with an optimum between 9.0 and 9.5. (for a comparison with data from *Anaerobranca horikoshii*: if the pH would be determined at 60°C (pH^{60°C}), the maximum and optimum pH will be approximately 0.8–1.0 pH unit lower (Wiegel, unpublished)). The temperature range is 45–70°C with an optimum around 58°C. *Anaerobranca californiensis* requires between 0.5% and 6% NaCl for growth with a broad optimum at 47–58°C, while a sharp optimum (2.5% w/v) was observed at 70°C. The shortest observed doubling time is 40 min at 58°C and pH^{20°C} 9.5.

The metabolism is obligately anaerobic, however, exposure to oxygen does not kill the cells. Exposure to air at 25°C is tolerated for several months without loss of viability. Yeast extract addition to the medium is required for growth and cannot be substituted with vitamin additions. The best growth promoting substrates were yeast extract, peptone, tryptone, malt extract, Casamino acids, and soy tone peptone. In the presence of yeast extract *Anaerobranca californiensis* can use

TABLE 226. Comparison of percentage lipid fatty acid profiles of two *Anaerobranca* species

Fatty acid	<i>A. horikoshii</i>	<i>A. gottschalkii</i>
C _{13:0}		2.6
C _{13:0 iso}		4.3
C _{14:0}	26	
C _{15:0 iso}	7.5	42
C _{15:0 ante}		12
C _{15:0}	11	
C _{16:0}	28	11
C _{17:0 ante}		3.4

fructose, sucrose, maltose, starch, glycogen, cellobiose, pyruvate (filter-sterilized), and glycerol as carbon sources.

During heterotrophic growth, thiosulfate selenite, sulfur, polysulfide (formed at the high pH and elevated temperatures) amorphous Fe(III) hydroxide, and Fe(III) citrate can serve as electron acceptors. Addition of thiosulfate, which is reduced to sulfide, lead to elevated final cell densities. The type strain can tolerate up to 40 mM sulfide. Additional isolates include strain PAOHA-2 (Gorlenko et al., 2004).

DNA G+C content (mol%): 30 (T_m).

Type strain: PAOHA-1, DSM 14826, UNIQEM 227.

GenBank accession number (16S rRNA gene): AY064218.

3. *Anaerobranca gottschalkii* Prowe and Antranikian 2001, 464^{VP}

gottschalkii. N.L. gen. n. *gottschalkii* of Gottschalk, after Gerhard Gottschalk, in recognition of his pioneering contributions to our knowledge of the physiology and metabolism of anaerobes.

Description of the species is based mainly on Prowe and Antranikian (2001).

Cells are rod-shaped, 0.3–0.5 µm in diameter and 3–5 µm long. Early exponential cells are motile. Cells stain Gram-negative, probably because the cell wall is uncharacteristically thin for a *Firmicutes* bacterium (Prowe and Antranikian, 2001; Gorlenko et al., 2004; unpublished results) and thus easily destained, especially when using ethanol in the destaining procedure. Surface colonies on agar plates (0.5% starch) are circular, entire (even), convex, and of a pale whitish color. Truly branched cells make up 2–10% of the total number of cells. Formation of spores was not detected using examination by light microscopy and a heat resistance assay (90°C for up to 10 min).

So far only one isolated strain has been characterized. It was isolated from enrichments inoculated with a sample from a hot lake inlet of Lake Bogoria (Kenya) using liquid enrichment media of pH^{20C} 9.0 containing starch and glucose and an incubation temperature of 50°C. Growth range is 30–65°C with an optimum between 50 and 55°C. At growth temperatures of 50°C the pH^{20C} range is 6.0–10.5 with optimum at pH^{20C} 9.5.

Growth is obligately anaerobic. Utilized substrates include carbohydrates (glucose, fructose, mannose, galactose, ribose, xylose, cellobiose, lactose, maltose, sucrose, starch, and pul-

lulan), proteins and peptides (tryptone, peptone, and yeast extract), and glycerol. The main fermentation product from glucose is acetate with small amounts of ethanol (no fermentation balance available). The addition of thiosulfate stimulates growth on glucose. The addition of thiosulfate or sulfur leads to the formation of sulfide which is inhibited by adding H₂ into the gas phase, indicating that both function as electron acceptor. No indication for dissimilatory sulfate reduction is observed (Gorlenko et al., 2004; Prowe and Antranikian, 2001). Also Fe(III), amorphous Fe(III) hydroxide, Fe(III) citrate, and selenite (Na₂SeO₃) can serve as electron donors forming Fe(II) ion (→ magnetite formation) and elemental selenium (red precipitation), and polyselenite as well as colorless Na₂Se, respectively. Bertoldo et al. (2004) described the characterization of a type I pullulanase (predicted molecular mass 98 kDa) identified from the genome sequence. Pullulan hydrolysis exhibits a pH optimum at pH 8.0 and highest activity at 70°C. Under these conditions the enzyme has a half life of 22 h.

Growth requires presence of Na ion which cannot be replaced by K⁺ ions, suggesting that Na⁺ ions are required for energy transduction. The uptake of several amino acids exhibits a strict requirement for Na⁺, and for L-leucine it was shown that the uptake occurs in symport with Na⁺ ions (Prowe et al., 1996). The pH and temperature optima for the leucine transport closely matches the optimal growth conditions for strain LBS3. ATPase activity using inside-out membrane vesicles was stimulated by both Na⁺ and Li⁺ ions. Consequently, Prowe et al. (1996) concluded that the primary mechanism of energy transduction in strain LBS3 is dependent on sodium cycling.

Antibiotic resistance: 25 µg/ml of chloramphenicol and monensin, 50 µg/ml nalidix acid, and 250 µg/ml streptomycin are inhibitory, but 50 µg/ml of rifampin and 100 µg/ml penicillin are not (see Peteranderl et al., 1990) for heat stability of antibiotics in solution). The profile of fatty acid from lipids is depicted in Table 226.

The complete genome sequence of the type strain is under analysis (Antranikian, private communication)

DNA G+C content (mol%): 30 (HPLC).

Type strain: LBS3, ATCC BAA-51, DSM 13577.

GenBank accession number (16S rRNA gene): AF203703

Family XV. Incertae Sedis

Previously assigned to the *Syntrophomonadaceae* by Garrity et al. (2005), subsequent analyses suggest that these genera, while closely related to each other, are not closely related to *Syntroph-*

omonas or a member of any other previously described family. For that reason, they are assigned to their own family *incertae sedis* (Figure 6).

Genus I. **Aminobacterium** Baena, Fardeau, Labat, Ollivier, Thomas, Garcia and Patel 1999c, 1325^{VP} (Effective publication: Baena, Fardeau, Labat, Ollivier, Thomas, Garcia and Patel 1998, 249.)

SANDRA BAENA, JEAN-LOUIS GARCIA, JEAN-LUC CAYOL AND BERNARD OLLIVIER

A. min.o.bac'te.ri.um. N.L. n. *aminum* amine; Gr. dim. n. *bakterion* a small rod; N.L. neut. n. *Aminobacterium* the amino acid rod.

Cells are strictly anaerobic, nonsporeforming, nonmotile or motile by means of one or two lateral flagella, slightly curved **rods**, occurring singly, in pairs, or, rarely, as chains. **Gram-stain-negative**. Mesophilic, neutrophilic. **Heterotrophic**, asaccharolytic. Growth by fermentation of a limited range of amino acids only in the presence of yeast extract.

DNA G+C content (mol%): 44–46.

Type species: Aminobacterium colombiense Baena, Fardeau, Labat, Ollivier, Thomas, Garcia and Patel 1999c, 1325^{VP} (Effective publication: Baena, Fardeau, Labat, Ollivier, Thomas, Garcia and Patel 1998, 249.).

Further descriptive information

Aminobacterium cells are 0.2–0.3 µm in width × 3–5 µm in length and occur singly, in pairs or, rarely, as chains (Figure 228) when grown on a medium containing serine and yeast extract. Spores are not observed from cells grown under various conditions. Ultrathin sections of cells reveal a multilayered, complex, thick cell wall with an external S-layer similar to that of Gram-positive type cell walls. They are strictly anaerobic, chemo-organotrophic bacteria. Cells grow at temperatures ranging from 20–42°C, with an optimum at 37°C. No growth is observed at 18 and 45°C. Cells do not require NaCl for growth, but tolerate less than 1.5% NaCl, with optimal growth occurring in the presence of 0.05–0.50% NaCl. The optimum pH for growth is around 7.3 and growth occurs between pH 6.6–8.5.

Aminobacterium cells do not grow in basal medium without yeast extract, and 0.2% yeast extract was routinely used for substrate utilization tests. Cells ferment serine, glycine, threonine, and pyruvate. Serine is fermented to acetate or to acetate and alanine. Threonine and glycine are degraded to acetate as the only fatty acid produced. Acetate and H₂ are the end products of metabolism from Casamino acids, peptone, biotrypcase, and cysteine, but these compounds are poorly used. Propionate is also produced in the case of α-ketoglutarate and 2-oxoglutarate. *Aminobacterium* cells do not perform the Stickland reaction when alanine is provided as an electron donor and glycine, serine, arginine, or proline are provided as electron acceptors. Carbohydrates, gelatin, casein, glycerol, ethanol, acetate, propionate, butyrate, lactate, citrate, fumarate, malate, and succinate are not utilized. Sulfate, thiosulfate, elemental sulfur, sulfite, nitrate, and fumarate are not utilized as electron acceptors.

Alanine, glutamate, valine, isoleucine, leucine, and aspartate are oxidized only by a mixed culture of *Aminobacterium* species and *Methanobacterium formicicum*. The end products resulting from the oxidation of alanine, leucine, isoleucine, and valine

were acetate, isobutyrate, 2-methyl-butyrate, and isovalerate, respectively.

Enrichment and isolation procedure

The Hungate technique (Hungate, 1969) should be used to isolate *Aminobacterium* species. The basal medium (BM) contains (per liter of distilled water): 0.3g NH₄Cl, 0.2g KH₂PO₄, 0.4g MgCl₂·6H₂O, 0.15g CaCl₂·2H₂O, 0.5g KCl, 1.0g NaCl, 1ml 0.1% resazurin, and 1ml trace mineral element solution (Imhoff-Stuckle and Pfennig, 1983). The pH is adjusted to 7.2 with 10M KOH. The medium is boiled under a stream of O₂-free N₂ gas and cooled to room temperature. Five ml aliquots are dispensed into Hungate tubes and 20 ml in serum bottles under a stream of O₂-free N₂ gas. The gas phase is subsequently replaced with N₂/CO₂ (80:20, v/v) gas and the sealed vessels are autoclaved for 45 min at 110°C. Prior to inoculation, 0.15 ml 2% Na₂S·9H₂O, 0.25 ml 10% NaHCO₃, and 0.05 ml Balch vitamin solution (Balch et al., 1979) are injected from sterile stock solutions. Amino acids are added from sterile (heat or filter-sterilized) anaerobic stock solutions.

For isolation, a tenfold serial dilution is prepared and inoculated into the Hungate tubes containing 5 ml basal medium with serine and yeast extract at final concentration of 10 mM and 0.2%, respectively. The highest dilution showing growth after 3–4 weeks incubation at 37°C is used for further isolation. Positive cultures are serially diluted and inoculated into roll tubes containing enrichment medium with 2% agar to get axenic cultures. Colonies (small, white, lens shaped) develop after 2 weeks incubation at 37°C. The process of serial dilution in roll tubes is repeated at least twice in order to purify the cultures.

Maintenance procedure

Stock cultures can be maintained on medium described by Baena et al. (1998) by monthly transfers. Liquid cultures retained viability after several weeks storage at 4°C, or when lyophilized, or after storage at –80°C in the basal medium containing 20% glycerol (v/v). Viability is best maintained from mid-exponential phase cultures.

Differentiation of the genus *Aminobacterium* from other genera

The genus *Aminobacterium* is represented by two species, *Aminobacterium colombiense* and *Aminobacterium mobile*. They are mesophilic and strictly anaerobic bacteria which ferment serine, threonine, glycine, and pyruvate but not carbohydrates. These characteristics are in common with the nonsaccharolytic

FIGURE 228. Photomicrograph of *Aminobacterium colombiense*. Bar = 5 μ m.

aminolytic species *Acidaminobacter hydrogeniformans* (Stams and Hansen, 1984), *Eubacterium acidaminophilum* (Zindel et al., 1988), *Thermanaerovibrio acidaminovorans* (Baena et al., 1999b) (formerly *Selenomonas acidaminovorans*; Guangsheng et al. (1992), *Peptostreptococcus anaerobius* (Paster et al., 1993), and several species of the genus *Clostridium* including *Clostridium sticklandii*, *Clostridium aminophilum*, *Clostridium morale*, *Clostridium pascui*, *Clostridium hydrobenzoicum*, and *Clostridium acetireducens*. Phylogenetically, the nonsaccharolytic aminolytic species are members of the low G+C containing Gram-positive clostridial branch which is currently comprised of 19 defined clusters and several distinct independent lineages (Collins et al., 1994). *Aminobacterium* species are also members of the low G+C containing Gram-positive clostridial branch and are therefore related to them, but only distantly. Further phylogenetic analysis revealed that *Aminobacterium* species form an independent line of descent together with *Aminomonas paucivorans* (Baena et al., 1999a), *Dethiosulfovibrio peptidovorans* (Magot et al., 1997), *Dictyoglomus thermophilum* (Saiki et al., 1985), *Anaerobaculum* species (Menes and Muxí, 2002; Rees et al., 1997), and *Thermanaerovibrio* species (Baena et al., 1999b; Zavarzina et al., 2000) (Figure 229) in the vicinity of cluster V (Collins et al., 1994) which currently consists of members of the genus *Thermoanaerobacter*.

Like *Aminobacterium* species, *Aminomonas paucivorans*, *Thermanaerovibrio* species, *Anaerobaculum* species, and *Dethiosulfovibrio peptidovorans* use amino acids. However, *Thermanaerovibrio*, and *Anaerobaculum* species are thermophiles which also utilize carbohydrates. Furthermore, *Aminobacterium* species differ from *Anaerobaculum thermoterrenum* and *Anaerobaculum mobile* as both microorganisms ferment several organic acids (Menes and Muxí, 2002; Rees et al., 1997). In contrast to *Dethiosulfovibrio peptidovorans*, *Aminomonas paucivorans* uses thiosulfate or elemental sulfur as terminal electron acceptors. Finally, *Amin-*

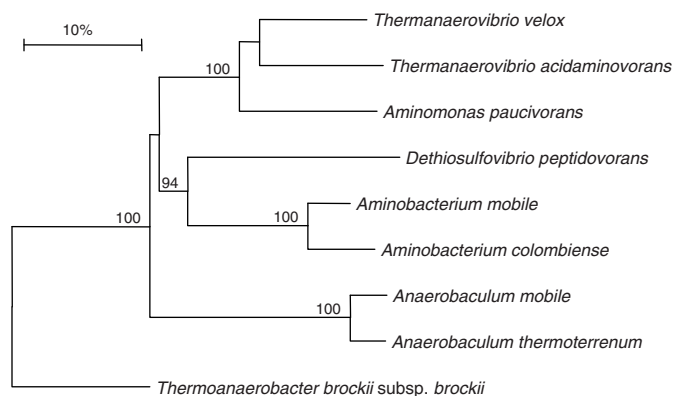

FIGURE 229. Phylogenetic tree based on 16S rRNA gene sequence comparison, and obtained by a neighbor-joining algorithm (PHYLIP package), indicating the position of *Aminobacterium* species and *Aminomonas paucivorans* among members of the low G+C Gram-positive bacteria (Firmicutes). Bootstrap values are shown at branching points. Only values above 80% were considered significant and reported. *Thermoanaerobacter brockii* subsp. *brockii* was used as outgroup. Bar = 10 substitutions per 100 nucleotides.

omonas paucivorans does not use pyruvate and the same range of amino acids as reported for *Aminobacterium* species.

It is noteworthy that one species of the genus *Aminobacterium*, *Anaerobaculum mobile* ferments serine into acetate and alanine (Baena et al., 2000). Alanine production from amino acid fermentation has rarely been reported. *Caloramator proteoclasticus* (Tarlera et al., 1997) was shown to produce this amino acid during glutamate fermentation, whereas *Clostridium ultunense* (Schnurer et al., 1996) produced it during cysteine degradation.

Threonine is fermented to acetate similarly to that described for some *Clostridium* species which include *Clostridium histolyticum*, *Clostridium sporosphaeroides*, *Clostridium sticklandii*, and *Clostridium subterminale* (Barker, 1981). However, most members of this genus produce propionate and n-butyrate and a few also produce 2-aminobutyrate. The conversion of glycine to acetate by *Aminobacterium* species suggests a pattern similar to that reported for *Eubacterium acidaminophilum* (Zindel et al., 1988), *Peptococcus anaerobius*, *Peptococcus magnus*, *Clostridium histolyticum*, and *Clostridium purinolyticum* (McInerney, 1988). *Aminobacterium* cells ferment amino acids such as serine, threonine, and glycine in pure cultures and is also able to oxidize additional amino acids such as alanine, valine, leucine, and isoleucine only in the presence of *Methanobacterium formicicum*, a well-known H₂ scavenger.

Alanine is oxidized to acetate, valine to isobutyrate, leucine to isovalerate, isoleucine to 2-methylbutyrate. Metabolism of these amino acids in mixed culture resembles that reported for the mesophiles *Acidaminobacter hydrogeniformans* (Stams and Hansen, 1984), *Thermanaerovibrio acidaminovorans* (Guangsheng et al., 1992), and *Eubacterium acidaminophilum* (Zindel et al., 1988), and also the thermophile *Thermoanaerobacter brockii* (Fardeau et al., 1997).

Differentiation between *Aminobacterium* species

The genus *Aminobacterium* comprises two species, *Aminobacterium mobile* and *Aminobacterium colombiense*. The former, unlike *Aminobacterium colombiense*, has a slightly lower DNA G + C content (44 mol% vs 46 mol%), is motile, and ferments serine to acetate and alanine.

Taxonomic comments

Aminobacterium is a genus consisting of two species (*Aminobacterium colombiense* and *Aminobacterium mobile*). Phenotypic and

genotypic characteristics clearly place it within a cluster of low G+C Gram-positive bacteria (designated *Clostridiales* Family XV *Incertae Sedis* in this volume) in the phylum *Firmicutes* containing *Thermanaerovibrio* species, *Aminobacterium* species, *Anaerobaculum* species, *Aminomonas paucivorans*, and *Dethiosulfovibrio peptidovorans*. This cluster is adjacent to *Thermoanaerobacter* (cluster V) based on 16S rRNA sequence analysis. For phylogenetic position see Figure 229.

List of species of the genus *Aminobacterium*

1. ***Aminobacterium colombiense*** Baena, Fardeau, Labat, Ollivier, Thomas, Garcia and Patel 1999c, 1325^{VP} (Effective publication: Baena, Fardeau, Labat, Ollivier, Thomas, Garcia and Patel 1998, 249.)

co.lom.bi.en'se. N.L. neut. adj. *colombiense* pertaining to Columbia, the origin of the isolate.

In addition to the properties listed in the genus description, the following properties are reported. Cells are 0.2–0.3 × 3–4 μm. Nonmotile. Colonies (up to 1.0 mm) are round, smooth, lens shaped and white. Grows at temperatures ranging from 20–42°C, with optimum growth at 37°C. Grows in the presence of NaCl at concentrations ranging from 0–1.5% NaCl, with optimum growth at 0.0–0.50% NaCl. The optimum pH for growth is 7.3 and growth occurs between pH 6.6–8.5. Heterotrophic, asaccharolytic. Yeast extract is required for growth. It ferments serine, threonine, glycine, and pyruvate and uses several other amino acids in mixed culture with *Methanobacterium formicicum* (alanine, glutamate, valine, leucine, isoleucine, aspartate, cysteine, and methionine). No growth is observed on succinate, malate, fumarate, citrate, lactate, glucose, sucrose, ribose, xylose, cellobiose, melobiose, maltose, galactose, mannose, arabinose, rhamnose, lactose, sorbose, mannitol, acetate, propionate, butyrate, glycerol, ethanol, gelatin, and casein. Sulfate, thiosulfate, elemental sulfur, sulfite, nitrate, and fumarate are not utilized as electron acceptors.

Isolated from anaerobic sludge of a dairy wastewater treatment plant in SantaFe de Bogota, Colombia. Adverse effects on animals and humans are not known. Because of the ability of *Aminobacterium colombiense* to degrade amino acids and peptides, the possibility of harmful effects cannot be excluded. Cautious handling and autoclaving of cultures before disposal is recommended.

DNA G+C content (mol%): 46 (HPLC).

Type strain: ALA-1, DSM 12261.

Genbank accession number (16S rRNA gene): AF069287.

2. ***Aminobacterium mobile*** Baena, Fardeau, Labat, Ollivier, Garcia and Patel 2000, 263^{VP}.

mo'bi.le. L. neut. adj. *mobile* motile.

In addition to the properties listed in the genus description, the following properties are reported. Cells are 0.2–0.3 × 4–5 μm. Cells are motile by means of one or two lateral flagella. Colonies (up to 1.0 mm) are round, smooth, lens shaped and white. Grows at temperatures ranging from 35–42°C, with optimum growth at 37°C. Grows in the presence of NaCl at concentrations ranging from 0–1.5% NaCl, with optimum growth between 0.05–0.50% NaCl. The optimum pH for growth is 7.4 and growth occurs between pH 6.7–8.3. Heterotrophic, asaccharolytic. Yeast extract is required for growth. It ferments serine, threonine, glycine, and pyruvate and uses alanine, glutamate, valine, leucine, isoleucine, and aspartate only in co-culture with *Methanobacterium formicicum*. No growth is observed on succinate, malate, fumarate, citrate, lactate, glucose, saccharose, ribose, xylose, cellobiose, melobiose, maltose, galactose, mannose, arabinose, rhamnose, lactose, sorbose, mannitol, acetate, propionate, butyrate, glycerol, ethanol, gelatin, and casein. Sulfate, thiosulfate, elemental sulfur, sulfite, nitrate, and fumarate are not utilized as electron acceptors. Isolated from anaerobic sludge of a dairy wastewater treatment plant in SantaFe de Bogota, Colombia. Adverse effects on animals and humans are not known. Because of the ability of *Aminobacterium mobile* to degrade amino acids and peptides, the possibility of harmful effects cannot be excluded. Cautious handling and autoclaving of cultures before disposal is recommended.

DNA G+C content (mol%): 44 (HPLC).

Type strain: ILE-3, ATCC BAA-7, DSM 12262.

GenBank accession number (16S rRNA gene): AF073521.

Genus II. *Aminomonas* Baena, Fardeau, Ollivier, Labat, Thomas, Garcia and Patel 1999a, 981^{VP}

SANDRA BAENA, JEAN-LOUIS GARCIA, JEAN-LUC CAYOL AND BERNARD OLLIVIER

A.mi.no.mo'nas. N.L. neut. n. *aminum* amine; Gr. n. *monas* a unit, monad; N.L. fem. n. *Aminomonas* amine-degrading monads.

Cells are strictly anaerobic, nonsporeforming, nonmotile, slightly curved rods, occurring singly or in pairs. **Gram-stain-negative**. Mesophilic, neutrophilic. Optimum growth at 35°C and pH 7.5 on arginine with a generation time of 16 h. **Heterotrophic**. Good growth on arginine, histidine, threonine, and glycine. Acetate

is the end product formed from all these substrates; in addition, trace amount of formate is detected from arginine and histidine. Ornithine is produced from arginine. Slow growth on glutamate with production of acetate, carbon dioxide, formate, hydrogen, and traces of propionate as the end products.

In syntrophic association with *Methanobacterium formicicum*, methane is produced from arginine, histidine, and glutamate which are oxidized into propionate as the major product together with acetate and carbon dioxide. Alanine and the branched-chain amino acids valine, leucine, and isoleucine are not degraded either in pure culture or in association with *Methanobacterium formicicum*.

DNA G+C content (mol%): 43.

Type species: *Aminomonas paucivorans* Baena, Fardeau, Ollivier, Labat, Thomas, Garcia and Patel 1999a, 981^{VP}.

Further descriptive information

Aminomonas paucivorans is the only species described so far within the genus *Aminomonas*. Cells are 0.3–0.4 µm in width and 4–6 µm in length and occur singly or in pairs when grown on a medium containing arginine and yeast extract. Motility is not observed and electron microscopy of negatively stained cells reveals the absence of flagella. Spores are not observed from cells grown under various conditions and cells are not heat resistant. Ultrathin sections of cells reveal a cytoplasmic membrane and a complex cell wall layer characteristic of a Gram-negative cell. *Aminomonas paucivorans* is a strictly anaerobic, chemoorganotrophic bacterium. Cells grow at temperatures ranging from 20–40°C, with an optimum at 35°C. No growth is observed at 18 and 42°C. Cells do not require NaCl for growth, but tolerate up to 2.0% NaCl, with optimal growth occurring in the presence of 0.05–0.50% NaCl. The optimum pH for growth is around 7.5, and growth occurs between pH 6.7–8.3.

Aminomonas paucivorans does not grow in basal medium without yeast extract, and 0.2% yeast extract was routinely used for substrate utilization tests. Cells ferment arginine, histidine, glutamate, threonine, and glycine (Table 227). Arginine is fermented to ornithine, acetate, and formate; histidine is fermented to acetate and formate; glutamate is fermented to acetate and, to a minor extent, propionate and formate. Threonine and glycine are degraded to acetate. Acetate is also the major end product of metabolism from Casamino acids, peptone, and cysteine, but they are poorly used. As 0.2% yeast extract has been used to test for the utilization of amino acids, the possibility that degradation occurs via the Stickland reaction cannot be ruled out. Sugars are not used. Sulfate, thiosulfate, elemental sulfur, sulfite, nitrate, and fumarate are not utilized as electron acceptors.

A mixed culture of *Aminomonas paucivorans* and *Methanobacterium formicicum* is unable to extend the range of utilizable

substrates. However, compared to pure cultures, association of *Aminomonas* with *Methanobacterium formicicum* results in a shift in end product formation during degradation of arginine, histidine, and glutamate with methane and propionate as the major fermentation products (Table 227). In contrast to the pure culture, ornithine does not accumulate during arginine degradation by the mixed culture. Methane is not detectable in mixed culture with glycine and threonine, and the same end product profile as for a pure culture is observed (data not shown).

Cultivation of *Aminomonas paucivorans* under a H₂/CO₂ (80:20) atmosphere does not affect the fermentation of arginine, histidine, glutamate, threonine, or glycine; the end products are similar to those found without a hydrogen atmosphere.

Enrichment and isolation procedure

The Hungate technique (Hungate, 1969) should be used to isolate *Aminomonas paucivorans* and relatives. The basal medium (BM) contains (per liter of distilled water): 0.3 g NH₄Cl, 0.2 g KH₂PO₄, 0.4 g MgCl₂·6H₂O, 0.15 g CaCl₂·2H₂O, 0.5 g KCl, 1.0 g NaCl, 1 ml 0.1% resazurin, and 1 ml trace mineral element solution (Imhoff-Stuckle and Pfennig, 1983). The pH is adjusted to 7.2 with 10 M KOH. The medium is boiled under a stream of O₂-free N₂ gas and cooled to room temperature. Five ml aliquots are dispensed into Hungate tubes and 20 ml in serum bottles, under a stream of O₂-free N₂ gas. The gas phase is subsequently replaced with N₂-CO₂ (80:20, v/v) gas and the sealed vessels are autoclaved for 45 min at 110°C. Prior to inoculation, 0.15 ml 2% Na₂S·9H₂O, 0.25 ml 10% NaHCO₃, and 0.05 ml Balch vitamin solution (Balch et al., 1979) are injected from sterile stock solutions. Amino acids are added from sterile (heat or filter-sterilized) anaerobic stock solutions.

For isolation, a tenfold serial dilution is prepared and inoculated into the Hungate tubes containing 5 ml basal medium with arginine and yeast extract at final concentrations of 10 mM and 0.2%, respectively. The highest dilution showing growth after 3–4 weeks incubation at 37°C is used for further isolation. This positive culture is serially diluted and inoculated into roll tubes containing basal medium, yeast extract (0.2%), arginine (10 mM), and agar (2%) to get axenic cultures. Only one type of colony (small, round, whitish with smooth edges) develops after 4 weeks incubation at 37°C. The process of serial dilution in roll tubes is repeated at least twice in order to purify the cultures.

TABLE 227. Fermentation of substrates that supported growth of *Aminomonas* in pure culture^a

Substrate ^c	Amino acid degraded (mM)	Products formed (mM) ^b					H ₂	ΔOD ₅₈₀
		Acetate	Propionate	Formate	Ornithine			
Arginine	6.1	1.0	0.0	2.5	4.7	+	0.240	
Histidine	ND	9.2	0.0	4.8	0.0	ND	0.220	
Glutamate	7.7	7.5	2.0	4.0	0.0	+	0.080	
Threonine	ND	9.4	0.0	0.0	0.0	ND	0.110	
Glycine	3.0	4.5	0.0	0.0	0.0	ND	0.082	

^aSymbols: ND, not determined. Results were recorded after 3 weeks incubation at 37°C. The basal medium contained 0.2% yeast extract. (Reprinted with publisher's permission from Baena et al. 1999a. Int. J. Syst. Bacteriol. 49: 975–982.)

^bTubes containing basal medium with 0.2% yeast extract but lacking substrates were used as control. All values were corrected for a small amount of acetate (2 mM) formed in the control tubes.

^cPoor growth with Casamino acids, peptone, and cysteine was observed, and acetate levels above those of the control were present.

Maintenance procedure

Stock cultures can be maintained on medium described by Baena et al. (1999a) by monthly transfers. Liquid cultures retain viability after several weeks storage at 4°C, or when lyophilized, or after storage at -80°C in the basal medium containing 20% glycerol (v/v). Viability is best maintained from mid-exponential phase cultures.

Differentiation of the genus *Aminomonas* from other genera

Aminomonas represented by only one species, *Aminomonas paucivorans* is a Gram-stain-negative, slightly curved, nonsporeforming, obligate amino acid-degrading anaerobe, and therefore cannot be assigned to the aminolytic members of the genus *Clostridium* which include *Clostridium sticklandii* and *Clostridium aminophilum* (Paster et al., 1993), *Clostridium litorale*, *Clostridium pascui*, and *Clostridium hydroxybenzoicum* (Fendrich et al., 1990; Wilde et al., 1997; Zhang et al., 1994), and *Clostridium acetireducens* (Örlygsson et al., 1996). These species are Gram-stain-positive, sporeforming, straight rods. This conclusion is confirmed by phylogenetic analysis which places *Aminomonas paucivorans* in the *Firmicutes* (low G+C Gram-positives) in the vicinity of *Thermanaerovibrio acidaminovorans* (Baena et al., 1999b) (formerly *Selenomonas acidaminovorans*; Guangsheng et al. (1992), *Thermanaerovibrio velox* (Zavarzina et al., 2000), *Aminobacterium* species (Baena et al., 2000, 1998), *Anaerobaculum species* (Menes and Muxí, 2002; Rees et al., 1997), and *Dethiosulfovibrio peptidovorans* (Magot et al., 1997), with *Thermanaerovibrio acidaminovorans* and *Thermanaerovibrio velox* being its closest relatives (Figure 229). Like *Aminomonas paucivorans*, *Thermanaerovibrio species*, *Anaerobaculum species*, and *Dethiosulfovibrio peptidovorans* use amino acids. However, *Thermanaerovibrio* and *Anaerobaculum* species are thermophiles which also utilize carbohydrates. Furthermore, *Aminomonas paucivorans* differs from *Anaerobaculum thermoterrenum* and *Aminobacterium mobile* as both microorganisms ferment several organic acids (Menes and Muxí, 2002; Rees et al., 1997). In contrast to *Dethiosulfovibrio peptidovorans*, *Aminomonas paucivorans* uses thiosulfate or elemental sulfur as terminal electron acceptors.

Aminomonas paucivorans ferments histidine to acetate and formate. This fermentative pathway is similar to that used by anaerobic bacteria as suggested by McSweeney et al. (1993) and may also be operating in *Aminomonas paucivorans*. The latter degrades arginine to ornithine and this characteristic is similar to that reported for *Selenomonas acidaminovorans* and *Synergistes jonesii* (McSweeney et al., 1993). This suggests that the arginine deaminase pathway may be operational in *Aminomonas paucivorans*.

In pure culture, *Aminomonas paucivorans* ferments glutamate to acetate, formate, and trace amounts of propionate, a property that closely resembles *Acidaminobacter hydrogenoformans* in pure culture (Stams and Hansen, 1984). This trait differentiates it from other amino acid-degrading members of the genera *Acidaminococcus*, *Peptostreptococcus*, *Fusobacterium*, and *Clostridium* (Barker, 1981; Rogosa, 1969; Wilde et al., 1997), which produce acetate, butyrate, carbon dioxide, ammonium, and hydrogen. In contrast to *Aminomonas paucivorans*, *Thermanaerovibrio acidaminovorans* (Guangsheng et al., 1992) and *Anaeromusa*

acidaminophila (Baena et al., 2000) (formerly *Selenomonas acidaminophila*; Nanninga et al., 1987) produce propionate as a major end product from glutamate fermentation. Acetate is the only fatty acid produced from threonine and glycine fermentation by *Aminomonas paucivorans*. In the case of threonine degradation, this end product is unusual as most species that degrade threonine, with the exception of a few examples such as *Clostridium sticklandii* and *Clostridium subterminale* (Barker, 1981), are known to produce acetate and propionate.

An increase in the range of amino acids utilized is not observed in mixed culture of *Aminomonas paucivorans* with *Methanobacterium formicicum*, in contrast to the situation observed for *Acidaminobacter hydrogenoformans* (Stams and Hansen, 1984), *Thermanaerovibrio acidaminovorans*, and *Eubacterium acidaminophilum* (Zindel et al., 1988). However, the metabolism of all the amino acids used by *Aminomonas paucivorans*, except threonine and glycine, is clearly influenced by the presence of the hydrogenotrophic methanogen. No increase in acetate production, no change in the end product profile, and the lack of methane production in the presence of the hydrogen scavenger suggest that threonine and glycine degradation occurs via a reductive rather than an oxidative process. In addition, a hydrogen gas phase did not alter the growth of *Aminomonas paucivorans* on these two substrates, further strengthening this hypothesis.

Co-culture of *Aminomonas paucivorans* with *Methanobacterium formicicum* shifted the metabolic end products of arginine, histidine, and glutamate degradation from acetate to propionate as the major end product. This trait is similar to that of *Acidaminobacter hydrogenoformans* when it is co-cultured on glutamate and histidine with a hydrogen scavenger (Stams and Hansen, 1984). This may occur because the partial pressure of H₂ is reduced due to consumption by the hydrogen scavenger, with propionate production becoming thermodynamically more favorable (McInerney, 1988; Plugge et al., 2001).

In spite of observed similarities between *Aminomonas paucivorans* and *Acidaminobacter hydrogenoformans* with respect to glutamate metabolism, the latter is inhibited by a hydrogen atmosphere when grown on this amino acid. In addition, there are marked differences in the amino acids utilized. For example, *Acidaminobacter hydrogenoformans* utilized arginine and threonine only in mixed culture with hydrogenotrophic bacteria (Stams and Hansen, 1984), whereas *Aminomonas paucivorans* could ferment both of these amino acids in pure culture. In addition, unlike *Acidaminobacter hydrogenoformans*, *Aminomonas paucivorans* does not utilize alanine, valine, leucine, or isoleucine in the presence of hydrogen scavenging bacteria.

Taxonomic comments

The genus *Aminomonas* consists of only one species (*Aminomonas paucivorans*). Phenotypic and genotypic characteristics clearly place it within a cluster (designated *Clostridiales* Family XV *Incertae Sedis* in this volume) in the phylum *Firmicutes* containing *Thermanaerovibrio* species, *Aminobacterium* species, *Anaerobaculum* species, and *Dethiosulfovibrio peptidovorans*. For phylogenetic position see Figure 229. Further isolation and characterization of more species which are representative of this genus is required to confirm the classification of this genus.

List of species of the genus *Aminomonas*

1. ***Aminomonas paucivorans*** Baena, Fardeau, Ollivier, Labat, Thomas, Garcia and Patel 1999a, 981^{VP}.

pau'ci.vor'ans. L. adj. *paucus* few, little; L. pres. part. *vorans* devouring, digesting; N.L. part. adj. *paucivorans* digesting little.

In addition to the properties listed in the genus description, the following properties are reported. Cells are $0.3 \times 4\text{--}6\ \mu\text{m}$. Colonies (up to 1.0 mm) are round, smooth, and white. Grows at temperatures ranging from 20–40°C, with optimum growth at 35°C. Grows in the presence of NaCl at concentrations ranging from 0–2% NaCl, with optimum growth at 0.05–0.50% NaCl. The optimum pH for growth is 7.5 and growth occurs at pH 6.7–8.3. Heterotrophic, asaccharolytic. Yeast extract is required for growth. No growth is observed on carbohydrates, gelatin, casein, pyruvate, succinate, malate, fumarate, α -ketoglutarate, mesaconate,

β -methylaspartate, oxaloacetate, glycerol, ethanol, acetate, propionate, butyrate, lactate, citrate, leucine, lysine, alanine, valine, proline, serine, methionine, asparagine, phenylalanine, and aspartate. Sulfate, thiosulfate, elemental sulfur, sulfite, nitrate, and fumarate are not utilized as electron acceptors. Isolated from anaerobic sludge of a dairy wastewater treatment plant in Santa Fe de Bogota, Colombia. Adverse effects on animals and humans are not known. Because of the ability of *Aminomonas paucivorans* to degrade amino acids and peptides, the possibility of harmful effects cannot be excluded. Cautious handling and autoclaving of cultures before disposal is recommended.

DNA G+C content (mol%): 43 (HPLC).

Type strain: GLU-3, ATCC BAA-6, DSM 12260.

GenBank accession number (16S rRNA gene): AF072581.

Genus III. ***Anaerobaculum*** Rees, Patel, Grassia and Sheehy 1997, 153^{VP} emend. Menes and Muxí 2002, 163

BHARAT K. C. PATEL AND PHILIP HUGENHOLTZ

An.ae.ro.ba'cu.lum. Gr. pref. *an* not; Gr. n. *aer* air; L. neut. n. *baculum* small stick; N.L. neut. n. *Anaerobaculum* rod which grows in the absence of air.

Straight to slightly curved rods. Occur singly or in pairs. Moderately thermophilic, chemorganotrophic anaerobes. May be motile by a single polar flagellum. In complex media, cells may or may not grow with sheathlike material that extends past the cell poles. Endospores have not been observed. Cells stain Gram-negative. Ferment organic acids, protein extracts, and a limited range of carbohydrates. Sulfur, thiosulfate, and cystine are reduced to hydrogen sulfide. Sulfate, sulfite, and nitrate are not reduced. Isolated from production waters of a petroleum reservoir and an anaerobic lagoon treating wool-scouring wastewater.

DNA G+C content (mol%): 44–51.5.

Type species: ***Anaerobaculum thermoterrenum*** Rees, Patel, Grassia and Sheehy 1997, 153^{VP}.

Further descriptive information

The two validly published species, *Anaerobaculum thermoterrenum* and *Aminobacterium mobile*, ferment tryptone, Casamino acids, yeast extract, starch, malate, tartrate, pyruvate, glycerol, glucose, and fructose but not lactose, xylose, cellulose, CM-cellulose, gelatin, maltose, sucrose, galactose, rhamnose, raffinose, gum arabic, malonate, lactate, or succinate. Both species reduce thiosulfate, sulfur, and cystine. Both species utilize tryptone and yeast extract as electron donors with thiosulfate, sulfur, and cystine as electron acceptors, which are reduced to sulfide. Butyrate is produced from crotonate reduction by both species, but *Aminobacterium mobile* is more efficient at crotonate reduction than is *Anaerobaculum thermoterrenum*.

Enrichment and isolation procedures

Anaerobaculum thermoterrenum can be enriched from production waters of petroleum reservoirs using a citrate-based, sulfate-free, brackish, bicarbonate-buffered, sulfide-reduced medium (Widdel and Bak, 1992) that is fortified with yeast extract, vitamins, and trace elements (Rees et al., 1997). Isolation is achieved by

inoculating enrichment medium, solidified with agar (2%), in an anaerobic chamber followed by the transfer of the plates into an anaerobic jar and incubation at 50°C until colonies develop, usually 3 weeks later. Single colonies that develop are picked and grown on a complex MMB medium (g/l) containing 0.1 g of Na₂SO₄, 0.5 g of NH₄Cl, 0.3 g of K₂HPO₄, 0.3 g of KH₂PO₄, 0.2 g of MgCl₂·6H₂O, 0.2 g of CaCl₂·2H₂O, 1 g of NaCl, 0.1 g of KCl, 0.8 g of sodium acetate, 0.5 g of cysteine-HCl, 5 g of yeast extract, 5 g of tryptone, 0.001 g of resazurin, and 1 ml of SL-10 trace element solution (Imhoff-Stuckle and Pfennig, 1983). The pH of the medium is adjusted to 7.0, the medium rendered anaerobic, and it is dispensed under oxygen-free nitrogen gas by using the method of Patel et al. (1985a, 1985b).

The isolation source for *Aminobacterium mobile* was a mixed microbial consortium that had been previously enriched in an oleic-acid containing medium inoculated with a wool-scouring wastewater treatment lagoon sludge sample. This mixed microbial consortium was then used to inoculate BCYT-crotonate medium, and incubated at 55°C to enrich for a crotonate-degrading consortium (Menes et al., 2001; Touzel and Albagnac, 1983). BCYT contains (g/l) 1 g of NH₄Cl, 0.6 g of K₂HPO₄, 0.3 g of KH₂PO₄, 0.1 g of MgCl₂·6H₂O, 0.08 g of CaCl₂·2H₂O, 0.08 g of NaCl, 20 ml of cysteine-HCl (1.25% w/v), 10 g of yeast extract, 5 g of tryptone, 0.002 g of resazurin, 3.6 g of KHCO₃, 10 ml of trace element solution, 11.92 g of HEPES, and crotonate (15 mM). The medium is prepared anaerobically and dispensed into 10-ml anaerobic tubes under oxygen-free nitrogen gas. The gas phase is then replaced with N₂:CO₂ (70:30, v/v), the pH adjusted to pH 7.0, and it is autoclaved for 15 min at 121°C. Prior to inoculation, 0.01 ml vitamin solution and 0.2 ml filter-sterilized sulfide-cysteine solution [1.25% (w/v) Na₂S·9H₂O, 1.25% (w/v) cysteine-HCl] are injected into the tube. A stable enrichment culture that developed after several subcultures at 55°C was serially diluted in BCYT-crotonate tubes containing 2% agar to isolate *Aminobacterium mobile* (Menes and Muxí, 2002).

Differentiation of the genus *Anaerobaculum* from other genera

Members of the genus *Anaerobaculum* are straight to slightly curved rods that grow under anaerobic conditions and ferment

amino acids. These are physiological traits that are shared by members of the phylogenetically related genera *Aminomonas*, *Aminobacterium*, *Dethiosulfovibrio*, *Thermoanaerovibrio*, and *Synergistes*. A number of criteria that can be used to differentiate these genera are listed in Table 228.

FIGURE 230. Phylogenetic position of *Anaerobaculum thermoterrenum* and *Aminobacterium mobile* relative to some members of the family *Syntrophomonadaceae* and Family XV *Incertae Sedis*, order *Clostridiales*, class *Clostridia*, phylum *Firmicutes*.

TABLE 228. Differential characteristics of the genus *Anaerobaculum* from other physiologically similar and phylogenetically related genera^a

^aSymbols: +, >85% positive; d, different strains give different reactions (16–84% positive); –, 0–15% positive; w, weak reaction; ND, not determined.

Taxonomic comments

A number of early phylogenetic analyses showed that *Anaerobaculum thermoterrenum* and *Aminobacterium mobile*, together with members of the genera *Dethiosulfovibrio*, *Aminobacterium*, *Thermanaerovibrio*, and *Aminomonas* formed a deep and equidistant branch in the vicinity of the members of the genus *Thermoanaerobacterium* (phylum *Firmicutes*) and members of the genus *Dictyoglomus* with a mean similarity of 82% (Menes et al., 2001; Rees et al., 1997; Zavarzina et al., 2000) (Figure 230). Consequently, all the members of these genera together with *Anaerobaculum thermoterrenum* and *Aminobacterium mobile* were placed in the family *Syntrophomonadaceae*, order *Clostridiales*, class "*Clostridia*", phylum *Firmicutes*. A subsequent phylogenetic analysis has suggested that the genus *Dictyoglomus* forms a new line of descent and it therefore should be accorded a phylum status, phylum *Dictyoglomi* (Garrity and Holt, 2001a). However, a more recent phylogenetic evaluation of the genus *Anaerobaculum* suggests that it forms a reproducible, monophyletic line of descent with members

of the genera *Synergistes*, *Dethiosulfovibrio*, *Aminobacterium*, "*Aminiphilus*", *Thermanaerovibrio*, *Aminomonas*, and *Thermovirga*. Therefore, we propose that a new phylum be created to represent this line of descent: phylum "*Aminanaerobia*" (Figure 231). This phylum has a 15% 16S rRNA divergence, which is on a par with a number of recognized bacterial phyla, e.g., *Cyanobacteria*, *Firmicutes*, and *Dictyoglomi*. Currently, the genus *Synergistes* has been placed as a genus *incertae sedis* in the phylum *Deferribacteres* (Garrity and Holt, 2001b). In light of the analysis, it should be transferred to phylum "*Aminanaerobia*". All characterized members of the proposed phylum reported to date are obligate anaerobes and have the ability to utilize amino acids and/or peptides (Table 228), and environmental 16S rRNA gene surveys have only identified representatives of this phylum in anaerobic habitats (termite hindgut, rumen, anaerobic digesters, subgingival crevice). The metabolic conformity among the members of the proposed phylum both supports and lends credence to the phylogenetic data.

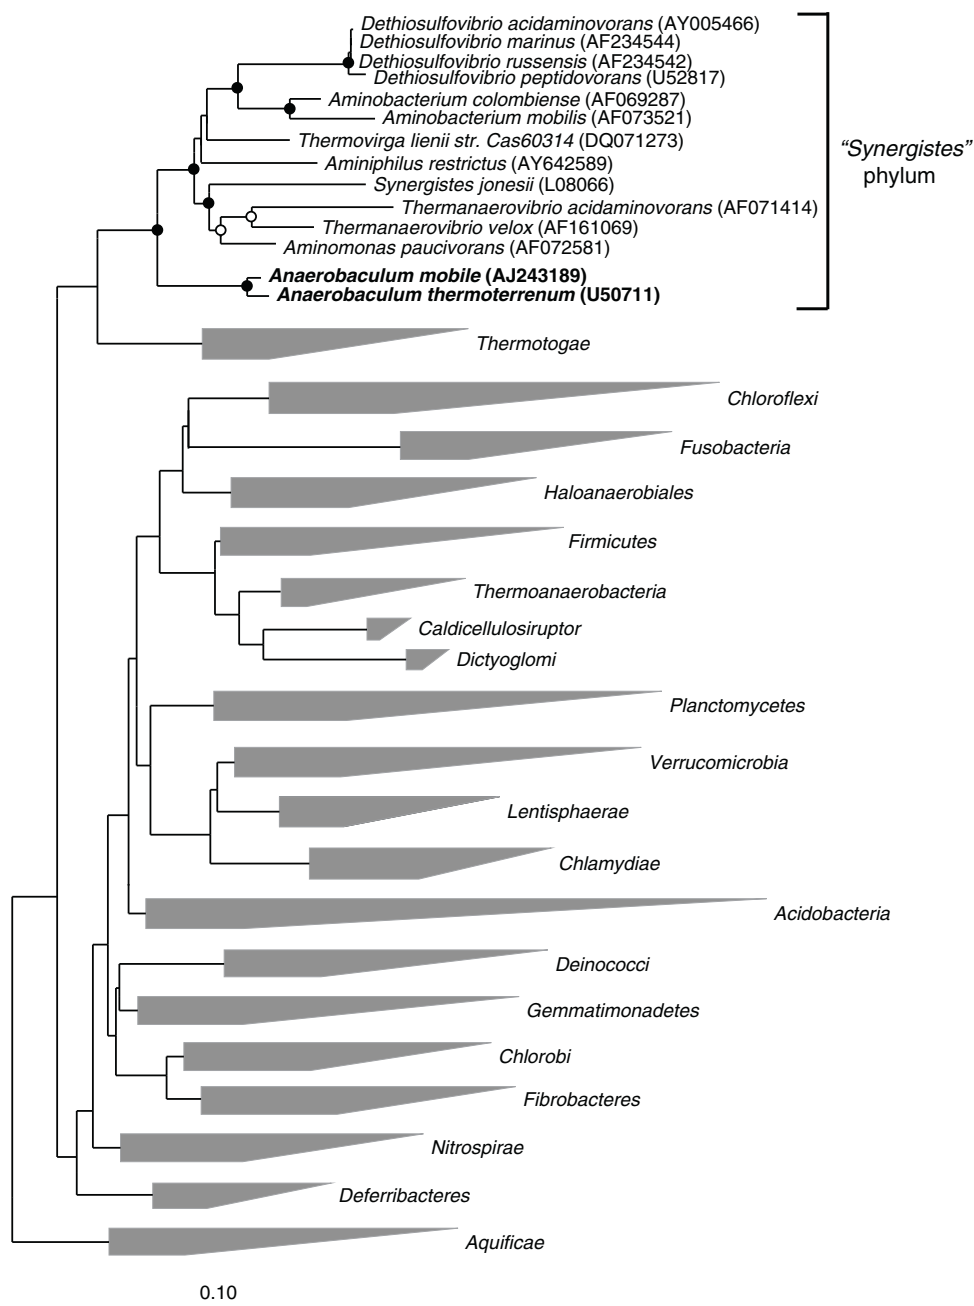

FIGURE 231. Maximum-likelihood tree of 16S rRNA gene sequences obtained from members of the "*Synergistes*" phylum and representatives of other bacterial phyla. *Anaerobaculum* species are bolded. Support for interior nodes is indicated by circles (filled, >90% bootstrap resampling support; open, >75% bootstrap resampling support). Data were obtained from the greengenes database (greengenes.lbl.gov).

Differentiation of the species of the genus *Anaerobaculum*

The characteristics that differentiate species of *Anaerobaculum* are listed in Table 229.

Key to the species of the genus *Anaerobaculum*

1. Single or paired straight to slightly curved rods that are surrounded by a sheathlike material when grown in complex medium. Ferments citrate, fumarate, glutamate, 2-oxoglutarate, pectin, and mannose. Requires 1% NaCl for optimal growth. Nonmotile and flagella are absent.
Anaerobaculum thermoterrenum
2. Single or paired straight rods. Does not ferment citrate, fumarate, glutamate, 2-oxoglutarate, pectin, and mannose. There is no requirement of NaCl for growth. Motile by means of a single flagellum.
Aminobacterium mobile

List of species of the genus *Anaerobaculum*

1. ***Anaerobaculum thermoterrenum*** Rees, Patel, Grassia and Sheehy 1997, 153^{VP}
ther.mo.ter.re'num. Gr. adj. *thermos* warm, hot; L. neut. adj. *terrenum* earthen, belonging to the earth; N.L. neut. adj. *thermoterrenum* from hot earth, describing the site of isolation.

Cells are 0.75 × 2 μm and occur singly or in pairs. A sheath-like material is observed in cells grown in complex medium but is absent in cells grown on citrate. Obligately anaerobic. The temperature range for growth is between 28 and 60°C, with an optimum of 55°C. Growth occurs in a medium

containing 0–20 g/l of NaCl with an optimum of 10 g/l. The pH range is from 5.5–8.6, with an optimum between 7 and 7.6. Ferments citrate, fumarate, malate, pyruvate, glutamate, 2-oxoglutarate, tartrate, starch, pectin, glucose, fructose, mannose, inositol, glycerol, protein extracts, and Casamino acids. Compounds that are not used are xylose, galactose, lactose, sucrose, maltose, rhamnose, raffinose, cellulose, carboxymethyl cellulose, gum arabic, malonate, succinate, glutarate, and lactate. Sulfide is produced from elemental sulfur, thiosulfate, and cystine. Sulfate, sulfite, and nitrate are not reduced. Growth is inhibited by H₂. Cytochromes are not present. Isolated from production fluid of a petroleum reservoir.

DNA G+C content (mol%): 44 (T_m).

Type strain: RWcit2, ACM 5076, DSM 13490.

GenBank accession number (16S rRNA gene): U50711.

2. *Anaerobaculum mobile* Menes and Muxí 2002, 163^{VP}

mo'bi.le. L. neut. adj. *mobile* motile.

Motile, straight rods, 0.5–1 × 2–4 μm, occurring singly or in pairs. Possess a single laterally inserted flagellum. Stains Gram-negative. Strictly anaerobic and chemo-organotrophic.

Spores have not been observed. Moderately thermophilic with a growth range between 35 and 65°C, and an optimum between 55 and 60°C. The pH growth range is pH 5.4–8.7, with an optimum between 6.6 and 7.3. The optimum NaCl concentration is 0.08 g/l but growth occurs with up to 15 g/l. Uses malate, tartrate, pyruvate, glycerol, starch, glucose, fructose, gluconate, Casamino acids, tryptone, and yeast extract. Carbohydrates and organic acids are converted to acetate, hydrogen, and CO₂. Oxidizes leucine to isovalerate with crotonate as electron acceptor, but not in co-culture with a methanogenic partner. Thiosulfate, sulfur, and cystine are reduced to sulfide. Crotonate is reduced to butyrate. Sulfate, fumarate, acetate, and nitrate are not reduced. No growth occurs on citrate, 2-oxoglutarate, glutamate, mannose, pectin, lactose, xylose, galactose, maltose, sucrose, rhamnose, raffinose, malonate, lactate, succinate, xylan, dextrin, inulin, melibiose, adonitol, cellobiose, arabinose, polygalacturonate, cellulose, gelatin, butyrate, or oleate.

DNA G+C content (mol%): 51.5 (HPLC).

Type strain: NGA, DSM 13181, ATCC BAA-54.

GenBank accession number (16S rRNA gene): AJ243189.

Genus IV. *Dethiosulfovibrio* Magot, Ravot, Campaignolle, Ollivier, Patel, Fardeau, Thomas, Crolet and Garcia 1997, 822^{VP}

WILLIAM B. WHITMAN

De.thi.o.sul.fo.vi'bri.o. L. pref. *de* from; Gr. n. *thion* sulfur, L. n. *sulfur* sulfur, *thiosulfo* thiosulfate; L. v. *vibrio* to vibrate, N.L. masc. n. *vibrio* that vibrates, a generic name; N.L. masc. n. *Dethiosulfovibrio* a vibrio that reduces thiosulfate.

Vibrios or curved rods. **Strictly anaerobic** heterotrophs that ferment peptides and amino acids. Sugars are not utilized. Reduces thiosulfate and elemental sulfur but not sulfate to hydrogen sulfide. Cells stain **Gram-negative** and possess multilayered cell walls. **Invaginations of the wall** are observed in some species. Endospores are not formed. **Motile** by means of **lateral flagella**. Isolated from the production water of oilfields and “*Thiodendron*” mats in consortia with spirochetes.

DNA G+C content (mol%): 51–56.

Type species: *Dethiosulfovibrio peptidovorans* Magot, Ravot, Campaignolle, Ollivier, Patel, Fardeau, Thomas, Crolet and Garcia 1997, 823^{VP}.

Further descriptive information

The description of *Dethiosulfovibrio* is based upon Magot et al. (1997) and Surkov et al. (2001). Phylogenetic analyses of 16S rRNA genes place *Dethiosulfovibrio* within Family XV *Incertainae Sedis* of the order *Clostridiales* (Ludwig et al., 2009). This well delineated, monophyletic group includes the other strict anaerobes *Anaerobaculum*, *Aminobacterium*, *Aminomonas*, and *Thermoanaerovibrio*. These genera all include straight to slightly curved rods that ferment amino acids. Some genera also utilize peptides or carbohydrates. Thiosulfate and/or elemental sulfur is also an electron acceptor for growth of some genera. Endospores are not formed, and these cells stain Gram-negative and possess multilayered cell walls.

The genus *Dethiosulfovibrio* is similar to other members of this family. Cells are curved rods or vibrioid in shape. They often occur in pairs and may form long, helical filaments during some phases of growth. Cells stain Gram-negative and possess

multilayered cell walls. In species where it has been examined, cells from the stationary growth phase form invaginations or incomplete cross-septa composed of in-growths of the cytoplasmic membrane and the peptidoglycan layer but not the outer wall (Surkov et al., 2001). Cells are motile by a tumbling movement and possess 1–6 flagella arranged laterally along the concave side of the cell. See Table 230 for further descriptive information.

The species of *Dethiosulfovibrio* were isolated for their ability to utilize either thiosulfate or elemental sulfur as an electron acceptor. Subsequently, it has been found that all species reduce both of these electron acceptors to sulfide, but they do not utilize sulfate. Moreover, thiosulfate and elemental sulfur are not disproportionated. When tested, sulfate, sulfite, fumarate, nitrate, Fe₂O₃, MnO₂, DMSO and Se⁰ were not reduced. Cytochromes are also absent. As carbon sources and electron donors, all species utilize peptides such as those found in Trypticase, peptone, and meat extract. Some individual amino acids, such as serine, are fermented. However, utilization of most amino acids requires an electron acceptor, either thiosulfate or elemental sulfur, and the specific amino acids used depends greatly upon the strain. Amino acids utilized by most if not all species include alanine, cysteine, glutamate, histidine, serine, threonine, and valine. Other amino acids utilized by at least one species are arginine, asparagine, isoleucine, leucine, lysine, and methionine. The branched-chain amino acids are oxidized to the branched-chain fatty acids. Methionine is oxidized to propionate. Alanine and asparagine are oxidized to acetate. Fatty acids and alcohols are not utilized, including: formate, acetate, propionate, butyrate, lactate, fumarate, succinate, ethanol, propanol, glycerol, and

mannitol. However, citrate, malate, pyruvate and 2-oxoglutarate are used by some species. Sugars are not utilized, including: arabinose, fructose, galactose, glucose, lactose, maltose, mannose, ribose, sucrose, trehalose, and xylose.

Dethiosulfovibrio peptidovorans may have a significant role in pipeline corrosion in oilfields where thiosulfate is present (Magot et al., 1997). Isolated from an oilfield with corroded pipes, it accelerates the rate of corrosion by at least an order of magnitude. In this regard, its effect is comparable to that of the sulfate-reducing bacteria. The remaining species were all isolated from "*Thiodendron*" mats (Surkov et al., 2001). These mats are common in shallow waters where H₂S is abundant (Dubinina et al., 1994b). Typical habitats also possess a salinity of 2 ‰, depths of 0.2–2 m, and mesophilic temperatures. The mats are composed of a co-culture of a spirochete and one or more sulfidogenic bacteria such as *Dethiosulfovibrio*. The spirochete oxidizes H₂S to elemental sulfur, which often appears as globules along its filaments. The sulfidogenic bacteria reduce the elemental sulfur back to H₂S using organic electron donors (Dubinina et al., 1994a).

Enrichment and isolation procedures

Dethiosulfovibrio peptidovorans was isolated from the production water of the Emerald oilfield in the Congo. The temperature of the oilfield was 38°C, and its waters possessed a total salinity of 52 g/l and 0.5 mM thiosulfate (Magot et al., 1997). The type strain was isolated following serial dilution and plating on half-strength tryptone-yeast extract-glucose medium under conditions for the cultivation of fermentative organisms.

"*Desulfonispora acidamionovorans*" and "*Dethiosulfovibrio russensis*" were isolated from sulfur "*Thiodendron*" mats in mineral

springs at the Staraja, Russia, health resort. "*Dethiosulfovibrio marinus*" was isolated from similar mats from the littoral zone at Kandalaksha Bay in the White Sea near Murmansk, Russia. Enrichments were performed anaerobically in medium containing yeast extract, peptone, citrate, and elemental sulfur.

Differentiation from closely related taxa

Dethiosulfovibrio may be differentiated by other members of Family XV *Incertae Sedis* of the order *Clostridiales* by its 16S rRNA gene sequence and a variety of phenotypic properties. Within this group, it and *Anaerobaculum* are the only genera that contain thiosulfate-reducing species. However, *Anaerobaculum* metabolizes sugars and is moderately thermophilic. *Dethiosulfovibrio* does not metabolize sugars and is mesophilic. While other members of this family tolerate low concentrations of NaCl, *Dethiosulfovibrio* is the only genus that requires 0.5 ‰ (w/v) or greater NaCl for growth.

Taxonomic comments

Although their descriptions were published in the *International Journal of Systematic and Evolutionary Microbiology*, the strains of "*Desulfonispora acidamionovorans*", "*Dethiosulfovibrio marinus*" and "*Dethiosulfovibrio russensis*" have only been deposited in one culture collection, the DSMZ. The revised Rule 27 of the Bacteriological Code requires that all type strains described after December 14, 2000, be deposited in two publicly accessible service collections in different countries (Euzéby and Tindall, 2004). Therefore, these names are not validly published. In contrast, *Dethiosulfovibrio peptidovorans*, which is also only deposited in the DSMZ, was published in 1997 and remains validly published.

List of species of the genus *Dethiosulfovibrio*

1. ***Dethiosulfovibrio peptidovorans*** Magot, Ravot, Campaignolle, Ollivier, Patel, Fardeau, Thomas, Crolet and Garcia 1997, 823^{VP}

pep.ti.do.vo'rans. Gr. adj. *peptos* cooked, L. v. *voros* to devour, N.L. part. adj. *peptidovorans* devouring peptides.

Properties are described in the genus description and Table 230.

DNA G+C content (mol%): 56 (HPLC).

Type strain: SEBR 4207, DSM 11002.

GenBank accession number (16S rRNA gene): U52817.

2. “**Dethiosulfovibrio acidaminovorans**” Surkov, Dubinina, Lysenko, Glöchner and Kuever 2001, 335
a.cid.a.mi.no.vo'rans. N.L. n. *acidum aminum* amino acid; L. v. *vorare* to devour or swallow; N.L. part. adj. *acidaminovorans* devouring amino acids.
 Properties are described in the genus description and Table 230.
DNA G+C content (mol%): 51 (T_m).
Type strain: SR15, DSM 12590.
GenBank accession number (16S rRNA gene): AY005466.
3. “**Dethiosulfovibrio marinus**” Surkov, Dubinina, Lysenko, Glöchner and Kuever 2001, 335
ma'ri.nus. L. adj. *marinus* marine.
 Properties are described in the genus description and Table 230.
DNA G+C content (mol%): 52 (T_m).
Type strain: WS100, DSM 12537.
GenBank accession number (16S rRNA gene): AF234544.
4. “**Dethiosulfovibrio russensis**” Surkov, Dubinina, Lysenko, Glöchner and Kuever 2001, 335
rus.sen'sis. N.L. adj. *russensis* pertaining to Staraja Russia.
 Properties are described in the genus description and Table 230.
DNA G+C content (mol%): 51 (T_m).
Type strain: SR12, DSM 12538.
GenBank accession number (16S rRNA gene): AF234542.

Genus V. **Thermanaerovibrio** Baena, Fardeau, Woo, Ollivier, Labat and Patel 1999b, 973^{VP} emend. Zavarzina, Zhilina, Tourova, Kuznetsov, Kostrikina and Bonch-Osmolovskaya 2000, 1293

DARIA G. ZAVARZINA

Therm.an.ae.ro.vib'ri.o. Gr. adj. *thermos* hot; Gr. pref. *an* not; Gr. n. *aer* air; N.L. masc. n. *vibrio* that vibrates; N.L. masc. n. *Thermanaerovibrio* a thermophilic vibrating anaerobe.

Cells are curved rods. Cell wall has **Gram-negative** structure. **Motile** by means of **lateral flagella located on the concave side** of the cells. Nonsporeforming. Obligate anaerobe. Neutrophilic. **Thermophilic. Chemo-organotrophic**; grows fermentatively with some amino acids, organic acids, and carbohydrates as substrates, or **lithoheterotrophically** with molecular **hydrogen** and **elemental sulfur**.

DNA G+C content (mol%): 54.5–56.5 (T_m).

Type species: **Thermanaerovibrio acidaminovorans** (Guangsheng, Plugge, Roelofsen, Houwen and Stams 1992) Baena, Fardeau, Woo, Ollivier, Labat and Patel 1999b, 973^{VP} (*Selenomonas acidaminovorans* Guangsheng, Plugge, Roelofsen, Houwen and Stams 1992, 174).

Further descriptive information

Based upon recent 16S rRNA analyses, *Thermanaerovibrio* has been classified in Family XV *Incertae Sedis* in this volume within the order *Clostridiales*. Previously, it had been classified within the family *Syntrophomonadaceae* and related genera of cluster V of the *Clostridium* group (Baena et al., 1999b; Collins et al., 1994). The genus includes two species, *Thermanaerovibrio acidaminovorans* and *Thermanaerovibrio velox*.

Phenotypically, members of the genus are moderately thermophilic, neutrophilic, obligate anaerobes. The most striking feature is the cell morphology – curved rods with a tuft of flagella located on the concave side of the cell (see Figure 232).

The glutamate catabolism of *Thermanaerovibrio acidaminovorans* was studied by the combined use of [¹³C]glutamate NMR measurements and enzyme activity determinations (Plugge et al., 2001). *Thermanaerovibrio acidaminovorans* converts glutamate to acetate, propionate, CO₂, NH₄⁺, and H₂. NMR spectra do not show any labeled acetate. The presence of key enzymes from the β-methylaspartate pathway indicates that, most likely, acetate forms through this pathway. *Thermanaerovibrio acidaminovorans* has a highly active glutamate dehydrogenase, both in the NAD-dependent and NADH-dependent directions, even when it is grown on glucose. Propionate formation occurs through the direct oxidation of glutamate via succinyl-CoA and methylmalonyl-CoA.

Members of the genus are organotrophic fermentative bacteria with different substrates utilized – many for *Thermanaerovibrio acidaminovorans* and more restricted for *Thermanaerovibrio velox*. In addition to fermentative capacity, both species are able to use an oxidative pathway with hydrogen as an electron donor and elemental sulfur as acceptor. Other acceptors including sulfate, sulfite, thiosulfate, nitrate, fumarate, and Fe(III) are not reduced by both species. Members of the genus are heterotrophic; the ability to grow autotrophically is not recorded.

Habitats are granular methanogenic sludge or neutral hot springs.

Enrichment and isolation procedures

Anaerobically prepared liquid bicarbonate-buffered medium and incubation at 55°C were used for the enrichments of *Thermanaerovibrio acidaminovorans* and *Thermanaerovibrio velox* (Guangsheng et al., 1992; Zavarzina et al., 2000). Pure cultures were obtained by isolation of single colonies in roll-tubes.

Maintenance procedures

Maintenance is not difficult. Cultures can be stored without transfer at room temperature for 1–2 weeks or in a refrigerator for 3–5 months. DSMZ maintains cultures in liquid nitrogen.

Differentiation of the genus *Thermanaerovibrio* from other genera

The differentiating characteristics of *Thermanaerovibrio* that distinguish it from the closely phylogenetically related genera *Dethiosulfovibrio* and *Anaerobaculum* are summarized in Table 231.

Taxonomic comments

The phylogenetic status of *Thermanaerovibrio* is based on 16S rRNA gene sequence analysis. The type species, *Thermanaerovibrio acidaminovorans*, was first assigned to the genus *Selenomonas* as a new species, *Selenomonas acidaminovorans*, based on its morphological characteristics, i.e., Gram-stain-negative, nonspore-forming, curved rods, motile by means of flagella located on the concave side of the cells (Guangsheng et al., 1992). The phylo-

FIGURE 232. Morphology of *Thermanaerovibrio velox*. (a) Phase-contrast light micrograph. Bar = 10 μm . (b) Flagella localization. Negatively stained cell. Bar = 1 μm .

genetic analysis of *Selenomonas acidaminovorans* was completed by Baena et al. (1999b). It revealed that *Selenomonas acidaminovorans* was placed distantly from the members of the genus *Selenomonas* with a similarity of only 80%. This organism was placed equidistantly between *Dethiosulfovibrio peptidovorans* and *Anaerobaculum thermoterrenum* with similarity of 85%. All three species share the common properties of requiring strict anaerobiosis for growth and curved cell morphology; each member forms an independent line of descent in vicinity of cluster V of *Clostridia* group (Collins et al., 1994; Magot et al., 1997; Rees et al., 1997). Based on phylogenetic separation alone, it was proposed to transfer *Selenomonas acidaminovorans* to a new genus, *Thermanaerovibrio* gen. nov., as *Thermanaerovibrio acidaminovorans* comb.

nov. In addition, some phenotypic characteristics (see Table 231) were the argument for the creation of a new genus (Baena et al., 1999b). In the current volume, *Thermanaerovibrio* is classified in Family XV *Incertae Sedis* along with the related genera *Aminobacterium*, *Aminomonas*, *Anaerobaculum*, and *Dethiosulfovibrio* (Figure 6).

The second species of the genus, *Thermanaerovibrio velox*, was placed in the genus *Thermanaerovibrio* according to its significant phenotypic similarity to *Thermanaerovibrio acidaminovorans*. The two species have similar morphology and physiology, and close DNA G+C content. However the level of DNA–DNA hybridization is rather low ($15 \pm 1\%$). The degree of similarity of 16S rRNA sequences of two species is at the level of generic differentiation 92.2% (Zavarzina et al., 2000). Table 232 shows some differential characteristics for the two *Thermanaerovibrio* species.

An inhibitory effect of elemental sulfur on growth of *Thermanaerovibrio acidaminovorans* growing on glucose was found. At the same time, both species of the genus *Thermanaerovibrio* are able to grow lithotrophically with molecular hydrogen and elemental sulfur. This feature was emended to description of genus *Thermanaerovibrio* (Zavarzina et al., 2000).

List of species of the genus *Thermanaerovibrio*

1. ***Thermanaerovibrio acidaminovorans*** (Guangsheng, Plugge, Roelofsen, Houwen and Stams 1992) Baena, Fardeau, Woo, Ollivier, Labat and Patel 1999b, 973^{VP} (*Selenomonas acidaminovorans* Guangsheng, Plugge, Roelofsen, Houwen and Stams 1992, 174) a.cid.a.mi.no.vo'rans. L. neut. n. *acidum* acid; N.L. neut. n. *aminum* amine; L. part. adj. *vorans* devouring; N.L. part. adj. *acidaminovorans* amino acid-digesting.

Curved cells 0.5–0.6 × 2.5–3.0 µm (when grown on succinate media) with rounded ends, single or in pairs, or in long chains when grown in complex media. On the concave side of the cell, 6–8 flagella are present.

Substrates used are listed in Table 233. Succinate is decarboxylated to propionate. Amino acids (see Table 233) are fermented to propionate, acetate, and hydrogen. Branched amino acids are degraded to branched-chain fatty acids. No growth occurs on glycine, aspartate, acetoin, malonate, and oxalate. Growth and substrate conversion are enhanced by co-cultivation with methanogens (*Methanobacterium thermoautotrophicum* ΔH) (Guangsheng et al., 1992). Elemental sulfur (1%) inhibits

growth on medium containing glucose (Zavarzina et al., 2000). Contains *b*-type cytochromes. Growth occurs in a pH range 6.5–8.1. The habitat is methanogenic granular sludge.

DNA G+C content (mol%): 56.5 ± 0.3 (*T_m*).

Type strain: Su883, ATCC 49978, DSM 6589.

GenBank accession number (16S rRNA gene): AF071414.

2. ***Thermanaerovibrio velox*** Zavarzina, Zhilina, Tourova, Kuznetsov, Kostrikin and Bonch-Osmolovskaya 2000, 1293^{VP} ve'lox. L. adj. *velox* quick, fast, motile.

Curved rods with tapering ends, 0.5–0.7 × 2.5–5.0 µm, with fast wave-like movement (Figure 232). Cells occur singly or in pairs. Ultrathin sections showed a typical Gram-stain-negative cell envelope profile with a multilayered cell wall (Figure 233). Colonies are small, white, irregular or round, 0.2 mm in diameter, with an even edge. Multiplication by binary fission. Growth occurs in a pH range 4.5–8.0.

Substrates used are listed in Table 233. No growth observed on sorbose, cellobiose, maltose, melibiose, raffinose, trehalose, acetate, ascorbate, butyrate, formate, glycolate, propionate, tartrate, L-dulcitol, L-inositol, manitol, propanol, L-sorbitol, glycogen, DL-lysine, sarcosine, tryptone, choline, cellulose, chitin, starch, or H₂ (in the absence of elemental sulfur). Yeast extract (0.25 g/l) and peptone (0.25 g/l) stimulate organotrophic growth on glucose. Yeast extract (0.1 g/l) is required for lithotrophic growth with H₂ and S⁰. Elemental sulfur stimulates organotrophic growth with glucose, peptone, yeast extract, trypticase, or Casamino acids and was reduced to H₂S. Isolated from thermophilic cyanobacterial mat from caldera Uzon, Kamchatka, Russia.

DNA G+C content (mol%): 54.6 ± 0.3 (*T_m*).

Type strain: Z-9701, DSM 12556.

GenBank accession number (16S rRNA gene): AF161069.

Family XVI. Incertae Sedis

Previously assigned to the *Syntrophomonadaceae* by Garrity et al. (2005), subsequent analyses suggest that this genus is not closely related to *Syntrophomonas* or a member of any other

previously described family. For that reason, it is assigned to its own family *incertae sedis*.

Genus I. *Carboxydocella* Sokolova, Kostrikina, Chernyh, Tourova, Kolganova and Bonch-Osmolovskaya 2002, 1965^{VP}

TATYANA G. SOKOLOVA

Car.bo.xy.do.cel'la. N.L. neut. n. *carboxydum* carbon monoxide; L. fem. n. *cella* cell; N.L. fem. n. *Carboxydocella* carbon monoxide-utilizing bacterium.

Cells are short **straight rods**. Cell wall of Gram-positive type. Cells divide by binary transverse fission. Obligate anaerobe. Colonies under 100% CO gas phase on solidified agar medium are round, white, 0.5–1 mm in diameter. **Hydrogenogenic CO-oxidizing bacteria that grow chemolithotrophically on CO. Utilize CO as the sole energy source with equimolar formation of H₂ and CO₂ according to the equation: CO + H₂O · CO₂ + H₂ ·** Neutrophilic, pH range for growth is 6.2–8.0, with an optimum of 6.8–7.0. Thermophilic, temperature range for growth 40–70°C.

DNA G+C content (mol%): 46–49.

Type species: Carboxydocella thermautotrophica Sokolova, Kostrikina, Chernyh, Tourova, Kolganova and Bonch-Osmolovskaya 2002, 1965^{VP}.

Further descriptive information

Species of the genus *Carboxydocella* are the members of the *Firmicutes*, but they do not possess strong similarities to any of the previously described families. The highest 16S rRNA gene sequence similarity is less than 89% with members of *Thermoanaerobacter*–*Syntrophomonas* group, but phylogenetic trees do not support a strong affiliation with either of these organisms. For this reason, it is classified with Family XVI *Incertae Sedis* in this volume (Figure 7).

Members of the genus *Carboxydocella* are currently represented by two species, *Carboxydocella thermautotrophica* and

Carboxydocella sporoproducens, which share 99.5% 16S rRNA gene sequence similarity. The level of DNA–DNA hybridization between type strains of *Carboxydocella thermautotrophica* and *Carboxydocella sporoproducens* is 45% (determined spectrophotometrically). Both species were isolated from hot springs of Kamchatka peninsula (Slepova et al., 2006; Sokolova et al., 2002). *Carboxydocella* species are widely spread in the Kamchatkan Geyzer Valley and the Uzon Caldera hot springs. These hot springs have temperatures and pH ranges of 50–70°C and 5.5–8.6, respectively.

Enrichment and isolation procedures

Members of the genus *Carboxydocella* have been isolated from terrestrial hot springs. There are no reports of members of this genus occurring in other environments. The methods of isolation are serial dilution transfers and single-colony isolations employing mineral medium supplemented with vitamins under 100% CO in the gas phase (Sokolova et al., 2002).

Maintenance procedures

Members of the genus *Carboxydocella* may be maintained on the medium of Sokolova et al. (2002). Liquid cultures may be stored at 4°C for 10–12 months without loss of viability. Lyophilization of the cultures performed in DSMZ resulted in good long-term preservation and recovery.

List of species of the genus *Carboxydocella*

1. ***Carboxydocella thermautotrophica*** Sokolova, Kostrikina, Chernyh, Tourova, Kolganova and Bonch-Osmolovskaya 2002, 1965^{VP}

therm.au.to.tro'phi.ca. Gr. adj. *thermos* hot; Gr. adv. *autos* self; Gr. n. *trophos* food; N.L. fem. adj. *thermautotrophica* indi-

cating that the organism grows at elevated temperatures and uses carbon monoxide as sole source for carbon and energy.

Cells are short straight rods of about 0.4–0.5 μm width and varying length from 1 to 3 μm, arranged singly or in

short chains of 3–5 bacteria. Nonsporeforming. Cell wall of Gram-stain-positive type. Motile due to lateral flagella. Cells divide by binary transverse fission. Obligate anaerobe. On solid medium, produces round, white, translucent colonies. Grows chemolithoautotrophically on CO. Utilizes CO as the sole energy source with equimolar formation of H₂ and CO₂ according to the equation: CO + H₂O → CO₂ + H₂. Does not grow on peptone, yeast extract, starch, cellobiose, sucrose, lactose, glucose, maltose, galactose, arabinose, fructose, acetate, formate, pyruvate, ethanol, methanol, H₂/CO₂ gas mixture (4:1, v/v), or on H₂, acetate, ethanol, or lactate in the presence or absence of elemental sulfur or sulfate. Does not reduce elemental sulfur or sulfate during growth with CO. Thermophile. Grows within the temperature range 40–68°C with an optimum at 58°C. pH for growth ranges from 6.5 to 7.6, with an optimum of 7.0. Growth and CO consumption are inhibited by penicillin, ampicillin, streptomycin, kanamycin, and neomycin. The habitat is terrestrial hot spring.

DNA G+C content (mol%): 46 ± 1 (T_m).

Type strain: 41, DSM 12326, VKM B-2282.

GenBank accession number (16S rRNA gene): AY061974.

2. **Carboxydocella sporoproducens** Slepova, Sokolova, Lysenko, Tourova, Kolganova, Kamzolkina, Karpov and Bonch-Osmolovskaya 2006, 799^{VP}

spo.ro.pro.du'cens. Gr. n. *spora* a seed and, in biology, a spore; L. part. adj. *producens* producing; N.L. part. adj. *sporo-producens* spore-producing.

Cells are short straight rods of about 0.5 µm in width and varying length from 1 to 6 µm. Forms round or ovoid refractile endospores in terminally swollen sporangia. Nonmotile. Cell wall is of the Gram-stain-positive type. Cells divide by binary transverse fission. Grows within the temperature range of 50–70°C with an optimum at 60°C. Growth pH ranges from 6.2 to 8.0, with an optimum of 6.8. Grows chemolithoautotrophically on CO. Grows organo-heterotrophically with yeast extract, sucrose, or pyruvate under N₂ in the gas phase. Does not grow on peptone, starch, cellobiose, glucose, arabinose, fructose, xylose, galactose, lactose, maltose, glycerol, acetate, citrate, succinate, formate, ethanol, methanol, H₂:CO₂ gas mixture (4:1, v/v). Does not reduce elemental sulfur, sulfate, or thio-sulfate in the presence of H₂, acetate, lactate, glycerol, or xylose or during growth with CO. Elemental sulfur, sulfide, and nitrate inhibit growth. Growth is inhibited by penicillin, novobiocin, streptomycin, kanamycin, and neomycin. The habitat is a terrestrial hot spring.

DNA G+C content (mol%): 49.5 ± 1 (T_m).

Type strain: Kar, DSM 16521, VKM B-2358.

GenBank accession number (16S rRNA gene): AY673988.

Family XVII. Incertae Sedis

Previously assigned to the “*Alicyclobacillaceae*” or *Syntrophomonadaceae* by Garrity et al. (2005), subsequent analyses suggest that these genera represent a very deep group

within the *Firmicutes* or, possibly, a novel phylum. Until their taxonomic status has been clarified, they are assigned to a family *incertae sedis*.

Genus I. **Sulfobacillus** Golovacheva and Karavaiko 1991, 179^{VP} (Effective publication: Golovacheva and Karavaiko 1978, 815.)

MILTON S. DA COSTA, FRED A. RAINEY AND LUCIANA ALBUQUERQUE

Sul.fo.ba.cil'lus. L. neut. n. *sulfur* sulfur; L. n. *bacillus* small rod; N.L. masc. n. *Sulfobacillus* small sulfur-oxidizing rod.

Straight rods, 0.5–0.8 µm in diameter by 3.0–5.0 µm in length. Terminal or subterminal ovoid or spherical **endospores**. In some strains, the sporangium is swollen. Gram-stain-positive. Strains are generally **nonmotile**; a few strains may be motile. **Colonies are not pigmented**. **Mesophilic or slightly thermophilic** with optimum growth temperatures between about 40 and 55°C; the temperature range for growth is between 20 and 60°C. **Acidophilic**, the pH range for growth is from about 1.5 to

5.5; the optimum is pH 1.9–2.4. **Menaquinone-7** is the predominant respiratory quinone. Fatty acids are primarily **iso-** and **anteiso-branched**; straight-chain fatty acids are also present. ω-Cyclohexane or ω-cycloheptane fatty acids are the major components of some strains. **Aerobic** with a strictly respiratory type of metabolism; some strains grow under **anaerobic** conditions with ferric iron as electron acceptor. Species are **mixotrophic**, with limited **autotrophic and chemoorganotrophic growth**. Mix-

otrophic growth occurs on Fe^{2+} , S^0 , $\text{S}_2\text{O}_3^{2-}$, $\text{S}_4\text{O}_6^{2-}$, and sulfide minerals in the presence of yeast extract or single organic compounds. Yeast extract and a few sugars and organic acids are used as sole carbon and energy sources. Strains require yeast extract for growth. Found in acidic soils and water of geothermal areas, mineral deposits, and ores.

DNA G+C content (mol%): 47–57 (T_m).

Type species: *Sulfobacillus thermosulfidooxidans* Golovacheva and Karavaiko 1991, 179^{VP}.

Further descriptive information

Four species are currently classified in the genus *Sulfobacillus*: *Sulfobacillus thermosulfidooxidans*, *Sulfobacillus acidophilus*, *Sulfobacillus sibiricus*, and *Sulfobacillus thermotolerans* (Bogdanova et al., 2006; Golovacheva and Karavaiko, 1978; Melamud et al., 2003; Norris et al., 1996a). The vast majority of the sulfobacilli produce endospores, which tend to be terminal or subterminal and have an ovoid morphology. Strains of the genus *Sulfobacillus* stain Gram-positive and the vast majority are not motile, although motility has been observed in strain L15, but flagella were not observed (Yahya et al., 1999).

The strains currently assigned to this genus are mesophilic or slightly thermophilic; the growth temperature range of these organisms varies between about 20 and 60 °C, with optimum growth temperatures ranging between about 40 and 55 °C (Bogdanova et al., 2006; Yahya et al., 1999). Organisms of the genus *Sulfobacillus* are extremely acidophilic with optimum pH of about 2.0. Some strains grow in media with pH as high as 5.0 and as low as 1.2 (Bogdanova et al., 2006).

Species of the genus *Sulfobacillus* are generally viewed as strict aerobes; however, several strains identified as *Sulfobacillus acidophilus* and *Sulfobacillus thermosulfidooxidans* are capable of growth under oxygen limitation or anaerobic conditions with ferric iron as terminal electron acceptor and glycerol as electron donor (Bridge and Johnson, 1998). Two of the four species of *Sulfobacillus* examined also appear to couple tetrathionate oxidation to ferric iron reduction and to be autotrophic under anaerobic conditions.

All strains of the genus *Sulfobacillus* have a mixotrophic metabolism on Fe^{2+} , S^0 , $\text{S}_4\text{O}_6^{2-}$, $\text{S}_2\text{O}_3^{2-}$, and sulfide minerals such as pyrite, arsenopyrite, and pyrotite in the presence of low levels of yeast extract (0.01–0.2%). Other organic compounds such as some sugars, amino acids, or reduced glutathione are also used as carbon sources under mixotrophic growth. Autotrophic growth on Fe^{2+} is generally poor, ceasing after a few transfers of the culture, and it is possible that autotrophic growth in some strains is due to carry over of organic compounds from mixotrophically grown inocula. Organotrophic growth is poor in all strains examined and generally limited to a few culture transfers. However, *Sulfobacillus thermosulfidooxidans* VKM B-1269^T grows indefinitely in medium containing 0.05% yeast extract as long as the culture is transferred daily, but *Sulfobacillus sibiricus* N1^T does not grow heterotrophically and appears not to grow under autotrophic conditions with elemental sulfur as the energy source (Melamud et al., 2003; Norris et al., 1996a). The energy metabolism of species of the genus *Sulfobacillus* has not been examined in any detail. It is known that *Sulfobacillus thermosulfidooxidans* VKM B-1269^T and *Sulfobacillus* strain 41 metabolize glucose primarily via the Entner–Doudoroff pathway,

but after enrichment of the medium with 5% CO_2 , glucose is metabolized via the Embden–Meyerhof pathway (Krasil'nikova et al., 2001). *Sulfobacillus sibiricus* N1^T, on the other hand, is reported to assimilate glucose via the fructose bisphosphate pathway and the pentose phosphate pathway (Zakharchuk et al., 2003). These authors also report the presence of ribulose-bisphosphate carboxylase indicating carbon dioxide fixation and autotrophic growth. Enzymes of sulfur metabolism, namely sulfite oxidase, sulfur oxygenase, adenylyl sulfate reductase, rhodanase, sulfur:Fe(III) oxidoreductase, and sulfite:Fe(III) oxidoreductase have been found in *Sulfobacillus sibiricus* N1^T and *Sulfobacillus* strain SSO (Krasil'nikova et al., 2004).

The sulfobacilli possess relatively high proportions of iso- and anteiso-branched fatty acids under mixotrophic growth conditions; ω -cyclohexane and ω -cycloheptane fatty acids are also present in some strains examined grown under organotrophic conditions. These ω -cyclic fatty acids have not been detected in *Sulfobacillus sibiricus* strain N1^T, probably because this organism does not grow heterotrophically (Melamud et al., 2003; Tsaplina et al., 1994). The type strain of *Sulfobacillus acidophilus* possesses relatively large proportions of cycloheptane and cyclohexane fatty acids, namely 18:0 ω -cycloheptane and 18:0 ω -cyclohexane (L. Albuquerque and M. S. da Costa, unpublished results), when grown on heterotrophic *Acidomicrobium* medium (Norris et al., 1996a). Terminal cyclic fatty acids are an important hallmark characteristic of 14 of the 17 described species of the genus *Alicyclobacillus*, but it should be noted that the presence of ω -cyclic fatty acids in the sulfobacilli does not necessarily imply a close phylogenetic relationship with the alicyclobacilli, since other unrelated bacteria, such as *Curvobacterium pusillum* (Suzuki et al., 1981) and *Propionibacterium cyclohexanicum* (Kusano et al., 1997) also possess these fatty acids. The major respiratory quinone is menaquinone-7 (Bogdanova et al., 2006).

Strains of the genus *Sulfobacillus* have been isolated from acidic environments associated with mineral deposits and ores, mineral processing mills, and acidic geothermal areas. The type strain of *Sulfobacillus acidophilus* and other closely related strains were isolated from coal spoil heaps in the UK, thermal springs in Iceland, and Yellowstone National Park (Norris et al., 1996a). The type strain of *Sulfobacillus thermosulfidooxidans* was isolated from a copper–zinc deposit in Kazakhstan (Golovacheva and Karavaiko, 1978), whereas the type strain of *Sulfobacillus thermotolerans* and other closely related strains (L15, RIV14, and Y0017) have been isolated during laboratory oxidation of a gold-containing concentrate, as well as from the acidic geothermal environments on the Island of Montserrat and Yellowstone National Park (Atkinson et al., 2000; Yahya et al., 1999). Three strains, designated M-13, M-16, and M-17, were isolated from uranium mines and uranium enrichment plants in Pakistan (Ghauri et al., 2003). Strain N1^T, the type strain of *Sulfobacillus sibiricus*, was isolated from a gold–arsenic concentrate obtained from an ore deposit in East Siberia (Melamud et al., 2003). Another strain, designated Fras1 (AF213055), was isolated from an unexpected environment for members of the genus *Sulfobacillus*, namely an acidic cave wall biofilm in Italy, but no further information regarding this strain has been published yet.

Enrichment, isolation and growth conditions

Enrichments of sulfobacilli and growth of the isolates are carried out in media containing low levels of yeast extract supplemented with reduced inorganic compounds, such as Fe^{2+} . One medium used extensively for the enrichment and cultivation of these organisms is modified 9K medium, also known as *Sulfobacillus* medium (Melamud and Pivovarova (1998); DSMZ medium 665). This medium is made up of three solutions. Solution A contains (g, all in 700 ml water adjusted to pH 1.8–2.0 with 5 M H_2SO_4): $(\text{NH}_4)_2\text{SO}_4$, 3.0; KCl, 0.1; K_2HPO_4 , 0.5; $\text{MgSO}_4 \cdot 7\text{H}_2\text{O}$, 0.5; and $\text{Ca}(\text{NO}_3)_2$, 0.01. Solution B contains 2.0 g ferrous iron in 300 ml water acidified with 1 ml 5 M H_2SO_4 . Solution C is 20 ml yeast extract solution (1%, w/v, in water). The three solutions are mixed after autoclaving. This medium can be supplemented with reduced sulfur compounds or sulfide ores (Bogdanova et al., 2006; Melamud et al., 2003; Norris et al., 1996a).

Maintenance procedures

Long-term cultures can be maintained frozen at -70°C in cryotubes containing liquid media, mentioned above, supplemented with a final concentration of 15% (v/v) glycerol. Freeze-dried and liquid nitrogen storage cultures have been maintained for several years without loss of viability.

Taxonomic comments

The taxonomy of the genus *Sulfobacillus* has suffered from the description of species whose names have not been validated and which, in some cases, have been poorly characterized (Johnson et al., 2003, 2005; Yahya et al., 1999). Phylogenetic analysis of 16S rRNA gene sequences has shown that some of these organisms, namely strains L15 (AY007663), RIV14 (AY007664), and YTE1 (AY007665), probably represent true genomic species of the genus *Sulfobacillus* (Figure 22). However, few taxonomic characteristics are available for these three strains.

Two strains formerly classified in the genus *Sulfobacillus* are now assigned as species of *Alicyclobacillus*. Strain SD-11^T

was classified as *Sulfobacillus disulfidooxidans* on the basis of its ability to utilize elemental sulfur and pyrite as sole source of energy under mixotrophic growth conditions (Dufresne et al., 1996). Phylogenetic analysis of the 16S rRNA gene sequence showed that strain SD-11^T fell within the radiation of species of the genus *Alicyclobacillus* (Goto et al., 2002, 2003; Matsubara et al., 2002) and it was classified as *Alicyclobacillus disulfidooxidans* (Figure 22) (Karavaiko et al., 2005). Another strain, designated K1^T, isolated from lead-zinc ores and initially named "*Sulfobacillus thermosulfidooxidans* subsp. *thermotolerans*" because it also had the ability to oxidize iron, elemental sulfur, and sulfides (Kovalenko and Malakhova, 1983), was reclassified as *Alicyclobacillus tolerans*, because of its close phylogenetic relationship to other species of *Alicyclobacillus* (Figure 22) (Karavaiko et al., 2005). It should be noted that *Sulfobacillus thermosulfidooxidans* was formerly divided into two subspecies informally named "*Sulfobacillus thermosulfidooxidans* subsp. *asporogenes*" for strain 41 and "*Sulfobacillus thermosulfidooxidans* subsp. *thermotolerans*" for strain K1^T (Kovalenko and Malakhova, 1983). As mentioned above, strain K1^T was reclassified as the type strain of the species *Alicyclobacillus tolerans* (Karavaiko et al., 2005), while the taxonomy of strain 41 has not been examined further.

The species of the genus *Sulfobacillus* form a monophyletic group supported by bootstrap analyses (Figure 22). *Sulfobacillus acidophilus* is the deepest branch of the genus cluster and shows 16S rRNA gene sequence similarity in the range 91.4–92.7% to other strains of this genus. The 16S rRNA gene sequence similarity range between members of the *Sulfobacillus* with validly published names is 91.4–98.8%, with the highest similarity found between *Sulfobacillus thermosulfidooxidans* and *Sulfobacillus sibiricus*. Strains L15 and RIV14, isolated from acidic geothermal environments on the island of Montserrat (Atkinson et al., 2000), are most closely related to *Sulfobacillus thermotolerans*, sharing 16S rRNA gene sequence similarities of 99.0 and 98.3%, respectively.

List of species of the genus *Sulfobacillus*

1. ***Sulfobacillus thermosulfidooxidans*** Golovacheva and Karavaiko 1991, 179^{VP} (Effective publication: Golovacheva and Karavaiko 1978, 815.)

ther.mo.sul.fi.do.ox.i'dans. Gr. adj. *thermos* hot; L. neut. n. *sulfur* sulfur; N.L. v. *oxidans* oxidize; N.L. part. adj. *thermosulfidooxidans* thermophilic sulfide oxidizing.

Strains of this species stain Gram-positive and form non-motile, rod-shaped cells, 1–6 μm in length and 0.6–0.8 μm in diameter with rounded or tapered ends. Cells occur singly, in pairs, or in short chains. Sporangia are slightly or markedly swollen; spherical or slightly oval endospores are located subterminally, terminally, or paracentrally. Colonies on agar media with Fe^{2+} are rounded, shining, initially yellowish and then reddish-brown in color. The pH range for growth is 1.5–5.5, optimum pH is around 1.9–2.4; the temperature range for growth is 20–60 $^\circ\text{C}$, optimum temperature is around 50–55 $^\circ\text{C}$. Strictly aerobic; anaerobic growth does not occur in medium contain-

ing nitrate. Mixotrophic and facultatively organotrophic; Fe^{2+} , S^0 , $\text{S}_2\text{O}_3^{2-}$, $\text{S}_4\text{O}_6^{2-}$, and sulfide minerals are oxidized in the presence of organic substrates. Strains grow poorly organotrophically on yeast extract, casein, glucose, sucrose, fructose, trehalose, mannose, raffinose, glutamate, and reduced glutathione. Autotrophic growth is very poor and limited to a small number of transfers. Strains of this species have been isolated from zones of spontaneous heating of ores in the Nikolaev copper-zinc-pyrite deposit.

DNA G+C content (mol%): 47.2–47.5 (T_m ; type strain).

Type strain: AT-1, DSM 9293, VKM B-1269.

GenBank accession number (16S rRNA gene): AB089844.

2. ***Sulfobacillus acidophilus*** Norris, Clark, Owen and Waterhouse 1996b, 1189^{VP} (Effective publication: Norris, Clark, Owen and Waterhouse 1996a, 781.)

a.ci.do'phi.us. L. n. *acidum* acid; Gr. adj. *philos* loving; N.L. adj. *acidophilus* acid-loving.

Strains of this species stain Gram-positive and form rod-shaped cells, 3–5 µm in length and 0.5–0.8 µm in diameter. Spherical endospores are located terminally. The optimum pH is around 2.0; the optimum temperature is around 45–50 °C. Aerobic, mixotrophic, autotrophic, and organotrophic. Some strains are facultatively anaerobic. Autotrophic growth occurs with ferrous iron and elemental sulfur as substrates. Mixotrophic; Fe²⁺, S⁰, S₄O₆²⁻, and sulfide minerals are oxidized in the presence of organic substrates. Strains utilize yeast extract for organotrophic growth; some strains use glucose, sucrose, fructose, and ribose. Strains of this species have been isolated from various acidic environments rich in iron, sulfur, or mineral sulfides.

DNA G+C content (mol%): 55–57 (*T_m*; type strain).

Type strain: NAL, DSM 10332.

GenBank accession number (16S rRNA gene): AF050169.

3. ***Sulfobacillus sibiricus*** Melamud, Pivovarova, Tourova, Kolgonova, Osipov, Lysenko, Kondrat'eva and Karavaiko 2006, 499^{VP} (Effective publication: Melamud, Pivovarova, Tourova, Kolgonova, Osipov, Lysenko, Kondrat'eva and Karavaiko 2003, 611.)

si.bi'ri.cus. N.L. masc. adj. *sibiricus* pertaining to Siberia.

Strains of this species stain Gram-positive and form nonmotile, rod-shaped cells, 1.0–3.0 µm in length and 0.7–1.1 µm in diameter. Spherical endospores are located subterminally. The pH range for growth is 1.1–2.6; optimum pH is around 2.0. The temperature range for growth is 17–60 °C; optimum temperature is around 55 °C. Mixotrophic. Branched-chain iso- and anteiso-fatty acids are produced under mixotrophic conditions. Stable growth is achieved with the simultaneous utiliza-

tion of ferrous iron, elemental sulfur, or sulfide minerals and reduced glutathione, yeast extract, glucose, fructose, sucrose, sorbitol, glutamate, and alanine.

DNA G+C content (mol%): 48.2 (*T_m*; type strain).

Type strain: N1, DSM 17363, VKM B-2280.

GenBank accession number (16S rRNA gene): AY079150.

4. ***Sulfobacillus thermotolerans*** Bogdanova, Tsaplina, Kondrat'eva, Duda, Suzina, Melamud, Tourova and Karavaiko 2006, 1041^{VP}

ther.mo.to'le.rans. Gr. adj. *thermos* hot; L. part. adj. *tolerans* tolerating; N.L. part. adj. *thermotolerans* hot-tolerating.

Strains of this species stain Gram-positive and form nonmotile, rod-shaped cells, 1.5–4.5 µm in length and 0.8–1.2 µm in diameter with rounded ends. Spherical endospores are located subterminally. The pH range for growth is 1.2–2.4; optimum pH is around 2.0. The temperature range for growth is 18–60 °C; optimum temperature is around 40–42 °C. Major respiratory quinone is menaquinone-7. Aerobic. Autotrophic and organotrophic growth is possible for a limited number of passages onto fresh medium. Mixotrophic; Fe²⁺, S⁰, S₂O₃²⁻, S₄O₆²⁻, and sulfide minerals are oxidized in the presence of organic substrates. Strains utilize yeast extract, malate, glucose, sucrose, fructose, and reduced glutathione for organotrophic growth. Strains of this species have been isolated during the course of pilot tests when a gold-containing sulfide concentrate was oxidized under mesophilic conditions.

DNA G+C content (mol%): 48.1 (*T_m*; type strain).

Type strain: Kr1, DSM 17362, VKM B-2339.

GenBank accession number (16S rRNA gene): DQ124681.

Genus II. ***Thermaerobacter*** Takai, Inoue and Horikoshi 1999, 625^{VP} emend. Spanevello, Yamamoto and Patel 2002, 799^{VP}

MARK D. SPANEVELLO AND BHARAT K. C. PATEL

Therm.ae.ro.bac'ter. Gr. adj. *thermos* hot; Gr. n. *aer* air; L. *bacter* masc. equivalent of Gr. neut. n. *bakterion* rod or staff; N.L. masc. n. *Thermaerobacter* rod, which grows at high temperatures in the presence of air.

Rods, 2–10 × 0.2–0.6 µm usually **arranged singly or in pairs**. **Stain Gram-negative or Gram-variable**. **Motile with monopolar or bipolar flagella**. Nonmotile species do not possess flagella. **May or may not form spores**. **Oxidase-positive**. **Strict aerobes**, having a strictly respiratory type of metabolism with oxygen as the terminal electron acceptor. **Thermophilic**, with growth occurring between 50 and 80 °C with optimum between 70 and 75 °C. **Neutrophiles or alkalophiles** with growth occurring between pH 5 and 10 with an optimum pH between 7 and 8.5. **Chemoheterotrophic**. May utilize organic substrates such as yeast extract, peptone, cellulose, starch, chitin, casein, Casamino acids, and a variety of sugars, carboxylic acids, and amino acids. Isolated from nonthermal sediments of the Mariana Trench, bore runoff channels of the thermal bore wells of Great Artesian Basin, and shallow marine hydrothermal vents.

DNA G+C content (mol%): 69–72.

Type species: Thermaerobacter marianesis Takai, Inoue and Horikoshi 1999, 625^{VP}.

Further descriptive information

The first member of the genus *Thermaerobacter*, *Thermaerobacter marianesis*, was isolated from the nonthermal sediments of Mariana Trench Challenger Deep, the world's deepest seafloor (10,897 m) (Takai et al., 1999) and the second member, *Thermaerobacter nagasakiensis*, was isolated from shallow marine hydrothermal vents (Nunoura et al., 2002). In addition, as of December 2005, "*Thermaerobacter riparius*" strain KW1 and "*Thermaerobacter*" strain C4-1 were isolated from coastal hydrothermal fields in Asia. 16S rRNA gene sequences of these isolates were deposited in GenBank under accession numbers AY936496 and AY094621, respectively, but phenotypic characteristics have not yet been reported. This could lead one to speculate that the

most likely primary habitat of *Thermaerobacter* species is the hydrothermal vents and that mantle subduction events led to the deposition of *Thermaerobacter marianensis* in the Mariana Trench Challenger Deep sediments. However, the isolation of the third species, *Thermaerobacter subterraneus*, from sediments of nonvolcanically heated subsurface freshwaters of an Australian bore well runoff channel suggests that *Thermaerobacter* may have a more diverse habitat than previously thought (Spanevello et al., 2002).

Enrichment and isolation procedures

The marine isolate *Thermaerobacter marianensis* was enriched at 75 °C on MJP medium and isolated by dilution to extinction as it did not form colonies on agar-fortified MJP medium (Sako et al., 1996a, 1996b) and *Thermaerobacter nagasakiensis* was enriched on JX medium at 70 °C and isolated by streaking on agar-amended JX medium (Sako et al., 1996b). Both these marine isolates can be grown on Medium 514, Bacto Marine Broth (BD, Inc., Franklin Lakes, NJ, USA) as recommended by the DSMZ (Deutsche Sammlung von Mikroorganismen und Zellkulturen), Braunschweig, Germany. The freshwater isolate, *Thermaerobacter subterraneus*, was enriched in Castenholz TYE media (ATCC medium 461) at 70 °C and isolated by streaking on agar-amended medium

Maintenance procedures

Thermaerobacter species can be stored at room temperature for up to 3 months. Cells can be suspended in a preservation broth, which consists of a 50:50 (v/v) mixture of growth medium and glycerol, and stored at -80 °C for long-term preservation.

Differentiation of *Thermaerobacter* from other genera

In this volume, the genus *Thermaerobacter* is classified with *Sulfobacillus* in Family XVII *Incertae Sedis* in recognition of the low sequence similarity of its 16S rRNA genes with those of other *Firmicutes* (Ludwig et al., 2009). While previous phylogenetic analyses placed the genus within the family *Syntrophomonadaceae* and order *Clostridiales* (Garrity et al., 2005), this conclusion is not consistent with the large phenotypic differences between these groups and examination of additional rRNA gene sequences (Figure 7). For instance, members of the order *Clostridiales* possess an anaerobic metabolism (Collins et al., 1994) with the exception of the three *Thermaerobacter* species and *Sulfobacillus*, which are all aerobes.

Taxonomic comments

The three validly published, named strains of *Thermaerobacter* species exhibit a high 16S rDNA similarity (98.3–99.7%) to one another, but phenotypic characteristics and DNA–DNA hybridization data justify recognition of *Thermaerobacter nagasakiensis* and *Thermaerobacter marianensis* as separate species. However, *Thermaerobacter nagasakiensis* and *Thermaerobacter subterraneus*, which have similar pH and temperature optima, can be distinguished on the basis of the presence or absence of flagella, motility, and spore-forming abilities. DNA–DNA hybridization studies between *Thermaerobacter marianensis* with *Thermaerobacter subterraneus* show only 5% homology and those between *Thermaerobacter nagasakiensis* and *Thermaerobacter marianensis*, 40%. DNA hybridization studies have not yet been performed between *Thermaerobacter subterraneus* and *Thermaerobacter nagasakiensis*. “*Thermaerobacter riparius*” and “*Thermaerobacter* strain C4-1” have a lower 16S rDNA similarity to the three described species (98% and 97%, respectively).

Spores have not been observed in *Thermaerobacter marianensis* and *Thermaerobacter nagasakiensis* though the sporulation gene *spo0A*, but not gene *ssp*, was detected by PCR. This is in direct contrast to *Thermaerobacter subterraneus*, which forms terminal ellipsoidal spores. This lack of congruence of phylogeny with physiology is notable, but not unusual. For example, all members of the family *Bacillaceae* are strict aerobes or facultative anaerobes with the exception of *Bacillus infernus* which is an obligate anaerobe, which necessitated amending the genus description (Boone et al., 1995).

Differentiation of the species of the genus *Thermaerobacter*

Three species of *Thermaerobacter* are currently described. Table 234 lists the features that differentiate these species.

List of species of the genus *Thermaerobacter**

- Thermaerobacter marianensis*** Takai, Inoue and Horikoshi 1999, 625^{VP}
ma.ri.a.nen'sis. N.L. masc. adj. *marianensis* pertaining to the Mariana Trench, the source of the type strain.
Rod-shaped cells, 2–7 × 0.3–0.6 μm. Gram-stain-negative or variable. Colonies are not formed on agar. Does not form spores and is nonmotile. Strictly aerobic and chemoheterotrophic. Growth occurs between 50 and 80 °C (opti-

mum is 70 °C), pH 5.4–9.5 (optimum is 7–7.5), and 0.5–5% NaCl (optimum, 2%).

DNA G+C content (mol %): 72.5 (HPLC).

Type strain: 7p75a, JCM 10246, DSM 12885, ATCC 700841.

GenBank accession number (16S rRNA gene): AB011495.

- Thermaerobacter nagasakiensis*** Nunoura, Akihara, Takai and Sako 2002, 344^{VP}
na.ga.sa.ki.en'sis. N.L. adj. *nagasakiensis* pertaining to Nagasaki Prefecture, the source of the type strain.

Rod-shaped cells, 1.5–4 × 0.3–0.5 μm. Gram-stain-negative. Colonies are ivory-white on JX medium amended with agar. Does not form spores and is motile by monopolar or dipolar

*Since acceptance of this chapter, a fourth species, *Thermaerobacter litoralis*, has been validly published by Tanaka et al. (2006).

TABLE 234. Characteristics differentiating the species of the genus *Thermaerobacter*^a

Characteristic	<i>T. marianesis</i>	<i>T. nagasakiensis</i>	<i>T. subterraneus</i>
Isolation source	Mud sample from the bottom of the 10,897 m. deep Mariana Trench	Shallow marine hydrothermal vent, Tachibana Bay, Nagasaki Prefecture, Japan	Water-sediment slurries of the runoff channel of New Lorne Bore (number 17263), Great Artesian Basin of Australia
Morphology and size (µm)	Curved rods, single or in pairs; 2–7 × 0.3–0.6 µm in exponential phase and 10 µm in stationary phase	Rods 1–4 × 0.2–0.5 µm	Rods occur singly or in pairs 2–10 × 0.3 µm
Gram stain	Positive in exponential phase and negative in stationary phase	Negative	Negative
DNA G+C content (mol%)	72.5 (HPLC)	68 (HPLC)	70 (<i>T_m</i>)
Spore-forming ability	–	–	+
Motility	–	+	–
Presence of flagella	–	+ (Monopolar or bipolar)	–
Temperature growth range (°C)	50–80	52–78	55–80
Temperature optimum (°C)	75	70	70
pH growth range	5.4–9.5	5–8	6–10
pH optimum	7.0–7.5	7	8.5
NaCl requirements	+	+	–
NaCl range for growth (optimum) (%)	0.5–5 (2)	0–4.5 (1)	0–1 (0)
Colony forming ability on agar	–	+	+
Requirement for yeast extract and peptone for growth	–	+	+
Growth on carbohydrates	+ ^b	–	–
Growth on amino acids	+ ^c	–	–
Growth on carboxylic acids	+ ^d	–	–

^aSymbols: +, >85% positive; –, 0–15% positive.

^bGrows well on starch, xylan, chitin, maltose, maltotriose, cellobiose, lactose, trehalose, sucrose, glucose, galactose, xylose, mannitol, inositol, and mannitol, with weak growth on cellulose.

^cGrows well on casein, Casamino acids, valine, isoleucine, cysteine, proline, serine, threonine, asparagine, glutamine, aspartate, glutamate, lysine, arginine, histidine but weakly on glycine, alanine, leucine, methionine, and phenylalanine.

^dGrows well on propionate, 2-aminobutyric acid, malate, pyruvate, tartarate, succinate, lactate, acetate, and glycerol.

flagella. Strictly aerobic and chemoheterotrophic. Growth between 52 and 78 °C (optimum is 70 °C), pH 5–8 (optimum is 7) and 0–4.5% NaCl (optimum is 1%).

DNA G+C content (mol%): 69 (HPLC).

Type strain: Ts1a, JCM 11223, DSM 14512.

GenBank accession number (16S rRNA gene): AB011495.

3. *Thermaerobacter subterraneus* Spanevello, Yamamoto and Patel 2002, 799^{VP}

sub.ter.ran'ē.us. L. masc. adj. *subterraneus* referring to under the earth, the source of the type strain.

Rod-shaped cells, 2–10 × 0.3 µm. Gram-stain-negative. Colonies are ivory-white on Castenholz TYE media (ATCC medium 461) amended with agar. Forms spores and is nonmotile. Strictly aerobic and chemoheterotrophic. Growth between 55 and 80 °C (optimum is 70 °C), pH 6.5–10.5 (optimum is 8.5), and 0–1% NaCl (optimum, 0%).

DNA G+C content (mol%): 71 (*T_m*).

Type strain: C21, ATCC BAA-137, DSM 13965.

GenBank accession number (16S rRNA gene): AF343566.

Family XVIII. Incertae Sedis

Symbiobacterium represents a very deep group within the *Firmicutes* or, possibly, a novel phylum. Until its taxonomic status has been clarified, it is assigned to its own family *incertae sedis*.

Genus I. **Symbiobacterium** Ohno, Shiratori, Park, Saitoh, Kumon, Yamashita, Hirata, Nishida, Ueda and Beppu 2000, 1832^{VP}

TERUHIKO BEPPU AND KENJI UEDA

Sym.bi.o.bac.te'ri.um. Gr. adj. *symbiotikos* symbiotic; Gr. dim. n. *bakterion* a small rod; N.L. neut. n. *Symbiobacterium* symbiotic small rod, referring to the growth dependence upon co-culture with other bacteria.

Straight, rod-shaped cells, 0.25–0.35 × 1.7–7 µm, with a multi-layered cell wall that stains Gram-negative. Exhibits low optical density. **Endospore-like structures are formed.** Peritrichously flagellated. Facultatively anaerobic. **Optimum growth occurs in broth co-culture with a thermophilic *Geobacillus* sp., but limited axenic growth is possible under a CO₂ atmosphere or with bicarbonate.** Small, translucent colonies are formed on gellan gum plates. **Analyses of the 16S rRNA gene indicate that this genus represents a deep bacterial lineage that is distinct from the *Firmicutes*, as well as from the *Actinobacteria*.**

DNA G+C content (mol%): 65–69.

Type species: Symbiobacterium thermophilum Ohno, Shiratori, Park, Saitoh, Kumon, Yamashita, Hirata, Nishida, Ueda and Beppu 2000, 1832^{VP}.

Further descriptive information

Cells are long, thin rods (Figure 234). The cell envelope is complex and composed of a multilayered structure outside the cytoplasmic membrane. The structure consists of an innermost electron-dense layer, an electron-transparent layer, and an outermost electron-dense layer (Ohno et al., 2000). The unit structure resembles the S-layer of *Bacillaceae*.

iso-Branched C_{15:0} and C_{17:0} acids are the major components of the cellular fatty acids. Menaquinone-6 is the major respiratory quinone. Indole is produced, as well as tryptophanase and tyrosine-phenyl lyase.

Co-culture with a *Geobacillus* sp. stimulates growth in a number of ways (see *Enrichment and Isolation Procedures*, below). *Geobacillus* produces bicarbonate, ammonia, and some amino acids that stimulate growth of *Symbiobacterium*. The stimulation by bicarbonate may be due to the absence of carbonic anhydrase in *Symbiobacterium* (Watsuji et al., 2006). Additionally, *Symbiobacterium* produces several indole derivatives that inhibit its own growth; co-cultivation with *Geobacillus* alleviates their toxicity (Watsuji et al., 2007).

The genome of the type species of the genus has been sequenced (Ueda et al., 2004). It contains a complete set of genes involved in endospore formation and an endospore-like structure has been observed (Ueda et al., 2004). However, the frequency of sporulation is extremely low and optimal conditions for endospore formation are not known. The genome also encodes many membrane transporters involved in peptide and amino acid uptake, most of the enzymes involved in primary metabolism, and a variety of respiratory systems including Nap nitrate reductase. However, genes for some biosynthetic enzymes and carbonic anhydrase are not present.

Symbiobacterium is widely distributed in compost, soil, animal intestines, and animal feeds (Ueda et al., 2001). It has also been isolated from seashells and other marine samples. Oyster shell

is a frequent isolation source. Cells are probably attached to the shell surface; they cannot be isolated from the digestive organs.

Enrichment and isolation procedures

The type species of the genus, *Symbiobacterium thermophilum*, was isolated from compost collected at Fukuyama (Hiroshima, Japan) as a result of its thermostable tryptophanase activity. The original thermophilic, tryptophanase-positive culture contained *Symbiobacterium thermophilum* in co-culture with a bacillus, strain S. The bacillus was subsequently identified by 16S rRNA gene sequence similarity analysis as a strain of *Geobacillus stearothermophilus* (GenBank accession no. AB051200). The co-culture grew well when incubated without shaking (Suzuki et al., 1988).

It was very difficult to isolate *Symbiobacterium thermophilum* from the co-culture. Subsequent studies obtained pure cultures by growing *Symbiobacterium* separated from strain S by only a dialysis membrane or in medium supplemented with culture broth of *Geobacillus stearothermophilus* strain S (Ohno et al., 1999). Colonies are obtained at an extremely low efficiency on agar medium, but at a higher frequency on gellan gum medium. Optimum growth is obtained by co-culture of the *Symbiobacterium thermophilum* and *Geobacillus stearothermophilus* strains without shaking. Axenic cultures can also be grown in dialysis culture flasks (Ohno et al., 1999). Limited growth also occurs in a liquid culture using LB medium with an anaerobic atmosphere containing CO₂ (N₂/CO₂/H₂; 8:1:1, by vol.) (Watsuji et al., 2006). Enrichment cultures containing *Symbiobacterium* cells can be obtained by inoculating a compost sample into LB liquid medium and incubating at 60 °C without shaking for 2–6 d (Ueda et al., 2001).

Maintenance procedures

The type strain is stored in LB medium without glycerol at –80 °C. Cultures may also be lyophilized. LB medium is composed of (g/l distilled water): yeast extract, 5.0; tryptone (Difco), 10.0; and NaCl, 5.0. Solid medium is prepared by the addition of 10 g/l gellan gum. LB liquid medium conditioned by *Geobacillus stearothermophilus* strain S (called “conditioned medium”) is prepared by adding filtrate of a fully grown culture of *Geobacillus stearothermophilus* strain S to fresh LB medium in a 1:1 ratio. The culture of *Geobacillus stearothermophilus* strain S is grown at 60 °C for 17 h in LB medium without shaking.

Taxonomic comments

This genus was originally described as a Gram-negative bacterium due to several features observed in traditional physiological characterization studies (Hirahara et al., 1993, 1992; Suzuki

FIGURE 234. Morphology of *Symbiobacterium thermophilum* in a thin-section from an electron micrograph. Bar = 0.4 μm . (Courtesy of A. Hirata.)

et al., 1988). However, in 16S rRNA gene trees, the genus *Symbiobacterium* is more closely related to the *Actinobacteria* and some *Firmicutes* and it forms a distinct branch associated with *Thermaerobacter* and *Sulfobacillus* (Figure 235; Ohno et al., 2000; see Ludwig et al., 2009). The complete genome sequence also reveals a number of features that indicate a stronger affiliation with the *Firmicutes*, in spite of the high G + C content of its DNA (Ueda et al., 2004). The absence of signature sequences that are characteristic of *Actinobacteria* also indicates that the

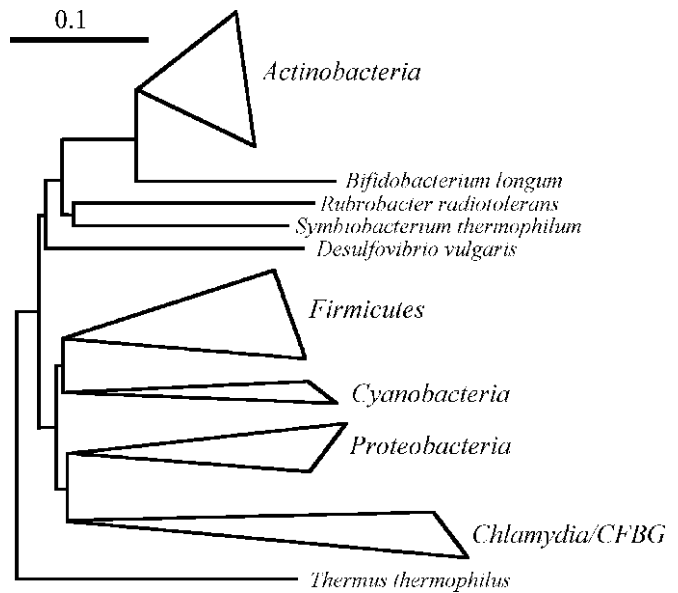

FIGURE 235. Phylogeny of *Symbiobacterium* based on 16S rRNA gene sequences reveals its distinct position outside the major bacterial lineages. The tree is a modification of the neighbor-joining distance tree by Gao and Gupta (2005). Bar = 10% sequence divergence.

genus should not be placed in the phylum *Actinobacteria* (Gao and Gupta, 2005). Phylogenetic analysis based on ribosomal protein sequences shows the affiliation of the genus with the class *Clostridia* (Nishida et al., 2009).

List of species of the genus *Symbiobacterium*

1. ***Symbiobacterium thermophilum*** Ohno, Shiratori, Park, Saitoh, Kumon, Yamashita, Hirata, Nishida, Ueda and Bepu 2000, 1832^{VP}

ther.mo'phil.um. Gr. n. *therme* heat: Gr. adj. *philos* friendly, loving; N.L. neut. n. *thermophilum* heat-loving, referring to the optimum growth at a high temperature.

Characteristics are as described for the genus with the following additional information. Colonies on LB medium solidified with 1% gellan gum are small (1–2 mm in diameter) and translucent. The efficiency of colony formation on agar medium is extremely low (<1%). Broth cultures have a very low optical density of only 10% of that *Escherichia coli* (Ohno et al., 1999). Resistant to kanamycin (100 $\mu\text{g}/\text{ml}$), but sensitive to neomycin. The maximum cellular yield of axenic cultures is about 1×10^7 cells/ml in LB medium under an anaerobic atmosphere of $\text{N}_2/\text{CO}_2/\text{H}_2$ (8:1:1, by vol.). A 3- to 5-fold increase in cellular yield is achieved by using LB medium supplemented with culture broth of *Geobacillus stearothermophilus* strain S (conditioned medium). Cells occur singly or in pairs. Growth occurs between pH 7.0 and 9.0, with optimum growth at pH 7.5. The temperature range for growth is 45–65 $^\circ\text{C}$, with optimum growth at 60 $^\circ\text{C}$. Minor fatty acids are $\text{C}_{17:0}$ anteiso⁺, $\text{C}_{15:0}$

anteiso⁺, $\text{C}_{16:0}$ iso⁺, and $\text{C}_{16:0}$. Catalase-positive. Produces thermostable tryptophanase and tyrosine-phenyl lyase.

The complete genome sequence is known. It is 3.57 Mb in size, contains more than 3300 protein coding sequences, and harbors many class C group II introns (Ueda et al., 2004).

DNA G+C content (mol%): 68.7 (genome sequencing method).

Type strain: T, JCM 14929.

GenBank accession number (16S rRNA gene): AB004913.

GenBank accession number (genome): AP006840.

2. **“*Symbiobacterium toebii*”** Sung, Bae, Kim, Kim, Song, Rhee, Jeon, Choi, Hong, Lee, Ha and Kang 2003, 1016

to.e'bi.i. N.L. neut. n. *toebii* referring to toebi, the farmland compost in Korea, the original source of the organism.

Characteristics are as described for the genus with the following additional information (Sung et al., 2003). Cells occur singly or in pairs. Growth occurs between pH 6.0 and 9.0, with optimum growth at pH 7.5. The temperature range for growth is 45–70 $^\circ\text{C}$, with optimum growth at 60 $^\circ\text{C}$. Minor fatty acids are $\text{C}_{16:0}$ iso⁺, $\text{C}_{16:0}$, $\text{C}_{17:0}$ anteiso⁺, $\text{C}_{15:0}$ anteiso⁺, and $\text{C}_{18:0}$. Resistant to kanamycin (200 $\mu\text{g}/\text{ml}$). Contains menaquinone-7 as a minor respiratory quinone. The 16S rRNA gene sequence

similarity and DNA–DNA hybridization with *Symbiobacterium thermophilum* are 98.5 and 30%, respectively. Enzymes produced include alkaline phosphatase, esterase (C4), leucine arylamidase, α -chymotrypsin, acid phosphatase, naphthol-phosphohydrolase, α -galactosidase, and α - and β -glucosidase.

Nitrate is reduced to nitrite. Isolated from farmland compost in Gongju, Korea.

DNA G+C content (mol%): 65 (HPLC).

Type strain: SC-1, KCTC 0307BP, DSM 15906.

GenBank accession number (16S rRNA gene): AF190460.

Family XIX. Incertae Sedis

The 16S rRNA gene sequence of *Acetoanaerobium* is not available. While phenotypic characteristics suggest an affiliation to

this order, it is not possible to assign it to a family. For that reason, it is classified within its own family *incertae sedis*.

Genus I. *Acetoanaerobium* Sleat, Mah and Robinson 1985, 13^{VP}

FRED A. RAINEY

A.ce.to.an.ae.ro'bi.um. L. n. *acetum* vinegar; Gr. pref. *an* not; Gr. n. *aer* air; Gr. n. *bios* life; N.L. neut. n. *Acetoanaerobium* vinegar anaerobe.

Cells are nonsporeforming rods. Cells stain Gram-negative but have an atypical Gram-negative wall structure. Obligate anaerobe. Chemo-organotrophic. Ferment carbohydrates, producing acetate and sometimes other volatile acids. Ferment yeast extract, producing acetate and several volatile acids. At slower growth rates produce acetate from H₂ and CO₂. May require yeast extract for growth.

DNA G+C content (mol%): 36.8 (Bd).

Type species: *Acetoanaerobium noterae* Sleat, Mah and Robinson 1985, 13^{VP}.

Taxonomic comments

The genus *Acetoanaerobium* was described for a strain that forms acetate from H₂ and CO₂ but differed from previously described acetogenic species in the genera *Clostridium*, *Acetobacterium*, and *Acetogenium*. These differences were for the most part phenotypic in nature including lack of spore formation, Gram staining and cell-wall structure. To date a 16S rRNA gene sequence has not been determined for *Acetoanaerobium noterae* and so the phylogenetic position of this genus remains unknown as does its true taxonomic status.

List of species of the genus *Acetoanaerobium*

1. *Acetoanaerobium noterae* Sleat, Mah and Robinson 1985, 13^{VP} no'ter.ae. L. gen. n. *noterae* of Notera; named for its source, the Notera oil exploration site in Israel.

Cells are straight rods, 1.0–5.0 μ m long and 0.8 μ m wide. Motile by three or four peritrichous flagella. Cells stain Gram-negative. Gram-positive cell-wall structure as determined

by transmission electron microscopy, is composed of two distinct layers, a darker inner layer and lighter outer layer. Colonies are rhizoid, opaque, and granular. Young colonies are white, older colonies are brownish and up to 2 cm in diameter after 1 month of incubation. Yeast extract, maltose, and glucose are used for heterotrophic growth. Compounds not supporting growth include arabinose, rhamnose, ribose, xylose, fructose, galactose, cellobiose, lactose, mannose, sucrose, melezitose, trehalose, erythritol, adonitol, dulcitol, inositol, mannitol, sorbitol, formate, acetate, pyruvate, lactate, malate, fumarate, succinate, citrate, glutamate, methylamine, trimethylamine, and methanol. Yeast extract is required for growth and H₂ utilization. Growth on yeast extract and H₂-CO₂ is biphasic, with an initial rapid growth phase independent of the presence of H₂, followed by H₂-dependent acetate production

during the second slower growth phase. Produces acetate, propionate, isobutyrate, butyrate, and isovalerate (and little or no H₂) during growth on yeast extract alone. Acetate is the only fermentation product from glucose or maltose. Optimum temperature for growth is 37 °C. Growth occurs in the pH range 6.6–8.4, optimum 7.6. Doubling times are 2.8 h for heterotrophic growth and 27 h for H₂-dependent growth. Vitamins are not required. Growth is inhibited by erythromycin, chloramphenicol, penicillin, cephalosporin, and cycloserine at concentrations of 100 ng/liter. The type strain was isolated from sediment collected near the Notera oil drilling site in the Hula swamp area of Galilee, Israel.

DNA G+C content (mol%) of the type strain: 36.8 (Bd).

Type strain: NOT-3, ATCC 35199.

GenBank accession number (16S rRNA gene): not determined.

- Sleat, R., R.A. Mah, and R. Robinson. 1985. *Acetoanaerobium noterae* gen. nov., sp. nov. an anaerobic bacterium that forms acetate from H₂ and CO₂. *Int. J. Syst. Bacteriol.* 35: 10–15.

Order II. Halanaerobiales corrig. Rainey and Zhilina 1995a, 879^{VP} (Effective publication: Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995b, 193.)

AHARON OREN

Hal.an.ae.ro.bi.a'les. N.L. fem. pl. n. *Halanaerobiaceae* type family of the order; *-ales* ending to denote an order; N.L. fem. pl. n. *Halanaerobiales* the *Halanaerobiaceae* order.

Cells are rod-shaped and **Gram-stain-negative**. Endospores are produced by some species. **Strictly anaerobic**. Oxidase- and catalase-negative. Most species ferment carbohydrates to products including acetate, ethanol, hydrogen, and carbon dioxide. Some species may grow fermentatively on amino acids, others have a homoacetogenic metabolism or may grow by anaerobic respiration on nitrate, trimethylamine *N*-oxide or selenate.

Further descriptive information

All known members of the *Halanaerobiales* are strictly anaerobic and moderately halophilic. One species (*Halothermothrix orenii*, isolated from Chott El Guettar, a warm saline lake in Tunisia) is thermophilic, growing optimally at 60 °C and tolerating up to 68 °C (Cayol et al., 1994a). Some species are moderately alkaliphilic or alkalitolerant. *Natroniella acetigena*, isolated from the alkaline hypersaline Lake Magadi, Kenya, is an obligate alkaliphile and grows between pH 8.1–10.7 with an optimum at 9.7–10.0 (Zhilina et al., 1996). The alkaline (pH 10.2) Lake Magadi was shown to harbor a varied anaerobic community including cellulolytic, proteolytic, saccharolytic, and homoacetogenic bacteria (Zhilina and Zavarzin, 1994) and it may therefore be expected that additional alkaliphilic members of the *Halanaerobiales* may be isolated from this interesting ecosystem in the future.

All species show a negative Gram-stain reaction. Heat-resistant endospores are produced by a number of species belonging to the family *Halobacteroidaceae*, one of the two families classified within the order. Endospore formation has not been

Moderately halophilic. NaCl concentrations between 0.5–3.4 M are required for optimal growth and no growth is observed below 0.3–1.7 M NaCl, depending on the species.

DNA G+C content (mol%): 27–40.

Type genus: **Halanaerobium** corrig. Zeikus, Hegge, Thompson, Phelps and Langworthy 1984, 503^{VP} (Effective publication: Zeikus, Hegge, Thompson, Phelps and Langworthy 1983, 232.)

reported in any representative of the family *Halanaerobiaceae*. A phenotypic test that may correlate between phylogenetic position in the *Halanaerobiales* within the *Firmicutes* and the ability to form endospores is hydrolysis of the D-isomer of *N*'-benzoyl-arginine-*p*-nitroanilide (BAPA). Four representatives of the *Halanaerobiales* were tested for D-BAPA and L-BAPA hydrolysis and three of them (*Halobacteroides halobius*, *Orenia marismortui*, and *Halanaerobium praevalens*, the last belonging to the family *Halanaerobiaceae*, in which endospore formation has never been observed as yet) hydrolyzed D-BAPA, whereas L-BAPA was not hydrolyzed. *Sporohalobacter lortetii* degrades neither of the BAPA stereoisomers (Oren et al., 1989).

Most species belonging to the *Halanaerobiales* obtain their energy by fermenting simple sugars. This type of metabolism is the only one detected thus far in the family *Halanaerobiaceae*. Within the family *Halobacteroidaceae*, the metabolic diversity appears to be much greater than that observed within the *Halanaerobiaceae*. In addition to sugar fermenters, there are species within the family *Halobacteroidaceae* that can ferment amino acids, either alone or using the Stickland reaction. The neu-

trophilic *Acetohalobium arabaticum* and the alkaliphilic *Natroniella acetigena* are homoacetogens. Finally, *Selenihalanaerobacter shriftii* oxidizes glycerol or glucose by anaerobic respiration with nitrate, trimethylamine *N*-oxide, or selenate as electron acceptor (Switzer Blum et al., 2001). It is the only representative of the order in which the presence of cytochromes has been documented thus far; no cytochromes have been detected in *Halanaerobium acetethylicum* (Rengpipat et al., 1988a), *Halobacteroides halobius* (Oren et al., 1984), *Sporohalobacter lortetii* (Oren, 1983), *Orenia marismortui* (Oren et al., 1987), or *Acetohalobium arabaticum* (Pushveva and Detkova, 1996).

Most halophilic and halotolerant representatives of the domain *Bacteria* (aerobic heterotrophs, aerobic and anaerobic phototrophs) use organic osmotic solutes such as glycine betaine, ectoine, and others to provide osmotic balance of the cytoplasm with the surrounding medium, while excluding salts from the cytoplasm to a large extent. No such organic osmotic solutes have been detected in most members of the *Halanaerobiales* tested. However, glycine betaine was found to be accumulated to 1.9–2.2 $\mu\text{mol}/\text{mg}$ protein when these bacteria were grown in medium containing yeast extract (Mouné et al., 2000). On the other hand, high concentrations of Na^+ , K^+ , and Cl^- , i.e., high enough to be at least isotonic with the medium, have been measured inside the cells of *Halanaerobium praevalens*, *Halanaerobium acetethylicum*, and *Halobacteroides halobius* (Oren, 1986; Oren et al., 1997; Rengpipat et al., 1988b). Using X-ray microanalysis with the transmission electron microscope, it was shown that in exponentially growing cells of *Halanaerobium praevalens*, K^+ was the major cation (70% of the cation sum). Stationary phase cells showed a high variability among individual cells, with NaCl often replacing KCl (Oren et al., 1997).

The intracellular enzymic machinery was found to be well adapted to function in the presence of the high salt concentrations found in the cytoplasm. The enzymes tested (including glyceraldehyde-3-phosphate dehydrogenase, NAD-linked alcohol dehydrogenase, pyruvate dehydrogenase, methyl viologen-linked hydrogenase from *Halanaerobium acetethylicum*, the fatty acid synthetase complex of *Halanaerobium praevalens*, hydrogenase and CO dehydrogenase activities of *Acetohalobium arabaticum*) functioned better in the presence of molar concentrations of salts than in salt-free medium (Oren and Gurevich, 1993; Rengpipat et al., 1988b; Zavarzin et al., 1994). A high content of acidic amino acids was found in the bulk cellular protein of *Halanaerobium praevalens*, *Halobacteroides halobius*, and *Sporohalobacter lortetii* (Oren, 1986). However, the ribosomal A-protein of *Halanaerobium praevalens* did not show an especially high content of acidic amino acids (Matheson et al., 1987) and proteins of *Halothermothrix orenii* also are not especially acidic, as proven by partial genomic sequence analysis (Mijts and Patel, 2001). The presence of high intracellular K^+ and Cl^- concentrations and highly acidic proteins adapted to function in the presence of these high ionic concentrations in the *Halanaerobiales* brings to mind the similar strategy of adaptation to salt in the aerobic *Archaea* of the order *Halobacteriales*.

Enrichment and isolation procedures

Species belonging to the order *Halanaerobiales* can probably be found in any hypersaline anaerobic environment in which simple organic compounds such as sugars and amino acids are available. They have been isolated from hypersaline lakes, both

with thalassohaline and athalassohaline ionic composition, including Great Salt Lake, Utah (Tsai et al., 1995; Zeikus et al., 1983), Salton Sea, California (Shiba, 1991; Shiba and Horikoshi, 1988; Shiba et al., 1989), the Dead Sea (Oren, 1983, 1987; Oren et al., 1984), hypersaline lakes and lagoons in the Crimea (Simankova et al., 1991, 1993, 1997; Zhilina and Zavarzin, 1990) and Senegal (Cayol et al., 1995, 1994b), saltern evaporation ponds in California (Liaw and Mah, 1992) and France (Mouné et al., 2000, 1999), a hot hypersaline lake in Tunisia (Cayol et al., 1994a), and the alkaline hypersaline lakes Magadi, Kenya (Shiba and Horikoshi, 1988; Zhilina et al., 1996) and Big Soda Lake, Nevada (Shiba and Horikoshi, 1988; Shiba et al., 1989). Brines associated with oil wells and petroleum reservoirs have also yielded a number of interesting species (Bhupathiraju et al., 1991, 1993, 1994, 1999; Ravot et al., 1997, 1988a). Finally, they may be present in salted fermented foods (Kobayashi et al., 2000a, 2000b).

Any anoxic reducing medium containing high salt concentrations (1–4M) and a suitable carbon source is a potential enrichment and growth medium for members of the *Halanaerobiales*. Simple sugars are used by most species. Strict anaerobic techniques should be used, including boiling the media under nitrogen or nitrogen/ CO_2 (80:20) and adding reducing agents such as sulfide, cysteine, dithionite, or ascorbate to the boiled media. Protocols for the preparation of media have been compiled by Oren (2001); details can be found in the original species descriptions.

Taxonomic comments

The order *Halanaerobiales* was created in 1995 during the course of a comprehensive in-depth study of the known anaerobic halophilic *Bacteria*. Based on 16S rRNA gene sequence comparisons, extensive taxonomic rearrangements were proposed. These included a reclassification of the species of the former family *Halanaerobiaceae* over two families: the *Halanaerobiaceae* and the newly created family *Halobacteroidaceae* (Rainey et al., 1995b). Differential characteristics of the genera of the order *Halanaerobiales* are given in Table 235. At the same time, many species were reclassified in new or extant genera on the basis of their 16S rRNA gene sequences. Physiologically, the group is coherent, to the extent that, as yet, no aerobes or non-halophiles are known to cluster phylogenetically within the order. There are, however, a few fermentative, anaerobic, moderately halophilic *Bacteria* that cluster outside the order. Examples are *Clostridium halophilum* (Fendrich et al., 1990) and *Thermohalobacter berrensis* (Cayol et al., 2000).

On the basis of their 16S rRNA gene sequences, the halophilic anaerobic bacteria should be classified in the domain *Bacteria* within the phylum *Firmicutes* (Figure 7). They form a coherent cluster close to the bifurcation point that separates the actinomycete subphylum and the *Bacillus/Clostridium* subphylum. Sequences of the halophilic anaerobes contain all of the few signature nucleotides that have been defined as characteristic of members of the *Bacillus/Clostridium* subphylum, whereas they lack any of the actinomycete-specific nucleotides. It was therefore suggested that the halophilic anaerobes be classified in the *Bacillus/Clostridium* subphylum (Patel et al., 1995; Rainey et al., 1995b; Tourova et al., 1995). Table 236 presents the signature nucleotides defining the *Halanaerobiales* within the *Bacillus/Clostridium* subphylum of the *Firmicutes*. The phy-

logenetic affiliation of *Halanaerobium praevalens* (the type species of the type genus of the type family) with the *Bacillus/Clostridium* group was confirmed by the amino acid sequence of its ribosomal A-protein (Matheson et al., 1987). The location of the branching point of the halophilic anaerobes close to the root of this subphylum is further evidence that certain descendants of the ancestors of the “Gram-positive bacteria” still maintain their Gram-negative wall type, as is the case with *Sporomusa* and its relatives. The deep branching justifies classification in a separate order (Rainey et al., 1995b). The order *Halanaerobiales* has been used as a paradigm to demonstrate the application of 16S rRNA gene sequencing and DNA–DNA hybridization in bacterial taxonomy (Tourova, 2000).

According to Rule 61 of the Bacteriological Code, the original spelling of the name of the order *Haloanaerobiales* (Rainey et al., 1995b) has been changed to *Halanaerobiales* (Oren, 2000).

Family I. **Halanaerobiaceae** corrig. Oren, Paster and Woese 1984b, 503^{VP} (Effective publication: Oren, Paster and Woese, 1984a, 79.)

AHARON OREN

Hal.an.ae.ro.bi.a'ce.ae. N.L. neut. n. *Halanaerobium* type genus of the family; -aceae ending to denote a family; N.L. fem. pl. n. *Halanaerobiaceae* the *Halanaerobium* family.

Cells are rod-shaped and **Gram-stain-negative**. Endospore formation is never observed. **Strictly anaerobic**. Oxidase- and catalase-negative. Carbohydrates are fermented to products including acetate, ethanol, hydrogen, and carbon dioxide. **Moderately halophilic**. NaCl concentrations in the range 1.7–2.6 M are required for optimal growth and no

Further descriptive information

All known members of the *Halanaerobiaceae* are moderately halophilic, but the most halophilic species known is *Halanaerobium lacusrosei*, which grows between 1.0 and 5.8 M NaCl and has its optimum at 3.4 M (Cayol et al., 1995). Some species are moderately alkaliphilic or alkalitolerant; *Halanaerobium alcaliphilum* grows optimally at neutral pH, but can grow at up to pH 10.0.

All species show a negative Gram-stain reaction. A typical Gram-negative type cell wall with an outer membrane and periplasmic space is often seen in electron micrographs of thin sections. *meso*-Diaminopimelic acid was detected in the peptidoglycan of *Halanaerobium saccharolyticum* subsp. *saccharolyticum* (Zhilina et al., 1992).

All known species belonging to the *Halanaerobiaceae* obtain their energy by fermenting simple sugars. Fermentation products typically include acetate, hydrogen, and carbon dioxide. In addition, some strains produce butyrate, lactate, propionate, and formate. Ethanol is produced by many, but not all, fermentative strains. Thus, *Halanaerobium congolense* does not form ethanol (Ravot et al., 1997). Cellulose is degraded anaerobically by *Halocella cellulolytica* (Simankova et al., 1993). *Halanaerobium saccharolyticum* ferments glycerol (Cayol et al., 1994b; Zhilina et al., 1992) and so does *Halanaerobium lacusrosei* (Cayol et al., 1995). No details have been published on the fermentation pathway and the products made during growth on glycerol. Glycerol oxidation by anaerobic halophiles was reported to be markedly improved through interspecies hydrogen transfer when glycerol fermenters were grown in co-culture with H₂-consuming, sulfate-reducing bacteria (Cayol et al., 1995).

Several interesting features of the assimilatory and dissimilatory metabolism of sulfur compounds in different representatives of the *Halanaerobiaceae* have been reported. Methanethiol can be used as an assimilatory sulfur source by *Halanaerobium saccharolyticum* (Kevbrin and Zavarzin, 1992; Zhilina et al., 1991b, 1997, 1992). *Halanaerobium congolense* uses thiosulfate and elemental sulfur as electron acceptors; the addition of thiosulfate or sulfur increases the growth yield by 6- and 3-fold, respectively, and growth rates were enhanced (Ravot et al., 1997). *Halanaerobium praevalens* can use nitro-substituted aromatic compounds such as nitrobenzene, nitrophenols, 2,4-dinitrophenol and 2,4-dinitroaniline as electron sinks (Oren et al., 1991).

Few biotechnological uses have been found thus far for the *Halanaerobiaceae*. The use of anaerobic halophilic bacteria in the industrial fermentation of complex organic matter and the production of organic solvents has been proposed (Lowe et al., 1993; Wise, 1987). It has also been suggested that certain halophilic

growth is observed below 0.3–1.7 M NaCl, depending on the species.

DNA G+C content (mol%): 27–40.

Type genus: **Halanaerobium** corrig. Zeikus, Hegge, Thompson, Phelps and Langworthy 1984, 503^{VP} (Effective publication: Zeikus, Hegge, Thompson, Phelps and Langworthy 1983, 232.).

anaerobes may be used in microbially enhanced oil recovery by plugging of porous reservoirs and by anaerobically metabolizing nutrients with the production of gases, biosurfactants, and polymers (Bhupathiraju et al., 1991). The recent isolation of *Halanaerobium fermentans* from traditionally fermented puffer fish ovaries in Japan (Kobayashi et al., 2000b) suggests that members of the *Halanaerobiaceae* have been involved in applied microbiological processes for centuries and that only now has their role started to become recognized.

Enrichment and isolation procedures

Species belonging to the family *Halanaerobiaceae* can probably be found in any hypersaline anaerobic environment in which simple sugars are available. They have been isolated from Great Salt Lake, Utah (Tsai et al., 1995; Zeikus et al., 1983), hypersaline lakes and lagoons in the Crimea (Simankova et al., 1993; Zhilina et al., 1992) and Senegal (Cayol et al., 1994b), a hot hypersaline lake in Tunisia (Cayol et al., 1994a), and from brines associated with oil wells and petroleum reservoirs (Bhupathiraju et al., 1993, 1999, 1994, 1991; Ravot et al., 1997; Rengpipat et al., 1988a). Finally, they may be present in salted fermented foods (Kobayashi et al., 2000a, 2000b).

Any anoxic reducing medium containing high salt concentrations (1–4 M) and simple sugars as carbon and energy sources is a potential enrichment and growth medium for members of the *Halanaerobiales*. Strict anaerobic techniques should be used, including boiling the media under nitrogen or nitrogen/CO₂ (80:20) and adding reducing agents such as cysteine, dithionite, or ascorbate plus thioglycollate to the boiled media. Protocols for the preparation of media have been compiled by Oren (2001); details can be found in the original species descriptions. For the enrichment of thermophiles such as *Halothermothrix*, the incubation temperature should be adjusted to that of the natural environment. No specific enrichment procedures that exclude development of members of the *Halobacteroidaceae* have been devised as yet.

Differentiation of the family *Halanaerobiaceae* from other families

The only sure way to distinguish members of the family *Halanaerobiaceae* from the sugar-fermenting members of the *Halobacteroidaceae* is by 16S rRNA relatedness. There are no known morphological, physiological, or biochemical tests that enable an unequivocal classification in either of the two families. Table 237 presents information on the 16S rRNA gene signature nucleotides defining the two families.

Taxonomic comments

The family *Halanaerobiaceae* (basonym: *Haloanaerobiaceae*) was created in 1984, when the first halophilic anaerobes became known. At that time, two genera were classified within the family: *Halanaerobium* (basonym *Haloanaerobium*) and *Halobacteroides* (Oren et al., 1984a, 1984b). With the rearrangement of the taxonomic status of many of the halophilic anaerobes and the creation of the order *Halanaerobiales* (basonym *Haloanaerobiales*) (Rainey et al., 1995a, 1995b), some genera previously classified within the family *Halanaerobiaceae* were transferred to the new family *Halobacteroidaceae*. These included the genera *Halobacteroides*, *Acetohalobium*, *Halanaerobacter* (basonym *Haloanaerobacter*), and *Sporohalobacter*. Presently, three genera are recognized within the *Halanaerobiaceae*: *Halanaerobium*, *Halothermothrix*, and *Halocella*.

According to Rule 61 of the Bacteriological Code, the original spelling of the name of the family *Haloanaerobiaceae* has been changed to *Halanaerobiaceae* (Oren, 2000).

Genus I. **Halanaerobium** corrig. Zeikus, Hegge, Thompson, Phelps and Langworthy 1984, 503^{VP} (Effective publication: Zeikus, Hegge, Thompson, Phelps and Langworthy 1983, 232.)

AHARON OREN

Hal.an.ae.ro'bi.um. Gr. n. *hals* salt; Gr. pref. *an* not; Gr. n. *aer* air; Gr. n. *bios* life; N.L. neut. n. *Halanaerobium* salt organism which grows in the absence of air.

Cells rod-shaped, non-motile or motile by peritrichous flagella, and Gram-stain-negative. **Strictly anaerobic**, chemo-organotrophic with fermentative metabolism. Carbohydrates are fermented with the production of acetate, H₂, and CO₂. In some species, ethanol, formate, propionate, butyrate, and lactate are also found. Thiosulfate and elemental sulfur may be used as electron acceptors in certain species. **Halophilic**, growing optimally at NaCl concentrations around 1.7–2.5 M and requiring a minimum of 0.3–1.7 M NaCl for growth, depending on the species. Neutral or slightly alkaline pH values are preferred. Endospore formation is never observed.

DNA G+C content (mol%): 27–37 (*T_m*, HPLC).

Type species: Halanaerobium praevalens corrig. Zeikus, Hegge, Thompson, Phelps and Langworthy 1984, 503^{VP} (Effective publication: Zeikus, Hegge, Thompson, Phelps and Langworthy 1983, 232.).

Further descriptive information

All *Halanaerobium* species are moderately halophilic. NaCl concentrations of up to saturation support growth of certain isolates. The most halophilic representative described thus far is *Halanaerobium lacusrosei*, which grows between 1.0 and 5.8 M NaCl with an optimum at 3.4 M (Cayol et al., 1995). It is also the most halophilic species within the order *Halanaerobiales*.

Most species of the genus *Halanaerobium* grow fermentatively on sugars, producing acetate, ethanol, hydrogen, and carbon dioxide. Some strains make additional products such as formate, propionate, butyrate, and lactate. *Halanaerobium congolense* does not form ethanol (Ravot et al., 1997). *Halanaerobium alcaliphilum* can also ferment glycine betaine with the formation of acetate and trimethylamine (Tsai et al., 1995).

The ability to use substrates such as glycerol, glucosylglycerol, and trehalose by different representatives of the genus *Halanaerobium* may be of particular ecological importance. These compounds are accumulated at high concentrations as organic osmotic solutes by aerobic, photosynthetic, halophilic microorganisms inhabiting salt lakes (glycerol by the green unicellular alga *Dunaliella*, glucosylglycerol and trehalose by a variety of cyanobacteria). Such compounds can thus be expected to be available to the anaerobic bacterial community in the bottom sediments of these lakes. *Halanaerobium saccharolyticum* (both subsp. *saccharolyticum* and subsp. *senegalense*) ferments glycerol (Cayol et al., 1994b; Zhilina et al., 1992) and so does *Halanaerobium lacusrosei* (Cayol et al., 1995). No details have been published on the fermentation products made when glycerol serves as the energy source. Glycerol oxidation by anaerobic halophiles was reported to be markedly improved through interspecies hydrogen transfer when glycerol fermenters were grown in co-culture with H₂-consuming sulfate-reducing bacteria (Cayol et al., 1995). *Halanaerobium saccharolyticum* was isolated from a cyanobacterial mat dominated by *Microcoleus chthonoplastes*, covering the bottom of a hypersaline lagoon in the Crimea. Its ability to use glucosylglycerol, the osmotic solute produced by *Microcoleus* and many other cyanobacteria, may be of great ecological importance. *Halanaerobium saccharolyticum* also degrades trehalose, produced by other cyanobacteria for similar purposes (Zhilina et al., 1992).

Several *Halanaerobium* species can use oxidized sulfur compounds as electron acceptors or electron sinks. Thus, *Halanaerobium congolense* uses thiosulfate and elemental sulfur as electron acceptors. Thiosulfate improved carbohydrate utilization and enhanced growth rates. Addition of thiosulfate or sulfur increased the growth yield by 6- or 3-fold, respectively. In addition, the presence of thiosulfate alleviated growth inhibition by accumulating hydrogen (Ravot et al., 1997). Reduction of elemental sulfur to sulfide was also reported in *Halanaerobium saccharolyticum* subsp. *saccharolyticum* (Zhilina et al., 1992). Nitrosubstituted aromatic compounds such as nitrobenzene, nitrophenols, 2,4-dinitrophenol, and 2,4-dinitroaniline are reduced to the amino derivatives by *Halanaerobium praevalens* (Oren et al., 1991).

Some *Halanaerobium* species may have biotechnological applications. *Halanaerobium fermentans* was isolated from "fugunoko nukaduke", a traditional Japanese food prepared from fermented salted puffer fish ovaries (Kobayashi et al., 2000b). Puffer fish ovaries are salted for at least 6 months and the ovaries are then fermented naturally with rice-bran, fish sauce, and koji for several years. *Halanaerobium fermentans* may be one of the main bacteria involved in the fermentation process (Kobayashi et al., 2000b). Other *Halanaerobium* species may find uses in microbially enhanced recovery of oil from oil reservoirs by plugging of porous reservoirs and by anaerobically metabolizing nutrients with the production of useful products such as gases, biosurfactants, polymers, etc., under

the environmental conditions that exist in such reservoirs (Bhupathiraju et al., 1991).

Enrichment and isolation procedures

Species of the genus *Halanaerobium* can probably be found in any hypersaline anaerobic environment in which simple sugars are available. They have been isolated from Great Salt Lake, Utah (Tsai et al., 1995; Zeikus et al., 1983), Lake Sivash in the Crimea (Zhilina et al., 1992), Lake Retba in Senegal (Cayol et al., 1994b), from brines associated with oil wells and petroleum reservoirs (Bhupathiraju et al., 1993, 1999, 1994, 1991; Ravot et al., 1997; Rengpipat et al., 1988a), and from salted fermented foods (Kobayashi et al., 2000b, 2000a).

Any anoxic reducing medium containing high salt concentrations (0.8–4.2 M NaCl) and containing glucose or other simple sugars as a carbon source is a potential enrichment and growth medium for anaerobic halophilic bacteria of the genus *Halanaerobium*. Details on the composition of suitable growth media can be found in Oren (2001) and in the original publications on the isolation of species. Strict anaerobic techniques should be used, including boiling the media under nitrogen or nitrogen/CO₂ (80:20) and adding reducing agents such as cysteine, thioglycollate, or sulfide to the boiled media.

No specific enrichment procedures have been designed as yet that enable growth of members of the genus *Halanaerobium* with the exclusion of other members of other genera of the families *Halanaerobiaceae* and *Halobacteroidaceae*.

Maintenance procedures

Lyophilization has proved satisfactory for the preservation of *Halanaerobium* species. *Halanaerobium acetethylicum* was successfully preserved by freezing anaerobic suspensions in 20% glycerol at –80 °C (Rengpipat et al., 1988a).

Differentiation of the species of the genus *Halanaerobium*

Identification of isolates and their assignment to the genus *Halanaerobium* should be based preferentially on the determination of their 16S rRNA gene sequences. In addition, phenotypic characterization should be performed and the properties of the strains should be compared with those of described species (see Table 238).

Taxonomic comments

The genus *Halanaerobium* (originally named *Haloanaerobium* and renamed *Halanaerobium* in accordance with Rule 61) (Oren, 2000) was the first effectively published member of the order *Halanaerobiales* (Zeikus et al., 1983). With its nine species with validly published names, it is now the largest genus within the order. Based on 16S rRNA gene sequence comparisons (Rainey et al., 1995b), a number of species formerly classified in other genera have been transferred to the genus *Halanaerobium*: the former *Halobacteroides acetothylis* (Rengpipat et al., 1988a) was reclassified as *Halanaerobium acetethylicum* (Oren, 2000; Patel et al., 1995; Rainey et al., 1995b); and the former *Haloicola saccharolyticum* (originally described under the name *Haloicola saccharolytica*) (Euzéby, 1998; Zhilina et al., 1991a) has been renamed as *Halanaerobium saccharolyticum*, with two subspecies, *saccharolyticum* and *senegalense* (Cayol et al., 1994b; Oren, 2000; Rainey et al., 1995b).

List of species of the genus *Halanaerobium*

1. ***Halanaerobium praevalens*** corrig. Zeikus, Hegge, Thompson, Phelps and Langworthy 1984, 503^{VP} (Effective publication: Zeikus, Hegge, Thompson, Phelps and Langworthy 1983, 232.)
 prae.va'lens L. adj. *praevalens* prevalent.
 Cells are non-motile rods, 0.9–1.1 × 2.0–2.6 µm in size. Halophilic, requiring between 0.3–5.1 M NaCl. Optimal growth occurs in 2.2 M NaCl and at pH 7.0–7.4. Temperature range for growth is 5–50 °C. Optimum temperature is 37 °C. Strictly anaerobic. Ferments carbohydrates with production of acetate, propionate, butyrate, H₂, and CO₂. Grows on a range of carbohydrates, including *N*-acetylglucosamine, fructose, D-glucose, D-mannose, and pectin. No growth has been found on cellobiose, chitin, galactose, glycerol, lactose, pyruvate, starch, sucrose, or xylose. The major fatty acids are C_{14:0}, C_{16:0}, and C_{16:1}. Methylmercaptan is produced during degradation of methionine.
Source: sediments of Great Salt Lake, UT, USA.
DNA G+C content (mol%): 27±1 (*T_m*).
Type strain: GSL, ATCC 33744, DSM 2228.
GenBank accession number (16S rRNA gene): AB022034, M59123.
2. ***Halanaerobium acetethylicum*** corrig. (Rengpipat, Langworthy and Zeikus 1988a) Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995a, 879^{VP} (Effective publication: Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995b, 197.) (*Halobacteroides acetoethylicus* Rengpipat, Langworthy and Zeikus 1988a, 33)
 a.cet.e.thy'li.cum. L. n. *acetum* vinegar; N.L. n. *ethyl* the ethyl radical; N.L. adj. *acetethylicum* producing vinegar and ethanol.
 Cells are rods, motile by peritrichous flagella, 0.4–0.7 × 1.0–1.6 µm in size. Halophilic, requiring between 0.8–3.8 M NaCl. Optimal growth occurs in 1.7 M NaCl and at pH 6.3–7.4. Temperature range for growth: 15–45 °C. Optimum temperature: 34 °C. Strictly anaerobic. Ferments carbohydrates with production of ethanol, acetate, H₂, and CO₂. Grows on a range of carbohydrates and other compounds, including *N*-acetylglucosamine, cellobiose, fructose, D-glucose, lactose, D-mannose, pyruvate, sucrose, and D-xylose. No growth on galactose, glycerol, pectin, or starch. The major fatty acids are C_{14:0}, C_{16:0}, and C_{16:1}.
Source: brines associated with offshore oil rigs in the Gulf of Mexico.
DNA G+C content (mol%): 32.0 (*T_m*).
Type strain: EIG1, ATCC 43120, DSM 3532.
GenBank accession number (16S rRNA gene): X89071.
3. ***Halanaerobium alcaliphilum*** corrig. Tsai, Garcia, Patel, Cayol, Baresi and Mah 1995, 305^{VP}
 al.ca.li'phi.lum. N.L. n. *alcali* from Ar. *al-qaliy* the soda ash; Gr. adj. *philos* loving; N.L. neut. adj. *alcaliphilum* liking alkaline media.
 Cells are rods, motile by peritrichous flagella, 0.8 × 3.3–5 µm in size. Halophilic, requiring 0.4–4.3 M NaCl. Can be grown over a wide range of pH values, from 5.8 to up to 10.0. Optimal growth occurs in 1.7 M NaCl and at pH 6.7–7.0. Temperature range for growth: 25–50 °C. Optimum temperature: 37–40 °C. Strictly anaerobic. Ferments carbohydrates with production of acetate, butyrate, lactate, H₂, and CO₂. Grows on a range of carbohydrates, including *N*-acetylglucosamine, fructose, D-glucose, maltose, D-mannose, pyruvate, and sucrose. Slight growth on raffinose. No growth on adonitol, L-arabinose, cellobiose, dulcitol, erythritol, galactose, glycerol, glycogen, inositol, lactose, mannitol, pectin, D-ribose, rhamnose, sorbitol, starch, trehalose, or D-xylose. Glycine betaine is fermented to acetate and trimethylamine.
Source: sediments of Great Salt Lake, UT, USA.
DNA G+C content (mol%): 31.0 (HPLC).
Type strain: GSLS, DSM 8275.
GenBank accession number (16S rRNA gene): X81850.
4. ***Halanaerobium congolense*** corrig. Ravot, Magot, Ollivier, Patel, Ageron, Grimont, Thomas and Garcia 1998, 1083^{VP} (Effective publication: Ravot, Magot, Ollivier, Patel, Ageron, Grimont, Thomas and Garcia 1997, 87.)
 con.go.len'se. N.L. neut. adj. *congolense* pertaining to Congo, Central Africa.
 Cells are short, non-motile rods, 0.5–1 × 2–4 µm in size. Halophilic, requiring 0.3–4.1 M NaCl. Optimal growth occurs in 1.7 M NaCl and at pH 7.0. Temperature range for growth: 20–45 °C. Optimum temperature: 42 °C. Strictly anaerobic. Ferments carbohydrates with production of acetate, H₂, and CO₂. Grows on a range of carbohydrates including fructose, galactose, D-glucose, maltose, D-mannose, D-ribose, sucrose, and trehalose. No growth on D-arabinose, dulcitol, lactate, lactose, propionate, rhamnose, or D-xylose. Thiosulfate and elemental sulfur are used as electron acceptors, enabling improved use of carbohydrates and enhanced biomass yields. The doubling time under optimal conditions in the presence of glucose and thiosulfate is about 2.5 h.
Source: oil injection water from an offshore oilfield, Congo, Central Africa.
DNA G+C content (mol%): 34 (HPLC).
Type strain: SEBR 4224, DSM 11287.
GenBank accession number (16S rRNA gene): U76632.
5. ***Halanaerobium fermentans*** corrig. Kobayashi, Kimura and Fujii 2000b, 1626^{VP}
 fer.men'tans. L. part. adj. *fermentans* fermenting.
 Cells are rods, motile by peritrichous flagella, 1.0–1.2 × 2.7–3.3 µm in size. Halophilic, requiring 1.2–4.3 M NaCl. Optimal growth occurs in 1.7 M NaCl and at pH 7.5. Temperature range for growth: 15–45 °C. Optimum temperature: 35 °C. Strictly anaerobic. Ferments carbohydrates with production of acetate, ethanol, formate, lactate, H₂, and CO₂. Grows on a range of carbohydrates, including *N*-acetylglucosamine, cellobiose, fructose, galactose, D-glucose, lactose, maltose, D-mannose, raffinose, D-ribose, sucrose, and D-xylose. No growth on L-arabinose, glycerol, pyruvate, rhamnose, or starch.
Source: fermenting salted puffer fish ovaries.
DNA G+C content (mol%): 33.3 (HPLC).
Type strain: R-9, JCM 10494.
GenBank accession number (16S rRNA gene): AB023308.

6. *Halanaerobium kushneri* corrig. Bhupathiraju, McInerney, Woese and Tanner 1999, 958^{VP}

kushneri. N.L. gen. n. *kushneri* named after Donn J. Kushner, a Canadian microbiologist and author of children's books.

Cells are rods, motile by peritrichous flagella or non-motile, $0.5\text{--}0.8 \times 0.7\text{--}3.3\ \mu\text{m}$ in size. Halophilic, requiring 1.5–3.1 M NaCl. Optimal growth occurs in 2.1 M NaCl and at pH 6.5–7.5. Temperature range for growth: 20–45 °C. Optimum temperature: 35–40 °C. Strictly anaerobic. Ferments carbohydrates with production of acetate, ethanol, formate, H₂, and CO₂. Grows on a range of carbohydrates and proteinaceous compounds including L-arabinose, cellobiose, fructose, galactose, D-glucose, inulin, maltose, D-mannose, peptone, sucrose, and trypticase. Growth on fucose, glucosamine, glycerol, lactose, mannitol, pyruvate, sorbose, and xylose is variable. No growth on L-alanine, L-ascorbate, adonitol, butyrate, cellulose, chitin, dulcitol, fumarate, glutamate, glycine, glycine betaine, glycogen, inositol, L-lysine, malate, pectin, starch, or sorbitol. Mixed amino acid fermentation (the Stickland reaction) is not used. The major fatty acids are C_{16:0}, C_{16:1 ω7}, C_{16:1 ω9}, and C_{14:0}.

Source: brines associated with petroleum reservoirs, Oklahoma, U.S.A.

DNA G+C content (mol%): 32–37 (HPLC); 34.1 (HPLC) for type strain.

Type strain: VS-751, ATCC 700103.

GenBank accession number (16S rRNA gene): U86446.

7. *Halanaerobium lacusrosei* corrig. Cayol, Ollivier, Patel, Ageron, Grimont, Prensier and Garcia 1995, 796^{VP}

lacusrosei. L. n. *lacus* lake; L. adj. *roseus* rose-colored; N.L. gen. n. *lacusrosei* of Rose Colored Lake, another name for Retba Lake in Senegal.

Cells are rods, motile by peritrichous flagella, $0.4\text{--}0.6 \times 2\text{--}3\ \mu\text{m}$ in size. Halophilic, requiring 1.3–5.8 M NaCl. Optimal growth occurs in 3.1–3.4 M NaCl and at pH 7.0. Temperature range for growth: 20–50 °C. Optimum temperature: 40 °C. Strictly anaerobic. Ferments carbohydrates with production of acetate, ethanol, H₂, and CO₂. Grows on a range of carbohydrates, including cellobiose, D-fructose, galactose, D-glucose, glycerol, lactose, maltose, D-mannitol, D-mannose, D-ribose, starch, sucrose, and D-xylose. No growth on L-arabinose, melibiose, rhamnose, or L-sorbose. The major fatty acids are C_{15:1}, C_{16:0}, and C_{16:1}.

Source: sediments of Lake Retba, Senegal.

DNA G+C content (mol%): 32 (HPLC).

Type strain: H200, ATCC 700560, CIP 105492, DSM 10165.

GenBank accession number (16S rRNA gene): L39787.

8. *Halanaerobium saccharolyticum* corrig. (Zhilina, Zavarzin, Bulygina, Kevbrin, Osipov and Chumakov 1992) Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995a, 879^{VP} (Effective publication: Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995b, 197.) (*Haloicola saccharolytica* Zhilina, Zavarzin, Bulygina, Kevbrin, Osipov and Chumakov 1991b, 283) *saccharolyticum*. L. n. *saccharum* sugar; Gr. adj. *lytikos* dissolving; N.L. neut. adj. *saccharolyticum* sugar-dissolving.

Cells are rods, motile by peritrichous flagella, $0.4\text{--}0.7 \times 1\text{--}5\ \mu\text{m}$ in size. Halophilic, requiring 0.5–5.1 M NaCl. Optimal growth occurs in 1.3–2.1 M NaCl and at pH 7.0–7.5. Temperature range for growth: 15–47 °C. Optimum temperature: 37–40 °C. Strictly anaerobic. Ferments carbohydrates with production of acetate, H₂, and CO₂.

Source: sediments of hypersaline lakes.

DNA G+C content (mol%): 31.3–32 (HPLC or T_m).

Two subspecies have been described: *Halanaerobium saccharolyticum* subsp. *saccharolyticum* and *Halanaerobium saccharolyticum* subsp. *senegalense*. The main differences between the subspecies are: the use of raffinose by the first and the use of galactose, gluconate, and L-xylose by the second; a difference in NaCl concentration range; and a different distribution of fatty acids in the membrane phospholipids.

- 8a. *Halanaerobium saccharolyticum* subsp. *saccharolyticum* corrig. (Zhilina, Zavarzin, Bulygina, Kevbrin, Osipov and Chumakov 1992) Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995a, 879^{VP} (Effective publication: Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995b, 197.) (*Haloicola saccharolytica* Zhilina, Zavarzin, Bulygina, Kevbrin, Osipov and Chumakov 1992, 283) (*Haloicola saccharolytica* subsp. *saccharolytica* Cayol, Ollivier, Soh, Fardeau, Ageron, Grimont, Prensier, Guezennec, Magot and Garcia 1994b, 810)

Cells are rods, motile by peritrichous flagella, $0.5\text{--}0.7 \times 1\text{--}5\ \mu\text{m}$ in size. Halophilic, requiring 0.5–5.1 M NaCl. Optimal growth occurs in 1.7 M NaCl and at pH 7.5. Temperature range for growth: 15–47 °C. Optimum temperature: 37–40 °C. Strictly anaerobic. Ferments carbohydrates with production of acetate, H₂, and CO₂. Grows on a range of carbohydrates and other compounds including L-arabinose, N-acetylglucosamine, cellobiose, erythritol, fructose, galactose, D-glucose, glucosylglycerol, glycerol, lactose, maltose, mannitol, D-mannose, melibiose, pyruvate, D-ribose, sucrose, trehalose, and D-xylose. No growth on adonitol, chitin, dulcitol, fucose, inositol, pectin, raffinose, rhamnose, sorbitol, L-sorbose, or starch. The major fatty acids are C_{12:1 3-OH}, C_{14:0}, C_{15:1}, and C_{16:1}.

Source: sediments of Lake Sivash, Crimea.

DNA G+C content (mol%): 31.3 (T_m).

Type strain: Z-7787, DSM 6643.

GenBank accession number (16S rRNA gene): L37424, X89069, Z49115.

- 8b. *Halanaerobium saccharolyticum* subsp. *senegalense* corrig. (Zhilina, Zavarzin, Bulygina, Kevbrin, Osipov and Chumakov 1992) Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995a, 880^{VP} (Effective publication: Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995b, 197.) (*Haloicola saccharolytica* Zhilina, Zavarzin, Bulygina, Kevbrin, Osipov and Chumakov (Zhilina et al., 1992), 283) (*Haloicola saccharolytica* subsp. *senegalensis* Cayol, Ollivier, Soh, Fardeau, Ageron, Grimont, Prensier, Guezennec, Magot and Garcia 1994b, 810) *senegalense*. N.L. neut. adj. *senegalense* pertaining to Senegal.

Cells are rods, motile by peritrichous flagella, $0.4\text{--}0.6 \times 2\text{--}5\ \mu\text{m}$ in size. Halophilic, requiring 0.8–4.3 M NaCl. Optimal growth occurs in 1.3–2.1 M NaCl and at pH 7.0. Temper-

ature range for growth: 20–47 °C. Optimum temperature: 40 °C. Strictly anaerobic. Ferments carbohydrates with production of acetate, H₂, and CO₂. Grows on a range of carbohydrates including cellobiose, fructose, D-glucose, glycerol, lactose, maltose, mannitol, D-mannose, raffinose, D-ribose, and sucrose. No growth on adonitol, L-arabinose, galactose, gluconate, pectin, rhamnose, L-sorbose, or D-xylose. The major fatty acids are C_{12:0 3-OH}, C_{14:0}, C_{15:1}, and C_{16:1}.

sal.su'gi.nis. L. n. *salsugo* water impregnated with salt; L. n. gen. *salsuginis* referring to isolation of this strain from an oilfield brine.

Cells are non-motile rods, 0.3–0.4 × 2.6–4 µm in size. Halophilic, requiring 1.0–4.1 M NaCl. Optimal growth occurs in 1.5 M NaCl and at pH 6.1. Temperature range for growth:

22–51 °C. Optimum temperature: 40 °C. Strictly anaerobic. Ferments carbohydrates with production of ethanol, acetate, H₂, and CO₂. Grows on a range of carbohydrates including L-arabinose, N-acetylglucosamine, fructose, galactose, glucosamine, D-glucose, lactose, maltotriose, melezitose, maltose, D-mannose, melibiose, pyruvate, raffinose, D-ribose, rhamnose, L-sorbose, sucrose, D-xylose, and trehalose. Yeast extract also supports growth. No growth on L-alanine, L-ascorbate, adonitol, betaine, butyrate, chitin, crotonate, Casamino acids, dextran, dulcitol, ethylene glycol, formate, fucose, fumarate, glutamate, glycine, glycogen, D-gluconate, inositol, inulin, L-lysine, lactate, malate, methanol, mannitol, methionine, glycerol, pectin, proline, propionate, peptone, starch, succinate, sarcosine, sorbitol, salicin, trypticase, or xylan. Amino acid mixtures such as alanine-glycine, leucine-proline, and other combinations were not utilized. The major fatty acids are C_{14:0}, C_{16:0}, C_{16:1}, and C_{17:0 cyclo}.

Genus II. ***Halocella*** Simankova, Chernych, Osipov and Zavarzin 1994, 182^{VP} (Effective publication: Simankova, Chernych, Osipov and Zavarzin 1993, 389.)

GEORGE A. ZAVARZIN

Ha.lo.cel'la. Gr. n. *hals* salt; L. n. fem. *cella* cell; N.L. fem. n. *Halocella* salt cell.

Cells are straight or slightly curved rods, non-sporulating, **motile** by means of peritrichous flagella. **Cell wall of Gram-negative** structure. **Obligately anaerobic**. Moderately **halophilic**. **Ferment carbohydrates, including cellulose**, producing acetate, ethanol, lactate, hydrogen, and carbon dioxide. Peptides and amino acids are not utilized.

DNA G+C content (mol%): 29 (T_m).

Type species: ***Halocella cellulositytica*** corrig. Simankova, Chernych, Osipov and Zavarzin 1994, 182^{VP} (Effective publication: Simankova, Chernych, Osipov and Zavarzin 1993, 389.).

Further descriptive information

On the basis of 16S rRNA gene sequence analysis, the genus *Halocella* belongs to the nonsporeforming branch of haloanaerobic eubacteria of the order *Haloanaerobiales* and the family *Haloanaerobiaceae* (Rainey et al., 1995b) emended by Oren (2000) to *Halanaerobiales* and *Halanaerobiaceae*, respectively. The genus includes the single species *Halocella cellulositytica*. Specific information on the species is given below.

Enrichment and isolation procedures

Samples of decomposing alga *Cladophora sivashensis* were the source of enrichment in the following mineral solution (g/l, except where stated otherwise): NaCl, 150; NaHCO₃, 1.5; MgCl₂·2H₂O, 33; KH₂PO₄, 0.33; CaCl₂·6H₂O, 0.33; NH₄Cl, 0.33; KCl, 0.33; Na₂S·9H₂O, 0.5; yeast extract (Difco), 0.2; trace element solution (Pfennig and Lippert, 1966), 2 ml/l; vitamins (Wolin et al., 1963), 10 ml/l; filter paper, 10 (w/v). Pure culture was obtained by serial dilutions and single colony

isolation on 2% agar in roll tubes with microcrystalline cellulose (Simankova et al., 1993).

Maintenance procedures

Cultures are maintained by regular transfer on cellulose. Lysis of cells at the end of active growth results in loss of viability. Cultures may be stored in liquid nitrogen.

Differentiation of the genus *Halocella* from other genera

The genus is differentiated from other genera of the family *Halanaerobiaceae* by its ability to decompose cellulose. *Halocella* differs from members of the genus *Halanaerobium* by its inability to utilize peptides and amino acids and from *Halothermothrix* species by its inability to grow at high temperatures.

Taxonomic comments

Analysis of 5S rRNA showed considerable differences between *Halocella* and other haloanaerobes (Zhilina et al., 1992). The generic status of *Halocella* is based on 16S rRNA gene sequences. The genus represents a distinct lineage in the family *Halanaerobiaceae* with sequence similarity in the range 89.6–89.9% to the other taxa. Its closest neighbor is *Halothermothrix orenii* (89.9% sequence similarity) (Rainey et al., 1995b). The lipid composition is made up of fatty acids, hydroxy fatty acids, and aldehydes. Both straight and branched lipid components are present. The main fatty acid components are C_{14:0} and C_{16:0}. The major hydroxy fatty acid is C_{12:0 3-OH} and the main aldehyde is C_{16:0} (Simankova et al., 1993).

List of species of the genus *Halocella*

1. ***Halocella cellulositytica*** corrig. Simankova, Chernych, Osipov and Zavarzin 1994, 182^{VP} (Effective publication: Simankova, Chernych, Osipov and Zavarzin 1993, 389.)

cel.lu.lo.si.ly'ti.ca. N.L. masc. adj. *lyticus* dissolving; N.L. n. *cellulosum* cellulose; N.L. fem. adj. *cellulositytica* organism which dissolves cellulose.

Cells are rods, straight or slightly curved in old cultures. Under optimal conditions cells are $0.4\text{--}0.6 \times 3.8\text{--}12\ \mu\text{m}$, but they are shorter under suboptimal conditions. Motile by means of peritrichous flagella. Cell wall of Gram-negative structure. Cells occur singly or in pairs or short chains. Multiply by constriction. Palisade arrangement due to copious slime production. In stationary phase, cells lyse with the formation of non-viable spheres.

Strictly anaerobic. Chemo-organotrophic. Utilizes cellulose in various forms including filter paper, microcrystalline cellulose, and carboxymethylcellulose. Good growth on dead mass of *Cladophora*. The cellulase complex in *Halocella cellulositytica* contains only one endoglucanase with optimal activity at pH 7.5 and 0.5 M NaCl of about 9.4×10^{-3} units of enzyme activity/ml, which is of the same order as that in non-halophilic bacteria, e.g., *Clostridium thermocellum* (Bolobova et al., 1992). Cellulose, cellobiose, and mannose are favored substrates and galactose, glucose, sucrose, sorbitol, and starch are utilized. Pentoses (arabinose, ribose, xylose), xylan and fructose are not utilized. During the initial phase of growth on cellulose, sugars are released into the medium. Products

of fermentation are acetate, ethanol, lactate, hydrogen, and carbon dioxide. The organism is highly resistant to H_2S up to 8 mM. Growth is completely inhibited by streptomycin, benzylpenicillin, vancomycin, rifampin, and bacitracin. Moderately halophilic with optimum salinity at 2.5 M NaCl, growth occurs in range 0.8–3.4 M NaCl. Neutrophilic with pH 7.0 being optimum for growth; no growth observed below pH 5.5 or above pH 8.5.

Halocella develops in saline lagoons where decomposition of the decaying dead mass of filamentous green alga *Cladophora* after algal blooms leads to sulfide production in Lake Sivash ("Rotten Sea") by the halophilic microbial community (Zhilina and Zavarzin, 1991). *Halocella* participates in the initial stages of decomposition. The dead alga might be brought by storms, diluted by seepage from irrigating channel water of Sivash of approximately 5% salinity, and deposited in lagoons with higher salinity where cyanobacterial mats develop. Several forms of anaerobic cellulolytic bacteria are found in the hypersaline lagoons of Lake Sivash including the extremely halophilic strain Z-41 at 4.2 M NaCl (Siman'kova and Zavarzin, 1992).

Source: anaerobic sediments from the lagoons of Lake Sivash that had variable salinity and dense cyanobacterial mats of *Microcoleus chthonoplastes*.

DNA G+C content (mol%): 29 (T_m).

Type strain: Z-10151, ATCC 700086, DSM 7362.

GenBank accession number (16S rRNA gene): X89072.

Genus III. ***Halothermothrix*** Cayol, Ollivier, Patel, Prensier, Guezennec and Garcia 1994a, 538^{VP}

JEAN-LUC CAYOL, BERNARD OLLIVIER AND JEAN-LOUIS GARCIA

Ha.lo.ther'mo'thrix. Gr. n. *hals*, *halos* salt; Gr. adj. *thermos* hot; Gr. n. *thrix* hair; N.L. fem. n. *Halothermothrix* a thermophilic fermentative halophile.

Long rod-shaped bacteria with cells that are $0.4\text{--}0.6 \times 10\text{--}20\ \mu\text{m}$, occurring mainly singly (Figure 236). **Motile by peritrichous flagella.** Non-sporulating. Gram-stain-negative. **Strictly anaerobic.** Chemo-organotrophic; oxidize carbohydrates to acetate, ethanol, H_2 , and CO_2 . NaCl and yeast extract are required for growth. **Grow in thermophilic conditions** (optimum temperature for growth is 60 °C).

DNA G+C content (mol%): 39.6 (HPLC).

Type species: ***Halothermothrix orenii*** Cayol, Ollivier, Patel, Prensier, Guezennec and Garcia 1994a, 538^{VP}.

Further descriptive information

Halothermothrix orenii belongs to the order *Halanaerobiales*. Members of this order comprise the families *Halanaerobiaceae* and *Halobacteroidaceae*, which promote their survival and proliferation in high-salt-containing environments by maintaining comparable high salt levels within their cytoplasm (Oren, 1986, 1999; Rengpipat et al., 1988b). Micro-organisms from these families differ from most other halophilic and halotolerant members of the domain *Bacteria*, which maintain low intracellular salt levels and synthesize or take up small organic molecules such as polyols or quaternary amines when available from the medium (Oren, 1999). This approach to maintaining cell integrity

requires both extracellular and intracellular enzymes and cell structures to be active or stable under salt conditions (Oren, 1999). In order to gain information about the genetic structure of *Halothermothrix orenii*, a recent analysis of the genome of this bacterium was performed by Mijts and Patel (2001). A pBluescriptSK+ vector library consisting of 3360 clones with a

FIGURE 236. Phase-contrast photomicrograph of *Halothermothrix orenii*. Bar = 10 μm .

mean insert size of 3.5 kb was constructed. Seventy-seven clones were sequenced from both ends using T3 and T7 vector primers generating 154 sequence tags, representing approximately 85 kb of the genome. Comparison of sequence tags against the GenBank database using BLASTX identified 66 known proteins and 15 conserved hypothetical proteins. The putative proteins included a V-ATPase, hydrogenases and enzymes with potential in industrial applications such as peptidases and esterases. These enzymes would be of particular use in applications where activity or stability at a range of salt levels and high temperatures is required. High levels of excess acidic amino acids were not detected in the putative proteins of *Halothermothrix orenii* as compared to the mesophilic halanaerobes. This may be the result of reduced activity of acidic, halophilic enzymes at high temperatures and intermediate salt concentrations (Mijts and Patel, 2001).

Enrichment and isolation procedures

Halothermothrix orenii has been isolated from the sediment of a Tunisian hypersaline lake (Chott El-Guettar) in samples collected at 20 cm intervals down to 1.20 m. It was only present in the 40–60 cm layer. It was isolated at 60 °C in a medium containing (per liter): NH₄Cl, 1.0 g; KH₂PO₄, 0.3 g; K₂HPO₄, 0.3 g; MgCl₂·6H₂O, 2.0 g; CaCl₂·2H₂O, 0.2 g; KCl, 4.0 g; CH₃COONa·3H₂O, 1.0 g; glucose, 10.0 g; NaCl, 100 g; Biotrypticase (bioMérieux), 3.0 g; yeast extract (Difco), 3.0 g; resazurin, 0.1% (w/v); trace element solution (Imhoff-Stuckle and Pfennig, 1983), 1 ml. The medium was adjusted to pH 7.0 with 10 M KOH, boiled under a stream of O₂-free N₂ and cooled to room temperature. Aliquots (20 ml) of medium were distributed into 60 ml serum bottles that were closed with butyl rubber stoppers according to the Hungate anaerobic technique (Hungate, 1969). The serum bottles were gassed with N₂/CO₂ (80:20) and sterilized for 45 min at 110 °C. After sterilization, 0.2 ml of 2% Na₂S·9H₂O, 1 ml of 10% NaHCO₃ (sterile anaerobic stock solutions), and 0.1 ml of a 0.2% sodium dithionite solution (filter-sterilized solution) were injected into the bottles. For preparing roll-tubes, 2% agar (Difco) was added to the medium and 5 ml portions of medium were distributed into Hungate tubes as described above. Pure cultures were obtained by repeated application of the agar shake dilution method in anaerobic Hungate tubes as described previously (Ollivier et al., 1991). Purity was checked by lack of growth in a complex rich NaCl-free medium at mesophilic and thermophilic temperatures.

Differentiation of the genus *Halothermothrix* from other genera

Research on hypersaline ecosystems has led to the description of two families: *Halanaerobiaceae*, which includes three genera and eleven species; and *Halobacteroidaceae*, which includes eight genera and thirteen species. These families comprise exclusively mesophilic and strictly anaerobic bacteria with the exception of *Halobacteroides lacunaris*, a moderately thermophilic bacterium with an upper temperature limit of 52 °C (Zhilina et al., 1991b). The characterization of *Halothermothrix orenii* extends the temperature limit for growth of halophilic anaerobic members of the order *Halanaerobiales* to 68 °C. To date, two moderately thermophilic, phylogenetically distinct halophiles have been described (Table 239), both of which are members of the *Firmicutes*. *Halothermothrix orenii*, a member of the order *Halanaerobiales*, grows optimally at 60 °C in the presence of 10% NaCl, whereas *Thermohalobacter berrensis*, a member of the order *Clostridiales*, grows optimally at 70 °C

TABLE 239. Main characteristics that differentiate *Halothermothrix orenii* from *Thermohalobacter berrensis*

in the presence of 15% NaCl (Cayol et al., 2000). The phospholipid fatty acid (PLFA) composition of *Halothermothrix orenii* contains a preponderance of branched saturated fatty acids (75.6%) of which C_{15:0 iso}, C_{15:0 anteiso}, and C_{16:0} dominate (Table 240). This is a trait commonly found in genuine thermophilic bacteria due to growth at high temperatures. *Halothermothrix orenii* is a thermophile, but its obligate salt requirement indicates that it is unrelated to other thermophilic bacteria, e.g., *Thermanaerobacter* (Lee et al., 1993). The absence of lactate production from glucose by *Halothermothrix orenii* also rules out any similarity with members of this genus for which lactate production is a characteristic.

Taxonomic comments

Halothermothrix orenii is a rod-shaped, anaerobic, and halophilic bacterium and therefore resembles members of the family *Hala-*

TABLE 241. Main characteristics that differentiate the genera *Halothermothrix*, *Halocella*, and *Halanaerobium* of the family *Halanaerobiaceae*^a

naerobiaceae. Considerable biochemical and physiological differences have been observed between *Halothermothrix orenii* and other members of the family *Halanaerobiaceae*, with *Halocella cellulositytica* and species of *Halanaerobium* being its closest phylogenetic relatives (similarities of 89% and 85–87%, respectively) (Table 241). The relationship between *Halothermothrix orenii* and members of this family is further strengthened by the presence of a common stretch of sequence at positions 821–842 (*Escherichia coli* numbering, according to Winkler and Woese, 1991) and the presence of a common shortened secondary structural variant in part of helix 47 at positions 1435–1466 (Figure 237). In contrast to some *Halanaerobium* species, *Halothermothrix orenii* oxidizes L-arabinose, sucrose, and D-xylose, it does not use peptides or produce lactate from glucose fermentation, and it grows at high temperatures (Table 241). *Halothermothrix orenii* differs from *Halocella cellulositytica* as it oxidizes L-arabinose, fructose, D-ribose, and D-xylose, but not sucrose, and grows at high temperatures, whereas *Halocella cellulositytica* produces lactate from glucose fermentation.

List of species of the genus *Halothermothrix*

1. *Halothermothrix orenii* Cayol, Ollivier, Patel, Prensier, Guezennec and Garcia 1994a, 538^{VP}

o.re'ni.i. N.L. gen. n. *orenii* of Oren, named after Aharon Oren who has made important contributions to the knowledge of halophilic anaerobic bacteria.

Cells are long, flexible rods (Figure 236), occurring mainly singly (10–20 by 0.4–0.6 µm) and cytoplasmic density was higher at the periphery of the cells. The cell wall is typical of Gram-stain-negative bacteria. Irregularities in the diameters of cells are observed. Motile with peritrichous flagella. Colonies are yellow, flat, and circular with diameters ranging from 0.5 to 1.0 mm, depending on incubation time.

Obligate anaerobe that oxidizes several carbohydrates including arabinose, cellobiose, fructose, galactose, glucose, mannose, melibiose, ribose, starch, and xylose. Does not use lactose, maltose, rhamnose, sucrose, sorbose, cellulose, formate, acetate, butyrate, propionate, fumarate, lactate, malate, succinate, adonitol, dulcitol, glycerol, mannitol,

Casamino acids, trimethylamine, or Biotrypticase. Yeast extract is required for growth. Products of glucose fermentation are ethanol, acetate, H₂, and CO₂.

Moderate halophile, thermophile, and neutrophile. The optimum NaCl concentration is between 5 and 10%, with the lower and upper limits of growth around 4 and 20%, respectively. The optimum temperature for growth is 60 °C; growth occurs between 45 and 68 °C. The pH range for growth is 5.5–8.2; the optimum pH is 6.5–7.0. Does not require MgCl₂, but tolerates it up to 0.7 M when 10% NaCl is present in the medium.

Does not possess unsaturated fatty acids in the lipid cell wall composition. Branched-chain saturates account for 75% of the total fatty acids, with C_{15:0 iso} fatty acid predominating.

Family II. **Halobacteroidaceae** Zhilina and Rainey 1995, 879^{VP} (Effective publication: Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995a, 193.)

AHARON OREN

Ha.lo.bac.te.ro.i.da'ce.ae. N.L. masc. n. *Halobacteroides* type genus of the family; -aceae ending to denote a family; N.L. fem. pl. n. *Halobacteroidaceae* the *Halobacteroides* family.

Cells are rod-shaped and **Gram-stain-negative**. Endospores are produced by some species. **Strictly anaerobic**. Oxidase- and catalase-negative. Most species ferment carbohydrates to products including acetate, ethanol, hydrogen, and carbon dioxide. Some species may grow fermentatively on amino acids; others have a homoacetogenic metabolism or grow by anaerobic respiration while reducing nitrate, trimethylamine *N*-oxide, or selenate. **Moderately halophilic**. NaCl concentrations in the range 1.7–2.5 M are required for optimal growth and no growth is observed below 0.3–1.7 M NaCl, depending on the species.

DNA *G+C* content (mol %): 30–50.

Type genus: Halobacteroides Oren, Weisburg, Kessel and Woese 1984a, 355^{VP} (Effective publication: Oren, Weisburg, Kessel and Woese 1984b, 68.).

Further descriptive information

All known members of the *Halobacteroidaceae* are strictly anaerobic and moderately halophilic. Most grow optimally at NaCl concentrations around 1.7–2.5 M. A minimal NaCl concentration of 0.3–1.7 M is required, depending on the species. *Natroniella acetigena*, isolated from the alkaline hypersaline Lake Magadi, Kenya, is an obligate alkaliphile, growing between pH 8.1–10.7 with optimum growth at pH 9.7–10.0 (Zhilina et al., 1996b).

All species show a Gram-stain-negative reaction. A typical Gram-stain-negative type of cell wall with an outer membrane and periplasmic space is often seen in electron micrographs of thin sections.

Heat-resistant endospores are produced by a number of species belonging to the family. These include *Sporohalobacter lortetii* (Oren, 1983) and *Orenia marismortui* (Oren et al., 1987). *Natroniella acetigena* produces spores infrequently (Zhilina et al., 1996b). When initially isolated, *Acetohalobium arabaticum* produced spores, but sporulation was not observed during subsequent transfers (Zavarzin et al., 1994). Special conditions may be required for induction of endospore formation. Growth on solid media or in nutrient-poor liquid media may enhance sporulation in certain species (Oren, 1983, 1987).

Most species belonging to the *Halobacteroidaceae* obtain their energy by fermenting simple sugars. Complex polysaccharides such as chitin may be used by certain species such as *Halanaerobacter chitinivorans*. Fermentation products typically include acetate, hydrogen, and carbon dioxide. Additionally, some strains produce butyrate, lactate, propionate, and formate. In addition to sugar fermenters, some species can ferment amino acids, either alone or by using the Stickland reaction. For example, *Halanaerobacter salinarius* and *Halanaerobacter chitinivorans* can use serine as an electron donor while reducing glycine betaine, with the formation of acetate, trimethylamine, CO₂, and NH₃ (Mouné et al., 1999). The neutrophilic *Acetohalobium arabaticum* and the alkaliphilic *Natroniella acetigena* are homoacetogens that do not use carbohydrates but grow chemoheterotrophically on substrates such as lactate, ethanol, pyruvate, glutamate, propanol, and glycine betaine. *Acetohalobium arabaticum* can also grow

chemoautotrophically on hydrogen plus carbon dioxide with the formation of acetate or as a methylotroph on trimethylamine, forming acetate and NH₃ (Zavarzin et al., 1994; Zhilina and Zavarzin, 1990c; Zhilina et al., 1996b).

Methanethiol can be used as an assimilatory sulfur source by several species, including *Halobacteroides halobius*, *Halobacteroides elegans*, and *Halanaerobacter lacunarum* (Kevbrin and Zavarzin, 1992b; Zhilina et al., 1991b, 1997b). Some species can use oxidized sulfur compounds as electron acceptors or electron sinks. *Acetohalobium arabaticum* slowly reduces sulfur to sulfide, but no growth enhancement has been observed (Kevbrin and Zavarzin, 1992c; Zavarzin et al., 1994). *Orenia marismortui* produces small amounts of sulfide from thiosulfate (Oren et al., 1987). Other compounds that may serve as electron sinks are nitrosubstituted aromatic compounds such as nitrobenzene, nitrophenols, 2,4-dinitrophenol, and 2,4-dinitroaniline, which are found to be reduced by *Orenia marismortui* (Oren et al., 1991).

Enrichment and isolation procedures

Species belonging to the family *Halobacteroidaceae* can probably be found in any hypersaline anaerobic environment in which simple organic compounds such as sugars and amino acids are available. They have been isolated from hypersaline lakes, both with thalassohaline and athalassohaline ionic composition, including the Dead Sea (Oren, 1983, 1987; Oren et al., 1984b), Salton Sea, California (Shiba, 1991; Shiba and Horikoshi, 1988, 1989), hypersaline lakes and lagoons in the Crimea (Zhilina et al., 1991a, 1997b, 1990c), saltern evaporation ponds in California (Liaw and Mah, 1992) and France (Mouné et al., 2000, 1999), and the alkaline hypersaline lakes Magadi, Kenya (Shiba and Horikoshi, 1988; Zhilina et al., 1996b) and Big Soda Lake, Nevada (Shiba and Horikoshi, 1988, 1989).

Any anoxic reducing medium containing high salt concentrations (0.8–4.2 M) and a suitable carbon source is a potential enrichment and growth medium for members of the *Halobacteroidaceae*. Simple sugars are used by most species. For the isolation of amino-acid-fermenting or homoacetogenic species, the medium composition should be adapted accordingly. For the isolation of *Selenihalanaerobacter*, selenate is the preferred electron acceptor as nitrate and trimethylamine *N*-oxide enable anaerobic growth of a variety of facultative anaerobes. The formation of heat-resistant endospores has been exploited in a selective enrichment procedure for *Halobacteroides halobius*-like bacteria, based on negative selection by pasteurization of the inoculum for 10–20 min at 80–100 °C (Oren, 1987). In view of the number of endospore-forming genera within the family (*Halobacteroides*, *Orenia*, *Sporohalobacter*, *Acetohalobium*, and *Natroniella*), such an enrichment strategy could be useful for the isolation of other members of the family.

Strictly anaerobic techniques should be used, including boiling the media under nitrogen or nitrogen/CO₂ (80:20) and adding reducing agents such as cysteine, thioglycollate, or sulfide to the boiled media. High pH media should be used

for the enrichment and isolation of alkaliphiles. Protocols for the preparation of media have been compiled by Oren (2001); details can be found in the original species descriptions. No specific enrichment procedures have been designed as yet that enable growth of the *Halobacteroidaceae* with the exclusion of the *Halanaerobiaceae*.

Properties that distinguish the family *Halobacteroidaceae* from other families

The only sure way to distinguish members of the family *Halobacteroidaceae* from the members of the *Halanaerobiaceae* is by 16S rRNA gene sequence relatedness. There are no known morphological, physiological, or biochemical tests that enable an unequivocal classification in either of the two families. Table 236 presents information on the 16S rRNA signature nucleotides defining the two families.

Taxonomic comments

The family *Halobacteroidaceae* was created in 1995 in the course of a comprehensive in-depth study of the anaerobic halophilic *Bacteria*. Based on 16S rRNA gene sequence comparisons, extensive taxonomic rearrangements were proposed. These included a

reclassification of the species of the former family *Haloanaerobiaceae* over two families: the *Haloanaerobiaceae* (renamed *Halanaerobiaceae*) and the newly created family *Halobacteroidaceae* (Rainey et al., 1995a). On that occasion, the genera *Halobacteroides*, *Acetohalobium*, *Halanaerobacter*, and *Sporohalobacter*, which were previously classified within the family *Halanaerobiaceae*, were transferred to the *Halobacteroidaceae*. Patel et al. (1995) then proposed the reclassification of *Haloanaerobacter chitinivorans* (*Halanaerobacter chitinivorans*) within the genus *Halobacteroides* on the basis of 16S rRNA gene sequence analyses. However, the dendrogram presented by Mouné et al. (1999) supports the recognition of *Halanaerobacter* as a separate genus.

Genus I. **Halobacteroides** Oren, Weisburg, Kessel and Woese 1984a, 355^{VP} (Effective publication: Oren, Weisburg, Kessel and Woese 1984b, 68.)

AHARON OREN

Ha.lo.bac.te.ro'i.des. Gr. n. *hals*, *halos* salt; N.L. masc. n. *bacter* the masc. equivalent of Gr. neut. n. *baktron* a staff or rod; Gr. n. *eidos* form, shape; N.L. masc. n. *Halobacteroides* rod-like salt organism.

Cells are long, thin, often flexible rods, motile by peritrichous flagella, Gram-stain-negative. Endospores may be formed. **Strictly anaerobic**, chemo-organotrophic with fermentative metabolism. Carbohydrates are fermented with production of acetate, ethanol, H₂, and CO₂. **Halophilic**, growing optimally at NaCl concentrations around 1.7–2.6M and requiring a minimum of 1.2–1.7M NaCl for growth.

DNA G+C content (mol%): 30.5–30.7 (Bd, HPLC).

Type species: Halobacteroides halobius Oren, Weisburg, Kessel and Woese 1984a, 355^{VP} (Effective publication: Oren, Weisburg, Kessel and Woese 1984b, 68.).

Further descriptive information

The two presently recognized species within the genus *Halobacteroides* ferment a variety of carbohydrates to acetate, ethanol, H₂, and CO₂. Both *Halobacteroides halobius* and *Halobacteroides elegans* can use methanethiol as the sole source of assimilatory sulfur for growth (Kevbrin and Zavarzin, 1992b; Zhilina et al., 1997b). Reduction of elemental sulfur to sulfide was reported in *Halobacteroides elegans* (Kevbrin and Zavarzin, 1992b; Zhilina et al., 1997b).

Electron microscopic examination of thin sections of cells shows a typical Gram-stain-negative type of cell wall. At the end of the exponential growth phase, cells rapidly degenerate to sphaeroplast-like structures and die.

Measurements of intracellular ionic concentrations in *Halobacteroides halobius* have shown the presence of molar concentrations of K⁺ and Cl⁻ (Oren, 1986).

Endospores may be formed. *Halobacteroides elegans* produces round, terminal endospores in culture. No endospores have

been observed in cultures of *Halobacteroides halobius*, but bacteria resembling this species could be grown from sediment samples obtained from the Dead Sea and other hypersaline anaerobic sediments following pasteurization for 10–20 min at 80–100 °C (Oren, 1987), thus suggesting that heat-resistant structures may be produced.

Enrichment and isolation procedures

Any anoxic reducing medium containing a high salt concentration (0.8–4.3M NaCl) and containing glucose or other simple sugars as a carbon source is a potential enrichment and growth medium for anaerobic halophilic bacteria of the genus *Halobacteroides*. Details on the composition of suitable growth media can be found in Oren (2001) and in the original publications on the isolation of species. Strictly anaerobic techniques should be used, including boiling the media under nitrogen or nitrogen/CO₂ (80:20) and adding cysteine as reducing agent to the boiled media. Enrichment cultures should be checked frequently for growth of *Halobacteroides*, as growth may be very rapid, followed by sphaeroplast formation and death of the cells.

The existence of heat-resistant endospores has been exploited in a selective enrichment procedure for *Halobacteroides halobius*-like bacteria, based on negative selection by pasteurization of the inoculum for 10–20 min at 80–100 °C (Oren, 1987). It remains to be determined to what extent this procedure is specific for *Halobacteroides*, excluding other endospore-forming, sugar-fermenting halophiles such as *Orenia* and *Sporohalobacter*. No other specific enrichment procedures for representatives of the genus *Halobacteroides* have been devised thus far.

Maintenance procedures

Lyophilization has proved satisfactory for the preservation of *Halobacteroides* species. Both *Halobacteroides halobius* and *Halobacteroides elegans* easily undergo autolysis, during which spherical degeneration forms can be observed (Oren et al., 1984b; Zhilina et al., 1997b). Lysis starts at the end of the exponential growth phase, especially when relatively high growth temperatures are employed. Death of cultures may be delayed by employment of media with a reduced nutrient content and the use of lower growth temperatures (15–25 °C). Weekly transfers may then suffice to maintain viable cultures.

Taxonomic comments

Presently, two species are recognized within the genus *Halobacteroides*: *Halobacteroides halobius* and *Halobacteroides elegans*. *Halobacteroides elegans* was originally described as a strain of *Halobacteroides halobius* (Zhilina et al., 1991a), but was subsequently described

as a new species on the basis of 16S rRNA gene sequence analysis (Zhilina et al., 1997b).

The former *Halobacteroides acetothyliticus* (Rengpipat et al., 1989) has been transferred to the new genus *Halanaerobium* as *Halanaerobium acetethylicum* comb. nov., nom. corrig. (Oren, 2000; Rainey et al., 1995b), and the former *Halobacteroides lacunaris* (Zhilina et al., 1992a) has been transferred to the genus *Halanaerobacter* as *Halanaerobacter lacunarum* comb. nov., nom. corrig. (Oren, 2000; Rainey et al., 1995a).

Differentiation of the species of the genus *Halobacteroides*

Identification of isolates and their assignment to the genus *Halobacteroides* should be based preferentially on the determination of their 16S rRNA gene sequences. In addition, phenotypic characterization should be performed and the properties of the strains should be compared with those of the described species.

List of species of the genus *Halobacteroides*

- 1. *Halobacteroides halobius*** Oren, Weisburg, Kessel and Woese 1984a, 355^{VP} (Effective publication: Oren, Weisburg, Kessel and Woese 1984b, 68.)
 ha.lo'bi.us. Gr. n. *hals* salt; Gr. n. *bios* life; N.L. adj. *halobius* living on salt.
 Cells are thin, flexible rods, 0.5–0.6 × 10–20 μm in size. Motile by peritrichous flagella. Sphaeroplasts are formed in ageing cultures. Halophilic, requiring 1.2–3.2 M NaCl for growth, and growing optimally at 1.5–2.6 M NaCl. Temperature range for growth: 30–47 °C. Optimum temperature: 37–42 °C. Strictly anaerobic. Ferments carbohydrates with production of acetate, ethanol, H₂, and CO₂. Grows on a range of carbohydrates and other compounds including fructose, galactose, D-glucose, maltose, pyruvate, raffinose, and starch. No growth on L-arabinose, cellobiose, L-fucose, D-gluconate, glycerol, lactose, D-mannitol, D-melezitose, D-melibiose, D-ribose, L-rhamnose, D-sorbitol, L-sorbose, or D-xylose. The major fatty acids in the lipids are C_{14:0}, C_{16:0}, and C_{16:1}.
Source: sediments of the Dead Sea, Israel.
DNA G+C content (mol%): 30.7 (T_m).
Type strain: MD-1, ATCC 35273, DSM 5150.
GenBank accession number (16S rRNA gene): U32595, X89074.
- 2. *Halobacteroides elegans*** Zhilina, Turova, Lysenko and Kevbrin 1997a, 1274^{VP} (Effective publication: Zhilina, Turova, Lysenko and Kevbrin 1997b, 97.)
 e'le.gans. L. adj. *elegans* choice, elegant.
 Cells are curved rods, 0.3–0.5 × 2–10 μm in size. Motile by peritrichous flagella. Produces terminal round endospores, 0.12–0.15 μm in diameter. Sphaeroplasts are formed in ageing cultures. Halophilic, requiring 1.7–5.1 M NaCl for growth, and growing optimally at 1.7–2.6 M NaCl. Temperature range for growth: 28–47 °C. Optimum temperature: 40 °C. Strictly anaerobic. Ferments carbohydrates with production of acetate, ethanol, H₂, and CO₂. Grows on a range of carbohydrates including fructose, D-glucose, mannose, starch, sucrose, and trehalose. Weak growth on cellobiose, galactose, maltose, mannitol, and pyruvate. No growth on N-acetylglucosamine, chitin, glycogen, raffinose, D-ribose, or sorbitol. The major fatty acids in the lipids are C_{14:0}, C_{16:0}, and C_{16:1}.
Source: cyanobacterial mats, Lake Sivash, Crimea.
DNA G+C content (mol%): 30.5 (T_m).
Type strain: Z-7287, DSM 6639.
GenBank accession number (16S rRNA gene): AJ238119, L37423.

Genus II. **Acetohalobium** Zhilina and Zavarzin 1990b, 470^{VP} (Effective publication: Zhilina and Zavarzin 1990c, 747.)

GEORGE A. ZAVARZIN AND TATJANA N. ZHILINA

A.ce.to.ha.lo'bi.um. N.L. neut. n. *acetum* vinegar; Gr. n. *hals*, *halos* salt; Gr. n. *bios* life; N.L. neut. n. *Acetohalobium* acetate-producing organism living in salt.

Rod-shaped cells. Motile with 1–2 subterminal flagella. Multiplication by binary fission is by constriction rather than septation. **Gram-stain-negative** cell wall structure. Thermoresistant endospores formed by some strains. **Strictly anaerobic.** Possess a respiratory type of **homoacetogenic metabolism.** **Extremely halophilic**, growing at 1.7–4 M NaCl. Obligately dependent on

sodium chloride. Neutrophilic. Mesophilic. **Metabolism variable; lithoheterotrophic**, utilizing hydrogen, formate, and carbon monoxide, **methylophilic**, utilizing methylamines and betaine, **or chemo-organotrophic**, fermenting some amino acids and organic acids. **Acetate is the end product** with all substrates utilized.

DNA G+C content (mol%): 33–35 (T_m).

Type species: Acetohalobium arabaticum Zhilina and Zavarzin 1990b, 470^{VP} (Effective publication: Zhilina and Zavarzin 1990c, 747.).

Further descriptive information

Phylogenetically, the genus *Acetohalobium* belongs to the spore-forming branch of the haloanaerobic eubacterial family *Halobacteroidaceae* (Rainey et al., 1995b; Tourova et al., 1995), order *Haloanaerobiales*, now spelled *Halanaerobiales* (Oren, 2000). The genus includes a single species, *Acetohalobium arabaticum*. Information regarding the species and, therefore, the genus is given in the species description.

Enrichment and isolation procedures

Strains of *Acetohalobium* can be enriched and isolated from extremely saline lagoons or salinas of thalassic origin with variable salinity under strictly anaerobic conditions under an $H_2 + CO_2$ atmosphere which can be substituted by $N_2 + CO_2$ in a selective mineral medium supplemented with trimethylamine (TMA) chloride or betaine and with inhibition of methylotrophic methanogens by 10 mM bromethanesulfonate (Zhilina and Zavarzin, 1990c). The medium has the following composition (per liter of distilled water): NaCl, 150 g; $MgCl_2 \cdot 6H_2O$, 4 g; NH_4Cl , 0.33 g; KCl, 0.33 g; KH_2PO_4 , 0.33 g; $Na_2S \cdot 9H_2O$, 0.5 g; yeast extract 0.1 g; 1 ml trace element solution (Kevbrin and Zavarzin, 1992a); and 10 ml vitamin solution (Wolin et al., 1963). Pure cultures are obtained by serial dilution in liquid medium supplemented with TMA chloride (3 g/l) as substrate followed by isolation of single colonies in Hungate roll tubes. Colonies are whitish yellow, lens shaped, and 0.5–1 mm in diameter.

Maintenance procedures

Acetohalobium is maintained by regular subculturing in liquid medium and stored in a refrigerator at 6 °C. In broth cultures,

rapid lysis occurs at the end of active growth. Consequently, preservation and maintenance of the culture is tedious. Cultures should be transferred every 2–3 weeks, but lysis of cells may occur. Strains of *Acetohalobium* may be stored in liquid nitrogen.

Differentiation of the genus *Acetohalobium* from other genera

Acetohalobium can be differentiated from other genera of haloanaerobic, saccharolytic bacteria of the family *Halobacteroidaceae* [*Halobacteroides*, *Halanaerobacter*, *Orenia*, *Sporohalobacter* (Oren, 2000; Rainey et al., 1995a), and *Halonatronum* (Zhilina et al., 2001b)] by its homoacetogenic type of metabolism and its inability to utilize sugars. In common with some of the above genera, *Acetohalobium* is extremely halophilic, with obligate dependence on NaCl at high concentrations. It differs from the haloalkaliphilic, homoacetogenic genus *Natroniella* (Zhilina et al., 1996b) by its inability to grow at high pH and the substrates utilized.

Taxonomic comments

The phylogenetic position of the genus was established first by E.S. Bulygina who showed by 5S rRNA gene sequence analysis that *Acetohalobium* clusters with the group of haloanaerobes (Zhilina et al., 1992b). Its generic status is based on 16S rRNA gene phylogeny. It represents a distinct lineage that clusters with halophilic eubacteria of the genus *Sporohalobacter* with levels of 16S rRNA gene sequence similarity of 96.1% (Rainey et al., 1995a; Tourova et al., 1995).

Cell lipids contain aliphatic fatty acids and β -hydroxy acids characteristic of Gram-stain-negative eubacteria. About 94% of the fatty acids are unsaturated straight-chain $C_{16:1}$, $C_{16:0}$, and $C_{12:1}$; β -hydroxy fatty acids are represented by $C_{16:1}$ and $C_{12:0}$, and sugars by pentoses and hexoses (Zhilina et al., 1992b).

List of species of the genus *Acetohalobium*

1. ***Acetohalobium arabaticum*** Zhilina and Zavarzin 1990b, 470^{VP} (Effective publication: Zhilina and Zavarzin 1990c, 747.)

a.ra.ba'ti.cum. N.L. neut. adj. *arabaticum* from Arabat, a peninsula between the Sea of Azov and Sivash.

Cells are rods, sometimes slightly bent, usually occurring singly or in pairs (Figure 238) and short chains. Motile with 1–2 subterminal flagella, 0.7–1 \times 2–5 μ m in size. Cell wall has typical Gram-stain-negative structure (Figure 239).

Multiplication by binary fission is often unequal, with formation of mini-cells on the end. Spores are rare, absent for the type strain in pure culture. Strain Z-7984 retains spore formation upon laboratory cultivation; spores are terminal and round (Figure 239).

Extremely halophilic; grows in 1.7–4.2 M NaCl with optimum for type strain at 2.5–3 M. Neutrophilic; grows at pH 5.6–8.4, pH optimum for the type strain is 7.8. Mesophilic; grows at 30–60 °C, optimum for the type strain is 38–40 °C, maximum 47 °C.

Strictly anaerobic. Fermentative with most substrates. O_2 , NO_3^- , SO_3^{2-} , $S_2O_3^{2-}$, SO_3^{2-} , and S^0 do not serve as electron

acceptors for catabolism. Homoacetogenic. Does not ferment carbohydrates or alcohols. *Acetohalobium arabaticum* uses the following substrates: $H_2 + CO_2$, CO, betaine, TMA, formate, lactate, pyruvate, histidine, aspartate, asparagine, and glutamate. Lactate, aspartate, and histidine are preferred substrates. The ability to utilize TMA chloride may be lost after cultivation on other substrates. Acetate is the product of fermentation. With betaine, the only products are acetate and TMA (Kevbrin et al., 1995, 1990a; Zhilina and Zavarzin, 1990c). Trace amounts of hydrogen are formed during the lag phase. Growth on all substrates is significantly stimulated by additives of protein origin. Yeast extract is needed for growth. Growth is initiated in the presence of bicarbonate (Kevbrin et al., 1995). *Acetohalobium* slowly reduces sulfur to sulfide and dimethylsulfoxide to dimethylsulfide, but without coupling of energy generation. Sulfite or dithionite at 1 mM concentration completely inhibits growth of the type strain. Sulfide is tolerated up to 12 mM (Kevbrin and Zavarzin, 1992a). Growth is inhibited by streptomycin, kanamycin, erythromycin, benzylpenicillin, gentamicin, vancomycin, and tetracycline.

FIGURE 238. Morphology of *Acetohalobium* strains as seen by light microscopy (bar = 10 µm). (a) Strain Z-7288^T on medium containing formate and 15% NaCl; (b) strain Z-7492 on medium containing TMA and 25% NaCl.

The metabolism of *Acetohalobium*, like that of other homo-acetogens, is based on CO dehydrogenase, which is found in both periplasmic and soluble cell fractions. Salt concentrations up to 5 M do not inhibit the activity of the enzyme. Hydrogenase activity is found in the periplasmic and membrane fractions, but is mostly in cytoplasmic fractions and is very high. It is stimulated by KCl and NaCl at concentrations of 3.0–4.5 M (Pushova, 1992). Neither cytochromes nor quinones are found in membranes of the type strain. Flavoproteins and various folates and corrinoids have been detected in the cells, causing their autofluorescence (Bykhovskiy et al., 1994; Zavarzin et al., 1994). Growth and acetogenesis on all substrates involves an Na⁺/H⁺ antiporter capable of Na⁺ extrusion from the cell against a NaCl concentration gradient as high as 2.56 M (Pushova and Detkova, 1996).

FIGURE 239. Electron micrograph of an ultrathin section of spore-forming cells of *Acetohalobium* strain Z-7492. Bar = 1 µm.

Acetohalobium was isolated from cyanobacterial mats in hypersaline lagoons where its trophic position was established during a search for micro-organisms responsible for the so-called non-competitive pathway of methylotrophic methanogenesis in halophilic microbial communities (Zhilina and Zavarzin, 1990a, 1990c). This pathway is driven by the decomposition of osmoprotective compounds and it is initiated by saccharolytic haloanaerobes decomposing sugars like trehalose and heterosides. The other step is caused by decomposition of betaine as osmolyte of proteobacteria with release of TMA and acetate. This step is performed by *Acetohalobium*, which is capable of utilizing TMA, a product of betaine decomposition. However, at this stage it is outcompeted by methylotrophic methanogens such as *Methanohalobium* species. In binary culture of *Acetohalobium* and *Methanohalobium evestigatum*, methane is produced from betaine (Zhilina and Zavarzin, 1990c). Hydrogen might serve as the substrate for *Acetohalobium*, but its consumption is outcompeted by hydrogenotrophic sulfate reducers. Trophic relationships in the anaerobic, halophilic, cyanobacterial community with emphasis on anaerobic decomposition of osmolytes have been discussed by Zhilina and Zavarzin (1991) and Zavarzin et al. (1994).

Source: cyanobacterial mats in hypersaline lagoons.

DNA G+C content (mol%): 33.6 (T_m).

Type strain: Z-7288, ATCC 49924, DSM 5501.

GenBank accession number (16S rRNA gene): L37422, X89077.

Additional remarks: *Acetohalobium arabaticum* strain Z-7492 differs in a number of traits from the type strain Z-7288^T. It has a DNA G+C content of 34.6 mol%, retains sporulation

in pure culture, has temperature optimum of 55 °C and range of 30–60 °C, and optimal salinity at 3.4–4 M NaCl in a range 2.5–4.2 M NaCl. Strain Z-7492 uses the same set

of substrates as the type strain. DNA–DNA hybridization of strain Z-7492 with strain Z-7288^T is 78% (Kevbrin et al., 1995; Zavarzin et al., 1994).

Genus III. **Halanaerobacter** Liaw and Mah 1996, 362^{VP} (Effective publication: Liaw and Mah 1992, 265.)
(*Halanaerobacter* [sic] Liaw and Mah 1992, 265)

NOHA M. MESBAH

Hal.an.ae.ro.bac'ter. Gr. n. *hals* salt; Gr. pref. *an* not; Gr. n. *aer* air; N.L. masc. n. *bacter* rod; N.L. masc. n. *Halanaerobacter* salt rod which grows in the absence of air.

Cells are rod-shaped or slightly curved, motile by means of peritrichous flagella. Gram-stain-negative. Strictly anaerobic. Chemo-organotrophic with fermentative metabolism; some strains can utilize amino acids in Stickland reactions or with H₂ as electron donor. Carbohydrates are fermented with production of acetate, H₂, and CO₂. In some species, ethanol, propionate, formate, and isobutyrate are also formed. Elemental sulfur can be used as an electron acceptor in a certain species. Halophilic; optimal growth occurs at NaCl concentrations around 2.0–3.0 M. Cells require a minimum of 0.5–1.6 M NaCl for growth. Neutral to slightly alkaline pH values required for optimal growth (6.5–7.8). Mesophilic to slightly thermotolerant, and optimal growth occurs between 35 and 45 °C. Endospores have not been observed; short degenerate cells and sphaeroplasts occur in stationary phase. Catalase- and oxidase-negative. Found in anoxic sediments in hypersaline environments.

DNA G+C content (mol%): 32–35.

Type species: **Halanaerobacter chitinivorans** corrig. Liaw and Mah 1996, 362^{VP} (Effective publication: Liaw and Mah 1992, 265.).

Further descriptive information

Phylogenetically, the genus *Halanaerobacter* belongs to the moderately halophilic family *Halobacteroidaceae*, order *Halanaerobiales* (Rainey et al., 1995a), and is closely related to the genus *Halanaerobium* (Figure 240). The genus includes three species.

Cells of all three species are long thin rods (0.5–8.0 μm × 0.3–0.5 μm). Cells are flexible; rods of *Halanaerobacter lacunarum* curl up into circular shapes during the late exponential growth phase (Zhilina et al., 1991b). After the end of exponential growth, cells of all species rapidly form sphaeroplasts and then lyse. All three species are motile by means of peritrichous flagella.

All *Halanaerobacter* species are halophilic. They grow optimally at 2.0–3.0 M NaCl. Depending on the species, a minimum of 0.5–1.6 M NaCl is required for growth. All species tolerate 5.0 M NaCl, which is close to saturation, and are neutrophilic, growing optimally at a pH around 7.0. *Halanaerobacter salinarius* is alkalitolerant and can grow at pH values up to 8.5 (Mouné et al., 1999). *Halanaerobacter salinarius* is also the most thermotolerant, growing optimally at 45 °C. *Halanaerobacter* species are

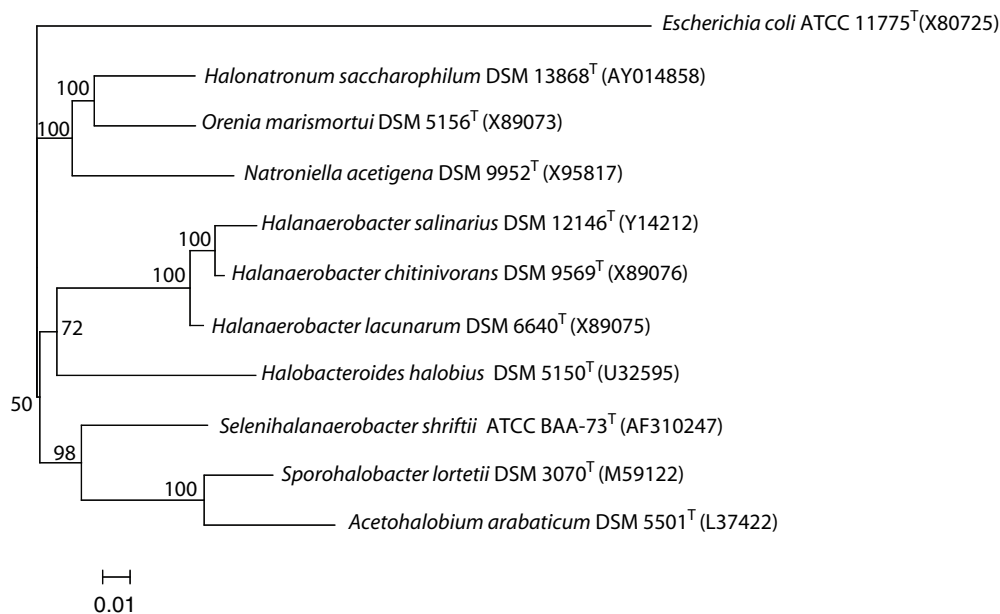

FIGURE 240. Neighbor-joining tree based on 16S rRNA gene sequences showing the position of species of the genus *Halanaerobacter* in relation to type species of genera within the family *Halobacteroidaceae*. Sequences were aligned with the CLUSTAL X program. The tree was constructed using the PHYLIP software package. Distances were calculated using the Jukes–Cantor algorithm of DNADIST, and branching order was determined via the neighbor-joining algorithm of NEIGHBOR. GenBank accession numbers are shown in parentheses. The tree is rooted with the 16S rRNA of *Escherichia coli* ATCC 11775^T as outgroup. Numbers at nodes denote bootstrap values based on 100 replicates; only values 50 or greater are shown. Bar, one nucleotide substitution per 100 nt.

distinguished from other genera among the *Halobacteroidaceae* by their ability to grow at 50 °C (Raine et al., 1995a).

All *Halanaerobacter* species grow fermentatively on sugars, producing acetate, H₂, and CO₂. Additional products made by some strains include ethanol, propionate, formate, and isobutyrate (Table 242). *Halanaerobacter chitinivorans* strain W5C8 displays chitinolytic activity and is capable of using chitin as a carbon and energy source (Liaw and Mah, 1992). *Halanaerobacter lacunarum* shows enhanced growth on sucrose and trehalose (Zhilina et al., 1991b), two frequently used osmotic solutes.

Halanaerobacter lacunarum is also able to use sodium sulfide both as an electron donor and a sulfur source for growth. When supplemented with 5–7 mM of elemental sulfur, *Halanaerobacter lacunarum* produces hydrogen sulfide. *Halanaerobacter lacunarum* has the highest tolerance to sulfide, and the presence of 50 mM of sulfide in the medium does not reduce the growth rate (Zhilina et al., 1991b). *Halanaerobacter salinarius* can tolerate 14 mM sulfide (Mouné et al., 1999). Tolerance to high sulfide concentrations is most likely an adaptation to the high sulfide concentrations commonly encountered in anoxic sediments present in hypersaline environments.

Neither *Halanaerobacter lacunarum* nor *Halanaerobacter chitinivorans* utilize amino acids as sole substrates. *Halanaerobacter salinarius* is distinguished from these two species by the ability to reduce glycine betaine to trimethylamine using either serine or hydrogen as electron donors (Mouné et al., 1999). This occurs via a Stickland reaction. In contrast, *Halanaerobacter lacunarum* is not capable of glycine betaine reduction and *Halanaerobacter chitinivorans* can reduce glycine betaine only in the presence of hydrogen. None of the *Halanaerobacter* species are capable of dissimilatory reduction of inorganic nitrogen (NO₃⁻).

The ability to use substrates such as glycine betaine, sucrose, and trehalose is of ecological importance. These compounds are accumulated at high concentrations as organic osmotic solutes by aerobic halophilic micro-organisms inhabiting saline and hypersaline lakes (Oren, 2008). It follows that these

compounds are widely distributed in hypersaline ecosystems and are available to the anaerobic bacterial community inhabiting the bottom sediments of these lakes.

Enrichment and isolation procedures

Species of the genus *Halanaerobacter* are found in anaerobic hypersaline environments where simple sugars are available. The three species available have been isolated from sediments of solar salterns in France, southern California, and Ukraine (Liaw and Mah, 1992; Mouné et al., 1999; Zhilina et al., 1991b). An anoxic reducing medium containing high NaCl concentrations (2.0–3.0 M) and simple sugars as a carbon source is a potential enrichment and growth medium for the anaerobic halophilic bacteria of the genus *Halanaerobacter*. Media suitable for growth of *Halanaerobacter* species are described by Oren (2006) and in the original publications on the species isolations. The *Halanaerobacter* species are obligate anaerobes; strict anaerobic techniques should be used, including boiling the media under nitrogen or nitrogen-CO₂, and adding reducing agents such as cysteine, sulfide, or thioglycollate to boiled media.

Isolation from enrichment cultures can be achieved by agar dilution series using 1.0–1.3% (w/v) agar. Higher concentrations of agar should be avoided, as the high salinity of the medium could result in a decrease in water activity. Use of anaerobic jars and/or agar-roll tubes sealed under nitrogen is necessary to maintain anaerobicity.

No specific enrichment or culture media have been designed that can select for members of the *Halanaerobacter* species over other members of the families *Halanaerobiaceae* and *Halobacteroidaceae*. Members of the *Halanaerobacter* genus can grow optimally at temperatures between 43 and 45 °C, so incubation at higher temperatures can provide a selective advantage. However, other species within the families *Halanaerobiaceae* and *Halobacteroidaceae* can survive temperatures as high as 52 °C, so multiple dilutions are necessary to ensure pure isolates.

TABLE 242. Differential characteristics of *Halanaerobacter* species

Maintenance procedures

Members of the genus *Halanaerobacter* undergo spherical degeneration and autolysis at the end of exponential growth phase, particularly when grown at higher temperatures. For short-term preservation, cultures may be inoculated, incubated for a few hours till slight turbidity appears (OD_{600} 0.3–0.4), and then stored at 6 °C. These cultures will remain viable for a few weeks. Long-term preservation should be under liquid nitrogen (T. Zhilina, personal communication).

Differentiation of the species of the genus *Halanaerobacter*

Characteristic properties for differentiation of *Halanaerobacter* species are summarized in Table 242. The genetic relationship

of *Halanaerobacter* species based on 16S rRNA sequences is shown in Figure 240.

Taxonomic comments

The genus *Halanaerobacter* was originally named *Haloanaerobacter* and renamed *Halanaerobacter* in accordance with Rule 61, Appendix 9 of the Bacteriological Code (Oren, 2000). Based on 16S rRNA sequence comparisons, the former *Halobacteroides lacunaris* was reclassified as *Halanaerobacter lacunaris* (Rainey et al., 1995a). Patel et al. (1995) proposed the reclassification of *Halanaerobacter chitinivorans* within the genus *Halobacteroides* on the basis of 16S rRNA sequence analysis, but phylogenetic analysis presented by Mouné et al. (1999) supports classification of *Halanaerobacter* as a separate genus.

List of species of the genus *Halanaerobacter*

1. ***Halanaerobacter chitinivorans*** Liaw and Mah 1996, 362^{VP} (Effective publication: Liaw and Mah, 1992, 265.)

chi.tin.i.vo'rans. N.L. n. *chitinum* chitin; L. v. *vorare* devour; N.L. part. adj. *chitinivorans* chitin-devouring.

Colonies are opaque and glossy with entire edges, colony diameters range from 0.5 to 1.0 mm. Cells are long thin rods, 1.4–8.0 µm by 0.5 µm in exponential growth phase, and short degenerate cells in stationary phase. Motile by means of peritrichous flagella. Gram-stain-negative. Endospores not observed. Halophilic. Growth occurs at 0.5–5.0 M NaCl and optimal growth at 2.0–3.0 M NaCl. Temperature range for growth and optimum temperature range are 23–50 °C and 30–45 °C, respectively. Optimal pH for growth is 7.0. Strictly anaerobic. Oxidase- and catalase-negative. Ferments carbohydrates. Major fermentation products from glucose are acetate, H₂, CO₂, and isobutyrate. The type strain, W5C8, uses chitin as a carbon source. Grows on a range of carbohydrates including glucose, fructose, mannose, acetylglucosamine, sucrose, maltose, and cellobiose. No growth occurs on acetate, glycerol, pyruvate, D-raffinose, cellulose, or pectin. Cells are resistant to penicillin, carbenicillin, D-cycloserine, streptomycin, and tetracycline, and are susceptible to chloramphenicol.

Isolated from organic sediment of a solar saltern in Southern California.

DNA G+C content (mol%): 34.8 ± 1 (Bd).

Type strain: W5C8, OGC 229; CIP 105156; DSM 9569.

GenBank accession number (16S rRNA gene): U32596, X89076.

2. ***Halanaerobacter lacunarium*** (Zhilina, Miroshnikova, Osipov and Zavarzin 1991b) Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995b, 879^{VP} (Effective publication: Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995a, 197.) (*Halobacteroides lacunaris* Zhilina, Miroshnikova, Osipov and Zavarzin 1991b, 503)

la.cu.na'rum. L. n. *lacuna* hole; L. gen. pl. n. *lacunarium* of holes; referring to the source of isolation.

Colonies are lens-shaped with a straight edge, light yellow, 0.5–1.0 mm in diameter. Cells (0.5–6.0 µm by 0.7–1.0 µm) are slightly bent flexible rods, single, paired or in short chains. Motile by means of peritrichous flagella. Gram-stain-negative.

Endospores not observed. Halophilic. Optimal growth occurs at 2.5–3.0 M NaCl, and NaCl range for growth is 1.6–5.0 M. Temperature range for growth is 5–52 °C, and optimal growth occurs at 35–40 °C. Optimal pH for growth is 6.5–7.0, and the pH range is 6.0–8.0. Strictly anaerobic. Oxidase- and catalase-negative. Ferments carbohydrates. Fermentation products from glucose are acetate, ethanol, H₂, and CO₂. Grows on wide range of carbohydrates including sucrose, trehalose, starch, mannitol, glycogen, glucitol, glucose, fructose, maltose, mannitol, and starch. Enhanced growth occurs with sucrose and trehalose. No growth was obtained with arabinose, xylose, rhamnose, ribitol, lactose, mellibiose, fucose, raffinose, cellulose, erythritol, dulcitol, inositol, organic acids, formate, acetate, propionate, butyrate, glycolate, lactate, gluconate, oxalate, succinate, adipic acid, fumaric acid, tartrate, citrate, ascorbic acid, amino acids, methylglycine, dimethylglycine, betaine, mono-, di- and trimethylamine, choline, N-acetylglucosamine, yeast extract, peptone, trypticase, pectin, chitin, methanol, and glycerol. Forms hydrogen sulfide in the presence of elemental sulfur. Can tolerate up to 50 mM of sulfide with no reduction in growth rate. The major fatty acids are Δ9-C_{16:1} and C_{16:0}.

Isolated from silt of saline Lake Chokrak, Kerch peninsula, Crimea, Ukraine.

DNA G+C content (mol%): 32.4 (T_m).

Type strain: Z-7888, ATCC 49944; DSM 6640.

GenBank accession number (16S rRNA gene): U32593, L37421, X89075.

3. ***Halanaerobacter salinarius*** Mouné, Manac'h, Hirschler, Caumette, Willison and Matheron 1999, 111^{VP}

sa.li.na'ri.us. L. adj. *salinarius* pertaining to *salinae* salterns; referring to the source of isolation.

Surface colonies are circular, glossy, translucent, and slightly yellow with entire edges. Colony diameters are 1–2 mm. Agar-embedded colonies are opaque. Cells are long flexible rods (5–8 µm by 0.3–0.4 µm). Motile by means of peritrichous flagella. Gram-stain-negative. Endospores not observed. Halophilic. Growth occurs at 0.8–5 M NaCl, and optimal growth at 2.3–2.5 M. Temperature range for growth is 10–50 °C with an optimum at 45 °C. The pH range for growth is 5.5–8.5, and optimal growth occurs at pH 7.4–7.8.

Strictly anaerobic. Oxidase- and catalase-negative. Ferments carbohydrates. Fermentation products from glucose are ethanol, propionate, acetate, formate, CO₂, and H₂. Grows on a range of carbohydrates including glucose, fructose, galactose, mannose, trehalose, sucrose, maltose, raffinose, cellobiose, glucosamine, *N*-acetylglucosamine, and mannitol. No growth with starch, chitin, pyruvate, malate, lactate, glutamate, serine, and trimethylamine. Glycine betaine is reductively cleaved via a Stickland reaction into trimethylamine and acetate; hydrogen and serine serve as electron donors. Incapable of dissimilatory reduction of nitrate, or the sulfur

compounds SO₄²⁻, SO₃²⁻, and S₂O₃²⁻. Sulfate and nitrate cannot serve as sulfur or nitrogen sources. Cysteine can be used as a nitrogen and sulfur source. Cells are resistant to anisomycin, kanamycin, tetracycline, and Na-taurocholate and susceptible to chloramphenicol and erythromycin.

Isolated from black sediment below a gypsum crust in hypersaline ponds of salterns of Salin-de-Giraud, France.

DNA G + C content (mol %): 31.6 (HPLC).

Type strain: SG 3903, DSM 12146, ATCC 700559, CIP 107181.

GenBank accession number (16S rRNA gene): Y14212.

Genus IV. **Halonatronum** Zhilina, Garnova, Tourova, Kostrikina and Zavarzin 2001a, 263^{VP}
(Effective publication: Zhilina, Garnova, Tourova, Kostrikina and Zavarzin 2001b, 70.)

TATJANA N. ZHILINA, GEORGE A. ZAVARZIN AND AHARON OREN

Ha.lo.na.tro'num. Gr. n. *hals*, *halos* salt; Ar. n. *natron* soda; N.L. neut. n. *Halonatronum* an organism growing with salt and soda.

Cells are rod-shaped, flexible, and motile by peritrichous flagella. The cell wall has a Gram-stain-negative structure. Strictly anaerobic. Chemo-organotrophic with fermentative metabolism. Carbohydrates, including soluble polysaccharides, are fermented to acetate, ethanol, formate, H₂, and CO₂. **Halophilic and alkaliphilic. Endospores produced.**

DNA G+C content (mol %): 34.4 (*T_m*).

Type species: **Halonatronum saccharophilum** Zhilina, Garnova, Tourova, Kostrikina and Zavarzin 2001a, 263^{VP} (Effective publication: Zhilina, Garnova, Tourova, Kostrikina and Zavarzin 2001b, 71.).

Further descriptive information

Currently, the genus contains a single species, namely *Halonatronum saccharophilum*. This bacterium was isolated from sediments collected from a coastal lagoon of Lake Magadi, Kenya (Zhilina et al., 2001b). The species is halophilic, alkaliphilic, moderately thermophilic, and produces endospores. Optimal growth is achieved in medium containing about 1M Na₂CO₃ + NaHCO₃ in addition to 0.85M NaCl. High concentrations of Na₂CO₃ + NaHCO₃ are specifically required; high NaCl media buffered with serine at the optimal pH (8.0–8.4) without carbonates do not support growth.

Enrichment and isolation procedures

The only isolate of the single recognized species within the genus was obtained from a mud sample collected from a coastal lagoon of Lake Magadi, Kenya. It was isolated from an anaerobic enrichment culture in hypersaline alkaline medium containing sucrose and yeast extract as organic nutrients. Selective isolation procedures for *Halonatronum* may possibly be designed on the basis of its requirement for high pH and high salt concentrations, its ability to grow at relatively high temperatures, and its formation of endospores, but such procedures have not yet been tested.

Maintenance procedures

Cells in the early exponential phase may be stored at 4°C for up to one month at least. For long-term preservation, storage in liquid nitrogen is recommended.

Taxonomic comments

Analysis of the 16S rRNA gene of the single species classified within the genus showed that *Halonatronum* belongs to the order *Halanaerobiales*, family *Halobacteroidaceae*. Phylogenetically, it is most closely related to members of the genus *Orenia* (91.4–92.8% similarity) and *Natroniella acetigena* (90.3% similarity).

List of species of the genus *Halonatronum*

1. **Halonatronum saccharophilum** Zhilina, Garnova, Tourova, Kostrikina and Zavarzin 2001a, 263^{VP} (Effective publication: Zhilina, Garnova, Tourova, Kostrikina and Zavarzin 2001b, 71.)

sac.cha.ro'phi.lum. Gr. n. *sakchâr* sugar; Gr. adj. *philos* loving; N.L. neut. adj. *saccharophilum* sugar-loving.

Cells are rod-shaped, 0.4–0.6 × 3.5–10 µm in size in young cultures. In older cultures, long thickened cells and sphaeroplasts occur. Motile by means of peritrichous flagella. Terminal endospores are round, 1.25 µm in diameter.

Halophilic and alkaliphilic, requiring 0.5–2.9M NaCl for growth, and growing optimally at 1.2–2.0M NaCl. Cells are lysed at NaCl concentrations below 0.5M. The pH range for growth is 7.7–10.3, with an optimum at pH 8.0–8.4.

High levels of Na₂CO₃ + NaHCO₃ are required. Moderately thermophilic with optimum growth at 36–55°C; capable of growing up to 60°C. The doubling time under optimal conditions is 2.5h. Strictly anaerobic. Ferments carbohydrates with production of acetate, ethanol, formate, H₂, and CO₂. Grows on a range of carbohydrates including glucose, fructose, sucrose, maltose, starch, glycogen, and *N*-acetyl-D-glucosamine. No growth on other hexoses, pentoses, disaccharides, sugar alcohols, or cellulose. Elemental sulfur is used as electron acceptor without energy generation.

Genus V. **Natroniella** Zhilina, Zavarzin, Detkova and Rainey 1996a, 1189^{VP} (Effective publication: Zhilina, Zavarzin, Detkova and Rainey 1996b, 324.)

GEORGE A. ZAVARZIN AND TATJANA N. ZHILINA

Na.tro.ni'el.la. Gr. n. *natron*, derived from Ar. *natrun* soda (sodium carbonate); N.L. fem. n. *Natroniella* organism growing in soda deposits.

Cells are rods, flexible, motile by peritrichous flagella. Spores may be formed. Cell wall has Gram-stain-negative structure. Strictly anaerobic. Possess a respiratory type of homoacetogenic metabolism. Extremely alkaliphilic, developing in soda brines at pH 9–10. **Halophilic,** growing at 1.7–4.4 M NaCl. **Obligately dependent on Na⁺, Cl⁻, and CO₃²⁻ ions.** Mesophilic. **Chemo-organotrophic;** some organic acids, amino acids, and alcohols are fermented. **Acetate is the product of fermentation.**

DNA G+C content (mol%): 32 (T_m).

Type species: Natroniella acetigena Zhilina, Zavarzin, Detkova and Rainey 1996a, 1189^{VP} (Effective publication: Zhilina, Zavarzin, Detkova and Rainey 1996b, 324.).

Further descriptive information

On the basis of 16S rRNA gene sequence analysis, *Natroniella* belongs to the main spore-forming branch of the order *Haloanaerobiales* Rainey and Zhilina (Rainey et al., 1995a), emended to *Halanaerobiales* by Oren (2000), family *Halobacteroidaceae* Zhilina and Rainey (Rainey et al., 1995a; Zhilina et al., 1996b). The genus is monospecific, with *Natroniella acetigena* as the type species. Information regarding the species is given in the species description.

Enrichment and isolation procedures

Natroniella acetigena was isolated from the sediment of a lagoon of Lake Magadi, Kenya, during the dry period from brine with a heavy bacterial population under the trona (Na₂CO₃·NaHCO₃·2H₂O) cover. A pure culture was obtained by anaerobic enrichment culture and by serial dilution in selective liquid medium I (Zhilina and Zavarzin, 1994) containing 2 M Na⁺ (1 M sodium carbonate and 1 M sodium chloride) with lactate (0.5%) as the substrate, incubated at 37 °C under N₂. The composition of the medium after its optimization is given by Zhilina et al. (1996b).

List of species of the genus *Natroniella*

1. ***Natroniella acetigena*** Zhilina, Zavarzin, Detkova and Rainey 1996a, 1189^{VP} (Effective publication: Zhilina, Zavarzin, Detkova and Rainey 1996b, 324.)

a.ce.ti'ge.na. L. neut. n. *acetum* acetic acid; N.L. fem. *gena* from N.L. fem. suff. *gena* producing; N.L. fem. adj. *acetigena* producing acetic acid.

Cells are large rods with rounded ends 1–1.2 by 6–15 μm. Motile by means of peritrichous flagella. Unequal fission leads to variation in length of cells with formation of filaments. Cell wall has Gram-stain-negative structure (Figure 241). Cell wall flexibility is characteristic of haloanaerobes. Spore formation is rare; when formed, spores are round and located at the end of non-swollen cells. In pure cultures, rapid and complete lysis is characteristic of the type strain.

Halophilic; growth occurs in highly alkaline NaCl/soda brines at salinities of 1.7–4.4 M with the optimum at 2–2.5 M

Maintenance procedures

Maintenance presents difficulties due to the rapid and complete lysis of non-actively metabolizing cells. Cultures in early exponential phase may be stored in a refrigerator, temperature 2–6 °C, for 3–4 months or, alternatively, strains can be subcultured at weekly intervals. Cultures can be preserved in liquid nitrogen.

Differentiation of the genus of *Natroniella* from other genera

The genus *Natroniella* can be differentiated from other genera of the *Halobacteroidaceae* including *Halobacteroides*, *Halanaerobacter*, *Orenia*, *Sporohalobacter* (Oren, 2000; Rainey et al., 1995a), and *Halonatronum* (Zhilina et al., 2001b) by its type of homoacetogenic metabolism and its inability to utilize sugars. In common with some of these genera, it exhibits extreme alkaliphily (pH 9–10) and obligate dependence on Na₂CO₃ + NaHCO₃ at high concentrations. It differs from the halophilic and homoacetogenic genus *Acetohalobium* by its inability to grow in the absence of high alkalinity and by the substrates utilized.

Taxonomic comments

The generic status *Natroniella* is based on 16S rRNA gene sequence data. It represents a distinct lineage within the family *Halobacteroidaceae* with sequence similarities in the range 86.8–90.5% to the other taxa. Its closest neighbor is *Orenia marismortui* (90.5% sequence similarity) (Zhilina et al., 1996b).

Cellular lipids contain aliphatic fatty acids and β-hydroxy acids characteristic of Gram-stain-negative eubacteria. However, the unusual combination of hydroxyacids and palmitoleic aldehydes found in *Natroniella* has, until now, been found only among Gram-stain-positive bacteria. The major fatty acids present in the type strain are C_{14:0}, C_{16:1 ω7}, and C_{16:0}, which contribute about 67% of total fatty acids. The major (about 18%) aldehyde is C_{16:1 ω7}, with C₁₆ and C_{18:1 ω9} as minor components (Zhilina et al., 1998). These lipid profiles suggest that *Natroniella* represents a separate taxon.

total salinity. Obligately dependent on Na⁺, Cl⁻, and CO₃²⁻ ions. Alkaliphilic; grows at pH 8.1–10.7, optimum at pH 9.7–10.0. Mesophilic. Growth temperature optimum at 37 °C and maximum growth temperature of 42 °C.

Chemo-organotrophic, obligate anaerobe that ferments a very limited number of substrates to acetic acid. Only lactate, pyruvate, glutamate, ethanol, and propanol are utilized. When growing on propanol, propionate is produced in addition to acetate. Yeast extract and vitamins stimulate growth. Non-cyclic homoacetogenic acetyl-CoA pathway is used for CO₂ fixation and high CO-dehydrogenase activity is present in cell extracts. Enzyme activity increases fourfold upon an increase in pH from 7.0 to 9.0 and is independent of the presence of sodium chloride and sodium bicarbonate ions. Rhodamine (3 μM) inhibits ATP synthesis and the addition of 100 μM monensin results in rapid lysis of the

FIGURE 241. Morphology of *Natroniella acetigena*. (A) Light microscopy; bar = 10 μm . (B) Electron microscopy; longitudinal and cross sections demonstrating Gram-negative type of cell-wall structure; bar = 1 μm .

cells, indicating inhibition of Na^+/H^+ antiport; Na^+ ions enter the cells causing death. ATP synthesis in *Natroniella* occurs in response to an artificial proton gradient upon addition of H^+ ions (Pushева et al., 1999a, 1999b, 2000). *Natroniella* may be considered as a halophile that has adapted to an alkaline environment. *Natroniella acetigena* is a peculiar organism, not only as an extremophile growing at high salinity and pH, but also as a member of alkaliphilic communities because of its

very restricted trophic needs that are oriented toward lactate and ethanol, the products of primary anaerobes, e.g., alkaliphilic spirochetes from the same Lake Magadi (Zavarzin and Zhilina, 2000; Zavarzin et al., 1999; Zhilina et al., 1996c).

Genus VI. **Orenia** Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995b, 880^{VP} (Effective publication: Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995a, 197.)

FRED A. RAINEY

O.re'ni.a. N.L. fem. n. *Orenia* named after Aharon Oren, an Israeli microbiologist.

Gram negative. Rods, 2.5–13 μm in length with round ends. Motile by peritrichous flagella. **Spores** are round, terminal or subterminal. Gas vacuoles detected in some species. Forms sphaeroplasts. **Strictly anaerobic.** Catalase- and oxidase-negative. **Halophilic;** optimum NaCl concentration for growth ranges 3–12%; no growth below 2% or above 25%. Mesophilic to slightly thermophilic. Optimum temperature range for growth 36–45 $^{\circ}\text{C}$, maximum below 52 $^{\circ}\text{C}$, minimum 25 $^{\circ}\text{C}$. **Chemooorganotrophic.** End products of glucose fermentation include H_2 , CO_2 , formate, lactate, acetate, butyrate, and ethanol.

DNA G + C content (mol%): 28.6–33.7.

Type species: **Orenia marismortui** (Oren, Pohla and Stackebrandt 1987) Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995b, 880^{VP} (Effective publication: Rainey, Zhilina,

Boulygina, Stackebrandt, Tourova and Zavarzin 1995a, 197.) (*Sporohalobacter marismortui* Oren, Pohla and Stackebrandt 1987, 245).

The description of the genus *Orenia* presented here is based on data published by Oren et al. (1987), Bhupathiraju et al. (1994), Zhilina et al., (1999), and Mouné et al. (2000).

Further descriptive information

The genus *Orenia* contains three species: *Orenia marismortui* (Oren et al., 1987; Rainey et al., 1995a), *Orenia sivashensis* (Zhilina et al., 1999), and *Orenia salinaria* (Mouné et al., 2000). Cells of the strains of this genus stain Gram negative and electron microscopy has revealed a typical Gram-negative cell wall structure. The cells are rod shaped, have rounded ends,

and range in diameter from 0.5–0.75 µm and in length from 2.5–13 µm. Zhilina et al. (1999) indicated that cells of *Orenia sivashensis* increase in diameter to 0.7–2.5 µm during spore formation. Endospores are formed by all species of this genus. In the case of *Orenia marismortui*, endospore formation is not observed when grown on standard growth medium, but spores are seen occasionally when grown on solidified medium. Cultures transferred to standard medium in which the yeast extract has been replaced with NH₄Cl (1 g/l) and L-leucine (1 g/l) sporulate within 2–3 d (Oren et al., 1987). *Orenia sivashensis* forms endospores when grown on solidified medium or when transferred from glucose to a glycogen containing medium (Zhilina et al., 1999). Gas vacuoles have been observed in *Orenia sivashensis* but not in *Orenia marismortui* or *Orenia salinaria*. Sphaeroplasts have been observed in all species of this genus forming both during the active growth phase in the case of *Orenia sivashensis* (Zhilina et al., 1999) and at the end of the exponential phase of growth for all three species (Mouné et al., 2000; Zhilina et al., 1999). Colony descriptions are available for *Orenia sivashensis* and *Orenia salinaria* but not for *Orenia marismortui*. Agar surface colonies of *Orenia sivashensis* are slightly elevated, white, even margined, slightly granular, and 5 mm in diameter after 4 d incubation; colonies in agar are lenticular (Zhilina et al., 1999). Colonies of *Orenia salinaria* are opaque in agar deeps and glossy on the surface of agar plates; they are 1–2 mm in diameter with entire margins and white to slightly yellow coloration (Mouné et al., 2000).

The species of the genus *Orenia* are moderate but obligate halophiles. *Orenia marismortui* grows at NaCl concentration of 0.5–3.0 M (~3–18%) and optimally at 0.5–2.0 M (~3–12%); no growth is observed below 0.5 M or above 3.0 M; at concentrations below 0.25 M (~1.5%) cell lysis occurs (Oren et al., 1987). Media containing 5–25% NaCl supports growth of *Orenia sivashensis* with optimal growth observed at 7–10%; cells lyse at NaCl concentrations of less than 5% (Zhilina et al., 1999). NaCl concentrations between 2 and 30% support the growth of *Orenia salinaria* as indicated in the main text of Mouné et al., (2000) or 2–25% as indicated in the actually species description of *Orenia salinaria* (Mouné et al., 2000). Cells of SG 3902^T at NaCl concentrations below 5% and above 10% are distorted and irregu-

lar, becoming elongated and rapidly forming sphaeroplasts at a concentration 2% NaCl (Mouné et al., 2000). On the basis of the temperature ranges for growth and optimal temperature ranges for growth, strains of the *Orenia* species fall at the upper end of the mesophilic range and could be considered moderately thermophilic (Zhilina et al., 1999). *Orenia marismortui* and *Orenia sivashensis* grow in the range 25–50 °C while *Orenia salinaria* grows between 10 and 50 °C. Optimal temperature ranges for growth are 36–45 °C for *Orenia marismortui* and 40–45 °C for both *Orenia sivashensis* and *Orenia salinaria*. The pH range and optima for growth have been determined for *Orenia sivashensis* and *Orenia salinaria* but not for *Orenia marismortui*. The former species have pH ranges for growth of 5.5–7.8 and 5.5–8.5, respectively. The optimal pH range for growth of *Orenia sivashensis* is 6.3–6.6 (Zhilina et al., 1999) and that of *Orenia salinaria* is in the range 7.2–7.4 (Mouné et al., 2000). Although the optimal pH for growth of *Orenia marismortui* was not recorded, it was routinely grown in medium at a pH 6.5 (Oren et al., 1987).

All species of the genus are obligate anaerobes; their relationship to oxygen has been tested in different ways for each species. *Orenia marismortui* is unable to grow in aerated medium; its sensitivity to oxygen is low with some growth in test tube cultures open to the air but containing a reducing agent. When cysteine is not included in the medium or cultures are shaken in cotton plugged flasks, no growth is observed (Oren et al., 1987). Reduced medium with a cotton plug or in a Hungate tube to which air has been added do not support growth of *Orenia sivashensis* (Zhilina et al., 1999). Mouné et al. (2000) indicate that *Orenia salinaria* does not grow in the presence of oxygen when the reducing agent is absent and tubes are open to the air or plugged with cotton-wool stoppers. The species of the genus *Orenia* are chemoorganotrophic with fermentative metabolism. Differences are observed in the substrate utilization patterns of the three species of the genus *Orenia*. These are given in Table 243, and the complete list of substrates utilized or not utilized is provided in the species descriptions below. Unfortunately, a fully comparable dataset for carbon and energy sources is not available due to incomplete datasets presented in the papers describing the species of the genus (Mouné et al., 2000; Oren et al., 1987; Zhilina et al., 1999).

^bData obtained from Oren et al. (1987), Zhilina et al. (1999), and Mouné et al. (2000).

The end products from the fermentation of glucose for all species of the genus include acetate, ethanol, formate, CO₂, and H₂. In addition, *Orenia marismortui* and *Orenia sivashensis* produce butyrate and *Orenia salinaria* produces lactate. *Orenia sivashensis* cannot reduce thiosulfate, but it does reduce elemental sulfur with the formation of H₂S, although growth was not stimulated by the addition of S⁰ (Zhilina et al., 1999). The species *Orenia marismortui* produces small amounts of sulfide, the production of which was stimulated by the addition of thiosulfate but not by the addition of sulfate (Oren et al., 1987). Sulfide concentrations up to 20 mM are tolerated by *Orenia salinaria*, but sulfur containing compounds are not reduced (Mouné et al., 2000). Interestingly, *Orenia salinaria* does not use nitrate or cysteine as a nitrogen source but can utilize and sustain growth on dinitrogen and ammonia in media lacking other sources of nitrogen (Mouné et al., 2000).

DNA G + C content (mol%): 28.6–33.7.

Enrichment, isolation and growth conditions

The species of the genus *Orenia* have been isolated from saline environments. In the case of *Orenia marismortui*, it was isolated from anaerobic black sediment collected from a salt flat on the Western shore of the Dead Sea near Masada, Israel (Oren et al., 1987). The Dead Sea mud samples were inoculated into medium that had been designed for the isolation of sulfate reducing bacteria. The medium contained (g/l): NaCl, 125; MgCl₂·6H₂O, 50; MgSO₄·7H₂O, 1.0; CaSO₄·2H₂O, 0.5; K₂HPO₄, 1.0; NH₄Cl, 1.0; FeSO₄·7H₂O, 0.1; Na-lactate, 2.0; Na-thioglycolate, 1.0; yeast extract, 0.5, pH 7–7.2 (Oren et al., 1987). The enrichment cultures were set up in completely filled 150 ml stoppered bottles. The resulting enriched cultures were transferred several times before being streaked on plates of the same medium containing 2% agar and 0.5% CaCO₃ and incubated at 37 °C (Oren et al., 1987). *Orenia sivashensis* was isolated from a cyanobacterial mat that had anaerobic mud under it collected from the saline lagoons of Lake Sivash, the Crimea (Zhilina et al., 1999). The enrichment culture was established by inoculating 2 g of cyanobacterial mat into 50 ml of bicarbonate medium containing 150 g/l NaCl and 2.5 g/l peptone; after 4 d of incubation, the enrichment culture was pasteurized at 75 °C for 30 min and used to inoculate a fresh culture in the same medium with glucose (5 g/l) and yeast extract (0.5 g/l) added. A pure culture was isolated after a second pasteurization step at 80 °C for 2 h and subsequent dilution and colony selection on solidified medium (Zhilina et al., 1999). Black anoxic sediment from below the gypsum and halite crust of hypersaline (20–34% total salinity) ponds in the Salin-de-Giraud, Camargue, France was used as an inoculum for the isolation of *Orenia*

salinaria (Mouné et al., 2000). The enrichment medium used for the isolation of *Orenia salinaria* contained (g/l): NaCl, 150; MgCl₂·6H₂O, 15; KCl, 3; NH₄Cl, 0.5; KH₂PO₄, 0.33; CaCl₂·H₂O, 0.05; yeast extract, 0.1; 0.01% resazurin solution, 1 ml; trace-element solution SL12 (Overmann et al., 1992), 1 ml; selenite/tungstate solution (Na₂SeO₃·H₂O, 6 mg/l; NaWO₄·2H₂O, 8 mg/l; NaOH, 0.4 g/l), 1 ml; NaHCO₃, 2 g; NaS·9H₂O, 0.5 g; vitamin solution V7 (Pfennig and Trüper, 1981), 1 ml; pH 7.2–7.4. The medium was prepared under a headspace of N₂/CO₂ (90:10). Strain SG 3902^T was obtained in pure culture using agar deeps with glucose as the substrate and incubation at 30 °C in the dark (Mouné et al., 2000).

Taxonomic comments

Orenia marismortui was originally described as *Sporohalobacter marismortui* due to its spore formation and some indication of a relationship to *Sporohalobacter lortetii* based on oligonucleotide catalogues (Oren et al., 1987). Subsequent phylogenetic analysis of the halophilic anaerobes demonstrated that *Sporohalobacter marismortui* and *Sporohalobacter lortetii* were not closely related, sharing only 88% 16S rRNA gene sequence similarity. On the basis of the phylogenetic position and lack of gas vesicle formation in *Sporohalobacter marismortui* as compared to *Sporohalobacter lortetii*, the genus *Orenia* was established with *Orenia marismortui* as the type and only species of the new genus (Rainey et al., 1995b, 1995a). Subsequently, two species *Orenia sivashensis* and *Orenia salinaria* were added to the genus (Mouné et al., 2000; Zhilina et al., 1999). The genus comprises a phylogenetic coherent cluster within the family *Halobacteroidaceae* (Rainey et al., 1995b, 1995a; Zhilina and Rainey, 1995) supported by a 100% bootstrap value (Figure 242). 16S rRNA gene sequence similarities between the species of the genus *Orenia* are in the range 93.6–94.5 with similarities of <92% to the related species *Halobacteroides halobius* (91–92%) and *Natroniella acetigena* (89.6–90.2). In addition to the <97% 16S rRNA gene sequence similarity between *Orenia marismortui* and *Orenia sivashensis*, the distinct species status of these two species was demonstrated by DNA–DNA hybridization studies in which a reassociation value of 44% was determined (Zhilina et al., 1999). In addition, phenotypic differences in substrate utilization and NaCl requirements further differentiate these species. *Orenia salinaria* was described after the publication of *Orenia sivashensis* and no direct comparison of these two species has been made in the literature. *Orenia salinaria* and *Orenia sivashensis* share only 93.6% 16S rRNA gene sequence similarity and differ in a number of phenotypic characteristics including gas vesicle formation, lower NaCl requirements for growth, substrate utilization patterns, and the mol% G + C content of their DNA (Table 243).

List of species of the genus *Orenia*

1. ***Orenia marismortui*** (Oren, Pohla and Stackebrandt 1987) Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin, 1995b, 880^{VP} (Effective publication: Rainey, Zhilina, Boulygina, Stackebrandt, Tourova and Zavarzin 1995a, 197.) (*Sporohalobacter marismortui* Oren, Pohla and Stackebrandt 1987, 245) ma.ris.mor'tu.i. L. gen. n. *maris* of the sea; L. adj. *mortuus* dead; N.L. gen. n. *marismortui* of the Dead Sea.

Gram negative. Rods with rounded ends, 0.6 μm in diameter and 3–13 μm in length. Motile by means of peritrichous flagella. Endospores formed. Gas vacuoles not detected. Sphaeroplasts are formed. Moderately halophilic; optimum NaCl concentration for growth ranges between 3 and 12%. No growth occurs below 3% or above 18% NaCl. The optimum temperature for growth is between 36 and 45 °C in the range

FIGURE 242. 16S rRNA based phylogeny of the order *Halanaerobiales*. The tree was constructed from distance matrices using the neighbor-joining method. The scale bar represents 2 nucleotide substitutions per 100 nucleotides.

25–50 °C. Major fatty acids include $C_{14:0}$, $C_{16:0}$, $C_{16:1}$, and $C_{18:0}$; minor compounds are C_{12} , $C_{14:0}$, and $C_{18:1}$. Carbon sources utilized include: D-glucose, D-mannose, D-maltose, D-ribose, sucrose, D-fructose, starch, and glycogen. Substrates not utilized include D-cellobiose, N-acetylglucosamine, pyruvate, Casamino acids, L-arginine, and L-glutamate. End products of glucose fermentation include H_2 , CO_2 , formate, acetate, butyrate, and ethanol. Isolated from Dead Sea sediment.

DNA G+C content (mol%): 29.6 (T_m).

Type strain: DY-1, ATCC 35420, DSM 5156.

GenBank accession number (16S rRNA gene): X89073.

2. **Orenia salinaria** Mouné, Eatock, Matheron, Willison, Hirschler, Herbert and Caumette 2000, 728^{VP}
sa.li.na'ria. L. adj. *salinaria* pertaining to *salinae* salterns, saltworks.

Gram negative. Rods with rounded ends, 1.0 μ m in diameter and 6–10 μ m in length. Motile by means of peritrichous flagella. Endospores formed and are spherical and subterminal in old cultures. Large degenerate cells and sphaeroplasts are observed in old cultures. Surface colonies are 1–2 mm in diameter, circular, translucent, glossy, and are white to slightly yellow with entire edges. Obligately halophilic, optimum NaCl concentration for growth ranges between 5 and 10%. No growth occurs below 2% or above 25% NaCl. The cells accumulate glycine-betaine. The optimum temperature for growth is between 40 and 45 °C in the range 10–50 °C. The pH range is 5.5–8.5, with an optimum at pH 7.2–7.4. Cells are susceptible to chloramphenicol, erythromycin, and tetracycline and resistant to anisomycin, kanamycin, and Na-taurocholate. Fermentative metabolism. Glucose, fructose, trehalose, sucrose, maltose, cellobiose, and mannitol are fermented. D-Mannose, starch, glycogen, pyruvate, Casamino acids, and L-glutamate are not utilized. The major products of glucose fermentation are ethanol,

formate, acetate, lactate, CO_2 , and H_2 . Growth occurs with N_2 as the sole nitrogen source. Isolated from sediment of salt ponds in the salterns of Salin-de-Giraud (Camargue, France).

DNA G+C content (mol%): 33.7 (HPLC).

Type strain: SG 3902, ATCC 700911.

GenBank accession number (16S rRNA gene): Y18485.

3. **Orenia sivashensis** Zhilina, Tourova, Kuznetsov, Kostrikina and Lysenko 2000, 3^{VP} (Effective publication: Zhilina, Tourova, Kuznetsov, Kostrikina and Lysenko 1999, 456.)
si.va.shen'sis. N.L. gen. n. *sivashensis* inhabiting Lake Sivash.

Gram negative. Rods with rounded ends, 0.5–0.75 μ m in diameter and 2.5–10 μ m in length; single, paired, or in short chains and filaments. Motile by means of peritrichous flagellation. Sporeforming. The spores are thermostable, round, terminal. Gas vacuoles are present in the cells and on mature spores. The colonies are white, 0.5 mm in diameter, lenticular with an even margin. Obligately anaerobic. Chemoorganotrophic. The substrates utilized include D-glucose, D-mannose, mannitol, D-maltose, sucrose, L-sorbitol, trehalose, D-cellobiose, D-ribose, starch, glycogen, N-acetylglucosamine, pyruvate, citrate, ascorbate, yeast extract, Casamino acids, L-arginine, L-glutamate, and DL-lysine. Yeast extract is necessary for growth on carbohydrates. Obligately halophilic; optimum NaCl concentration for growth ranges between 7 and 10% in the range 5–25%. The optimal temperature for growth is 40–45 °C, in the growth temperature range 25–50 °C. The range of growth pH is 5.5–7.8, with an optimum pH at 6.3–6.6. The habitat is sea lagoons with variable salinity, up to halite deposition. Isolated from a cyanobacterial mat of Lake Sivash lagoons (the Crimea).

DNA G + C content (mol%): 28.6 (T_m).

Type strain: Z-7191, DSM 12596.

GenBank accession number (16S rRNA gene): AF152595.

Genus VII. **Selenihalanaerobacter** Switzer Blum, Stolz, Oren and Oremland 2001b, 1229^{VP} (Effective publication: Switzer Blum, Stolz, Oren and Oremland 2001a, 217.)

AHARON OREN, RONALD S. OREMLAND AND JOHN F. STOLZ

Se.le.ni.hal.an.ae.ro.bac'ter. Gr. n. *selene* moon; N.L. n. *selenium* element 34; Gr. n. *hals*, *halos* salt; Gr. pref. *an* not; Gr. n. *aer* air; N.L. masc. n. *bacter* the masc. equivalent of Gr. neut. n. *baktron* a staff or rod; N.L. masc. n. *Selenihalanaerobacter* the salty anaerobic selenium rod.

Gram-stain-negative, rod-shaped cells, non-motile. Halophilic, growing optimally at 3.6M NaCl and requiring a minimum of 1.7M NaCl for growth. Temperature optimum about 38 °C. **Strictly anaerobic**. Grow by anaerobic respiration on organic electron donors, using selenate and other electron acceptors. Fermentative growth not observed. **Endospores not produced**.

DNA G+C content (mol%): 31.2 (HPLC).

Type species: Selenihalanaerobacter shriftii Switzer Blum, Stolz, Oren and Oremland 2001b, 1229^{VP} (Effective publication: Switzer Blum, Stolz, Oren and Oremland 2001a, 217.).

Further descriptive information

The genus contains a single species, *Selenihalanaerobacter shriftii*. This bacterium was isolated from sediments of the Dead Sea from an anaerobic enrichment culture that contained diluted Dead Sea water, glycerol, and selenate (Switzer Blum et al., 2001a).

Phylogenetically, *Selenihalanaerobacter* can unequivocally be classified within the order *Halanaerobiales*, family *Halobacteroidaceae*. However, its physiology is very different from that of the other known representatives of the order. No fermentative or homoacetogenic metabolism has been demonstrated in the genus and its only mode of energy generation appears to be anaerobic respiration. Selenate, nitrate, and trimethylamine N-oxide are the only suitable electron acceptors and the range of electron donors supporting growth of the single described species is limited. Of a wide range of compounds tested, glycerol and glucose were the only compounds capable of serving as an energy source. Both are partially oxidized to acetate + CO₂, while selenate is reduced to a mixture of selenite and elemental selenium. In accordance with its respiratory mode of metabolism, *Selenihalanaerobacter shriftii* contains cytochromes and *Selenihalanaerobacter* is thereby the only genus within the *Halanaerobiales* with a representative in which the presence of cytochromes has been detected thus far.

Enrichment and isolation procedures

The single isolate of the only recognized species within the genus was isolated from a sediment sample collected from a depth of 18m from the Dead Sea, Israel. It was obtained from an anaerobic enrichment culture containing Dead Sea water diluted to 75% of its original salinity and amended with glycerol, selenate, and cysteine as a reducing agent. Formation of an orange-red precipitate of elemental selenium can be used as evidence for growth. The organism can then be isolated by streaking on agar plates containing NaCl (3M), other salts, glycerol or glucose, selenate, yeast extract, and cysteine, followed by incubation under nitrogen. Strictly anaerobic techniques should be used, including boiling the media under nitrogen and adding cysteine as reducing agent to the boiled media. The composition of the medium for growth of *Selenihalanaerobacter shriftii* is given by Switzer Blum et al. (2001a).

Although nitrate and trimethylamine N-oxide are suitable electron acceptors for the growth of *Selenihalanaerobacter shriftii*, use of these oxidants in the enrichment medium instead of selenate is not to be recommended as facultatively anaerobic halophilic *Bacteria* or *Archaea* that can use these electron acceptors may outcompete the relatively slowly growing *Selenihalanaerobacter*.

Maintenance procedures

Selenihalanaerobacter cultures can be maintained by freezing in liquid nitrogen or by lyophilization.

Taxonomic comments

Analysis of the 16S rRNA gene sequence of the single species classified within the genus showed it to be most closely related to *Acetohalobium arabaticum* (90% sequence similarity) and *Sporohalobacter lortetii* (Switzer Blum et al., 2001a).

List of species of the genus *Selenihalanaerobacter*

1. ***Selenihalanaerobacter shriftii*** Switzer Blum, Stolz, Oren and Oremland 2001b, 1229^{VP} (Effective publication: Switzer Blum, Stolz, Oren and Oremland 2001a, 217.)

shrif'ti.i. N.L. gen. n. *shriftii* of Shrift, named after Alex Shrift, an American microbiologist.

Cells are rod-shaped, 0.6 × 2–6 μm in size. Non-motile. Halophilic, requiring 1.7–4.1M NaCl for growth, and growing optimally at 3.6M NaCl. Temperature range for growth: 16–42 °C. Optimum temperature: 38 °C. Strictly anaerobic. Oxidizes glycerol and glucose to acetate + CO₂ while reducing selenate to selenite and elemental selenium.

Also uses nitrate and trimethylamine N-oxide as electron acceptors. Nitrite, arsenate, fumarate, dimethylsulfoxide, thiosulfate, elemental sulfur, sulfite, and sulfate do not serve as electron acceptors. No growth is observed on short-chain fatty acids, alcohols, amino acids, formate, lactate, pyruvate, or other organic acids. Fermentative growth is not observed.

Source: sediments of the Dead Sea, Israel.

DNA G+C content (mol%): 31.2 (HPLC).

Type strain: DSSe-1, ATCC BAA-73.

GenBank accession number (16S rRNA gene): AF310247.

Genus VIII. **Sporohalobacter** Oren, Pohla and Stackebrandt 1988, 136^{VP} (Effective publication: Oren, Pohla and Stackebrandt 1987, 245.)

AHARON OREN

Spo.ro.ha.lo.bac'ter. Gr. n. *spora* seed; Gr. n. *hals*, *halos* salt; N.L. masc. n. *bacter* the masc. equivalent of Gr. neut. n. *baktron* a staff or rod; N.L. masc. n. *Sporohalobacter* spore-producing salt rod.

Gram-stain-negative, rod-shaped cells, motile by peritrichous flagella. Halophilic, growing optimally at 1.4–1.5 M NaCl and requiring a minimum of 0.7 M NaCl for growth. Temperature optimum about 40 °C. **Strictly anaerobic**. Ferments amino acids with production of acetate, propionate and other acids, H₂, and CO₂. Sugars poorly used. **Endospores produced**. Gas vesicles are attached to the endospores in the single species described.

DNA G+C content (mol%): 31.5 (Bd).

Type species: Sporohalobacter lortetii (Oren 1983) Oren, Pohla and Stackebrandt 1988, 136^{VP} (Effective publication: Oren, Pohla and Stackebrandt 1987, 245.) (*Clostridium lortetii* Oren 1983, 47).

Further descriptive information

The genus contains one species, namely *Sporohalobacter lortetii*. This bacterium was isolated from sediments of the Dead Sea from an anaerobic enrichment culture that contained lactate and yeast extract as carbon sources. On solid media, endospores are produced. Sporulating cells are terminally swollen. Adjacent to the endospores, gas vesicles are produced and these remain attached to the mature endospores after degeneration of the cells, possibly to enable dispersion of the endospores.

The metabolism of *Sporohalobacter* has not been characterized in depth. Amino acids appear to be the preferred substrate for fermentation. Glucose added to the medium was utilized only after other, more easily fermentable substrates, were exhausted (Oren, 1983).

Enrichment and isolation procedures

The single isolate of the only recognized species within the genus was isolated from a sediment sample collected from a depth of 60 m from the Dead Sea, Israel. It was obtained from an anaerobic enrichment culture containing Dead Sea water diluted to 80% of its original salinity, supplemented with lactate and yeast extract, and with thioglycollate and ascorbate as reducing agents, followed

by serial dilution in agar tubes containing similar medium with 70% Dead Sea water and FeSO₄ (Oren, 1983).

The production of heat-resistant endospores may enable the development of a more selective enrichment procedure for *Sporohalobacter*, based on negative selection by pasteurization of the inoculum. However, such a strategy may also yield other endospore-forming halophilic anaerobic genera such as *Halobacteroides* (Oren et al., 1987), *Orenia*, and possibly others. Successful isolation of *Sporohalobacter* using such a negative selection procedure has not yet been reported.

Strictly anaerobic techniques should be used, including boiling the media under nitrogen or nitrogen/CO₂ (80:20) and adding cysteine as a reducing agent to the boiled media. The composition of the medium for growth of *Sporohalobacter lortetii* can be found in Oren (1983, 2006).

Maintenance procedures

The most reliable way to maintain cultures is by lyophilization; they are maintained thus by culture collections. No data on the long-term viability of the mature endospores are yet available.

Taxonomic comments

The single species classified within the genus was originally described as *Clostridium lortetii* (Oren, 1983, 1984). After it became obvious that the isolate was not closely related phylogenetically to members of the genus *Clostridium*, the isolate was transferred to the genus *Sporohalobacter*, which was newly created to accommodate endospore-forming members of the family *Halobacteroidaceae* (Oren et al., 1987). *Sporohalobacter marismortui*, the second species at that time classified within the genus *Sporohalobacter* (Oren et al., 1987, 1988), has been transferred to the new genus *Orenia* as *Orenia marismortui* comb. nov. on the basis of 16S rRNA gene sequence data (Rainey et al., 1995a).

List of species of the genus *Sporohalobacter*

1. ***Sporohalobacter lortetii*** (Oren 1983) Oren, Pohla and Stackebrandt 1988, 136^{VP} (Effective publication: Oren, Pohla and Stackebrandt 1987, 245.) (*Clostridium lortetii* Oren 1983, 47)

lor.tet'i.i. N.L. gen. n. *lortetii* of Lortet, named after M.L. Lortet, a French microbiologist.

Cells are rod-shaped, 0.5–0.6 × 2.5–10 μm in size. Motile by peritrichous flagella. Halophilic, requiring 0.7–2.6 M NaCl for growth and growing optimally at 1.4–1.5 M NaCl. Temperature range for growth: 25–52 °C. Optimum temperature: 37–45 °C. Strictly anaerobic. Ferments amino acids with

production of acetate, propionate, isobutyrate, isovalerate, H₂, and CO₂ in medium containing L-glutamic acid, Casamino acids, yeast extract, and nutrient broth. Certain sugars (fructose, D-glucose, maltose, starch, and sucrose) stimulate growth. No growth stimulation by cellobiose, galactose, lactose, or mannose. Endospores produced in terminally swollen cells. Gas vesicles are attached to the endospores. The major fatty acids in the lipids are C_{16:0} and C_{16:1}.

Source: sediments of the Dead Sea, Israel.

DNA G+C content (mol%): 31.5 (Bd).

Type strain: MD-2, ATCC 35059, DSM 3070.

GenBank accession number (16S rRNA gene): M59122.

Order III. Thermoanaerobacterales ord. nov.

JUERGEN WIEGEL

Ther.mo.an.ae.ro.bac.ter.a'les. N.L. masc. n. *Thermoanaerobacter* type genus of the order; -ales ending to denote an order; N.L. fem. n. *Thermoanaerobacterales* the order *Thermoanaerobacter*.

The order presently consists of the families *Thermoanaerobacteraceae* and *Thermodesulfobiaceae*, plus two families *incertae sedis*.

Type genus: Thermoanaerobacter Wiegel and Ljungdahl 1982, 384^{VP} emend. Lee, Dashti, Prange, Rainey, Rohde, Whitman and Wiegel 2007, 1433 (Effective publication: Wiegel and Ljungdahl 1981, 348.).

References

Taxonomic comment

Presently, there is some uncertainty whether the members of this order belong to the phylum *Firmicutes* and class *Clostridia* or whether they should constitute a separate novel phylum (Ludwig and Schleifer, personal communication).

Family I. *Thermoanaerobacteraceae* fam. nov.

JUERGEN WIEGEL

Ther.mo.an.ae.ro.bac.ter.a'ce.ae. N.L. masc. n. *Thermoanaerobacter* type genus of the family; -aceae ending to denote family; N.L. fem. n. *Thermoanaerobacteraceae* the *Thermoanaerobacter* family.

The family presently contains eight genera of thermophilic anaerobic species, mainly heterotrophic; however, some are able to grow chemolithoautotrophically (e.g., members of the genus *Moorella*). As of August 2007, the recognized genera of this family are *Thermoanaerobacter*, *Ammonifex*, *Caldanaerobacter*, *Carboxydotherrmus*, *Gelria*, *Moorella*, *Thermacetogenium*, and *Thermanaeromonas*.

The type species of the genera *Thermoanaerobium* (*sic*) and *Thermobacteroides* (*sic*) have been transferred to the genus *Thermoanaerobacter*.

Type genus: Thermoanaerobacter Wiegel and Ljungdahl 1982, 384^{VP} emend. Lee, Dashti, Prange, Rainey, Rohde, Whitman and Wiegel 2007a, 1433 (Effective publication: Wiegel and Ljungdahl 1981, 348.).

Genus I. *Thermoanaerobacter* Wiegel and Ljungdahl 1982, 384^{VP} emend. Lee, Dashti, Prange, Rainey, Rohde, Whitman and Wiegel 2007a, 1433 (Effective publication: Wiegel and Ljungdahl 1981, 348.)

ROB U. ONYENWOKE AND JUERGEN WIEGEL

Ther.mo.an.ae.ro.bac'ter. Gr. adj. *thermos* hot; Gr. pref. *an* not; Gr. n. *aer* air; M.L. *bacter* masc. equivalent of Gr. neut. dim. n. *bakterion* rod staff; N.L. masc. n. *Thermoanaerobacter* rod which grows in the absence of air at elevated temperatures.

All species are **obligately anaerobic thermophiles** and have a **Gram-positive cell wall**, i.e., although the **Gram-stain reaction varies** among the individual species and even within strains from the same species, they have a Gram-positive cell-wall structure. Most species exhibit a **sluggish motility** and a peritrichous arrangement of 2–6 flagella (retarded peritrichous flagellation). Cells are **rod shaped** and occur in various arrangements that vary by species. Many of the *Thermoanaerobacter* species form **pleomorphic cells** during the late exponential and stationary growth phases assembling through nonsymmetric cell division chains of alternating rod-shaped and coccoid cells. Other types of pleomorphic rods are formed, presumably through weakening of the cell wall by lysozyme-like enzymes that are the remnants of the sporulation process (**Figure 243**). Growth temperature optima range from 55–75 °C, with **growth ranges of 35–78 °C** and a **temperature span over 35 °C**. The pH for growth ranges from **pH^{25°C} 4.0–9.9**, with a pH optimum of 5.8–8.5. Several species also exhibit a wide pH optimum of about 3 units without a sharp peak. All species are able to grow **organoheterotrophically** using various fermentation pathways including the homoacetogenic or Wood–Ljungdahl pathway, or using inorganic electron acceptors (e.g., *Thermoanaerobacter sulfuriphilus* using S⁰ as an electron acceptor and lactate as an electron donor and carbon source). Some *Thermoanaerobacter* strains are also able to grow **chemolithoheterotrophically by coupling H₂ oxidation** to growth (Fardeau et al., 1994). Furthermore, others are **facultative chemolithoautotrophs**, growing with H₂ + CO₂ (such as *Thermoanaerobacter kivui*) or Fe(III) + H₂ + CO₂ (such as *Thermoanaerobacter siderophilus*). Generally, typical fermentation products from hexoses are ethanol, acetate, lactate, H₂, and CO₂.

DNA G+C content (mol%): 30–39.

Type species: Thermoanaerobacter ethanolicus Wiegel and Ljungdahl 1982, 384^{VP} (Effective publication: Wiegel and Ljungdahl 1981, 348.).

Further descriptive information

Biochemical analysis. Isoprenoid quinones, lipid fatty acids (PFLAs) and the cell-wall diaminopimelic acid isomers have been analyzed for a few species (Yamamoto et al., 1998). The menaquinone MK-7 has been found in the type strains of *Thermoanaerobacter brockii*, *Thermoanaerobacter thermohydrosulfuricus*, and *Thermoanaerobacter thermocopriae*. However, MK-7 is absent in the type strain of the type species, *Thermoanaerobacter ethanolicus* JW200. A similar variation in the presence of MK-7 is observed in the physiologically similar species of *Thermoanaerobacterium*. The main lipid fatty acids (PLFAs) observed in the above strains of *Thermoanaerobacter* (as well as in some strains of *Thermoanaerobacterium*) are C_{15:0 iso} (45–55%) and C_{17:0 iso} (20–25%). The cell walls from *Thermoanaerobacter thermohydrosulfuricus*, *Thermoanaerobacter brockii* subsp. *finnii* and *Thermoanaerobacter thermocopriae* contain *meso*-diaminopimelic acid (Yamamoto et al., 1998).

Endospores. Endospore formation has been observed for all species except *Thermoanaerobacter acetoethylicus*, *Thermoanaerobacter ethanolicus*, *Thermoanaerobacter kivui*, *Thermoanaerobacter mathranii* subsp. *alimentarius*, and *Thermoanaerobacter sulfurophilus*. However, the presence of the characteristic, spore-specific genes has been demonstrated for several species in which no spores have been observed. These species are regarded as asporogenic, meaning that most of the characteristic sporulation genes can be identified in the genome even though spores have not been observed. This distinguishes them from non-sporogenic species that lack all sporulation genes (Onyenwoke et al., 2004). Spore formation is highly variable. In some species, it is rarely observed, e.g., *Thermoanaerobacter brockii* subsp. *brockii* (Cook et al., 1991). In contrast, strains of *Thermoanaerobacter thermohydrosulfuricus* readily form spores, with greater than 50% of the cells sporulating upon reaching the stationary growth phase (Wiegel et al., 1979).

Conversion of thiosulfate to H_2S or S^0 . One of the characteristics previously thought to be diagnostic of the genus was the reduction of thiosulfate to H_2S (Lee et al., 1993). However, recently characterized species were found to produce from thiosulfate either $\text{H}_2\text{S} + \text{S}^0$ (*Thermoanaerobacter italicus*; Kozianowski et al., 1997) or exclusively S^0 (*Thermoanaerobacter sulfurifignens*; Lee et al., 2007a; Table 244). Sulfur accumulates in the medium and in cells of *Thermoanaerobacter italicus* and *Thermoanaerobacter sulfurifignens* (Figure 244 and Figure 245). The latter organism

tolerates high concentrations of thiosulfate and converts up to 1M thiosulfate to sulfur. It also grows in the presence of up to 90mM sulfite (Lee et al., 2007b). Several other species tolerate thiosulfate concentrations around 250mM and sulfite concentrations about 30mM (*Thermoanaerobacter uzonii*; Wagner et al., 2008). The different effects of thiosulfate on H_2 oxidation and glucose and xylose metabolism in *Thermoanaerobacter brockii* subsp. *lactiethylicus* and *Thermoanaerobacter brockii* subsp. *finnii* have been studied to understand the breakdown

of carbohydrates found in sulfide-, elemental sulfur-, or sulfate-rich thermal hot springs and oilfields (Fardeau et al., 1996) and literature cited therein). Variations in peptide and amino acid oxidation in the presence of thiosulfate by members of the genus have also been reported by Faudon et al. (1995).

Temperature and pH ranges. Growth temperature optima vary from 55–75 °C, with growth ranges of 35–78 °C. Many species also exhibit a wide temperature span for growth of over 35 °C (Wiegel, 1990, 1998b). The temperature versus growth rate plots for these species exhibit biphasic curves with two maxima (the first more or less pronounced) and broken Arrhenius plots, indicating changes in the rate-limiting steps. Wiegel (1990, 1998b) suggested an evolutionary relevance and that these bacteria contain, for some critical metabolic steps, two different enzymes: one for growth at the lower temperature and a second one for growth at the higher temperature. Several species also exhibit a wide pH optimum of about 3 pH units without a specific peak, e.g., *Thermoanaerobacter ethanolicus* JW200. However, for comparison of pH ranges, one must take into consideration that different authors measured the pH differently. It is frequently not known whether or not they corrected for the temperature effect on the pK_a values of various medium components and correspondingly calibrated the pH meter at the elevated growth temperature (i.e., calibration and analysis temperature indicated as superscript; Wiegel, 1998a). *Thermoanaerobacter wiegeli* was used to study the effect of the medium pH on ATP synthesis, the proton motive force, and membrane potential (Cook, 2000).

Ethanol fermentation. *Thermoanaerobacter ethanolicus* was the first wild-type bacterium to receive protection by a U.S. patent. This patent was based upon the nearly quantitative conversion of hexose to ethanol, a property common to both *Thermoanaerobacter ethanolicus* and *Thermoanaerobacter pseudethanolicus* (Larsen et al., 1997; Lovitt et al., 1984; Wiegel et al., 1983; Wiegel and Ljungdahl, 1981). The generalized fermentation balance for these organisms is (in moles): $1.0 \text{ glucose} + 0.1 \text{ H}_2\text{O} \rightarrow 1.8 \text{ ethanol} + 0.1 \text{ acetic acid} + 0.1 \text{ lactic acid} + 1.9 \text{ CO}_2 + 0.2 \text{ H}_2$. Variations in end products are observed. The amount of ethanol formed depends upon the pH. Higher ethanol yields are obtained when the culture is started above $\text{pH}^{25^\circ\text{C}}$ 7.2, and then the pH is allowed to decrease to 6.8 or below during the fermentation. Cultures kept at a constant $\text{pH}^{25^\circ\text{C}}$ produce only 0.8–1.1 mol of ethanol/mol of glucose consumed with a corresponding increase in formation of acetate and lactate. A decrease in the ratio of yeast extract to fermented carbohydrate also leads to a decrease in ethanol production and an increase in acetate and lactate production (Hild et al., 2003). The ethanol yield also depends on the growth conditions and the substrate combinations, such as starch and glucose (Parkkinen, 1986) or glucose and xylose (Carreira et al., 1983; Wiegel et al., 1983; Patel et al., 1988; Laci and Lawford, 1992, and literature cited therein; Cook and Morgan, 1994; Heitmann et al., 1996). In species such as *Thermoanaerobacter thermohydrosulfuricus* and *Thermoanaerobacter ethanolicus*, yeast extract is not only required for growth but also for ethanol production by resting cells (Wiegel et al., 1979).

Several *Thermoanaerobacter* species are suitable for ethanol production from pretreated hemicellulosic hydrolysates of wheat straw (Ahring et al., 1996), steam exploded wood extracts (Wiegel et al., 1983, 1986) and other hemicellulosic waste material

(Sommer et al., 2004). Although the strains produce lower concentrations, a relatively high tolerance to ethanol of 8% v/v and 5% have been obtained for *Thermoanaerobacter ethanolicus* JW200 and *Thermoanaerobacter mathranii* subsp. *mathranii*, respectively, by stepwise adaptation (Wiegel et al., unpublished results; Ahring et al., 1999).

Co-cultures of *Thermoanaerobacter ethanolicus* and *Thermoanaerobacter pseudethanolicus* with cellulolytic bacteria such as *Clostridium thermocellum* have been used to obtain saccharification of cellulosic material and conversion to ethanol in a single vessel (Ljungdahl and Wiegel, 1981; Ng et al., 1981). *Thermoanaerobacter* strain YM3 requires yeast extract for growth unless it is grown in co-culture with *Clostridium thermocellum* strain YM4 or the cell-free broth of YM4 (Mori, 1995).

Instead of ethanol, L-lactate was the main fermentation product in *Thermoanaerobacter* mutants defective in either acetate kinase or phosphotransacetylase (Mayer et al., 1995; Ljungdahl et al., unpublished results). Several groups are working presently to develop bioengineered strains lacking the enzymic activities leading to the formation of the minor products acetate and lactate. Under various conditions and after extended culturing, these side products (especially acetate) can become major products. The formation of acetate also yields one more ATP per acetate formed through substrate level phosphorylation. These studies are aided by the genome sequences for strains of *Thermoanaerobacter pseudethanolicus* and for *Thermoanaerobacter ethanolicus* JW200, which have recently become available (see below).

Enzymes. Because of their thermophily (Vieille and Zeikus, 2001; Zamost et al., 1991), *Thermoanaerobacter* species have been exploited as a source of a wide variety of thermostable enzymes for carbohydrate breakdown and alcohol production (Alister et al., 1990; Canganella and Wiegel, 1993; Fardeau et al., 1996; Kuriki and Imanaka, 1999; Svensson, 1994; Zeikus et al., 1991).

Carbohydrate-hydrolyzing enzymes. Enzymes involved in the transformation of starchy and hemicellulosic biomass that have been studied include saccharolytic, cellulolytic, hemicellulolytic, and other sugar-metabolizing enzymes.

Some of the saccharolytic enzymes studied are the following. The thermostable amylolytic and pullulolytic enzymes have been studied from *Thermoanaerobacter italicus* (Ahring et al., 1996, 1999), *Thermoanaerobacter Brockii* subsp. *finnii* (Antranikian, 1989), and *Thermoanaerobacter thermohydrosulfuricus* (Antranikian et al., 1987; Melasniemi, 1987). The recombinant *Thermoanaerobacter thermohydrosulfuricus* enzyme has also been heterologously expressed in *Escherichia coli* (Melasniemi and Paloheimo, 1989). Some of these enzymes possess temperature optima of 80–85 °C. The biochemistry of the active site and the regulation of expression have been studied for glucoamylase and pullulanase from *Thermoanaerobacter pseudethanolicus* (Hyun and Zeikus, 1985; Lin and Leu, 2002; Mathupala et al., 1993, 1994). The α -glucosidase from *Thermoanaerobacter thermohydrosulfuricus* exhibits maltase, glucohydrolase, and “maltodextrinohydrolase” activity (Wimmer et al., 1997). The β -1,4-glucosidase from an unidentified species was characterized (Mitchell et al., 1982). Two different β -glucosidases were studied from *Thermoanaerobacter Brockii* subsp. *Brockii* (Breves et al., 1997). A recombinant cyclodextrin glycosyltransferase was studied from an unidentified species (Jorgensen et al., 1997). The catalytic center of a cyclomaltodextrinase was studied from *Thermoanaerobacter*

pseudethanolicus (Podkovyrov et al., 1993). A novel thermostable dextranase was studied from a *Thermoanaerobacter* species (Wynter et al., 1997).

Some biosynthetic capabilities of *Thermoanaerobacter* enzymes have been studied including the production of cyclodextrin from raw corn starch by cyclodextrin glycosyltransferase (Kim et al., 1997), the synthesis of glycosyl glycerol by cyclodextrin glucanotransferases (Nakano et al., 2003), and the synthesis of oligosaccharides by immobilized cyclodextrin glycosyltransferases (Martin et al., 2001, 2004).

The cellulolytic and hemicellulolytic enzymes that have been studied include an extracellular cellulase from *Thermoanaerobacter thermocopriae* (Chaen et al., 2001), the thermostable xylanolytic enzymes from *Thermoanaerobacter italicus* (Antranikian, 1989), a xylulose kinase from *Thermoanaerobacter pseudethanolicus* 39E (Erbeznik et al., 1998a; Jones et al., 2002b), and a β -xylosidase and a bifunctional xylosidase-arabinosidase (*xarB*) from *Thermoanaerobacter ethanolicus* JW200 (Mai et al., 2000; Shao and Wiegel, 1992). The genes for a xylose ABC transport operon (Erbeznik et al., 2004), xylose-binding protein XylF, and the maltose ABC transport system (Jones et al., 2002a) have been characterized in *Thermoanaerobacter pseudethanolicus* 39E (Erbeznik et al., 1998b).

Other sugar metabolizing enzymes that have been studied include a β -galactosidase from an unidentified species (Lind et al., 1989) and *Thermoanaerobacter pseudethanolicus* (Fokina and Velikodvorskaia, 1997), xylose(glucose) isomerases from *Thermoanaerobacter pseudethanolicus* 39E (Erbeznik et al., 1998a, 1998b) and *Thermoanaerobacter brockii* subsp. *brockii* (Okada et al., 2003), the arabinose isomerase from *Thermoanaerobacter mathranii* (Jorgensen et al., 2004), and two thermoactive pectate lyases from *Thermoanaerobacter italicus* (Kozianowski et al., 1997). The kojibiose phosphorylase of *Thermoanaerobacter brockii* subsp. *brockii* has been used for the synthesis of oligosaccharides (Okada et al., 2003). The kojibiose phosphorylase activities from *Thermoanaerobacter brockii* subsp. *brockii* were studied further (Maruta et al., 2006; Yamamoto et al., 2006, and literature cited therein), and chimeras of the kojibiose and trehalose phosphorylase were constructed (Yamamoto et al., 2006). The conversion of D-galactose into D-tagatose has been studied in *Thermoanaerobacter mathranii* subsp. *mathranii* (Jorgensen et al., 2004).

Alcohol dehydrogenases and other enzymes. The ethanol formation in *Thermoanaerobacter* species from hexoses includes two reversible redox reactions: acetyl-CoA to acetaldehyde and acetaldehyde to ethanol. Several studies focused on the acetaldehyde dehydrogenase (ALDH, EC 1.2.1.10) and alcohol dehydrogenases (ADH). Two alcohol dehydrogenases, a primary alcohol dehydrogenase (EC 1.1.1.1) and a secondary alcohol dehydrogenase (EC 1.1.1.2.) were purified and characterized from several of the species. However, their functions in the alcohol formation were not unequivocally elucidated. Because of the early formation of the secondary alcohol dehydrogenase during growth, it was suggested that it is mainly involved in alcohol formation. Bryant et al. (1988) showed that this enzyme from *Thermoanaerobacter ethanolicus* JW200 also had a high affinity for acetaldehyde, and Burdette and Zeikus (1994) demonstrated that the enzyme from *Thermoanaerobacter pseudethanolicus* 39E has reductive thioesterase activity suggesting that it is a bifunctional enzyme that forms ethanol from acetyl-CoA and acetaldehyde released by an aldehyde dehydrogenase. The unequivocal role and interactions of these three enzymes

in vivo needs to be studied further using molecular approaches. The three terms: primary and secondary alcohol dehydrogenase and aldehyde dehydrogenase are not always used consistently in the literature.

The primary alcohol dehydrogenase (encoded by *adhA*) is a zinc-containing, NADP(H)-dependent, tetrameric enzyme and has been purified from *Thermoanaerobacter ethanolicus* JW200 and its mutants (Bryant et al., 1988, 1992) and from *Thermoanaerobacter pseudethanolicus* (Burdette and Zeikus, 1994). The enzyme from JW200 was heterologously expressed in *Escherichia coli* (Holt et al., 2000). It oxidizes primary alcohols up to heptanol, but it is inactive with secondary alcohols.

The secondary alcohol dehydrogenase, encoded by *adhB*, has been studied from *Thermoanaerobacter ethanolicus* JW200 (Pham and Phillips, 1990), *Thermoanaerobacter brockii*, (Korkhin et al., 1998) and *Thermoanaerobacter pseudethanolicus* 39E. These studies of the enzymes from *Thermoanaerobacter ethanolicus* JW200 and *Thermoanaerobacter pseudethanolicus* 39E include various biophysical analyses and comparisons of the effects of site specific mutations (Burdette et al., 1997; Heiss et al., 2001; Tripp et al., 1998). Arni et al. (1996) determined the crystal structure. Phillips (2002b, and literature cited therein) used amino acid substitutions in the active site to change the substrate specificity. Burdette et al. (2000) explored the physiological role of the enzyme in the alcohol tolerance of the bacterium. The enzyme can be encapsulated for reactions in organic solvents and also used for the asymmetric reduction of aldehydes and ketones (Musa et al., 2007a, 2007b; Phillips, 1996). A modification of the enzyme has also been developed for the reduction of the solvents phenylacetone and benzylacetone (Ziegelmann-Fjeld et al., 2007). Interestingly, the stereochemistries of the primary and secondary alcohol dehydrogenases from *Thermoanaerobacter ethanolicus* JW200 and *Thermoanaerobacter pseudethanolicus* 39E are temperature dependent and switch around 35 °C which is close to the minimal growth temperature for both species (for reviews, see Phillips, 1996; Yang et al., 1997). The stereospecificity is also dependent on the pH, the active site water content (Phillips, 2002a) and the choice of substrates and cofactor analogs (Zheng and Phillips, 1992). The secondary alcohol dehydrogenase from *Thermoanaerobacter brockii* subsp. *brockii* is a NADPH-dependent enzyme, contains zinc, and possesses a tetrameric quaternary structure. It was isolated and fully characterized (including amino acid sequence and crystal structure) by Peretz and Burstein (1989) and Li et al. (1999) and isolated by affinity chromatography (McMahon and Mulcahy, 2002). The obtained information allowed the characterization of the zinc-containing active site (Bogin et al., 1997), the effect of substitution of cobalt which leads to a lower energy barrier for catalysis (Kleifeld et al., 2004), modification of specific amino acids such as cysteine and proline (Peretz et al., 1997a, 1997b), and a detailed correlation of the structure and activity with temperature stability (Korkhin et al., 1999). This information enabled the construction of chimeras (Korkhin et al., 1998) and mutations of critical amino acids (Bogin et al., 1998a, 1998b) in the alcohol dehydrogenase from the mesophilic *Clostridium beijerinckii* to enhance its temperature stability. Miroliaei and Nemat-Gorgani (2002) and Olofsson et al. (2005) studied the reactivity in water-permissible solvents. Furthermore, the alcohol dehydrogenase of *Thermoanaerobacter brockii* subsp. *brockii* has been included in studies of disulfide modification and antioxidant properties of S-allylmercaptogluthathione (Rabinkov et al., 2000).

The acetaldehyde dehydrogenase has been studied in *Thermoanaerobacter pseudethanolicus* 39E (Burdette and Zeikus, 1994). The lactate dehydrogenase has been studied from *Thermoanaerobacter pseudethanolicus* (Germain et al., 1986) and *Thermoanaerobacter thermohydrosulfuricus* (Turunen et al., 1987). A number of other types of enzymes have been examined. The intracellular protease and extracellular keratinolytic enzymes from *Thermoanaerobacter keratinophilus* 2KXI effectively degrade feathers (Riessen and Antranikian, 2001). The type and only strain of *Thermoanaerobacter keratinophilus* is a patent strain, similar to the keratinolytic *Thermoanaerobacter* strain S290 (French Patent Application FR-04 50513; Tsirolunikov et al., 2004) and therefore could not be validly published. Thus *Thermoanaerobacter keratinophilus* is described below in the section *Other named isolates*. Other purified and characterized enzymes include the trehalose phosphorylase (Maruta et al., 2006) and the chaperonin 60 and 10 from *Thermoanaerobacter brockii* subsp. *brockii* (Todd et al., 1995; Truscott et al., 1994) and GroE from strain Rt6.G4 isolated from Rotorua, New Zealand (Truscott and Scopes, 1998). The thermostable DNA polymerase (Sha et al., 1997) and its regulation by protein phosphorylation (Londesborough, 1986) have been studied in *Thermoanaerobacter thermohydrosulfuricus*. The kinetics of the temperature dependence of the 3-phosphoglycerate kinase from a *Thermoanaerobacter* species has been compared to that of the mesophilic enzyme (Thomas and Scopes, 1998). The histidine biosynthetic pathway of *Thermoanaerobacter pseudethanolicus* has also been studied (Erbeznik et al., 2000).

Industrial applications. The hexagonal S-layer lattice of *Thermoanaerobacter thermohydrosulfuricus* L111-69 has been tested as a surface for binding of various enzymes (e.g., Kupcu et al., 1995) and several immunological reactions such as immunoassays requiring immobilization of human IgG (Kupcu et al., 1996; Weber et al., 2001). Other possible uses include immobilization of cell-wall fragments (Sleytr et al., 1999, and literature cited therein), macromolecules such as ferritin and invertase (Sára and Sleytr, 1989), and recombinant major birch pollen allergen Bet v 1 (Jahn-Schmid et al., 1996).

Thermoanaerobacter species have also been screened for their potential in solid substrate cultivation (an alternative culture method using wetted solid substrates) for biomass-supported bioremediation and animal feed enrichments (Chinn et al., 2006).

Thermoanaerobacter mathranii subsp. *mathranii* has been utilized in an upflow anaerobic sludge blanket (UASB) purification reactor for the detoxification of water derived from an industrial ethanol fermentation (Rabinkov et al., 2000; Torry-Smith et al., 2003).

Biotechnological processes have been developed that rely upon *Thermoanaerobacter brockii* subsp. *brockii* to reduce β -oxoesters (Seebach et al., 1984) or *Thermoanaerobacter kivui* to produce Ca-Mg-acetate as an alternate road deicer (Kevbrina et al., 1996; Ljungdahl et al., 1985; Wiegel et al., 1991). *Thermoanaerobacter brockii* subsp. *finni* has been used to develop a bioluminescence assay for pyridine nucleotide that detects levels as low as 1 pmol in cell extracts (Schmid et al., 1989). The alcohol dehydrogenases from *Thermoanaerobacter ethanolicus* and *Thermoanaerobacter pseudethanolicus* have been used for asymmetric reduction of aliphatic and cyclic ketones (Zheng et al., 1994).

Molecular and genetic studies. Genus-specific oligonucleotide probes for the detection of *Thermoanaerobacter* species are available (Subbotina et al., 2003).

Peteranderl et al. (1993) developed a system for regeneration of wall-less autoplasts of *Thermoanaerobacter*, *Thermoanaerobacterium*, and related strains to cell-wall-containing rods. This meth-

odology led to the development of efficient electroporation and genetic systems for these anaerobic thermophiles (Mai et al., 2000). These methods were later extended to *Clostridium thermocellum* (Tyurin et al., 2006, and literature cited therein). The first, successful gene transfer to *Thermoanaerobacter ethanolicus* JW200^T has recently been documented by Peng et al. (2006).

The genome sequences of *Thermoanaerobacter ethanolicus* JW200 and *Thermoanaerobacter pseudethanolicus* strains 39E and X514 have been completed by the Joint Genome Institute.

Enrichment and isolation procedures

Many *Thermoanaerobacter* species have been isolated from a great variety of geothermally heated sources, including slightly alkaline and slightly acidic hot springs (Wiegel and Ljungdahl, 1981), the Australian Great Artesian Basin (Wynter et al., 1996), and high temperature petroleum reservoirs (Grassia et al., 1996; Slobodkin et al., 1999b). They can also be isolated from many mesobiotic environments (Wiegel et al., 1979). For example, the sporulating species *Thermoanaerobacter thermohydrosulfuricus* and *Thermoanaerobacter thermosaccharolyticus* (basonym *Clostridium thermosaccharolyticum*) can be isolated nearly from all types of soil and sediments including permanently frozen soils and snow of Antarctica. Culture-independent methods, such as cloning and sequencing of 16S rRNA genes, have identified *Thermoanaerobacter* as the dominant microorganism in many environments (Leu et al., 1998; Orphan et al., 2000). Szewzyk et al. (1994) have isolated glucose- and starch-degrading strains related to the *Thermoanaerobacter* from a deep borehole in granite. Slobodkin et al. (1999a, 1999b), Zhou et al. (2001) and Roh et al. (2002) have reported on the isolation and characterization of metal-reducing *Thermoanaerobacter pseudethanolicus*-like strains from deep subsurface environments (Jizhong Zhou, personal communication). On the other hand, the type species (type strain JW200) was isolated only once from a slightly alkaline hot spring from Yellowstone National Park (Wiegel and Ljungdahl, 1981), and all other attempts to reisolate this species have yielded only strains of *Thermoanaerobacter pseudethanolicus* (Onyenwoke et al., 2007) or different, but novel, species. This includes strain JW 201 which was originally described prior to 16S rRNA sequencing as a second strain of *Thermoanaerobacter ethanolicus* (Wagner and Wiegel, unpublished results).

Media for enrichments and isolations are typically mineral-based, phosphate- and/or carbonate-buffered, supplemented with 0.05–0.2% yeast extract, and incubated at 60–70 °C. Species have also been enriched from petroleum reservoirs by the direct supplementation of production waters with glucose and either yeast extract, peptone, tryptone, or Casamino acids (Grassia et al., 1996; Slobodkin et al., 1999a), or xylose plus thiosulfate (*Thermoanaerobacter sulfurigignens*; Lee et al., 2007a), or on crotonate (*Thermoanaerobacter uzonensis*; Wagner and Wiegel unpublished results). After enrichment in broth cultures, axenic cultures can be obtained by plating in anaerobic jars or agar-shake-roll tubes prepared with 1.5–2.2% (w/v) agar. Specifics on anaerobic techniques are further described in Ljungdahl and Wiegel (1986).

Maintenance procedures

Freeze-dried cultures have been stored for many years. In addition, some species, i.e., *Thermoanaerobacter ethanolicus* JW200 and *Thermoanaerobacter thermohydrosulfuricus* JW102, have been stored in pre-reduced medium containing 40–45% (v/v) glycerol as cryoprotectant at –20 °C for more than 28 years. This method is convenient for frequent sampling because the mixture remains

liquid and small portions can be removed with a syringe without changing the temperature of the stock. For longer storage, the culture is kept at -80°C . Working cultures can be stored at room temperature and transferred at regular intervals of about 2 weeks, and several species need only be transferred every 3–6 months (e.g., *Thermoanaerobacter ethanolicus*). Sporulating strains can be maintained on agar slants after growth on low concentrations, i.e., less than 0.15% (w/v) of slowly utilizable substrates. Alternatively, the spores may be harvested by centrifugation, resuspended in phosphate buffer or medium, and stored at either 4°C or room temperature. Spores of *Thermoanaerobacter thermohydrosulfuricus* JW 102 retain viability under aerobic conditions at 4 – 25°C for more than 30 years (Wiegel, unpublished results).

Taxonomic comments

The genus *Thermoanaerobacter* is a member of the *Thermoanaerobacterales* and the family *Thermoanaerobacteraceae* (Figure 246). However, in contrast to all previous analyses, the detailed phylogenetic 16S rRNA tree for the *Firmicutes* suggests that this group (which is not monophyletic) may constitute its own class (Ludwig et al., 2009). Thus, further phylogenetic analyses are warranted.

List of species of the genus *Thermoanaerobacter*

1. ***Thermoanaerobacter ethanolicus*** Wiegel and Ljungdahl 1982, 384^{VP} (Effective publication: Wiegel and Ljungdahl 1981, 348.)

e.tha.no'li.cus. N.L. masc. n. *ethanol* corresponding alcohol of ethane (ethane + ol); N.L. masc. adj. *ethanolicus* indicating the production of ethanol.

Description is based on the type strain JW200. To date, the species is represented by only one strain, and this descrip-

tion reflects the properties of that strain. Cells in the early exponential growth phase are rods, 0.3 – 0.8×4 – $8\mu\text{m}$, sometimes with pointed ends. In older cultures, cells can be long and filamentous, up to $100\mu\text{m}$ in length without detectable septation, or form chains of rod-shaped cells frequently interspersed with coccoid cells, 0.8 – $1.5\mu\text{m}$ in diameter. In addition, cells with protuberances are frequently observed in older cultures (Figure 243). Cells have 1–12 peritrichous

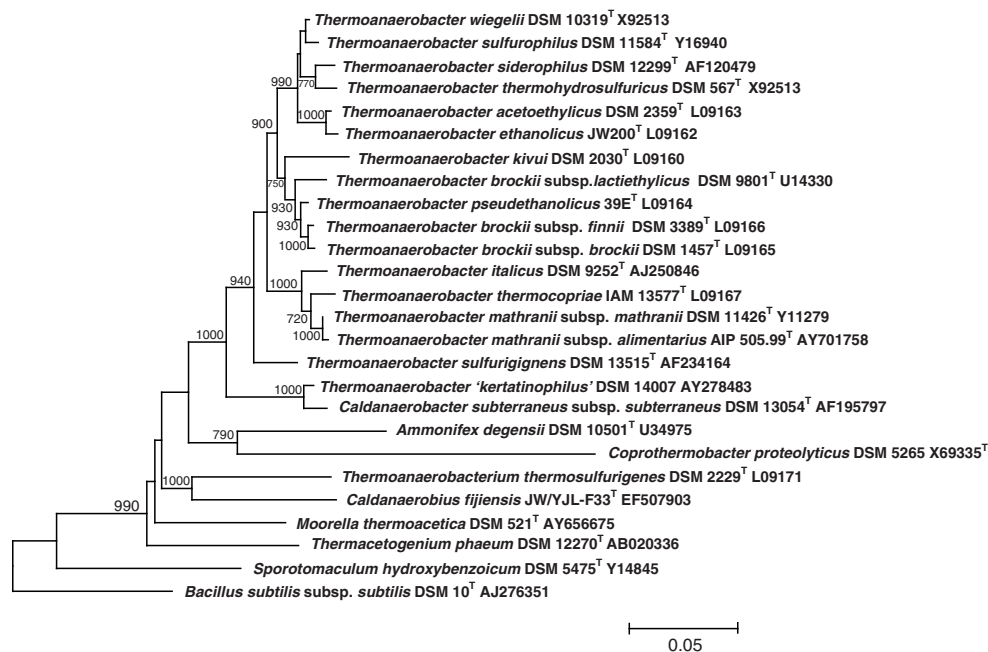

FIGURE 246. Phylogenetic tree for the genus *Thermoanaerobacter*. Neighbor-joining tree showing the estimated phylogenetic relationships for the type strains of each species within the genus *Thermoanaerobacter* based on 16S rRNA gene sequence data with Jukes–Cantor correction for synonymous changes. Numbers at nodes indicate bootstrap values for 1000 replicates. Bar = 0.05 nucleotide substitutions per site. The superscript “T” denotes the sequence from the type strain for the species. GenBank accession numbers are indicated after the strain designations.

flagella that are up to 50 µm in length and 4–8 pili. Spores are not observed, although sporulation specific genes are present. Cells are Gram-stain-variable. However, the cell-wall structure is Gram-positive, as observed by electron microscopy, and contains *meso*-diaminopimelic acid (Aγ1-cell-wall type). Strain JW200 is able to form stable, wall-free cells following induction of autolysis. These cells can regenerate back to a walled form (Peteranderl et al., 1993). Colonies that form in deep agar (2% w/v) at 60 °C are 0.5–1.0 mm in diameter, lenticular and white. After 40 h at 60 °C, colonies become 2–4 mm in diameter, white, smooth, round to irregular, and flat. In older cultures, the colonies turn brown, but no pigment has ever been identified.

Cells are obligate anaerobes that grow from pH 4.4–9.9 with a broad pH_{opt} of 5.8–8.5. These values possess a small systematic error because, although the pH was measured at 70 °C with a pH meter equipped with a temperature probe, the pH electrode was calibrated at room temperature. (For a more thorough discussion on the accurate determination of pH at elevated temperatures, see Wiegel, 1998a). The growth temperature range is from 37–78 °C (optimum at 69 °C). Fermented carbohydrates include glucose, fructose, galactose, mannose, ribose, xylose, cellobiose, lactose, maltose, sucrose, starch, and pyruvate but not cellulose, raffinose, rhamnose, fucose, *m*-erythritol, *m*-inositol, xylitol, glycerol, mannitol, sorbitol, trehalose, melezitose, melibiose, niacinamide, or amygdalin (Lacis and Lawford, 1985; Wiegel and Ljungdahl, 1981). Esculin and gelatin are hydrolyzed, but cells are negative for catalase, indole production, and lipase and cellulase activity. The major end products of glucose fermentation are ethanol and CO₂. The generalized fermentation balance (in moles) is: 1.0 glucose + 0.1 H₂O → 1.8 ethanol + 0.1 acetic acid + 0.1 lactic acid + 1.9 CO₂ + 0.2 H₂. Methanol is a major metabolic end product of pectin fermentation (Schink and Zeikus, 1980).

Cells in the late (but not early) exponential growth phase lyse on exposure to 100 µg/ml of polymyxin B for 30 min at 37 °C or 50 °C (pH 7.2). Cells are inhibited by chloramphenicol but are resistant to erythromycin, tetracycline, and penicillin G. H₂ is inhibitory at 10% (v/v), and growth does not occur at 75% or higher concentrations. Lactic acid, acetic acid, and ethanol are inhibitory at 65 °C above 100 mM, 200 mM, and 500 mM, respectively. However, the type strain can easily be adapted to grow in the presence of 1.7 M ethanol (Wiegel, unpublished results). Strain JW200 was isolated from water and mud samples with a pH of about 8.8 and temperature of 45–50 °C that were collected from the slightly alkaline hot spring in the Octopus pool area of White Creek at Fire Hole Lake Drive in the Yellowstone National Park, Wyoming, USA.

In contrast to other species, strain JW200 does not contain menaquinone MK-7 (Yamamoto et al., 1998).

Taxonomic note: No other strains of *Thermoanaerobacter ethanolicus* are currently available. Strain 39E (Lee et al., 1993) has been reassigned to *Thermoanaerobacter pseudethanolicus* (Onyenwoke et al., 2007). Recent analysis of the 16S rRNA gene of strain JW201, which was isolated from Yellowstone National Park at the same time as JW200 (Wiegel and Ljungdahl, 1981), suggests that it is not closely related despite the similarity in physiology and that it may represent a novel species (Wiegel et al., unpublished results).

DNA G+C content (mol%): 32 (T_m); 39 (Bd); 38 (chemical).

Type strain: JW200, ATCC 31550, DSM 2246.

GenBank accession number (16S rRNA gene): L09162.

2. **Thermoanaerobacter acetoethylicus** (Ben-Bassat and Zeikus 1981) Rainey and Stackebrandt 1993, 857^{VP} (*Thermobacteroides acetoethylicus* Ben-Bassat and Zeikus 1981, 367)

a.ce.to.e.thy.licus. L. n. *acetum* vinegar. N.L. adj. *ethylicus* of ethyl alcohol; N.L. masc. n. *acetoethylicus* producing acetate and ethanol.

This description is based on the type strain HTB2 and isolate HTD1 (Zeikus et al., 1980; Zeikus et al., 1979). Cells are motile rods, 0.6 × 1.5–2.5 µm, that occur singly or in pairs. Flagella are arranged peritrichously. Spores have never been observed. The cells have a multi-layered, Gram-positive cell-wall structure; even though it stains Gram-stain-negative, it lacks an outer membrane. Colonies are uniformly round, flat, mucoid, and nonpigmented, with a diameter of 3 mm after 48 h. Cytochrome pigment and catalase are both absent.

The optimum temperature for growth is 65 °C. The maximum and minimum growth temperatures are <80 °C and >40 °C, respectively. The pH range for growth is 5.5–8.5 at 65 °C. Cells are obligate anaerobes that use the glycolytic Embden–Meyerhof–Parnas pathway. The major end products of glucose fermentation are equal amounts of acetic acid and ethanol, lesser amounts of isobutyric and butyric acid, but no lactic acid. Fermentation analysis as reported (unbalanced, given in µmol): 130 glucose → 102 ethanol + 126 acetic acid + 157 CO₂ + 165 H₂ + biomass. The lower yield for ethanol is one of the reasons to distinguish *Thermoanaerobacter acetoethylicus* from *Thermoanaerobacter ethanolicus* despite the high (> 99%) sequence similarity of their 16S rRNAs. DNA–DNA hybridization studies are needed for further clarification.

Other carbohydrates fermented by *Thermoanaerobacter acetoethylicus* include glucose, mannose, cellobiose, maltose, sucrose, lactose, and starch. Fermentation products include ethanol, acetate, lactate, and CO₂. Exogenous H₂ does not inhibit growth, but the addition of 0.4–1.0 atm H₂ to a cellobiose fermentation increases the ratio of ethanol to acetate produced (Lamed and Zeikus, 1980).

Sulfate is not reduced. Growth is inhibited by air; NaCl (2% w/v); and tetracycline, streptomycin, penicillin G, vancomycin, and neomycin (all at 10 µg/ml). Strain HTB2 was isolated from an algal-bacterial mat at Octopus Spring in Yellowstone National Park, Wyoming, USA on trypticase peptone-yeast extract glucose (TYEG) medium (pH 7.2).

DNA G+C content (mol%): 31 (T_m).

Type strain: HTB2, HTB2/W, ATCC 33265, DSM 2359.

GenBank accession number (16S rRNA gene): L09163, X69336.

3. **Thermoanaerobacter brockii** (Zeikus, Hegge and Anderson 1979) Lee, Jain, Lee, Lowe and Zeikus 1993, 49^{VP} emend. Cayol, Ollivier, Patel, Ravot, Magot, Ageron, Grimont and Garcia 1995, 787 (*Thermoanaerobium brockii* Zeikus, Hegge and Anderson 1979, 47)

brock'i.i. N.L. gen. n. *brockii* of Brock, named for Thomas Dale Brock who pioneered studies on the physiology and ecology of thermophiles.

The species is composed of three subspecies, *Thermoanaerobacter brockii* subsp. *brockii*, *Thermoanaerobacter brockii* subsp.

finnii, and *Thermoanaerobacter brockii* subsp. *lactiethylicus*. The description of the species is the same as for the subspecies *Thermoanaerobacter brockii* subsp. *brockii*.

- 3a. **Thermoanaerobacter brockii** subsp. **brockii** (Zeikus, Hegge and Anderson 1979) Lee, Jain, Lee, Lowe and Zeikus 1993, 49^{VP} emend. Cayol, Ollivier, Patel, Ravot, Magot, Ageron, Grimont and Garcia 1995, 787 (*Thermoanaerobium brockii* Zeikus, Hegge and Anderson 1979, 47)

Cells are Gram-stain-positive short rods, $1.0 \times 2\text{--}20\ \mu\text{m}$ and exhibit a Gram-positive cell-wall structure. Cell length frequently varies, and minicells are common. Cells occur in pairs, chains, and filaments. Round, heat-resistant terminal spores are observed, but only rarely (Cook et al., 1991). Cytochromes and catalase are absent. Colonies on agar plates are circular, 0.2–0.3 mm in diameter, flat, mucoid, and nonpigmented.

Cells grow chemoorganotrophically with yeast extract, and a fermentable carbohydrate is required for growth. The optimum temperature for growth is 65–70 °C, with a temperature range of >35 °C–77 °C (J. Wiegel unpublished results). The pH^{25°C} range is 5.5–9.5, with an optimum of 7.5. (J. Wiegel, unpublished results). The doubling time at optimal conditions is about 1 h. Cells are obligate anaerobes and ferment a wide variety of substrates, including glucose, maltose, sucrose, lactose, cellobiose, starch, and pyruvate but not xylose, cellulose, arabinose, mannose, lactate, tartrate, ethanol, tryptone, Casamino acids, or pectin. Serine, leucine, isoleucine, and valine are utilized (Fardeau et al., 1997). Oxygen, sulfate, nitrate, and fumarate are not reduced. Protein is not hydrolyzed. Cell growth is inhibited by penicillin, cycloserine, streptomycin, tetracycline, and chloramphenicol (all at 100 µg/ml); exposure to air (21% O₂); and 2% NaCl.

Strain HTD4 was isolated from Washburn pool B spring sediment at Yellowstone National Park, Wyoming, USA using TYEG medium (pH 7.2–7.4). In addition to the type strain, other strains include HTA1, HTD4, HTD6 and HTR1 = DSM 2599, ATCC 35047 (Zeikus et al., 1979).

DNA G+C content (mol%): 30–31 (T_m).

Type strain: HTD4, ATCC 33075, ATCC 53556, DSM 1457.

GenBank accession number (16S rRNA gene): L09165.

- 3b. **Thermoanaerobacter brockii** subsp. **finnii** Schmid, Giesel, Schoberth and Sahn 1986) Cayol, Ollivier, Patel, Ravot, Magot, Ageron, Grimont and Garcia 1995, 788^{VP} (*Thermoanaerobacter finnii* Schmid, Giesel, Schoberth and Sahn 1986, 84)

fin'ni.i. N.L. gen. n. *finnii* of Finn, named for Robert K. Finn who made important contributions to the development of the ethanol vacuum fermentation process.

The description is based on the type and only available strain. Short rods, $0.4\text{--}0.6 \times 1\text{--}4\ \mu\text{m}$, occurring singly, in pairs, and short chains. Occasionally forms coccoid cells. Motile. Cells have Gram-positive cell-wall structure, but are Gram-stain-variable. Forms heat-resistant terminal spores. Colonies on agar plates are circular, 1–3 mm in diameter, smooth, white, and round. The cell wall contains peptidoglycan of *meso*-diaminopimelic acid and is of the A1 γ type. Temperature optimum for growth is 65 °C, with a temperature

range from 40–75 °C. The optimum pH is between 6.5–6.8. An obligate anaerobe and chemoorganotroph. Fermented sugars include glucose, fructose, galactose, mannose, cellobiose, maltose, melibiose, sucrose, lactose, xylose, ribose, mannitol, and pyruvate. Fermentation occurs according to the following equation (in moles): 1 glucose \rightarrow 1.45 ethanol + 0.25 acetic acid + 0.3 lactic acid + 1.7 CO₂ + 0.5 H₂. Penicillin G and tetracycline (both at 6 µg/ml) inhibit growth. Strain AKO-1 was isolated from sediment sludge from Lake Kivu in East Africa using M-1 media (which included lactic acid, glucose, and yeast extract) at 60 °C.

DNA G+C content (mol%): 32 (HPLC).

Type strain: AKO-1, ATCC 43586, DSM 3389.

GenBank accession number (16S rRNA gene): L09166.

- 3c. **Thermoanaerobacter brockii** subsp. **lactiethylicus** Cayol, Ollivier, Patel, Ravot, Magot, Ageron, Grimont and Garcia 1995, 788^{VP}

lac.ti.e.thy'li.cus. N.L. n. *acidum lacticum* lactic acid; N.L. n. *ethylicus* ethyl alcohol; N.L. masc. n. *lactiethylicus* referring to the production of both lactic acid and ethanol.

Description is based on the type strain and strains SEBR 7311 and SEBR 7312 (Cayol et al., 1995). Cells are straight rods, $0.5 \times 2\text{--}3\ \mu\text{m}$, motile by means of peritrichous flagella and occur singly or in pairs in young cultures. Pleomorphic filamentous cells, 15 µm in length, appear in older cultures. Cells are Gram-stain-positive. They form spores in a medium containing D-xylose as an electron donor and thiosulfate as an electron acceptor. Spores are not formed in medium with D-glucose. Colonies in roll tubes are 4 mm in diameter after 2 d of incubation at 60 °C, smooth, uniformly round, mucoid, nonpigmented, and flat. Temperature range for growth is 40–75 °C, with a temperature optimum of 55–60 °C. The pH range is 5.6–8.8, and the optimum is around 7.3. Fermentable substrates are glucose, fructose, galactose, mannose, D-ribose, D-xylose, cellobiose, lactose, maltose, sucrose, mannitol, starch, yeast extract, and pyruvate but not L-arabinose, cellulose, L-rhamnose, glycerol, ribitol, galactitol, sorbose, or melibiose. Under optimal conditions, the doubling time with glucose is 2 h. Sulfite and elemental sulfur are reduced to hydrogen sulfide. Sulfate, nitrate and fumarate are not reduced. The optimum NaCl concentration for growth is 1% (w/v). Concentrations up to 4.5% are tolerated. Strain SEBR 5268^T was isolated from French oil samples that had been geothermally heated to 92 °C. Enrichments were performed in anaerobic, glucose-based medium at 60 °C.

DNA G+C content (mol%): 35 (HPLC).

Type strain: SEBR 5268, DSM 9801.

GenBank accession number (16S rRNA gene): U14330.

4. **Thermoanaerobacter italicus** Kozianowski, Canganella, Rainey, Hippe and Antranikian 1998, 1083^{VP} (Effective publication: Kozianowski, Canganella, Rainey, Hippe and Antranikian 1997, 179.)

i.ta.li.cus. L. masc. adj. *italicus* pertaining to Italy, where the organism was isolated.

Description is based primarily on the properties of the type strain, although other strains have been isolated. Cells are nonmotile rods, $0.4\text{--}0.75 \times 2\text{--}6\ \mu\text{m}$, that form chains up to 50 µm in length during growth on glucose. Cells stain

Gram-stain-negative but contain Gram-positive cell-wall structure. The peptidoglycan contains *meso*-diaminopimelic acid, and the cell wall is of the A1 γ type. Spherical, terminal spores are produced with xylose as substrate. Colonies on agar plates with glucose are 2–3 mm in diameter, round with entire margins, grayish-white and opaque with a glassy surface. Growth occurs in the temperature range of 45–78 °C, with a temperature optimum of 70 °C. The pH optimum is around 7.0. Fermentable carbohydrates include amygdalin, arabinose, cellobiose, esculin, fructose, glucose, galactose, lactose, maltose, mannose, melezitose, melibiose, mannitol, raffinose, sucrose, trehalose, starch, xylan, glycogen, D-glucosamine, sucrose, inulin, pectin, and xylose but not cellulose. At 70 °C, the doubling times during growth on glucose and pectin are 2.1 h and 3 h, respectively. End products of the fermentation of 28 mM glucose are ethanol (26 mM), lactic acid (12.4 mM), acetic acid (2.2 mM), succinate (0.3 mM), CO₂, and H₂ (not quantified). Similar products are obtained from pectin. NaCl, 1% (w/v), did not inhibit growth. Cephalosporin, erythromycin, kanamycin, and rifampin (all at 10 μ g/ml) totally inhibit growth. Strains were isolated from water and mud samples (40–70 °C) from thermal spas at Abano Terme, Calzignano Terme, Montegrotto Terme, Battaglia Terme, Sirmione, and Agano Terme in northern Italy. Pectin and pectate (polygalacturonic acid) were the substrates used for the enrichments. Strain Ab9 was isolated from medicinal mud (fangò) from Abano Terme, Italy.

DNA G+C content (mol%): 34.4 (HPLC).

Type strain: Ab9, DSM 9252.

GenBank accession number (16S rRNA gene): AJ250846.

5. **Thermoanaerobacter kivui** Leigh, Mayer and Wolfe 1981) Collins, Lawson, Willems, Cordoba, Fernández-Garayzábal, Garcia, Cai, Hippe and Farrow 1994, 824^{VP} (*Acetogenium kivui* Leigh, Mayer and Wolfe 1981, 279)

ki'vui. N.L. gen. n. *kivuius* pertaining to Kivu, named for its source, Lake Kivu.

The only strain available is the type, upon which this description is based. Cells are rods, 0.7–2–3.5 μ m during growth on H₂ and CO₂ and 0.7–0.8 \times 5.5–7.5 μ m during growth on glucose. Cells occur in pairs or chains and are not flagellated. Gram-stain-negative, but the cell wall is of the Gram-positive structure and covered by a hexagonal S-layer composed of 80 kDa subunits (Lupas et al., 1994). Endospores not observed. Colonies on agar plates are convex, circular, entire, translucent, tan in color, and have a smooth, shiny surface. After 1 week, colonies are 2 mm in diameter. Cells are catalase negative.

The temperature optimum is 66 °C, with growth occurring from 50–72 °C. Growth is obligately anaerobic and requires a reducing agent such as cysteine-sulfide in the medium. Small amounts of O₂ in semisolid and liquid media caused a lag phase but did not alter the ability of the bacterium to synthesize acetate via the Wood–Ljungdahl pathway of autotrophic acetyl-coenzyme A biosynthesis (Karnholz et al., 2002). The pH optimum is around 6.4, and the range is 5.3–7.3. Fermentable carbohydrates include glucose, mannose, fructose, and pyruvate. Acetic acid is the sole fermentation product, according to the reaction (Ryabokon et al., 1995): 1 glucose \rightarrow (2 acetate + 2 CO₂ + 4 H₂) \rightarrow 3 acetate. Galactose, malt-

ose, raffinose, ribose, sucrose, lactose, trehalose, cellobiose, cellulose, pectin, starch, mannitol, and inositol cannot serve as substrates. Chemolithoautotrophic growth is also possible with H₂ and CO₂, forming acetate as the product of CO₂ reduction. Under optimal conditions, the doubling time for chemolithoautotrophic growth is 1.75 h at 60 °C. Poor cell yields are obtained when H₂ is replaced with formate. Yeast extract and trypticase increase growth. Currently, *Thermoanaerobacter kivui* has only been isolated from the sediments of Lake Kivu, Africa, and was enriched with H₂ and CO₂ (67%: 33%, v/v) at 60 °C.

DNA G+C content (mol%): 38 (Bd).

Type strain: LKT-1, ATCC 33488, DSM 2030.

GenBank accession number (16S rRNA gene): L09160.

6. **Thermoanaerobacter mathranii** Larsen, Nielsen and Ahring 1998, 328^{VP} emend. Carlier, Bonne and Bedora-Faure 2006, 157 (Effective publication: Larsen, Nielsen and Ahring 1997, 118.)

ma.thra'ni.i. N.L. gen. n. *mathranii* of Mathrani, in honor of Indra M. Mathrani, who contributed to the understanding of thermophilic anaerobes from hot springs during his short career.

The species is composed of two subspecies, *Thermoanaerobacter mathranii* subsp. *mathranii* and *Thermoanaerobacter mathranii* subsp. *alimentarius*. The description of the species is the same as the subspecies.

- 6a. **Thermoanaerobacter mathranii subsp. mathranii** Larsen, Nielsen and Ahring 1998, 328^{VP} emend. Carlier, Bonne and Bedora-Faure 2006, 157 (Effective publication: Larsen, Nielsen and Ahring 1997, 118.)

Cells are straight rods, occurring singly and, under suboptimal conditions, in long chains, and are Gram-stain-variable although cell-wall structure is Gram positive. In the exponential growth phase, cells are 0.7 \times 1.8–3.9 μ m and motile. They form terminal, spherical spores that swell the sporangium. Cells are typically longer when either sporulating (6.4–8.2 μ m) or growing under suboptimal conditions, e.g., at a temperature of 75 °C. Colonies on agar plates are white and irregular, with a diameter of 1 mm after growth on beech wood xylan for 7 d. The surface of the colonies is granulated with “top formation” (Sonne-Hansen et al., 1993). The optimum growth temperature is around 70 °C, and no growth is observed at 47 or 78 °C. The pH optimum is 6.8–7.8. The lowest pH for which growth has been observed is 4.7, the highest pH is 8.8. Cells are catalase negative. The doubling time on xylose is 74 min at 69 °C and pH 7.0. Sulfide is produced from casein-peptone and sulfate. Carbohydrates that support growth include amygdalin, L-arabinose, cellobiose, D-fructose, D-glucose, glycogen, lactose, maltose, D-mannitol, mannose, melezitose, melibiose, raffinose, D-ribose, sucrose, trehalose, xylan, and D-xylose but not avicel, casein-peptone, cellulose, D-galactose, glycerol, inulin, pectin, L-rhamnose, salicin, sorbitol, or yeast extract. Its carbohydrate fermentation is represented by the simplified equation (Ahring et al., 1999): 1 xylose + H₂O \rightarrow 1.1 ethanol + 0.4 acetic acid + 0.06 lactic acid + 1.81 CO₂ + 0.9 H₂. Growth is inhibited by tetracycline, chloramphenicol, penicillin G, neomycin, or vancomycin (all at 100 mg/l). Growth occurs in the presence of 10 μ g/l of chloramphenicol or neomycin. *Thermoanaerobacter*

mathranii subsp. *mathranii* is not inhibited by 51 kPa overpressure of H₂, 2% NaCl, or addition of 5% (w/v) ethanol. When *Thermoanaerobacter mathranii* subsp. *mathranii* is grown with a wet-oxidized wheat straw hydrolysate, growth is inhibited, presumably due to aromatic monomers and breakdown products such as phenolic aldehydes and, to a lesser extent, phenol ketones (Klinke et al., 2001). Strain A3 was isolated from a mixed biomat and sediment sample taken from a slightly alkaline (pH 8.5) hot spring (70 °C) in Hverðagerdi-Hengil, Iceland (Sonne-Hansen et al., 1993) using beech wood xylan supplemented mineral medium at 68 °C and pH 8.4.

DNA G+C content (mol%): 37 (HPLC).

Type strain: A3, AIP 130-05, CIP 108742, DSM 11426.

GenBank accession number (16S rRNA gene): Y11279.

6b. **Thermoanaerobacter mathranii subsp. alimentarius** Carlier, Bonne and Bedora-Faure 2007, 1^{VP} (Effective publication: Carlier, Bonne and Bedora-Faure 2006, 157.)

a.li.men.ta'ri.us. L. adj. *alimentarius* related to food.

Cells stain Gram-stain-negative at all growth phases and are straight rods, 1.4–2.7 × 0.3–0.6 μm. Cells are motile by peritrichous flagella and occur singly or in long chains. Spores are never observed. Strict anaerobe. The optimum growth temperature is 55–60 °C, and the temperature range is 50–75 °C. Cells are catalase and nitrate reduction negative. Milk is coagulated. Gas is produced. Acid is produced from lactose and salicin. Substrates include arabinose, cellobiose, esculin, fructose, galactose, glucose, lactose, maltose, ribose, salicin, sucrose, and starch but not cellulose (Avicel), glycerol, inositol, mannitol, melezitose, melibiose, raffinose, or trehalose. Metabolic end products of carbohydrate fermentation in 3% trypticase-peptone/2% yeast extract medium are (in mM); ethanol (16), acetic acid (8), and lactic acid (55). Growth is observed at 2% (w/v) ethanol but not at 4%. The type strain AIP 505.99 was isolated at 55 °C from spoiled meat. In addition to the type, strain AIP 431.03 (= CIP 108191 = CCUG 49567) is also available (Carlier et al., 2006). GenBank accession numbers for *recA*, *hsp70* and *hsp60* are DQ422958, DQ431192 and DQ439967, respectively.

DNA G+C content (mol%): 31.5 (HPLC).

Type strain: AIP 505.99, CCUG 49566, CIP108280.

GenBank accession numbers (16S rRNA gene): AY701758.

7. **Thermoanaerobacter pseudethanolicus** Onyenwoke, Kevbrin, Lysenko and Wiegel 2007, 2192^{VP}

pseud'e.tha.no'li.cus. Gr. adj. *pseudēs* false; N.L. adj. *ethanolicus* a bacteria-specific epithet; N.L. masc. adj. *pseudethanolicus* a false (*Thermoanaerobacter ethanolicus*).

The description is based upon the properties of the type strain 39E as described by Lee et al. (1993). Cells are rod shaped and sporulate when grown with xylose. Cells stain Gram-stain-variable, but the wall is Gram positive in structure. Cells are motile. Strain 39E is usually grown in Tryptone-Yeast Extract-Glucose (TYEG) medium, pH 7.0. Details of the pH and temperature ranges not reported. The temperature optimum is around 65 °C. Substrates allowing heterotrophic fermentation include glucose, maltose, xylose, cellobiose, sucrose, and starch. H₂/CO₂ does not support growth. Thiosulfate is reduced to H₂S. The generation time is 75 min.

The Embden–Meyerhof–Parnas and the pentose-phosphate pathways are used during the catabolism of hexoses and pentoses to pyruvate, respectively (Zeikus et al., 1981). Fermented carbohydrates include xylose, cellobiose, starch, glucose, maltose, and sucrose. Glucose is consumed in preference to cellobiose (Ng and Zeikus, 1982). Zeikus et al. (1980) reported that the generalized fermentation products (μmol/ml) from 0.5% glucose growing in 10 ml TYEG medium are: 54.9 ethanol + 3.1 acetic acid + 5.0 lactic acid + 3.1 H₂. CO₂ was not reported, and the equation was not balanced.

Alpha, omega-dicarboxylic acids constitute 40% of the fatty acyl components of the membrane lipids (Jung et al., 1994). Yamamoto et al. (1998) reported the presence of MK-7 as major (>90%) menaquinone.

Ethanol tolerance is not temperature-dependent in the parental strain 39E, but it is in mutants (Burdette et al., 2002). Glucose is not fermented at an ethanol concentration of 2.0% (w/v) by strain 39E, but mutants ferment glucose at 45 °C and 8.0% ethanol and at 68 °C and 3.3% ethanol (Lovitt et al., 1984). The type strain 39E was isolated from the Octopus Spring algal-bacterial mat in Yellowstone National Park, Wyoming, USA at the same pool as *Thermoanaerobacter ethanolicus* JW200. The enrichment was performed at 65 °C in TYEG medium and modified TYEG medium, respectively, that contained 5% xylose instead of glucose.

In addition, strains X514, X531 and 561, which were previously designated *Thermoanaerobacter ethanolicus*, belong to this species (unpublished results; J. Zhou, personal communication; Roh et al., 2002). The genome sequences of 39E and X514 are available from the Joint Genome Institute.

DNA G+C content (mol%): 34 (from the genome sequence).

Type strain: 39E, ATCC 33223, DSM 2355.

GenBank accession number (16S rRNA gene): L09164.

8. **Thermoanaerobacter siderophilus** Slobodkin, Tourova, Kuznetsov, Kostrikina, Chernyh and Bonch-Osmolovskaya 1999b, 1477^{VP}

si.de.ro'phil.us. Gr. n. *sideros* iron; Gr. adj. *philos* loving; N.L. adj. *siderophilus* iron-loving.

Description is based on the type strain, which is the only available strain. Cells are straight to curved rods, 0.4–0.6 × 3.5–9.0 μm, that occur singly or in short chains. They stain Gram-positive and have a Gram-positive cell-wall structure. Round, refractile, heat-resistant spores are formed in terminally swollen sporangia. Maximum sporulation occurs during growth with 9,10-anthraquinone 2,6-disulfonic acid (AQDS) as an electron acceptor. Colonies in agar-shake-roll tubes are uniformly round, 0.5–1.0 mm in diameter, and white. Cells exhibit slight tumbling motility due to peritrichous flagellation. Obligate anaerobe.

Growth temperature range and optimum are 39–78 °C and 69–71 °C, respectively. The pH range and optimum for growth are 4.8–8.2 and 6.3–6.5, respectively. Substrates utilized in both the presence and absence of the electron acceptor Fe(III) include peptone, yeast extract, beef extract, casein, starch, glycerol, pyruvate, glucose, sucrose, fructose, maltose, xylose, cellobiose, and sorbitol but not formate, acetate, lactate, methanol, ethanol, propanol, 2-propanol, butanol, propionate, *n*-butyrate, succinate, malate, maleate, glycine, alanine, arginine, L-arabinose, olive oil, xylan, and

cellulose. Electron acceptors include amorphous iron(III) oxide, AQDS, sulfite, thiosulfate, elemental sulfur, and MnO_2 . The products of amorphous iron(III) oxide reduction are magnetite and siderite. Molecular hydrogen and CO_2 can be utilized for growth in the presence of Fe(III). Acetic acid is not produced during glucose fermentation. Sulfite and elemental sulfur are reduced to hydrogen sulfide. Nitrate, sulfate, and O_2 are not electron acceptors for growth. Growth is inhibited by chloramphenicol, neomycin, polymyxin B, and kanamycin (all at 100 $\mu\text{g}/\text{ml}$) but not by penicillin, ampicillin, streptomycin, or novobiocin (all at 100 $\mu\text{g}/\text{ml}$). Growth occurs with NaCl concentrations from 0–3.5% (w/v).

The Fe(III) reduction in *Thermoanaerobacter siderophilus* prevents the production of inhibitory concentrations of H_2 (Gavrilov et al., 2003). The type strain SR4 was isolated from a hydrothermal vent with a temperature of 70–94 °C in the area of the Karymsky volcano on the Kamchatka peninsula, Far East Russia. The anaerobic medium contained amorphous iron(III) oxide and peptone at a pH of 6.8–6.9 and 70 °C.

DNA G+C content (mol%): 32 (T_m).

Type strain: SR4, DSM 12299.

GenBank accession number (16S rRNA gene): AF120479.

9. **Thermoanaerobacter sulfurigignens** Lee, Dashti, Prange, Rainey, Rohde, Whitman and Wiegel 2007a, 1433^{VP}

sul.furi'gig.nens. L. n. *sulfur* sulfur, brimstone; L. part. adj. *gignere* producing; N.L. part. adj. *sulfurigignens* relating to the formation of sulfur droplets from thiosulfate.

This description is based on the type strain JW/SL-NZ826 and a second isolate, JW/SL-NZ824, from the same vicinity. Cells are rods, 0.3–0.8 \times 1.2–4.0 μm during exponential growth, motile by peritrichous flagella, and nonpigmented. They form round, terminal spores, 0.4–0.85 μm in diameter, during the late exponential or early stationary growth phase. Cells tend to be longer during the stationary phase, with lengths up to 35 μm being observed. Cells stain Gram-negative but have a Gram-positive cell-wall structure. Colonies in agar-shake-roll tubes are creamy white, circular, and 1–2 mm in diameter. The temperature range and optimum for growth at pH^{25C} are 34–74 °C and 63–65 °C, respectively. The pH^{25C} range and optimum for growth at 60 °C is 4.0–8.0 and 5.8–6.5, respectively. It grows at 90% of the optimal growth rate within the pH range of 4.8–6.5. Thus, it is one of the most acidophilic, thermophilic, anaerobic bacteria, comparable to *Thermoanaerobacterium acidotolerans* and *Thermoanaerobacterium aotearoense* (Wagner and Wiegel, 2008). Xylose, glucose, starch, lactose, galactose, maltose, fructose, sucrose, mannose, cellobiose, raffinose, pyruvate, methanol, and mannitol are fermented in the presence of 0.3% yeast extract. A generalized fermentation balance (in the presence of 0.3% yeast extract) is: 1 glucose \rightarrow 0.7 ethanol + 0.4 acetic acid + 0.9 lactic acid + 1.1 CO_2 + 0.8 H_2 . Ribose, arabinose, dextran, xylan, cellulose, glycerol, xylitol, formate, and gluconate are not fermented. The addition of 0.5% peptone, tryptone, casein hydrolysate, or Casamino acids in the presence of 0.3% yeast extract does not increase growth. Weak growth is observed with fumarate and succinate. Cells are catalase and indole negative. Sulfate and sulfite are not reduced.

Growth is inhibited by neomycin and chloramphenicol (100 $\mu\text{g}/\text{ml}$) and gramicidin (10 $\mu\text{g}/\text{ml}$). Cells are resistant to vancomycin, bacitracin, tetracycline, and ampicillin (all at 10 $\mu\text{g}/\text{ml}$), and kanamycin, streptomycin, cycloheximide, and cycloserine (all at 100 $\mu\text{g}/\text{ml}$). The strains tolerate up to 1.1 M thiosulfate and 90 mM sulfite, presumably a response to the conditions of the sulfuriferous environment from which they were isolated. The type strain JW/SL-NZ826 was isolated from an acidic volcanic stream outlet on White Island, New Zealand, at 60 °C and pH^{25C} of 5.0–5.5 using a pre-reduced mineral medium supplemented with 20 mM thiosulfate, 0.5% (w/v) yeast extract and 0.5% (w/v) xylose.

DNA G+C content (mol%): 34.5 (HPLC).

Type strain: JW/SL-NZ826, ATCC 700320, DSM 17917.

GenBank accession number (16S rRNA gene): AF234164.

10. **Thermoanaerobacter sulfurophilus** Bonch-Osmolovskaya, Miroschnichenko, Chernykh, Kostrikina, Pikuta and Rainey 1998, 631^{VP} (Effective publication: Bonch-Osmolovskaya, Miroschnichenko, Chernykh, Kostrikina, Pikuta and Rainey 1997, 488.)

sul.fu.ro.phi'lus. L. n. *sulfur* sulfur; Gr. masc. adj. *philos*-lik-ing; N.L. masc. adj. *sulfurophilus* liking elemental sulfur.

The description is based on the type strain L-64 and other isolates from the same origin, including P-82, G-1, and L-64. Cells stain Gram-stain-positive and have Gram-positive wall structure. They are curved rods, 0.5 \times 3–7 μm . In older or nutrient deficient cultures, cells occur in long chains with interspersed coccoid cells. Spores are not observed. Sluggish motility through peritrichous flagella. The temperature range and optimum for the growth are 44–75 °C and 55–60 °C, respectively. The pH range and optimum for growth are 4.5–8.0 and 6.8–7.2, respectively. Obligate anaerobe. Fermentable carbohydrates include glucose, fructose, lactose, rhamnose, arabinose, xylose, sorbitol, inositol, mannitol, sucrose, cellobiose, maltose, starch, pectin, pyruvate, and lactate. Cellulose, succinate, citrate, formate, acetate, propionate, butyrate, methanol, ethanol, and H_2 (in the presence or absence of elemental sulfur) do not support growth. Elemental sulfur stimulates growth and is reduced to sulfide. Fermentation products while growing on 0.5% (w/v) lactate (utilized amount not determined) using S^0 as the electron acceptor were (in $\mu\text{mol}/\text{ml}$ of culture): 3.0 H_2S + 0.14 acetic acid + 0.2 H_2 + CO_2 (not quantified).

Nitrate, sulfate, and sulfite are not reduced. The type strain L-64 was isolated from a sulfur-containing cyanobacterial mat occurring along the rim of a hot (53–58 °C) pond at the Uzon caldera, Kamchatka. The enrichment medium contained peptone, glucose, and lactate and was incubated at 55 °C and pH 7.0 (Bonch-Osmolovskaya et al., 1997).

DNA G+C content (mol%): 30–31 (T_m).

Type strain: L-64, DSM 11584.

GenBank accession number (16S rRNA gene): Y16940.

11. **Thermoanaerobacter thermocopriae** (Jin, Yamasato and Toda 1988) Collins, Lawson, Willems, Cordoba, Fernández-Garayzábal, Garcia, Cai, Hippe and Farrow 1994, 824^{VP} (*Clostridium thermocopriae* Jin, Yamasato and Toda 1988, 280)

ther.mo.co'pri.ae. Gr. adj. *thermos* hot; Gr. n. *kopria* compost; N.L. gen. n. *thermocopriae* relating to the isolation from compost at elevated temperature.

Description is based upon the type strain (Jin et al., 1988). Cells are sluggishly motile, straight rods, $0.5\text{--}0.7 \times 2.2\text{--}6.0 \mu\text{m}$, and produce terminal, spherical spores with a diameter of $1.2\text{--}1.6 \mu\text{m}$ that swell the sporangium. Cells stain Gram-negative but have Gram-positive wall structure. The temperature range and optimum for growth is $47\text{--}74^\circ\text{C}$ and 60°C , respectively. The pH range and optimum for growth is $6.0\text{--}8.0$ and $6.5\text{--}7.3$, respectively. The bacterium is an obligate anaerobe and has a broad substrate specificity for numerous carbohydrates, including cellulose, hemicellulose, cellobiose, glucose, fructose, maltose, arabinose, lactose, trehalose, glycogen, starch, amygdalin, xylan, and mannose but not melibiose, pectin, inulin, or mannitol. The ratio of fermentation products from cellobiose is $0.8\text{--}4.0$ butyric acid + $0.3\text{--}1.7$ acetic acid + <0.8 lactic acid + $2\text{--}5$ ethanol + H_2S (not quantified).

Esculin is hydrolyzed. Indole is not produced, gelatin is not digested, and nitrate is not reduced. The type strain JT3-3 was isolated from a compost of camel feces. Other strains have been isolated from soil and hot springs in Japan (The University of Tokyo and Kinugawa) following anaerobic enrichment with cellobiose- or cellulose-containing medium at 60°C and pH 7.1. In addition to the type, other strains that have been described include strains JT1, JT2, JT3-1, JT3-2, JT5 (Jin and Toda, 1987, 1988).

DNA G+C content (mol%): 37.2 (T_m).

Type strain: JT3-3, ATCC 51646, IAM 13577, JCM 7501.

GenBank accession number (16S rRNA gene): L09167.

12. **Thermoanaerobacter thermohydrosulfuricus** (Klaushofer and Parkkinen, 1965) Lee, Jain, Lee, Lowe and Zeikus 1993, 49^{VP} (*Clostridium thermohydrosulfuricum* Klaushofer and Parkkinen 1965, 448)

ther.mo.hy.dro.sul.fur'i.cus. Gr. masc. adj. *thermos* hot; N.L. masc. adj. *hydrosulfuricum* pertaining to hydrogen sulfide formation; N.L. masc. adj. *thermohydrosulfuricus* indicating that the organism grows at high temperatures and reduces sulfite to H_2S .

This description is based on the type strain E100-69 (Hollaus and Sleytr, 1972) and strain JW102 (Wiegel et al., 1979). Cells are $0.3\text{--}0.6 \times 2.0\text{--}13.0 \mu\text{m}$ and motile by peritrichous flagella. Cells occur singly, in short chains, or, in some strains, as long, filaments with cells up to $40 \mu\text{m}$ in length. As shown by freeze fracture planes, the core of flagella are empty, possibly for the transport of flagellin molecules during assembly (Sleytr and Glauert, 1973). Spores are spherical and terminal. The mother cells are terminally swollen and elongated, resembling a drum stick. Cells stain Gram-variable but have a Gram-positive cell wall composed of two layers and *meso*-diaminopimelic acid. The cell wall is covered by a hexagonal S-layer consisting of 14.2 nm center-to-center spaced gly-

coprotein units (Bock et al., 1994; Crowther and Sleytr, 1977; Messner et al., 1995; Sára and U.B. Sleytr, 1996). The molecular mass of the glycoprotein is about 20,000 (Christian et al., 1988; Sára et al., 1989). The cells are catalase negative.

Obligate anaerobe. Growth occurs at a pH range and optimum of $5.5\text{--}9.2$ and $6.9\text{--}7.5$, respectively. The optimum growth temperature is $67\text{--}69^\circ\text{C}$, with no growth occurring at $76\text{--}78^\circ\text{C}$. Growth at 37°C is poor, and no growth is observed at or below 35°C . H_2 at 10% (v/v) in the head space and lactate at $>30 \text{ mM}$ inhibit growth (Wiegel et al., 1979). Fructose, galactose, glucose, mannose, xylose, cellobiose, maltose, sucrose, trehalose, pectin, esculin, and salicin are fermented. Yeast extract is required for growth and for metabolic activity (Wiegel et al., 1979). Growth with PYG medium yields H_2 , CO_2 , acetic acid, lactic acid, and ethanol as well as trace amounts of formate, butyrate, isovalerate, isocaproate, propanol, and 2-propanol. Glucose fermentation in the presence of 0.2% yeast extract is described by the simplified equation: $1 \text{ glucose} + 0.5 \text{ H}_2\text{O} \rightarrow 1 \text{ ethanol} + 0.5 \text{ acetic acid} + 0.5 \text{ lactic acid} + 1.5 \text{ CO}_2 + \text{H}_2$. Fermentation of dextrin, potato starch, mannitol, dulcitol, and sorbitol and coagulation of litmus milk are variable. Inositol, erythritol, glycerol, lactate, tartrate, and cellulose are not fermented. Sulfite is reduced to hydrogen sulfide, but sulfate is not reduced. H_2S is produced from tryptone, peptone, and yeast extract. Nitrate, but not nitrite, is reduced. Acetyl methyl carbinol and indole are not produced. Strains of *Thermoanaerobacter thermohydrosulfuricus* have been isolated from many sources, including extraction juices of beet sugar factories (E100-69^T; L 110-69 = DSM 568; L 77-66 = DSM 569; S 100-69 = DSM 570; Klaushofer and Parkkinen, 1965; Hollaus and Klaushofer, 1973), mesobiotic mud and soil (Klingeberg et al., 1990; Wiegel et al., 1979), hot springs in Utah and Wyoming, USA, a sewage plant in Georgia, USA (JW102 = DSM 2247; Wiegel et al., 1979), a sugar refinery in Germany (DSM 7021 and DSM 7022; Klingeberg et al., 1990), household dust (Wiegel, unpublished results) and in co-culture with *Clostridium thermocellum* (YM3; Mori, (1990, 1995).

Major lipid fatty acids found in the type strain are 42% $\text{C}_{15:0 \text{ iso}}$ and 23% $\text{C}_{17:0 \text{ iso}}$. MK-7 is the major menaquinone.

The ubiquitous distribution of *Thermoanaerobacter thermohydrosulfuricus* in mesobiotic and in geothermally and anthropogenically heated or thermobiotic environments may be partly due to its ability to form spores and its wide substrate spectrum.

DNA G+C content (mol%): 35–37 (T_m , Bd, HPLC).

Type strain: E100-69, ATCC 35045, DSM 567, LMG 6659, NCIMB 10956.

GenBank accession number (16S rRNA gene): L09161.

13. **Thermoanaerobacter wiegeli** Cook, Rainey, Patel and Morgan 1996, 126^{VP}

wie.gel'i.i. N.L. gen. n. *wiegeli* of Juergen Wiegel, in recognition of his contributions to the study of thermophilic anaerobes.

Cells grown on solid trypticase peptone-yeast extract-glucose (TYEG) medium produce nonpigmented colonies, 0.5–2.0 mm in diameter, that are smooth and uniformly round. Cells stain Gram-stain-negative but have Gram-positive cell-wall structure. Rod-shaped cells, 0.4–0.6 $\mu\text{m} \times 4$ –10 μm , that occur singly, in pairs, or less frequently in chains depending upon growth conditions. Electron micrographs of the cell wall reveal a two-layer structure. The inner layer, which is adjacent to the cytoplasmic membrane, stains intensely, whereas the outer layer is less dense. Cells are usually sluggishly motile by less than 8 peritrichous flagella. Cells growing on TYEG medium do not sporulate. However, in a minimal medium at 65 °C, round spores are produced in elongated and filamentous, terminally distended cells. Spore suspensions remain viable after 80 min at 115 °C.

Obligate anaerobe. Growth occurs at pH 5.5–7.2 but not at pH 5.0 or 7.25. The pH optimum is 6.8. The growth temperature range and optimum are 38–78 °C and 65–68 °C, respectively. Cultures do not grow at 34 or 80 °C. Yeast extract and trypticase are not required for growth and can be replaced by vitamin-free Casamino acids and vitamins. Trypticase, peptone, and yeast extract do not serve as sole carbon sources. Carbohydrates that are utilized include glucose, xylose, maltose, lactose, cellobiose, raffinose, glucosamine, galactose, fructose, mannose, sucrose, glycerol, soluble starch, pectin, and chitin. Sorbitol, mannitol, and trehalose are also fermented, but ethanol, DL-lactate, sodium citrate, sodium succinate, transaconitate, malonate, glutamate, glutamine, sodium pyruvate, 2-deoxyglucose, α -methyl-glucoside, L-arabinose, α -L-rhamnose, dulcitol, *m*-inositol, ribose, α -L-fucose, and L-sorbose are not. The doubling time on glucose is 72 min. Similar to *Thermoanaerobacter ethanolicus* and *Thermoanaerobacter thermohydrosulfuricus*, glucose and xylose are used simultaneously when supplied together (Carreira et al., 1983; Cook et al., 1996). Propionate, an unusual fermentation product for a member of this genus, is formed during growth on xylose and cellobiose.

Sulfite is reduced to hydrogen sulfide. Nitrate, oxygen, sulfate, and sulfur are not reduced. Indole is not produced, and esculin and gelatin are not hydrolyzed. Cells do not accumulate anthrone-reactive material when they are grown with glucose.

Cephalosporin C, erythromycin, bacitracin, tetracycline, and polymyxin B completely inhibit growth (all at 10 $\mu\text{g}/\text{ml}$). Trimethoprim, rifampin, amphotericin B, D-cycloserine, penicillin G, streptomycin sulfate, chloramphenicol, and ampicillin do not inhibit growth at concentrations up to 100 $\mu\text{g}/\text{ml}$. Monensin (100 mM), 2,4-dinitrophenol (500 mM), tetrachlorosalicylanilide (10 mM), *N,N*-dicyclohexylcarboimide (500 mM) and iodoacetate (500 mM), sodium azide, sodium fluoride, potassium cyanide, and sodium arsenate (all at final

concentrations of 5 mM) inhibit growth of exponentially growing cultures with glucose as carbon and energy source. The presence of oxygen completely inhibits growth.

The type strain Rt8.B1 was isolated from neutral to alkaline, geothermally heated water (56–69 °C) in Government Gardens, Rotorua, New Zealand. The primary enrichment cultures were prepared by adding 0.2 ml of pool water to 10 ml of prerduced TYEG medium under an N_2 atmosphere and were incubated at 70 °C. Purification involved the use of TYEG agar deeps.

DNA G+C content (mol%): 35.6 (HPLC).

Type strain: Rt8.B1, DSM 10319.

GenBank accession number (16S rRNA gene): X92513.

Other named isolates

1. “*Thermoanaerobacter keratinophilus*” Riessen and Antranikian 2001, 406

ke.ra.ti.no'phil.us. Gr. n. *keras* keratin; Gr. adj. *philos* loving; N.L. adj. *keratinophilus* keratin-loving.

Taxonomic note: The only strain of this species is covered by a patent with a restricted distribution and thus cannot be a type strain. Hence, the name is not validly published.

Exponential growth phase cells are slightly curved rods, 0.2–0.3 \times 1–3.0 μm , and occur singly, in pairs or in short chains. Cells stain Gram-negative regardless of the growth phase but have Gram-positive cell-wall structure. Stationary growth phase cells are pleomorphic, and some form filaments 10–15 μm in length. Asymmetric cell division leads to formation of coccoid cells. Does not form spores. Temperature range and optimum for growth are 50 to just below 80 °C and 70 °C, respectively. The pH range and optimum are pH 5.0–9.0 and 7.0, respectively. The range and optimal NaCl concentration for growth are 0–30 g/l and 5–10 g/l, respectively. Growth is fermentative and obligately anaerobic. Yeast extract plus tryptone, both at 0.05% (w/v), are required for growth on carbohydrates. Under optimal conditions in the presence of 0.5% each of yeast extract and tryptone, the doubling time is 67 min. Utilized substrates include casein, bactopectone, yeast extract, tryptone, collagen, gelatin, starch, pectin, glucose, fructose, galactose, mannose, pyruvate, maltose, and cellobiose but not xylan, cellulose, pullulan, xylose, arabinose, lactose, or olive oil. Growth can be achieved solely with merino wool or chicken feathers. Thiosulfate and sulfate both serve as electron acceptors. Thiosulfate stimulates growth to approximately threefold that of sulfate but is not required for growth. Ampicillin, kanamycin, and streptomycin inhibit growth at 10 $\mu\text{g}/\text{ml}$. Strain 2KXI was isolated from a hydrothermal vent (74 °C, pH 6.0) in the area of Furnas on the Azorean island São Miguel using merino wool and chicken feathers as substrates. The incubation temperature was 70 °C.

DNA G+C content (mol%): 37.6 (HPLC).

Proposed type strain: 2KXI, DSM 14007.

GenBank accession number (16S rRNA gene): AY278483.

Genus II. **Ammonifex** Huber and Stetter 1996, 836^{VP} (Effective publication: Huber, Rossnagel, Woese, Rachel, Langworthy and Stetter 1996, 47.)

ROBERT HUBER

Am.mo'ni.fex. L. neut. n. *sal ammoniacum* salt of Ammon (NH₄Cl); L. v. *facere* to make; N.L. masc. n. *Ammonifex* the ammonium-maker.

Rod-shaped, straight or slightly curved cells with rounded ends, usually about 2–3 × 0.6 μm. The cells occur singly, in pairs, and in short chains of up to six cells. Complex cell envelope. **Muramic acid present; diaminopimelic acid absent.** Nonsporulating. **Gram-stain-negative.** Motile by terminal and lateral flagellation. Core lipids consist mainly of (non-phytanyl) ether lipids and fatty acid methyl esters. Sensitive to lysozyme and antibiotics. Extremely thermophilic. Growth between 57 °C and 77 °C (optimum 70 °C), pH 5.0 and 8.0 (optimum 7.5), and 0–1.5% NaCl (optimum 0.1%). Growth occurs on solid surfaces. **Strictly anaerobic. Autotrophic growth by oxidation of hydrogen and reduction of nitrate, sulfate, or sulfur.** Nitrate ammonification. Facultatively chemolithoautotrophic. Based on 16S rDNA analysis, *Ammonifex* belongs to the low G+C subgroup of the Gram-stain-positive bacteria.

DNA G+C content (mol%): 54.

Type species: Ammonifex degensii Huber and Stetter 1996, 836^{VP} (Effective publication: Huber, Rossnagel, Woese, Rachel, Langworthy and Stetter 1996, 47.).

Further descriptive information

Phylogenetic analysis by 16S rRNA gene sequence comparison shows that the genus *Ammonifex* is a member of the Gram-stain-positive bacteria where it represents a separate lineage (Huber et al., 1996).

Cells of *Ammonifex degensii* were Gram-stain-negative, straight or slightly curved rods with rounded ends, and exhibited terminal and lateral flagellation (Figure 247). After treatment with lysozyme, the rods appear granular within one minute, however, the cell morphology remains stable. Ultrathin sections revealed a cytoplasmic membrane (width: 5.0 nm) and a rather complex cell wall with a total width of 40 nm. The cell wall consists of a peptidoglycan layer (width: 10 nm) and a surface layer with a zig-zag profile (width: 15 nm; periodicity 9.0 nm) covered by a 15 nm thick strongly contrasted surface coat. The isolated surface layer was composed of protein complexes arranged on a p4 lattice (center to center distance: 11.0 nm).

Three polar lipid compounds have been identified in *Ammonifex degensii*: glycerol diethers (85%), glycerol monoethers, and fatty acid methyl esters. In total, a series of nine glycerol diethers with C₁₆:C₁₆ (34%), C₁₆:C₁₇ (18%), and C₁₇:C₁₇ (20%) side chains as major components have been detected. In addition, a series of monoethers with C₁₅ (21%) and C₁₆ (62%) alkyl chain monoethers as the major constituents have been identified. The identity and distribution of the *O*-alkyl side chains of the diethers and monoethers is shown in Table 245. The fatty acids have a composition similar to the *O*-alkyl chains of the diethers and monoethers consisting of C_{14:0} (0.6%), C_{15:0} (13.9%), C_{15 ante} (5.4%), C_{15:0} (0.6%), C_{16:0 iso} (12.5%), C_{16:0} (25.5%), C_{17:0 iso} (13.5%), C_{17:0 ante} (20.0%), C_{17:0} (1.4%), C_{18:0 ante} (1.2%), and C_{18:0} (4.2%) fatty acids. The structure of the glycerol mono- and diethers of *Ammonifex degensii* were very similar

FIGURE 247. Transmission electron micrograph of a single, flagellated cell of *Ammonifex degensii*, platinum-shadowed. Bar = 1 μm.

TABLE 245. Distribution of the *O*-alkyl hydrocarbon chains of the glycerol diethers and glycerol monoethers of *Ammonifex degensii*

Carbon number	Compound	Diether (relative %)	Monoether (relative %)
C14	iso-Tetradecane	0.2	0.6
C14	Tetradecane	1.4	4.4
C15	iso-Pentadecane	7.7	14.2
C15	anteiso-Pentadecane	4.1	6.4
C15	Pentadecane	1.7	2.9
C16	iso-Hexadecane	27.5	32.9
C16	Hexadecane	32	29.1
C17	iso-Heptadecane	6.1	2.4
C17	anteiso-Heptadecane	14.9	4.8
C17	Heptadecane	1.2	0.7
C18	anteiso-Octadecane	0.7	0.4
C18	Octadecane	2.5	1.2

to the lipids known from the extremely thermophilic sulfate-reducer *Thermodesulfobacterium commune* (Langworthy et al., 1983). No isoprenoid glycerol ethers or isoprenoid side chains characteristic of archaeal glycerol ether lipids were detected in *Ammonifex degensii*.

Ammonifex degensii grows autotrophically by oxidation of hydrogen and reduction of nitrate with maximal cell densities up to 5 × 10⁸ cells/ml (10 mmol/l KNO₃, final concentration). Stoichiometric amounts of nitrate and hydrogen consumption versus ammonium production have been determined (Thauer et al., 1977) according to the equation: NO₃⁻ + 2 H⁺ + 4 H₂ → NH₄⁺ + 3 H₂O. NO₂⁻, NO, N₂O, and N₂ are not detected. Instead of nitrate, sulfate or sulfur is used as the electron acceptor and H₂S is formed as the end product (3–5 μmol H₂S/10⁸ cells in the presence of sulfate). Instead of hydrogen, *Ammonifex degensii* is able to use formate as the electron donor in the presence of nitrate or sulfate. Depending on the electron acceptor, ammonium or H₂S is formed.

In the absence of a suitable external electron acceptor, pyruvate is fermented to hydrogen and to stoichiometric amounts of acetate and CO₂. Addition of 0.1% potassium phosphate stimulates growth and CO₂ in the medium is essential. The same products are formed when nitrate or sulfate is added to the medium indicating a fermentation of pyruvate also in the presence of an external electron acceptor.

In combination with formate, thiosulfate, pyruvate (each 0.05%, final concentration), or hydrogen (300 kPa H₂/CO₂; 80:20; v/v), no growth is observed under microaerophilic conditions in the presence of oxygen (0.02, 0.1, 0.5, 2% tested). Furthermore, no growth is obtained with hydrogen as electron donor and KNO₂, Na₂S₂O₃, Na₂SO₃, FeCl₃, Na₂Se₄O₄, MnCl₂, or fumarate as possible electron acceptors (0.01 and 0.1% tested). In addition, no growth is observed with nitrate in combination with 0.5% S⁰, 0.1% Na₂SO₃, or 0.05% Na₂S₂O₃. *Ammonifex degensii* is also unable to grow under a 300 kPa N₂/CO₂ atmosphere (80:20, v/v) with 0.1% KNO₃ as electron acceptor in the presence of benzoate, meat extract, peptone, yeast extract (each 0.01%, final concentration), ethanol, 2-propanol, acetate, propionate, succinate, formamide, formaldehyde, fumarate, DL-malate, L(+)-lactate, butyrate, D(+)-glucose, maltose, glycogen, or Casamino acids (each 0.05%, final concentration).

Growth of *Ammonifex degensii* was inhibited by addition of ampicillin, chloramphenicol, gentamicin, hygromycin, kanamycin, neomycin, penicillin, phosphomycin, rifampin, and vancomycin (each 10 µg/ml; final concentration).

Ammonifex degensii has been isolated only once from sample KC4, obtained during a land expedition of R/V Sonne cruise in Indonesia (Huber et al., 1991, 1992). The sample was taken anaerobically within the Kawah Candradimuka crater (Dieng Plateau, Java) from the flux of a strongly gassed, grayish water hole with a diameter of about 6 m. Sample KC4 consisted of a mixture of water and grayish and black sedi-

ment; the original temperature was 80 °C, the original pH was 7.5 (Huber et al., 1996).

Enrichment and isolation procedures

For the enrichment and isolation of *Ammonifex degensii*, the anaerobic technique of Balch and Wolfe (1976) is suitable. Modified medium 1 supplemented with 0.1% sodium nitrate (Balch et al., 1979), a pH of 7.5, a gas phase of 300 kPa H₂/CO₂ (80:20, v/v), and an incubation temperature of 75 °C is recommended (Huber et al., 1996). Single colonies of *Ammonifex degensii* can be obtained by plating under anaerobic conditions using a stainless-steel anaerobic jar (Balch et al., 1979) and plates and solidified by addition of 2% agar. White, round colonies about 1 mm in diameter will be formed after anaerobic incubation for about 14 d at 75 °C under a H₂/CO₂ atmosphere (200 kPa; 80:20, v/v). Packed cells obtained from large-scale fermentations exhibited an olive green appearance.

Maintenance procedures

Ammonifex degensii can be stored long-term in liquid nitrogen at -140 °C in the presence of 5% dimethylsulfoxide.

Differentiation of the genus *Ammonifex* from other genera

From other closely related taxa, *Ammonifex degensii* can be phylogenetically differentiated by comparison of the 16S rDNA sequences. Furthermore, *Ammonifex degensii* is unique by its metabolic flexibility i.e., the anaerobic growth under autotrophic conditions with hydrogen as the electron donor and nitrate, sulfate, or sulfur as the electron acceptor.

List of species of the genus *Ammonifex*

1. ***Ammonifex degensii*** Huber and Stetter 1996, 836^{VP} (Effective publication: Huber, Rossnagel, Woese, Rachel, Langworthy and Stetter 1996, 47.)
de.gen'si.i. N.L. gen. n. *degensii* of Degens honoring Egon T. Degens.

Description is the same as for the genus.
DNA G+C content (mol%): 53 (T_m) and 55.5 (HPLC).
Type strain: KC4, DSM 10501.
GenBank accession number (16S rRNA gene): U34975.

Genus III. ***Caldanaerobacter*** Fardeau, Bonilla-Salinas, L'Haridon, Jeanthon, Verhé, Cayol, Patel, Garcia and Ollivier 2004, 471^{VP}

MARIE-LAURE FARDEAU, BERNARD OLLIVIER AND JEAN-LUC CAYOL

Cald.an.ae.ro.bac'ter. L. adj. *caldu*s hot; Gr. pref. *an* not; Gr. n. *aer* air; N.L. masc. n. *bacter* equivalent of Gr. neut. dim. n. *bakterion* rod, staff; N.L. masc. n. *Caldanaerobacter* a rod that grows in the absence of air at high temperatures.

Cells are **straight rods** that stain **Gram-positive or negative**. Endospores may be observed. **Strictly anaerobic heterotrophs**. Acetate and **L-alanine** are major end products of glucose fermentation, with approximately 1 mol of L-alanine being produced per mol of glucose. **Thermophilic** member of the family *Thermoanaerobacteraceae*.

DNA G+C content (mol%): 33–41.

Type species: ***Caldanaerobacter subterraneus*** (Fardeau, Magot, Patel, Thomas, Garcia and Ollivier 2000) Fardeau, Bonilla-Salinas,

L'Haridon, Jeanthon, Verhé, Cayol, Patel and Garcia 2004, 471^{VP} (*Thermoanaerobacter subterraneus* Fardeau, Magot, Patel, Thomas, Garcia and Ollivier 2000, 2145).

Further descriptive information

Members of *Caldanaerobacter* were originally classified in the genera *Thermoanaerobacter* (e.g., *Thermoanaerobacter subterraneus*, *Thermoanaerobacter yonseiensis* and *Thermoanaerobacter tengcongensis*; Fardeau et al., 2000; Kim et al., 2001; Xue et al.,

2001) or *Carboxydibrachium* (e.g., *Caldanaerobacter pacificum*; Sokolova et al., 2001). On the basis of phylogenetic, phenotypic, and metabolic characteristics, all of these species were reclassified within *Caldanaerobacter* as different subspecies of *Caldanaerobacter subterraneus*, the only representative of this genus so far characterized. A remarkable metabolic feature of these organisms is their ability to ferment glucose to L-alanine in nearly equal molar amounts. Most strains grow at 80 °C and are, therefore, considered extreme thermophiles. They all require yeast extract for growth, and several subspecies oxidize CO to CO₂ and H₂. Strains may be isolated from hot terrestrial and subterrestrial ecosystems as well as deep-sea hydrothermal vents.

Enrichment and isolation procedure

These strict anaerobes are cultivated using Hungate techniques (Hungate, 1969). Enrichments of *Caldanaerobacter* can be obtained on media containing yeast extract and sugars as energy sources (Fardeau et al., 2000; Kim et al., 2001; Xue et al., 2001). CO may also be utilized (Sokolova et al., 2001). They may require a seawater-based medium, depending on their source of isolation (Sokolova et al., 2001).

One typical *Caldanaerobacter* medium is as follows (per liter of distilled water): 1 g of NH₄Cl, 0.3 g of K₂HPO₄, 0.3 g of KH₂PO₄, 0.1 g of CaCl₂·2H₂O, 0.2 g of KCl, 0.5 g of MgCl₂·6H₂O, 2.0 g of yeast extract, 2.0 g of bio-Trypticase, 10.0 g of NaCl, 3.6 g of glucose, 0.5 g of cysteine-HCl, and 10 ml of trace element solution (Balch et al., 1979). The NaCl concentration can be increased up to 18 g/l for recovering marine isolates, and CO may replace sugars as the energy source (Sokolova et al., 2001). The pH is adjusted to 7.0 with 10 M KOH, and the medium is autoclaved for 45 min at 110 °C. Prior to inoculation, Na₂S·9H₂O and NaHCO₃ are added from sterile stock solutions.

Maintenance procedure

Anaerobic cultures can be maintained for at least one year in basal medium plus 20% glycerol at -80 °C or plus 50% glycerol at -20 °C.

Differentiation of the genus *Caldanaerobacter* from other genera

Caldanaerobacter may be distinguished from *Thermoanaerobacter* by differences in the sequences of their 16S rRNA genes (mean sequence similarity of 92–95%), differences in the mol% G+C contents of their DNA, and the ability to produce large amounts of L-alanine during the glucose fermentation.

Taxonomics comments

These subspecies of *Caldanaerobacter subterraneus* (*Caldanaerobacter subterraneus* subsp. *subterraneus*, *Caldanaerobacter subterraneus* subsp. *tengcongensis*, *Caldanaerobacter subterraneus* subsp. *yonseiensis*, and *Caldanaerobacter subterraneus* subsp. *pacificus*) constitute a distinct phylogenetic lineage within the family *Thermoanaerobacteraceae* (Figure 248). For instance, the 16S rRNA gene of *Caldanaerobacter subterraneus* subsp. *subterraneus* possesses 97.2, 97.7, and 98.2% sequence similarity with the genes of *Caldanaerobacter subterraneus* subsp. *pacificus*, *Caldanaerobacter subterraneus* subsp. *tengcongensis*, and *Caldanaerobacter subterraneus* subsp. *yonseiensis*, respectively. Similarly, DNA–DNA similarity values between these subspecies all exceed 68%. Despite these molecular similarities, the phenotypes of these subspecies are significantly different, especially the mol% G+C contents of their DNA and their ability to oxidize CO (Table 246).

Differentiation of the species of the genus *Caldanaerobacter*

Only one species, *Caldanaerobacter subterraneus*, with four subspecies is currently known.

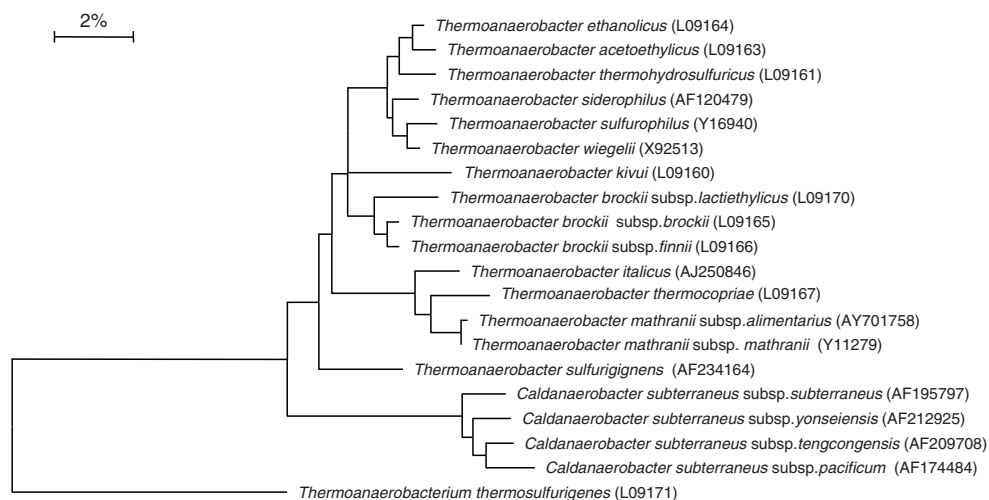

FIGURE 248. Phylogeny of *Caldanaerobacter subterraneus* and *Thermoanaerobacter* species. The phylogenetic tree of the 16S rRNA genes was constructed by the neighbor-joining method using the type species of *Thermoanaerobacterium* as outgroup. Bar indicates 2% inferred substitutions.

^fIn addition to L-alanine, acetate, H₂, and CO₂, which are produced by all subspecies from glucose.

List of species of the genus *Caldanaerobacter*

1. ***Caldanaerobacter subterraneus*** (Fardeau, Magot, Patel, Thomas, Garcia and Ollivier 2000) Fardeau, Bonilla-Salinas, L'Haridon, Jeanthon, Verhé, Cayol, Patel and Garcia 2004, 471^{VP} (*Thermoanaerobacter subterraneus* Fardeau, Magot, Patel, Thomas, Garcia and Ollivier 2000, 2145.)

sub.ter.ra'ne.us. L. masc. adj. *subterraneus* underground, subterranean, describing its site of isolation.

Same description as that given for the genus. L-alanine, acetate, lactate, H₂, and CO₂ are produced during glucose fermentation.

DNA G+C content (mol%): 38.4–41 (HPLC).

Type strain: ATCC BAA-225, DSM 13054, CNCM I-2383, SEBR 7858.

GenBank accession number (16S rRNA gene): AF195797, AF174484, AF209708, and AF212925.

- 1a. ***Caldanaerobacter subterraneus* subsp. *subterraneus*** (Fardeau, Magot, Patel, Thomas, Garcia and Ollivier 2000) Fardeau, Bonilla-Salinas, L'Haridon, Jeanthon, Verhé, Cayol, Patel and Garcia 2004, 471^{VP} (*Thermoanaerobacter subterraneus* Fardeau, Magot, Patel, Thomas, Garcia and Ollivier 2000, 2145.)

Rods (0.5–0.7 × 2–8 μm) that occur singly or in pairs and possess laterally inserted flagella. Spores are not observed, but cultures exposed to 120 °C for 45 min retain viability, indicating the presence of heat-resistant forms. Electron microscopic examination reveals a Gram-positive type cell wall. Round colonies (3 mm in diameter) develop on Phytagel plates or in roll-tubes after 3 d of incubation at 70 °C. Obligately anaerobic chemo-organotroph. Thermophilic. Optimum temperature for growth is 65–75 °C; temperature range is 40–80 °C. Optimum pH is 7.0–7.5; the pH range is 5.7–9.2. Halotolerant; grows in the presence of up to 3% NaCl. Either yeast extract or bio-Trypticase is required for growth on carbohydrates, and both compounds together greatly enhance growth. Yeast extract cannot be replaced by vitamins. Ferments cellobiose, D-fructose, D-galactose, D-glucose, DL-lactose, DL-maltose, D-mannose, melibiose, D-ribose, starch, D-xylose, glycerol, mannitol, pyruvate, and

xylan. L-alanine, acetate, lactate, H₂, and CO₂ are produced during glucose fermentation. Elemental sulfur, thiosulfate, and sulfite, but not sulfate, are used as electron acceptors. The type strain was isolated from oilfield water located in southwest France.

DNA G+C content (mol%): 41 (HPLC).

Type strain: ATCC BAA-225, CNCM I-2383, DSM 13054, SEBR 7858.

GenBank accession number (16S rRNA gene): AF195797.

- 1b. ***Caldanaerobacter subterraneus* subsp. *pacificus*** (Sokolova, González, Kostrikina, Chernyh, Tourova, Kato, Bonch-Osmolovskaya and Robb 2001) Fardeau, Bonilla-Salinas, L'Haridon, Jeanthon, Verhé, Cayol, Patel and Garcia 2004, 54^{VP} (*Carboxydobrachium pacificum* Sokolova, González, Kostrikina, Chernyh, Tourova, Kato, Bonch-Osmolovskaya and Robb 2001, 147.)

pa.ci'fi.cus. L. masc. adj. *pacificus* peaceful; pertaining to the Pacific Ocean, the eastern part of which is the source of the type strain.

Cells are long, thin, straight, nonmotile rods, about 0.3 × 4–10 μm. Occur singly or form chains of three to five cells. Cells sometimes branch. They have a Gram-positive type of cell wall that is covered with an S-layer. On solid medium, round, white, translucent colonies are produced. Obligate anaerobe. Extreme thermophile. Grows within the temperature range of 50–80 °C; optimum growth is at 70 °C. The pH growth range is 5.8–7.6; the optimum is 6.8–7.2. Grows chemolithotrophically on CO. Growth and CO consumption are not inhibited by penicillin, but ampicillin, streptomycin, kanamycin, and neomycin inhibit growth and CO utilization. Requires seawater-based medium. The optimum concentration of sea salts is 20.5–25.5 g/l. This species utilizes CO as the sole energy source with formation of H₂ and CO₂ according to the equation: CO + H₂O → CO₂ + H₂. Requires yeast extract, peptone, or acetate as a carbon source. Cells grow organotrophically on peptone, yeast extract, starch, cellobiose, glucose, galactose, fruc-

tose, and pyruvate. The products of organotrophic growth are acetate, CO₂, and H₂. An H₂/CO₂ gas mixture does not support growth. Reduces thiosulfate to sulfide. This species was isolated from a submarine hydrothermal vent in the Okinawa Trough.

DNA G+C content (mol%): 33 (T_m).

Type strain: ATCC BAA-271, JM, DSM 12653.

GenBank accession number (16S rRNA gene): AF174484.

1c. *Caldanaerobacter subterraneus* subsp. *tengcongensis* (Xue, Xu, Liu, Ma and Zhou 2001) Fardeau, Bonilla-Salinas, L'Haridon, Jeanthon, Verhé, Cayol, Patel and Garcia 2004, 472^{VP} (*Thermoanaerobacter tengcongensis* Xue, Xu, Liu, Ma and Zhou 2001, 1340)

teng.con.gen'sis. N.L. masc. adj. *tengcongensis* pertaining to Tengcong, China.

Cells are rods, 0.5–0.6 × 1–10 μm, that stain Gram-negative. They occur singly, in pairs, or in chains. No spores are observed. Heterotrophic growth requires yeast extract, which cannot be replaced by Tryptone or Casamino acids. Utilizes glucose, galactose, maltose, cellobiose, mannose, fructose, lactose, maltose, and starch. The major fermentation products on glucose are L-alanine and acetate. Oxidizes CO. Hydrogen and sulfite inhibit growth. Thiosulfate and sulfur stimulate growth. Chloromycetin, polymyxin B, streptomycin sulfate, and tetracycline HCl inhibit growth. This bacterium has been isolated from a hot spring in Tengcong in China.

DNA G+C content (mol%): 33 (T_m).

Type strain: Chinese Collection of Microorganisms AS 1.2430, DSM 15242, JCM 11007, MB4.

GenBank accession number (16S rRNA gene): AF209708.

1d. *Caldanaerobacter subterraneus* subsp. *yonseiensis* (Kim, Grote, Lee, Antranikian and Pyun 2001) Fardeau, Bonilla-Salinas, L'Haridon, Jeanthon, Verhé, Cayol, Patel and Garcia 2004, 472^{VP} (*Thermoanaerobacter yonseiensis* Kim, Grote, Lee, Antranikian and Pyun 2001, 1546)

yon.sei.en'sis. N.L. masc. adj. *yonseiensis* pertaining to Yonsei University, Seoul, Korea, in recognition of its support of research into extreme thermophiles and their thermostable enzymes.

Cells are motile, straight rods, 0.4–0.8 μm × 1.0–3.0 μm. Gram-positive. Under suboptimal growth conditions, cells occur in long chains and form terminal spores. Optimal conditions for growth are 75 °C (range 50–85 °C) and pH 6.5 (range 4.5–9.0). The doubling time under optimal conditions on medium containing starch, yeast extract, and thiosulfate is 60 min. Cells grow chemoorganotrophically under strictly anaerobic conditions on glucose, fructose, lactose, maltose, D-xylose, D-galactose, mannose, sucrose, cellobiose, starch, pullulan, yeast extract, tryptone, and peptone. Cells require yeast extract, elemental sulfur, L-cysteine, sodium nitrate, or sodium thiosulfate for growth. Oxidizes CO. Major fermentation products on glucose are L-alanine, lactate, acetate, ethanol, CO₂, and H₂S. Propionate, butyrate, isovalerate, 2-propanol, and 1-pentanol are formed in small amounts. Growth on glucose is inhibited by tetracycline, chloramphenicol, penicillin G, neomycin, vancomycin, kanamycin, and rifampin. Respiratory lipoquinones are absent. Approximately 1 mol of L-alanine is produced per mol of glucose fermented. This subspecies was isolated from mud samples taken from a hot stream at Sileri in the Dieng volcanic area located on the island of Java, Indonesia.

DNA G+C content (mol%): 37 (HPLC).

Type strain: DSM 13777, KB-1^P, KFCC 11116^P.

GenBank accession number (16S rRNA gene): AF212925.

Genus IV. *Carboxydothemus* Svetlichny, Sokolova, Gerhardt, Ringpfeil, Kostrikina and Zavarzin 1991b, 580^{VP} (Effective publication: Svetlichny, Sokolova, Gerhardt, Ringpfeil, Kostrikina and Zavarzin 1991a, 258; emend. Slobodkin, Sokolova, Lysenko and Wiegel 2006, 2350.)

JUERGEN WIEGEL

Car.bo.xy.do.ther'mus. N.L. n. *carboxydum* carbon monoxide; Gr. adj. *thermos* hot; N.L. masc. n. *Carboxydothemus* utilizing carbon monoxide while living in hot places.

Cells are straight to slightly curved rods, 0.3–0.5 × 1.3–2.7 μm. **Gram-stain-positive with a Gram-positive cell-wall structure.** Metabolism is **obligately anaerobic, chemolithotrophic or chemo- or organoheterotrophic.** Characteristic feature of the genus is the **utilization of CO.**

The type species is obligately carboxydrotrophic, forming H₂ and CO₂ from CO. The other species can also oxidize organic substances such as glycerol, mainly to acetate. While additional electron acceptors are not required, some that are used include Fe(III), sulfite, thiosulfate, elemental sulfur, nitrate, fumarate, and 9,10-anthraquinone-2,6-disulfonate. Growth occurs in the slightly acidic to slightly alkaline pH range. All described species are **thermophilic.** Sulfate is not reduced.

DNA G+C content (mol%): 39–41.

Type species: **Carboxydothemus hydrogenoformans** Svetlichny, Sokolova, Gerhardt, Ringpfeil, Kostrikina and Zavarzin 1991b, 580^{VP} (Effective publication: Svetlichny, Sokolova, Gerhardt, Ringpfeil, Kostrikina and Zavarzin 1991a, 258.).

Further descriptive information

Obligately anaerobic. The optimal temperature for growth of both species is 65–70 °C. Both species grow above 70 °C; thus, they are regarded as extremely thermophilic anaerobes. The pH^{25°C} range for growth is from slightly acidic to slightly alkaline. Both species can grow chemolithoautotrophically with CO but with different electron acceptors. *Carboxydothemus hydrogenoformans* is an obligate CO-utilizer. It uses protons as the electron acceptor in the reaction: CO + H₂O → CO₂ + H₂. *Carboxydothemus ferrireducens* requires electron acceptors other than protons to oxidize CO. It can also grow chemo- or organoheterotrophically. For organoheterotrophic growth, the medium is supplemented with glycerol (30 mM) as an electron donor and a carbon source and fumarate (20 mM) and/or ferrihydrite [90 mM; a poorly crystalline Fe(III) oxide/hydroxide, freshly prepared] as electron acceptors. Other electron acceptors include Fe(III) citrate (20 mM), Fe(III) EDTA (15 mM), thiosulfate (20 mM), fumarate (10 mM), 9,10-anthraquinone-2,6-disulfonate (20 mM), and, with lactate as electron donor,

precipitated or sublimated elemental sulfur (2 g/l), sulfite (10 mM), and nitrate (10 mM). Electron donors may include CO (100% of the headspace gas), H₂ (in the presence of CO₂ in a 80:20 ratio), formate (20 mM), lactate (20 mM), or glycerol (30 mM). Growth is poor or absent on hexoses. Both species are inhibited by 100 µg/ml chloramphenicol. The sensitivity to other antibiotics differs between the two species. Under optimal growth conditions, the doubling times are around 2–3 h.

Enrichment and isolation procedures

Habitats are terrestrial geothermally heated features. *Carboxydotherrmus hydrogenoformans* was isolated from geothermally heated swamp mud of the Kinashir Island, Kamchatka, Far-East Russia (Svetlichny et al., 1991a). *Carboxydotherrmus ferrireducens* was isolated from a hot spring in Yellowstone National Park, USA (Slobodkin et al., 1997b).

The enrichment and isolation of *Carboxydotherrmus* is based on either of the two distinguishing characteristics, the ability to oxidize CO to H₂ and CO₂ or to couple CO oxidation with ferrihydrite reduction to magnetite. For routine cultivation, both species are grown at 60–70 °C in a bicarbonate-buffered mineral medium at neutral pH plus 0.2 g/l yeast extract (Slobodkin et al., 1997b; Svetlichny et al., 1991a). For *Carboxydotherrmus hydrogenoformans*, the headspace gas is 100% CO. For *Carboxydotherrmus ferrireducens*, the headspace gas is N₂ and the medium is supplemented with 30 mM glycerol, 20 mM fumarate and/or 90 mM ferrihydrite (freshly prepared). Single colonies of *Carboxydotherrmus hydrogenoformans* have been obtained using roll-flasks with 5% (w/v) agar, whereas *Carboxydotherrmus ferrireducens* has been isolated from 2.2% agar-shake roll tubes (Ljungdahl and Wiegel, 1986).

Maintenance procedures

Carboxydotherrmus ferrireducens cultures can be kept for several weeks at room temperature when grown in Fe(III)-containing mineral media. Cultures supplemented with 40–50% glycerol (by vol., final concentration) can be stored for years at –20 °C, which is ideal for frequent withdrawals with a syringe since the stock remains liquid, and at –80 °C for even longer storage. Collections store the culture after lyophilization in sealed glass ampoules.

Taxonomic and phylogenetic comments

The genus *Carboxydotherrmus* belongs to the family “*Thermoanaerobacteraceae*” of the order “*Thermoanaerobacteriales*”. Like some of the other genera of this group, sporulation has never been observed. The phylogenetic position of *Carboxydotherrmus hydrogenoformans* has been confirmed by the recently published whole-genome sequence (Wu et al., 2005).

Differentiation of the genus *Carboxydotherrmus* from other carboxydotherrmophilic bacteria

Several anaerobic, thermophilic, carboxydotrophic, hydrogenogenic bacteria have been described. They belong to several phylogenetically diverse taxa. They all grow lithotrophically on CO, performing the metabolic reaction $\text{CO} + \text{H}_2\text{O} \rightarrow \text{CO}_2 + \text{H}_2$ ($\Delta G^0 = -20 \text{ kJ/mol}$). The first bacterium to be isolated was *Carboxydotherrmus hydrogenoformans* (Svetlichny et al., 1991a), followed

by *Caldanaerobacter subterraneus* subsp. *pacificus* (Fardeau et al., 2004; Sokolova et al., 2001), *Carboxydocella thermotrophica* (Sokolova et al., 2002), *Thermosinus carboxydvorans* (Sokolova et al., 2004a) and *Thermincola carboxydiphila* (Sokolova et al., 2005), as well as others that will be published in the near future (T.G. Sokolova, personal communication). Furthermore, a hyperthermophilic carboxydotrophic hydrogenogenic archaeon belonging to the genus *Thermococcus* was isolated recently (Sokolova et al., 2004b). So far, all these taxa are neutrophiles (pH range 6.5–7.8); only *Thermincola carboxydiphila*, isolated from Lake Baikal, is a moderate alkaliphile. The main difference between bacterial taxa with very similar metabolism and *Carboxydotherrmus hydrogenoformans* is their different phylogenetic positions based on 16S rRNA sequence analysis. In addition, the other species of *Carboxydotherrmus*, *Carboxydotherrmus ferrireducens*, is not a carboxydotrophic hydrogenogenic chemolithoautotroph, but a chemoheterotrophic Fe(III)-reducing bacterium. Other taxa and strains also exhibit very similar physiology, i.e., the ability to reduce Fe(III) using H₂ as an electron donor (Gavrilov et al., 2003; Slobodkin et al., 1999b; Slobodkin and Wiegel, 1997; Sokolova et al., 2007), and CO utilization has not been tested for most of them so it is premature at this time to give a key for differentiation of this genus from other taxa; this will only be possible when further species have been isolated and described.

Differentiation of the species of the genus *Carboxydotherrmus*

The differences between the two species of *Carboxydotherrmus* may partly reflect the isolation conditions, since only single characterized strains exist for each species. Physiologically similar strains have been isolated, but they have not been characterized and are not available in culture collections. The DNA–DNA hybridization between the two type strains is 53%, which supports their classification into two species despite their 98.4% 16S rRNA gene sequence similarity and some similar metabolic properties. Based on the properties of the type strains, the two species utilize CO differently (Henstra and Stams, 2004; Pusheva and Sokolova, 1995). Whereas *Carboxydotherrmus hydrogenoformans* is a chemolithoautotrophic CO-utilizer (in the presence of 0.05–0.5%, w/v, yeast extract), *Carboxydotherrmus ferrireducens* was isolated as a chemoheterotrophic (dissimilatory) Fe(III) reducer. *Carboxydotherrmus hydrogenoformans* is capable of Fe(III) reduction with H₂ as an electron donor and ferrihydrite as an electron acceptor. It also oxidizes CO to H₂ and CO₂, but it cannot grow chemolithotrophically on these products. In contrast, *Carboxydotherrmus ferrireducens* grows on CO, utilizing an external electron acceptor such as Fe(III), but without producing hydrogen or acetate. After 7 d of cultivation, the cell yield is 2.5–3.0 × 10⁷ cells/ml, having converted 26–28 mM ferrihydrite to Fe(II) as a black magnetic precipitate and consumed 14 mM equivalents of CO. In contrast, *Carboxydotherrmus hydrogenoformans* does not grow with CO in the presence of ferrihydrite, Fe(III) citrate or Fe(III) EDTA. However, with H₂, ferrihydrite is reduced to 20–22 mM Fe(II) after 7 d, with a maximal cell yield of 3.5–4.0 × 10⁷ cells/ml. Acetate does not accumulate, indicating that this is not a homoacetogenic fermentation.

List of species of the genus *Carboxydotherrmus*

1. ***Carboxydotherrmus hydrogenoformans*** Svetlichny, Sokolova, Gerhardt, Ringpfeil, Kostrikina and Zavarzin 1991b, 580^{VP}

(Effective publication: Svetlichny, Sokolova, Gerhardt, Ringpfeil, Kostrikina and Zavarzin 1991a, 258.)

hydro.gen.o.for'mans. N.L. n. *hydrogenum* hydrogen; L. part. adj. *formans* forming, N.L. part. adj. *hydrogenoformans* hydrogen-forming.

This description is based mainly on Svetlichny et al. (1991a) and Henstra and Stams (2004). Cells form round, white, translucent colonies during growth on agar plates under 100% CO. They are straight to slightly curved rods, 0.4–0.5 × 1.3–2.4 µm. Spores are not observed. Cells occur singly, in pairs, in short chains, or in palisade-like aggregates. Cells from the early exponential growth phase are motile and contain 1–2 laterally inserted flagella. An S-layer is present. Cells stain Gram-positive. During late exponential growth phase, lysis occurs and L-shaped cells form.

Growth temperature range is 40–78 °C, with an optimum around 70–72 °C (no growth at 37 or 80 °C). The pH range for growth is 6.4–7.7, with an optimum of pH 6.8–7.0 (no growth at pH 6.0 or 8.0).

Obligately anaerobic carboxydrotroph, i.e., obligately anaerobic chemolithoautotroph with no growth in the absence of CO using peptone, yeast extract, or other organic substrates.

Sulfate and sulfur are not reduced.

Isolated from a hot swamp in Kinashir Island (Kamchatka, Far-East Russia).

Penicillin, streptomycin, and chloramphenicol prevent growth at 100 µg/ml.

DNA G+C content (mol%): 39 (T_m).

Type strain: Z-2901, DSM 6008, ATCC BAA-161.

GenBank accession number (16S rRNA gene): AF244579.

2. **Carboxyothermus ferrireducens** (Slobodkin, Reysenbach, Strutz, Dreier and Wiegel 1997b) Slobodkin, Sokolova, Lysenko and Wiegel 2006, 2350^{VP} (*Thermoterrabacterium ferrireducens* Slobodkin, Reysenbach, Strutz, Dreier and Wiegel 1997b, 546)

ferr.ri.re.du'cens. L. n. *ferrum* iron; L. part. adj. *reducens* converting to a different state; N.L. part. adj. *ferrireducens* reducing ferric iron.

The description is based on Slobodkin et al. (1997b), with additional data from Gavrilov et al. (2003), Henstra & Stams (2004), and Slobodkin et al. (2006).

Cells are straight to slightly curved rods, 0.3–0.4 × 1.6–2.7 µm, with rounded ends. They occur in liquid culture as single cells or in pairs. Flagellation is of the retarded peritrichous type leading mainly to a tumbling motility. Cells stain Gram-positive. Spores are not observed. Obligately anaerobic metabolism. Cells do not require complex media compo-

nents for growth. Growth occurs at 50–74 °C, with optimum growth at 65 °C, and at a pH^{65C} range of 5.5–7.6, with optimum growth at 6.0–6.2. No growth is observed at or below 48 °C, at or above 76 °C, at or below a pH^{65C} of 5.3, or at or above a pH^{65C} of 7.8. Grows in 0.0–1.0% (w/v) NaCl, but not 2% NaCl.

In the presence of CO₂, strain JW/AS-Y7^T grows with glycerol as the sole organic carbon source and forms the incompletely oxidized product acetate while reducing ferrihydrite, Fe(III) citrate, or Fe(III) EDTA. H₂ is not formed. The ratio of acetate formed per glycerol utilized is greater than one and, based on the stoichiometries observed, suggests the use of an acetogenic pathway (not yet elucidated) according to the hypothetical equations 4 C₃H₈O₃ + 2 HCO₃⁻ → 7 C₂H₃O₂⁻ + 5 H⁺ + 4 H₂O ($\Delta G^0 = -151.5$ kJ/mol glycerol) and, in the presence of Fe(III) ions, 8 C₃H₈O₃ + 2 HCO₃⁻ + 8 Fe³⁺ → 13 C₂H₃O₂⁻ + 19 H⁺ + 4 H₂O + 8 Fe²⁺ ($\Delta G^0 = -252.6$ kJ/mol glycerol).

The following substrates are also utilized: lactate, 1,2-propanediol, glycerate, pyruvate, yeast extract, and peptone. In addition, glucose, fructose, and mannose support weak growth with acetate as the only organic product. Lithoautotrophic growth is possible with H₂ and ferrihydrite as the electron acceptor. CO₂ or CO can serve as the only carbon source. Carbon monoxide is oxidized with ferrihydrite, fumarate, or 9,10-anthraquinone-2,6-disulfonate as electron acceptors without production of H₂. No growth occurs with acetate, methanol, ethanol, *n*-propanol, *i*-propanol, *n*-butanol, propionate, acetone, ethyleneglycol, 1,3-propanediol, fumarate, succinate, phenol, benzoate, 9,10-anthraquinone-2,6-disulfonate, starch, olive oil, elemental sulfur, sucrose, galactose, xylose, cellobiose, or arabinose, with or without Fe(III). Reduces Fe(III) to Fe(II), 9,10-anthraquinone-2,6-disulfonate to 9,10-anthrahydroquinone-2,6-disulfonate, fumarate (20 mM) to succinate, thiosulfate (20 mM) to elemental sulfur or sulfide, and, with 20 mM lactate as carbon source and electron donor [Henstra and Stams (2004) in contrast to Slobodkin et al. (1997b)], 10 mM sulfite to sulfide, 2 g/l elemental sulfur to sulfide, and 10 mM nitrate to nitrite and ammonium. Does not reduce MnO₂. Chloramphenicol, erythromycin, and rifampin prevent growth at 100 µg/ml, whereas 100 µg/ml ampicillin, streptomycin, and tetracycline have no effect.

Isolated from a freshwater hot spring in the Calcite Springs area in Yellowstone National Park, Wyoming, USA.

DNA G+C content (mol%): 41 (HPLC).

Type strain: JW/AS-Y7, DSM 11255, VKM B-2392.

GenBank accession number (16S rRNA gene): U76363.

Genus V. *Gelria* Plugge, Balk, Zoetendal and Stams 2002, 406^{VP}

CAROLINE M. PLUGGE

Gel.ri'a. N.L. fem. n. *Gelria* Gelre or Gelderland, one of the 12 provinces in The Netherlands, in which Wageningen is located.

Cells are **rod-shaped** 0.5 × 3–20 µm in glucose-containing liquid cultures. **Cells vary in length dependent on growth substrate.** Cells are short rods (<2 µm) when grown in co-culture with a methanogenic partner on glutamate. **Nonmotile** and **Gram-stain-positive**. Formation of **terminal spores, 0.5 × 0.5 µm, during**

late exponential phase. Strictly anaerobic chemo-organotroph. Moderately thermophilic between 37 and 60 °C with an optimum at 50–55 °C. **Neutrophilic**; pH range 5.5–8. **Saccharolytic growth** in pure culture. **Hydrogen formed can be transferred to a syntrophic methanogenic partner**, not to sulfate, sulfite,

thiosulfate, nitrate, or fumarate. Isolated from granular sludge from an upflow anaerobic sludge bed reactor.

DNA G+C content (mol%): 33.8 (T_m).

Type species: **Gelria glutamica** Plugge, Balk, Zoetendal and Stams 2002, 406^{VP}.

Enrichment and isolation procedures

The type species of the genus *Gelria*, *Gelria glutamica*, has been isolated from methanogenic granular sludge originating from an upflow anaerobic sludge bed reactor. The bicarbonate-buffered mineral salts medium used for enrichment and cultivation is as described under genus *Syntrophobacter* (see McInerney et al., 2004). In addition, 0.5 g yeast extract per liter is added as a source of unknown growth factors.

For primary enrichments, the basal medium with 20 mM sodium glutamate and sodium sulfide as the reductant is used. This medium is also inoculated or pregrown with a pure culture of a methanogen, to allow degradation of glutamate via interspecies electron transfer. The type strain can only convert glutamate in the presence of a methanogenic partner. A pure culture of *Gelria glutamica* was obtained by serial dilution in basal medium containing agar with pyruvate as the carbon and energy source. Defined syntrophic co-cultures of *Gelria glutam-*

ica are constructed by growing the pure culture in glutamate basal medium that has also been inoculated with a pure culture of *Methanothermobacter thermoautotrophicus* Z-245.

Maintenance procedures

For short-term maintenance, members of this genus can be stored in their original growth medium at 4 °C in the dark. For long-term storage, a glucose-grown pure culture can be freeze-dried. Recovery of a syntrophic co-culture converting glutamate from a freeze-dried culture is achieved by growing the pure culture in glutamate-containing basal medium that has also been inoculated with a pure culture of *Methanothermobacter thermoautotrophicus* Z-245. The addition of 5 mM pyruvate to this co-culture significantly shortens the lag phase.

Taxonomic comments

Phylogenetically, the type strain *Gelria glutamica* is only distantly related to *Moorella glycerini* and *Moorella thermoacetica* with similarities of the 16S rRNA gene sequence between 90–92%. The 16S rRNA gene sequence of *Gelria glutamica* has additional loops in the V1, V7, and V9 helices. These additional loops are only present in the 16S rRNA gene sequence and are not transcribed to the 16S rRNA.

List of species of the genus *Gelria*

1. **Gelria glutamica** Plugge, Balk, Zoetendal and Stams 2002, 406^{VP}

glu.ta'mi.ca. N.L. n. *acidum glutamicum* glutamic acid; N.L. fem. adj. *glutamica* referring to glutamic acid, on which the bacterium grows.

Colonies appear white and round at the surface and are 0.7–1.0 mm in diameter when grown on pyruvate-containing soft agar (0.7–0.8%) media at 55 °C. Subsurface colonies are lenticular. Cells are 0.5 by 0.5–6 µm, variations depending on the growth substrate. In pure culture the strain can grow on pyruvate, lactate, glycerol, glucose, rhamnose, and galactose. In syntrophic association with a hydrogenotrophic

methanogen, the organism can utilize glutamate, 2-oxoglutarate, proline, Casamino acids, and a variety of sugars. Glutamate and proline are degraded to propionate, H₂, NH₄⁺, and HCO₃⁻. Propionate formation from glutamate occurs via direct oxidation through the intermediate methylmalonyl-CoA (Plugge et al., 2001). Sugars are converted to acetate, propionate, HCO₃⁻, and H₂ as main products. Growth occurs between 37–60 °C with an optimum at 50–55 °C and pH 5.5–8 (optimum 7).

DNA G+C content (mol%): 33.8 (T_m).

Type strain: TGO, ATCC BAA-262, DSM 14054.

GenBank accession number (16S rRNA gene): AF321086.

Genus VI. **Moorella** Collins, Lawson, Willems, Cordoba, Fernández-Garayzábal, Garcia, Cai, Hippe and Farrow 1994, 822^{VP}

JUERGEN WIEGEL

Moo.rel'la. N.L. fem. n. *Moorella* in honor of W.E.C. (Ed) Moore, an American bacteriologist, who worked with anaerobes.

In early exponential growth phase, cells stain Gram-positive. However, some species stain negative during the late exponential and stationary growth phases. **Straight rods with a tendency to polymorphism** under stress conditions such as high glucose or high acetate concentrations. **Physiology is obligately anaerobic, thermophilic, and chemolithoautotrophic and/or heterotrophic**; produces acetate as sole or main fermentation product from sugars, C₁ carbon sources, and other substrates. Produces nearly 3 moles of acetate per mole of glucose consumed, which is sometimes called “homoacetogenic” fermentation. While growing on substrates other than hexoses, CO, or

CO₂/H₂, *Moorella* species can produce various products. May use nitrate, nitrite or fumarate as electron acceptors. Forms various aromatic compounds via decarboxylation of aryllic acids, which are used as CO₂ donors under CO₂-limited conditions. The cell wall contains LL-diaminopimelate (DAP).

DNA G+C content (mol%): 53–55.

Type species: **Moorella thermoacetica** (Fontaine, Peterson, McCoy, Johnson and Ritter 1942) Collins, Lawson, Willems, Cordoba, Fernández-Garayzábal, Garcia, Cai, Hippe and Farrow 1994, 824^{VP} (*Clostridium thermoaceticum* Fontaine, Peterson, McCoy, Johnson and Ritter 1942, 705).

Further descriptive information

Physiology. Currently, the genus *Moorella* contains four species, all of which use the Wood–Ljungdahl pathway of autotrophic acetyl-CoA biosynthesis, with tetrahydrofolate (THF) as the characteristic cofactor for the fixation of CO₂ or CO into acetate. The pathway has been elucidated mainly in *Moorella thermoacetica*, but has also been demonstrated in other species through analysis of key enzyme activities and cofactors (for reviews see Drake et al., 2008; Ragsdale, 2008). Glucose is first metabolized by enzymes of the Embden–Meyerhof–Parnas pathway to pyruvate, which is then converted via the ferredoxin-dependent pyruvate oxidoreductase, phosphotransacetylase, and acetate kinase to 2 acetate, 2 CO₂, 8 reducing equivalents, and 2 ATP via substrate-level phosphorylation. These 2 CO₂ and 8 reducing equivalents are then converted via the two branches of the Wood–Ljungdahl pathway (the methyl and carbonyl branches) to the third acetate, making it a homoacetogenic fermentation. For that reason, these bacteria have historically been called “homoacetogenic bacteria”. However, more recently this term has been replaced with “acetogenic” upon the realization that *Moorella* and other similar bacteria produce a range of products on other, less common substrates, including succinate from fumarate and aromatic compounds from aromatic acids (Daniel et al., 1990; Drake, 1994; Schink, 1994; Seifritz et al., 2002). In the methyl branch, one of the CO₂ molecules is reduced to methyl-THF. The methyl group is then transferred to a corrinoid protein. The other CO₂ is activated via the carbonyl branch and combined with the methyl moiety to form acetyl-CoA by the enzyme acetyl-CoA synthase. Because of its ability to oxidize CO, this enzyme has also been called carbon monoxide dehydrogenase. Due to electron-transport phosphorylation (ETP) during the reduction of formyl-THF to methyl-THF in the methyl branch, this pathway is the most energy-efficient fermentation of glucose, yielding at least 6 moles of ATP per mole of fermented glucose: 2 ATP from the Embden–Meyerhof pathway, 3 ATP from the conversion of acetyl-CoA to acetate, and 1 ATP derived from ETP. This conclusion is in agreement with Y_{glucose} values (Ljungdahl, 1994).

Hexose-utilizing *Moorella* species (as well as other acetogens) contain an anaerobic electron-transport chain that uses H₂ or CO as electron donors and methylene-THF as a physiological electron acceptor and generates a proton motive force for ATP synthesis (Diekert and Thauer, 1978; Daniel et al., (1990) and references therein). The electron-transport chain contains cytochrome *b*₅₅₄, cytochrome *b*₅₅₉ (Das et al., 2005), menaquinone (Das et al., 1987), a flavoprotein, a 4Fe-4S- and an 8Fe-8S-ferredoxin (Elliott and Ljungdahl, 1982; Yang et al., 1977), and rubredoxin (Yang et al., 1980). However, a definite role for rubredoxin is still not clear. Electron-transport also drives the uptake of amino acids (Hugenholtz and Ljungdahl, 1989, 1990a). The electron-transport chain used during CO-dependent growth has also been partly elucidated (Hugenholtz et al., 1987). Lastly, *Moorella thermoautotrophica* contains an F₀F₁ ATPase that is not functionally compatible with the enzyme in *Escherichia coli* and, therefore, appears to be different (Das et al., 1997; Das and Ljungdahl, 1993).

The first step in the methyl branch is catalyzed by formate dehydrogenase, which is one of the most oxygen-sensitive enzymes known (Das, 2003; Drake, 1994; Ljungdahl, 1994;

Ragsdale, 2008; Wood and Ljungdahl, 1991; Yamamoto et al., 1983). This enzyme was the first tungsten-dependent enzyme discovered in biology (Andreesen and Ljungdahl, 1973). More recently, tungsten has been shown to replace molybdenum in many pterin-containing enzymes of deep-sea hyperthermophiles (Kletzin and Adams, 1996). All of the remaining enzymes of this important pathway have been purified and characterized from *Moorella* species (mainly *Moorella thermoacetica*). For an extended discussion of their distribution among acetate-forming bacteria and the bioenergetics and biochemistry of acetogenesis, the reader is referred to recent reviews (Das and Ljungdahl, 1993; Drake, 1994; Drake et al., 2008; Hugenholtz and Ljungdahl, 1990b; Ragsdale, 2008; Wood and Ljungdahl, 1991).

O₂ metabolism in *Moorella* has not been fully elucidated (Das et al., 2005). Recent studies with acetogenic bacteria from the termite hindgut (Boga and Brune, 2003) and *Moorella thermoautotrophica* (J. Wiegel, unpublished results) suggested that *Moorella* can reduce O₂ even though it will not grow under microaerophilic conditions.

Under CO₂-limiting conditions, carboxylated aromatic compounds can be used as a source of required CO₂ (Hsu et al., 1990). Two interesting, although unnamed, isolates reveal novel metabolic properties for this taxa. On the basis of their 16S rRNA gene sequences, both isolates are closely related to *Moorella thermoacetica*. Karita et al. (2003) isolated the cellulolytic strain F21, which may make it possible to efficiently produce acetate directly from cellulose. For biotechnological applications, such as production of the road de-icer calcium-magnesium acetate (CMA), this strain makes it possible to avoid the costly saccharification procedures. Inokuma et al. (2007) reported on the enzymology of the *Moorella* strain H4C22-1, which produces some ethanol during growth on H₂/CO₂. Yields are typically 120 mM acetate and 5.2 mM ethanol. The level of *aldh* mRNA, which encodes an aldehyde dehydrogenase, was threefold higher during growth on H₂/CO₂ than on fructose. In contrast, the levels of *adhA*, *B*, and *C*, which encode the primary and secondary alcohol dehydrogenases, decreased. Thus, it appears likely that *Moorella thermoacetica* and other *Moorella* species may use alternative fermentation pathways under certain conditions. In the presence of viologen dyes, methanol is formed from CO instead of acetate (White et al., 1987). *Moorella* species are apparently able to synthesize branched-chain amino acids via the common pathway or via the reductive carboxylation/transamination of the corresponding fatty acid pathway (Allison et al., 1984; Wiegel et al., 1981; Wiegel and Schlegel, 1977).

All described *Moorella* species produce heat-stable spores, although the extent differs among the species and strains. Sporulation is especially common following chemolithoautotrophic growth on methanol or glycerol with *Moorella glycerini*. For spores, the decimal reduction times or D₁₀ times are around 15 min at 120 °C for the type species and type strain following growth on glucose in rich media. D₁₀ times have not been determined for spores formed following chemolithoautotrophic growth (Fontaine et al., 1942). The D₁₀ time at 121 °C for spores of *Moorella mulderi* (Balk et al., 2003) is 31 min. For spores from cells of *Moorella thermoautotrophica* and *Moorella thermoacetica* strain JW/DB-4 (=ATCC 39073), grown chemolithoautotrophically at 60 °C, D₁₀ times at 121 °C are 30–80 min (J. Wiegel, unpublished results) and 111 min, respectively (Byrer et al., 2000).

Full activation of spore suspensions requires incubations of more than 10 min and up to 1 h at 100 °C. In contrast, activation of spores for many other glycolytic thermophiles and mesophiles typically requires 1–3 min at 100 or 80 °C, respectively. Moreover, spores of strains of *Moorella thermoacetica*, *Moorella thermoautotrophica*, and *Moorella mulderi* were not significantly deactivated at incubations for several hours at 100 °C (Balk et al., 2003; Byrer et al., 2000). The spore population is apparently comprised of subpopulations that differ in their heat-resistance, since the courses for spore activation and inactivation at 121 °C are bi- or even multi-phasic (Byrer et al., 2000).

The type strain of *Moorella thermoautotrophica* fixes N₂. It is presently not known whether or not the other species also fix N₂ (Bogdahn and Kleiner, 1986).

Phylogeny. The genus *Moorella* is classified within the family *Thermoanaerobacteraceae*, the first of four families of the order *Thermoanaerobacteriales* of the class *Clostridia* within the phylum *Firmicutes* (see Ludwig et al., 2009). In previously published 16S rRNA gene-based phylogenetic trees, the closest relatives to *Moorella* species have been species of the spore-forming, sulfate-reducing bacterium *Desulfotomaculum*, asporogenic and syntrophic fatty-acid-degrading thermophiles and mesophiles, and several thermophilic glycolytic or saccharolytic thermophiles such as members of *Thermoanaerobacter* and *Thermoanaerobacterium*. However, extensive analysis of the phylogeny of *Firmicutes* by Ludwig and others (this volume) classifies *Moorella* with nonacetogenic heterotrophic (e.g., *Thermoanaerobacter*) and chemolithoautotrophic bacteria (e.g., *Carboxydotherrmus*) within the family *Thermoanaerobacteraceae* fam. nov. However, this assignment is not strongly supported and future studies may indicate the need for reassignment. Similarly, classification of the genus *Thermoanaerobacterium*, which is assigned to a family *incertae sedis* within the *Thermanaerobacteriales*, is awaiting further clarification. *Desulfotomaculum* and the syntrophic organisms appear to be outside this order and unrelated to *Moorella*. Except for members of the genus *Thermacetogenium* and the species *Thermoanaerobacter kivui*, which are also classified within the *Thermoanaerobacteraceae*, other physiologically similar bacteria exhibiting homoacetogenic fermentation and possessing the Wood–Ljungdahl pathway are classified in different orders. These include: the mesophiles *Clostridium formiceticum*, *Clostridium aceticum*, *Clostridium ljungdahlii* and *Sporomusa* species; the psychrophilic *Acetobacterium* species; and the thermophile *Caloramator fervidus* (Drake et al., 2008; Ragsdale, 2008; Rainey et al., 2006; Tanner and Woese, 1994).

Industrial applications. *Moorella thermoacetica* and *Moorella thermoautotrophica* have been used commercially to produce the environmentally friendly road deicer CMA from dolime and hydrolyzed corn starch. CMA, which is sold as Crytech CMA40, can be produced from adapted wild-type strains (Ljungdahl et al., 1986; Wiegel et al., 1991) as well as mutants, e.g., C5-2 (=ATCC 49707; U.S. Patents 4506012 and 4513084) and ATCC 39289, which are both improved acetate-producing mutants derived from ATCC 35608^T, and strain 99-78-22 (=ATCC 31490; U.S. Patent 4371619) (Schwartz and Keller, 1982a, 1982b, 1983). Wiegel et al. (1991) compared two laboratory strains of *Moorella thermoacetica* and two isolates of *Moorella thermoautotrophica* with respect to properties important for the production of CMA. *Moorella thermoacetica* lab-strain LJD and lab-strain Wood both

tolerated 250 mM CaCl₂, whereas *Moorella thermoautotrophica* strains JW 701/3^T and JW 701/5 only tolerated 25 mM CaCl₂. All other properties varied as much between the species as they did within each species. Using a novel felt-pad rotating fermenter and lab-strain LJD-EMS concentrations of 2 M acetate/ acetic acid (equivalent to 120 g/l acetic acid) were produced and production rates of up to 4 g/l/h CMA were achieved with cell recycling (Wiegel et al., 1991). Using continuous cultures without cell recycling and dolime as neutralizing reagent, the mutant JW/YS 701/5 P-Na 20 produced over 250 g/l CMA at pH 6.9. In continuous culture with cell recycling, the rates of CMA production were up to 4 g/l/h and the ratio of acetate formed per metabolized glucose moiety was about 2.8. Each *Moorella* species has different advantages and disadvantages (Wiegel et al., 1991).

The improvement of acetate production from 30 mM lactose by growing *Moorella thermoautotrophica* in co-culture with *Methanothermobacter thermoautotrophicus* and *Clostridium thermolacticum* has been suggested (Talabardon et al., 2000). Through efficient *in situ* H₂ scavenging within the consortium, acetate formation was improved at the expense of reduced by-products like ethanol. The use of this thermophilic anaerobic consortium opens new opportunities for the efficient valorization of lactose, a major waste product from the cheese industry, and production of CMA (Collet et al., 2003).

The production of acetate from cellulose by *Clostridium thermocellum*–*Moorella thermoautotrophica* co-cultures was investigated by Freier and Wiegel (1981). Acetate yields of 2.8 mol per mol of cellobiose equivalents fermented were obtained (Wiegel, 1988; Wiegel et al., 1986; J. Wiegel, unpublished results; Simankova and Nozhevnikova, 1989). Supernatants of cultures producing CMA, as well as the CMA itself, have negligible ecological impact on plants and animals. Culture supernatants are not toxic to mice.

Habitats and isolation. Known habitats are horse manure (which was the source of the type strain of the type species), emu droppings (R. Tanner, personal communication), sewage sludge, mesobiotic freshwater sediments (Wiegel et al., 1981), canned food samples (Carlier and Bedora-Faure, 2006), and dahlia tubers (Drent and Gottschal, 1991), but species have been isolated mainly from hot springs, including those in Japan (Karita et al., 2003), Kamchatka (Far-eastern Russia) (J. Wiegel, unpublished results), Wyoming (USA) (Rainey et al., 1993), and New Zealand (J. Wiegel, unpublished results). Since more than 70% of the methane formed in the environment is formed via acetate, it has become evident that acetogenesis, along with methanogenesis, is one of the most important processes in the environment. Thus, these bacteria are no longer considered a curiosity. Instead, they are an ecological and industrially important taxon. When *Moorella thermoautotrophica* and *Moorella thermoacetica* are isolated under autotrophic conditions, inhibitors for methanogens such as bromoethanesulfonate (3–10 μM) should be included. Otherwise, *Methanothermobacter thermoautotrophicus*-like strains will out-compete and overgrow the acetogens in the enrichments and on agar plates, presumably due to the higher affinity of methanogens for H₂. Mesobiotic sediments from freshwater streams in Germany contain up to about 100 viable cells of *Moorella*-like H₂- or methanol-utilizing and acetate-forming thermophiles. A proportion (depending on the sample) of those cells are in the vegetative state, as estimated

by comparing MPNs before and after 80 °C heat treatment of the initial sample (Braun et al., 1979; J. Wiegel, unpublished results). Because laboratory cultures of this species did not grow at less than 37 °C and the bulk temperature in those sediments is never over 30 °C, it is unclear whether or not *Moorella* is growing in the mesobiotic environment or just remaining viable by maintenance metabolism. J. Wiegel (unpublished results) has shown that the methanogenic counterpart *Methanothermobacter thermoautotrophicus* can grow in autoclaved (121 °C, 40 min) natural sediments at temperatures as low as 22 °C and can produce methane at temperatures at least as low as 16 °C (J. Wiegel, unpublished results). To date, comparable experiments have not been performed with *Moorella*. In addition to the possibility of *Moorella thermoautotrophica*-like strains growing at lower temperatures in natural settings, there is also the possibility that growth occurs mainly in microniches with temporarily elevated temperatures due to release of heat from biodegradative processes. *Moorella thermoacetica* has been found growing commensally with *Thermicanus aegyptius* in an Egyptian soil, an ecological situation that may occur much more frequently than presently realized (Drake et al., 2008; Gössner et al., 1999).

Although nickel is a required metal ion for several enzymes in the acetogens, due to the presence of a high-affinity transport system for nickel observed in *Moorella thermoacetica*, the necessity of adding nickel salts is not usually observed during isolations or for growth in media containing complex nutrients such as yeast extract (Lundie et al., 1988).

Taxonomic comments

The original species names were *Clostridium thermoaceticum* (*sic*) and *Clostridium thermoautotrophicum* (*sic*). The presently acknowledged proper latinized form would require that the connect-

ing vowel "o" be dropped; and the names should be "*Moorella thermacetica*" and "*Moorella thermoautotrophica*", as used intermittently (Trüper, 1999). However, the Notification List (Int. J. Syst. Bacteriol., 1995, 45: 199–200) uses the names with the "o" and thus, according to the new Rule 61, the valid species names are *Moorella thermoacetica* and *Moorella thermoautotrophica* (see J.P. Euzéby "Grammatical or orthographical changes prohibited by Rule 61" at <http://www.bacterio.cict.fr/corrections2.html>).

Differentiation of the genus *Moorella* from other thermophiles and mesophilic acetogens

In addition to their separate position in 16S rRNA gene-based phylogenetic trees, *Moorella* species differ from other glycolytic and chemolithoautotrophic mesophilic acetogens by being thermophilic. They differ from most other thermophiles by the use of the Wood–Ljungdahl pathway, producing 3 acetate per mol fermented glucose minus the glucose and acetyl-CoA used for biosynthesis. Fermentations typically yield ratios of about 2.85 acetate molecules per glucose. *Moorella* species have cell walls containing LL-DAP, whereas the clostridia *sensu stricto* and *Thermoanaerobacter* and related species have m-DAP-direct type cell walls. The relatively high G+C values of 53–55 mol% further separate *Moorella* from *Clostridium sensu stricto*, which possess values below 35 mol%, and other thermophilic acetogens carrying out homoacetogenic fermentation. The latter species are *Thermoanaerobacter kivui*, which possesses an m-DAP-direct type of cell wall; *Caloramator fervidus*, which has a much lower mol% G+C content; and *Thermacetogenium phaeum*, which in contrast to all *Moorella* strains can syntrophically oxidize acetate in co-culture with a hydrogenotrophic methanogen. In addition, several phylogenetically unidentified thermophilic acetogenic isolates have been described. For a detailed overview on the various acetogenic bacteria, see Drake et al. (2008).

TABLE 247. Properties that differentiate species of the genus *Moorella*^a

Property	<i>M. thermoacetica</i> ^b	<i>M. thermoautotrophica</i> ^b	<i>M. glycerini</i> ^c	<i>M. mulderi</i> ^d
Origin	Horse manure	Mesobiotic and thermobiotic sediment and soil	Hot spring, Yellowstone National Park (USA)	Anaerobic digester (The Netherlands)
Cell size (µm)	0.4 × 2.8	0.8–1 × 3–6 ^e	0.4–0.6 × 3–6.5	0.4–0.6 × 2–8
Temperature range (optimum) ^e	47–65 (56–60) ^e	42–66 (60–62) ^e	43–65 (58)	40–70 (65)
pH ^{25°C} range (optimum) ^e	5.7–7.65 ^f (6.6–6.8)	4.8–7.3 (6.5–6.6 on glucose; 5.5 on glycerate)	5.9–7.8 (6.3–6.5)	5.5–85 (7.0)
Doubling time (glucose) (h) ^e	4–8	5	4	ND (on methanol >20 h)
CaCl ₂ tolerance (mM)	250	25	ND	ND
MgCl ₂ tolerance (mM)	250	250–350 ^e	ND	ND

^cSlobodkin et al. (1997a).

^dBalk et al. (2003).

^eStrain-dependent and using glucose as substrate.

^fFor starting growth; final pH of culture can be as low as 4.1.

Differentiation of the species of the genus *Moorella*

Differentiation of the species is largely based on 16S rRNA gene analysis. The type species *Moorella thermoacetica* and *Moorella thermoautotrophica* are very similar in their physiological capabilities. Many of the physiological differences, such as differences in chemolithoautotrophic growth, methanol utilization, growth rates, sporulation, and cell sizes (Wiegel, 1982), which justified the formation of novel species at the time of their publications now to appear to be minor and within the range of variation often observed between strains. Moreover, besides the difference in capability for chemolithoautotrophic growth, originally the two species were differentiated on the ability to use pyruvate. At the time, it was believed the *Moorella thermoautotrophica* was unable to use pyruvate. However, this conclusion was probably due to mistakes in media preparation, because the pyruvate was sterilized by autoclaving instead of filtration (J. Wiegel, unpublished results). DNA–DNA hybridization between strains of *Moorella thermoautotrophica* (type strain JW 701/3^T and strain KIVU) and *Moorella thermoacetica* DSM 521^T is between 48 and 52%, which supports the creation of two species (Wiegel et al., 1981). However, more recent hybridization results have yielded higher values (R. Tanner, personal communication). The phylogenetic position of strains *Moorella thermoacetica* JW/DB-4 and JW/DB-2, based on 16S rRNA gene sequences, is intermediary between *Moorella thermoacetica* and *Moorella thermoautotrophica*. This relationship is also reflected in the physiological properties and the extent of sporulation, which is only slightly less for the new strains than for *Moorella thermoautotrophica* (Byrer et al., 2000; Wiegel, 1982). Thus, the extent of differences, including in the 16S rRNA genes, between *Moorella thermoacetica* and *Moorella thermoautotrophica* is borderline for their separation into two different species. Possibly, when more strains related to *Moorella thermoacetica* have been isolated and characterized, a more informed decision can be made as to whether or not *Moorella thermoautotrophica* should remain classified as a separate species or a subspecies of *Moorella thermoacetica*. It is also quite possible that if strains of the two species were subjected to the same growth conditions for extended periods of time, they would become physiologically indistinguishable. However, glyoxylate-dependent growth in medium containing nitrite, as observed with *Moorella thermoacetica*, has not been observed for *Moorella thermoautotrophica* (Seifritz et al., 2003, 2002).

Moorella mulderi and *Moorella glycerini* differ from *Moorella thermoacetica* and *Moorella thermoautotrophica* mainly in their inability to use nitrate as an electron acceptor (Table 247). *Moorella mulderi* differs from *Moorella glycerini* in its inability to use glycerol as a carbon source. *Moorella glycerini* differs from *Moorella thermoautotrophica* and *Moorella thermoacetica* in that it reduces thiosulfate only to elemental sulfur and not to H₂S. It also differs from all three of the other species in that it does not grow chemolithoautotrophically.

The pH optima of these bacteria depend strongly on the growth substrate. Differences in pH optima between *Moorella mulderi*, *Moorella thermoautotrophica*, and *Moorella thermoacetica* are small when the same growth substrates are used. The originally published pH optimum of around 5.7 for *Moorella thermoautotrophica* was determined during chemolithoautotrophic growth or with glycerate as a substrate. Glycerate is convenient because it is converted in a 1:1 ratio to acetate and thus does not significantly change the pH of the culture, making it easier to determine pH profiles. Growth on methanol, H₂/CO₂, and glycerate does not require the use of all the enzymes of the Embden–Meyerhof–Parnas pathway and has more neutral or slight alkaline pH optima than when only the Wood–Ljungdahl pathway is used. The pH optima for *Moorella thermoautotrophica* and *Moorella thermoacetica* during growth on glucose are around 6.6–6.8 (Wiegel et al., 1981, 1991). For *Moorella mulderi*, it is pH 7.0 when the pH is determined at 25 °C using temperature-corrected standards (M. Balk, personal communication).

Additional isolates

Besides the industrially interesting derivatives of the type species, several isolates have been described that possess 16S rRNA gene sequences that are closely related to that of the type species *M. thermoacetica*. These include: two strains with highly thermoresistant spores, *Moorella thermoacetica* JW/BD-2 and JW/BD-4 (Byrer et al., 2000); the cellulolytic strain F21 (Karita et al., 2003); and the ethanol-producing strain H4C22-1 (Sakai et al., 2004).

Wiegel et al. (1981) described 15 strains of *Moorella thermoautotrophica*, eight of which were partially characterized in the original publication. These strains are all methylotrophic, able to grow on H₂/CO₂, and able to grow heterotrophically on glycerate, glucose, fructose, and galactose. However, taxonomic assignments were based solely on physiological properties, which are probably not a reliable method for this group of bacteria. Sa (1985) isolated an additional methylotrophic strain. Drent and Gottschal (1991) isolated strain II following growth on inulin, a polymer of fructose, from Dahlia tubers. This strain contains one or more inulinases that function optimally at 60 °C and neutral pH. Enzyme activity was found bound to the cells, as well as free in the medium. The strain differs from the type strain of *Moorella thermoautotrophica* with respect to fermentation products, substrate spectrum, and optimum temperature for growth. Berestovskaya et al. (1987) isolated strain Z-99, which released about 500 μmol H₂ per h per mg protein during the lag phase in glucose-containing medium. During growth on methanol at 55 °C, hydrogenase activity was 50 mmol/min/mg protein. In the late exponential growth phase, growth yields were 4.5 g of biomass per mole methanol utilized.

List of species of the genus *Moorella*

1. ***Moorella thermoacetica*** (Fontaine, Peterson, McCoy, Johnson and Ritter 1942) Collins, Lawson, Willems, Cordoba, Fernández-Garayzábal, Garcia, Cai, Hippe and Farrow 1994, 824^{VP} (*Clostridium thermoaceticum* Fontaine, Peterson, McCoy, Johnson and Ritter 1942, 705)

ther.mo.a.ce'ti.ca. Gr. adj. *thermos* hot; L. neut. adj. *aceticum* pertaining to vinegar (acetic acid); N.L. fem. adj. *thermoacetica* producing acetic acid at elevated temperatures.

This description is based mainly on the original reports of Fontaine et al. (1942), Ljungdahl et al. (1985), and Wiegel

et al. (1991). The type strain was isolated from horse manure at elevated temperatures in medium containing nitrate. There are significant variations in the properties of cultures of the type strain from different laboratories (termed lab-strains LJD, Wood, and Drake, respectively), although they all were derived from the same culture, i.e., the one isolated by Fontaine et al. (1942). The differences are clearly due to selection during extensive subculturing under different growth conditions.

Cells are straight or slightly bent rods of $0.4 \times 2.8 \mu\text{m}$, found singly or in pairs, but rarely in chains when grown heterotrophically on peptone-yeast extract-glucose (PYG) or yeast extract-methanol medium. Cells are slightly smaller when grown chemolithoautotrophically. They stain Gram-positive in the exponential growth phase, but may stain Gram-negative in the stationary growth phase. Although flagella were described in the original report of Fontaine et al. (1942), cells are usually nonmotile; if motility does occur, only tumbling motion is seen during growth on methanol or on agar cultures with low nutrient concentrations.

Spores are rarely observed in PYG medium, especially in lab-strain LJD (=ATCC 39079), which was maintained in the laboratory of L.G. Ljungdahl (University of Georgia, Athens, USA) in rich complex medium continuously sparged with CO_2 . In contrast, in methanol-grown cultures of lab-strain Wood (obtained by the author from the laboratory of the late H.G. Wood), up to 10% of the cells sporulate. Differences between the two lab-strains are even more pronounced with respect to chemolithoautotrophic growth, e.g., lab-strain LJD is difficult to adapt to chemolithoautotrophic growth and is much slower than lab strain Wood. Spores of the type strain survive for 15 min at 120°C . *Moorella thermoacetica* strain JW/DB-4 (=ATCC BB-48), which was isolated in the author's laboratory as a contaminant in autoclaved and uninoculated chemolithoautotrophic medium, produced spores after chemolithoautotrophic growth at 60°C with D_{10} times at 121°C of about 2 h (Byrer et al., 2000).

The temperature ranges for strains LJD and Wood growing on complex medium with glucose as main carbon source are $51\text{--}65^\circ\text{C}$ (optimum 60°C) and $47\text{--}65^\circ\text{C}$ (optimum $56\text{--}58^\circ\text{C}$), respectively. The corresponding pH ranges are $5.7\text{--}7.65$ (optimum pH 6.8) and $5.7\text{--}6.8$ (optimum pH 6.6), respectively. However, the pH optimum for growth on methanol and glycerate is about pH 6.0. The original description listed growth between 45 and 65°C , with an optimum between 55 and 60°C . During growth with glucose, the pH can reach values down to pH 4.1 in the stationary phase; however, no growth occurs upon transfer into new media at this pH. CaCl_2 and MgCl_2 tolerances for both strains are 250 mM. The minimal concentration of yeast extract required for growth is 0.005% (w/v). It can be replaced by nicotinic acid, nickel, selenium, and tungsten (Lundie and Drake, 1984). Cultures in complex media need to be stirred or agitated by sparging with CO_2 . Otherwise, cells flocculate and settle at the bottom of the culture vessel and the growth yield is reduced. To ensure growth, it is recommended that fresh agar shake tubes are prepared. Strain LJD is assumed to be sensitive to reduced water activity conditions such as found in old medium containing 2% (w/v) agar. Glucose, fructose, and trehalose can serve as sole carbon sources.

Moorella thermoacetica was described for more than 40 years as a heterotrophic bacterium. However, *Moorella thermoacetica* can grow on C_1 compounds, including methanol/ CO_2 , chemolithoautotrophically on carbon monoxide (with or without H_2), and with H_2/CO_2 (Kerby and Zeikus, 1983; Savage et al., 1987; Wiegel, 1982). Under CO_2 limitation, the carboxyl group of hydroxyaromatic acids can serve as a CO_2 source (Hsu et al., 1990). Other recently described acetogenic substrates are oxalate and glyoxylate. Nitrate and nitrite can serve as electron acceptors and reduce the yield of acetate. In an undefined medium containing 0.1% yeast extract, 5 mM nitrate served as an electron acceptor with glyoxylate as substrate, but not with glucose.

DNA G+C content (mol%): 54 (T_m).

Type strain: ATCC 35608, DSM 521, JCM 9319.

GenBank accession number (16S rRNA gene): AY656675.

Additional remarks: the genomic sequence from lab-strain LJD (=ATCC 39073) is available (<http://genome.ornl.gov/microbial/>).

2. ***Moorella glycerini*** Slobodkin, Reysenbach, Mayer and Wiegel 1997a, 973^{VP}

gly.ce.ri'ni. Gr. adj. *glykeros* sweet; N.L. adj. *glycerini* of glycerol, referring to utilization of glycerol as a substrate.

During all growth phases, cells stain Gram-positive and are rods of $0.4\text{--}0.6 \times 3.0\text{--}6.5 \mu\text{m}$, exhibiting tumbling motility due to retarded peritrichous flagellation. Cells usually occur singly. Round endospores with a diameter of $1.0\text{--}1.5 \mu\text{m}$ occur readily in the late exponential growth phase in terminal swollen sporangia. Cells are covered with tetragonal type S-layer proteins containing subunits of center-to-center distances of 10 nm. Heterotrophic growth occurs with glycerol as sole carbon source, although yeast extract stimulates growth rate and yield. Glucose, fructose, xylose, mannose, galactose, lactate, glycerate, and pyruvate serve as carbon and energy sources with acetate as the sole fermentation product. Traces of lactate and branched chain fatty acids occur at elevated yeast extract concentrations. Formate (with or without fumarate), succinate, and benzoate do not support growth; neither do short-chain alcohols (C_1 to C_5). However, fumarate is reduced to succinate in the presence of a metabolizable carbon source such as pyruvate. Nitrate, sulfate, sulfite, amorphous Fe(III), and MnO_2 are not reduced. Ampicillin, chloramphenicol, erythromycin, rifampin, and tetracycline (all at $100 \mu\text{g}/\text{ml}$) prevent growth.

Isolated from hot springs at the Calcite Spring site in Yellowstone National Park (WY, USA) using mineral medium supplemented with yeast extract and glycerol as the main carbon and energy sources and incubation at 60°C . Enrichments included autoclaving the culture for 10 min at 121°C to obtain the thermophilic, endospore-forming culture (for spore resistance, see genus description above).

DNA G+C content (mol%): 54.5 ± 0.4 (HPLC).

Type strain: JW/ASY6, ATCC 700316, DSM 11254.

GenBank accession number (16S rRNA gene): U82327.

3. ***Moorella mulderi*** Balk, Weijma, Friedrich and Stams 2005, 1^{VP} (Effective publication: Balk, Weijma, Friedrich and Stams 2003, 319.)

mul.de'ri. N.L. gen. n. *mulderi* of Mulder, named in honor of Eppe G. Mulder, head of the Microbiology Department at Wageningen, The Netherlands, 1956–1981.

Spore-forming, straight rods of $0.4\text{--}0.6\ \mu\text{m} \times 2\text{--}8\ \mu\text{m}$, which stain Gram-positive and grow as single cells or in pairs. Growth on glucose is observed in the temperature range $40\text{--}70\ ^\circ\text{C}$, with an optimum at $65\ ^\circ\text{C}$, and in the pH range $5.5\text{--}8.5$, with an optimum about 7.0, under obligately anaerobic conditions. NaCl concentrations of $0\text{--}4.5\%$ (w/v) NaCl support growth, with an optimum around 1% NaCl. Grows with methanol, H_2/CO_2 (80%/20%, v/v), formate, lactate, pyruvate, glucose, fructose, cellobiose, and pectin. Thiosulfate is reduced to sulfide. Comparison of 16S rRNA genes reveals that strain TMS^T is most closely related to *Moorella glycerini* (96% sequence similarity), *Moorella thermoacetica* (92%), and *Moorella thermoautotrophica* (92%).

Isolated from a thermophilic bioreactor operated at $65\ ^\circ\text{C}$ with methanol as the energy source. Methanol was used as the carbon source for the enrichment.

DNA G+C content (mol%): 53 (T_m).

Type strain: TMS, ATCC BAA-608, DSM 14980.

GenBank accession number (16S rRNA gene): AF487538.

4. ***Moorella thermoautotrophica*** (Wiegel, Braun and Gottschalk 1982) Collins, Lawson, Willems, Cordoba, Fernández-Garayzábal, Garcia, Cai, Hippe and Farrow 1994, 824^{VP} (*Clostridium thermoautotrophicum* Wiegel, Braun and Gottschalk 1982, 384) therm.au.to.tro'phi.ca. Gr. adj. *thermos* hot; Gr. pron. *autos* self; Gr. n. *trophos* a feeder; N.L. fem. adj. *thermautotrophica* indicating that the organism grows at elevated temperatures with CO_2 as carbon source and H_2 as energy source and consequently is chemolithoautotrophic.

The description is based mainly on the reports of Wiegel et al. (1981, 1991) and Clark et al. (1982) and the type strain JW-YS701/3 and isolate JW-YS701/5, both from hot springs in Yellowstone National Park.

Straight or slightly bent rods of $0.8\text{--}1.0 \times 3.0\text{--}6.0\ \mu\text{m}$ (when grown heterotrophically on PYG medium or yeast extract-methanol) or slightly smaller when grown chemolithoauto-

trophically, found singly or in pairs, rarely in chains. Cells stain Gram-positive in exponential growth phase, but tend to stain Gram-negative from the beginning of the late exponential growth phase. Cells are slightly motile and have 3–8 peritrichous flagella that sometimes have unusual multiple (up to 8) basal plates. Flagella are $140\text{--}150\ \text{nm}$ thick and $8\text{--}15\ \mu\text{m}$ long. The cell surface is covered with an S-layer with a tetragonal array comprised of subunits $11.2\ \text{nm}$ in diameter. The round to slightly oval spores are found in sporangia of $2\text{--}3\ \mu\text{m}$ and have a diameter of $1\text{--}2.5\ \mu\text{m}$ when released. In PYG medium, the extent of sporulation is about 5–10%. In chemolithoautotrophic medium or following growth on methanol, it is over 90%. In agar shake roll tubes and on agar plates ($2\text{--}2.2\%$ w/v agar), colonies reach diameters of about 3 mm after about 7–12 d and are circular, flat to convex, smooth, and tannish white in color. No growth is obtained with fucose, cellulose, dulcitol, erythritol, xylitol, ethanol, propanol, inositol, glycerol, glycol, citrate, succinate, malate, or glutamate. Casamino acids and egg yolk cannot replace yeast extract and do not allow for growth in the presence of trace amounts of yeast extract. In the presence of 2 mg/l nicotinic acid, the type strain can be adapted to grow in mineral media without yeast extract (Savage and Drake, 1986). The type strain utilizes glucose, fructose, arabinose, trehalose, and rhamnose and weakly utilizes ribose. The type and other strains grow well on 100% CO after several days lag phase, on mixtures of CO/H_2 , and on CO/CO_2 with or without H_2 . Growth occurs at $\text{pH}^{25\text{C}}$ $4.8\text{--}7.3$, although the $\text{pH}^{25\text{C}}$ in stationary cultures reaches values around 4.0.

Moorella thermoautotrophica strains can be isolated from nearly every sediment with a bulk pH between 4.0 and 9.0 in a temperate climate, where the sediment/soil freezes in winter, and from geothermally heated features, manure piles, and artificially heated soils. Of the *Moorella* species, this one is nearly ubiquitous.

DNA G+C content (mol%): 54.5 ± 0.4 (HPLC).

Type strain: JW 701/3, ATCC 33924, DSM 1974.

GenBank accession number (16S rRNA gene): L09168, X58353, X77849.

Genus VII. *Thermacetogenium* Hattori, Kamagata, Hanada and Shoun 2000, 1608^{VP}

YOICHI KAMAGATA

Therm.a.ce.to.ge'ni.um. Gr. adj. *thermos* hot; L. n. *acetum* vinegar; Gr. v. suff. *genium* producing; N.L. neut. n. *Thermacetogenium* thermophilic vinegar producer.

Cells are rod-shaped. Strictly anaerobic and thermophilic. Chemoautotrophic and chemo-organotrophic. Gram reaction is negative, but has a Gram-stain-positive cell-wall structure. Round terminal endospores are sometimes formed. Colonies are disk-shaped. **Able to oxidize acetate in co-culture with hydrogenotrophic micro-organisms.** Acetate can also be utilized by sulfate reduction in pure culture. Possesses **menaquinone-7. Grows acetogenically on several alcohols, methoxylated aromatics, organic acids, amino acids, and H_2/CO_2 .** Sugars are not utilized. Additional supplements are not required.

DNA G+C content (mol%): 53.5.

Type species: ***Thermacetogenium phaeum*** Hattori, Kamagata, Hanada and Shoun 2000, 1608^{VP}.

Further descriptive information

On the basis of the phylogenetic analysis, the representative strain *Thermacetogenium phaeum* PB^T was found to be a member of the *Bacillus*–*Clostridium* subphylum of the Gram-stain-positive bacteria, and the closest relative is *Thermoterrabacterium ferrireducens* (87.4% 16S rRNA gene similarity), since reclassified as *Carboxydotherrus ferrireducens*. It is a strictly anaerobic, thermophilic, syntrophic, acetate-oxidizing bacterium.

Acetate is one of the most important intermediates for methanogenesis in anaerobic mineralization of organic materials. Of a number of methanogens described previously, only the genera *Methanosarcina* and *Methanosaeta* are known to produce methane from acetate. Methanogenesis from acetate by these organisms is catalyzed by an acetoclastic reaction in which the methyl group of acetate is reduced to methane (Ferry, 1992). In contrast to these methanogens, some syntrophic proton-reducing organisms are found to oxidize acetate to form methane in association with hydrogenotrophic methanogens (Schnurer et al., 1996; Zinder and Koch, 1984). Metabolically, this syntrophic association consists of two reactions which were originally proposed by Barker (1936). In the first reaction, acetate is oxidized to form H_2 and CO_2 ($CH_3COO^- + 4 H_2O = 4 H_2 + 2 HCO_3^- + H^+$) which are, in the second reaction, converted to methane ($4 H_2 + HCO_3^- + H^+ = CH_4 + 3 H_2O$). As with other anaerobic, syntrophic, fatty acid oxidations, the former reaction is highly endergonic under the standard conditions ($\Delta G^\circ = +104$ kJ per mol) unless it couples with the latter reaction ($\Delta G^\circ = -135$ kJ per mol). Thus, syntrophic acetate degradation is possible only when syntrophic micro-organisms and H_2 -consuming micro-organisms cooperate ($CH_3COO^- + H_2O = CH_4 + HCO_3^-$; $\Delta G^\circ = -31$ kJ per mol). As a matter of fact, the H_2 partial pressure is kept below 40–80 Pa in the *Thermacetogenium* and *Methanothermobacter* co-culture (Hattori et al., 2001; Luo et al., 2002).

Two syntrophic acetate oxidizers in association with hydrogenotrophic methanogens were reported before *Thermacetogenium* was isolated. The first description was strain AOR, which was a thermophilic acetate oxidizer isolated from a methanogenic reactor in co-culture with *Methanobacterium* species (Zinder and Koch, 1984). The isolate was later found to be a homoacetogen which forms acetate from H_2/CO_2 in pure culture, whereas acetate oxidation, i.e., reverse reaction of acetogenesis, occurs in co-culture with the methanogen (Lee and Zinder, 1988). The second acetate syntroph was described as *Clostridium ultunense* which mesophilically oxidizes acetate in the presence of hydrogenotrophic methanogens (Schnurer et al., 1996). Although *Clostridium ultunense* is phylogenetically and chemotaxonomically well characterized, the phylogenetic position of the thermophilic strain AOR is not known. Moreover, the isolate was not deposited to any culture collections and is no longer available.

The genus *Thermacetogenium* is the thirdly described micro-organism that is able to oxidize acetate in co-culture with methanogens. Since strain AOR is no longer available, the genus *Thermacetogenium* is the only thermophilic acetate-oxidizing syntrophic organism that is phylogenetically and chemotaxonomically characterized.

The type strain of *Thermacetogenium* was isolated from sludge in a thermophilic methane-fermenting reactor which had been treating kraft-pulp wastewater. The ecological significance and abundance is, however, unknown. In moderately thermophilic environments (around 55 °C), *Methanosarcina* and *Methanosaeta* usually predominate as acetate degraders and play a crucial role in the mineralization of acetate. Besides those methanogens, some thermophilic sulfate-reducing bacteria such as *Desulfotomaculum thermoacetoxidans* (Min and Zinder, 1990) are known to be able to oxidize acetate in the presence of sulfate. Whether *Thermacetogenium* contributes to acetate oxidation to a great extent in methanogenic environments remains unclear, but evidence indicates that the organism is very versatile.

First, like strain AOR (Lee and Zinder, 1988), *Thermacetogenium* is a homoacetogen which forms acetate from H_2/CO_2 in pure culture. Acetogenesis is the reverse reaction of acetate oxidation that occurs in co-culture with the methanogen. Secondly, the organism is capable of utilizing a variety of substrates including pyruvate, methanol, ethanol, 1-propanol, 1-butanol, 2,3-butanediol, 3,4,5-trimethoxybenzoate, syringate, vanillate, glycine, cysteine, and formate (Hattori et al., 2000). Acetate is the sole or major fermentation product. In utilization of 3,4,5-trimethoxybenzoate, syringate, and vanillate, the methoxy group of each compound is converted to form acetate with a corresponding demethoxylated skeleton. Thirdly, *Thermacetogenium* is able to reduce sulfate and thiosulfate with acetate as the electron donor. Menaquinone-7 should function as the electron carrier in sulfate and thiosulfate reduction, though genes and enzymes involved in sulfate and thiosulfate reduction have not been studied. The *Desulfotomaculum* group is distantly related to *Thermacetogenium* on 16S rRNA gene basis, but it is likely that sulfate-reducing abilities are widely distributed among the cluster including *Thermacetogenium* and *Desulfotomaculum*. From these traits, it can be concluded that *Thermacetogenium* might thrive as an acetogen that could use a number of alcohols and methoxylated compounds. If sulfate is available, it could grow as sulfate reducer. The oxidation of acetate coupled with an H_2 -consuming methanogen may be only one of the alternatives to survive in anaerobic environments.

Regarding the syntrophic acetate-oxidizing reaction, the traits of the partner methanogen may be crucial. *Thermacetogenium phaeum* strain PB was grown on acetate with two different strains of *Methanothermobacter thermautotrophicus* (Hattori et al., 2001). *Thermacetogenium* grew well in co-culture with the strain TM that was isolated from a thermophilic methane reactor from which the *Thermacetogenium* strain was also isolated. By contrast, the organism grew much more slowly when co-cultured with strain ΔH , a well-known representative of *Methanothermobacter thermautotrophicus*. The only recognizable difference between the two strains was that strain ΔH is not capable of utilizing formate, whereas strain TM is. In addition, *Thermacetogenium* was found to produce a trace amount of formate as well as H_2 . Both *Thermacetogenium* and *Methanothermobacter thermautotrophicus* strain TM possess formate dehydrogenase, whereas *Methanothermobacter thermautotrophicus* strain ΔH does not. These results strongly indicate that both H_2 and formate are involved in interspecies electron transfer in the syntrophic acetate oxidation by the organism.

The acetate oxidation in co-culture and acetate formation in pure culture are both driven by the carbon monoxide dehydrogenase (CODH)/acetyl-CoA pathway. The major enzymes (CODH, formyl-tetrahydrofolate synthase, methylene-tetrahydrofolate dehydrogenase, formate dehydrogenase, and hydrogenase) related to the pathway were detected both in cells grown syntrophically on acetate and in cells grown in pure culture on pyruvate (Hattori et al., 2005). Cells grown syntrophically on acetate could immediately convert H_2/CO_2 to form acetate in the presence of a methanogenesis inhibitor, bromoethane sulfonate. However, cells grown on methanol or pyruvate in pure culture cannot immediately convert acetate by mixing resting cells of *Methanothermobacter thermautotrophicus* grown on H_2/CO_2 or *Methanothermobacter thermautotrophicus* cells selectively obtained from a syntrophically acetate-oxidizing co-culture after

selective lysis of *Thermacetogenium* cells. Such new co-cultures recombined from separate pure cultures could start acetate oxidation and methane formation after a significant lag phase of about a month (Hattori et al., 2005). These results suggest that pure culture cells of *Thermacetogenium* may need time to rearrange necessary proteins for syntrophic acetate oxidation.

Enrichment and isolation procedures

The organism may be present in high temperature (around 55 °C) anaerobic environments where methanogenesis occurs. For the primary enrichment of a syntrophic acetate-oxidizing co-culture, a sample taken from a thermophilic anaerobic reactor is serially diluted and inoculated into the basal medium (see *Maintenance procedures*) containing 40–80 mM sodium acetate. Yeast extract, peptones, or other organic nutrients should be avoided since those could allow irrelevant heterotrophs to outgrow. After months of incubation at 55 °C, the microorganisms may grow. However, *Thermacetogenium* could grow together with aceticlastic methanogens such as *Methanosaeta* or *Methanosarcina*, or those methanogens could outcompete it. This may be very much dependent on the population size of this organism. If it is predominant in the original samples, the culture receiving high dilution may consist primarily of *Methanothermobacter*-like methanogens and rod-shaped organisms. It is a good indication if the culture does not contain *Methanosarcina*- and *Methanosaeta*-like methanogens but instead contains hydrogenotrophic methanogens such as *Methanothermobacter* and produces methane stoichiometrically from acetate. Careful microscopic examination would easily differentiate the *Methanothermobacter* type of methanogens from *Methanosarcina* and *Methanosaeta*. Once an acetate-oxidizing, methane-forming enrichment culture which only contains hydrogenotrophic methanogens has been identified, it is very likely that an H₂-forming species would predominate this culture together with an H₂-consuming methanogen. For highly purifying the two-membered co-culture, repeated transfer to fresh acetate medium with serial dilutions would be desired.

Attempts to isolate *Thermacetogenium* from “pure co-culture” with hydrogenotrophic methanogens have so far been unsuccessful, since they do not form visible colonies consisting of the

two species of microbes. Therefore, when isolating *Thermacetogenium*, it would be better to inoculate the highly enriched co-culture on agar medium containing simple organic substrates such as pyruvate, methanol, ethanol, 1-propanol, 1-butanol, 2,3-butanediol, or methoxylated aromatics (such as syringate, vanillate, and 3,4,5-trimethoxybenzoate) since *Thermacetogenium* could grow in pure culture on some of those substrates. Bromoethane sulfonate (BES, 20 mM) should be added to the medium to inhibit the concomitant growth of methanogens.

The only culture representative of this genus, *Thermacetogenium phaeum*, forms colonies on 2% agar medium containing 80 mM pyruvate as the sole carbon and energy source (Hattori et al., 2000). After 2 months of incubation, the colonies that grew up to 2 mm in diameter were picked with a sterile Pasteur pipette and subcultured in liquid medium containing 80 mM pyruvate and 20 mM BES. Purity of the strain was checked by inoculating it into medium containing 0.1% yeast extract and 1% Bacto Tryptone (Difco) and by microscopy. The “partner” hydrogenotrophic methanogen, *Methanothermobacter* was also isolated from the enrichment culture by using the same procedure, except that pyruvate was replaced with H₂/CO₂ (80:20, v/v, 151 kPa) and BES was omitted.

One of the hardest parts of cultivation is reconstruction of the co-culture from pure cultures of *Thermacetogenium* and *Methanothermobacter thermautotrophicus* to verify that the co-culture is able to oxidize acetate and form methane. In the case of *Thermacetogenium phaeum*, to prove that it is a syntrophic acetate-oxidizing bacterium, it was co-inoculated along with the *Methanothermobacter* strain into the basal medium containing 80 mM sodium acetate and incubated at 55 °C. As the control experiments, strains PB^T and TM were separately inoculated into the basal medium under the same conditions. Growth was observed only in the mixed culture after 40 d of incubation. Acetate was converted to methane. The co-culture was able to retain methanogenic activity from acetate after further transfer into fresh medium.

Maintenance procedures

Because of the strict anaerobic nature of this organism, all manipulations must be done using anaerobic techniques. The composition of the basal medium is based on DSM 334 medium.

FIGURE 249. Transmission electron micrographs of pure culture of *Thermacetogenium phaeum* (a) and syntrophic coculture showing terminal endospore (b).

The basal medium contains (per liter): NH_4Cl , 1.0 g; KH_2PO_4 , 0.3 g; NaCl , 0.6 g; $\text{MgCl}_2 \cdot 2\text{H}_2\text{O}$, 0.1 g; $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$, 0.08 g; KHCO_3 , 3.5 g; sodium resazurin, 0.001 g; 10 ml of vitamin solution, 5 ml of trace element solution. The vitamin solution was replaced with that of DSM 141 medium. The composition is as follows (per liter): biotin, 2.0 mg; folic acid, 2.0 mg; pyridoxine.HCl, 10.0 mg; thiamine.HCl, 5.0 mg; riboflavin, 5.0 mg; nicotinic acid, 5.0 mg; DL-calcium pantothenate, 5.0 mg; vitamin B₉, 0.1 mg; *p*-aminobenzoate, 5.0 mg; lipoic acid, 5.0 mg. The trace element solution is based on DSM medium 318 (per liter): nitrilotriacetic acid (NTA), 12.8 g; $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$, 1.35 g; $\text{MnCl}_2 \cdot 4\text{H}_2\text{O}$, 0.1 g; $\text{CoCl}_2 \cdot 6\text{H}_2\text{O}$, 0.024 g; $\text{CaCl}_2 \cdot 2\text{H}_2\text{O}$, 0.1 g; ZnCl_2 , 0.1 g; $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$, 0.025 g; H_3BO_3 , 0.01 g; $\text{Na}_2\text{MoO}_4 \cdot 4\text{H}_2\text{O}$, 0.024 g; NaCl , 1.0 g; $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$, 0.12 g; $\text{Na}_2\text{SeO}_3 \cdot 5\text{H}_2\text{O}$, 4.0 mg; $\text{Na}_2\text{WO}_4 \cdot 2\text{H}_2\text{O}$, 4.0 mg. The trace element solution is adjusted to pH 6.5 with 1 M KOH. For growth of the syntrophic acetate-oxidizing co-culture, the medium contains 80 mM sodium acetate. For pure culture, 80 mM sodium pyruvate is used as the substrate. The medium is anaerobically dispensed into serum vials or bottles under a N_2/CO_2 (80:20, v/v) atmosphere. The vials or bottles are sealed with butyl rubber stoppers fitted with caps. The medium is autoclaved for 20 min at 121 °C. The pH of the autoclaved medium is approximately 6.9–7.1. Prior to inoculation, the medium is reduced with sterile stock solutions

of Na_2S and cysteine/HCl (final concentration: 0.3 g/l each). Cultures are incubated at 55 °C in the dark without shaking.

Once the two-membered co-culture (*Thermacetogenium* and *Methanothermobacter*) is established, it can be maintained stably. Cultures after stationary phase can be left at ambient temperature for at least several months. However, pure culture of *Thermacetogenium* is sometimes very difficult to maintain in this manner since it sometimes lyses very quickly after stationary phase. Pure cultures and co-cultures can be stored in liquid nitrogen or at –80 °C in medium plus 15–20% glycerol.

Differentiation of the genus *Thermacetogenium* from other genera

Thermacetogenium is phylogenetically distant from any known bacterium. *Thermoterrabacterium ferrireducens*, since reclassified as *Carboxydotherrmus ferrireducens*, is related (Slobodkin et al., 1997b), but it is an iron-reducing micro-organism, whereas *Thermacetogenium* is not able to reduce iron. The most outstanding feature that differentiates *Thermacetogenium* from other organisms is that it oxidizes acetate syntrophically with H_2 -consuming methanogens. The other acetate-oxidizing syntroph previously known and well-characterized is *Clostridium ultunense*, but it is mesophilic whereas *Thermacetogenium* is thermophilic.

List of species of the genus *Thermacetogenium*

1. *Thermacetogenium phaeum* Hattori, Kamagata, Hanada and Shoun 2000, 1608^{VP}

phae.um. N.L. neut. adj. *phaeum* brown, referring to the color of the colonies.

Straight or slightly curved rod-shaped cells (Figure 249a), 0.4–0.7 µm wide and 2.0–12.6 µm long. It occurs singly, in pairs, or in chains. Round terminal endospores are observed (Figure 249b). Colonies are disk-shaped, 1.0–3.0 mm in diameter, smooth, and brownish. Methanol, ethanol, *n*-propanol, *n*-butanol, 2,3-butanediol, ethanalamine, pyruvate, 3,4,5-trimethoxybenzoate, syringate, vanillate, glycine, cysteine, formate, and H_2/CO_2 are utilized in pure culture. Acetate is the primary fermentation product. Sugars not utilized. Organic

nutrients such as yeast extract are not required for growth. Acetate is oxidized to CO_2 in co-culture with H_2 -utilizing methanogens. Acetate is also oxidized to CO_2 in pure culture with reduction of sulfate or thiosulfate as electron acceptor. Sulfite, nitrate, nitrite, Fe(III), and fumarate are not utilized when acetate is used as electron donor. Temperature range for growth is 40–65 °C, with an optimum at 58 °C. Growth is observed at a pH range from 5.9 to 8.4, and the optimum is 6.8. Growth occurs in the presence of NaCl concentrations at 0.05–4.5 % (w/v). The major quinone is menaquinone-7.

DNA G+C content (mol%): 53.5 (HPLC).

Type strain: PB, ATCC BAA-254, DSM12270.

GenBank accession number (16S rRNA gene): AB020336.

Genus VIII. *Thermanaeromonas* Mori, Hanada, Maruyama and Marumo 2002, 1679^{VP}

KOJI MORI AND SATOSHI HANADA

Ther.man.aer.o.mo'nas. Gr. n. *thermos* hot; Gr. pref. *an* not; Gr. n. *aer* air; Gr. n. *monas* a unit, monad; N.L. fem. n. *Thermanaeromonas* a thermophilic, anaerobic monad.

Straight, rod-shaped cells, 0.6 µm in diameter and 2–6 µm in length. Gram stain reaction is negative. Nonmotile. **Terminal endospore formation. Strictly anaerobic. Thermophilic.** Growth occurs between 55 and 73 °C, with an optimum at 70 °C. The pH range for growth is 5.5–8.5, with an optimum at pH 6.5. Growth does not occur above 1% NaCl concentration. **Chemoorgano-heterotrophic.** Various organic compounds used for growth. Growth by fermentation or anaerobic respiration. **Thiosulfate, nitrate, and nitrite used as electron acceptor. Menaquinone 7** is the major quinone. Major cellular fatty acids are **C_{15:0 iso}** and

C_{17:0 iso}. Isolated from a geothermal aquifer at a depth of 550 m in Toyoha Mines (Hokkaido, Japan).

DNA G+C content (mol%): 49.6.

Type species: ***Thermanaeromonas toyohensis*** Mori, Hanada, Maruyama and Marumo 2002, 1679^{VP}.

Further descriptive information

Transmission electron microscopic observation showed that *Thermanaeromonas toyohensis* has a Gram-positive cell-wall structure, although the Gram-stain is negative (Figure 250).

FIGURE 250. Cell morphology of *Thermanaeromonas toyohensis*. (a) Phase-contrast micrograph. (b, c) Ultrathin sections of *Thermanaeromonas toyohensis*. Spore is formed at the end of *Thermanaeromonas toyohensis* cell (Reproduced with permission from Mori et al. (2002). *Int. J. Syst. Evol. Microbiol.* 52: 1675–1680.)

Thermanaeromonas toyohensis also contains menaquinone 8 as a minor quinone in addition to a major quinone, menaquinone 7. $C_{16:0}$ is also detected as the minor cellular fatty acid (8% of the total fatty acids) along with major components ($C_{15:0\text{ iso}}$ and $C_{17:0\text{ iso}}$). The cellular polyamines in *Thermanaeromonas toyohensis* are mainly two quaternary pentaamines, N^{β} -bis(aminopropyl)spermidine and N^{β} -bis(aminopropyl)norspermidine (Hosoya et al., 2004).

White colonies of *Thermanaeromonas toyohensis*, showing approximately 1 mm in diameter, take 3 d to develop in a solidified medium containing 0.05% (w/v) glucose, 0.05% yeast extract, and 0.08% thiosulfate. *Thermanaeromonas toyohensis* grows chemoorganoheterotrophically under anaerobic conditions by fermentation or anaerobic respiration. Substrates for anaerobic respiration are arabinose, cellobiose, fructose, glucose, inositol, maltose, mannose, sucrose, trehalose, xylose, yeast extract, formate, lactate, and pyruvate. With the exception of formate, these substrates are also used for fermentative growth. Under anaerobic respiratory conditions, *Thermanaeromonas toyohensis* uses thiosulfate, nitrate, or nitrite as an electron acceptor. The following electron acceptors do not support growth: sulfate, sulfite, elemental sulfur, iron (III) citrate, and fumarate. The cell yield and growth rate under conditions favoring anaerobic respiration with thiosulfate as an electron acceptor are clearly higher than those resulting from fermentative growth.

Only one strain of *Thermanaeromonas toyohensis* has been isolated. The isolate was obtained from a geothermal aquifer that emanated from a crack at 550 m below sea level at the Toyoha Mines in Hokkaido, Japan. The Toyoha Mine is a Ag/Pb/Zn/

Cu polymetallic vein-type deposit and the mineralization of the deposit occurred from 3–0.5 million years ago. The collected hot water was 71 °C and pH 5.8. It welled out from the wall at a rate of 11/min.

Enrichment and isolation procedures

Enrichment and isolation can be performed in the presence of glucose, yeast extract, and thiosulfate under N_2/CO_2 (80/20, v/v) conditions. The medium also contains (per liter): KH_2PO_4 , 0.75 g; K_2HPO_4 , 0.78 g; NH_4Cl , 0.53 g; $NaHCO_3$, 5.0 g; Na_3EDTA , 0.041 g; $FeSO_4 \cdot 7H_2O$, 0.011 g; $MgSO_4 \cdot 7H_2O$, 0.25 g; $CaCl_2 \cdot 2H_2O$, 0.029 g; $NaCl$, 0.23 g; trace-element solution DSM 334 (DSMZ, 1993), 10 ml; vitamin solution DSM 141 (DSMZ, 1993), 10 ml. Incubation at approximately 70 °C is recommended. After enrichment, colonies form in this medium solidified with 0.6% (w/v) gellan gum (Wako Pure Chemicals). After 3 d of incubation under N_2/CO_2 (80/20), white colonies can be observed in pour plates.

Maintenance procedures

Liquid cultures retain viability for several months at room temperature. Long-term preservation in liquid nitrogen is possible in the presence of 5% (v/v) dimethylsulfoxide or 10% (v/v) glycerol under anaerobic conditions.

Differentiation of the genus *Thermanaeromonas* from other genera

Thermanaeromonas toyohensis can be clearly differentiated from other genera within the family *Thermoanaerobacteraceae* by comparison of 16S rRNA gene sequences (Figure 251). *Therman-*

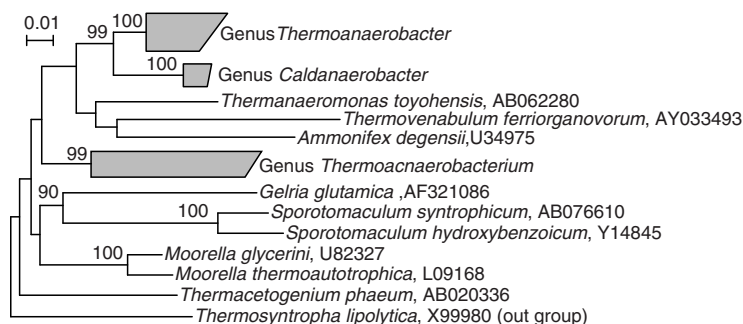

FIGURE 251. Phylogenetic relationships based on 16S rRNA gene sequences in the family *Thermoanaerobacteraceae*, inferred from the neighbor-joining method after alignment using the ARB program. Bootstrap probabilities are indicated at branching points, and scale bar shows substitutions per the compared nucleotides.

TABLE 248. Comparison of properties among *Thermanaeromonas* and related genera^a

Character	<i>Thermanaeromonas</i>	<i>Ammonifex</i>	<i>Caldanaerobacter</i>	<i>Thermoanaerobacter</i>	<i>Thermovenabulum</i>
Morphology	Rods	Rods	Rods (sometimes branching)	Rods	Rods (sometimes branching)
Size (μm)	0.6 × 2–6	0.6 × 2–8.5	0.3 × 4–10	0.4–0.8 × 1–10	0.5 × 1.5–7
Habitat	Thermal aquifer	Hot spring	Submarine, thermal vent, and oilfield	Hot spring, oil well, and lake	Hot spring
Temperature range for growth (°C)	55–73	57–77	50–85	35–85	45–76
DNA G+C content (mol%)	49.6	54	33–41	29–41	36
Spore formation	+	–	ND	+ ^b	+

^aSymbols: +, >85% positive; –, 0–15% positive; ND, not data.

^bWith the exception of some species.

aeromonas toyohensis is phylogenetically distant from the other genera, with low sequence similarities of less than 90%. The phylogenetic relatives are the genera *Ammonifex*, *Caldanaerobacter*, *Thermoanaerobacter*, and *Thermovenabulum*. While all species in the related genera are thermophilic anaerobes like *Thermanaeromonas toyohensis*, there are obvious differences in the genotypic and phenotypic characteristics between the genus *Thermanaeromonas* and the related genera (see Table 248). The genomic DNA G+C content of *Thermanaeromonas toyohensis* is 49.6 mol%, and the value is higher than those in the related genera, except the genus *Ammonifex*. The G+C content of *Ammonifex degensii* is high enough to distinguish it from *Thermanaeromonas toyohensis* (Huber et al., 1996). *Thermanaeromonas toyohensis* is not autotrophic, whereas all species in the genus *Thermoanaerobacter* are autotrophic. However, *Ammonifex degensii* can grow autotrophically on hydrogen and carbon dioxide in the presence of nitrate, sulfate, or sulfur as an electron acceptor (Huber et al., 1996), and three of four subspecies of *Caldanaerobacter subterraneus* show autotrophic growth on CO as a sole energy source (Fardeau et al., 2004; Sokolova et al., 2001). Use of electron acceptors is a significant trait for differentiation of *Thermanaero-*

monas toyohensis from the related organisms. In the presence of lactate as a sole substrate, *Thermanaeromonas toyohensis* uses thio-sulfate, nitrate, and nitrite as an electron acceptor, but cannot use sulfate, sulfite, or elemental sulfur. *Thermovenabulum ferriorganovorum* can reduce Fe(III) in the medium with molecular hydrogen and organic substrates (Zavarzina et al., 2002).

Taxonomic comments

Sequence analysis of the 16S rRNA gene indicates that *Thermanaeromonas toyohensis* belongs to the family *Thermoanaerobacteraceae* in the phylum *Firmicutes*. The closest relatives are the genera *Thermoanaerobacter* and *Caldanaerobacter*, although their sequence similarities to *Thermanaeromonas toyohensis* are very low (88–89%) and the genus is clearly distant from the related organisms in the phylogenetic tree (Figure 251).

The genus *Thermanaeromonas* contains only one species, *Thermanaeromonas toyohensis*, and this species is represented by only a single strain (strain ToBE). However, a very closely related strain, designated BA-5, has been isolated from a geothermal aquifer in a gold mine by A.S. Bonin, and its 16S rRNA gene sequence has been deposited in GenBank database under

accession number AY695836 (sequence similarity is 93%). In addition, one environmental clone sequence (accession no. DQ097672) recovered from an oilfield in China is shown in the DDBJ and is thought to be a phylogenetic relative to *Thermanaeromonas*

toyohensis (sequence similarity is 93%) (Nazina et al., 2005). These isolate and clone sequences were both found in subterranean hot environments similar to that where *Thermanaeromonas toyohensis* is found.

List of species of the genus *Thermanaeromonas*

1. ***Thermanaeromonas toyohensis*** Mori, Hanada, Maruyama and Marumo 2002, 1679^{VP}
to.yo.hen'sis. N.L. adj. *toyohensis* from Toyoha, referring to its isolation from the Toyoha Mines.
The description is as given for the genus.

Isolated from a geothermal aquifer at a depth of 550 m in Toyoha Mines (Hokkaido, Japan).
DNA G+C content (mol%): 49.6 (HPLC).
Type strain: ToBE, DSM 14490, JCM 11376, NBRC 101528.
GenBank accession number (16S rRNA gene): AB062280.

Family II. **Thermodesulfobiaceae** Mori, Kim, Kakegawa and Hanada 2004, 1^{VP} (Effective publication: Mori, Kim, Kakegawa and Hanada 2003, 288.)

KOJI MORI AND SATOSHI HANADA

Ther.mo.de.sul.fo.bi.a'ce.ae. N.L. neut. n. *Thermodesulfobium* type genus of the family; suff. -aceae denoting a family; N.L. fem. pl. n. *Thermodesulfobiaceae* the family of *Thermodesulfobium*.

Rod-shaped cells that **stain Gram-negative. Nonsporeforming. Moderately thermophilic.** Chemoautotrophic and strictly anaerobic. Growth occurs by **anaerobic respiration with sulfate or nitrate** as electron acceptors. Represents a distinct phylogenetic lineage based on 16S rRNA gene sequence analyses. The family contains two genera, *Thermodesulfobium* and *Coprothermobacter*.

DNA G+C content (mol%): 35.1–43.0.

Type genus: Thermodesulfobium Mori, Kim, Kakegawa and Hanada 2004, 1^{VP} (Effective publication: Mori, Kim, Kakegawa and Hanada 2003, 288.).

Genus I. **Thermodesulfobium** Mori, Kim, Kakegawa and Hanada 2004, 1^{VP} (Effective publication: Mori, Kim, Kakegawa and Hanada 2003, 288.)

KOJI MORI AND SATOSHI HANADA

Ther.mo.de.sul.fo'bi.um. Gr. adj. *thermos* hot, L. pref. *de* from, L. neut. n. *sulfur* sulfur, Gr. masc. n. *bios* life, N.L. neut. n. *Thermodesulfobium* a thermophilic organism that reduces a sulfur compound.

Strictly anaerobic, nonmotile rods about 0.5 µm × 2–4 µm. **Stains Gram-negative.** Nonsporeforming. **Moderately thermophilic.** Growth temperature range is 37–65 °C, with an optimum of 50–55 °C. **The pH range for growth is 4.0–6.5.** Growth does not occur above a NaCl concentration of 1% (w/v). **Chemoautotrophic.** Growth occurs on H₂/CO₂ or formate by **anaerobic respiration with sulfate, thiosulfate, nitrate, or nitrite** as electron acceptors. The major cellular fatty acid is C_{16:0}. MK-7(H₂) and MK-7 are the major quinones.

DNA G+C content (mol%): 35.1.

Type species: Thermodesulfobium narugense Mori, Kim, Kakegawa and Hanada 2004, 1^{VP} (Effective publication: Mori, Kim, Kakegawa and Hanada 2003, 288.).

Further descriptive information

This genus contains only one species, *Thermodesulfobium narugense*, which was isolated from a microbial mat in a Japanese hot spring. The species is a moderate thermophile and is able to tolerate temperatures up to 65 °C.

Rod-shaped, Gram-stain-negative, nonsporeforming, and nonmotile. The presence of a typical Gram-negative cell wall with an outer membrane is visualized by transmission electron microscopy (Figure 252). This result is confirmed by the polymyxin B-LPS test (Wiegel and Quandt, 1982) where the fibrous structure and blebs typical of lipopolysaccharides are observed on the surface of polymyxin-B-treated cells.

Thermodesulfobium narugense is a strictly anaerobic bacterium able to grow under an H₂/CO₂ atmosphere. Anaerobic growth is coupled to sulfate reduction. At the optimal growth temperature of 55 °C and pH of 5.5, the doubling time is 14 h. When H₂ and CO₂ are provided as energy and carbon sources, thiosulfate, nitrate, or nitrite also serve as electron acceptors. Sulfite, elemental sulfur, Fe(III), citrate, fumarate, dimethyl sulfoxide, and O₂ do not serve as electron acceptors. In the presence of sulfate, the bacterium also uses formate instead of H₂ as an electron donor, but the growth is clearly slower. The following organic compounds are not utilized as substrates: glucose, ace-

tate, lactate, pyruvate, malate, propionate, butyrate, fumarate, succinate, citrate, ethanol, propanol, and methanol.

The major quinones are MK-7(H₂) and MK-7 (approx. 90% of total). Trace amounts of MK-8 and MK-7(H₄) are also found. Palmitic acid (C_{16:0}) accounts for approximately 46% of the total cellular fatty acids. In addition, the following fatty acids are present as minor components: C_{19:0 ω9c cyclo}, C_{18:0}, C_{18:1 ω9c}, C_{20:0}, C_{14:0}, C_{12:0 3OH}, and C_{12:0}.

Enrichment and isolation procedures

Thermodesulfobium narugense is occasionally found in a microbial mat formed in a hot spring at 45–60 °C and pH 6–7. For enrichment of the sulfate-reducing bacterium, a piece of the mat is inoculated into an enrichment medium composed of the following salts and solutions (per liter): KH₂PO₄, 0.75 g; K₂HPO₄, 0.78 g; NH₄Cl, 0.53 g; Na₃EDTA, 0.041 g; FeSO₄·7H₂O, 0.011 g; MgSO₄·7H₂O, 0.25 g; CaCl₂·2H₂O, 0.029 g; NaCl, 0.23 g; Na₂SO₄, 2.8 g; sodium acetate, 0.16 g; trace element solution DSM 334, 10 ml; and vitamin solution DSM 141, 10 ml. The medium is autoclaved under a N₂/CO₂ (4:1, v/v) atmosphere in vials with butyl rubber stoppers and aluminum seals. Prior to inoculation, the medium is reduced with a sterile stock solution of cysteine HCl (final concentration of 0.25 g/l), and the gas phase is replaced by H₂/CO₂ (4:1, v/v; 152 kPa). The pH of the medium is adjusted to 6.0. As an indicator for sulfide production, an FeSO₄ solution (final concentration of 0.2 g/l) is added to the medium. After 1 week of incubation at 55 °C, pronounced sulfide production is observed. The enrichment culture is transferred several times to new medium of the same composition. For isolation of a pure culture, the same medium is solidified with 2% (w/v) agar and incubated under identical anaerobic conditions for 2–3 weeks.

Maintenance procedures

Thermodesulfobium narugense is maintained in the enrichment medium under a H₂/CO₂ (4:1, v/v) atmosphere at 55 °C. The culture should be transferred every 2 weeks. After growth, the

FIGURE 252. Ultrathin section of *Thermodesulfobium narugense* showing a Gram-negative type of cell wall with an outer membrane.

culture can also be stored at room temperature for several weeks. For long-term storage, it can be preserved in liquid nitrogen (-196°C) under strictly anaerobic conditions with 5% dimethylsulfoxide or 10% glycerol as the cryoprotectant. Liquid drying is also successful with a protective medium composed of 0.1 M potassium phosphate buffer (pH 7.0), 3% sodium glutamate, 1.5% ribitol, and 0.05% cysteine hydrochloride monohydrate.

Differentiation of the genus *Thermodesulfobium* from other genera

Phylogenetic analysis based on the 16S rRNA gene sequence (Figure 253) reveals that *Thermodesulfobium narugense* is only distantly related to other known sulfate-reducing bacteria, such as *Thermodesulfobacterium* spp., *Thermodesulfobivibrio* spp., *Desulfobacter* spp. (within the class *Deltaproteobacteria*), and *Desulfotomaculum* spp. (within the phylum *Firmicutes*). With sequence similarities less than 79%, *Thermodesulfobium narugense* is clearly distinguished from these other sulfate-reducing bacteria. Sequence analyses of the *dsrAB* (alpha and beta subunits of dissimilatory sulfite reductase) and *apsA* (alpha subunit of adenosine-5'-phosphosulfate reductase) genes also support the phylogenetically solitary position of *Thermodesulfobium narugense* (Mori et al., 2003).

In spite of their phylogenetic differences, *Thermodesulfobium narugense* shares a number of phenotypic similarities with *Thermodesulfobacterium* spp. and *Thermodesulfovibrio* spp., including

cell walls that stain Gram-stain-negative, thermophily, absence of spores, and low G+C content of the DNA (Table 249). However, *Thermodesulfobium narugense* differs in some ways from these genera (Henry et al., 1994; Jeanthon et al., 2002; Sonne-Hansen and Ahring, 1999). The optimum growth temperature of all species in the genera *Thermodesulfobivibrio* and *Thermodesulfobacterium* is above 65°C , while the temperature maximum of *Thermodesulfobium narugense* is 55°C . With the exception of *Thermodesulfobacterium hydrogeniphilum*, *Thermodesulfobivibrio* and *Thermodesulfobacterium* spp. are chemoheterotrophs and can also grow fermentatively. *Thermodesulfobium narugense* grows chemoautotrophically and can not ferment. *Thermodesulfobivibrio* and *Thermodesulfobacterium* spp. do not use nitrate or nitrite, but *Thermodesulfobium narugense* does. *Thermodesulfobivibrio* and *Thermodesulfobacterium* spp. prefer neutral or basic pH for growth, while *Thermodesulfobium narugense* prefers slightly acidic conditions. Moderate acidophily is rare among sulfate-reducing organisms whether they are thermophilic or mesophilic.

Taxonomic comments

The circumscription of the genus *Thermodesulfobium* is based on the features of a single isolate. Further isolation and characterization of related strains is necessary to elucidate the phenotypic diversity of the genus.

The taxonomic affiliation of the genus *Thermodesulfobium* is still unsettled. In the Bergey's Taxonomic Outline, release 5, May (<http://www.bergeysoutline.com>), this genus was classified in the order *Thermoanaerobacteriales* in the class *Clostridia* of the phylum *Firmicutes*. However, this taxonomic assignment is probably inaccurate (Ludwig et al., 2009; Mori et al., 2003). Phylogenetic analyses of the 16S rRNA gene clearly demonstrates that *Thermodesulfobium narugense* is only distantly related to members of other phyla including the *Firmicutes* and the candidate divisions of environmental clones (Figure 253). Phylogenetic trees constructed by neighbor-joining, maximum-likelihood, and maximum-parsimony methods all indicate that the closest relative of *Thermodesulfobium narugense* is the environmental clone OPB46 retrieved from a Yellowstone hot spring and classified within the candidate division OP9 (Hugenholtz et al., 1998). However, their sequence similarity is merely 81%, and the bootstrap value of the branching node is quite low. The low bootstrap values suggest that the affiliation of *Thermodesulfobium narugense* with OP9 is unreliable and that they are not in the same clade. These results support the conclusion that *Thermodesulfobium narugense* is sufficiently isolated from previously described bacteria to justify creation of a new phylum even though the analysis is based upon a single isolate.

List of species of the genus *Thermodesulfobium*

1. ***Thermodesulfobium narugense*** Mori, Kim, Kakegawa and Hanada 2004, 1^{VP} (Effective publication: Mori, Kim, Kakegawa and Hanada 2003, 288.)

na.ru.gen'se. N.L. neut. adj. *narugense* from Narugo, the hot spring in Japan where the species was isolated.

The description is the same as given for the genus. Isolated from a microbial mat in Narugo hot spring, Miyagi, Japan (the temperature and pH of the hot water were 58°C

and 6.9, respectively). The mat was composed mainly of a moderately thermophilic sulfur-oxidizing bacterium, *Thiomonas thermosulfata*, which belongs to the class *Betaproteobacteria*.

DNA G+C content (mol%): 35.1 (HPLC).

Type strain: Na82, DSM 14796, JCM 11510, NBRC 100082.

GenBank accession number (16S rRNA gene): AB077817.

FIGURE 253. Phylogenetic tree of the 16S rRNA gene of *Thermodesulfobium narugense* with representatives of other bacterial phyla. The tree was constructed with the ARB program based upon the tree reported by Hugenholtz (2002). The scale bar shows substitutions per compared positions. Phyla or other taxa containing sulfate-reducing organisms are indicated with bold font.

Genus II. *Coprothermobacter* Rainey and Stackebrandt 1993a, 857^{VP}

BERNARD OLLIVIER AND JEAN-LOUIS GARCIA

Co.pro.ther'mo.bac'ter. Gr. fem. n. *kopros* manure; Gr. adj. *thermos* warm; Gr. masc. dim. n. *bakterion* rod; N.L. masc. n. *Coprothermobacter* a thermophilic rod from manure.

Rod-shaped cells, 0.5 × 1.0–6.0 μm; occur singly or in pairs in young cultures; pleomorphic in old cultures. Colonies are white, circular (diameter 1–2 mm), convex, smooth with entire edges. Gram-stain-negative. Nonsporeforming. **Nonmotile. Strictly anaerobic. Thermophilic.** Optimum temperature, 55–70 °C. Neutrophilic. Chemo-organotrophic. Proteolytic using gelatin and peptones. Sugars are used poorly unless yeast extract or rumen fluid is added. Trypticase peptone stimulates glucose utilization. The principal fermentation end products from sugar or protein fermentation are acetic acid, H₂, and CO₂. Thiosulfate, but not sulfate, is used as electron acceptor for growth. Isolated from thermophilic digestors. The type species, *Coprothermobacter proteolyticus*, represents a deeply branched taxon of the domain *Bacteria*.

DNA G+C content (mol%): 43.

Type species: Coprothermobacter proteolyticus (Ollivier, Mah, Ferguson, Boone, Garcia and Robinson 1985) Rainey and Stackebrandt 1993a, 857^{VP} (*Thermobacteroides proteolyticus* Ollivier, Mah, Ferguson, Boone, Garcia and Robinson 1985, 427).

Further descriptive information

Electron micrographs of thin sections of the two species of the genus *Coprothermobacter*, *Coprothermobacter proteolyticus* and *Coprothermobacter platensis*, reveal a thin inner wall layer and a heavy outer wall. Both species grow poorly on proteins or sugars in mineral medium in the absence of organic compounds (yeast

extract), indicating that cofactor(s) present in yeast extract are required for good growth. In the case of *Coprothermobacter proteolyticus*, yeast extract cannot be replaced by trypticase peptones, coenzyme M, or sodium acetate; trypticase peptone stimulates the fermentation of glucose, but Casamino acids do not; synthesis of cell material is not always proportional to the amount of carbon and energy source utilized, particularly with maltose and mannose (Ollivier et al., 1985). *Coprothermobacter platensis* (Etchebehere et al., 1998) differs from *Coprothermobacter proteolyticus* in optimum temperature for growth, antibiotic susceptibility, and sugar utilization (Table 250). Gelatin fermentation by *Coprothermobacter proteolyticus* leads to the formation of ammonium, acetate, H₂, and CO₂ along with smaller amounts of isobutyrate and isovalerate, but also trace amounts of propionate (Kerstens et al., 1993; Ollivier et al., 1985). Interestingly, co-cultures of *Coprothermobacter proteolyticus* and a hydrogenotrophic methanogen (*Methanobacterium* species) show an increase in propionate and isobutyrate production (Ollivier et al., 1986) suggesting that some peptides or amino acids are only oxidized via interspecies hydrogen transfer by this micro-organism. Both species reduce thiosulfate, but not sulfate, to sulfide with a concomitant increase in growth and glucose utilization (Etchebehere et al., 1998). Degradation of gelatin by *Coprothermobacter proteolyticus* is not influenced by ammonium chloride concentrations up to 6 g/l; growth is inhibited by Na⁺ (0.60 M), neomycin (0.15 g/l), and penicillin G (20 U/

ml); vancomycin, polymyxin B, sodium azide, and kanamycin are not effective inhibitors (Kersters et al., 1994). Vancomycin (2.5 mg/l), neomycin (0.15 g/l), and polymyxin (20 mg/l) inhibit growth of *Coprothermobacter platensis* (Etchebehere et al., 1998). The major polyamines synthesized by *Coprothermobacter proteolyticus* are putrescine, spermidine, and spermine (Hamana et al., 1996). *Coprothermobacter proteolyticus* possesses a thermostable protease with optimal temperature of 85 °C and optimal pH of 9.5. The protease retains about 90% of its activity at pH 10.0 and appears quite specific as compared to enzymes from other thermophilic or hyperthermophilic proteolytic microorganisms (Klingeberg et al., 1991).

Enrichment and isolation procedures

Coprothermobacter species can be enriched from anaerobic thermophilic digesters treating proteinaceous wastes such as tannery wastes and food wastes using media and procedures similar to those described by Ollivier et al. (1986) with gelatin as the energy source and Na₂S and cysteine as the reductive agents. Similarly, the use of peptone-yeast medium (Holdeman et al., 1977) is recommended to enrich proteolytic bacteria in general and *Coprothermobacter proteolyticus* in particular as described by Kersters et al. (1994). At least three subcultures in the same growth conditions, at temperature from 55 °C up to 70 °C are needed before isolation.

After several transfers, the enrichment cultures are serially diluted using the method of Hungate (1969) with roll tubes containing the basal medium, gelatin as the energy source, and purified agar at a concentration of 2%. For isolation, agar medium can be also poured in plates within an anaerobic chamber. In order to detect selectively proteolytic colonies during the first steps of isolation, casein can be used as substrate. Colonies, surrounded with large clearing zones are picked and restreaked on gelatin agar plates or roll tubes. At least two colonies are picked, and the process of serial dilution in roll tubes is repeated in order to purify the cultures.

Maintenance procedures

Stock cultures can be maintained on the medium described by Ollivier et al. (1986) and transferred at least monthly. Liquid cultures retain viability after several weeks of storage at room temperature. As a precaution, cultures also have to be refrigerated. Because of easy death/lysis of cells when cultures are further incubated at high temperature, it is recommended to stock cultures before the end of the exponential growth phase.

Taxonomic and phylogenetic considerations

The genus *Coprothermobacter* contains two species, *Coprothermobacter proteolyticus* and *Coprothermobacter platensis* (Etchebehere et al., 1998). The type species, *Coprothermobacter proteolyticus*, was originally placed in the genus *Thermobacteroides*, mainly because of phenotypic similarities to the type species of that genus (*Thermobacteroides acetoethylicus*) (Ben-Bassat and Zeikus, 1981). However, phylogenetic analysis of 16S rRNA sequences later led to the reclassification of *Thermobacteroides acetoethylicus* as *Thermoanaerobacter acetoethylicus* (Rainey and Stackebrandt, 1993b, 1993a). *Coprothermobacter proteolyticus*, being phylogenetically only distantly related to any species known at that time, was placed in the new genus *Coprothermobacter* as the type species. According to the 16S rRNA phylogenetic analysis presented in the roadmap to this volume (Figure 7), the genus *Coprothermobacter* is a member of the family *Thermodesulfobiaceae*, order *Thermoanaerobacteriales*, class *Clostridia* in the phylum *Firmicutes*.

Differentiation of the genus *Coprothermobacter* from other genera

Characteristics by which *Coprothermobacter* may be differentiated from phenotypically similar genera and species are shown in Table 251.

List of species of the genus *Coprothermobacter*

- Coprothermobacter proteolyticus*** (Ollivier, Mah, Ferguson, Boone, Garcia and Robinson 1985) Rainey and Stackebrandt 1993a, 857^{VP} (*Thermobacteroides proteolyticus* Ollivier, Mah, Ferguson, Boone, Garcia and Robinson 1985, 427)

Cells are rod-shaped, 0.5 × 1–6 µm, occurring singly or in pairs in young cultures (Figure 254); pleomorphic in old

cultures. No lysis is observed in the stationary phase. Colonies in roll tubes are 1–2 mm in diameter after 3–4 d; they are opaque, whitish, crenated or entire, circular, and slightly convex. Gram-negative cell-wall structure (Figure 255). Non-motile. Nonsporeforming.

Obligately anaerobic. Ferments peptone, gelatin, casein, trypticase peptone, and bovine serum albumin in the presence of 0.1% yeast extract. Grows on D-glucose,

^cND, Not determined.

^dSulfide produced from sulfur reduction.

^eSulfur produced from thiosulfate reduction.

D-fructose, maltose, sucrose, D-mannose, and starch when 1% yeast extract is added. Does not grow on D-arabinose, melibiose, and cellulose. Trypticase peptone stimulates glucose utilization. The major fermentation products from gelatin and glucose in the presence of yeast extract are acetic acid, H₂, and CO₂. Ammonium along with smaller quantities of propionic, isobutyric, and isovaleric acids are produced during gelatin fermentation. Thiosulfate and elemental sulfur, but not sulfate, are used as electron acceptors for growth.

Optimal temperature for growth is 63–70 °C (range, 35–70 °C); optimal pH is 6.8–7.5 (range, pH 5.0–9.4). Growth is inhibited by neomycin (0.15 g/l) and penicillin G (20 U/ml). Sensitive to vancomycin (5 mg/l). Concentration of 0.7 M Na⁺ is inhibitory. The major cellular fatty acids are C_{15:0 iso}, C_{16:0}, C_{14:0 iso 3OH}, C_{17:0 iso} and a fatty acid with an equivalent chain-length of 15.360.

FIGURE 254. Phase-contrast photomicrograph of *Coprothermobacter proteolyticus*. Bar = 10 μm.

Two strains were isolated from anaerobic thermophilic digesters. Strain BT (=ATCC 35245 = OCM 4 = DSM 5265 = LMG 11567) was isolated from a digester that was fermenting tannery wastes and cattle manure, whereas strain I8 (=LMG 14268) was isolated from a biokitchen waste digester.

DNA G+C content (mol%): 43–45 (ultracentrifugation).

Type strain: BT, ATCC 35245, OCM 4, DSM 5265, LMG 11567.

GenBank accession number (16S rRNA gene): X69335.

2. *Coprothermobacter platensis* Etchebehere, Pavan, Zorzópolos, Soubes and Muxi 1998, 1302^{VP}

pla.ten'sis. L. masc. adj. *platensis* pertaining to Rio de la Plata, a river between Uruguay and Argentina, the region where the strain was isolated.

Cells are straight rods, 0.5 × 1.5–2 μm, that occur singly or in pairs in young cultures. Lysis is observed in the

FIGURE 255. Ultrathin section of *Coprothermobacter proteolyticus* showing a cell-wall structure typical of Gram-negative bacteria. Bar = 0.5 μm.

stationary phase. Colonies in PY agar plates are circular, 1 mm in diameter, with an entire border, transparent to whitish. Stains Gram-negative, but the cell wall under the electron microscope is atypical with a dense inner layer and a less dense outer layer. Nonmotile and nonspore-forming.

Obligately anaerobic. Proteolytic. Ferments gelatin, casein, bovine albumin, peptone, and yeast extract. Glucose, fructose, sucrose, maltose, and starch are poorly fermented. Fermentation products from glucose are acetate, H₂, and CO₂. The major fermentation products from gelatin are acetate, propionate, H₂, and CO₂. Growth on glucose is stimulated by thiosulfate, which is reduced to sulfide. Sulfate and nitrate are not reduced. Moderately thermophilic;

optimum temperature 55 °C (range 35–65 °C). Optimum pH 7.0 (range 4.3–8.3). Yeast extract is required. Growth is inhibited by vancomycin (2.5 mg/l), neomycin (0.15 g/l), and polymyxin B (20 mg/l). Resistant to penicillin G (20 U/ml), kanamycin (600 ng/ml), and sodium azide (0.5 g/l). NaCl, 0.4 M or higher, is inhibitory. Phylogenetically closely related to *Coprothermobacter proteolyticus* according to the 16S rDNA sequence analysis. Both are included in one of the earlier branches of the domain *Bacteria*. Isolated from a mesophilic upflow anaerobic sludge blanket reactor of a baker's yeast factory.

DNA G+C content (mol%): 43 (HPLC).

Type strain: 3R, DSM 11748.

GenBank accession number (16S rRNA gene): Y08935.

Family III. Incertae Sedis

Members of this monophyletic cluster were previously assigned to the family “*Thermoanaerobacteriaceae*” by Garrity et al. (2005). Because the current outline proposes that *Thermoanaerobacter* and not *Thermoanaerobacterium* is the type of the, now, *Thermoanaerobacteraceae* fam. nov., the taxonomic sta-

tus of these genera is ambiguous. Although classified within a single family *incertae sedis*, the evidence for the relationship between *Thermoanaerobacterium* and the other members of this group is not strong. Thus, subsequent analyses may suggest reorganization.

Genus I. **Caldicellulosiruptor** Rainey, Donnison, Janssen, Saul, Rodrigo, Bergquisy, Daniel, Stackebrandt and Morgan 1995, 197^{VP} (Effective publication: Rainey, Donnison, Janssen, Saul, Rodrigo, Bergquist, Daniel, Stackebrandt and Morgan 1994, 264.) emend. Onyenwoke, Lee, Dabrowski, Ahring and Wiegel 2006, 1394

FRED A. RAINEY

Cal.di.cel.lu.lo.si.rup'tor. L. adj. *caldus* hot; N.L. n. *cellulosum* cellulose; L. masc. n. *ruptor* breaker; N.L. masc. n. *Caldicellulosiruptor* cellulose-breaker living under hot conditions.

Cells are straight **rods**. **Gram-stain-negative**. Endospores not observed. Growth not obtained after heat treatment at 115 °C for 20 min. Growth **strictly anaerobic**, occurring over the temperature range of 45–82 °C with optima in the range of 65–75 °C. No growth detected below 45 °C or above 82 °C. Monosaccharides, disaccharides and polysaccharides serve as fermentable substrates. **Cellulose is hydrolyzed by most strains**.

DNA G+C content (mol%): 35–37.5 (T_m , HPLC).

Type species: Caldicellulosiruptor saccharolyticus Rainey, Donnison, Janssen, Saul, Rodrigo, Bergquisy, Daniel, Stackebrandt and Morgan 1995, 197^{VP} (Effective publication: Rainey, Donnison, Janssen, Saul, Rodrigo, Bergquist, Daniel, Stackebrandt and Morgan 1994, 265.).

Further descriptive information

The genus *Caldicellulosiruptor* contains five species: *Caldicellulosiruptor saccharolyticus* (Rainey et al., 1994) *Caldicellulosiruptor acetigenus* (Onyenwoke et al., 2006), *Caldicellulosiruptor kristjanssonii* (Bredholt et al., 1999), *Caldicellulosiruptor lactoaceticus* (Mladenovska et al., 1995) and *Caldicellulosiruptor owensensis* (Huang et al., 1998). All strains are rod-shaped, varying in length from 1.5 to 9.4 µm and in diameter from 0.4 to 1.0 µm. Cells have rounded ends and occur singly, in pairs or in short chains. In the case of *Caldicellulosiruptor acetigenus* chains of up to eight cells have been observed (Nielsen et al., 1993). During the exponential-phase, *Caldicellulosiruptor owensensis* cultures contain small coccoid cells (Huang et al., 1998). Although this genus falls within the radiation of the low G+C Gram-positive taxa (*Firmicutes*), all strains tested stain Gram-negative. A Gram-positive cell-wall structure based on electron microscopy studies has been shown in *Caldicellulosiruptor owensensis* (Huang et al., 1998) and *Caldicellulosiruptor acetigenus* (Nielsen et al., 1993; Onyenwoke et al., 2006). Flagella have been observed in two of the five species of this genus; *Caldicellulosiruptor kristjanssonii* is nonmotile, but peritrichous flagella are observed in exponential-phase cultures and two subterminal flagella were seen in old cultures (Bredholt et al., 1999). Although motility has not been observed, young cells of *Caldicellulosiruptor owensensis* have lophotrichous flagella (Huang et al., 1998). One of the main phenotypic characteristics differentiating the cellulose-degrading species of *Caldicellulosiruptor* from cellulolytic species of the genus *Clostridium* is the absence of endospores in species of *Caldicellulosiruptor*. Endospores or similar heat resistant structures

have not been observed in any species of the genus *Caldicellulosiruptor* and in some cases this has been confirmed by heat treatments such as boiling for 5 min. *Caldicellulosiruptor kristjanssonii* (Bredholt et al., 1999) and *Caldicellulosiruptor acetigenus* (Nielsen et al., 1993), or heating culture to 115 °C for 20 min., *Caldicellulosiruptor saccharolyticus* (Rainey et al., 1994). Sphaeroplasts have been observed in *Caldicellulosiruptor acetigenus* when it was grown on minimal salts media and xylose (Nielsen et al., 1993). Colony descriptions have been provided for all species of the genus *Caldicellulosiruptor*, but growth on different media and under different conditions makes these characteristics of little comparative value. Colonies of *Caldicellulosiruptor saccharolyticus* grown on 2/1 cellobiose agar are 2–5 mm in diameter, cream-colored, and umbonate (Rainey et al., 1994). *Caldicellulosiruptor acetigenus* on xylan containing agar forms colonies that are off white, milky-colored and have clearing zones around them of up to 2 cm in diameter (Nielsen et al., 1993); after 7 d incubation in agar roll tubes surface colonies of *Caldicellulosiruptor lactoaceticus* are circular, white, opalescent, 1 mm in diameter with an entire edge (Mladenovska et al., 1995). *Caldicellulosiruptor owensensis* forms circular, convex, opaque, yellowish colonies with smooth edges that are up to 2 mm in diameter (Huang et al., 1998). Colonies of *Caldicellulosiruptor kristjanssonii* in roll tubes containing Avicel (microcrystalline cellulose) are 0.5–1.0 mm in diameter, flat with fringed edges and after 9–14 d incubation show 2–4 mm zones of clearing (Bredholt et al., 1999).

The genus *Caldicellulosiruptor* can be differentiated from the thermophilic, cellulolytic *Clostridium* species (*Clostridium stercorarium*, *Clostridium thermocellum* and *Clostridium thermocopriae*) and related strains based on maximum growth temperature. In the numerical taxonomy study of Rainey et al. (1993a) growth at 75 °C and at 80 °C was determined for 51 strains, 43 of which did not form endospores and clustered separately from the eight spore-forming strains (including the type strains of the species *Clostridium stercorarium*, *Clostridium thermocellum* and *Clostridium thermocopriae*). The strains falling in clusters A–D are considered to be *Caldicellulosiruptor* strains (including the strains Tp8T 6331^T, COMP. B1, Wai35. B1, RI2. B1, Z-1203, Rt8. B7, Rt8. B15, and Ok9. B1) and all grow at 75 °C and ~70% of them at 80 °C, in contrast to the endospore forming strains, 60% of which grow at 75 °C and none at 80 °C (Rainey et al., 1993a). Growth of the described species of the genus *Caldicellulosiruptor* is in the temperature range of 45–82 °C with optima

in the range of 65–78 °C (see species descriptions below). *Caldicellulosiruptor kristjanssonii* has both the highest temperature maximum for growth at 82 °C and optimum for growth at 78 °C (Bredholt et al., 1999). *Caldicellulosiruptor* species are neutrophiles growing optimally at pH ~7.0. The pH range for growth of the species of this genus is 5.2–9.0 (see species descriptions below). *Caldicellulosiruptor owenensis* is described as an alkalitolerant species growing up to pH 9.0 (Huang et al., 1998).

All species of the genus are obligately anaerobic chemorganotrophs with fermentative metabolism. Monosaccharides, disaccharides, sugar alcohols, and polysaccharides serve as fermentable substrates. The species of the genus can be differentiated based on substrate utilization patterns (Table 252). *Caldicellulosiruptor lactoaceticus* uses a limited number of substrates including Avicel, starch and xylan (Table 252, Mladenovska et al., 1995). Growth of the species *Caldicellulosiruptor saccharolyticus*, *Caldicellulosiruptor lactoaceticus* and *Caldicellulosiruptor kristjanssonii* is supported by Avicel, starch and xylan (Bredholt et al., 1999; Mladenovska et al., 1995; Rainey et al., 1994). *Caldicellulosiruptor owenensis* also grows on starch, xylan and cellulose but the type of cellulose tested is not provided, therefore the ability of this species to degrade crystalline cellulose is undetermined (Huang et al., 1998). *Caldicellulosiruptor acetigenus* is the only species of the genus *Caldicellulosiruptor* that does not degrade cellulose either filter paper or Avicel, but does display cellulase enzyme activity when grown on carboxymethylcellulose (Nielsen et al., 1993; Onyenwoke et al., 2006). The end products of fermentation of sugars for the species of the genus include acetate, ethanol, CO₂ and H₂. Lactate is produced as the main product of fermentation by *Caldicellulosiruptor lactoaceticus* and in smaller amounts by *Caldicellulosiruptor saccharolyticus*, *Caldicellulosiruptor owenensis* and *Caldicellulosiruptor kristjanssonii*. *Caldicellulosiruptor acetigenus* does not produce lactate as an end product of fermentation, but does produce trace amounts of iso-butyrate (Nielsen et al., 1993; Onyenwoke et al., 2006).

The G+C content is in the range of 35.0–37.5 mol% for the type strains of the species of the genus *Caldicellulosiruptor*. The

values for the species *Caldicellulosiruptor acetigenus*, *Caldicellulosiruptor lactoaceticus* and *Caldicellulosiruptor kristjanssonii* were determined by the HPLC method while those of *Caldicellulosiruptor saccharolyticus* and *Caldicellulosiruptor owenensis* were determined by the thermal denaturation and buoyant gradient density methods respectively.

Enrichment, isolation and growth conditions

Four of the five species of the genus *Caldicellulosiruptor* have been isolated from thermal springs or material associated with thermal springs, the exception being *Caldicellulosiruptor owenensis* which was isolated from a freshwater pond with a temperature of 32 °C in the dry lake bed of Owens Lake, California, USA. Species of this genus can be isolated using anaerobic techniques with xylan or cellulose as substrates in enrichment cultures. The roll tube method (Hungate, 1969) can be used for the isolation of single colonies that give zones of clearing in the xylan- or cellulose-containing agar. *Caldicellulosiruptor saccharolyticus* strain Tp8T 6331^T was isolated from the decomposed end of a *Pinus radiata* plank in the downstream flow of a thermal spring TP10, Taupo, New Zealand (Sissons et al., 1987). Thermal spring TP10 had a temperature of 78 °C and the downstream flow at which the pine wood plank was located (TP8) had a temperature of 48 °C (Sissons et al., 1987). Strain Tp8T 6331^T was isolated from the homogenized wood sample inoculated into basal salts medium containing 0.5% MN 300 cellulose and subsequent serial dilution with cellobiose (Sissons et al., 1987). A cellulose-clearing colony was selected and further purified on cellobiose agar and liquid cultures containing cellobiose and Sigmacell 50 (Sissons et al., 1987). *Caldicellulosiruptor acetigenus* was originally isolated as a xylanolytic, non-spore-forming bacterium, and described as *Thermoanaerobium acetigenum* (Nielsen et al., 1993) before being transferred to the genus *Caldicellulosiruptor* (Onyenwoke et al., 2006). The type strain XB6^T of *Caldicellulosiruptor acetigenus* was isolated from sediment and biomat collected from a thermal spring with

^fData from Huang et al. (1998).

a temperature of 70 °C and a pH of ~8.5 in the Hverðagerdi-Hengill geothermal area, Iceland (Nielsen et al., 1993). The enrichment cultures were established at 68 °C in mineral medium at pH 7.0 containing 4 g/l of beech wood xylan and 10% (v/v) of sediment as an inoculum (Nielsen et al., 1993). Enrichments showing solubilization of xylan, and over pressure, were transferred to fresh medium several times before pure cultures were isolated on xylan containing media solidified with Gelrite using the roll tube technique (Nielsen et al., 1993). The isolation of *Caldicellulosiruptor kristjanssonii* followed the same techniques used in the isolation of *Caldicellulosiruptor acetigenus*, except that xylan was replaced with Avicel. The inoculum was a biomat from a hot spring at pH 8.7 and the enrichment was established at 78 °C (Bredholt et al., 1999). Avicel was also used as the substrate in the enrichment culture from which *Caldicellulosiruptor lactoaceticus* was isolated (Mladenovska et al., 1995). The isolation source of *Caldicellulosiruptor owensensis* indicated that species of this genus can be isolated from non-thermal sources. *Caldicellulosiruptor owensensis* was isolated from sediment samples (pH 9.0 and 32 °C) collected from a small freshwater pond in the dry bed of Owens Lake (Huang et al., 1998). The enrichment temperature of 75 °C selected for thermophilic organisms and xylan added to the carbonate buffered culture medium selected for species that were xylanolytic (Huang et al., 1998).

Taxonomic comments

It is the lack of spore formation and ability to grow at >75 °C that differentiated these thermophilic cellulolytic bacteria from the spore-forming, thermophilic, cellulolytic species of the genus *Clostridium*. The numerical taxonomy study of Rainey et al. (1993a) involved the determination of 92 characteristics for 51 strains, 43 that did not form endospores and eight spore-forming strains (including the type strains of the species *Clostridium stercorarium*, *Clostridium thermocellum* and *Clostridium thermocopriae*). At the 72% similarity level in a S_{SM} unweighted pair-group method with averages (UPGMA) analysis, five clusters (designated A–E) were formed (Rainey et al., 1993a). The thermophilic, cellulolytic *Clostridium* species all fell into cluster E, while the non-spore-forming strains that grew at 75 °C or above fell into clusters A–D. This study demonstrated that at the phenotypic level the non-spore-forming, cellulolytic, thermophiles could be differentiated from *Clostridium* species. Phylogenetic analysis based on partial 16S rRNA gene sequences of 16 of the strains from clusters A through D grouped them separately from the cellulolytic thermophilic species of the genus *Clostridium* (Rainey et al., 1993a). Comparison of seven full 16S rRNA gene sequences of strains from clusters A through D with other thermophilic anaerobic bacteria demonstrated that they warranted novel genus status (Rainey et al., 1993b). The genus *Caldicellulosiruptor* was described for the strain Tp8T 6331 with the species *Caldicellulosiruptor saccharolyticus* designated the type species (Rainey et al., 1994). Since then four additional species have been added to the genus based on 16S rRNA gene sequence comparisons, phenotypic differences and DNA–DNA hybridization studies (Bredholt et al., 1999; Huang et al., 1998;

Mladenovska et al., 1995; Nielsen et al., 1993; Onyenwoke et al., 2006). Figure 256 shows the phylogenetic relationships of the type strains of the species of *Caldicellulosiruptor*, as well as a number of undescribed strains for which full 16S rRNA gene sequences are available. The 16S rRNA gene sequence similarities between the described species of *Caldicellulosiruptor* are in the range of 95.5–99.6, with the most closely related species being *Caldicellulosiruptor kristjanssonii* and *Caldicellulosiruptor acetigenus* (clone 1). These two species share 99.6% 16S rRNA gene sequence similarity, but it should be noted that the type strain of the species *Caldicellulosiruptor acetigenus* contains two copies of the 16S rRNA gene which share only 98.87% similarity (Onyenwoke et al., 2006). This considerably large difference between the two gene copies results in the 16S rRNA gene copy designated clone 2 (AY772477) being more similar (99.43%) to the type strain of *Caldicellulosiruptor lactoaceticus* than to the other 16S rRNA gene copy designated clone 1 (AY772476) (98.78% similarity). DNA–DNA hybridization studies demonstrated the true species status of *Caldicellulosiruptor acetigenus* when compared to *Caldicellulosiruptor kristjanssonii*, *Caldicellulosiruptor lactoaceticus* and *Caldicellulosiruptor saccharolyticus*, with reassociation values of 53.1, 50.9 and 34.3 respectively (Onyenwoke et al., 2006). The inclusion of the additional strains of the genus for which full 16S rRNA gene sequences are available (Figure 256) clearly demonstrates the species status of some of these strains including those not validly named, “*Anaerocellum thermophilum*” Z-1203 (Svetlichnyi et al., 1990) and “*Thermoanaerobacter cellulolyticus*” NA10 (Taya et al., 1988, 1985).

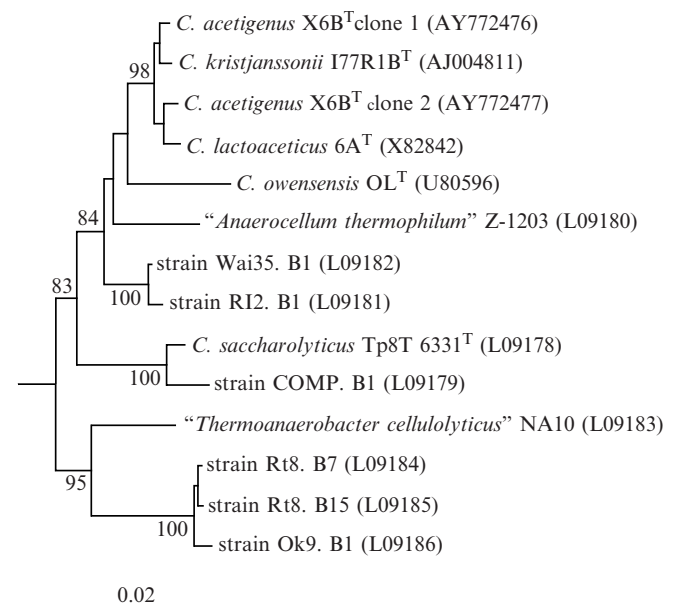

FIGURE 256. 16S rRNA based phylogeny of the species and strains of the genus *Caldicellulosiruptor*. The tree was constructed from distance matrices using the neighbor-joining method. The scale bar represents 2 nucleotide substitutions per 100 nucleotides.

List of species of the genus *Caldicellulosiruptor*

1. ***Caldicellulosiruptor saccharolyticus*** Rainey, Donnison, Jansen, Saul, Rodrigo, Bergquisy, Daniel, Stackebrandt and Morgan 1995, 197^{VP} (Effective publication: Rainey, Donnison, Janssen, Saul, Rodrigo, Bergquist, Daniel, Stackebrandt and Morgan 1994, 265.)
 sac.cha.ro.ly'ti.cus. Gr. n. *sakchar* sugar; Gr. adj. *lutikos* able to loosen; N.L. masc. adj. *saccharolyticus* breaking up polysaccharides.
 Cells are straight rods 0.4–0.6 µm in diameter and 3.0–4.0 µm in length, occurring both singly and in pairs. Endospores are not formed. On 2/1 cellobiose agar colonies are 2–5 mm in diameter, cream-colored and umbonate. The optimum temperature for growth is 70 °C in the range of 45–80 °C. The pH range is 5.5–8.0, with an optimum at pH 7.0. The main fermentation products on 2/1 cellobiose medium are acetate and lactate with trace amounts of ethanol. Hydrogen sulfide is not produced. Acid is produced from arabinose, amorphous cellulose, Avicel, cellobiose, fructose, galactose, glucose, glycogen, gum guar, gum locust bean, lactose, laminarin, lichenin, maltose, mannose, pullulan, pectin, rhamnose, Sigmacell 20, Sigmacell 50, Sigmacell 100, starch, sucrose, xylan, and xylose. Acid is not produced from amygdalin, erythritol, glycerol, inositol, inulin, mannitol, melibiose, melezitose, raffinose, ribose, sorbitol, or sorbose. Culture supernatants hydrolyse carboxymethylcellulose, gum guar, gum locust bean, laminarin, lichenin, pullulan, starch, and xylan, but not arabinogalactan, chitin, glycogen, gum karaya, inulin, or mannan. Growth is inhibited by penicillin, neomycin and polymyxin B at 10 µg/ml and by novobiocin at 100 µg/ml. Rifampin is not inhibitory at 1000 µg/ml. *Caldicellulosiruptor saccharolyticus* was isolated from pinewood in the flow of a geothermal spring, Taupo, New Zealand.
 DNA G+C content (mol%): 37.5 (T_m).
 Type strain: Tp8T 6331, ATCC 43494, DSM 8903.
 GenBank accession number (16S rRNA gene): L09178.
2. ***Caldicellulosiruptor acetigenus*** (Nielsen, Mathrani and Ahring 1993) Onyenwoke, Lee, Dabrowski, Ahring and Wiegel 2006, 1394^{VP} (*Thermoanaerobium acetigenum* Nielsen, Mathrani and Ahring 1993, 464)
 a.ce.ti'ge.nus. L. n. *acetum* vinegar; L. v. *genere gignere* to produce; N.L. masc. adj. *acetigenus* vinegar- or acetic acid-producing.
 Cells are rod-shaped, 0.7–1.0 µm in diameter and 3.6–5.9 µm in length, occurring singly, in pairs or in chains of up to eight cells. *Caldicellulosiruptor acetigenus* strains are Gram-stain-negative, but have a Gram-positive cell-wall structure. On solidified xylan-containing medium, off-white, milky-colored colonies are observed. It is a strictly anaerobic chemoorganoheterotroph.
 The optimum temperature for growth is 65–68 °C in the range of 50–78 °C. The pH range is 5.2–8.6, with an optimum at pH 7.0. Doubling time under optimal conditions is approximately 4 h. Growth is supported by arabinose, cellobiose, fructose, D-galactose, D-glucose, lactose, maltose, mannose, raffinose, soluble starch, sucrose, trehalose, D-xylose, and xylan. Growth and CMC-cellulase activity is observed when grown on carboxymethylcellulose (Hercules CMC, 7LT, or 7M) in the presence of traces of yeast extract, but not with filter paper or crystalline cellulose (Avicel). The end products of growth on glucose or D-xylose include acetate, CO₂, H₂, ethanol and traces of isobutyric acid (but not lactate). Isolated from a combined biomat and sediment sample from a slightly alkaline hot spring at Hverðagerdi, Iceland.
 DNA G+C content (mol%): 35.7 (HPLC).
 Type strain: X6B, ATCC BAA-1149, DSM 7040.
 GenBank accession number (16S rRNA gene): AY772476, AY772477.
3. ***Caldicellulosiruptor kristjanssonii*** Bredholt, Sonne-Hansen, Nielsen, Mathrani and Ahring. 1999, 995^{VP}
 kris.tjans.son'ii. N.L. gen. n. *kristjanssonii* named after Jakob K. Kristjansson.
 Cells are rod-shaped with rounded ends, 0.7–1.0 µm in diameter and 2.8–9.4 µm in length, occurring singly, in pairs or in short chains, and are Gram-stain-negative. Endospores are not found. Motility is not observed, but two subterminal flagella are present. When grown in roll-tubes on mineral medium plus Avicel, colonies are flat, cream in color, with a fringed edge. After 9–14 d, clearing zones around colonies are 2–4 mm. The optimum temperature for growth is 78 °C with a range of 45–82 °C. The pH range is 5.8–8.0, with an optimum at pH 7.0. Obligately anaerobic chemoorganotroph. Growth is supported by Avicel, cellobiose, dextrin, D-fructose, D-galactose, D-glucose, lactose, maltose, mannose, pectin, salicin, soluble starch, sucrose, trehalose, xylan, and xylose. It does not utilize D-ribose, L-arabinose, esculin, glycerol, inulin, lactic acid, mannitol, pyruvate, raffinose, L-rhamnose, D-ribose, sorbitol, casein peptone, or yeast extract. Growth is inhibited by air, chloramphenicol, neomycin, penicillin, streptomycin, tetracycline, and vancomycin. The major end products of growth are acetic acid, H₂ and CO₂, with smaller amounts of lactic acid and ethanol and trace amounts of formic acid. Hydrogen sulfide is not produced from sulfate, thiosulfate, or casein peptone. *Caldicellulosiruptor kristjanssonii* was isolated from microbial mats and cellulosic materials, e.g., wood or straw, in Icelandic thermal and slightly alkaline springs.
 DNA G+C content (mol%): 35.0 (HPLC).
 Type strain: I77R1B, ATCC 700853, DSM 12137.
 GenBank accession number (16S rRNA gene): AJ004811.
4. ***Caldicellulosiruptor lactoaceticus*** Mladenovska, Mathrani and Ahring 1997, 1274^{VP} (Effective publication: Mladenovska, Mathrani and Ahring 1995, 229.)
 lac.to.acet.i'cus. N.L. adj. *acidum lacticum* lactic acid; L. neut. n. *acetum* vinegar; N.L. neut. adj. *lactoaceticum*, referring to production of lactic acids as major fermentation products.
 Cells are Gram-stain-negative, rod-shaped with rounded ends, 0.7 µm in diameter and 1.5–3.5 µm in length, occurring singly, in pairs or in short chains. Endospores are not formed. Cells are non-motile and flagella are not observed. Colonies are 1 mm in diameter, round, white, opalescent and circular with an entire edge after incubation in agar roll tubes for approximately 1 week. The optimum temperature for growth is 68 °C with a range of 50–78 °C. The pH range is >5.6–<9.0, with an optimum at pH 7.0. Cells are obligately anaerobic and chemoorganoheterotrophic. Growth occurs with Avicel, cellobiose, lactose, maltose, pectin, soluble starch, xylan,

and xylose. No growth occurs on acetate, arabinose, arbutin, casein peptone, dextran, ethanol, fructose, galactose, glucose, lactate, mannitol, mannose, methanol, pyruvate, D-ribose, raffinose, rhamnose, sorbitol, sucrose, trehalose, yeast extract, or H₂ + CO₂. Fermentation products are lactate and acetate with small amounts of ethanol, CO₂, and H₂ are produced. Sulfate, thiosulfate, and sulfite are not reduced. Nitrate does not stimulate growth. No growth occurs in the presence of ampicillin, chloramphenicol, kanamycin, neomycin, streptomycin sulfate, penicillin V, tetracycline, or vancomycin (at 10 µg/ml). Cells are resistant to D-cycloserine (100 µg/ml). *Caldicellulosiruptor lactoaceticus* was isolated from microbial mats and cellulosic materials, e.g., wood or straw, in slightly alkaline Icelandic thermal springs.

DNA G+C content (mol%): 35.2 (HPLC).

Type strain: 6A, DSM 9545.

GenBank accession number (16S rRNA gene): X82842.

5. ***Caldicellulosiruptor owensensis*** Huang, Patel, Mah and Barresi 1998, 95^{VP}

o.wen.sen'sis. N.L. adj. *owensensis* from Owens Lake, CA, USA.

Cells are rod-shaped, 0.5–0.8 µm in diameter and 2.0–5.0 µm in length, occurring singly, in pairs or in chains and are non-motile, but have lophotrichous flagella. Gram-stain-negative.

Endospores are not formed. Colonies are <2 mm in diameter, circular with smooth edges, convex, opaque and yellowish.

The optimum temperature for growth is 75 °C with a range of 50–80 °C. The pH range is 5.5–9.0, with an optimum at pH 7.5. Cells are alkali tolerant. Yeast extract or vitamin solutions are not required for growth. Growth is inhibited by penicillin G, streptomycin, chloramphenicol, and ampicillin at 100 µg/ml. Cells are resistant to D-cycloserine (100 µg/ml), erythromycin (200 µg/ml) and tetracycline (100 µg/ml). Growth is strictly anaerobic. Chemoorganotrophic. Growth occurs with arabinose, cellobiose, cellulose, dextrin, fructose, galactose, glucose, glycogen, inositol, lactose, mannitol, maltose, mannose, pectin, raffinose, rhamnose, ribose, starch, sucrose, tagatose, xylan, xylose, and yeast extract. It does not grow on acetate, amygdalin, arbutin, erythritol, glycerol, lactate, melezitose, melibiose, methanol, pyruvate, sorbitol, trehalose, trypticase peptone, or H₂ + CO₂. The end products from glucose fermentation are acetate, lactate, ethanol, H₂, and CO₂. Cells do not reduce nitrate, sulfate, sulfite or thiosulfate. *Caldicellulosiruptor owensensis* was isolated from the Owens Lake in California, USA.

DNA G+C content (mol%): 36.6 (Bd).

Type strain: OL, ATCC 700167, DSM 13100.

GenBank accession number (16S rRNA gene): U80596.

Genus II. ***Thermoanaerobacterium*** Lee, Jain, Lee, Lowe and Zeikus 1993a, 48^{VP}

ROB U. ONYENWOKE AND JUERGEN WIEGEL

Ther.mo.an.ae.ro.bac'te.ri.um. Gr. n. *thermos* hot, Gr. pref. *an* not, Gr. n. *aer* air, Gr. n. *bakterion* a small rod, N.L. neut. n. *Thermoanaerobacterium* a rod which grows in the absence of air at high temperatures.

Extreme thermophiles with growth temperature optima between 55 and 70 °C. Cells have **Gram-positive cell-wall structure**, but many strains are **Gram-stain-negative**. Cells are rod-shaped and motile by peritrichously inserted flagella, except for *Thermoanaerobacterium aciditolerans*, which has a single, polar flagellum. **Endospores are present in some species**. Hexagonal S-layer typically present. However, it may be difficult to visualize because of extracellular hydrolytic enzymes attached to the cells. **Obligate anaerobes** and catalase-negative.

The temperature growth range for the members of the genus is extremely broad (35–75 °C; for discussion of this topic, see Wiegel (1990, 1998). The pH range for growth is equally broad, 3.2–8.5. The lowest pH optimum is 5.2 for *Thermoanaerobacterium aotearoense*, which is the lowest pH optimum for a validly published, anaerobic, thermophilic bacterium. Similarly, *Thermoanaerobacterium aciditolerans* has the lowest minimum pH for growth, 3.2. The highest pH optimum is 7.8–8.0 for *Thermoanaerobacterium thermosaccharolyticum*. No true alkalithermophilic species have been isolated so far (Table 253). **Chemo-organotrophs** and yeast extract stimulates growth for most species. Fermentation end products from hexoses (unless noted otherwise below) are: acetic acid, ethanol, lactic acid, H₂, and CO₂ in various stoichiometries. In some instances, butyrate and butanol are formed (e.g., *Thermoanaerobacterium thermosaccharolyticum*). All strains with the exception of *Thermoanaerobacterium thermosaccharolyticum* contain menaquinone-7 as the major component of their isoprenoid quinone system. Members of the genus include some well-characterized species, such as *Thermoanaero-*

bacterium thermosaccharolyticum (basonym *Clostridium*) or the “swelling can food spoilers” (Collins et al., 1994; Dotzauer et al., 2002; McClung, 1935; Prevot, 1938). A comparison of the properties of the various *Thermoanaerobacterium* species is given in Table 253.

DNA G+C content (mol%): 29–46.

Type species: ***Thermoanaerobacterium thermosulfurigenes*** (Schink and Zeikus 1983a) Lee, Jain, Lee, Lowe and Zeikus 1993a, 48^{VP} (*Clostridium thermosulfurogenes* Schink and Zeikus 1983a, 1156).

Further descriptive information

Sporulation. Sporulation has only been observed in some of the species, and it is not regarded as a reliable taxonomic marker because a mutation in one of the many sequentially operating gene products can prevent a species from sporulating. Microorganisms that possess all or most of the sporulation genes but fail to sporulate are termed “asporulating” (Onyenwoke et al., 2004). Common sporulation genes are present in some of the asporulating *Thermoanaerobacterium* species (Brill and Wiegel, 1997; Onyenwoke et al., 2004; unpublished results). The inactivation kinetics of *Thermoanaerobacterium thermosaccharolyticum* endospores during pressure-assisted thermal processing have been studied to better understand the endospore inactivation (Ahn et al., 2007).

Thiosulfate metabolism. The reduction of thiosulfate to elemental sulfur instead of H₂S was once considered a feature

^bAll species are motile and produce acetic acid, ethanol, H₂, and CO₂ when fermenting glucose.

that distinguished this genus from *Thermoanaerobacter* (Lee et al., 1993a). With the reclassification *Clostridium thermosaccharolyticum*, which produces sulfide from thiosulfate, to *Thermoanaerobacterium* (Collins et al., 1994) and the isolation of *Thermoanaerobacter sulfurigenes*, which only produces sulfur (Lee et al., 2007a, 2007b), this generalization proved unreliable. Sulfur granules in both *Thermoanaerobacter sulfurigenes* and *Thermoanaerobacterium thermosulfurigenes* consist of linear sulfur chains with organic residues at the ends (Lee et al., 2007). Meyer et al. (1990) suggest that a rubredoxin might have a role in cellular sulfur metabolism in *Thermoanaerobacterium thermosaccharolyticum*.

Cell structure. Most *Thermoanaerobacterium* species contain an S-layer. The *Thermoanaerobacterium thermosaccharolyticum* S-layer is unusual because it lacks a covalent linkage between the S-layer glycan, the peptidoglycan, and the S-layer protein (Schaffer et al., 2000, and literature cited therein). The molecular mass of the monomeric subunit of the major S-layer protein from strain E207-71 was determined to be ~75 kDa (Allmaier et al., 1995). Altman et al. (1990) determined the chemical properties from the S layer units from *Clostridium thermosaccharolyticum* D120-70 and Cejka and Baumeister (1987) determined the three-dimensional structure.

Cytoskeletal elements of *Thermoanaerobacterium thermosaccharolyticum* were observed by immunoelectron microscopy and proposed to play roles in maintaining cell shape as well as forming membrane vesicles for release of starch-hydrolyzing enzymes (Mayer et al., 1998; Mayer, 2006, and literature cited therein).

Enzymes and industrial applications. The thermostable enzymes produced by *Thermoanaerobacterium* species have the potential for important industrial applications. A few examples are given below.

The xylose isomerase can be used as a glucose isomerase for fructose production. The enzyme from *Thermoanaerobacterium saccharolyticum* (Lee et al., 1993d) and *Thermoanaerobacterium thermosulfurigenes* 4B is highly thermostable (Lee et al., 1990a; Lee and Zeikus, 1991) and has been heterologously expressed in *Escherichia coli* and *Bacillus* (Lee et al., 1990b). The crystal structure was determined (Huber et al., 1996; Kim et al., 2001; Lloyd et al., 1994), which allowed further optimization of this industrial enzyme (Sriprapundh et al., 2000). The role of the aromatic amino acids for the catalysis and substrate specificity (Meng et al., 1993b) as well as thermal stabilization has been elucidated (Meng et al., 1993a). In contrast to the commercial enzymes, the xylose isomerase from *Thermoanaerobacterium saccharolyticum* JW/SL-YS489 exhibits an acidic pH optimum. Thus, it is more suitable for industrial applications (Liu et al., 1996c) because it is no longer necessary to change the pH after saccharification. Comparison with the xylose isomerase from strain 4B suggests that the lower pH optimum results from substitutions that are outside of the catalytic site. Divalent metal cations such as Co²⁺ are not only important for the catalysis but also for enzyme stability (Epting et al., 2005). Recombinant xylose isomerases have also been used for saccharidase synthesis (Lee et al., 1990a, 1993d) and single-step processes for sweetener production (Lee and Zeikus, 1991). The gene for the D-xylose ketol-isomerase of *Thermoanaerobacterium thermosulfurigenes* has

also been proposed as a selectable genetic marker within transgenic plant cells (Kim et al., 2001; Meng et al., 1993b, 1993a).

Since the solubility of starch increases with temperature, *Thermoanaerobacterium* species (including strains of *Thermoanaerobacterium thermosulfurigenes*, *Thermoanaerobacterium thermosaccharolyticum*, and *Thermoanaerobacterium saccharolyticum*) are of considerable interest for production of thermostable and thermoactive amylolytic enzymes. This includes glucoamylase (Specka et al., 1991), pullulanase, glucoamylase, and α -glucosidase from *Thermoanaerobacterium thermosaccharolyticum* (Feng et al., 2002; Ganghofner et al., 1998); and pullulanase (Burchhardt et al., 1991) and amylopullulanase (Saha et al., 1990) from *Thermoanaerobacterium thermosulfurigenes* EM1. Some genes have also been heterologously expressed, including the α -amylase (Haeckel and Bahl, 1989), glycosyl hydrolases (Matuschek et al., 1994) and associated ABC transporter (Matuschek et al., 1997), and pullulanase (Matuschek et al., 1996) from *Thermoanaerobacterium thermosulfurigenes* EM1. From *Thermoanaerobacterium thermosaccharolyticum*, the endo-acting amylopullulanase has also been heterologously expressed (Ramesh et al., 1994). The crystal structures of the glucoamylase from *Thermoanaerobacterium thermosaccharolyticum* (Aleshin et al., 2003) and the cyclodextrin glycosyltransferase of *Thermoanaerobacterium thermosulfurigenes* EM1 have been resolved at 2.3 Å (Knegtel et al., 1996; Wind et al., 1998, and literature cited therein; Leemhuis et al., 2003). The structural information was then used to engineer the glycosyltransferase for specific changes in product formation and pH optima. Hyun and Zeikus (1985) described the enhanced formation of the *Thermoanaerobacterium thermosulfurigenes* amylase during ethanol production. For *Thermoanaerobacterium thermosulfurigenes* strain EM1, the saccharolytic enzymes are excreted via membrane vesicles that are shed during cell wall renewal (Antranikian et al., 1987). The C-termini of the glycosyl hydrolases contain repeated sequences similar to repeated units in the S-layer proteins, suggesting that the enzymes intercalate into the S-layer and thus remain loosely associated with the cell envelope (Matuschek et al., 1996). Presently, it is not clear whether these two mechanisms for excreting hydrolytic enzymes onto the cell surface and localizing extracellular enzymes are general strategies among related thermophilic anaerobes.

The kinetic properties and structure of the β -galactosidase from *Thermoanaerobacterium thermosulfurigenes* EM1 has been reported (Burchhardt and Bahl, 1991; Zolotarev et al., 2003). Xylan and hemicellulose are hydrolyzed and the resulting xylose is fermented by nearly all *Thermoanaerobacterium* species. A number of hemicellulolytic enzymes have been studied in detail. *Thermoanaerobacterium saccharolyticum* JW/SL-YS485 produces high-molecular-weight xylanases which act synergistically with other hydrolytic enzymes (Liu et al., 1996a; Shao et al., 1995a), three xylosidases (Lorenz and Wiegel, 1997; Shao and Wiegel, 1995), glucuronidase (Shao et al., 1995b), and two acetylesterases (Shao and Wiegel, 1995), one of which has cephalosporin C deacetylase activity (Lorenz and Wiegel, 1997). The high-molecular-weight xylanase, similar to the glycosyl hydrolases from *Thermoanaerobacterium sulfurigenes* EM1 (Matuschek et al., 1996), possesses C-terminal repeated modules similar to the modules from the S-layer protein, suggesting that these enzymes also intercalate into the S-layer. This might explain why the enzyme can only be effectively isolated from

whole cells and not from the culture supernatant. It also suggests that the enzymes and the reaction products remain associated the cells, a situation similar to that of the cellulosome of another thermophilic anaerobe *Clostridium thermocellum*. The hemicellulolytic system of *Thermoanaerobacterium saccharolyticum* B6A-RI^T has also been studied in detail and it differs from the one in strain JW/SL-YS485 (Hespell, 1992; Lee et al., 1993b, 1993c; Weimer, 1985). The enzymes studied include the recombinant endoxylanase (Lee et al., 1993c) and β -D-xylosidase (Lee and Zeikus, 1993; Yang et al., 2004). Armand et al. (1996) studied in detail the stereochemistry of the xylanases, and Vocadlo et al. (2002a, 2002b) showed that xylosidase is the acid/base catalyst facilitating the reverse protonation of glutamine residue 160. The three-dimensional structure of the β -D-xylosidase from *Thermoanaerobacterium saccharolyticum* B6A-RI^T, a family 39 glucuronidase, has been determined by Yang et al. (2004). Bronnenmeier et al. (1995) and Haldrup et al. (1998) described the second characterized thermophilic glucuronidase from another strain, *Thermoanaerobacterium thermosaccharolyticum* HG-8. While the sugar transport systems in *Thermoanaerobacterium* have not received much attention, the binding protein-dependent maltose transport system in *Thermoanaerobacterium thermosulfurigenes* EM1 has been characterized (Sahm et al., 1996).

A new enzyme-coupled assay for the quantification of D-xylose was developed from the enzymes of *Thermoanaerobacterium saccharolyticum* JW/SL-YS 485 (Wagschal et al., 2005). The assay uses readily available enzymes and allows for the kinetic evaluation of hemicellulolytic enzymes leading to xylose formation from xylo-oligosaccharide substrates.

Mannases have been rarely determined in this group of bacteria. *Thermoanaerobacterium polysaccharolyticum* produces a highly active multidomain enzyme exhibiting both mannanase and endoglucanase activity (Cann et al., 1999). Furthermore, its thermostable α -galactosidase is useful for pre-treating food ingredients that can elicit gastrointestinal disturbances if not modified by this enzyme (King et al., 2002).

Pectin is degraded at high rates by *Thermoanaerobacterium thermosulfurigenes*, which has very active pectinases, a high ethanol/lactate ratio during growth on pentoses, and polygalacturonase hydrolase activity. A pectin methyltransferase leads to the formation of methanol, which is a typical product for anaerobic pectin degradation but otherwise a rare fermentation endproduct (Schink and Zeikus, 1980).

Thermoanaerobacterium thermosaccharolyticum has been implicated in hydrogen gas production during the thermophilic conversion of food waste and an artificial garbage slurry in a continuously stirred tank reactor (Shin and Youn, 2005; Ueno et al., 2006). It has also been used for production of 1,2-propanediol (1,2-PD; Sanchezriera et al., 1987; Cameron et al., 1998; Altaras et al., 2001; and literature cited therein). Co-cultures of *Thermoanaerobacterium thermosaccharolyticum* and *Clostridium thermocellum* have been tested for their potential to produce ethanol from hydrolyzed cellulose (Hyun and Zeikus, 1985; Lynd, 1996; Vancanneyt et al., 1987; Venkateswaran and Demain, 1986). The ethanol tolerance and ethanol yields of *Thermoanaerobacterium thermosaccharolyticum* have been increased through adaptation (Saddler and Chan, 1984), using cell recycling (Mistry and Cooney, 1989) during continuous culture fermentation (Baskaran et al., 1995a), and genetic manipulation (Klapatch et al., 1994; Simpson and Cowan, 1997), including the deletion

of the lactate dehydrogenase gene (Desai et al., 2004). Lynd et al. (2001) showed that high concentrations of ethanol do not limit growth of *Thermoanaerobacterium thermosaccharolyticum* HG-8 at elevated xylose concentrations. Instead, salt accumulation resulting from the addition of base to control pH inhibits growth.

Since its growth rate is rapid and its substrate range is extensive at slightly acidic pH values ($\text{pH}_{\text{opt}}^{25^\circ\text{C}}$ 5.5), *Thermoanaerobacterium aotearoense* may be advantageous for the biodegradation of influent anaerobic granular sludge rich in carbohydrate (Heron et al., 2006). *Thermoanaerobacterium* species—like many other thermophilic *Firmicutes*—contain heat-stable ferredoxins (e.g., *Thermoanaerobacterium thermosaccharolyticum*; Wilder et al., 1963; Tanaka et al., 1973). *Thermoanaerobacterium thermosulfurigenes* EM1 synthesizes four heat-shock proteins at elevated levels between 10 and 15 min. after a temperature shift-up from 50 °C to 62 °C (Narberhaus et al., 1994).

Genetics and molecular manipulations. *Thermoanaerobacterium saccharolyticum* may be a useful host for expression of recombinant genes from other thermophiles, and vectors have been constructed for this purpose (Mai and Wiegel, 2001; Tyurin et al., 2006). The system is based on a procedure for regenerating autoplasts of *Thermoanaerobacter* developed by Peterandel et al. (1993). It has been adapted for other thermophiles with a Gram-positive cell-wall structure (Tyurin et al., 2006, and literature cited therein), although less successfully for *Thermoanaerobacter ethanolicus* JW200^T (Wiegel and Mai, unpublished data). Plasmids from *Thermoanaerobacterium thermosaccharolyticum* DSM 571^T have been mapped and characterized (Delver et al., 1996; Belogurova et al., 2002, and literature cited therein). Klapatch et al. (1996b) described a procedure for the electrotransformation of *Thermoanaerobacterium thermosaccharolyticum* HG-8. During electrotransformation of *Thermoanaerobacterium saccharolyticum* JW/SL-YS 485 (as well as of *Clostridium thermocellum* JW20), spontaneously arising current oscillations of about 24 MHz occur at field strengths of 10 kV/cm that have a large beneficial effect on transformation efficiency. The maximum tested field strength that did not repress the current oscillation (25 kV/cm) resulted in the highest transformation efficiency (Tyurin et al., 2005, 2006). Klapatch et al. (1996a) reported that a specific restriction endonuclease activity in cell extracts of *Thermoanaerobacterium thermosaccharolyticum* HG-8 could interfere with the genetic manipulations. The utility of a CAKI-derived phagemid, a proposed gene transfer system for the clostridia, was used to express recombinant *Thermoanaerobacterium polysaccharolyticum manA* in *Escherichia coli* (Li and Blaschek, 2002).

The β -galactosidase gene from *Thermoanaerobacterium thermosulfurigenes* EM1 has been used as a reporter for characterization of promoters required for solventogenesis and acidogenesis in *Clostridium acetobutylicum* (Feustel et al., 2004). Mutagenesis of *Thermoanaerobacterium thermosulfurigenes* EM1 illustrates the importance of surface layer homology domains in the attachment of proteins to bacterial cell walls (May et al., 2006).

The unambiguous description of plasmids is rare among the thermophilic anaerobic *Firmicutes*. Belogurova et al. (2002, 1991) characterized a plasmid from *Thermoanaerobacterium thermosaccharolyticum*, which is, so far, the only one described from *Thermoanaerobacterium*.

Habitats. Known habitats include geothermal and man-made thermobiotic environments, such as slightly alkaline, neutral

and slightly acidic hot springs, high temperature petroleum reservoirs, organic waste piles, industrial streams at elevated temperatures containing carbohydrates (Wiegel, unpublished results), and thermal volcanic algal-bacterial mats as well as some mesobiotic environments, such as various soils (including agricultural fields), sediments of slightly alkaline and acid springs, tartrate infusion of grape residues, pond and river sediments, and fruit juice waste products.

Enrichment and isolation procedures

Isolation procedures for *Thermoanaerobacterium* include enrichments using medium containing yeast extract and glucose, with subsequent isolation on agar plates or agar shake-roll tubes at 60 °C. A more specific isolation scheme for *Thermoanaerobacterium* employs an enrichment at 60 °C and a medium containing 0.1% (w/v) yeast extract, 0.5% (w/v) xylose, and 15–25 mM thiosulfate. Subsequent plating on this same medium solidified with 2% (w/v) agar yields a high percentage of colonies containing extracellular sulfur globules and cells of *Thermoanaerobacterium* containing intracellular sulfur-globules (Wiegel and Liu, unpublished results).

Maintenance procedures

The most reliable method for preservation is storage in liquid nitrogen. Cultures may also be freeze-dried for long-term storage. Some species have also been stored for up to 20 years in pre-reduced medium containing 40–45% (v/v) glycerol as cryoprotectant at –20 °C (unpublished observation). Because the suspension remains liquid, aliquots are easily transferred into subcultures via sterile syringes. For longer term storage, the suspension is kept at –80 °C. Working stock cultures can be maintained by transfer into the appropriate liquid medium at regular intervals of 1–2 weeks, although most species can be maintained for 3–6 months at room temperature after they have reached the late-exponential or early stationary growth phase. Sporulating strains can be maintained on agar slants after growth on low concentrations (0.10% w/v or less) of slowly utilizable substrates or after harvesting the spores. The spores are resuspended in mineral medium or 20 mM (Na, K, H)₃-phosphate buffer, $\text{pH}^{25^\circ\text{C}}$ around 7.0, and stored at 4 °C or room temperature. Spores can even be maintained under aerobic conditions for years at 4–20 °C (Wiegel, unpublished results).

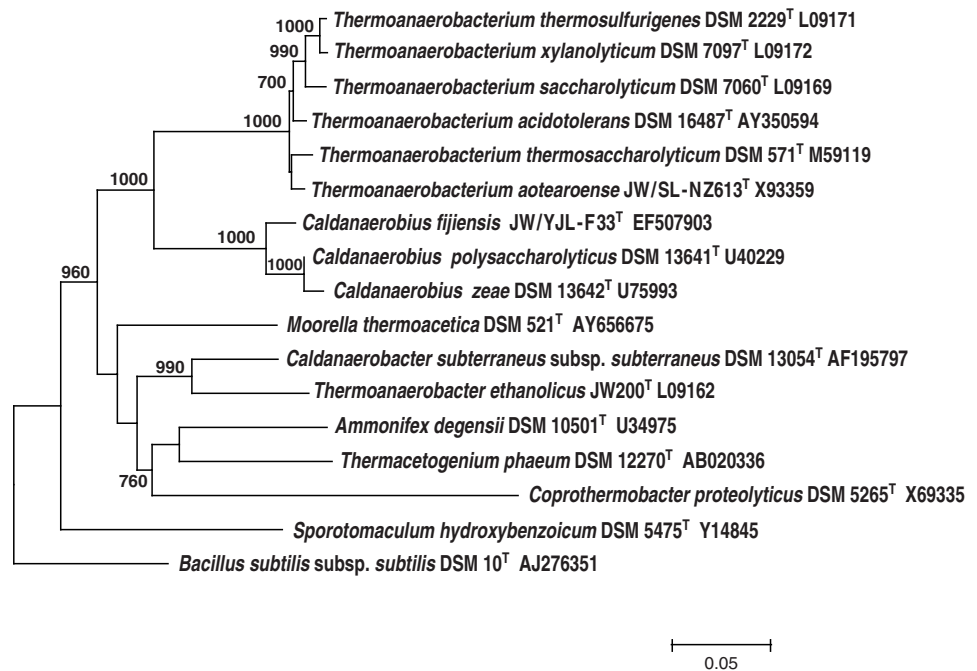

Taxonomic comments

The genus *Thermoanaerobacterium* is currently classified within Family III *Incertae Sedis* of the order *Thermoanaerobacterales* ord. nov. (Ludwig et al., 2009). Other genera within this group include *Caldicellulosiruptor*, *Thermosediminibacter*, and *Thermovibrio*. However, the evidence for an affiliation of *Thermoanaerobacterium* with these genera is not strong, and a reclassification is warranted in the future.

Hamana et al. (2001) and Hosoya et al. (2004) have described the use of polyamines to differentiate the “*Thermoanaerobacteriales*” from thermophiles in the orders *Clostridiales* and *Bacillales*.

Lastly, *Thermoanaerobacterium polysaccharolyticum* and *Thermoanaerobacterium zeae* (Cann et al., 2001) have recently been reassigned to a novel genus *Caldanaerobius*, the type species of which is *Caldanaerobius fijiensis* (Lee et al., 2008). This reclassification is based upon the low sequence similarity of their 16S rRNA genes, less than 90% similarity to the genes from *Thermoanaerobacterium*, *Caldanaerobacter*, and *Thermoanaerobacter* (Figure 257). It is supported

FIGURE 257. Neighbor-joining tree showing the estimated phylogenetic relationships for the type strains of each species within the genus *Thermoanaerobacterium* based on 16S rRNA gene sequence data with Jukes–Cantor correction for synonymous changes. The 16S rRNA gene data used represent *Bacillus subtilis* subsp. *subtilis* DSM 10^T nucleotide positions 45–1423. Numbers at nodes indicate bootstrap support values for 1000 replicates. Bar indicates 0.05 nucleotide substitutions per site. The superscript “T” denotes the sequence is from the type strain for the species. GenBank accession numbers are given after the strain designations. *Thermoanaerobacterium polysaccharolyticum* and *Thermoanaerobacterium zae* are indicated by their newly assigned names, i.e., *Caldanaerobius polysaccharolyticus* and *Caldanaerobius zae*, respectively (Lee et al., 2008).

by the higher mol% G+C content of their DNA (42–46 mol%) compared to 29–36 mol% for the remaining species of *Thermoanaerobacterium* as well as the formation of formate, indicating the presence of the pyruvate–formate lyase in these species.

List of species in the genus *Thermoanaerobacterium*

1. ***Thermoanaerobacterium thermosulfurigenes*** (Schink and Zeikus 1983a) Lee, Jain, Lee, Lowe and Zeikus 1993a, 48^{VP} (*Clostridium thermosulfurogenes* Schink and Zeikus 1983a, 1156) ther.mo.sul.fur.i'ge.nes. Gr. adj. *thermos* hot; L.n. *sulfur* brimstone; Gr. suff. *genes* born from; N.L. neut. adj. *thermosulfurigenes* releasing sulfur in heat.

Cells are straight rods (0.5 × >2 μm), which vary in length from 2 μm (single cells) to > 20 μm (filamentous chains). Motile with peritrichous flagella. Stain Gram-negative, but electron micrographs reveal a double-layered cell wall without the presence of an outer membranous layer (Gram-positive cell-wall structure). Other distinctive features include numerous internal membranes that appear vesicular and large and cytoplasmic granules that are electron-dense. The components of the cell envelope of strain EMI and the

purified S-layer protein have been characterized (Brechtel et al., 1999). In this strain, the S-layer homology domains do not attach to the peptidoglycan (Brechtel and Bahl, 1999). Significant differences in the cell envelope structure were observed when the cells were grown in continuous culture under glucose limitation as compared to starch limitation (Antranikian et al., 1987; Mayer et al., 1998). This phenomenon is likely due to an increase in production of α-amylase and pullulanase during starch limitation (Antranikian et al., 1987; Mayer and Gottschalk, 2004). Agar-embedded colonies are fluffy, 0.5–1.5 mm in diameter, and without pigment. Terminal, spherical, refractile spores with distinctly swollen sporangia are observed when grown with xylose or pectin but never with glucose as the energy and carbon source. Free spores are rare. Catalase-negative. Cytochromes are not present.

Yeast extract and tryptone enhance growth. The optimum temperature is near 60 °C. The minimum and maximum growth temperatures are above 35 °C and below 75 °C, respectively. The pH optimum for growth on glucose is 5.5–6.5. No growth is found below 4.0 or above 7.6. Fermentable carbohydrates include pectin, starch, polygalacturonic acid, amygdalin, esculin, salicin, D-xylose, galactose, glucose, inositol, mannitol, melibiose, rhamnose, trehalose, mannose, cellobiose, maltose, L-arabinose, and sucrose. No growth is found on H₂/CO₂, cellulose, arabinogalactan, galacturonate, citrate, pyruvate, lactate, tartrate, lactose, melezitose, raffinose, D-ribose, sorbitol, methanol, or glycerol. Doubling times on glucose or pectin are approximately 2 h. Sulfate and nitrate are not reduced. Sulfur droplets are localized in the cytoplasm (Liu et al., 1996b). Addition of sulfite inhibits growth and does not lead to the formation of elemental sulfur. Thiosulfate or other inorganic sulfur compounds are not required for growth. Gelatin is liquefied, but indole, acetylmethylcarbinol, and hydrogen sulfide are not produced. Glucose (0.5% w/v) is fermented according to the simplified fermentation balance (Schink and Zeikus, 1983b): 1 glucose → 0.9 ethanol + 0.6 acetic acid + 0.5 lactic acid + 1.5 CO₂ + 1.2 H₂. During pectin fermentation, the acetate/ethanol ratio is 8.6, and the acetate/lactate ratio is 6.8. Less lactate is produced during growth on polygalacturonic acid, and the acetate/lactate ratio is 11.5. *Thermoanaerobacterium thermosulfurigenes* is the main pectin utilizer in hot springs and the major source of methanol. Small amounts of 2-propanol, but not butyrate, are also produced (Schink and Zeikus, 1980).

Cell growth is inhibited by antibiotics (penicillin, streptomycin, cycloserine, tetracycline, or chloramphenicol; 100 µg/ml), sodium azide (500 µg/ml), sodium chloride (2% w/v), O₂ (20.3 kPa), or sulfite. Hydrogen gas does not cause inhibition. The type strain was isolated from an algal-bacterial community of a hot spring at 55–65 °C at Octopus Spring, Yellowstone National Park, Wyoming, USA. The enrichment contained pectin as an energy source (Schink and Zeikus, 1983a). Another strain, EM1 or DSM 3896, has also been obtained from fruit juice waste products in Germany (Madi et al., 1987).

DNA G+C content (mol%): 32.6 (T_m).

Type strain: 4BT, ATCC 33743, DSM 2229.

GenBank accession number (16S rRNA gene): L09171.

2. ***Thermoanaerobacterium aciditolerans*** Kublanov, Prokofeva, Kostrikina, Kolganova, Tourova, Wiegel and Bonch-Osmolovskaya 2007, 263^{VP}

a.ci.di.to'ler.ans. N.L. neut. n. *acidum* an acid; L. pres. part. *tolerans* tolerating; N.L. part. adj. *aciditolerans* acid-tolerating.

Description based on the type strain. Cells are rods, 3–12 × 0.4 µm, and typically sluggishly motile by a single polar flagellum. Cells have a Gram-positive cell-wall structure and form endospores. Moderate acidophile growing at a pH range from 3.2–7.1, with a pH optimum of 5.7 at 55 °C. No growth is observed at or below pH 2.8 and at or above pH 7.5. All pH values reported here are measured at 20 °C. At their optimum pH, strain 761–119^T grows over a temperature range from 37–68 °C, with an optimum of 55 °C. No

growth is observed within 5 d at or below 35 °C and at or above 70 °C. The doubling time under optimal conditions is 1 h. Grows by fermentation of glucose, maltose, fructose, sucrose, lactose, xylose, ribose, arabinose, galactose, yeast extract, sorbitol, starch, xylan, gelatin, and albumin. Glycerol, ethanol, pyruvate, and citrate are not utilized. Glucose is fermented to acetate, ethanol, and lactate at a ratio of 14.5:9:1. H₂ and CO₂ are also formed. In contrast, *Thermoanaerobacterium aotearoense* forms these same products at ratio of 1:1:0.05. Sulfite is reduced to sulfide. Thiosulfate is converted to sulfur granules, which probably also occurs at low pH due to chemical disproportionation. Growth occurs in the presence of 0–3% (w/v) NaCl. No growth at 4% NaCl. The type strain was isolated from a hydrothermal vent at pH 3.8 and 48 °C in the Orange Field of the Uzon Caldera on Kamchatka in far-eastern Russia (54° 30.237' N, 160° 00.038' E). The type strain was isolated under anaerobic conditions on medium containing 2.5% yeast extract and 0.2% sucrose at pH 4.0 and 60 °C.

DNA G+C content (mol%): 34 ± 0.5 (T_m).

Type strain: 761-119, DSM 16487, VKM B-2363.

GenBank accession number (16S rRNA gene): AY350594.

3. ***Thermoanaerobacterium aotearoense*** Liu, Rainey, Morgan, Mayer and Wiegel 1996b, 395^{VP}

ao.te.a'ro.en.se. Maori n. *ao* cloud; Maori adj. *tea* white; Maori adj. *roa* long; N.L. adj. *aotearoense* long white cloud, referring to the native Maori name for New Zealand, Aotearoa, Land of the Long White Cloud.

Description is mainly based on the type strain, although several strains have been isolated with less than 0.5% evolutionary distance within their 16S rRNA gene sequences. Rods are 0.7–1.0 × 2.1–14.3 µm, typically peritrichous, and exhibit tumbling motility. Cells stain Gram-negative but have a Gram-positive cell-wall structure covered with hexagonal S-layer lattices. Beginning in the late-exponential growth phase, oval and terminal endospores, 1.4–2.1 × 2.8–2.9 µm, are produced in slightly swollen sporangia by 5–15% of cells. Thiosulfate is converted to intracellular sulfur granules, which are each surrounded by a membrane. Granules are also found in low pH media, but these probably form due to chemical disproportionation. The temperature range and optimum for growth at pH 5.2 is 35–66 °C and 60–63 °C, respectively. The pH range and optimum for growth at 60 °C is pH 3.8–6.8 and pH 5.2, respectively. pH values were measured at 25 °C. Substrates utilized in the presence of 0.055% (w/v) yeast extract are L-arabinose, galactose, cellobiose, glucose, mannose, fructose, lactose, pectin, sucrose, xylose, maltose, starch, rhamnose, pectin, xylan, N-acetylglucosamine, and salacin. Some strains also utilize ribose and raffinose. The fermentation of glucose yields acetate, ethanol, lactate, CO₂, and H₂ in the approximate ratio of 1:1:0.5:2:2. The fermentation of xylose yields the same products in the ratio of 1:1:0.1:2:2. No dissimilatory sulfate reduction with glucose, acetate, and lactate as electron donors.

Thermoanaerobacterium aotearoense has only been isolated from various hot springs in New Zealand (North Island). The type strain was isolated from a small pool in the Weimangu Thermal Valley at the Warbick Terrace.

DNA G+C content (mol%): 34.5–35 (HPLC).

Type strain: JW/SL-NZ613, DSM 10170.

GenBank accession number (16S rRNA gene): X93359.

4. **Thermoanaerobacterium polysaccharolyticum** Cann, Stroot, Mackie, White and Mackie 2001, 299^{VP}

poly.sac.cha.ro.ly'ti.cum. Gr. adj. *polus* many; Gr. n. *sakchar* sugar; Gr. adj. *lutikos* dissolving; N.L. neut. adj. *polysaccharolyticum* dissolving many sugars.

Description based on the type strain. Cells are straight rods occurring singly or in pairs. Tumbling motility by peritrichously inserted flagella. Gram-stain variable, but has a Gram-positive ultrastructure as determined by electron microscopy. Spores not observed. A surface layer-like protein has been observed; however the array structure has not been determined. Cells are catalase-negative. Major fatty acids are C_{15:0 iso} (70.6%), C_{17:0 iso} (19.2%), and straight chain C_{16:0} (10.1%).

An obligate anaerobe that tolerates exposure to air, it will only grow in sealed tubes after reduction of the oxidized medium. It only grows in the anaerobic region of a stab culture. Yeast extract is not required for growth. A wide variety of complex and simple carbohydrates are fermented including melibiose, raffinose, arabinose, galactose, lactose, maltose, mannose, rhamnose, sucrose, trehalose, xylose, cellobiose, and melezitose, but not cellulose, starch, xylan, cracked corn, pectin, or sorbose. It also does not use mannitol, malate, fumarate, citrate, glycerol, or H₂/CO₂. The major end products of glucose fermentation are ethanol and carbon dioxide, with H₂, acetate, formate, and lactate formed in lesser amounts. Glucose and xylose are used simultaneously when supplied in equal proportions. Doubling times at 68 °C with glucose, raffinose, and melibiose as the carbon sources are 2.1, 3.4, and 5.5 h, respectively. Nitrate, sulfate, and sulfur are not reduced. Indole is not produced. The optimum temperature for growth is 65–68 °C at pH 6.8 on glucose. The maximum growth temperature is 70 °C. No growth is observed below 45 °C. At 65 °C, the pH range and optimum for growth are 5.0–8.0 and 6.8–7.0, respectively. Strain KMTHCJ was isolated from an organic waste pile at a canning factory in Hoopston, Illinois, USA, in enrichments containing raffinose as the sole carbon source at 60 °C.

Thermoanaerobacterium polysaccharolyticum has recently been reassigned to the genus *Caldanaerobius* as *Caldanaerobius polysaccharolyticus* (Lee et al., 2008).

DNA G+C content (mol%): 46 (T_m).

Type strain: KMTHCJ, ATCC BAA-17, DSM 13641.

GenBank accession number (16S rRNA gene): U40229.

5. **Thermoanaerobacterium saccharolyticum** Lee, Jain, Lee, Lowe and Zeikus 1993a, 49^{VP}

sac.cha.ro.ly'ti.cum. Gr. n. *sakchar* sugar; Gr. adj. *lutikos* dissolving; N.L. neut. adj. *saccharolyticum* sugar-dissolving.

Description is mainly based upon the type strain B6A-RIT and strain JW/SL-YS 485 (Wiegel and Liu, unpublished result). Cells are rods, 0.8–1.0 × 3.0–30 μm, occurring in chains of varying lengths. Longer cells are formed during nutrient limitation or stationary phase. Cells are motile with peritrichous flagella and stain Gram-negative. Catalase-negative. The cell wall of strain B6A-RIT contains three electron-dense layers that are 5 nm thick and alternating with electron-transparent layers of similar thickness. Colonies

on agar plates are soft, tan, circular, and convex with hollow centers (“donut”-shaped). Colony diameters range from 0.5–4.0 mm after 4 d at 55 °C. Although spores have not been observed for strain B6A-RIT, they have been found at a very low frequency for strain JW/SL-YS 485. Cells of the type strain contain a 1.5 Mb plasmid.

Growth is observed with xylan and starch but not cellulose, pectin, ribose, melibiose, melezitose, xylitol, or sorbitol. Other complex and simple carbohydrates fermented include maltose, lactose, sucrose, cellobiose, glucose, xylose, galactose, mannose, fructose, trehalose, rhamnose, raffinose, and mannitol. Landuyt et al. (1995) have also demonstrated growth on paraffin oil. No growth occurs in the absence of a fermentable carbohydrate. The major fermentation products from either glucose or xylan are acetic acid and ethanol in approximately equal amounts. L-rhamnose fermentation yields equimolar amounts of 1,2-propandiol and a mixture of ethanol, acetic acid, lactic acid, H₂, and CO₂.

The pH range for growth is from 5.0 to less than 7.5, and the optimum is about 6.0. The temperature range for growth is 45–70 °C, with an optimum of 60 °C. A culture of the type strain can survive 85 °C for 15 min but not 90 °C for 5 min. Growth is inhibited by antibiotics (penicillin G [200 μg/ml], chloramphenicol, and neomycin [100 μg/ml]), and O₂ (0.2 atm. [or 20 kPa]). Growth occurs in the presence of up to 2% (w/v) NaCl. Strains were isolated from geothermal sites in the Thermopolis areas of Yellowstone National Park, Wyoming, USA, the Steamboat area, Nevada, USA, and New Zealand. The type strain was isolated from sediments of the Frying Pan thermal acid spring in Yellowstone National Park using xylan as the carbon source (Lee et al., 1993a). Strains JW/SL-YS 485 (DSM 8691) and JW/SL-YS 489 (DSM 8685) were isolated from Weimangu Thermal Valley (North Island; NZ) using thiosulfate and xylose containing medium at pH 5.0 (Wiegel and Liu, unpublished results). At this time it is not clear whether the type strain B6A-RI and the strain B6A originally isolated by Paul Weimer (1985) are identical or represent two different strains.

DNA G+C content (mol%): 36 (T_m).

Type strain: B6A-RI, ATCC 49915, DSM 7060.

GenBank accession number (16S rRNA gene): L09169.

6. **Thermoanaerobacterium thermosaccharolyticum** (McClung 1935) Collins, Lawson, Willems, Cordoba, Fernandez-Garayzabal, Garcia, Cai, Hippe and Farrow 1994, 824^{VP} (*Clostridium thermosaccharolyticum* McClung 1935, 200)

ther.mo.sac.cha.ro.ly'ti.cum. Gr. adj. *thermos* hot; Gr. n. *sakchar* sugar; Gr. adj. *lutikos* dissolving; N.L. neut. adj. *thermosaccharolyticum* referring to thermophily and sugar-dissolving.

This description is based on that of McClung (1935) under the subjective synonym *Therminosporus thermosaccharolyticus* Hollaus and Sleytr 1972, and on study of the type strain LMG 2811^T. In many industrially oriented and technical papers, this species is often referred to as the “can-swelling (micro)organism” and named *Clostridium thermosaccharolyticum* McClung 1935. Also *Clostridium tartarivorum* Hollaus and Klaushofer 1973 is now regarded as a tartaric-acid-metabolizing strain of *Thermoanaerobacterium thermosaccharolyticum* (Matteuzzi et al., 1978).

Colonies on blood agar plates are non-hemolytic and small (<0.5 mm), circular or slightly irregular, grayish white

in color, smooth and shiny appearance with a low convex, but a mottled internal structure. Colonies on pea-infusion agar are 2–4 mm, granular with indistinct feathered edges, and grayish-white with an often slightly raised center. Cells in PYG (peptone-yeast extract-glucose) broth culture are Gram-stain-negative but possess a Gram-positive cell-wall structure containing *meso*-diaminopimelic acid and an S-layer with a rectangular (tetragonal) matrix and subunits spaced at 9.5 nm. Cells are typically motile by peritrichous flagella and catalase-negative. Cells are rods, 0.4–0.7 × 2.4–16 µm, occurring singly or in pairs but never in chains. Spores are round or oval, 1.3–1.5 µm, and located in terminally distended cells, sometimes with elongation of the mother cell (Pheil and Ordal, 1967; Campbell and Ordal, 1968; Hsu and Ordal, 1970; unpublished results). Sporulation is enhanced by carbon sources yielding a low growth rate (e.g., α- or β-methylglucoside, cellobiose, galactose, salicin, and starch; Hsu and Ordal, 1969b, 1969a, 1970). Sporulation is enhanced by the addition of L-xylose or L-arabinose to a basal medium, and the pH optimum for sporulation is 5.0–5.5 (Pheil and Ordal, 1967). Cells become shorter and thicker and do not sporulate (at least less than 1 in 10⁸ cells) in medium containing glucose.

No growth occurs in the absence of a fermentable carbohydrate. Fermentation end products during growth on PYG broth include acetic, butyric, lactic and succinic acids, ethanol, and H₂ (Nikitina et al., 1993). Hill et al. (1993) investigated end product regulation during the fermentation of xylose under nutrient limitations using continuous and batch cultures. Under some conditions, butanol was a major end product. The occurrence of ethanol, butyric acid, and butanol as well as succinic acid depends on the strain. In the type strain, the growth conditions also have a large effect. Elongated, sporulating cells form ethanol at an ethanol/glucose ratio above 1.2 (Hsu and Ordal (1970); Landuyt and Hsu, 1985; Freier-Schroder et al., 1989; unpublished results).

Growth optimization has been reported, including effects of antibiotics (Baskaran et al., 1995b; Mosolova et al., 1991). The optimum temperature for growth is 55–62 °C, with some growth at 37 °C and poor if any growth at 30 °C. Growth also occurs up to 69 °C but not at 70 °C (unpublished results). The pH range and optimum for growth are 6.5–8.5 and 7.8, respectively (Liu et al., 1996b; Mosolova et al., 1991). Dextrin, pectin (Hollaus and Sleytr, 1972), arabinose, fructose, galactose, glucose, mannose, xylose, cellobiose, lactose, maltose, sucrose, trehalose, glycogen, starch, xylan, and salicin are fermented but not rhamnose, pyruvate, inulin, or mannitol. Notably, cells originally cultured on pyruvate will ferment pyruvate, while cells originally cultured on glucose are unable to ferment it (Lee and Ordal, 1967). Diauxic growth occurs on glucose and xylose (Aduseopoku and Mitchell, 1988). When present together, the type strain can use glucose as the carbon source and pyruvate solely as an energy source to form ATP. Pectin utilization involves an intracellular oligogalacturonate hydrolase (van Rijssel et al., 1993). Nitrate is reduced. Thiosulfate and sulfite are reduced to H₂S. Most other species of *Thermoanaerobacterium* form S⁰. Contains nitrogenase (Bogdahn and Kleiner, 1986; Clarke, 1949). Major fatty acids are C₁₄ and C₁₆, but C_{15 iso} and C₁₇ are also present. This is the only species in the genus *Ther-*

moanaerobacterium for which a plasmid has been characterized (Belogurova et al., 2002, and literature cited therein).

The original soil isolate was obtained by McClung (1935). *Thermoanaerobacterium thermosaccharolyticum* is ubiquitous and can be isolated from many mesobiotic and thermobiotic environments, including slightly acidic (pH >4) to slightly alkaline (pH <9.5) hot springs and various manures (unpublished results) and pond sediments (van Rijssel and Hansen, 1989). “*Clostridium tartarivorum*”, now classified as *Thermoanaerobacterium thermosaccharolyticum* (Matteuzzi et al., 1978), was isolated from tartrate infusion of grape residue (Mercer and Vaughn, 1951). It has also been isolated once from human gingival crevices, but it is not regarded as pathogenic (DeCampos et al., 1981).

In addition to the type, other available strains are HG-6 (ATCC 31925), HG-8 (ATCC 31960; McClung, 1935; Hollaus and Klaushofer, 1973; Cameron and Cooney, 1986), T9-1 (DSM 572, ATCC 27384, *Clostridium tartarivorum*), DSM 573 (Matteuzzi et al., 1978; Mercer and Vaughn, 1951), DSM 869 (ATCC 25773; Prévot, 1938), DSM 7416 (van Rijssel and Hansen, 1989), and FHI (Hoster et al., 2001). Other strains that have been characterized include strain E207.71 and D120-70 (Altman et al., 1996).

DNA G+C content (mol%): 29–32 (HPLC).

Type strain: ATCC 7956, DSM 571, HAMBI 2225, LMG 2811.

GenBank accession number (16S rRNA gene): M59119.

7. ***Thermoanaerobacterium xylanolyticum*** Lee, Jain, Lee, Lowe and Zeikus 1993a, 48^{VP}

xy.lan.o.ly'ti.cum. Gr. n. *xylanosum* xylan; Gr. adj. *lutikos* dissolving; N.L. adj. *xylanolyticum* xylan-dissolving.

Description is based on the type strain. Cells stain Gram-negative but have a Gram-positive cell-wall structure; motile, short rods (0.8–1.0 × 2.0–7.0 µm) that occur singly or in pairs. Unlike *Thermoanaerobacterium saccharolyticum*, this species does not develop elongated cells during nutrient limitation or stationary phase, and the cytoplasm is much less granular. Terminal, spherical spores are formed, and free spores are rarely seen. Surface colonies on agar are circular, cloudy to white in color, 2–5 mm in diameter, with a rough surface texture and with smooth edges.

Growth on xylan and starch but not cellulose, ribose, melibiose, melezitose, xylitol, pectin, or lactate. Other fermented carbohydrates include maltose, lactose, sucrose, cellobiose, glucose, xylose, galactose, mannose, fructose, rhamnose, and mannitol. Major fermentation products from either glucose or xylan are acetic acid and ethanol in approximately equal amounts but not lactic acid. The pH range and optimum for growth are 5.0–7.5 and 6.0, respectively. The temperature range and optimum for growth are 45–70 °C and 60 °C, respectively. Growth is inhibited by penicillin G (200 µg/ml); neomycin sulfate, ampicillin, streptomycin sulfate, rifampin, polymyxin B, erythromycin, tetracycline, or acridine orange (all at 100 µg/ml); or by NaCl (1% w/v). Strain LX-11^T was isolated from sediments of the acidic thermal spring Frying Pan in Yellowstone National Park, Wyoming, USA, using xylan as the carbon source (Lee et al., 1993a).

DNA G+C content (mol%): 36.1 (T_m).

Type strain: LX-11, ATCC 49914, DSM 7097.

GenBank accession number (16S rRNA gene): L09172.

8. ***Thermoanaerobacterium zeae*** Cann, Stroot, Mackie, White and Mackie 2001, 300^{VP}

ze. ae. L. gen. n. *zeae* of corn (*Zea mays*), describing the use of corn as a substrate for growth.

Cells are Gram-stain-variable, straight rods that occur singly or in pairs, and motile by means of peritrichous flagella. Spore formation has never been observed. Catalase-negative. Nitrate, sulfate, and sulfur are not reduced. Indole is not produced. Ferments a wide variety of complex and simple carbohydrates, including cracked corn, starch, xylan, glucose, melibiose, raffinose, arabinose, galactose, lactose, maltose, mannose, rhamnose, salicin, sucrose, trehalose, xylose, cellobiose, melizitose, and pyruvate. Cellulose, pectin, sorbose, mannitol, malate, fumarate, citrate, glycerol, and H₂/CO₂ do not support growth. The optimum temperature for growth on glucose at pH 6.8 is 65–70°C. The maximum temperature for growth is 72°C, and growth does not occur below 37°C. The pH range for growth is 3.9–7.9. Under optimal

conditions with glucose, the doubling time is 1.8 h. The major fermentation products of glucose are ethanol and carbon dioxide. Small amounts of H₂, acetate, and formate are formed. The quantities of formate exceed that of acetate. Growth occurs in the presence of 300 mM NaCl, 450 mM KCl, and 150 mM NH₄Cl. Sulfur granules and H₂S are not formed from thiosulfate; sulfate and elemental sulfur are not reduced. Growth is completely inhibited by tetracycline, rifampin, kanamycin, and erythromycin (50 µg/ml for all).

Strain mel2^T was isolated from an organic waste pile from a canning factory in Hoopeston, Illinois, USA, following enrichment at 60°C with melibiose as the sole carbon source.

DNA G+C content (mol %): 42 (*T_m*).

Type strain: mel2, ATCC BAA-16, DSM 13642.

GenBank accession number (16S rRNA gene): U75993.

Taxonomic note: *Thermoanaerobacterium zeae* has recently been reassigned to the genus *Caldanaerobius* as *Caldanaerobius zeae* (Lee et al., 2008).

Genus III. ***Thermosediminibacter*** Lee, Wagner, Brice, Kevbrin, Mills, Romanek and Wiegel 2006, 925^{VP} (Effective publication: Lee, Wagner, Brice, Kevbrin, Mills, Romanek and Wiegel 2005, 381.)

JUERGEN WIEGEL

Ther.mo.se.di.mi.ni.bac'ter. Gr. adj. *thermos* hot; L. neut. n. *sediment -inis* sediment; N.L. masc. n. *bacter* (from Gr. neut. n. *baktron*) a rod or staff; N.L. masc. n. *Thermosediminibacter* thermophilic rod isolated from sediment.

Gram-positive cell-wall structure, but stains Gram-negative. Slightly curved rods, occasionally branched or swollen with the tendency to form autoplasts in the early stationary growth phase (Figure 258). Physiology is obligately **anaerobic, thermophilic, and heterotrophic**, requiring yeast extract for growth. Cell wall is of the *meso*-DAP direct type.

DNA G+C content (mol %): 45–50.

Type species: ***Thermosediminibacter oceani*** Lee, Wagner, Brice, Kevbrin, Mills, Romanek and Wiegel 2006, 925^{VP} (Effective publication: Lee, Wagner, Brice, Kevbrin, Mills, Romanek and Wiegel 2005, 382.).

Further descriptive information

The genus *Thermosediminibacter* is to date represented by two species. The most closely related validly published genus is the thermophile *Thermovenabulum* (Zarvarzina et al., 2002) whose 16S rRNA gene sequence possesses an evolutionary distance of 0.06–0.12, depending upon the mask employed (Figure 259). Phylogenetic trees place this genus within the radiation of the *Thermoanaerobacterales* ord. nov. (Ludwig et al., 2009). Known habitats are ocean sediments from the Peru Margin.

Enrichment and habitat

The strains of *Thermosediminibacter oceani* that have been isolated are from the Trujillo Basin in the Peru continental shelf or the outer shelf edge of the Peruvian high productivity upwelling system at depths of 252–426 m and temperatures of 9–12°C. The ages of the sediments used for isolation are estimated to be about 50,000 years. Strains were isolated with glucose, mannose, xylose, or pyruvate supplemented media and possessed 16S rRNA sequence similarity of approximately 99%.

The second species, *Thermosediminibacter litoriperuensis*, was isolated from sediments from the Peru Margin, which is the

lower slope of the Peru Trench, at a depth of 5086 m below sea level and from 10 m depth of sediment at a temperature of 2°C. This sediment contained volcanic ash, and the age is estimated to be 10,000–15,000 years (Lee et al., 2005). Further details on the sediments can be found in D'Hondt et al. (2003). Other habitats are presently unknown. The selective utilization of Mn(IV) ions as an electron acceptor and the tolerance for 4–6% NaCl may be a hint that these species are indeed marine bacteria. However, the presence of volcanic glass particles in the sediment suggests the possibility that the bacteria could be from terrestrial geothermal features blown into the ocean by volcanic eruptions and/or wind (D'Hondt et al., 2003).

Maintenance procedures

The best method of preservation appears to be in liquid nitrogen or as a freeze-dried culture. Short term storage in 30–50% pre-reduced glycerol at –20 or –80°C, respectively, has been successful for more than three years. Cultures grown to the late-exponential phase can also be stored at 12–25°C for 4 months without losing viability.

Differentiation of the genus *Thermosediminibacter* from related taxa

Besides its distinctive 16S rRNA gene sequence (Figure 259) and a difference of more than 10 mol% in the G+C content of its DNA, most phenotypic properties are very similar to those of the heterotrophs within the *Thermoanaerobacterales*. None of the *Thermosediminibacter* isolates can reduce sulfate or Fe(III). Formation of heat-resistant spores has not been observed. Similar to other members of the *Thermoanaerobacterales*, asymmetrical cell division, i.e., formation of coccoid-shaped cells intermittently in cell chains, occurs under various growth conditions (Wiegel and Ljungdahl, 1981). Similar to some other genera, such as *Anaerobranca* within

FIGURE 258. Phase-contrast micrographs of *Thermosediminibacter oceani* JW/IW-1228^T and *Thermosediminibacter litoriperuensis* JW/YJL-1230-7/2^T. (a) *Thermosediminibacter oceani* cells from mid-exponential growth phase and (b) the late-exponential growth phase exhibiting partly swollen cells and L-form-like cells. (c) *Thermosediminibacter litoriperuensis* cells from the mid-exponential growth phase and (d) late-exponential growth phase showing primary branches. Arrows indicate branched cells. (e) Transmission electron micrograph of *Thermosediminibacter litoriperuensis*. Arrowheads indicate periodicity. Bars = 10 μm (a, b, c, d) and 1 μm (e).

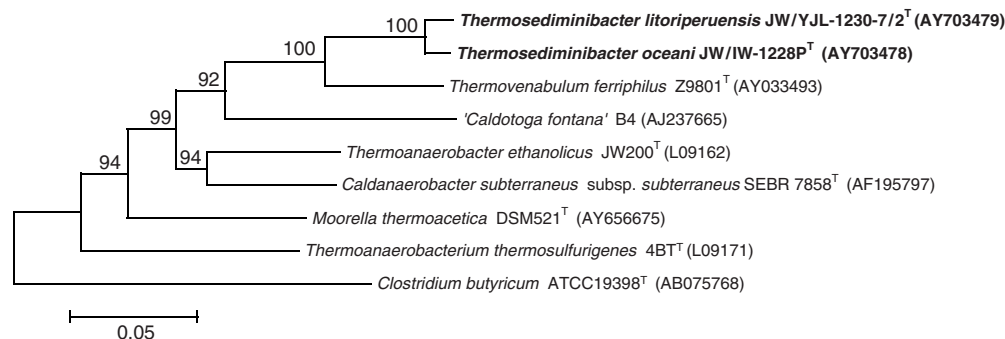

FIGURE 259. Phylogenetic dendrogram based on 16S rRNA gene sequences showing the positions of *Thermosediminibacter oceani* JW/IW-1228P and *Thermosediminibacter litoriperuensis* JW/YJL-1230-7/2 among members of the family *Thermoanaerobacteraceae*. The tree was constructed using the neighbor-joining method with Jukes–Cantor distance corrections. Numbers at the nodes represent the bootstrap values (1000 replicates); values above 90% were considered significant. Scale bar = 5 nucleotide substitutions per 100 nucleotides.

Family XIV *Incertae Sedis* in the *Clostridiales* (Engle et al., 1995; Ludwig et al., 2009), truly branched cells are observed infrequently but not with all strains under all growth conditions (Figure 258).

List of species of the genus *Thermosediminibacter*

- 1. *Thermosediminibacter oceani*** Lee, Wagner, Brice, Kevbrin, Mills, Romanek and Wiegel 2006, 925^{VP} (Effective publication: Lee, Wagner, Brice, Kevbrin, Mills, Romanek and Wiegel 2005, 382.)

o.ce.a'ni. L. masc. n. *oceanus* ocean; L. gen. masc. n. *oceani* of an ocean, referring to the source of isolation.

Strains grow in agar-shake roll tubes as irregular shaped, white colonies. Vegetative cells grown in liquid cultures are straight, sometimes highly elongated rods, 0.2–0.7 μm × 1.5–16 μm. Cells stain Gram-negative at all growth phases. Without agitation, cells have the tendency to elongate, form chains or/and aggregates, and flocculate. In the late-exponential or stationary growth phase, the elongated cells exhibit swollen ends and bulging sections, and the cytoplasm becomes granular and heterogeneous, eventually forming autoplasts (L-shaped cells). In chains of 5–10 cells, coccoid cells are infrequently interspersed. Sporulation has never been observed under any growth conditions. Cells possess 1–4 peritrichous flagella. Tumbling, but not swimming motility is observed. The major fatty acids are C_{15:0 iso}, C_{16:1 ω9c}, C_{16:0} and C_{18:1 ω9c}, with a small amount of the polyunsaturated C_{18:2 ω6} (Lee et al., 2005).

The temperature range for growth is 52–76 °C, with an optimum at around 68 °C. The pH^{25C} range for growth is 6.3–9.3 with an optimum at 7.5 (Wiegel, 1998). The salinity range for growth is 0–6% (w/v) with an optimum at 1–2% NaCl added to the mineral media.

Yeast extract is required for growth. In the presence of 0.02% yeast extract, Casamino acids (0.2% w/v), fructose, glucose, mannose, sucrose, and xylose (20 mM) serve as carbon and

energy sources. Weak growth is observed on Difco Beef extract, tryptone (0.2% w/v), lactate, pyruvate, methanol, inositol, manitol, sorbitol, cellobiose, maltose, raffinose, and trehalose (20 mM). No growth found on H₂/CO₂ (80:20, v/v) in the presence of 0.02% yeast extract and in the presence or absence of Fe(III). In the presence of 0.3% yeast extract as sole carbon and energy source, thiosulfate, elemental sulfur, and MnO₂ serve as electron acceptors, but sulfate and Fe(III) do not, even though the addition of ferric citrate enhances growth.

Several strains (available from the author) have been isolated (JW/IW-1227G, JW/IW-1227M, JW/IW-1227X, JW/IW-1228T), although only from samples of two different boreholes of the Trujillo Basin and the Peru continental shelf.

DNA G+C content (mol%): 50 (HPLC).

Type strain: JW/IW-1228P, ATCC BAA-1034, DSM 16646.

GenBank accession number (16S rRNA gene): AY703478.

- 2. *Thermosediminibacter litoriperuensis*** Lee, Wagner, Brice, Kevbrin, Mills, Romanek and Wiegel 2006, 925^{VP} (Effective publication: Lee, Wagner, Brice, Kevbrin, Mills, Romanek and Wiegel 2005, 382.)

li.to.ri.pe.ru.en'sis. L. neut. n. *litus-oris* the seashore, seaside, beach, coast; N.L. masc. adj. *peruensis* pertaining to Peru; N.L. masc. adj. *litoriperuensis* of a Peruvian coast, referring to its origin from the coast of Peru.

Colonies in agar-shake roll tubes are irregularly shaped, 0.1–1.5 mm in diameter. Cells in liquid cultures are straight rods, 0.3–0.5 μm × 2.0–10.0 μm (or less elongated than *Thermosediminibacter oceani*). Frequently forms chains. Strain JW/YJL-1230-7/2^T also produces swollen ends, but infrequently

forms autoplasts. Gram-stain reaction is negative at all growth phases. Cells possess 2–4 peritrichous flagella with a wavelength periodicity of ~1–1.3 μm (Figure 258). Fewer than 5% of cells are branched. Spores have not been observed either microscopically or by resistance to heat treatment.

The temperature range for growth is 43–76 °C with an optimum at around 64 °C. The pH^{25°C} range for growth is from 5–9.5 with an optimum at 7.9–8.4. The salinity range for growth is from 0–4.5% (w/v).

Substrates utilized include tryptone (0.2%), acetate, lactate, inositol, mannitol, xylitol, fructose, galactose, glucose, mannose, raffinose, sucrose, and xylose (20 mM). In the presence of 0.3% yeast extract as sole carbon and energy

source, thiosulfate, elemental sulfur, and MnO₂ serve as electron acceptors but sulfate and Fe(III) do not. However, the addition of ferric citrate to the medium enhances growth. The main fermentation end products in glucose-containing medium supplemented with yeast extract are acetate and small amounts of propionate, isobutyrate, and isovalerate.

Strains (available from the author) JW/YJL-1230-7/1 through/3 and JW/YJL-1230-8/1 through/3 were all isolated from sediments of the Peru Margin.

DNA G+C content (mol%): 45–46 (HPLC).

Type strain: JW/YJL-1230-7/2, ATCC BAA-1035, DSM 16647.

GenBank accession number (16S rRNA gene): AY703479.

Genus IV. *Thermovenabulum* Zavarzina, Tourova, Kuznetsov, Bonch-Osmolovskaya and Slobodkin 2002, 1741^{VP}

ALEXANDER SLOBODKIN

Ther.mo.ve.na'bu.lum. Gr. adj. *thermos* hot; L. neut. n. *venabulum* a hunting spear; N.L. neut. n. *Thermovenabulum* hot hunting spear-shaped cell, referring to the branched cell morphology.

Straight, **sometimes branched rods** 0.5–0.6 μm in diameter and 1.5–7.0 μm in length. **Gram-positive cell-wall structure. Forms protrusions of cell envelope.** Cells occur singly or in short chains and exhibit tumbling motility due to peritrichous flagellation. **Form** round refractile **endospores** in terminally swollen sporangia. **Anaerobic. Thermophilic;** the temperature range for growth is 45–76 °C. Neutrophilic. Growth occurs at NaCl concentrations from 0–3.5% (w/v). **Grows organotrophically** on a number of proteinaceous substrates and carbohydrates. **Utilizes molecular hydrogen in the presence of Fe(III) and an organic electron donor.** Reduces amorphous Fe(III) oxide, Fe(III) citrate, 9,10-anthraquinone-2,6-disulfonate, fumarate, nitrate, sulfite, thiosulfate, elemental sulfur, and MnO₂. None of the electron acceptors utilized, except fumarate, stimulates growth.

DNA G+C content (mol%): 36.

Type species: *Thermovenabulum ferriorganovorum* Zavarzina, Tourova, Kuznetsov, Bonch-Osmolovskaya and Slobodkin 2002, 1741^{VP}.

Further descriptive information

The genus *Thermovenabulum* is currently represented by a single species, *Thermovenabulum ferriorganovorum*, which was isolated from hydrothermal source in Kamchatka, Russia.

About 2% of vegetative cells of *Thermovenabulum* may be branched, having Y-like shape morphology. Some cells have protrusions of cell envelope and cytoplasm, 0.1–0.3 μm in length. In the late-exponential phase of growth, up to 15% of the cells may contain heat-resistant endospores.

Members of the genus *Thermovenabulum* utilize complex proteinaceous substrates such as yeast extract, beef extract, Casamino acids, and peptone in the presence as well as in the absence of an external electron acceptor. They reduce amorphous Fe(III) oxide, Fe(III) citrate, 9,10-anthraquinone-2,6-disulfonate, fumarate, nitrate, sulfite, thiosulfate, elemental

sulfur, and MnO₂, but none of these electron acceptors, except fumarate, stimulates growth. Fe(III) stimulates growth only in the medium with H₂ and a low concentration of yeast extract (0.2 g/l). In the presence of Fe(III) and high concentrations of proteinaceous substrate, *Thermovenabulum* consumes molecular hydrogen. *Thermovenabulum ferriorganovorum* also grows fermentatively on a number of sugars but not on glucose. The fermentation products from melibiose are ethanol, acetate, H₂, and CO₂.

Enrichment and isolation procedures

The type and the sole species of the genus *Thermovenabulum* has been isolated from a terrestrial hydrothermal source with Fe(III) deposits located in the Uzon caldera on the Kamchatka peninsula (Zavarzina et al., 2002). There are no reports that members of this genus occur in other environments. Employment of the anaerobic media with amorphous Fe(III) oxide, molecular hydrogen, and proteinaceous substrates and incubation in the temperature range of 60–70 °C may favor the enrichment of *Thermovenabulum* spp. In this medium, formation of a black magnetic precipitate is a helpful indicator for microbial growth. The type species of *Thermovenabulum* forms colonies on 1.5% (w/v) agar in the presence of various electron acceptors.

Maintenance procedures

Members of the genus *Thermovenabulum* may be maintained on the medium of Zavarzina et al. (2002) with yeast extract, molecular hydrogen, and amorphous Fe(III) oxide. The highest growth yields could be obtained in liquid medium of the same mineral composition lacking H₂ and Fe(III), pre-reduced with Na₂S·9H₂O (0.5 g/l), and supplied with beef extract and fumarate. Vacuum-drying of the cultures performed at the DSMZ result in good recovery. Liquid cultures may be stored at 4 °C for 6–7 months without loss of viability.

List of species of the genus *Thermovenabulum*

1. ***Thermovenabulum ferriorganovorum*** Zavarzina, Tourova, Kuznetsov, Bonch-Osmolovskaya and Slobodkin 2002, 1741^{VP} fer.ri.or.ga.no.vo'rum. L. n. *ferrum* iron; N.L. n. *organum* organic compound; L. v. *voru* to eat, consume; N.L. neut. adj. *ferriorganovorum* using iron and organic compounds.

Cells are straight, sometimes branched rods, 0.5–0.6 µm in diameter and 1.5–7.0 µm in length, forming round, refractile, heat-resistant endospores in terminally swollen sporangia. Cells occur singly or in short chains and exhibit slight tumbling motility due to peritrichous flagellation. The temperature range for growth is 45–76 °C, with an optimum at 63–65 °C. The pH range for growth is 4.8–8.2, with an optimum at 6.7–6.9. Growth occurs in NaCl concentrations of 0–3.5% (w/v). Anaerobic. Substrates utilized include peptone, yeast extract, beef extract, Casamino acids, starch, pyruvate, melibiose, sucrose, fructose, maltose, xylose, and ribose. Utilizes molecular hydrogen in the presence of Fe(III) and

an organic electron donor. No growth occurs with formate, acetate, propionate, lactate, methanol, ethanol, glycerol, glucose, mannose, galactose, arabinose, cellobiose, or glyco-gen. The fermentation products from melibiose are ethanol, acetate, H₂, and CO₂. Reduces amorphous Fe(III) oxide, Fe(III) citrate, 9,10-anthraquinone-2,6-disulfonate, fumarate, nitrate, sulfite, thiosulfate, elemental sulfur, and MnO₂. Nitrate is reduced to ammonium. Sulfite, thiosulfate, and elemental sulfur are reduced to hydrogen sulfide. None of the electron acceptors utilized, except fumarate, stimulates growth. Does not reduce sulfate and is incapable of growth with O₂. Growth is inhibited by chloramphenicol, neomycin, polymyxin B, kanamycin, and streptomycin but not by penicillin.

DNA G+C content (mol%): 36 (T_m).

Type strain: Z-9801, DSM 14006, UNIQEM 210.

GenBank accession number (16S rRNA gene): AY033493.

Family IV. Incertae Sedis

This genus is not closely related to members of any previously described family. While some rRNA analyses suggests an affiliation with the *Clostridiales*, other analyses and phenotypic properties suggest a relationship to *Thermoanaerobacteraceae* fam. nov. and *Thermoanaerobacterales* fam. nov. Family III *Incertae Sedis*. In view of these ambiguities, this genus is assigned to its own family *incertae sedis* (Figure 6).

moanaerobacteraceae fam. nov. and *Thermoanaerobacterales* fam. nov. Family III *Incertae Sedis*. In view of these ambiguities, this genus is assigned to its own family *incertae sedis* (Figure 6).

Genus I. *Mahella* Bonilla-Salinas, Fardeau, Thomas, Cayol, Patel and Ollivier 2004, 2172^{VP}

MONICA BONILLA-SALINAS, BERNARD OLLIVIER, BHARAT K.C. PATEL AND JEAN-LUC CAYOL

Mah.el'la. L. dim. ending *-ella*; N.L. fem. n. *Mahella* named in honor of the American microbiologist Robert A. Mah for his important contribution to the taxonomy of anaerobes.

Cells are **straight rods**, about 3–20 µm × 0.5 µm, occurring singly or in pairs. The rods are motile by **peritrichous flagella** and stain **Gram-positive**. **Spores** are formed. **Obligately anaerobic**. Moderately **thermophilic**; the optimum growth temperature is 50 °C. **Halotolerant** and grows in the presence of up to 4% NaCl with an optimum of 0.1%. The pH optimum is 7.5. **Heterotroph**. Glucose is fermented to lactate, formate, H₂, and CO₂. Yeast extract is not required for growth. Elemental sulfur, sulfate, thiosulfate, sulfite, nitrate, and nitrite are not used as electron acceptors.

DNA G+C content (mol%): 55.5.

Type species: *Mahella australensis* Bonilla-Salinas, Fardeau, Thomas, Cayol, Patel and Ollivier 2004, 2172^{VP}.

Further descriptive information

Forms white, round, smooth colonies (1–2 mm in diameter) after 7 d in Hungate tubes with medium solidified with 2% Noble agar. A Gram-positive cell wall structure is visible by electron microscopy of ultrathin sections. Cells form terminal endospores with swollen sporangia (Figure 260).

Cells grow anaerobically with the following carbon and energy sources: arabinose, cellobiose, fructose, galactose, glucose, mannose, sucrose, xylose, and yeast extract. Glucose is fermented into (mol per mol of glucose consumed): lactate, 1.3; formate, 1.5; acetate, 0.2; ethanol, 0.5; H₂, and CO₂. Acetate together with H₂ and CO₂ are the products of pyruvate fermentation. Yeast extract is not required but increases growth. The following compounds are not fermented: ethanol, methanol,

1-propanol, glycerol, 1,2-propanediol, olive oil, starch, benzoate, formate, succinate, lactate, fumarate, acetate, propionate, peptone, and Casamino acids. The doubling time under optimal conditions is 11 h.

Cells are resistant to penicillin and ampicillin, which do not inhibit growth at concentrations of 200 µg/ml. Cells are sensitive to chloramphenicol at a concentration of 50 µg/ml.

The organism was isolated from an oil-well water sample collected from the Riverslea oilfield in the Bowen-Surat Basin of Queensland in eastern Australia.

Enrichment and isolation procedure

Cells are strictly anaerobic and their cultivation requires the Hungate technique (Hungate, 1969). The initial enrichment medium contains complex organic substrates (e.g., yeast extract and bioTrypticase as energy sources) and (per liter of distilled water): 0.3 g of K₂HPO₄, 0.3 g of KH₂PO₄, 0.2 g of MgCl₂·6H₂O, 0.1 g of CaCl₂·2H₂O, 0.5 g of cysteine hydrochloride, 1 mg of resazurin, 0.1 g of KCl, 1 g of NaCl, 1 g of NH₄Cl, and 10 ml of trace mineral solution (Balch et al., 1979). The pH is adjusted to 7.0 with 10 M KOH. Vessels are autoclaved for 45 min at 110 °C. Prior to inoculation, Na₂S·9H₂O and NaHCO₃ are added from sterile stock solutions. The type strain was enriched from 2 ml of oil well water inoculated into 20 ml of enrichment medium and incubated at 50 °C. Growth was observed after 3–4 d. The basal medium used for characterization was similar to the enrichment medium supplemented with 20 mM glucose.

TABLE 254. Major discriminating characteristics between *Mahella australensis* and its closest relatives *Thermoanaerobacterium thermosulfurogenes* and *Thermoanaerobacterium aotearoense*^a

Characteristic	<i>M. australensis</i> ^b	<i>T. thermosulfurogenes</i> ^b	<i>T. aotearoense</i> ^c
Temperature range (°C)	30–60	35–75	35–66
Optimum temperature (°C)	50	60	60–63
DNA G + C content (mol%)	55.5	32.6	34.5–35.0
Reduction of thiosulfate	–	+	+
End products of glucose fermentation	L, F, E, A, H₂, CO₂	E, A, L, H₂, CO₂	E, A, L, H₂, CO₂

^aSymbols and abbreviations: +, present; –, absent; A, acetate; E, ethanol; F, formate; L, lactate. Major end products of metabolism are indicated in bold type.

^bData from Bonilla-Salinas et al. (2004).

^cData from Schink and Zeikus (1983).

^dData from Liu et al. (1996).

FIGURE 260. Phase-contrast micrograph of *Mahella australiensis* showing terminal spores and swollen sporangia. Bar = 10 μ m. (Reprinted with permission from Bonilla-Salinas et al., 2004. *Int. J. Syst. Evol. Microbiol.* 54: 2169–2173.)

Maintenance procedure

For a long-term storage of at least one year, anaerobic cultures can be maintained at -80°C in enrichment medium plus 20% glycerol.

Differentiation of the genus *Mahella* from other genera

On the basis of 16S rRNA gene sequence analyses, *Mahella* is related to members of the family *Thermoanaerobacteraceae*. This family includes thermophiles of the genera *Thermoanaerobacter* and *Thermoanaerobacterium* that use thiosulfate as a terminal electron acceptor, reducing it to sulfide or elemental sulfur, respectively. The 16S rRNA genes of *Thermoanaerobacterium thermosulfurigenes* and *Thermoanaerobacterium aotearoense* possess the highest sequence similarity to *Mahella australiensis*, 85.7 and 85.5%, respectively (Figure 261). However, unlike both species, *Mahella australiensis* is unable to reduce thiosulfate and does not grow at temperatures above 60°C . In addition, the DNA G+C content of *Mahella australiensis* is much higher than that of the *Thermoanaerobacterium* species (Table 254). Differences are also apparent in the fermentation products. *Mahella australiensis* is also clearly distinguished by molecular and phenotypic criteria from other anaerobic, spore-forming bacteria belonging to the order *Clostridiales*.

Taxonomics comments

By 16S rRNA sequence analyses, *Mahella* is related to cluster VI of the order *Clostridiales* (Figure 261), but the assignment of *Mahella* to a family is not clear. Despite its close relationships with members of the family *Thermoanaerobacteraceae*, there are significant metabolic differences (e.g., its inability to use thiosulfate as terminal electron acceptor and grow above 60°C) that indicate that *Mahella* should be classified in a novel family. This conclusion is supported by detailed phylogenetic analyses of the *Clostridiales* and suggests that the family *Thermoanaerobacteraceae* is itself paraphyletic and represents multiple lineages (Ludwig et al., 2009).

Differentiation of species of the genus *Mahella*

Only one species, *Mahella australiensis*, is currently known.

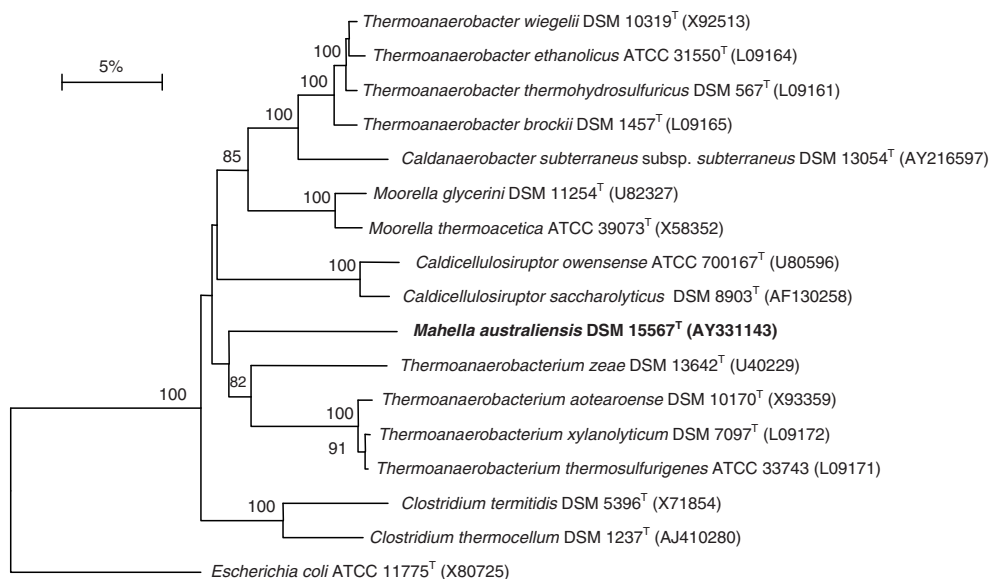

FIGURE 261. Neighbor-joining phylogenetic tree of *Mahella australiensis* and representatives of the *Thermoanaerobacterales* and other members of the *Clostridiales* based upon the 16S rRNA gene. *Escherichia coli* is the outgroup. Bootstrap values from 100 replicates are shown at the nodes. Only values greater than 80 are reported. The bar represents 5 inferred substitutions per 100 positions.

List of species of the genus *Mahella*

1. ***Mahella australiensis*** Bonilla-Salinas, Fardeau, Thomas, Cayol, Patel and Ollivier 2004, 2172^{VP}
aus.tra.li.en'sis. N.L. fem. adj. *australiensis* related to Australia.

Description is the same as for the genus.
DNA G+C content (mol%): 55.5 (HPLC).
Type strain: 50-1 BON, CIP 107919, DSM 15567.
GenBank accession number (16S rRNA gene): AY331143.

Class III. ***Erysipelotrichia*** class. nov.

WOLFGANG LUDWIG, KARL-HEINZ SCHLEIFER AND WILLIAM B. WHITMAN

E.ry.si.pe.lo.tri'chia. N.L. fem. n. *Erysipelothrix* type genus of the type order of the class; suff. *-ia* ending proposed by Gibbons and Murray and by Stackebrandt et al. to denote a class; N.L. neut. pl. n. *Erysipelotrichia* the *Erysipelothrix* class.

The class *Erysipelotrichia* is circumscribed for this volume on the basis of the phylogenetic analyses of the 16S rRNA sequences and includes only the order *Erysipelotrichales* and the family *Ery-*

sipelotrichaceae. The description of the class is the same as the order.

Type order: ***Erysipelotrichales*** ord. nov.

Order I. ***Erysipelotrichales*** ord. nov.

WOLFGANG LUDWIG, KARL-HEINZ SCHLEIFER AND WILLIAM B. WHITMAN

E.ry.si.pe.lo.tri'cha.les. N.L. fem. n. *Erysipelothrix* type genus of the order; suff. *-ales* ending to denote an order; N.L. fem. pl. n. *Erysipelotrichales* the *Erysipelothrix* order.

The order *Erysipelotrichales* is circumscribed for this volume on the basis of the phylogenetic analyses of the 16S rRNA sequences and includes only the family *Erysipelotrichaceae* and its eight genera. It is composed of nonmotile, slender rods with a Gram-positive cell-wall structure. Endospores are not produced.

Aerobic to facultatively anaerobic. Chemo-organotrophic, metabolism respiratory and weakly fermentative. Cytochromes and isoprenoid quinones absent. Otherwise, the description of the order is the same as for the family.

Type genus: ***Erysipelothrix*** Rosenbach 1909, 367^{AL}.

Family I. **Erysipelotrichaceae** Verborg, Rheims, Emus, Frühling, Kroppenstedt, Stackebrandt and Schumann 2004, 223^{VP}

ERKO STACKEBRANDT

E.ry.si.pe.lo.thri.cha'ce.ae. N.L. fem. n. *Erysipelothrix* type genus of the family; -aceae ending to denote a family; N.L. fem. pl. n. *Erysipelotrichaceae* the *Erysipelothrix* family.

Straight, or slightly curved, slender rods; some strains with a tendency to form long filaments. Nonmotile. Endospores are not produced. Aerobic to **facultatively anaerobic**. **Chemo-organotrophic, metabolism respiratory and weakly fermentative**. Acid but no gas produced from glucose and other carbohydrates. **Cytochromes and isoprenoid quinones absent**. Members of some genera contain **peptidoglycan belonging to the B-cross-linking type**, having L-alanine in position three of the peptide subunit and an interpeptide bridge consisting of the peptide Gly→L-Lys→L-Lys. Predominant fatty acids are C_{16:0}, C_{18:1 cis9}, and C_{18:0}. Some strains pathogenic for mammals and birds. Phylogenetically a member of the phylum *Firmicutes* (Figure 4).

DNA G+C content (mol%): 36–40 (HPLC, T_m, Bd).

Type genus: **Erysipelothrix** Rosenbach 1909, 367^{AL}.

Further descriptive information

The hallmark of *Erysipelothrix* is the presence of a cell wall of peptidoglycan group B in which the peptide bridge is formed between amino acids at positions 2 and 4 of adjacent peptide side chains and not, as in the vast majority of bacteria, between amino acids at positions 3 and 4. To link the two carboxylic groups of amino acids at positions 2 and 4, the interpeptide bridge of B-group must contain at least one diamino acid residue. The B-type occurs within the family *Microbacteriaceae*,

phylum *Actinobacteria*, order *Actinomycetales*, and in some members of the class *Clostridia*, e.g., *Erysipelothrix*, *Holdemania*, *Acetobacterium*, *Clostridium barkeri*, and *Eubacterium limosum* (Schleifer and Kandler, 1972; Schubert and Fiedler, 2001; Willems et al., 1997).

In comparison to the original description, the family *Erysipelotrichaceae* was extended to include four additional genera. Besides one newly described genus *Allobaculum* (Greetham et al., 2004), three of them were transferred from other families. The family is now organized in eight genera: *Erysipelothrix*, *Allobaculum*, *Bulleidia*, *Catenibacterium* (formerly *Lachnospiraceae*), *Coprobacillus* (formerly *Clostridia*), *Holdemania*, *Solobacterium*, and *Turicibacter* (formerly *incertae sedis* among *Bacillales*).

Furthermore, a number of type species validly published as members of genera not assigned to the *Erysipelotrichaceae* are members of this family. *Clostridium cateniformis*, *Clostridium cocleatum*, *Clostridium innocuum*, *Clostridium ramosum*, and *Clostridium spiroforme* as well as *Eubacterium bifforme*, *Eubacterium cylindroides*, *Eubacterium dolichum*, and *Eubacterium tortuosum* apparently are misclassified in *Clostridiales* and consequently should be transferred to *Erysipelotrichaceae*. Similarly, phylogenetically *Lactobacillus cateniformis* and *Lactobacillus vitulinus*, as well as *Streptococcus pleomorphus*, do not belong to the *Lactobacillales* but are members of the *Erysipelotrichaceae*.

Genus I. **Erysipelothrix** Rosenbach 1909, 367^{AL}

ERKO STACKEBRANDT

E.ry.si.pe'lo.thrix. Gr. neut. n. *erysipelas* erysipelas; Gr. fem. n. *thrix* hair; N.L. fem. n. *Erysipelothrix* erysipelas thread.

Straight, or slightly curved, slender rods with a tendency to form long filaments. Rods usually 0.2–0.4 μm to 0.8–2.5 μm or 0.5 μm in diameter and 1.5–3.0 μm in length with rounded ends; occur singly in short chains, in pairs at an angle to give V-forms, or in groups with no particular arrangement. Filaments may be 60 μm or more in length. **Nonmotile**. Capsules not formed. **Do not form spores**. Gram-positive. Not acid-fast. **Facultatively anaerobic**. Colonies small, usually transparent and nonpigmented. Narrow zones of α-hemolysis may occur on blood agar. No β-hemolysis. Optimum temperature 30–37 °C; growth occurs between 5 and 42 °C. Do not survive heating at 60 °C for 15 min. Catalase-negative. Oxidase-negative. Fermentative activity weak. **Acid but no gas produced from glucose and certain other carbohydrates**. Organic growth factors are required. **Cell wall contains a group B peptidoglycan based on lysine. Mycolic acids not present. The fatty acids are primarily of the straight chain mono-unsaturated (C_{18:1 cis9}) and straight chain saturated series (C_{16:0}, C_{18:0})**. Widely distributed in nature. May be parasitic on mammals, birds and fish; some strains pathogenic for mammals and birds.

DNA G+C content (mol%): 36–40 (T_m, Bd).

Type species: **Erysipelothrix rhusiopathiae** (Migula 1900) Buchanan 1918, 55^{AL}.

Further descriptive information*

The species of clinical interest is *Erysipelothrix rhusiopathiae*. The great variation in serological, biochemical, chemical, and genomic properties of the species was noted (Erler, 1972; Feist, 1972; Flossmann and Erler, 1972; Takahashi et al., 1992; White and Mirikitani, 1976) which led to the description of *Erysipelothrix tonsillarum* (also named *Erysipelothrix tonsillae* in the older literature (Takahashi et al., 1989) for serotype 7 strains that were frequently isolated from the tonsils of apparently healthy pigs (Takahashi et al., 1987a). Takahashi et al. (2000) reported the evidence that some of these strains may actually be canine pathogens. The species *Erysipelothrix inopinata*, as yet represented by a single strain, was isolated from sterile-filtered vegetable broth (Verborg et al., 2004); serotype 13 strains of *Erysipelothrix rhusiopathiae* may be included in this species (see *Molecular differentiation of strains and species*, below).

*Based on the description given in the first edition by Jones (1986a).

As summarized by Jones (1986a), strains of *Erysipelothrix rhusiopathiae* exist in a rough and smooth form each characterized by closely associated morphological and colonial features (a property not mentioned in the species description of *Erysipelothrix tonsillarum* and *Erysipelothrix inopinata*). In the smooth form (S-form) the cells appear as small, straight, or slightly curved Gram-positive rods. Colonies (24–48 h) are very small, 0.3–1.5 mm in diameter, convex, circular, transparent with smooth glistening surface, and entire. In older cultures the colonies become slightly larger and the center becomes opaque. In the rough form (R-form), long filaments often more than 60 µm in length predominate. R-form colonies are larger, flatter, and more opaque; the surface is matt, uneven and the edge irregular. R-form colonies may resemble miniature anthrax colonies (Wilson and Miles, 1975). Both forms may be decolorized easily when Gram-stained. Both rods and filaments may appear Gram-negative, but contain Gram-positive granules that give them a beaded appearance. In smears of blood and tissue taken from acute forms of infection, especially in cases of septicemia, the organisms are of the S-form; in chronic infections with arthritis and endocarditis, the R-form is isolated frequently, and S-forms are usually present along with R-forms (Ewald, 1981). The cell morphology varies to some extent with the growth medium and conditions of incubation. It has been reported that a pH of 7.6–8.2 favors the S-form while at pH values below 7.0 the R-form predominates (Wilson and Miles, 1975). Grieco and Sheldon (1970) claimed that S-forms grow better at 33 °C, and at 37 °C the R-form is favored. The distinction between S-form and R-form colonies is not always sharp; intermediate forms may exist (Barber, 1939; Ewald, 1981). S-form colonies dissociate to give rise to intermediate and R-form colonies, while R-forms may also give rise to S-form colonies.

Erysipelothrix rhusiopathiae and *Erysipelothrix tonsillarum* strains produce a characteristic “pipe cleaner” type of growth in gelatin stab cultures incubated at 22 °C (*Erysipelothrix inopinata* was not tested). At first (24 h), growth is faint and hazy and confined to an area just below the surface. After a few days the growth appears as a column extending to the bottom of the tube. The column of growth is composed of fine lateral outgrowths, which in S-form organisms extend only 2 or 3 mm from the stab but may reach the sides of the tube in R-form organisms. Gelatin is not liquefied when incubation is at 22, 30, or 37 °C.

Members are microaerophilic. Especially on first isolation, *Erysipelothrix rhusiopathiae* grows in a band just below the surface of a soft agar culture. Whether this is due to a preference for CO₂ or reduced oxygen tension is not resolved. Laboratory cultures grow well aerobically and anaerobically.

Growth is favored by a slightly alkaline pH. The optimum pH for growth is between 7.2 and 7.6; pH limits of growth have been reported as 6.8–8.2 (Karlson and Merchant, 1941) and 6.7–9.2 (Sneath et al., 1951). *Erysipelothrix inopinata* grows under aerobic and anaerobic conditions in BHI and Columbia Blood, preferably at pH 8.

Growth of *Erysipelothrix rhusiopathiae* in nutrient agar is improved by the addition of glucose (0.2–0.5% w/v) or serum (5–10% v/v). The exact growth requirements of either type strain have not been determined; for growth of *Erysipelothrix rhusiopathiae* several amino acids, riboflavin, and small amounts of oleic acid are required (Hunter, 1942.). Ewald (1981) noted that tryptophan enhanced growth.

The majority of *Erysipelothrix rhusiopathiae* strains produce H₂S, but the results can vary with the medium used. The use of lead acetate paper with cultures in a liquid or solid medium does not always detect H₂S production. Tests are best carried out in triple-sugar iron agar (Wood, 1965). Notably, an occasional old laboratory or vaccine strain does not produce detectable H₂S in triple-sugar iron agar (R.L. Wood, personal communication to D. Jones).

Most known strains produce hyaluronidase and it has been speculated that virulence is correlated with hyaluronidase production; good hyaluronidase producers usually belong to serovar 1 (Ewald, 1957, 1981). Neuraminidase is produced in differing amounts by all strains, and the level of neuraminidase activity appears to correlate with virulence (Krasemann and Müller, 1975; Müller and Krasemann, 1976; Müller and Seidler, 1975; Nikolov and Abrashev, 1976).

Erysipelothrix rhusiopathiae strains may be identified serologically. Heat and acid-stable, type-specific, and heat-labile species antigens occur. This accounts for differences observed between antisera prepared with boiled and unboiled strains. Most strains agglutinate with unabsorbed sera prepared against unboiled antigens. The type-specific antigens are polysaccharide complexes. Several serovars have been detected and different serotyping schemes proposed (Kucsera, 1973). Dedić (1949) recognized two serovars, A and B, and proposed that all those strains which showed no reaction with A- or B-type specific anti-serum be designated a third group, “N”. As new or supposedly new serovars were detected within group N, they were designated by consecutive letters of the alphabet. Unfortunately, new serovars were not always compared with strains belonging to different serovars and the serological methods used were different. To overcome this problem, Kucsera (1973) recommended the use of a uniform serological method (in particular, the double agar-gel diffusion precipitation test with autoclaved antigens and type-specific antisera) and a uniform system for designating the serovar using Arabic numbers.

Although capital letters of the alphabet are still used by some workers to designate the two main serovars (A and B), the numbered system introduced by Kucsera (1973) is now preferred by most investigators interested in the serotyping of *Erysipelothrix rhusiopathiae*. Under this system, Dedić’s original serovars A and B are designated 1 and 2, respectively. All the other serovars recognized to date have been found within Dedić’s group N (Kucsera, 1973; Norrung, 1979; Wood et al., 1978). Of the 23 serovars, 1 and 2 are the most common; the other 21 are relatively rare. Strains with serotype 3, 7 (including the type strains), 10, 14, 20, 22, and 23 are now classified in *Erysipelothrix tonsillarum*. Cultures of serovar 2 agglutinate chicken red blood cells, which lyse when complement is added to the complex (Dinter et al., 1976).

L-Forms of *Erysipelothrix rhusiopathiae* have been described (Ewald, 1981). Bacteriophages active on *Erysipelothrix rhusiopathiae* strains have been isolated, though a functional phage typing system has never been developed. Lysogeny has been reported (Ewald, 1981).

In vitro, most strains of *Erysipelothrix rhusiopathiae* (and probably *Erysipelothrix tonsillarum*) are resistant to sulfonamides, colistin, gentamicin, kanamycin, neomycin, novobiocin, and polymyxin and are sensitive to penicillin, streptomycin, chloramphenicol, tetracycline, and other antibiotics (Fuji, 1963; Sneath et al., 1951; Wood, 1965).

The organisms grow in the presence of phenol (0.2% w/v), potassium tellurite (0.05% w/v), sodium azide (0.1% w/v), thallos acetate (0.02% w/v), 2,3,5-triphenyltetrazolium chloride (0.2% w/v), and crystal violet (0.001% w/v) (Ewald, 1981; Sneath et al., 1951).

On blood agar, α -hemolysis may be so intense that after 48 h incubation, a slight clearing may be seen. Care must be taken in observing the plates because true β -hemolysis never occurs.

Physiological properties. For *Erysipelothrix rhusiopathiae*, acid production from carbohydrates is usually poor or inconsistent when grown in 1% (w/v) peptone water. Most workers recommend the addition of sterile horse serum (5–10% v/v) to the basal medium (Seeliger, 1974; White and Shuman, 1961; Wood, 1970). It is not always convenient to use serum: good results are achieved by testing for acid production in nutrient broth (Oxoid) with the test carbohydrate (0.5–1% w/v) and phenol red as indicator.

The methyl red test is usually reported as negative, but Wilkinson and Jones (1977) reported all strains examined gave a weak positive reaction when incubated at 35 °C for 7 d in BM broth. Acetoin (Voges–Proskauer test) was not produced in this medium. BM broth consists of peptone (Oxoid), 10.0 g; Lab Lemco (Oxoid), 8.0 g; yeast extract (Oxoid), 4.0 g; glucose, 5.0 g; Tween 80, 1 ml; K_2HPO_4 , 5.0 g; $MgSO_4 \cdot 7H_2O$, 0.2 g; $MnSO_4 \cdot 5H_2O$, 0.05 g; and distilled water, 1000 ml. Fermentation of glucose results in the production of mainly L(+)-lactic acid with smaller amounts of acetic acid, formic acid, ethyl alcohol, and carbon dioxide. Glucose metabolism is via the Embden–Meyerhof–Parnas pathway, although a small amount of glucose is dissimilated by the hexose monophosphate pathway (Robertson and McCullough, 1968). The evidence available indicates that the tricarboxylic acid cycle is relatively unimportant in *Erysipelothrix rhusiopathiae* (Robertson and McCullough, 1968). Exogenous citrate is not utilized.

Utilization of substrates and enzyme activities of type strains of *Erysipelothrix* species and some additional *Erysipelothrix rhusiopathiae* strains were determined using Biolog GP and API STREPT microplate plate panels, respectively (Verborg et al., 2004). Most substrates revealed identical reactions by type strains of the species (see species description), but sufficient differences are observed which allow their discrimination (Table 255).

Habitat. *Erysipelothrix rhusiopathiae* has a very wide distribution in nature. It is parasitic on mammals, birds, and fish. Most frequently it is found in pigs where it is the causative agent of the economically important disease, swine erysipelas. Infection probably occurs by the oral route through the ingestion of contaminated material. It has been isolated, not in association with infection, from the surfaces of fish, shellfish, fish slime, and fish boxes (Ewald, 1981; Grieco and Sheldon, 1970; Woodbine, 1950).

Besides from swine erysipelas, *Erysipelothrix rhusiopathiae* has been isolated from bovine tonsils (Hassanein et al., 2003), causing endocarditis in dogs (Takahashi et al., 2000), polyarthritis in lambs and calves, septicemia in turkeys and ducks, septicemia and urticaria in dolphins, and cutaneous lesions in humans (Takahashi et al., 1987b). Natural infections, with epizootics, also occur in other domestic animals (sheep, lambs, cows, horses, dogs, and mice) and birds (turkeys, chickens, geese, and pheasants) and also in wild and zoo animals. Strains of this species have been isolated from the slime on the bodies of a variety of different fish, and from cephalopods and crustaceans,

including oysters and lobsters (Fidalgo et al., 2000), from salted or pickled bacon after several weeks, and from ham 3 months after smoking. Viable organisms have been recovered from a buried carcass after 9 months. Heat and direct sunlight diminish the viability of *Erysipelothrix rhusiopathiae*. A low temperature, alkaline conditions, and organic matter favor its survival (Ewald, 1981; Grieco and Sheldon, 1970; Woodbine, 1950).

Pathogenic strains of *Erysipelothrix rhusiopathiae* have been isolated from the feces of apparently healthy swine, and asymptomatic swine commonly harbor this organism in their tonsils and other lymphoid tissues (Wood, 1974a). Some of these isolates are included in *Erysipelothrix tonsillarum* (Takahashi et al., 1987a). Contamination of soil and water occurs not only from the feces and urine of sick animals but also from the activities of asymptomatic carrier pigs (Wood, 1974b). The shedding of the organisms by asymptomatic pigs into the soil of pigpens is probably the reason that *Erysipelothrix rhusiopathiae* may be isolated from farms on which no cases of swine erysipelas have occurred for many years (Wood and Packer, 1972). Isolates of the genus have also been recovered from the tonsils of healthy cattle in Japan (Hassanein et al., 2001). Contaminated surface water, rodents, wild birds, and insects may be responsible for carrying the organisms to farms and fish factories. *Erysipelothrix* spp. were isolated from the lung and intestine of a diseased blue penguin (Boerner et al., 2004), which is the first reported case

of erysipelas infection in a captive aquatic bird. In man it causes a skin infection known as erysipeloid. The majority of reported infections result from direct handling of contaminated organic matter such as swine carcasses, fish, and poultry. The infections are largely limited to veterinarians, butchers, and fish handlers. Generally, infection is confined to the skin of the hands and lower arms where the organisms gain entry through cuts and abrasions. Only rarely does the infection become systemic, causing arthritis and endocarditis. Most fatal cases have been shown to occur among excessive users of alcohol (Ewald, 1981). The occurrence of *Erysipelothrix rhusiopathiae* in men has been summarized by Stackebrandt et al. (2005). For a non-sporeforming organism, *Erysipelothrix rhusiopathiae* is remarkably persistent in the environment. Organisms remain viable in drinking water for up to 5 d and for up to 15 d in sewage. However, it does not survive heating at 60 °C for 15 min and does not grow in 10% (w/v) NaCl.

Erysipelothrix inopinata was isolated in the course of the validation of production processes in aseptic manufacturing of pharmaceuticals when a vegetable-based growth medium was tested for its dilution performance (Verborg et al., 2004).

Enrichment and isolation procedures

A number of procedures have been devised for the isolation of *Erysipelothrix rhusiopathiae*. These methods may also refer to *Erysipelothrix tonsillarum*, classified as *Erysipelothrix rhusiopathiae* in the past. Most procedures are based on the ability of the organism to grow in the presence of various substances which are bacteriocidal or bacteriostatic for other organisms (Ewald, 1981; Wood, 1965).

Erysipelothrix rhusiopathiae can be isolated easily from the blood of infected animals. A small quantity of blood is placed in a tube of semisolid nutrient agar supplemented with 0.2% (w/v) glucose or horse serum (5–10%, v/v), incubated at 35 °C for 24–48 h. The layer of growth, which develops below the surface, is then plated onto a suitable solid medium (Blood Agar Base No. 2 [Difco] plus 0.2%, w/v, glucose), incubated at 35 °C for up to 48 h, and examined for colonies.

Successful isolation of *Erysipelothrix rhusiopathiae* from pig or human skin requires the removal of a small piece of the entire thickness of the dermis because the organisms are located in the deeper parts of the skin. *Erysipelothrix rhusiopathiae* is rarely the only bacterium present in skin samples or in pieces of other tissues (spleen, kidney, liver, lung, and tonsils). Isolation is best achieved by placing the skin or small pieces of tissue in 10 ml of modified ESB medium (Wood, 1965). [ESB medium is Nutrient Broth No. 2 (Oxoid), 25.0 g and distilled water, 1000 ml. After sterilization at 121 °C for 15 min, 50 ml of horse serum, 400 mg of kanamycin, 50 mg of neomycin, and 25 mg of vancomycin are added aseptically. This medium may be stored at 4 °C for not more than 2 weeks.]

After overnight incubation at 35 °C, about 5 ml of the liquid portion is placed in a sterile tube and centrifuged for 20 min at approximately 1400 × g. The supernatant is discarded, the sediment resuspended in 1–2 ml physiological buffer (0.85% w/v) and a portion plated on MBA medium (Harrington and Hulse, 1971). [MBA medium is Heart Infusion Agar (Difco), 40.0 g; sodium azide, 0.4 g; distilled water, 1000 ml. After sterilization at 121 °C for 15 min, 20 ml of horse blood and 50 ml of

horse serum are added aseptically.] After incubation at 35 °C for 24–48 h, the plate is examined for colonies.

Isolation from feces or contaminated soil may be achieved in much the same way. Samples (approx. 100 g) are placed in a sterile blender containing 220 ml of sterile 0.1 M phosphate buffer. After mixing for 10 min, the whole is transferred to a sterile centrifuge bottle and centrifuged at a low speed for 10 min. The bottle is shaken slightly to resuspend the top 5–10 ml of the sediment and the cloudy supernatant decanted into a sterile 1-l screw-capped flask containing 200 ml of double-strength ESB medium (but the volume of serum is not doubled, i.e., it remains 5%, v/v). After mixing, the flask is incubated at 35 °C for 48 h. Samples are then plated on Packer's agar with 5% (v/v) horse serum (Packer, 1943), incubated at 35 °C for 24–48 h, and the plates then examined for colonies. Packer's agar is recommended for grossly contaminated specimens such as soil or feces because it is more selective for *Erysipelothrix rhusiopathiae* than is MBA medium (R.L. Wood, personal communication to D. Jones).

A fluorescent antibody technique may be used to detect *Erysipelothrix rhusiopathiae* in tissues (Dacres and Groth, 1959; Seidler et al., 1971) and in enrichment broth cultures (Harrington et al., 1974).

Sakuma et al. (1973) used whole-body autobacteriography to study localization of *Erysipelothrix rhusiopathiae* in the whole body of mice. Bacterial localization as demonstrated by this technique was very similar to that observed when infected mice were investigated by conventional bacteriological techniques. The inoculated organisms eventually localized in organs such as the spleen, liver, and subcutaneous and intramuscular tissue. They then multiplied in these tissues and finally distributed widely as in a bacteremia.

Erysipelothrix inopinata was enriched in the course of preparation of a vegetable CSB medium (peptone vegetable 20.0 g; D(+)-glucose, 2.5 g; K₂HPO₄, 2.5 g; water, 1000 ml). The water used for dilution was heated to 80 °C for 1 h and allowed to cool down to room temperature. The dehydrated medium was then added to the water and the solution was filtered through a membrane filter (pore width, 0.2 μm). Following incubation of a medium sample at room temperature for 3 d, the medium became turbid. Microscopic analysis and plating in medium TSA (tryptic soy agar: casein peptone, 15 g; soy peptone, 5.0 g; NaCl, 5.0 g; agar, 15.0 g, water, 1000 ml; pH 7.3) and TSS (TSA + 5% sheep blood) indicated the presence of a single contaminant, MF-EP02^T (DSM 15511^T), the type strain of *Erysipelothrix inopinata* (Verborg et al., 2004).

Enrichment of *Erysipelothrix tonsillarum* strains, originally described for serotype 7 of *Erysipelothrix rhusiopathiae*, is identical to that of strains of this species (Takahashi et al., 1987a).

Maintenance procedures

The organisms may be preserved for several months by stab inoculation into screw-capped tubes of nutrient agar (pH 7.4). After overnight growth at 30 °C, the tubes are tightly closed and kept at room or refrigerator temperature in the dark. Longer-term preservation (over 5 years) may be achieved by freezing on glass beads at 70 °C (Feltham et al., 1978). The organisms can also be preserved by freeze drying or storage in liquid nitrogen.

Differentiation of the genus *Erysipelothrix* from other genera

Holdemanella filiformis, the closest phylogenetic neighbor of *Erysipelothrix* (Figure 262), differs from members of *Erysipelothrix* in strictly anaerobic growth, composition of fatty acids (presence of C_{16:1 cis9}, C_{10:1}, C_{18:1 cis9} dimethyl acetal, and C_{16:0} dimethyl acetal) and in the presence of an interpeptide bridge consisting of L-Asp→L-Lys instead of L-Lys→L-Lys in the B-group peptidoglycan.

Traditionally and still widely used in clinical laboratories, new isolates of *Erysipelothrix rhusiopathiae* will be identified by examination of cell morphology, growth characteristics in nutrient gelatin, maximum growth temperature, catalase and oxidase tests, production of acid from carbohydrates in a suitable medium, and hydrogen sulfide production (Jones, 1986a). Serological identification and the mouse protection test by specific hyperimmune anti-*Erysipelothrix* serum may be necessary for certain identification of *Erysipelothrix rhusiopathiae*, but they are not normally required. Table 256 lists the features most

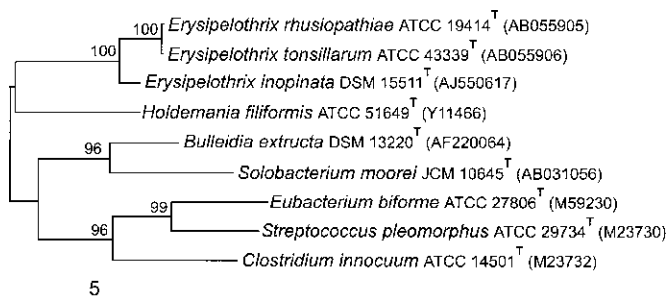

FIGURE 262. 16S rRNA gene sequence dendrogram (DeSoete, 1983) displaying the phylogenetic position *Erysipelothrix* strains among some phylogenetic neighbors. Numbers indicate the percentage of bootstrap (>95%) samplings (Felsenstein, 1993), derived from 1000 resamplings. Bar indicates 5% sequence divergence. Numbers in parentheses are accession numbers of 16S rRNA gene sequences.

TABLE 256. Useful characters in differentiating the genera *Erysipelothrix*, *Brochothrix*, *Kurthia*, *Listeria*, and *Corynebacterium**

Characteristic	<i>Erysipelothrix</i>	<i>Brochothrix</i>	<i>Kurthia</i>	<i>Listeria</i>	<i>Corynebacterium</i>

*Data from Collins and Cummins (1986), Reyn (1986), and Seeliger and Jones (1986).

^bSome organisms are aerobic.

useful in differentiating strains of *Erysipelothrix* from some other Gram-positive, non-sporeforming, rod-shaped bacteria with which they may be possibly confused.

Brochothrix thermosphacta also differs from *Erysipelothrix rhusiopathiae* in producing acid from far more carbohydrates, producing acetoin (Voges–Proskauer-positive), not producing H₂S, growing well on the selective medium of Gardner (1966), not exhibiting a “pipe cleaner” type of growth in nutrient gelatin, and containing cytochromes. *Listeria* may be further distinguished from *Erysipelothrix rhusiopathiae* by growing well on the usual nutrient media; producing colonies with a marked blue-green sheen on Tryptose Agar (Difco); exhibiting motility; possessing a more marked saccharolytic activity; hydrolysis of esculin; greater tolerance of NaCl (*Listeria monocytogenes* grows in nutrient broth plus 8.5% w/v NaCl, *Erysipelothrix* does not); producing acetoin; sensitivity to neomycin (Fuji, 1963); hydrolysis of Tweens 20 and 80; not producing H₂S. Strains of *Listeria* and *Erysipelothrix* are serologically distinct; *Listeria* contains menaquinones and cytochromes. The mouse protection test is considered by some clinical workers, especially veterinarians, to be the best method of identifying new isolates of *Erysipelothrix rhusiopathiae* with complete certainty. However, the test will detect only strains virulent for mice.

Mouse protection test (Jones, 1986a) Commercial horse anti-*Erysipelothrix* serum is satisfactory for the test. It can be obtained from manufacturers specializing in veterinary products. Three to six mice are injected subcutaneously with 0.1 ml of a 24-h broth culture of the suspected strain. The loose skin of the flank is recommended. At the same time, 0.3 ml of antiserum is injected into the opposite flank. If the organism is *Erysipelothrix rhusiopathiae*, the mice that received culture and antiserum should survive; those receiving culture alone should die within 6 d. It is recommended that a control test using a known virulent strain of *Erysipelothrix rhusiopathiae* be set up in parallel as a check on the antiserum.

Chemotaxonomic analyses

To circumscribe novel isolates of *Erysipelothrix*, chemical properties of taxonomic relevance for members of the *Clostridium* subphylum should be analyzed. Cells for isoprenoid quinones analysis can be obtained from biomass grown under aerobic and anaerobic conditions on TSB agar + 5% sheep blood. Menaquinone may be extracted by chloroform-methanol (2:1, v/v) from lyophilized cells, purified by preparative TLC on silica gel and analyzed by the HPLC method (Collins et al., 1977; Groth et al., 1996). None of the *Erysipelothrix* strains contain significant amount of isoprenoid quinones, i.e., menaquinones, no matter under which conditions cells were grown for the preparation of menaquinones. Only traces of MK-7 were detected in cells of *Erysipelothrix tonsillarum* DSM 14972^T following aerobic cultivation. The lack of significant amounts of menaquinones in strains of *Erysipelothrix rhusiopathiae* confirms the results of Collins and Jones (1981).

The composition of fatty acids reveals high similarity among all *Erysipelothrix* species. The pattern is dominated by C_{18:1 cis9} (>30%), C_{16:0} (>24%), and C_{18:0} (>10%) fatty acid methyl esters; quantitative values are given in the species description. This pattern differs from that of the phylogenetic neighbor *Holdemanella filiformis* ATCC 51649^T which contains higher amounts of C_{18:1 cis9} (50%), additional minor components, and significant amounts of dimethyl acetals [C_{18:1 cis9} (12%) and C_{16:0} (4%)] (Willems et al., 1997).

The method of analysis of the peptidoglycan structure is described by Schleifer and Kandler (1972), modified as described by Willems et al. (1997). The two-dimensional thin-layer chromatogram of the partial acid hydrolysate of *Erysipelothrix* strains (Schleifer and Kandler, 1972; Verborg et al., 2004) revealed the presence of lysine, glutamic acid, glycine, serine, alanine, muramic acid, and glucosamine, and fragments including D-Glu→Gly, L-Ser→D-Glu, and L-Lys→L-Lys, while aspartic acid or fragments containing aspartic acid were missing. The quantitative amino acid composition of *Erysipelothrix inopinata* was Ala:Gly:Ser:Glu:Lys = 1.7:0.7:0.9:1.0:1.5. It was deduced that the peptidoglycan type is B1δ with the interpeptide bridge being Gly→L-Lys→L-Lys, identical to that reported for *Erysipelothrix rhusiopathiae* (Schubert and Fiedler, 2001).

The range of mol% G+C values of DNA base composition is rapidly determined by HPLC (Mesbah et al., 1989). The HPLC values of 36–40 mol% support those obtained with older methods (T_m , Bd) (Takahashi et al., 1992).

Molecular differentiation of strains and species

Today, molecular analysis by sequencing parts or the almost entire 16S rRNA gene is the most reliable and fastest way to determine the phylogenetic position. Another rapid identification method is the PCR amplification of taxon-specific 16S rRNA gene fragments (Fidalgo and Riley, 2004; Makino et al., 1994; Takeshi et al., 1999), e.g., the forward primer 5'-TGATGC-CATAGAACTGGTA-3' and the reverse primer 5'-CTGTATC-CGCCATAACTA-3' (Makino et al., 1994). *In silico* analysis of the 16S rRNA gene sequence of *Erysipelothrix inopinata* DSM 15511^T for target sites for a primer pair, indicates that these primers would also identify strains of this species. Shimoji et al. (1998) describe the use of a genus-specific primer pair suitable to amplify a 937-bp long fragment of the chromosome and used this system to identify enriched *Erysipelothrix rhusiopathiae* strains in specimens from swine with arthritis. This method clearly identifies *Erysipelothrix* strains and separates them from genera listed above and from those with which they were confused in the past, at least in certain stages of growth, e.g., streptococci, *Gemella*, and lactobacilli (Jones, 1986a).

The most commonly used methods for determining intra- and interspecific relationships of the closely related species *Erysipelothrix rhusiopathiae* and *Erysipelothrix tonsillarum* were serotyping and DNA–DNA hybridization (Imada et al., 2004; Opriessnig et al., 2004; Takahashi et al., 1987a, 1992, 2000). Based on the latter method, Takahashi et al. (1992) determined serovars 1, 2, 4, 5, 6, 8, 9, 11, 12, 15, 16, 17, 19, and 21 to exhibit more than 73% hybridization with the type strain of *Erysipelothrix rhusiopathiae* but less than 24% hybridization with the type strain of *Erysipelothrix tonsillarum*. This species embraced serovars 3, 7, 10, 14, 20, and 22, as well as 23 strains with higher than 66% hybridization but less than 27% hybridization with the type strain of *Erysipelothrix rhusiopathiae*. The fact that strains representing serovars 13 and 18 exhibited low levels of hybridization (16–47%) with both type strains indicated the presence of two additional genomic species. Strains of serovar 13 may be considered strains of *Erysipelothrix inopinata* inasmuch as the partial 16S rRNA gene sequence of one representative of serovar 13, Pécs 56, is 99.9% similar with that of the type strain DSM 15511^T. Two species of the genus and two genomospecies

(serovar 13 probably representing *Erysipelothrix inopinata*) can be distinguished by a set of four specific 16S rRNA gene primers (Takeshi et al., 1999). Other methods of high discriminatory potential are pulsed-field gel electrophoresis (PFGE) (Okatani et al., 2001; Opriessnig et al., 2004), restriction fragment length polymorphism (RFLP) (Ahrne et al., 1995), random amplified polymorphic DNA analysis (RAPD) (Imada et al., 2004; Okatani et al., 2000), comparison of protein patterns by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (Bernath et al., 1997, 2001; Tamura et al., 1993), multi-locus enzyme electrophoresis (MLEE) (Chooromoney et al., 1994), 16S rRNA gene sequence analyses, and ribotyping (Verborg et al., 2004). Except for the latter two methods, which were applied to all three species, all other methods were only applied to *Erysipelothrix rhusiopathiae* and *Erysipelothrix tonsillarum*. Results of serotyping and MLEE were not exclusively in accord with the taxonomic separation of the two species. Ribotyping and 16S rRNA gene sequence analysis demonstrated the close phylogenetic distance between these two species, while *Erysipelothrix inopinata* was significantly different.

Taxonomic comments

As summarized by Jones (1986a), Reboli and Farrar (1991), and Stackebrandt et al. (2005), the close relationship between the genera *Erysipelothrix* and *Listeria* was once discussed (Barber, 1939), but subsequent results of numerical phenetic studies (Davis and Newton, 1969; Feresu and Jones, 1988; Jones, 1975; Stuart and Pease, 1972; Wilkinson and Jones, 1977), chemotaxonomic studies (Schleifer and Kandler, 1972; Tadayan and Carroll, 1971; Verborg et al., 2004), and DNA hybridization studies (Stuart and Welshimer, 1974) did not support this conclusion. Enzyme, numerical phenetic and DNA-base ratio studies reveal a closer relationship of *Erysipelothrix* to the family *Lactobacillaceae* and to streptococci (Jones, 1986a) than to *Corynebacteriaceae* (Flossmann and Erler, 1972; Jones, 1975; White and Mirikitani, 1976), but *Erysipelothrix* was classified among the regular non-sporeforming Gram-positive rods, containing *Corynebacteriaceae* (Jones, 1986a). In another study, the closest similarity of *Erysipelothrix* was to the genus *Gemella* (Wilkinson and Jones, 1977).

16S rRNA gene sequence analyses indicated relationship of *Erysipelothrix* species to the *Firmicutes* (Kiuchi et al., 2000; Verborg et al., 2004), belonging to the family *Erysipelotrichaceae* (*Clostridium* cluster XVI according to Collins et al., 1994; Verborg et al., 2004), a lineage that also embraces *Holdemania filiformis* (Willems et al., 1997). Less closely related are *Bulleidia extracta* (Downes et al., 2000), *Solobacterium moorei* (Kageyama and Benno, 2000a), and non-authentic members of *Eubacterium*, *Streptococcus*, and *Clostridium* (Figure 262). The 16S rRNA gene sequences of the *Erysipelothrix rhusiopathiae* strains ATCC 19414^T (DSM 555^T), DSM 5056, and three strains from the Czech National Collection of Type Cultures (CNCTC 6291, CNCTC 6291, and CNCTC 6327) were identical and highly similar to the sequence of *Erysipelothrix tonsillarum* ATCC 4339^T (99.8% similarity). The gene sequence of *Erysipelothrix inopinata* DSM 15511^T is less related (96.4% similarity) to those of the type strains of another two species. *Erysipelothrix rhusiopathiae* strains serotype 13 (AB019249) and serotype 18 (AB019250) (Takeshi et al., 1999), covering the 3' half of the

molecule (about 790 nucleotides) only share 97.5 and 97.8% similarity, respectively, with the corresponding fragment of the gene of DSM 15511^T. DNA–DNA reassociation values obtained for these strains range only between 18 and 36%, which confirm differences at the physiological level, hence their separate species status.

In addition to those features given in the generic description, acid is usually produced in a suitable medium from glucose, galactose, fructose, lactose, maltose, dextrin, and *N*-acetylglucosamine. Weak or delayed acid production from mannose and sometimes sucrose. Acid is not produced usually from glycerol, erythritol, arabinose, xylose, adonitol, β -methylxyloside, sorbose, rhamnose, dulcitol, inositol, mannitol, sorbitol, *n*-methyl-D-mannoside, α -methyl-D-glucoside, amygdalin, arbutin, esculin, salicin, cellobiose, melibiose, trehalose, inulin, melezitose, raffinose, amidone, glycogen, xylitol, β -gentobiose, D-turanose, D-lyxose, D-tagatose, D-fucose, or L-fucose. Weak acid or no change in litmus milk. Methyl red reaction negative or very weakly positive. Acetoin (Voges–Proskauer test) not produced. Indole not produced. Exogenous citrate not utilized. Hydrogen sulfide produced. Nitrates not reduced. Ammonia not produced from peptone. According to API 32 STREPT substrate panel, positive for glycyl-tryptophan arylamidase, and pyroglutamic acid arylamidase; negative for oxidase, aminopeptidase, hydrolysis of starch, gelatin, DNA, casein, and urease; acid from mannitol, sorbitol, raffinose, sucrose, L-arabinose, D-arabitol, cyclodextrin, glycogen, pullulan, maltose, melibiose, melezitose, tagatose, β -glucuronidase; production of acetoin; hydrolysis of hippurate.

As determined with Biolog GP the following substrates are utilized: adenosine, uridine, methylpyruvate, *N*-acetylglucosamine and α -D-glucose. All strains are negative in β -methyl-D-glucoside, D-tagatose, lactamide, alaninamide, D-arabitol, lactulose, α -methyl-D-mannoside, D-lactic acid methyl ester, D-alanine, β -cyclodextrin, maltose, palatinose, turanose, L-lactic acid, L-alanine, dextrin, maltotriose, xylitol, D-malic acid, L-asparagine, glycogen, D-mannitol, D-raffinose, L-malic acid, inulin, L-fucose, L-rhamnose, acetic acid, L-glutamic acid, adenosine-5'-monophosphate, mannan, D-melezitose, α -hydroxy-butyric acid, mono-methyl succinate, glycyl-L-glutamic acid, thymidine-5'-monophosphate, Tween 40, D-galacturonic acid, D-melibiose, β -hydroxy-butyric acid, propionic acid, L-pyroglutamic acid, uridine-5'-monophosphate, Tween 60, α -methyl D-galactoside, sedoheptulosan, γ -hydroxy-butyric acid, pyruvic acid, L-serine, fructose 6-phosphate, D-gluconic acid, β -methyl D-galactoside, D-sorbitol, *p*-hydroxy-phenyl acetic acid, succinamic acid, putrescine, glucose-1-phosphate, stachyose, α -ketoglutaric acid, succinic acid, 2,3-butane-diol, glucose 6-phosphate, amygdalin, *m*-inositol, α -methyl D-glucoside, sucrose, α -keto valeric acid, *N*-acetyl L-glutamic

acid, and D-L- α -glycerol phosphate. Gelatin not liquefied, but most strains exhibit characteristic pipe cleaner growth in gelatin stab cultures incubated at 22 °C. Urea, sodium hippurate, esculin, starch, cellulose, casein, and Tweens 20, 40, and 60 not hydrolyzed. Tyrosine and xanthine not degraded. Neuraminidase but not sulfatase, deoxyribonuclease, and ribonuclease is produced. Most strains produce hyaluronidase. Some strains produce phosphatase and lecithinase.

On potassium tellurite (0.05%, w/v) agar, colonies grayish after 24 h, becoming black at 2–3 d. Grow in presence of, but do not reduce, 2,3,5-triphenyltetrazolium chloride (0.2% w/v). Most strains do not grow in 6.5% (w/v) NaCl; none grows in 10% (w/v) NaCl. Do not grow on the medium of Gardner (1966) or on MRS medium (De Man et al., 1960).

Twenty-two serovars can be distinguished on the basis of heat-stable somatic antigens.

Causes swine erysipelas. Sometimes pathogenic to man causing erysipeloid. Mice and pigeons are very susceptible; septicemia is produced. Rabbits are less susceptible and guinea pigs are more resistant.

Major fatty acids of the type strain are C_{18:1 cis-9} (39.3%), C_{16:0} (31.7%), and C_{18:0} (10.1%); others in smaller amounts (>1% to <5%) are C_{14:0} (1.6%), C_{16:1 cis-8} (1.3%), C_{17:0} (1.0%), C_{18:2} (6.5%), and C_{18:1 cis-11} (1.9%).

DNA G+C content (mol %): 36–40 (*T_m*, Bd); type strain, 36 (Bd).

Type strain: ATCC 19414, CCUG 221, CIP 105957, DSM 5055, NCTC 8163.

GenBank accession no. (16S rRNA gene): AB055905.

2. ***Erysipelothrix inopinata*** Verberg, Rheims, Emus, Frühling, Kroppenstedt, Stackebrandt and Schumann 2004, 224^{VP} in.o.pi.na'ta. L. adj. *inopinatus* -a unexpected.

In addition to those features given in the generic description, cells are approximately 0.5 μ m width and 1.5–3.0 μ m long. Surface colonies on BHI (Difco) after 2 d of incubation are punctiform to approximately 1.5 mm in diameter, creamy white, undulate, convex, translucent, and soft. Growth occurs under aerobic and anaerobic conditions in BHI and Columbia Blood, preferably at pH 8. Growth occurs at 20 and 40 °C, but not at 45 °C. The optimal temperature for growth is 25–30 °C. According to API 32 STREPT substrate panel, positive for acid from glucose, glycyl-tryptophan arylamidase, and pyroglutamic acid arylamidase; negative for oxidase, aminopeptidase, hydrolysis of starch, gelatin, DNA and casein, urease, acid from mannitol, sorbitol, raffinose, sucrose, L-arabinose, D-arabitol, cyclodextrin, glycogen, pullulan, maltose, melibiose, melezitose, tagatose, β -glucuronidase, production of acetoin, and hydrolysis of hippurate.

As determined with Biolog GP, the following substrates are utilized by the type strain: adenosine, uridine, methylpyruvate, *N*-acetylglucosamine and α -D-glucose. Negative in β -methyl-D-glucoside, D-tagatose, lactamide, alaninamide, D-arabitol, lactulose, α -methyl-D-mannoside, D-lactic acid methyl ester, D-alanine, β -cyclodextrin, maltose, palatinose, turanose, L-lactic acid, L-alanine, dextrin, maltotriose, xylitol, D-malic acid, L-asparagine, glycogen, D-mannitol, D-raffinose, L-malic acid, inulin, L-fucose, L-rhamnose, acetic acid, L-glutamic acid, adenosine-5'-monophosphate, mannan, D-melezitose, α -hydroxy-butyric acid, mono-methyl succinate, glycyl-L-glutamic acid, thymidine-5'-monophosphate, Tweens 40 and 60, D-galacturonic acid, D-melibiose, β -hydroxy-butyric acid, propionic acid, L-pyroglytamic acid, uridine-5'-monophosphate, α -methyl-D-galactoside, sedoheptulosan, γ -hydroxy-butyric acid, pyruvic acid, L-serine, fructose 6-phosphate, D-gluconic acid, β -methyl D-galactoside, D-sorbitol, *p*-hydroxy-phenyl acetic acid, succinamic acid, putrescine, glucose-1-phosphate, stachyose, α -keto glutaric acid, succinic acid, 2,3-butanediol, glucose 6-phosphate, amygdalin, *m*-inositol, α -methyl D-glucoside, sucrose, α -keto valeric acid, *N*-acetyl L-glutamic acid, and D-L- α -glycerol phosphate. Major fatty acids (>5%) are C_{18:1 cis9} (33.1%), C_{16:0} (34.2%), and C_{18:0} (12.9%); smaller amounts (>1% to <5%) are C_{10:0} (3.0%), C_{14:0} (3.0%), C_{16:1 cis8} (1.2%), C_{17:0} (1.2%), C_{18:2} (2.8%), and C_{18:1 cis12} (2.5%). Isolated from vegetable broth used for preparation of growth media, Germany.

DNA G+C content (mol%): 37.5 (HPLC).

Type strain: CIP 107935, DSM 15511^T, strain MF-EP02.

GenBank accession number (16S rRNA gene): AJ550617.

3. *Erysipelothrix tonsillarum* Takahashi, Fujisawa, Benno, Tamura, Sawada, Suzuki, Muramatsu and Mitsuoka 1987a, 168^{VP} ton.sil.la'rum. L. gen. n. *tonsillarum* of the tonsils.

In addition to characters listed in the generic description, cells are about 0.3 μ m wide by 1.0–1.5 μ m long. Surface colonies on BI agar after 2 d of incubation are punctiform to approximately 1 mm in diameter, circular, entire, convex, colorless, transparent, and soft. Acid from dextrin maltose, galactose, levulose, lactose, and glucose. Weak acid from sucrose and mannose. Glycerol, salicin, inositol, dulcitol, raffinose, mannitol, rhamnose, trehalose, xylose, sorbitol, and arabinose not fermented. H₂S produced. Gelatin not

liquefied. "Test-tube brush" growth in gelatin. Esculin not hydrolyzed. Litmus milk not acidified. According to API 32 STREPT substrate panel, the type strain is positive for acid production from glucose, glycyl-tryptophan arylamidase, and pyroglytamic acid arylamidase; negative for oxidase, aminopeptidase, hydrolysis of starch, gelatin, DNA, and casein, urease, acid from mannitol, sorbitol, raffinose, sucrose, L-arabinose, D-arabitol, cyclodextrin, glycogen, pululan, maltose, melibiose, melezitose, tagatose, β -glucuronidase, production of acetoin and hydrolysis of hippurate. As determined with Biolog GP, the following substrates are utilized by the type strain: adenosine, uridine, methylpyruvate, *N*-acetylglucosamine and α -D-glucose. All strains are negative in β -methyl-D-glucoside, D-tagatose, lactamide, alaninamide, D-arabitol, lactulose, α -methyl-D-mannoside, D-lactic acid methyl ester, D-alanine, β -cyclodextrin, maltose, palatinose, turanose, L-lactic acid, L-alanine, dextrin, maltotriose, xylitol, D-malic acid, L-asparagine, glycogen, D-mannitol, D-raffinose, L-malic acid, inulin, L-fucose, L-rhamnose, acetic acid, L-glutamic acid, adenosine-5'-monophosphate, mannan, D-melezitose, α -hydroxy-butyric acid, mono-methyl succinate, glycyl-L-glutamic acid, thymidine-5'-monophosphate, Tween 40, D-galacturonic acid, D-melibiose, β -hydroxy-butyric acid, propionic acid, L-pyroglytamic acid, uridine-5'-monophosphate, Tween 60, α -methyl-D-galactoside, sedoheptulosan, γ -hydroxy-butyric acid, pyruvic acid, L-serine, fructose 6-phosphate, D-gluconic acid, β -methyl D-galactoside, D-sorbitol, *p*-hydroxy-phenyl acetic acid, succinamic acid, putrescine, glucose-1-phosphate, stachyose, α -keto-glutaric acid, succinic acid, 2,3-butanediol, glucose 6-phosphate, amygdalin, *m*-inositol, α -methyl D-glucoside, sucrose, α -keto-valeric acid, *N*-acetyl L-glutamic acid, and D-L- α -glycerol phosphate. Susceptible to ampicillin and erythromycin. Major fatty acids are C_{18:1 cis9} (32.5%), C_{16:0} (28.2%), and C_{18:0} (19.6%); others in smaller amounts (>1% to <5%) are C_{14:0} (2.7%), C_{17:0} (1.4%), C_{18:2} (5.0%), and C_{18:1 cis12} (5.8%). Type strain isolated from tonsils of apparently healthy pigs, Japan.

DNA G+C content (mol%): 37.9 \pm 2.0 (*T_m*), 37.4 (HPLC).

Type strain: ATCC 43339^T, CCUG 31352, CIP 105960, DSM 14972, JCM 8533, strain T-305.

GenBank accession number (16S rRNA gene): AB055906.

Genus II. *Allobaculum* Greetham, Gibson, Giffard, Hippe, Merkhoffer, Steiner, Falsen and Collins 2006, 1459^{VP} (Effective publication: Greetham, Gibson, Giffard, Hippe, Merkhoffer, Steiner, Falsen and Collins 2004, 306.)

THE EDITORIAL BOARD

Al.lo.bac.u.lum. Gr. pref. *allo* the other; L. neut. n. *baculum* small rod; N.L. neut. n. *Allobaculum* the other small rod.

Nonsporeforming rods in pairs or chains. **Gram-stain-positive**. Nonmotile. **Strictly anaerobic** and catalase-negative. Produce lactic and butyric acids and small amounts of ethanol from glucose. **Hydrolyze esculin** but not gelatin, starch, or urea. Lecithinase- and lipase-negative. **Cannot produce indole or reduce nitrate to nitrate**. Have a **type A wall** containing *meso*-diaminopimelic acid.

DNA G+C content (mol%): 37.9.

Type species: *Allobaculum stercoricanis* Greetham, Gibson, Giffard, Hippe, Merkhoffer, Steiner, Falsen and Collins 2006, 1459^{VP} (Effective publication: Greetham, Gibson, Giffard, Hippe, Merkhoffer, Steiner, Falsen and Collins 2004, 306.).

Further descriptive information

16S rRNA gene treeing analysis and sequence divergence reveals that the genus forms a new branch at the periphery of

Clostridium rRNA cluster XVI and related taxa. Nevertheless, sequence divergence (13–15%) with members of this cluster indicates only a distant relationship to these species.

The only species in the genus was isolated from dog feces on reinforced clostridial agar. Its detection in all fecal samples and high mean abundance of 1.5% suggests that occurrence is widespread in the canine gut.

Enrichment and isolation methods

A 10% (w/v) anaerobic slurry of feces collected immediately after defecation was prepared in pre-reduced 0.1 M phosphate buffered saline (pH 7) and homogenized in an atmosphere of 10% H₂, 10% CO₂, and 80% N₂. Serial tenfold dilutions prepared in half-strength peptone water and cysteine-HCl (0.5 g/l) were plated and incubated (37 °C, 48 h) on reinforced clostridial agar (novobiocin 8 mg/l and colistin 8 mg/l).

List of species of the genus *Allobaculum*

1. ***Allobaculum stercoricanis*** Greetham, Gibson, Giffard, Hippe, Merkhoffer, Steiner, Falsen and Collins 2006, 1459^{VP} (Effective publication: Greetham, Gibson, Giffard, Hippe, Merkhoffer, Steiner, Falsen and Collins 2004, 306.)

ster.co.ri.ca'nis. L. n. *stercus*, *oris* feces; L. genit. n. *canis* of the dog; L. gen. n. *stercoricanis* from dog feces.

Colonies (up to 3 mm in diameter) are irregular, translucent, grayish in color and have erose margins. Cells are rod-shaped (0.75–0.9 × 1.2–2.0 μm), nonhemolytic, and grow at 30–40 °C but not at 20 °C or 45 °C; optimum ~37–40 °C.

Produces acid from glucose (pH of PY-1% glucose medium decreases after 6 d from 6.8 to 5.7). Acid is produced from cellobiose, fructose, galactose, maltose, salicin, and sucrose but not from amygdalin, arabinose, glycogen, inositol, lactose, mannitol, mannose, melezitose, melibiose, raffinose, rhamnose, ribose, sorbitol, starch, trehalose, or xylose. API tests detect activity for acid phosphatase, alkaline phosphatase, arginine arylamidase, esterase C-4, ester

Differentiation of the genus *Allobaculum* from other genera

Allobaculum can be distinguished from *Eubacterium* by lower DNA G+C content (37 versus 45–55 mol%), wall type (type A wall based on *meso*-diaminopimelic acid vs. type B murein), and phylogenetically (approx. 20% 16S rRNA sequence divergence). Also, *Allobaculum* is phylogenetically distant from *Catenibacterium*, *Coprobacillus*, *Erysipelothrix*, *Holdeman*, and *Solobacterium* (greater than 13% sequence divergence). It can be differentiated on the basis of acid end products (lactic and butyric acids from *Allobaculum*; acetic, butyric, isobutyric, and lactic acids from *Catenibacterium*; acetic and lactic acids from *Coprobacillus*; lactic acid from *Erysipelothrix*; and acetic, lactic, and butyric acids from *Solobacterium*) and on the basis of cell-wall composition (type A wall containing *meso*-diaminopimelic acid for *Allobaculum*; *Erysipelothrix*, and *Holdeman* both type B murein based on L-lysine).

lipase C8, and phosphoamidase but not for alanine arylamidase, alanine phenylalanine, proline arylamidase, arginine dihydrolase, α-arabinosidase, trypsin, chymotrypsin, α-fucosidase, α-glucosidase, β-glucosidase, β-glucuronidase, α-galactosidase, β-galactosidase-6-phosphate, glutamic acid decarboxylase, glutamyl glutamic acid arylamidase, glycyl tryptophan arylamidase, glycine arylamidase, histidine arylamidase, leucine arylamidase, leucyl glycine arylamidase, lipase C14, α-mannosidase, β-mannosidase, phenyl alanine arylamidase, proline arylamidase, pyroglutamic acid arylamidase, serine arylamidase, valine arylamidase, urease, or tyrosine arylamidase, and (depending on the test kit) may or may not detect activity for *N*-acetyl-β-glucosaminidase and β-galactosidase.

For all other characteristics, refer to the genus description.

DNA G+C content (mol%): 37.9 (HPLC).

Type strain: DSM 13633, CCG 45212.

GenBank accession number (16S rRNA gene): AJ417075.

Genus III. *Bulleidia* Downes, Olsvik, Hiom, Spratt, Cheeseman, Olsen, Weightman and Wade 2000, 982^{VP}

WILLIAM G. WADE AND JULIA DOWNES

Bulleidia. L.n., named to honor Arthur Bulleid, a distinguished British oral microbiologist.

Straight or slightly curved, short rods which occur singly or in pairs. Rods 0.5 μm in diameter and 0.8–2.5 μm in length. **Gram-stain-positive** but intensity of staining variable. **Nonsporeforming and nonmotile. Obligately anaerobic.** Optimal growth temperature 30–37 °C. Colonies are 0.7–0.9 mm in diameter, circular, entire, low convex, gray-white and opaque with a glossy appearance after 7 d incubation on blood agar.

Saccharolytic. Principal end products of glucose fermentation are acetic and lactic acids with trace amounts of succinic acid produced. **Growth in broth media is poor** but stimulated by the addition of 0.5% Tween 80 in the presence of fermentable carbohydrates. Catalase-negative. Nitrate not reduced. Indole and H₂S not produced. Urea not hydrolyzed. Gelatin not liquefied. No growth in 20% bile. **Arginine is hydrolyzed.**

DNA G+C content (mol%): 38 (HPLC).

Type species: ***Bulleidia extracta*** Downes, Olsvik, Hiom, Spratt, Cheeseman, Olsen, Weightman and Wade 2000, 982^{VP}.

Further descriptive information

Found in the oral cavity of man where it has been isolated from periodontal pockets and dentoalveolar abscesses.

Enrichment and isolation procedures

Strains of *Bulleidia* species can be isolated on complex media appropriate for culture of anaerobes including blood agar, enriched brain heart infusion agar (Holdeman et al., 1977), and fastidious anaerobe agar (FAA, LabM, Bury, UK).

Maintenance procedures

Lyophilization of cultures in the early stationary phase of growth is recommended for long-term storage of most strains. Strains can also be stored at –70 °C in brain heart infusion broth supplemented with 10% glycerol.

Procedures and methods for characterization tests

The general methods described for the characterization of anaerobes in the VPI Anaerobe Laboratory Manual (Holdeman et al., 1977) and the Wadsworth-KTL Anaerobic Laboratory Manual (Jousimies-Somer et al., 2002) are suitable for the study of members of this genus. The Rapid ID32A anaerobe identification kit (bioMérieux) is useful for the generation of enzyme profiles that distinguish members of this genus from related taxa.

Differentiation from closely related taxa

Descriptive characteristics of *Bulleidia extracta* and characteristics that differentiate *Bulleidia extracta* from closely related species are shown in Table 257. The description of *Bulleidia extracta* is based on six strains isolated from the oral cavity. The characteristics of *Solobacterium moorei* listed in Table 257 are based on the study of three strains isolated from human feces (Kageyama and Benno, 2000a) and eight strains isolated from the oral cavity (Downes et al., 2001). Demonstration of production of acid from sugars is dependent on good growth in the test broth; false negative reactions occur. Perhaps because of this, Kageyama and Benno (2000a) reported that the three fecal strains did not produce acid from sucrose, although we have found their strains and our oral strains to be positive for this test. Moderate amounts of acetic and lactic acids are produced by *Solobacterium moorei* strains, grown to a turbidity of 3 to 4+ (on a negative to 4+ scale), in peptone-yeast extract-glucose broth supplemented with 0.5 % Tween 80. Kageyama and Benno (2000a) reported the production of moderate amounts of acetic, lactic, and butyric acids when the fecal strains were grown in peptone-yeast extract-Fildes-glucose (PYFG) broth (Kaneuchi et al., 1976).

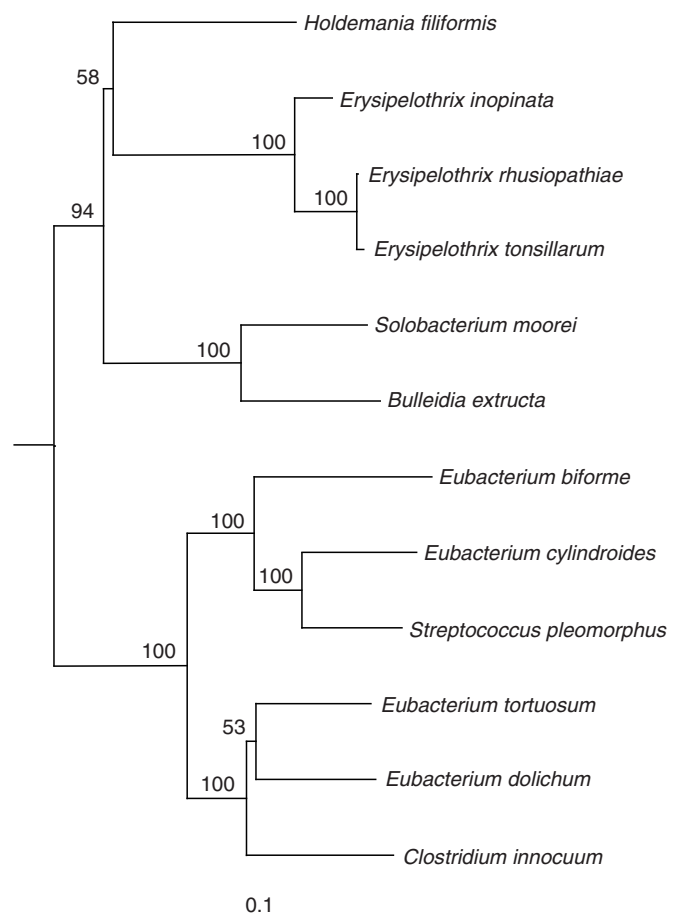

FIGURE 263. Phylogenetic tree based on 16S rRNA gene sequence comparisons over 1355 aligned bases showing relationships between *Bulleidia extracta* and related species. Tree was constructed using the neighbor-joining method following distance analysis of aligned sequences. Numbers represent bootstrap values for each branch based on data for 100 trees.

This discrepancy in reported metabolic end products could in part be due to differences in culture media or composition of the anaerobic atmosphere as both these factors can influence the end products formed.

The characteristics of *Holdemaniana filiformis* are based on the description of three strains isolated from human feces (Willems et al., 1997) supplemented with data from additional tests (enzyme profile, vancomycin sensitivity, H₂S production, urea hydrolysis, and growth in 20% bile) on the type strain. As with the other species listed in Table 257, growth of *Holdemaniana filiformis* in broth media is stimulated by both fermentable carbohydrates and Tween 80. Production of acid from fermentable carbohydrates is also unreliable and in part dependent on good growth in the medium. The characteristics for *Erysipelothrix rhusiopathiae* are as described by Jones (1986a) augmented by enzyme profile and bile sensitivity tests performed on the type strain.

Taxonomic comments

Phylogenetic analysis reveals that the genus *Bulleidia* belongs to the family *Erysipelotrichaceae*, class *Mollicutes*, and phylum *Firmicutes*; the order is uncertain. It is also related to the genus *Holdemaniana* (Figure 263).

Solobacterium moorei (Kageyama and Benno, 2000a) is a closely related species. (Figure 263). Since the type strains of *Solobacterium moorei* and *Bulleidia extracta* share 93.2% similarity in their 16S rRNA gene sequences and many phenotypic characteristics, *Solobacterium moorei* appears to represent a novel species within the genus *Bulleidia*. The generic name *Bulleidia* would have precedence by prior publication under Rule 27 of the Bacteriological Code.

List of species of the genus *Bulleidia*

1. ***Bulleidia extracta*** Downes, Olsvik, Hiom, Spratt, Cheeseman, Olsen, Weightman and Wade 2000, 982^{VP}

ex.truc'ta. L. adj. *extracta* slow, referring to the slow growth of the organism.

Description is based on six strains isolated from the oral cavity. Cells are obligately anaerobic, nonsporeforming, nonmotile, Gram-stain-positive short bacilli (0.5 × 0.8–2.5 μm) occurring singly and in pairs aligned side by side. After 7d incubation on FAA plates, colonies are 0.7–0.9 mm in diameter, circular, entire, low convex, gray to off-white, opaque, and glossy.

Growth is poor in pre-reduced aerobically sterilized media supplemented with 0.5% Tween 80 with arabinose, cellobiose, lactose, mannitol, mannose, melezitose, melibiose, raffinose, rhamnose, salicin, sorbitol, sucrose, trehalose,

or xylose. Growth is stimulated by fructose, glucose, and maltose in the presence of 0.5% Tween 80. Glucose and maltose are fermented; fructose is not fermented. Moderate amounts of acetate and lactate and trace amounts of succinate are produced as the end products of glucose metabolism in PYG. Arginine is hydrolyzed. Catalase and indole are not produced; nitrate is not reduced. Esculin and urea are not hydrolyzed. There is no growth in 20% bile. Gelatin is not liquefied and H₂S is not produced.

Isolated from human periodontal pockets and dentoalveolar infections.

DNA G+C content (mol%): 38 (HPLC).

Type strain: W1219, ATCC BAA-170, DSM 13220.

GenBank accession number (16S rRNA gene): AF220064.

Genus IV. *Catenibacterium* Kageyama and Benno 2000e, 1598^{VP}

FRED A. RAINEY

Ca.te.ni.bac.te'ri.um. L. fem. n. *catena* chain; Gr. dim. n. *bakterion* a small rod; N.L. neut. n. *Catenibacterium* chain rodlet.

Cells occur in tangled chains. Gram-stain-positive and obligately anaerobic. Spores are absent. Fermentation products of glucose are acetic, lactic, butyric and isobutyric acids. Cell wall contains an A1c-type peptidoglycan with an (L-Ala)-D-Glu-m-Dpm peptide subunit. The genus *Catenibacterium* is a member of the *Clostridium* subphylum of the

Gram-positive bacteria and exhibits a close phylogenetic association with *Lactobacillus catenaformis* and *Lactobacillus vitulinus*.

DNA G+C content (mol%): 36–39 (HPLC).

Type species: ***Catenibacterium mitsuokai*** Kageyama and Benno 2000e, 1598^{VP}.

List of species of the genus *Catenibacterium*

1. ***Catenibacterium mitsuokai*** Kageyama and Benno 2000e, 1598^{VP}
mit.su.o'kai. N.L. gen. n. *mitsuokai* of Mitsuoka, named after K. Mitsuoka, a Japanese microbiologist.

This description is based on a study of six strains isolated from human feces. Cells are 0.4 μm × 1.2 μm long and occur

in tangled chains. Nonmotile. Gram-stain-positive and obligately anaerobic. Spores are absent. Can be cultivated in 2 d at 37 °C on EG agar in an anaerobic jar with 100% CO₂. Cells produce acid from glucose, mannose, galactose, fructose, sucrose, maltose, cellobiose, lactose and salicin but

not from arabinose, xylose, rhamnose, ribose, trehalose, raffinose, melezitose, starch, glycogen, mannitol, sorbitol, inositol, erythritol, esculin, or amygdalin. Hydrolysis of starch is positive and that of esculin is negative. Gas formation, indole production, nitrate reduction, gelatin liquefaction and H₂S production are all negative. Cell wall contains

A17-type peptidoglycan with an (L-Ala)-D-Glu-*m*-Dpm peptide subunit. The type strain was isolated from human feces.

DNA G+C content (mol%): 36–39 (HPLC).

Type strain: RCA14-39, CIP 106738, JCM 10609.

GenBank accession number (16S rRNA gene): AB030224.

Genus V. *Coprobacillus* Kageyama and Benno 2000d, 949^{VP} (Effective publication: Kageyama and Benno 2000c, 27.)

THE EDITORIAL BOARD

Co.pro.ba.cil'us. L. n. *copro* feces; L. dim. n. *bacillus* a small rod; N.L. n. *Coprobacillus* rodlet isolated from feces.

Gram-positive short rods that occur in chains. Spores are not formed. Nonmotile. **Obligate anaerobe** that produces acetate and lactate from glucose.

DNA G+C content (mol%): 32–34 (HPLC).

Type species: ***Coprobacillus cateniformis*** corrig. Kageyama and Benno 2000d, 949^{VP} (Effective publication: *Coprobacillus cateniformis* [sic] Kageyama and Benno 2000c, 28.).

Further descriptive information

This description is based upon the initial report of Kageyama and Benno (2000c), which describes three closely related strains of the only species *Coprobacillus cateniformis*. These strains occur as short rods, 0.4 × 1.2–1.7 μm, in chains of variable length. All strains produce acid from glucose, mannose, fructose, sucrose, maltose, cellobiose, lactose, trehalose, and salicin. No acid is produced from arabinose, xylose, rhamnose, ribose, raffinose, melezitose, starch, glycogen, mannitol, sorbitol, inositol, erythritol, esculin, and amygdalin. The strains do not form gas, produce indole or H₂S, reduce nitrate, or hydrolyze gelatin. During

growth on complex medium, moderate amounts of acetate and lactate and minor amounts of butyrate, valerate, and isobutyrate are produced. Growth is inhibited by 20% bile.

All strains were isolated at 37 °C from human feces on EG agar that contained (per liter): 5% horse blood, 3g beef extract, 5g yeast extract, 10g peptone, 1.5g glucose, 0.5g L-cysteine-HCl, 0.2g L-cystine, 4g Na₂HPO₄, 0.5g soluble starch, 0.5g Tween 80, 0.5g silicone, and 15g agar, pH 7.7, in an anaerobic incubation jar under an atmosphere of 100% CO₂. Subsequently, strains may be cultured in PYFG broth comprised of 10g trypticase, 10g yeast extract, 0.5g cystine, and 40ml of salt solution (per liter: 0.2g CaCl₂, 0.2g MgSO₄, 1g K₂HPO₄, 1g KH₂PO₄, 10g NaHCO₃, and 2g NaCl) and a pH of 7.6.

Coprobacillus is classified within the *Erysipelotrichaceae* on the basis of its 16S rRNA gene sequence (Ludwig et al., 2009). Similarly, *Clostridium ramosum* and *Clostridium spiroforme*, whose 16S rRNA genes possess about 90% sequence similarity that of *Coprobacillus*, should also be reclassified to this family.

Type strain: JCM 10604.

GenBank accession number (16S rRNA gene): AB030218.

Genus VI. *Holdeman* Willems, Moore, Weiss and Collins 1997, 1203^{VP}

ANNE WILLEMS

Hold.eman'ia. L. n. named in honor of Lillian V. Holdeman Moore, a contemporary American microbiologist, for her outstanding contribution to anaerobic bacteriology.

Gram-stain-positive, strictly anaerobic, nonsporeforming rods. Cells occur in pairs and short chains. Catalase-negative. **Fermentative metabolism.** Growth in broth media is enhanced by the addition of Tween 80. **Major end products from glucose fermentation are acetic and lactic acid. Succinic acid is also produced but in smaller quantities. The cell-wall peptidoglycan is of type B1** with an L-Asp-L-Lys interpeptide bridge. **Major cellular fatty acids are nonhydroxylated, monounsaturated or saturated.** The only known representatives are three strains that were isolated from human feces.

DNA G+C content (mol%): 38.

Type species: ***Holdeman* filiformis** Willems, Moore, Weiss and Collins 1997, 1203^{VP}.

Further descriptive information

The genus currently has only one species, therefore the following information also describes the species *Holdeman* filiformis. It is based on the study of three strains isolated from the feces of healthy humans (Willems et al., 1997).

Phylogenetic treatment. According to the 16S rRNA phylogenetic analysis presented in the roadmap to this volume (Figure 4), the genus *Holdeman* is a member of the family *Erysipelotrichaceae*, order *Erysipelotrichales*, class *Erysipelotrichia* in the phylum *Firmicutes*. It is closely related to subphylum XVI of Collins et al. (1994). Its closest relatives at 90% or less sequence similarity are *Erysipelothrix rhusiopathiae*, the causal agent of

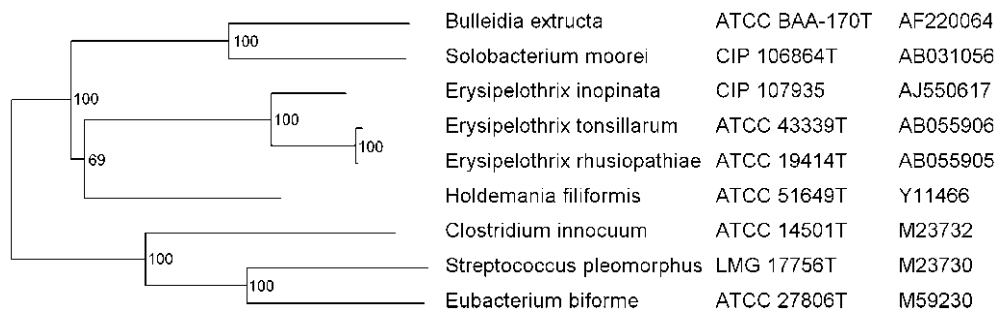

FIGURE 264. Neighbor-joining tree on the basis of 16S rDNA sequences showing the phylogenetic position of the genus *Holdemanina*. Distances were calculated using the Kimura 2-correction. Bootstrap values, expressed as a percentage of 1000 replicates, are shown at branching points.

erysipelas in swine (Willems et al., 1997), *Erysipelothrix tonsillarum* from the tonsils of healthy pigs (Takahashi et al., 1987a), *Erysipelothrix inopinata* from vegetable peptone broth (Verbarg et al., 2004), *Bulleidia extructa* from oral infections (Downes et al., 2000), and *Solobacterium moorei* (Kageyama and Benno, 2000a). A phylogenetic tree is shown in Figure 264.

Cell morphology. Cells are short to long, Gram-stain-positive rods that decolorize easily. Occur in pairs and short chains. Longer cells may have central to terminal swellings, although no spores or heat resistance have been observed.

Cell-wall composition. The cell-wall peptidoglycan is of type B1 δ - \rightarrow (Schleifer and Kandler, 1972) with an L-Asp \rightarrow L-Lys interpeptide bridge (Willems et al., 1997). This is similar to that of *Erysipelothrix rhusiopathiae* and *Erysipelothrix inopinata* which have type B1 δ L \rightarrow with a Gly \rightarrow L-Lys \rightarrow L-Lys interpeptide bridge (Schubert and Fiedler, 2001; Verbarg et al., 2004).

Colonial and cultural characteristics. Anaerobic growth in brain heart infusion agar streak tubes produces circular, low convex colonies with an entire margin, translucent with a granular appearance, 1.0 mm in diameter. No growth on the surface of solid media incubated in air enriched to 10% CO₂. Cultures in peptone-yeast extract-Tween (PYT)-glucose broth are turbid with a smooth, white sediment (Willems et al., 1997).

Nutrition and growth conditions. Good growth in PYT broth medium with esculin, fructose, glucose, salicin, or sucrose, even though the pH is just 5.8–6.2. Weak growth in PYT broth without carbohydrates or with amygdalin, arabinose, cellobiose, erythritol, glycogen, inositol, mannitol, mannose, melezitose, melibiose, raffinose, rhamnose, ribose, sorbitol, starch, trehalose, or xylose. The pH in these media is 6.2–6.5. Moderate growth in peptone-yeast extract broth with lactose or maltose.

Metabolism and metabolic pathways. *Holdemanina* has a strictly anaerobic metabolism, is saccharolytic, and is not proteolytic. Fermentation end products in PYT-glucose broth acidified to pH 2.0 are (in milliequivalents per ml of culture): acetic acid (0.8), lactic acid (0.9), and succinic acid (0.2); formic acid is sometimes detected. Catalase and indole are not produced; esculin is hydrolyzed, but gelatin and meat are not digested and milk is unchanged. Nitrate is not reduced and arginine is not deaminated.

Chemotaxonomic characteristics. The cellular fatty acid composition of *Holdemanina filiformis* cells grown in PYT-glucose broth comprises the following components at more than 4% (based on four analyses of two isolates; Willems et al., 1997):

C_{18:1}^{o9c} fatty acid methyl ester (50% \pm 11.5% standard deviation), C_{18:1}^{o9c} dimethyl acetal (12% \pm 4.5%), C_{16:1}^{o7c} fatty acid methyl ester (6% \pm 3.4%), C_{10:1} fatty acid methyl ester (5% \pm 4.0%), C_{16:0} fatty acid methyl ester (4% \pm 3.2%), and C_{16:0} dimethyl acetal (4% \pm 0.6%). Hydroxylated or branched-chain fatty acids were not detected.

Antibiotic sensitivity. Resistant to vancomycin by the disk diffusion method using 5 μ g disks (Downes et al., 2000).

Ecology. *Holdemanina filiformis* is isolated from the feces of healthy people. The significance or abundance of these organisms in the intestinal microflora remains unknown.

Enrichment and isolation procedures

No specific isolation procedures have been described for *Holdemanina*. Up to now, three strains (J1-31B-1, J1-37, and S4B-1) have been described. They were isolated from the feces of healthy humans by using routine isolation and cultivation procedures for anaerobic, saccharolytic bacteria (Holdeman et al., 1977).

Maintenance procedures

Strains can be maintained in prerduced, anaerobically sterilized PYT-glucose broth (Holdeman et al., 1977). For long-term preservation, strains can also be lyophilized.

Differentiation of the genus *Holdemanina* from other taxa

The nearest phylogenetic neighbor of *Holdemanina* are members of the genus *Erysipelothrix*. *Holdemanina* differs from *Erysipelothrix* in the following properties: the amino acid sequence of the interpeptide bridge of its peptidoglycan, the absence of hydroxylated and branched chain fatty acids and the presence of dimethylacetal components in the cell membranes, and the absence of arginine dihydrolase and the presence of esculin hydrolase (Takahashi et al., 1987a; Verbarg et al., 2004; Willems et al., 1997). *Holdemanina* can be differentiated from the genus *Bulleidia* by its ability to hydrolyze esculin but not arginine and its resistance to vancomycin (5 μ g disk) (Downes et al., 2000). Fermentation products from glucose (acetic and lactic acids) permit differentiation from the genus *Solobacterium* (acetic, lactic, and butyric acids) (Kageyama and Benno, 2000a).

Taxonomic comments

The three human fecal isolates that comprise *Holdemanina filiformis* were part of the Moore collection of the Virginia Poly-

technic Institute and State University (Blacksburg, VA, USA). As Gram-stain-positive, nonsporeforming, strictly anaerobic, catalase-negative rods that produce mainly acetic and lactic acid and some succinic acid from PYT broth, they were provisionally designated *Eubacterium* group S14. Their phylogenetic affiliation was determined from the 16S rDNA sequence of two strains (J1-31B-1 and S4B-1) and they were found to form a relatively isolated lineage among *Clostridium* groups XVI, XVII, and XVIII (Collins et al., 1994; Willems et al., 1997). Many of the taxa in these groups have been isolated from human feces. The closest relatives, although still quite remote at 90% or less sequence similarity, are *Erysipelothrix*, *Bulleidia*, and *Solobacterium*. In view

of this absence of close relatives and its phenotypic distinctness, group S14 was designated a new genus with one species, *Holdemaniana filiformis* (Willems et al., 1997). According to the 16S rRNA phylogenetic analysis presented in the roadmap to this volume (Figure 4), the genus *Holdemaniana* is a member of the family *Erysipelotrichaceae*, order *Erysipelotrichales*, class *Erysipelotrichia* in the phylum *Firmicutes*.

AKIKO KAGEYAMA AND YOSHIMI BENNO

So.lo.bac.te'ri.um. L. adj. *solus* sole; Gr. dim n. *bakterion* a small rod; N.L. neut. n. *Solobacterium* sole bacterium.

Cells are 0.2 μm \times 0.4–0.7 μm and **occur singly. Gram-positive. Obligatorily anaerobic.** Colonies appear after cultivation for 2 d at 37 °C on EG agar in an anaerobic jar containing 100% CO₂. **Spores and flagella are absent. Fermentation products of glucose are mainly acetic, lactic, and butyric acids; pyruvic acid is produced in a small amount.** Strains are isolated from humans. Comparative 16S rDNA sequence analysis revealed that strains are members of the *Clostridiales* and that 16S rDNA sequence is most similar to that of members of *Clostridium* cluster XVI (Collins et al., 1994).

DNA G+C content (mol%): 37–39.

Type species: *Solobacterium moorei* Kageyama and Benno 2000b, 1415^{VP}.

Further descriptive information

The genus *Eubacterium* contains all Gram-positive, anaerobic, nonsporeforming, rod-shaped bacteria, which do not belong to the genera *Propionibacterium*, *Lactobacillus*, or *Bifidobacterium*. Differentiation among these genera is based on fermentation products from glucose: propionic acid as a major end product for *Propionibacterium*, lactic acid as a major end product for *Lactobacillus*, acetic acid (and to a lesser extent) lactic acid as major end products for *Bifidobacterium*, butyric, acetic, or formic acid as a major product for *Eubacterium*, and mainly acetic, lactic, butyric acids, and a small amount of pyruvic acid for *Solobacterium*. On this basis, *Solobacterium* isolates would be identified as members of the genus *Eubacterium*. Over the years, the genus *Eubacterium* has been used as a holding place for a large number of phenotypically diverse species, some of which have been transferred to new genera. From these reasons, the new genus *Solobacterium* was proposed.

Phylogenetic analyses of the 16S rDNA sequence revealed that *Solobacterium* is most closely related to the *Clostridia*, specifically to members of *Clostridium* cluster XVI (Collins et al., 1994) (Figure 265). In an analysis including all taxa from cluster XVI and related clusters, *Solobacterium moorei* forms a distinct lineage, that is most closely aligned with *Holdemaniana filiformis* (87% sequence similarity; Willems et al., 1997), and *Erysipelothrix rhusiopathiae* (86% sequence similarity). Bootstrap analysis (value 100%) showed this association to be statistically significant.

Enrichment and isolation procedures

The strains were isolated from humans. Fecal samples were diluted and then an aliquot (0.05 ml) of the diluted sample was spread on the EG agar plates. Bacterial strains were cultivated for 2 d at 37 °C on EG agar medium [premixed EG agar (Eiken Chemical Co., Tokyo, Japan) supplemented with 5% horse blood containing 3 g of beef extract, 5 g of yeast extract, 10 g of peptone, 1.5 g of glucose, 0.5 g of L-cysteine HCl, 0.2 g of L-cystine, 4 g of Na₂HPO₄, 0.5 g of soluble starch, 0.5 g of Tween 80, 0.5 g of silicone, and 15 g of agar in 1000 ml, pH 7.7] in an anaerobic jar containing 100% CO₂.

Maintenance procedures

Stock cultures were prepared by growing isolates on EG agar plates for 4–5 d, as described above. Cultures remain viable for up to 1 week. For longer term preservation, cultures can be frozen at –80 °C in EG medium containing 10% glycerol, or by lyophilization using 10% skim milk as the cryoprotectant.

FIGURE 265. Phylogenetic tree derived from 16S rDNA sequences showing the position of *Solobacterium*. The tree was created using the neighbor-joining method and K_{nuc} values. The numbers on the tree indicate bootstrap values for the branch points with greater than 50% bootstrap support.

^h*Bifidobacterium* ferments large amounts of acetic acid better than lactic acid.

Differentiation of the genus *Solobacterium* from other genera

Solobacterium is a Gram-positive, anaerobic, nonsporeforming, rod-shaped bacterium. Other genera that are Gram-positive, anaerobic, nonsporeforming, rod-shaped bacteria, include *Propionibacterium*, *Lactobacillus*, *Bifidobacterium*, and *Eubacterium*. Differentiation among these genera is based on fermentation products from glucose: propionic acid as a major end product for *Propionibacterium*, lactic acid as a major end product for *Lactobacillus*, acetic acid (and to a lesser extent lactic acid) as major end products for *Bifidobacterium*, and butyric, acetic, or formic acid as a major product for *Eubacterium*. Because of its broad

definition, the genus *Eubacterium*, has over the years, acted as a depository for a large number of phenotypically diverse species (Andreesen, 1992). *Solobacterium* produces mainly acetic, lactic, and butyric acids, and a small amount of pyruvic acid from glucose. Using this criterion, *Solobacterium* resembles *Eubacterium* species. The genus *Holdemania* is also a Gram-positive, anaerobic, nonsporeforming, rod-shaped bacterium resembling *Eubacterium*, but it has been proposed as a separate genus.

Table 258 lists the features most useful in differentiating the genus *Solobacterium* from other phenotypically and genetically related Gram-positive, nonsporeforming, anaerobic, rod-shaped bacteria.

List of species of the genus *Solobacterium*

1. ***Solobacterium moorei*** Kageyama and Benno 2000b, 1415^{VP} (Effective publication: Kageyama and Benno 2000a, 226.)

moorei. N.L. gen. n. *moorei* of Moore, named in honor of W.E.C. (Ed) Moore, an American microbiologist.

In addition to the features given in the genus description, cells produce acid from ribose, glucose, galactose, fructose, and maltose but not from arabinose, xylose, rhamnose, mannose, sucrose, cellobiose, lactose, trehalose, raffinose,

melezitose, starch, glycogen, mannitol, sorbitol, inositol, erythritol, esculin, salicin, or amygdalin. The hydrolysis of starch is negative and that of esculin is positive. Gas formation, indole production, nitrate reduction, gelatin liquefaction, and H₂S production are negative. Its habitat is the human intestinal tract.

DNA G+C content (mol%): 37–39 (HPLC).

Type strain: JCM 10645.

Genus VIII. ***Turicibacter*** Bosshard, Zbinden and Altwegg 2002, 1266^{VP}

PHILIPP P. BOSSHARD

Tu.ri.ci.bac'ter. L. neut. n. *Turicum* the L. name of Zürich; N.L. masc. n. *bacter* equivalent of a Gr. neut. dim. n. *bakterion* a small rod; N.L. masc. n. *Turicibacter* a rod-shaped organism from Zürich, Switzerland, where the bacterium was first isolated.

Cells are irregularly shaped, nonbranching rods, 0.5–2.0 × 0.7–7.0 μm in size, chain-forming (up to 30 μm) Figure 266. Cells stain **Gram-stain-positive**. **Anaerobic, nonsporeforming**. Chemo-organotrophic, fermentative metabolism. Catalase-negative and oxidase-negative. **Lactate** is the main fermentation product.

DNA G+C content (mol%): 36.9.

Type species: ***Turicibacter sanguinis*** Bosshard, Zbinden and Altwegg 2002, 1266^{VP}.

Further descriptive information

Phylogenetically, the genus *Turicibacter* is distantly related to other taxa of the *Firmicutes*. Similarities of the 16S rRNA gene sequence with those of other genera are less than 88% (Bosshard et al., 2002). According to the 16S rRNA phylogenetic analysis presented in the roadmap to this volume, the genus *Turicibacter* is a deep branch of the family *Erysipelotrichaceae*, order *Erysipelotrichales*, class *Erysipelotrichia* in the phylum *Firmicutes*. However, there are reasons to be cautious about this assignment. Placements of deep branches in phylogenetic trees are frequently

problematic and subject to change as additional sequences or improved methods become available. Moreover, the other *Erysipelotrichaceae* are aerobic or facultatively anaerobic, whereas *Turicibacter* is strictly anaerobic. Therefore, this classification warrants further investigation.

Three strains of *Turicibacter sanguinis* have been isolated from blood cultures; the type strain MOL361^T was isolated in Zurich (Switzerland) from a febrile 35-year-old man with acute appendicitis, one strain was isolated in Gothenburg (Sweden) from a febrile 79-year-old woman, and one strain was isolated in Edmonton, Alberta (Canada). With 16S rRNA gene sequence libraries, closely related sequences of uncultured bacteria have been isolated from human gut, hot compost, raw milk, dairy waste, and the gut of beetles.

Isolation and maintenance procedures

Turicibacter sanguinis may be maintained lyophilized and stored at –70 °C. The bacteria can not be recultivated when preserved at –70 °C for 1 d in skim milk, Protector tubes (TSC) or glycerol (10, 40, or 70%).

FIGURE 266. Gram-stain (a) and transmission electron micrograph (b) of *Turicibacter sanguinis* isolate MOL361^T from a 3 d culture on chocolate agar. (Reprinted with permission from Bosshard et al. 2002. *Int. J. Syst. Evol. Microbiol.* 52:1263–1266.)

List of species of the genus *Turicibacter*1. ***Turicibacter sanguinis*** Bosshard, Zbinden and Altwegg 2002, 1266^{VP}

san'gui.nis. L. masc. gen. n. *sanguinis* of blood, indicating that the bacterium was isolated from a blood culture.

The species description is identical to that of the genus with the following additions.

Colonies are nonhemolytic, grayish white with a convex elevation, and irregular in form with spreading, undulating margins. Strictly anaerobic. Growth is observed at 25–46°C, with an optimum at 37°C. Optimum pH is 7.5; no growth occurs at pH ≤6.5 or pH ≥8.0. Grows on sheep blood, chocolate and Bru-

cella agar, and in chopped meat carbohydrate and thioglycolate. Maltose and 5-keto-gluconate are the only carbohydrates utilized. Activity for α-glucosidase and α- and β-galactosidase is detected. Nitrates are not reduced. Indole is not produced. Lactate and minimal amounts of acetate are the only fermentation products. Susceptible to penicillin, vancomycin, and kanamycin; resistant to colistin. The major cellular fatty acids are C_{16:0} (37%), C_{18:0} (15.5%), and C_{18:1 69c} (14.5%).

DNA G+C content (mol%): 36.9 (HPLC).

Type strain: MOL361, DSM 14220, NCCB 100008.

GenBank accession number (16S rDNA gene): AF349724.

Appendix 1. Validly published names, conserved and rejected names, and taxonomic opinions cited in the *International Journal of Systematic and Evolutionary Microbiology* since publication of Volume 2 of the Second Edition of the *Systematics**

JEAN P. EUZÉBY

New phyla

Names above the rank of class are not covered by the Rules of the *Bacteriological Code* (1990 Revision), and the names of phyla are not to be regarded as having been validly published. These names are listed for completeness.

Lentisphaerae Cho et al. 2004 – Valid publication: Validation List no. 98 – Effective publication: J.C. Cho et al. (2004)

Proteobacteria Garrity et al. 2005 – Valid publication: Validation List no. 106 – Effective publication: Garrity et al. (2005i)

New classes

Alphaproteobacteria Garrity et al. 2006, 1^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xv)

Anaerolineae Yamada et al. 2006, 1336^{VP}

Betaproteobacteria Garrity et al. 2006, 1^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xxii)

Caldilineae Yamada et al. 2006, 1339^{VP}

Deltaproteobacteria Kuever et al. 2006, 1^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005a)

Epsilonproteobacteria Garrity et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xxxviii)

Gammaproteobacteria Garrity et al. 2005, 2236^{VP} – Valid publication: Validation List no. 106 – Effective publication: Garrity et al. (2005ii)

Ktedonobacteria corrig. Cavaletti et al. 2007, 433^{VP} – Valid publication: Validation List no. 114 – Effective publication: Cavaletti et al. (2006b)

Thermolithobacteria Sokolova et al. 2007, 1372^{VP} – Valid publication: Validation List no. 116 – Effective publication: Sokolova et al. (2007)

Opitutae Choo et al. 2007, 535^{VP}

New orders

Acidithiobacillales Garrity et al. 2005, 2235^{VP} – Valid publication: Validation List no. 106 – Effective publication: Garrity et al. (2005iii)

Aeromonadales Martin-Carnahan and Joseph 2005, 2235^{VP} – Valid publication: Validation List no. 106 – Effective publication: Martin-Carnahan and Joseph (2005)

Alteromonadales Bowman and McMeekin 2005, 2235^{VP} – Valid publication: Validation List no. 106 – Effective publication: Bowman and McMeekin (2005)

Anaerolineales Yamada et al. 2006, 1338^{VP}

Bdellovibrionales Garrity et al. 2006, 1^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xxxvi)

Burkholderiales Garrity et al. 2006, 1^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xxiii)

Caldilineales Yamada et al. 2006, 1339^{VP}

Campylobacterales Garrity et al. 2006, 1^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xxxix)

Cardiobacteriales Garrity et al. 2005, 2235^{VP} – Valid publication: Validation List no. 106 – Effective publication: Garrity et al. (2005vi)

Chromatiales Imhoff 2005, 2235^{VP} – Valid publication: Validation List no. 106 – Effective publication: Imhoff (2005)

Desulfarculales corrig. Kuever et al. 2006, 1^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005o)

Desulfobacterales Kuever et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005j)

Desulfovibrionales Kuever et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005d)

Desulfurellales Kuever et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005b)

Desulfuromonadales corrig. Kuever et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005r)

Hydrogenophilales Garrity et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xxvi)

Kordiimonadales K.K. Kwon et al. 2005, 2036^{VP}

Ktedonobacterales corrig. Cavaletti et al. 2007, 433^{VP} – Valid publication: Validation List no. 114 – Effective publication: Cavaletti et al. (2006b)

Legionellales Garrity et al. 2005, 2236^{VP} – Valid publication: Validation List no. 106 – Effective publication: Garrity et al. (2005ix)

Lentisphaerales Cho et al. 2004, 1005^{VP} – Valid publication: Validation List no. 98 – Effective publication: J.C. Cho et al. (2004)

Methylococcales Bowman 2005, 2236^{VP} – Valid publication: Validation List no. 106 – Effective publication: Bowman (2005b)

Methylophilales Garrity et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xxviii)

* Citations for the original authorities for basonyms, synonyms, and emendations do not appear in the bibliography unless cited elsewhere in this book. References for Validation Lists and Lists of Changes in Taxonomic Opinion are provided at the end of the chapter.

- Natranaerobiales* Mesbah et al. 2007, 2511^{VP}
- Nautiliales* Miroschnichenko et al. 2004, 43^{VP}
- Neisseriales* Tønnum 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Tønnum (2005)
- Nitrosomonadales* Garrity et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xxx)
- Oceanospirillales* Garrity et al. 2005, 2236^{VP} – Valid publication: Validation List no. 106 – Effective publication: Garrity et al. (2005xi)
- Opitutales* Choo et al. 2007, 536^{VP}
- Pasteurellales* Garrity et al. 2005, 2236^{VP} – Valid publication: Validation List no. 106 – Effective publication: Garrity et al. (2005xiv)
- Puniceicoccales* Choo et al. 2007, 536^{VP}
- Rhizobiales* Kuykendall 2006, 3^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuykendall (2005)
- According to Rule 51b(1), the order name *Rhizobiales* Kuykendall 2006 is illegitimate.
- Rhodobacterales* Garrity et al. 2006, 3^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xvi)
- Rhodocyclales* Garrity et al. 2006, 3^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xxxii)
- Sphingomonadales* Yabuuchi and Kosako 2006, 3^{VP} – Valid publication: Validation List no. 107 – Effective publication: Yabuuchi and Kosako (2005)
- Syntrophobacterales* Kuever et al. 2006, 3^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005t)
- Thermolithobacterales* Sokolova et al. 2007, 1372^{VP} – Valid publication: Validation List no. 116 – Effective publication: Sokolova et al. (2007)
- Thiotrichales* Garrity et al. 2005, 2236^{VP} – Valid publication: Validation List no. 106 – Effective publication: Garrity et al. (2005vii)
- Victivallales* Cho et al. 2004, 1005^{VP} – Valid publication: Validation List no. 98 – Effective publication: J.C. Cho et al. (2004)
- Xanthomonadales* Saddler and Bradbury 2005, 2236^{VP} – Valid publication: Validation List no. 106 – Effective publication: Saddler and Bradbury (2005a)

New suborders

- Catenulisporineae* Cavaletti et al. 2006a, 1751^{VP}
- Cystobacterineae* Reichenbach 2007, 894^{VP} – Valid publication: Validation List no. 115 – Effective publication: Reichenbach (2005a)
- Nannocystineae* Reichenbach 2007, 894^{VP} – Valid publication: Validation List no. 115 – Effective publication: Reichenbach (2005a)
- Sorangiiineae* corrig. Reichenbach 2007, 894^{VP} – Valid publication: Validation List no. 115 – Effective publication: Reichenbach (2005a)

New families

- Acidithiobacillaceae* Garrity et al. 2005, 2235^{VP} – Valid publication: Validation List no. 106 – Effective publication: Garrity et al. (2005iv)
- Actinospicaceae* Cavaletti et al. 2006a, 1751^{VP}
- Alcanivoracaceae* corrig. Golyshin et al. 2005, 2235^{VP} – Valid publication: Validation List no. 106 – Effective publication: Golyshin et al. (2005)
- Anaerolineaceae* Yamada et al. 2006, 1338^{VP}
- Bacteriovoracaceae* Davidov and Jurkevitch 2004, 1450^{VP}
- Bdellovibrionaceae* Garrity et al. 2006, 1^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xxvii)
- According to Rule 51b(1), the family name *Bdellovibrionaceae* Garrity et al. 2006 is illegitimate.
- Beijerinckiaceae* Garrity et al. 2006, 1^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xviii)
- Bradyrhizobiaceae* Garrity et al. 2006, 1^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xix)
- According to Rule 51b(1), the family name *Bradyrhizobiaceae* Garrity et al. 2006 is illegitimate.
- Burkholderiaceae* Garrity et al. 2006, 1^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xxiv)
- Caldilineaceae* Yamada et al. 2006, 1339^{VP}
- Catenulisporaceae* Busti et al. 2006, 1745^{VP}
- Colwelliaceae* Ivanova et al. 2004d, 1785^{VP}
- Conexibacteraceae* Stackebrandt 2005, 547^{VP} – Valid publication: Validation List no. 102 – Effective publication: Stackebrandt (2004)
- Coxiellaceae* Garrity et al. 2005, 2235^{VP} – Valid publication: Validation List no. 106 – Effective publication: Garrity et al. (2005x)
- Desulfarculaceae* Kuever et al. 2006, 1^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005p)
- Desulfobacteraceae* Kuever et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005k)
- Desulfobulbaceae* Kuever et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005n)
- Desulfogalobiaceae* Kuever et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005g)
- Desulfomicrobiaceae* Kuever et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005f)
- Desulfonatronaceae* corrig. Kuever et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005i)
- Desulfovibrionaceae* Kuever et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005e)

- Desulfurellaceae* Kuever et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005c)
- Desulfurobacteriaceae* L'Haridon et al. 2006, 2850^{VP}
- Desulfuromonadaceae* corrig. Kuever et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005s)
- Erysipelotrichaceae* Verborg et al. 2004, 223^{VP}
- Erythrobacteraceae* K.B. Lee et al. 2005, 1916^{VP}
- Ferrimonadaceae* Ivanova et al. 2004d, 1785^{VP}
- Francisellaceae* Sjöstedt 2005, 2236^{VP} – Valid publication: Validation List no. 106 – Effective publication: Sjöstedt (2005)
- Geobacteraceae* Garrity et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xxxv)
- According to Rule 24b(2), *Geobacteraceae* Holmes et al. 2004a has priority.
- Geobacteraceae* Holmes et al. 2004a, 1597^{VP}
- Geodermatophilaceae* Normand 2006, 2277^{VP}
- Hahellaceae* Garrity et al. 2005, 2236^{VP} – Valid publication: Validation List no. 106 – Effective publication: Garrity et al. (2005xiii)
- Halothiobacillaceae* Kelly and Wood 2005, 2236^{VP} – Valid publication: Validation List no. 106 – Effective publication: Kelly and Wood (2005a)
- Helicobacteraceae* Garrity et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xl)
- Holosporaceae* Görtz and Schmidt 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Görtz and Schmidt (2005)
- Hydrogenophilaceae* Garrity et al. 2006, 2^{VP} – Valid publication: Validation List no. 107 – Effective publication: Garrity et al. (2005xxvii)
- Hyphomonadaceae* K.B. Lee et al. 2005, 1915^{VP}
- Idiomarinaceae* Ivanova et al. 2004d, 1784^{VP}
- Kofleriaceae* Reichenbach 2007, 894^{VP} – Valid publication: Validation List no. 115 – Effective publication: Reichenbach (2005l)
- Ktedonobacteraceae* corrig. Cavaletti et al. 2007, 433^{VP} – Valid publication: Validation List no. 114 – Effective publication: Cavaletti et al. (2006b)

- Yania flava* W.J. Li et al. 2005e, 1937^{VP}
- The name *Yania flava* W.J. Li et al. 2005e is illegitimate because the genus name is illegitimate (see above *Yania* W.J. Li et al. 2004a, 529^{VP}).
- Yania halotolerans* W.J. Li et al. 2004a, 530^{VP}
- The name *Yania halotolerans* W.J. Li et al. 2004a is illegitimate because the genus name is illegitimate (see above *Yania* W.J. Li et al. 2004a, 529^{VP}).
- Yeosuana aromatorans* K.K. Kwon et al. 2006a, 731^{VP}
- Yersinia aleksiciae* Sprague and Neubauer 2005, 834^{VP}
- Yonghaparkia alkaliphila* J.H. Yoon et al. 2006k, 2418^{VP}
- Zeaxanthinibacter enoshimensis* Asker et al. 2007a, 841^{VP}
- Zhihengliuella halotolerans* Y.Q. Zhang et al. 2007a, 1020^{VP}
- Zhouia amylobytica* Z.P. Liu et al. 2006a, 2827^{VP}
- Zimmermannella alba* Y.C. Lin et al. 2004, 1675^{VP}
- According to Rule 37a(1), *Zimmermannella alba* Y.C. Lin et al. 2004 cannot be maintained in the genus *Zimmermannella*.
- Zimmermannella bifida* Y.C. Lin et al. 2004, 1675^{VP}
- According to Rule 37a (1), *Zimmermannella bifida* Y.C. Lin et al. 2004 cannot be maintained in the genus *Zimmermannella*.
- Zimmermannella faecalis* Y.C. Lin et al. 2004, 1675^{VP}
- According to Rule 37a (1), *Zimmermannella faecalis* Y.C. Lin et al. 2004 cannot be maintained in the genus *Zimmermannella*.
- Zimmermannella helvola* Lin et al. 2004, 1674^{VP}
- Strict application of the Rule 51b(1) indicates that the genus name *Zimmermannella helvola* Y.C. Lin et al. 2004 is illegitimate.
- Zobellella denitrificans* Y.T. Lin and Shieh 2006, 1214^{VP}
- Zobellella taiwanensis* Y.T. Lin and Shieh 2006, 1214^{VP}
- Zobellia amurskyensis* Nedashkovskaya et al. 2004f, 1647^{VP}
- Zobellia laminariae* Nedashkovskaya et al. 2004f, 1647^{VP}
- Zobellia russellii* Nedashkovskaya et al. 2004f, 1647^{VP}
- Zoogloea oryzae* Xie and Yokota 2006a, 622^{VP}
- Zunongwangia profunda* corrig. Qin et al. 2007, 1372^{VP} – Valid publication: Validation List no. 116 – Effective publication: Qin et al. (2007)

New subspecies

- Alcaligenes faecalis* subsp. *phenolicus* Rehfuss and Urban 2006, 1^{VP} – Valid publication: Validation List no. 107 – Effective publication: Rehfuss and Urban (2005a)
- Bifidobacterium animalis* subsp. *animalis* (Mitsuoka 1969) Scardovi and Trovatielli 1974, 1142^{VP} – Reference: Masco et al. (2004)
- Caldanaerobacter subterraneus* subsp. *pacificus* Fardeau et al. 2004, 472^{VP}

- Caldanaerobacter subterraneus* subsp. *subterraneus* (Fardeau et al. 2000) Fardeau et al. 2004, 471^{VP}
- Enterobacter cloacae* subsp. *cloacae* (Jordan 1890) Hormaeche and Edwards 1960, 1395^{VP} – Valid publication: Validation List no. 104 – Effective publication: Hoffmann et al. (2005a)
- Francisella philomiragia* subsp. *noatunensis* Mikalsen et al. 2007, 1964^{VP}
- Francisella philomiragia* subsp. *philomiragia* (Jensen et al. 1969) Hollis et al. 1990, 1964^{VP}
- Lactobacillus delbrueckii* subsp. *indicus* Dellaglio et al. 2005b, 403^{VP}
- Lactobacillus kefiranofaciens* subsp. *kefiranofaciens* Fujisawa et al. 1988, 555^{VP} – Reference: Vancanneyt et al. (2004b)
- Lactobacillus plantarum* subsp. *argenteratensis* Bringel et al. 2005, 1633^{VP}
- Lactobacillus plantarum* subsp. *plantarum* (Orla-Jensen 1919) Bergey et al. 1923, 1633^{VP} – Reference: Bringel et al. (2005)
- Leucobacter chromiireducens* subsp. *chromiireducens* Morais et al. 2005, 2774^{VP}
- Leucobacter chromiireducens* subsp. *solipictus* Muir and Tan 2007, 2774^{VP}
- Oceanobacillus oncorhynchi* subsp. *incaldanensis* Romano et al. 2006b, 808^{VP}
- Oceanobacillus oncorhynchi* subsp. *oncorhynchi* Yumoto et al. 2005, 809^{VP} – Reference: Romano et al. (2006b)
- Photorhabdus asymbiotica* subsp. *asymbiotica* Fischer-Le Saux et al. 1999, 1309^{VP} – Reference: Akhurst et al. (2004)
- Photorhabdus asymbiotica* subsp. *australis* Akhurst et al. 2004, 1309^{VP}
- Photorhabdus luminescens* subsp. *kayaii* Hazir et al. 2004, 1005^{VP} – Valid publication: Validation List no. 98 – Effective publication: Hazir et al. (2004)
- Photorhabdus luminescens* subsp. *thracensis* Hazir et al. 2004, 1005^{VP} – Valid publication: Validation List no. 98 – Effective publication: Hazir et al. (2004)
- Pseudomonas chlororaphis* subsp. *chlororaphis* (Guignard and Sauvageau 1894) Bergey et al. 1930, 1289^{VP}
- Salinivibrio costicola* subsp. *alcaliphilus* Romano et al. 2005, 984^{VP} – Valid publication: Validation List no. 103 – Effective publication: Romano et al. (2005a)
- Salmonella enterica* subsp. *enterica* (ex Kauffmann and Edwards 1952) Le Minor and Popoff 1987, 519^{VP} – Reference: Judicial Commission of the International Committee on Systematics of Prokaryotes 2005b (Opinion 80)
- Streptococcus equi* subsp. *ruminatorum* Fernández et al. 2004, 2295^{VP}
- Thermoanaerobacter mathranii* subsp. *alimentarius* Carlier et al. 2007, 1^{VP} – Valid publication: Validation List no. 113 – Effective publication: Carlier et al. (2006)
- Thermoanaerobacter mathranii* subsp. *mathranii* Larsen et al. 1998, 1^{VP} – Valid publication: Validation List no. 113 – Effective publication: Carlier et al. (2006)
- Xanthomonas alfalfae* subsp. *alfalfae* (ex Riker et al. 1935) Schaad et al. 2007, 895^{VP} – Valid publication: Validation List no. 115 – Effective publication: Schaad et al. (2006)
- Xanthomonas alfalfae* subsp. *citrumelonis* Schaad et al. 2007, 895^{VP} – Valid publication: Validation List no. 115 – Effective publication: Schaad et al. (2006)
- Xanthomonas citri* subsp. *citri* (ex Hasse 1915) Gabriel et al. 1989, 895^{VP} – Valid publication: Validation List no. 115 – Effective publication: Schaad et al. (2006)
- Xanthomonas fuscans* subsp. *aurantifolii* Schaad et al. 2007, 895^{VP} – Valid publication: Validation List no. 115 – Effective publication: Schaad et al. (2006)
- Xanthomonas fuscans* subsp. *fuscans* Schaad et al. 2007, 895^{VP} – Valid publication: Validation List no. 115 – Effective publication: Schaad et al. (2006)
- Zymomonas mobilis* subsp. *francensis* Coton et al. 2006, 125^{VP}

New combinations

- Acholeplasma pleciae* (Tully et al. 1994) Knight Jr. 2004, 1952^{VP} – Basonym: *Mesoplasma pleciae* Tully et al. 1994
- Actinotalea fermentans* (Bagnara et al. 1985) Yi et al. 2007b, 155^{VP} – Basonym: *Cellulomonas fermentans* Bagnara et al. 1985
- Aerococcus urinaeequi* (Garvie 1988) Felis et al. 2005, 1327^{VP} – Basonym: *Pediococcus urinaeequi* (ex Mees 1934) Garvie 1988
- Aggregatibacter actinomycetemcomitans* (Klinger 1912) Nørskov-Lauritsen and Kilian 2006, 2143^{VP} – Basonym: *Actinobacillus actinomycetemcomitans* (Klinger 1912) Topley and Wilson 1929 (Approved Lists 1980)
- Aggregatibacter aphrophilus* (Khairat 1940) Nørskov-Lauritsen and Kilian 2006, 2143^{VP} – Basonym: *Hemophilus aphrophilus* Khairat 1940 (Approved Lists 1980)
- Aggregatibacter segnis* (Kilian 1977) Nørskov-Lauritsen and Kilian 2006, 2144^{VP} – Basonym: *Hemophilus segnis* Kilian 1977 (Approved Lists 1980)
- Agromyces hippuratus* (Zgurskaya et al. 1992) Ortiz-Martinez et al. 2004, 1555^{VP} – Basonym: *Agromyces fucosus* subsp. *hippuratus* Zgurskaya et al. 1992
- Algicola bacteriolytica* (Sawabe et al. 1998) Ivanova et al. 2004d, 1784^{VP} – Basonym: *Pseudoalteromonas bacteriolytica* Sawabe et al. 1998
- Algicola sagamiensis* (Kobayashi et al. 2003) Y.D. Nam et al. 2007b, 17^{VP} – Basonym: *Pseudoalteromonas sagamiensis* Kobayashi et al. 2003
- Algoriphagus alkaliphilus* (Tiago et al. 2006) Nedashkovskaya et al. 2007b, 1993^{VP} – Basonym: *Chimaericella alkaliphila* Tiago et al. 2006a
- Algoriphagus boritolrans* (Ahmed et al. 2007c) Nedashkovskaya et al. 2007b, 1993^{VP} – Basonym: *Chimaericella boritolrans* Ahmed et al. 2007c
- Algoriphagus halophilus* (Yi and Chun 2004) Nedashkovskaya et al. 2004h, 1763^{VP} – Basonym: *Hongiella halophila* Yi and Chun 2004a
- Algoriphagus mannitolivorans* (Yi and Chun 2004) Nedashkovskaya et al. 2007b, 1993^{VP} – Basonym: *Hongiella mannitolivorans* Yi and Chun 2004a
- Algoriphagus marincola* (Yoon et al. 2004) Nedashkovskaya et al. 2007b, 1993^{VP} – Basonym: *Hongiella marincola* J.H. Yoon et al. 2004o
- Algoriphagus ornithinivorans* (Yi and Chun 2004) Nedashkovskaya et al. 2007b, 1993^{VP} – Basonym: *Hongiella ornithinivorans* Yi and Chun 2004a

- Alicyclobacillus disulfidooxidans* (Dufresne et al. 1996) Karavaiko et al. 2005, 946^{VP} – Basonym: *Sulfobacillus disulfidooxidans* Dufresne et al. 1996
- Aliivibrio fischeri* (Beijerinck 1889) Urbanczyk et al. 2007, 2827^{VP} – Basonym: *Vibrio fischeri* (Beijerinck 1889) Lehmann and Neumann 1896 (Approved Lists 1980)
- Aliivibrio logei* (Harwood et al. 1980) Urbanczyk et al. 2007, 2827^{VP} – Basonym: *Photobacterium logei* (ex Bang et al. 1978) Harwood et al. 1980
- Aliivibrio salmonicida* (Egidius et al. 1986) Urbanczyk et al. 2007, 2827^{VP} – Basonym: *Vibrio salmonicida* Egidius et al. 1986
- Aliivibrio wodanis* (Lunder et al. 2000) Urbanczyk et al. 2007, 2828^{VP} – Basonym: *Vibrio wodanis* Lunder et al. 2000
- Alkalibacillus haloalkaliphilus* (Fritze 1996) Jeon et al. 2005b, 1894^{VP} – Basonym: *Bacillus haloalkaliphilus* Fritze 1996
- Altererythrobacter luteolus* (Yoon et al. 2005) K.K. Kwon et al. 2007, 2210^{VP} – Basonym: *Erythrobacter luteolus* J.H. Yoon et al. 2005a
- Alysiaella crassa* (Schmid 1922) Xie and Yokota 2005, 1395^{VP} – Basonym: *Simonsiella crassa* Schmid 1922 (Approved Lists 1980) – Valid publication: Validation List no. 104 – Effective publication: Xie and Yokota (2005a)
- Amycolatopsis lurida* (Lechevalier et al. 1986) Stackebrandt et al. 2004a, 267^{VP} – Basonym: *Amycolatopsis orientalis* subsp. *lurida* (ex Grundy et al. 1957) Lechevalier et al. 1986
- Aquimarina brevivitae* (Yoon et al. 2006) Nedashkovskaya et al. 2006f, 2040^{VP} – Basonym: *Gaetbulimicrobium brevivitae* J.H. Yoon et al. 2006a
- Aquimarina latercula* (Lewin 1969) Nedashkovskaya et al. 2006f, 2040^{VP} – Basonym: *Cytophaga latercula* Lewin 1969 (Approved Lists 1980)
- Avibacterium avium* (Hinz and Kunjara 1977) Blackall et al. 2005, 360^{VP} – Basonym: *Hemophilus avium* Hinz and Kunjara 1977 (Approved Lists 1980)
- Avibacterium gallinarum* (Hall et al. 1955) Blackall et al. 2005, 359^{VP} – Basonym: *Pasteurella gallinarum* Hall et al. 1955 (Approved Lists 1980)
- Avibacterium paragallinarum* (Biberstein and White 1969) Blackall et al. 2005, 360^{VP} – Basonym: *Hemophilus paragallinarum* Biberstein and White 1969 (Approved Lists 1980)
- Avibacterium volantium* (Mutters et al. 1985) Blackall et al. 2005, 360^{VP} – Basonym: *Pasteurella volantium* Mutters et al. 1985
- Azohydromonas lata* (Palleroni and Palleroni 1978) Xie and Yokota 2005f, 2423^{VP} – Basonym: *Alcaligenes latus* Palleroni and Palleroni 1978 (Approved Lists 1980)
- Bergeriella denitrificans* (Berger 1962) Xie and Yokota 2005, 1395^{VP} – Basonym: *Neisseria denitrificans* Berger 1962 (Approved Lists 1980) – Valid publication: Validation List no. 104 – Effective publication: Xie and Yokota (2005a)
- Bibersteinia trehalosi* (Sneath and Stevens 1990) Blackall et al. 2007, 673^{VP} – Basonym: *Pasteurella trehalosi* Sneath and Stevens 1990
- Bifidobacterium animalis* subsp. *lactis* (Meile et al. 1997) Masco et al. 2004, 1142^{VP} – Basonym: *Bifidobacterium lactis* Meile et al. 1997
- Blastopirellula marina* (Schlesner 1987) Schlesner et al. 2004, 1578^{VP} – Basonym: *Pirellula marina* (Schlesner 1987) Schlesner and Hirsch 1987
- Brachyspira intermedia* (Stanton et al. 1997) Hampson and La 2006, 1011^{VP} – Basonym: *Serpulina intermedia* Stanton et al. 1997
- Brachyspira murdochii* (Stanton et al. 1997) Hampson and La 2006, 1011^{VP} – Basonym: *Serpulina murdochii* Stanton et al. 1997
- Caldanaerobacter subterraneus* (Fardeau et al. 2000) Fardeau et al. 2004, 471^{VP} – Basonym: *Thermoanaerobacter subterraneus* Fardeau et al. 2000
- Caldanaerobacter subterraneus* subsp. *tengcongensis* (Xue et al. 2001) Fardeau et al. 2004, 472^{VP} – Basonym: *Thermoanaerobacter tengcongensis* Xue et al. 2001
- Caldanaerobacter subterraneus* subsp. *yonseiensis* (Kim et al. 2001) Fardeau et al. 2004, 472^{VP} – Basonym: *Thermoanaerobacter yonseiensis* Kim et al. 2001
- Caldicellulosiruptor acetigenus* (Nielsen et al. 1994) Onyenwoke et al. 2006, 1394^{VP} – Basonym: *Thermoanaerobium acetigenum* Nielsen et al. 1994
- Carboxydotherrus ferrireducens* (Slobodkin et al. 1997) Slobodkin et al. 2006a, 2350^{VP} – Basonym: *Thermoterrabacterium ferrireducens* Slobodkin et al. 1997
- Castellaniella defragrans* (Foss et al. 1998) Kämpfer et al. 2006d, 818^{VP} – Basonym: *Alcaligenes defragrans* Foss et al. 1998
- Catellatospora methionotrophica* (Asano and Kawamoto 1988) Ara and Kudo 2006, 399^{VP} – Basonym: *Catellatospora citrea* subsp. *methionotrophica* Asano and Kawamoto 1988
- Chitinophaga arvensicola* (Oyaizu et al. 1983) Kämpfer et al. 2006k, 2226^{VP} – Basonym: *Cytophaga arvensicola* Oyaizu et al. 1983
- Chitinophaga filiformis* (Reichenbach 1989) Kämpfer et al. 2006k, 2225^{VP} – Basonym: *Flexibacter filiformis* (ex Solntseva 1940) Reichenbach 1989
- Chitinophaga japonensis* (Fujita et al. 1997) Kämpfer et al. 2006k, 2225^{VP} – Basonym: *Flexibacter japonensis* Fujita et al. 1997
- Chitinophaga sancti* (Lewin 1969) Kämpfer et al. 2006k, 2225^{VP} – Basonym: *Flexibacter sancti* Lewin 1969 (Approved Lists 1980)
- Chromohalobacter beijerinckii* (Hof 1935) Peçonek et al. 2006, 1956^{VP} – Basonym: *Pseudomonas beijerinckii* Hof 1935 (Approved Lists 1980)
- Conchiformibius steedae* corrig. (Kuhn and Gregory 1979) Xie and Yokota 2005, 1395^{VP} – Basonym: *Simonsiella steedae* Kuhn and Gregory 1979 (Approved Lists 1980) – Valid publication: Validation List no. 104 – Effective publication: Xie and Yokota (2005a)
- Coralococcus coralloides* (Thaxter 1892) Reichenbach 2007, 893^{VP} – Basonym: *Myxococcus coralloides* Thaxter 1892 (Approved Lists 1980) – Valid publication: Validation List no. 115 – Effective publication: Reichenbach (2005b)
- Cupriavidus basilensis* (Steinle et al. 1999) Vandamme and Coenye 2004, 2287^{VP} – Basonym: *Ralstonia basilensis* Steinle et al. 1999
- Cupriavidus campinensis* (Goris et al. 2001) Vandamme and Coenye 2004, 2287^{VP} – Basonym: *Ralstonia campinensis* Goris et al. 2001
- Cupriavidus gilardii* (Coenye et al. 1999) Vandamme and Coenye 2004, 2287^{VP} – Basonym: *Ralstonia gilardii* Coenye et al. 1999

- Cupriavidus metallidurans* (Goris et al. 2001) Vandamme and Coenye 2004, 2287^{VP} – Basonym: *Ralstonia metallidurans* Goris et al. 2001
- Cupriavidus oxalaticus* (Sahin et al. 2000) Vandamme and Coenye 2004, 2287^{VP} – Basonym: *Ralstonia oxalatica* (ex Khambata and Bhat 1953) Sahin et al. 2000
- Cupriavidus pauculus* (Vandamme et al. 1999) Vandamme and Coenye 2004, 2288^{VP} – Basonym: *Ralstonia paucula* Vandamme et al. 1999
- Cupriavidus respiraculi* (Coenye et al. 2003) Vandamme and Coenye 2004, 2288^{VP} – Basonym: *Ralstonia respiraculi* Coenye et al. 2003
- Cupriavidus taiwanensis* (Chen et al. 2001) Vandamme and Coenye 2004, 2288^{VP} – Basonym: *Ralstonia taiwanensis* Chen et al. 2001
- Curvibacter delicatus* (Leifson 1962) Ding and Yokota 2004, 2229^{VP} – Basonym: *Aquaspirillum delicatum* (Leifson 1962) Hylemon et al. 1973 (Approved Lists 1980)
- Curvibacter lanceolatus* (Leifson 1962) Ding and Yokota 2004, 2228^{VP} – Basonym: *Pseudomonas lanceolata* Leifson 1962 (Approved Lists 1980)
- Desulfarculus baarsii* (Widdel 1981) Kuever et al. 2006, 2^{VP} – Basonym: *Desulfovibrio baarsii* Widdel 1981 – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005q)
- Desulfofaba hansenii* (Finster et al. 2001) Abildgaard et al. 2004, 398^{VP} – Basonym: *Desulfomusa hansenii* Finster et al. 2001
- Desulfosarcina cetonica* corrig. (Galushko and Rozanova 1994) Kuever et al. 2006, 2^{VP} – Basonym: *Desulfobacterium cetonicum* Galushko and Rozanova 1994 – Valid publication: Validation List no. 107 – Effective publication: Kuever et al. (2005m)
- Desulfovibrio oxamicus* (Postgate and Campbell 1966) López-Cortés et al. 2006a, 1498^{VP} – Basonym: *Desulfovibrio vulgaris* subsp. *oxamicus* Postgate and Campbell 1966 (Approved Lists 1980)
- Dickeya chrysanthemi* (Burkholder et al. 1953) Samson et al. 2005, 1423^{VP} – Basonym: *Erwinia chrysanthemi* Burkholder et al. 1953 (Approved Lists 1980)
- Dickeya paradisiaca* (Fernandez-Borrero and Lopez-Duque 1970) Samson et al. 2005, 1425^{VP} – Basonym: *Erwinia paradisiaca* Fernandez-Borrero and Lopez-Duque 1970 (Approved Lists 1980)
- Elizabethkingia meningoseptica* (King 1959) K.K. Kim et al. 2005b, 1291^{VP} – Basonym: *Flavobacterium meningosepticum* King 1959 (Approved Lists 1980)
- Elizabethkingia miricola* (Li et al. 2004) K.K. Kim et al. 2005b, 1292^{VP} – Basonym: *Chryseobacterium miricola* Y. Li et al. 2004
- Enterobacter cloacae* subsp. *dissolvens* (Rosen 1922) Hoffmann et al. 2005, 1396^{VP} – Basonym: *Erwinia dissolvens* (Rosen 1922) Burkholder 1948 (Approved Lists 1980) – Valid publication: Validation List no. 104 – Effective publication: Hoffmann et al. (2005a)
- Geobacillus pallidus* (Scholz et al. 1988) Banat et al. 2004, 2200^{VP} – Basonym: *Bacillus pallidus* Scholz et al. 1988
- Geobacillus vulcani* (Caccamo et al. 2000) Nazina et al. 2004, 2023^{VP} – Basonym: *Bacillus vulcani* Caccamo et al. 2000
- Geobacter thiogenes* (De Wever et al. 2001) Nevin et al. 2007, 465^{VP} – Basonym: *Trichlorobacter thiogenes* De Wever et al. 2001
- Giesbergeria anulus* (Williams and Rittenberg 1957) Grabovich et al. 2006, 575^{VP} – Basonym: *Aquaspirillum anulus* (Williams and Rittenberg 1957) Hylemon et al. 1973 (Approved Lists 1980)
- Giesbergeria giesbergeri* (Williams and Rittenberg 1957) Grabovich et al. 2006, 575^{VP} – Basonym: *Aquaspirillum giesbergeri* (Williams and Rittenberg 1957) Hylemon et al. 1973 (Approved Lists 1980)
- Giesbergeria sinuosa* (Williams and Rittenberg 1957) Grabovich et al. 2006, 575^{VP} – Basonym: *Aquaspirillum sinuosum* (Williams and Rittenberg 1957) Hylemon et al. 1973 (Approved Lists 1980)
- Goodfellowia coeruleoviolacea* (Preobrazhenskaya and Sveshnikova 1974) Labeda and Kroppenstedt 2006, 1206^{VP} – Basonym: *Actinomadura coeruleoviolacea* Preobrazhenskaya and Terekhova 1987
- The name *Goodfellowia coeruleoviolacea* (Preobrazhenskaya and Sveshnikova 1974) Labeda and Kroppenstedt 2006 is illegitimate because the genus name is illegitimate (see above *Goodfellowia* Labeda and Kroppenstedt 2006, 1205^{VP}).
- Haematobacter massiliensis* (Greub and Raoult 2006) Helsel et al. 2007, 1371^{VP} – Basonym: *Rhodobacter massiliensis* Greub and Raoult 2006 – Valid publication: Validation List no. 116 – Effective publication: Helsel et al. (2007)
- Herbaspirillum autotrophicum* (Aragno and Schlegel 1978) Ding and Yokota 2004, 2228^{VP} – Basonym: *Aquaspirillum autotrophicum* Aragno and Schlegel 1978 (Approved Lists 1980)
- Herbaspirillum huttiense* (Leifson 1962) Ding and Yokota 2004, 2228^{VP} – Basonym: *Pseudomonas huttiensis* Leifson 1962 (Approved Lists 1980)
- Hylemonella gracilis* (Canale-Parola et al. 1966) Spring et al. 2004, 104^{VP} – Basonym: *Aquaspirillum gracile* (Canale-Parola et al. 1966) Hylemon et al. 1973 (Approved Lists 1980)
- Ignatzschineria larvae* (Tóth et al. 2001) Tóth et al. 2007, 180^{VP} – Illegitimate basonym: *Schineria larvae* Tóth et al. 2001
- Insolitispirillum peregrinum* (Pretorius 1963) J.H. Yoon et al. 2007xxvi, 2834^{VP} – Basonym: *Aquaspirillum peregrinum* (Pretorius 1963) Hylemon et al. 1973 (Approved Lists 1980)
- Insolitispirillum peregrinum* subsp. *integrum* (Terasaki 1973) J.H. Yoon et al. 2007xxvi, 2834^{VP} – Basonym: *Aquaspirillum peregrinum* subsp. *integrum* (Terasaki 1973) Terasaki 1979 (Approved Lists 1980)
- Insolitispirillum peregrinum* subsp. *peregrinum* (Pretorius 1963) J.H. Yoon et al. 2007xxvi, 2834^{VP} – Basonym: *Aquaspirillum peregrinum* subsp. *peregrinum* (Pretorius 1963) Hylemon et al. 1973 (Approved Lists 1980)
- Isoptericola variabilis* (Bakalidou et al. 2002) Stackebrandt et al. 2004b, 687^{VP} – Basonym: *Cellulosimicrobium variabile* Bakalidou et al. 2002
- Kluyvera intermedia* (Izard et al. 1980) Pavan et al. 2005, 441^{VP} – Basonym: *Enterobacter intermedius* corrig. Izard et al. 1980
- Labrenzia aggregata* (Uchino et al. 1999) Biebl et al. 2007, 1105^{VP} – Basonym: *Stappia aggregata* (ex Ahrens 1968) Uchino et al. 1999
- Labrenzia alba* (Pujalte et al. 2006) Biebl et al. 2007, 1105^{VP} – Basonym: *Stappia alba* Pujalte et al. 2006
- Labrenzia marina* (Kim et al. 2006) Biebl et al. 2007, 1105^{VP} – Basonym: *Stappia marina* B.C. Kim et al. 2006

- Laceyella putida* (Lacey and Cross 1989) J.H. Yoon et al. 2005n, 399^{VP} – Basonym: *Thermoactinomyces putidus* Lacey and Cross 1989
- Laceyella sacchari* (Lacey 1971) J.H. Yoon et al. 2005n, 398^{VP} – Basonym: *Thermoactinomyces sacchari* Lacey 1971 (Approved Lists 1980)
- Lactobacillus kefiranofaciens* subsp. *kefirgranum* (Takizawa et al. 1994) Vancanneyt et al. 2004b, 555^{VP} – Basonym: *Lactobacillus kefirgranum* Takizawa et al. 1994
- Leeuwenhoekiella marinoflava* (Reichenbach 1989) Nedashkovskaya et al. 2005m, 1035^{VP} – Basonym: *Cytophaga marinoflava* (ex Colwell et al. 1966) Reichenbach 1989
- Lysinibacillus fusiformis* (Priest et al. 1989) Ahmed et al. 2007d, 1122^{VP} – Basonym: *Bacillus fusiformis* (ex Meyer and Gottheil 1901) Priest et al. 1989
- Lysinibacillus sphaericus* (Meyer and Neide 1904) Ahmed et al. 2007d, 1123^{VP} – Basonym: *Bacillus sphaericus* Meyer and Neide 1904 (Approved Lists 1980)
- Malikia spinosa* (Leifson 1962) Spring et al. 2005b, 628^{VP} – Basonym: *Pseudomonas spinosa* Leifson 1962 (Approved Lists 1980)
- Marinovum algicola* (Lafay et al. 1995) Martens et al. 2006, 1302^{VP} – Basonym: *Roseobacter algicola* Lafay et al. 1995
- Mycoplasma coccoides* (Schilling 1928) Neimark et al. 2005, 1389^{VP} – Basonym: *Eperythrozoon coccoides* Schilling 1928 (Approved Lists 1980)
- According to Rule 28b(2), the new combination *Mycoplasma coccoides* (Schilling 1928) Neimark et al. 2005 is not validly published (see the Request for an Opinion by Neimark et al., 2005).
- Mycoplasma ovis* (Neitz et al. 1934) Neimark et al. 2004, 369^{VP} – Basonym: *Eperythrozoon ovis* Neitz et al. 1934 (Approved Lists 1980)
- Nakamurella multipartita* (Yoshimi et al. 1996) Tao et al. 2004, 999^{VP} – Illegitimate basonym: *Microsphaera multipartita* Yoshimi et al. 1996
- Novispirillum itersonii* (Giesberger 1936) J.H. Yoon et al. 2007xxvi, 2833^{VP} – Basonym: *Aquaspirillum itersonii* (Giesberger 1936) Hylemon et al. 1973 (Approved Lists 1980)
- Novispirillum itersonii* subsp. *itersonii* (Giesberger 1936) J.H. Yoon et al. 2007xxvi, 2833^{VP} – Basonym: *Aquaspirillum itersonii* subsp. *itersonii* (Giesberger 1936) Hylemon et al. 1973 (Approved Lists 1980)
- Novispirillum itersonii* subsp. *nipponicum* (Terasaki 1973) J.H. Yoon et al. 2007xxvi, 2834^{VP} – Basonym: *Aquaspirillum itersonii* subsp. *nipponicum* (Terasaki 1973) Terasaki 1979 (Approved Lists 1980)
- Novosphingobium resinovororum* (Delaporte and Daste 1956) Y.W. Lim et al. 2007, 1907^{VP} – Basonym: *Flavobacterium resinovororum* Delaporte and Daste 1956 (Approved Lists 1980)
- Oceanobacillus picturae* (Heyrman et al. 2003) J.S. Lee et al. 2006b, 256^{VP} – Basonym: *Virgibacillus picturae* Heyrman et al. 2003
- Paenibacillus chitinolyticus* (Kuroshima et al. 1996) J.S. Lee et al. 2004, 932^{VP} – Basonym: *Bacillus chitinolyticus* Kuroshima et al. 1996
- Paenibacillus ehimensis* (Kuroshima et al. 1996) J.S. Lee et al. 2004, 931^{VP} – Basonym: *Bacillus ehimensis* Kuroshima et al. 1996
- Parabacteroides distasonis* (Eggerth and Gagnon 1933) Sakamoto and Benno 2006, 1602^{VP} – Basonym: *Bacteroides distasonis* Eggerth and Gagnon 1933 (Approved Lists 1980)
- Parabacteroides goldsteinii* (Song et al. 2006) Sakamoto and Benno 2006, 1602^{VP} – Basonym: *Bacteroides goldsteinii* Song et al. 2006
- Parabacteroides merdae* (Johnson et al. 1986) Sakamoto and Benno 2006, 1604^{VP} – Basonym: *Bacteroides merdae* Johnson et al. 1986
- Parvimonas micra* (Prévot 1933) Tindall and Euzéby 2006, 2712^{VP} – Basonym: *Peptostreptococcus micros* (Prévot 1933) Smith 1957 (Approved Lists 1980)
- Pelomonas saccharophila* (Doudoroff 1940) Xie and Yokota 2005f, 2424^{VP} – Basonym: *Pseudomonas saccharophila* Doudoroff 1940 (Approved Lists 1980)
- Peredibacter starrii* (Seidler et al. 1972) Davidov and Jurkevitch 2004, 1451^{VP} – Basonym: *Bdellovibrio starrii* Seidler et al. 1972 (Approved Lists 1980)
- Phaeobacter gallaeciensis* (Ruiz-Ponte et al. 1998) Martens et al. 2006, 1301^{VP} – Basonym: *Roseobacter gallaeciensis* Ruiz-Ponte et al. 1998
- Photobacterium indicum* (Johnson and Weisrock 1969) Ivanova et al. 2004d, 1785^{VP} – Basonym: *Hyphomicrobium indicum* Johnson and Weisrock 1969
- Photobacterium indicum* (Johnson and Weisrock 1969) Xie and Yokota 2004, 2115^{VP} – Basonym: *Hyphomicrobium indicum* Johnson and Weisrock 1969 (Approved Lists 1980)
- According to Rule 24b(2), *Photobacterium indicum* (Johnson and Weisrock 1969) Ivanova et al. 2004d has priority.
- Planomicrobium alkanoclasticum* (Engelhardt et al. 2001) Dai et al. 2005, 702^{VP} – Basonym: *Planococcus alkanoclasticus* Engelhardt et al. 2001
- Planomicrobium psychrophilum* (Reddy et al. 2002) Dai et al. 2005, 702^{VP} – Basonym: *Planococcus psychrophilus* Reddy et al. 2002
- Pseudomonas chlororaphis* subsp. *aurantiaca* (Nakhimovskaya 1948) Peix et al. 2007, 1289^{VP} – Basonym: *Pseudomonas aurantiaca* Nakhimovskaya 1948 (Approved Lists 1980)
- Pseudomonas chlororaphis* subsp. *aureofaciens* (Kluyver 1956) Peix et al. 2007, 1289^{VP} – Basonym: *Pseudomonas aureofaciens* Kluyver 1956 (Approved Lists 1980)
- Pullulanibacillus naganensis* (Tomimura et al. 1990) Hatayama et al. 2006, 2550^{VP} – Basonym: *Bacillus naganensis* Tomimura et al. 1990
- Quatrionicoccus australiensis* (Maszenan et al. 2002) Tindall and Euzéby 2006, 2712^{VP} – Illegitimate basonym: *Quadricoccus australiensis* Maszenan et al. 2002
- Ralstonia syzygii* (Roberts et al. 1990) Vaneechoutte et al. 2004, 321^{VP} – Basonym: *Pseudomonas syzygii* Roberts et al. 1990
- Reichenbachiella agariperforans* (Nedashkovskaya et al. 2003) Nedashkovskaya et al. 2005l, 2587^{VP} – Illegitimate basonym: *Reichenbachia agariperforans* Nedashkovskaya et al. 2003
- Rhizobium larrymoorei* (Bouzar and Jones 2001) J.M. Young 2004, 149^{VP} – Basonym: *Agrobacterium larrymoorei* Bouzar and Jones 2001

- Rhodococcus corynebacterioides* (Serrano et al. 1972) Yassin and Schaal 2005, 1347^{VP} – Basonym: *Nocardia corynebacterioides* Serrano et al. 1972 (Approved Lists 1980)
- Roseivirga seohaensis* (Yoon et al. 2005) S.C. Lau et al. 2006b, 1064^{VP} – Basonym: *Marinicola seohaensis* J.H. Yoon et al. 2005c
- Ruegeria lacuscaerulensis* (Petursdottir and Kristjansson 1999) Yi et al. 2007, 818^{VP} – Basonym: *Silicibacter lacuscaerulensis* Petursdottir and Kristjansson 1999
- Ruegeria pomeroyi* (González et al. 2003) Yi et al. 2007, 818^{VP} – Basonym: *Silicibacter pomeroyi* González et al. 2003
- Salimicrobium album* (Hao et al. 1985) J.H. Yoon et al. 2007xxi, 2409^{VP} – Basonym: *Marinococcus albus* Hao et al. 1985
- Salimicrobium halophilum* (Ventosa et al. 1990) J.H. Yoon et al. 2007xxi, 2409^{VP} – Basonym: *Bacillus halophilus* Ventosa et al. 1990
- Salmonella enterica* subsp. *arizonae* (Borman 1957) Le Minor and Popoff 1987, 519^{VP} – Basonym: *Salmonella arizonae* (Borman 1957) Kauffmann 1964 (Approved Lists 1980) – Reference: Judicial Commission of the International Committee on Systematics of Prokaryotes 2005b (Opinion 80)
- Salmonella enterica* subsp. *bongori* (Le Minor et al. 1985) Le Minor and Popoff 1987, 519^{VP} – Basonym: *Salmonella choleraesuis* subsp. *bongori* corrig. Le Minor et al. 1985 – Reference: Judicial Commission of the International Committee on Systematics of Prokaryotes 2005b (Opinion 80)
- Salmonella enterica* subsp. *diarizonae* (Le Minor et al. 1985) Le Minor and Popoff 1987, 519^{VP} – Basonym: *Salmonella choleraesuis* subsp. *diarizonae* corrig. Le Minor et al. 1985 – Reference: Judicial Commission of the International Committee on Systematics of Prokaryotes 2005b (Opinion 80)
- Salmonella enterica* subsp. *houtenae* (Le Minor et al. 1985) Le Minor and Popoff 1987, 519^{VP} – Basonym: *Salmonella choleraesuis* subsp. *houtenae* corrig. Le Minor et al. 1985 – Reference: Judicial Commission of the International Committee on Systematics of Prokaryotes 2005b (Opinion 80)
- Salmonella enterica* subsp. *indica* (Le Minor et al. 1987) Le Minor and Popoff 1987, 519^{VP} – Basonym: *Salmonella choleraesuis* subsp. *indica* Le Minor et al. 1987 – Reference: Judicial Commission of the International Committee on Systematics of Prokaryotes 2005b (Opinion 80)
- Salmonella enterica* subsp. *salamae* (Le Minor et al. 1985) Le Minor and Popoff 1987, 519^{VP} – Basonym: *Salmonella choleraesuis* subsp. *salamae* corrig. Le Minor et al. 1985 – Reference: Judicial Commission of the International Committee on Systematics of Prokaryotes 2005b (Opinion 80)
- Seinonella peptonophila* (Nonomura and Ohara 1971) J.H. Yoon et al. 2005n, 400^{VP} – Basonym: *Thermoactinomyces peptonophilus* Nonomura and Ohara 1971 (Approved Lists 1980)
- Simplicispira metamorpha* (Terasaki 1961) Grabovich et al. 2006, 575^{VP} – Basonym: *Aquaspirillum metamorphum* (Terasaki 1961) Hylemon et al. 1973 (Approved Lists 1980)
- Simplicispira psychrophila* (Terasaki 1973) Grabovich et al. 2006, 575^{VP} – Basonym: *Aquaspirillum psychrophilum* (Terasaki 1973) Terasaki 1979 (Approved Lists 1980)
- Sorangium cellulosum* (Brockman 1989) Reichenbach 2007, 894^{VP} – Basonym: *Polyangium cellulosum* (ex Imshenetski and Solntseva 1936) Brockman 1989 – Valid publication: Validation List no. 115 – Effective publication: Reichenbach (2005i)
- Sphaerisporangium viridialbum* corrig. (Nonomura and Ohara 1960) Ara and Kudo 2007, 2449^{VP} – Basonym: *Streptosporangium viridialbum* Nonomura and Ohara 1960 – Valid publication: Validation List no. 118 – Effective publication: Ara and Kudo (2007b)
- Sphingobium chungbukense* (Kim et al. 2000) Pal et al. 2005, 1971^{VP} – Basonym: *Sphingomonas chungbukensis* Kim et al. 2000
- Sphingobium cloacae* (Fujii et al. 2001) Prakash and Lal 2006, 2151^{VP} – Basonym: *Sphingomonas cloacae* Fujii et al. 2001
- Sphingobium xenophagum* (Stolz et al. 2000) Pal et al. 2006, 669^{VP} – Basonym: *Sphingomonas xenophaga* Stolz et al. 2000
- Sphingopyxis taejonensis* (Lee et al. 2001) Pal et al. 2006, 670^{VP} – Basonym: *Sphingomonas taejonensis* Lee et al. 2001
- Sporolactobacillus laevolacticus* (Andersch et al. 1994) Hatayama et al. 2006, 2550^{VP} – Basonym: *Bacillus laevolacticus* (ex Nakayama and Yanoshi 1967) Andersch et al. 1994
- Stanielia latercula* (Lewin 1969) Nedashkovskaya et al. 2005h, 228^{VP} – Basonym: *Cytophaga latercula* Lewin 1969 (Approved Lists 1980)
- Sulfitobacter guttiformis* (Labrenz et al. 2000) J.H. Yoon et al. 2007x, 1791^{VP} – Basonym: *Staleyia guttiformis* Labrenz et al. 2000
- Sulfurimonas denitrificans* (Timmer-ten Hoor 1975) Takai et al. 2006b, 1732^{VP} – Basonym: *Thiomicrospira denitrificans* Timmer-ten Hoor 1975 (Approved Lists 1980)
- Syntrophomonas bryantii* (Stieb and Schink 1985) C. Wu et al. 2006, 2335 – Basonym: *Clostridium bryantii* Stieb and Schink 1985
- According to Rule 27(3), *Syntrophomonas bryantii* (Stieb and Schink 1985) C. Wu et al. 2006 is not validly published because the type strain is not deposited in two different collections in two different countries.
- Terrimonas ferruginea* (Sickles and Shaw 1934) Xie and Yokota 2006c, 1120^{VP} – Basonym: *Flavobacterium ferrugineum* Sickles and Shaw 1934 (Approved Lists 1980)
- Tetragenococcus solitarius* (Collins et al. 1989) Ennahar and Cai 2005, 592^{VP} – Basonym: *Enterococcus solitarius* Collins et al. 1989
- Tetrasphaera duodecadis* (Lochhead 1958) Ishikawa and Yokota 2006, 1371^{VP} – Basonym: *Arthrobacter duodecadis* Lochhead 1958 (Approved Lists 1980)
- Thalassobius gelatinovorius* (Rüger and Höfle 1992) Arahall et al. 2006, 3^{VP} – Basonym: *Agrobacterium gelatinovorium* (ex Ahrens 1968) Rüger and Höfle 1992 – Valid publication: Validation List no. 107 – Effective publication: Arahall et al. (2006)
- Thermoflavimicrobium dichotomicum* (Krasil'nikov and Agre 1964) J.H. Yoon et al. 2005n, 399^{VP} – Basonym: *Thermoactinomyces dichotomicus* corrig. (Krasil'nikov and Agre 1964) Cross and Goodfellow 1973 (Approved Lists 1980)
- Thermopolyspora flexuosa* (Meyer 1989) Goodfellow et al. 2005, 1982^{VP} – Basonym: *Actinomadura flexuosa* (ex Krasil'nikov and Agre 1964) Meyer 1989
- Thiomonas delicata* (Katayama-Fujimura et al. 1984) Kelly and Wood 2006, 926^{VP} – Basonym: *Thiobacillus delicatus* (ex Mizoguchi et al. 1976) Katayama-Fujimura et al. 1984 – Valid publication: Val-

- idation List no. 109 – Effective publication: Kelly and Wood (2005b)
- Turneriella parva* (Hovind-Hougen et al. 1982) Levett et al. 2005, 1499^{VP} – Basonym: *Leptospira parva* Hovind-Hougen et al. 1982
- Umezawaea tangerina* (Kinoshita et al. 2000) Labeda and Kropfenstedt 2007, 2761^{VP} – Basonym: *Saccharothrix tangerinus* Kinoshita et al. 2000
- Virgibacillus halodenitrificans* (Denariáz et al. 1989) J.H. Yoon et al. 2004k, 2166^{VP} – Basonym: *Bacillus halodenitrificans* Denariáz et al. 1989
- Viridibacillus arenosi* (Heyrman et al. 2005) Albert et al. 2007, 2735^{VP} – Basonym: *Bacillus arenosi* Heyrman et al. 2005b
- Viridibacillus arvi* (Heyrman et al. 2005) Albert et al. 2007, 2735^{VP} – Basonym: *Bacillus arvi* Heyrman et al. 2005b
- Viridibacillus neidei* (Nakamura et al. 2002) Albert et al. 2007, 2735^{VP} – Basonym: *Bacillus neidei* Nakamura et al. 2002
- Wautersia basileensis* (Steinle et al. 1999) Vaneechoutte et al. 2004, 323^{VP} – Basonym: *Ralstonia basileensis* Steinle et al. 1999
- Wautersia campinensis* (Goris et al. 2001) Vaneechoutte et al. 2004, 323^{VP} – Basonym: *Ralstonia campinensis* Goris et al. 2001
- Wautersia eutropha* (Davis 1969) Vaneechoutte et al. 2004, 323^{VP} – Basonym: *Alcaligenes eutrophus* Davis 1969 (Approved Lists 1980)
- Wautersia gilardii* (Coenye et al. 1999) Vaneechoutte et al. 2004, 324^{VP} – Basonym: *Ralstonia gilardii* Coenye et al. 1999
- Wautersia metallidurans* (Goris et al. 2001) Vaneechoutte et al. 2004, 324^{VP} – Basonym: *Ralstonia metallidurans* Goris et al. 2001
- Wautersia oxalatica* (Sahin et al. 2000) Vaneechoutte et al. 2004, 324^{VP} – Basonym: *Ralstonia oxalatica* (ex Khambata and Bhat 1953) Sahin et al. 2000
- Wautersia paucula* (Vandamme et al. 1999) Vaneechoutte et al. 2004, 325^{VP} – Basonym: *Ralstonia paucula* Vandamme et al. 1999
- Wautersia respiraculi* (Coenye et al. 2003) Vaneechoutte et al. 2004, 325^{VP} – Basonym: *Ralstonia respiraculi* Coenye et al. 2003
- Wautersia taiwanensis* (Chen et al. 2001) Vaneechoutte et al. 2004, 325^{VP} – Basonym: *Ralstonia taiwanensis* Chen et al. 2001
- Xylanimicrobium pachnodae* (Cazemier et al. 2004) Stackebrandt and Schumann 2004, 1385^{VP} – Basonym: *Promicromonospora pachnodae* Cazemier et al. 2004
- Revived names**
- Byssovorax cruenta* (ex Thaxter 1897) Reichenbach 2006, 2363^{VP}, sp. nov., nom. rev. – Synonym: “*Myxococcus cruentus*” Thaxter 1897
- Corallococcus exiguus* (ex Kofler 1913) Reichenbach 2007, 893^{VP}, nom. rev., comb. nov. – Synonym: “*Myxococcus exiguus*” Kofler 1913 – Valid publication: Validation List no. 115 – Effective publication: Reichenbach (2005b)
- Cystobacter violaceus* (ex Kühlwein and Gallwitz 1958) Reichenbach 2007, 894^{VP}, nom. rev., comb. nov. – Synonyms: “*Polyangium violaceum*” Kühlwein and Gallwitz 1958, “*Archangium violaceum*” Kühlwein and Reichenbach 1964 – Valid publication: Validation List no. 115 – Effective publication: Reichenbach (2005d)
- Flammeovirga arenaria* (ex Lewin 1969) M. Takahashi et al. 2006, 2099^{VP}, nom. rev., comb. nov. – Synonym: “*Microscilla arenaria*” Lewin 1969
- Gluconobacter albidus* (ex Kondo and Ameyama 1958) Yukphan et al. 2005, 983^{VP}, nom. rev., comb. nov. – Synonym: “*Acetobacter albidus*” Kondo and Ameyama 1958 – Valid publication: Validation List no. 103 – Effective publication: Yukphan et al. (2004b)
- Jahnella thaxteri* corrig. (ex Jahn 1924) Reichenbach 2007, 894^{VP}, nom. rev., comb. nov. – Synonym: “*Archangium thaxteri*” Jahn 1924 – Valid publication: Validation List no. 115 – Effective publication: Reichenbach (2005h)
- Kofleria flava* (ex Kofler 1913) Reichenbach 2007, 894^{VP}, nom. rev., comb. nov. – Synonyms: “*Polyangium flavum*” Kofler 1913, “*Archangium flavum*” (Kofler 1913) Jahn 1924 – Valid publication: Validation List no. 115 – Effective publication: Reichenbach (2005m)
- Mycobacterium salmoniphilum* (ex Ross 1960) Whipps et al. 2007, 2529^{VP}, sp. nov., nom. rev. – Synonym: “*Mycobacterium salmoniphilum*” Ross 1960
- Salmonella enterica* (ex Kauffmann and Edwards 1952) Le Minor and Popoff 1987, 519^{VP}, sp. nov., nom. rev. – Synonym: “*Salmonella enterica*” Kauffmann and Edwards 1952 – Reference: Judicial Commission of the International Committee on Systematics of Prokaryotes 2005b (Opinion 80)
- Sorangium* (ex Jahn 1924) Reichenbach 2007, 894^{VP}, gen. nov., nom. rev. – Synonym: “*Sorangium*” Jahn 1924 – Valid publication: Validation List no. 115 – Effective publication: Reichenbach (2005i)
- Thermopolyspora* (ex Krasil'nikov and Agre 1964) Goodfellow et al. 2005, 1980^{VP}, gen. nov., nom. rev. – Synonym: “*Thermopolyspora*” Krassilnikov and Agre 1964
- Xanthomonas alfalfae* (ex Riker et al. 1935) Schaad et al. 2007, 894^{VP}, sp. nov., nom. rev. – Synonym: “*Xanthomonas alfalfae*” (ex Riker et al. 1935) Dowson 1943 – Valid publication: Validation List no. 115 – Effective publication: Schaad et al. (2006)
- Xanthomonas citri* subsp. *malvacearum* (ex Smith 1901) Schaad et al. 2007, 895^{VP}, subsp. nov., nom. rev. – Synonym: “*Xanthomonas malvacearum*” (Smith 1901) Dowson 1939 – Valid publication: Validation List no. 115 – Effective publication: Schaad et al. (2006)
- Xanthomonas gardneri* (ex Sutic 1957) Jones et al. 2006, 926^{VP}, nom. rev., comb. nov. – Synonym: “*Pseudomonas gardneri*” Sutic 1957 – Valid publication: Validation List no. 109 – Effective publication: J.B. Jones et al. (2004)
- Conserved specific epithet**
- enterica* in *Salmonella enterica* (ex Kauffmann and Edwards 1952) Le Minor and Popoff 1987 – Reference: Judicial Commission of the International Committee on Systematics of Prokaryotes 2005b (Opinion 80)
- Rejected names**
- Pelczaria* Poston 1994 – Reference: Judicial Commission of the International Committee on Systematics of Prokaryotes 2005a (Opinion 78)

- Pelczaria aurantia* Poston 1994 – Reference: Judicial Commission of the International Committee on Systematics of Prokaryotes 2005a (Opinion 78)
- Emendations**
- Acidaminococcus* Rogosa 1969 emend. Jumas-Bilak et al. 2007b
- Acidianus* Segerer et al. 1986 emend. Plumb et al. 2007
- Acidomonas methanolica* (Uhlig et al. 1986) Urakami et al. 1989 emend. Yamashita et al. 2004
- Acidomonas* Urakami et al. 1989 emend. Yamashita et al. 2004
- Actinobacillus capsulatus* Arseculeratne 1962 (Approved Lists 1980) emend. Kuhnert et al. 2007
- Actinobacillus rossii* Sneath and Stevens 1990 emend. Christensen et al. 2005
- Aeromicrobium* Miller et al. 1991 emend. J.H. Yoon et al. 2005q
- Agromyces fucosus* Zgurskaya et al. 1992 emend. Ortiz-Martinez et al. 2004
- Alcaligenes faecalis* Castellani and Chalmers 1919 (Approved Lists 1980) emend. Rehfuß and Urban 2005a – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 3
- Algibacter* Nedashkovskaya et al. 2004d emend. Nedashkovskaya et al. 2007e
- Algoriphagus* Bowman et al. 2003 emend. Nedashkovskaya et al. 2004h
- Algoriphagus* Bowman et al. 2003 emend. Nedashkovskaya et al. 2007b
- Alicyclobacillus acidocaldarius* (Darland and Brock 1971) Wisotzkey et al. 1992 emend. Goto et al. 2006 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 5
- Alicyclobacillus* Wisotzkey et al. 1992 emend. Karavaiko et al. 2005
- Alteromonadaceae* Ivanova and Mikhailov 2001 emend. Ivanova et al. 2004d
- Alteromonas* Baumann et al. 1972 (Approved Lists 1980) emend. Van Trappen et al. 2004b
- Alteromonas macleodii* Baumann et al. 1972 (Approved Lists 1980) emend. Yi et al. 2004
- Amphibacillus* Niimura et al. 1990 emend. S.Y. An et al. 2007e
- Anaerolinea* Sekiguchi et al. 2003 emend. Yamada et al. 2006
- Aquificales* Reysenbach 2002 emend. L'Haridon et al. 2006
- Aquimarina* Nedashkovskaya et al. 2005h emend. Nedashkovskaya et al. 2006f
- Arcanobacterium* Collins et al. 1983 emend. Lehnen et al. 2006
- Arenibacter* Ivanova et al. 2001 emend. Nedashkovskaya et al. 2006g
- Arenibacter latericius* Ivanova et al. 2001 emend. Nedashkovskaya et al. 2006g
- Arthrobacter cumminsii* Funke et al. 1997 emend. Funke et al. 1998 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1
- Aureispira* Hosoya et al. 2006 emend. Hosoya et al. 2007
- Azospira* Reinhold-Hurek and Hurek 2000 emend. H.S. Bae et al. 2007
- Bacillus coagulans* Hammer 1915 (Approved Lists 1980) emend. De Clerck et al. 2004a – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1
- Bacillus mojavensis* Roberts et al. 1994 emend. L.T. Wang et al. 2007
- Bacillus simplex* (ex Meyer and Gottheil 1901) Priest et al. 1989 emend. Heyrman et al. 2005a
- Bifidobacterium animalis* (Mitsuoka 1969) Scardovi and Trovattelli 1974 emend. Masco et al. 2004
- Blastococcus aggregatus* Ahrens and Moll 1970 (Approved Lists 1980) emend. Urzi et al. 2004
- Blastococcus* Ahrens and Moll 1970 (Approved Lists 1980) emend. S.D. Lee 2006g
- Blastococcus* Ahrens and Moll 1970 (Approved Lists 1980) emend. Urzi et al. 2004
- Burkholderia pyrocinia* (Imanaka et al. 1965) Vandamme et al. 1997 emend. Storms et al. 2004 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1
- Caldicellulosiruptor* Rainey et al. 1995 emend. Onyenwoke et al. 2006
- Carboxydotherrmus* Svetlichny et al. 1991 emend. Slobodkin et al. 2006a
- Cardiobacterium valvarum* Han et al. 2004 emend. Han and Falsen 2005 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 3
- Cellulosimicrobium* Schumann et al. 2001 emend. J.M. Brown et al. 2006
- Cellulosimicrobium* Schumann et al. 2001 emend. J.H. Yoon et al. 2007xxv
- Chitinimonas* S.C. Chang et al. 2004 emend. B.Y. Kim et al. 2006d
- Chitinophaga arvensicola* (Oyaizu et al. 1983) Kämpfer et al. 2006k emend. Pankratov et al. 2006
- Chitinophaga* Sangkhobol and Skerman 1981 emend. Kämpfer et al. 2006k
- Chloroflexi* Garrity and Holt 2001 emend. Hugenholtz and Stackebrandt 2004 (category not covered by the Rules)
- Clostridium bifermentans* (Weinberg and Séguin 1918) Bergey et al. 1923 (Approved Lists 1980) emend. Chamkha et al. 2001 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1
- Clostridium sardiniense* Prévot 1938 (Approved Lists 1980) emend. X. Wang et al. 2005
- Corynebacterium aurimucosum* Yassin et al. 2002 emend. Daneshvar et al. 2004 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1
- Cupriavidus* Makkar and Casida 1987 emend. Vandamme and Coenye 2004
- Cyclobacterium* Raj and Maloy 1990 emend. Ying et al. 2006
- Desulfatibacillum* Cravo-Laureau et al. 2004a emend. Cravo-Laureau et al. 2004b
- Desulfitobacterium hafniense* Christiansen and Ahring 1996 emend. Niggemyer et al. 2001 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 2

- Desulfofabia* Knoblauch et al. 1999 emend. Abildgaard et al. 2004
- Desulfurobacterium* L'Haridon et al. 1998 emend. L'Haridon et al. 2006
- Desulfurobacterium* L'Haridon et al. 1998 emend. Alain et al. 2003 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 2
- Desulfurococcus* Zillig and Stetter 1983 emend. Perevalova et al. 2005
- Devosia* Nakagawa et al. 1996 emend. Yoo et al. 2006
- Devosia* Nakagawa et al. 1996 emend. J.H. Yoon et al. 2007xvii
- Dialister* (ex Bergey et al. 1923) Moore and Moore 1994 emend. Jumas-Bilak et al. 2005
- Dialister pneumosintes* (Olitsky and Gates 1921) Moore and Moore 1994 emend. Jumas-Bilak et al. 2005
- Dyadobacter* Chelius and Triplett 2000 emend. Reddy and Garcia-Pichel 2005
- Enterobacter asburiae* Brenner et al. 1988 emend. Hoffmann et al. 2005a – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 2
- Enterobacter kobei* Kosako et al. 1997 emend. Hoffmann et al. 2005a – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 2
- Flammeovirga aprica* (Reichenbach 1989) Nakagawa et al. 1997 emend. M. Takahashi et al. 2006
- Flammeovirga* Nakagawa et al. 1997 emend. M. Takahashi et al. 2006
- Flexithrix dorotheae* Lewin 1970 (Approved Lists 1980) emend. Hosoya and Yokota 2007a
- Flexithrix* Lewin 1970 (Approved Lists 1980) emend. Hosoya and Yokota 2007a
- Formosa algae* Ivanova et al. 2004a emend. Nedashkovskaya et al. 2006d
- Formosa* Ivanova et al. 2004a emend. Nedashkovskaya et al. 2006d
- Georgenia* Altenburger et al. 2002 emend. W.J. Li et al. 2007
- Glaciecola* Bowman et al. 1998 emend. Van Trappen et al. 2004c
- Gluconacetobacter hansenii* corrig. (Gosselé et al. 1983) Yamada et al. 1998
- Glycomyces* Labeda et al. 1985 emend. Labeda and Kroppenstedt 2004
- Glycomycetaceae* Rainey et al. 1997 (complete authorship reads Rainey, Ward-Rainey and Stackebrandt) emend. Labeda and Kroppenstedt 2005
- Hahella* Lee et al. 2001 emend. Baik et al. 2005
- Halobacillus* Spring et al. 1996 emend. J.H. Yoon et al. 2007vi
- Halobacterium salinarum* corrig. (Harrison and Kennedy 1922) Elazari-Volcani 1957 (Approved Lists 1980) emend. Gruber et al. 2004 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 2
- Halochromatium* Imhoff et al. 1998 emend. Anil Kumar et al. 2007c
- Halomonadaceae* Franzmann et al. 1989 emend. Ben Ali Gam et al. 2007
- Halomonadaceae* Franzmann et al. 1989 emend. Ntougias et al. 2007b
- Halovibrio* Fendrich 1989 emend. Sorokin et al. 2006a
- Hongiella* Yi and Chun 2004 emend. Nedashkovskaya et al. 2004h
- Hymenobacter* Hirsch et al. 1999 emend. Buczolits et al. 2006
- Idiomarinaceae* Ivanova et al. 2004d emend. Jean et al. 2006b
- Labrys monachus* corrig. Vasilyeva and Semenov 1985 emend. Islam et al. 2007
- Labrys* Vasilyeva and Semenov 1985 emend. Islam et al. 2007
- Lactobacillus fermentum* Beijerinck 1901 (Approved Lists 1980) emend. Dellaglio et al. 2004
- Lactobacillus kefiranofaciens* Fujisawa et al. 1988 emend. Vancanneyt et al. 2004b
- Lactobacillus salivarius* Rogosa et al. 1953 (Approved Lists 1980) emend. Y. Li et al. 2006
- Y. Li et al. 2006 propose that the infraspecific division of *Lactobacillus salivarius* Rogosa et al. 1953 (Approved Lists 1980) into the subspecies *Lactobacillus salivarius* subsp. *salicinius* Rogosa et al. 1953 (Approved Lists 1980) and *Lactobacillus salivarius* subsp. *salivarius* Rogosa et al. 1953 (Approved Lists 1980) be discontinued.
- Lactobacillus vaccिनostercus* Kozaki and Okada 1983 emend. Dellaglio et al. 2006
- Lampropedia hyalina* (Ehrenberg 1832) Schroeter 1886 (Approved Lists 1980) emend. N. Lee et al. 2004
- Lampropedia hyalina* (Ehrenberg 1832) Schroeter 1886 (Approved Lists 1980) emend. Xie and Yokota 2003 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 2
- Lampropedia* Schroeter 1886 (Approved Lists 1980) emend. N. Lee et al. 2004
- Leisingera* Schaefer et al. 2002 emend. Martens et al. 2006
- Lentibacillus* Yoon et al. 2002 emend. Jeon et al. 2005a
- Leptospiraceae* Hovind-Hougen 1979 (Approved Lists 1980) emend. Levett et al. 2005
- Leucobacter chromiireducens* Morais et al. 2005 emend. Muir and Tan 2007
- Lewinella cohaerens* (Lewin 1970) Sly et al. 1998 emend. Khan et al. 2007a
- Lewinella nigricans* (Lewin 1970) Sly et al. 1998 emend. Khan et al. 2007a
- Lewinella persica* (Lewin 1970) Sly et al. 1998 emend. Khan et al. 2007a
- Lewinella* Sly et al. 1998 emend. Khan et al. 2007a
- Marinibacillus* Yoon et al. 2001 emend. J.H. Yoon et al. 2004g
- Massilia timonae* La Scola et al. 2000 emend. Lindquist et al. 2003 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1
- Mesonina* Nedashkovskaya et al. 2003 emend. Nedashkovskaya et al. 2006e
- Methanoculleus thermophilus* corrig. (Rivard and Smith 1982) Maestrojuán et al. 1990 emend. Spring et al. 2005a
- Methanogenium* Romesser et al. 1981 emend. Spring et al. 2005a

- Methanogenium thermophilicum* Rivard and Smith 1982 emend. Zabel et al. 1985 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1
- Methanosarcina baltica* von Klein et al. 2002 emend. Singh et al. 2005
- Methylibium* Nakatsu et al. 2006 emend. M.H. Yoon et al. 2007c
- Methylocella* Dedysh et al. 2000 emend. Dedysh et al. 2004
- Methylocystis* (ex Whittenbury et al. 1970) Bowman et al. 1993 emend. Dedysh et al. 2007
- Methylosarcina* Wise et al. 2001 emend. Kalyuzhnaya et al. 2005
- Methylovorus glucosotrophus* Govorukhina and Trotsenko 1991 emend. Doronina et al. 2005
- Methylovorus* Govorukhina and Trotsenko 1991 emend. Doronina et al. 2005
- Methylovorus mays* Doronina et al. 2001 emend. Doronina et al. 2005
- Microcella* Tiago et al. 2005b emend. Tiago et al. 2006b
- Mobiluncus curtisii* Spiegel and Roberts 1984 emend. Hoyles et al. 2004 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1

- Streptomyces colombiensis* Pridham et al. 1958 (Approved Lists 1980) emend. Lanoot et al. 2004 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1
- Streptomyces corchorusii* Ahmad and Bhuiyan 1958 (Approved Lists 1980) emend. Lanoot et al. 2005
- Streptomyces filamentosus* Okami and Umezawa 1953 (Approved Lists 1980) emend. Lanoot et al. 2004 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1
- Streptomyces flavovirens* (Waksman 1923) Waksman and Henrici 1948 (Approved Lists 1980) emend. Lanoot et al. 2005
- Streptomyces fradiae* (Waksman and Curtis 1916) Waksman and Henrici 1948 (Approved Lists 1980) emend. Lanoot et al. 2004 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1
- Streptomyces griseus* (Krainsky 1914) Waksman and Henrici 1948 (Approved Lists 1980) emend. Z. Liu et al. 2005b
- Streptomyces microflavus* (Krainsky 1914) Waksman and Henrici 1948 (Approved Lists 1980) emend. Lanoot et al. 2005
- Streptomyces minutiscleroticus* (Thirumalachar 1965) Pridham 1970 (Approved Lists 1980) emend. Lanoot et al. 2005
- Streptomyces phaeopurpureus* Shinobu 1957 (Approved Lists 1980) emend. Lanoot et al. 2004 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1
- Streptomyces tricolor* (Wollenweber 1920) Waksman 1961 (Approved Lists 1980) emend. Lanoot et al. 2004 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1
- Streptomyces vinaceus* Jones 1952 (Approved Lists 1980) emend. Lanoot et al. 2004 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1
- Sulfitobacter* Sorokin 1996 emend. J.H. Yoon et al. 2007x
- Sulfurihydrogenibium azorense* Aguiar et al. 2004 emend. S. Nakagawa et al. 2005b
- Sulfurihydrogenibium subterraneum* Takai et al. 2003 emend. S. Nakagawa et al. 2005b
- Sulfurihydrogenibium* Takai et al. 2003 emend. S. Nakagawa et al. 2005b
- Sulfurimonas* Inagaki et al. 2003 emend. Takai et al. 2006b
- Suttonella* Dewhirst et al. 1990 emend. Foster et al. 2005
- Syntrophobacter* Boone and Bryant 1984 emend. S. Chen et al. 2005
- Syntrophomonas* McInerney et al. 1982 emend. C. Wu et al. 2006
- Tepidimonas* Moreira et al. 2000 emend. Albuquerque et al. 2006 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 5
- Tetrasphaera* Maszenan et al. 2000 emend. Ishikawa and Yokota 2006
- Thalassobacter* Macián et al. 2005a emend. Pujalte et al. 2005b
- Thalassomonas* Macián et al. 2001 emend. Jean et al. 2006c
- Thalassospira* López-López et al. 2002 emend. C. Liu et al. 2007
- Thermoactinomyces* Tsilinsky 1899 (Approved Lists 1980) emend. J.H. Yoon et al. 2005n
- Thermoanaerobacter mathranii* Larsen et al. 1998 emend. Carlier et al. 2006 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 5
- Thermoanaerobacter* Wiegel and Ljungdahl 1982 emend. Y.J. Lee et al. 2007a
- Thermomicrobia* Garrity and Holt 2002 emend. Hugenholtz and Stackebrandt 2004
- Thioalkalivibrio* Sorokin et al. 2001 emend. Banciu et al. 2004 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 2

- Thiomonas cuprina* Moreira and Amils 1997 emend. Kelly et al. 2007
- Thiomonas delicata* (Katayama-Fujimura et al. 1984) Kelly and Wood 2006 emend. Katayama et al. 2006
- Thiomonas* Moreira and Amils 1997 emend. Kelly et al. 2007
- Tissierella* Collins and Shah 1986 emend. J.W. Bae et al. 2004
- Trichococcus collinsii* Liu et al. 2002 emend. Pikuta et al. 2006a
- Xanthomonas citri* (ex Hasse 1915) Gabriel et al. 1989 emend. Schaad et al. 2006 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 6
- Yania* W.J. Li et al. 2004a emend. W.J. Li et al. 2005e
- Zymomonas mobilis* subsp. *mobilis* (Lindner 1928) De Ley and Swings 1976 emend. Coton et al. 2006
- Zymomonas mobilis* subsp. *pomaceae* (Millis 1956) De Ley and Swings 1976 emend. Coton et al. 2006
- ### Synonyms
- Aeromonas culicicola* Pidiyar et al. 2002 pro synonym. *Aeromonas veronii* Hickman-Brenner et al. 1988 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 3 – Original publication: Huys et al. (2005)
- Bacillus axarquiensis* Ruiz-García et al. 2005 pro synonym. *Bacillus mojavensis* Roberts et al. 1994 – Publication in the IJSEM: Wang et al. (2007)
- Bacillus malacitensis* Ruiz-García et al. 2005 pro synonym. *Bacillus mojavensis* Roberts et al. 1994 – Publication in the IJSEM: L.T. Wang et al. (2007)
- Brevibacterium liquefaciens* Okabayashi and Masuo 1960 (Approved Lists 1980) pro synonym. *Arthrobacter nicotianae* Giovannozzi-Sermanni 1959 (Approved List 1980) – Publication in the IJSEM: Gelsomino et al. (2004)
- Caenibacterium* Manaia et al. 2003 pro synonym. *Schlegelella* Elbanna et al. 2003 – Publication in the IJSEM: Lütke-Eversloh et al. (2004) [Rule 37a(1)]
- Caenibacterium thermophilum* Manaia et al. 2003 pro synonym. *Schlegelella thermodepolymerans* Elbanna et al. 2003 – Publication in the IJSEM: Lütke-Eversloh et al. (2004)
- Chimaericella* Tiago et al. 2006a pro synonym. *Algoriphagus* Bowman et al. 2003 – Publication in the IJSEM: Nedashkovskaya et al. (2007b) [Rule 37a(1)]
- Clostridium absonum* Nakamura et al. 1973 (Approved Lists 1980) pro synonym. *Clostridium sardiniense* Prévot 1938 (Approved Lists 1980) – Publication in the IJSEM: X. Wang et al. (2005)
- Clostridium hastiforme* MacLennan 1939 (Approved Lists 1980) pro synonym. *Tissierella praeacuta* (Tissier 1908) Collins and Shah 1986 – Publication in the IJSEM: J.W. Bae et al. (2004)
- Corynebacterium mooreparkense* Brennan et al. 2001 pro synonym. *Corynebacterium variabile* corrig. (Müller 1961) Collins 1987 – Publication in the IJSEM: Gelsomino et al. (2005)
- Corynebacterium nigricans* Shukla et al. 2004 pro synonym. *Corynebacterium aurimucosum* Yassin et al. 2002 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1 – Original publication: Daneshvar et al. (2004)
- Desulfitobacterium frappieri* Bouchard et al. 1996 pro synonym. *Desulfitobacterium hafniense* Christiansen and Ahring 1996 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 2 – Original publication: Niggemeyer et al. (2001)
- Desulfomusa* Finster et al. 2001 pro synonym. *Desulfofaba* Knoblauch et al. 1999 – Publication in the IJSEM: Abildgaard et al. (2004) [Rule 37a(1)]
- Enterococcus flavescens* Pompei et al. 1992 pro synonym. *Enterococcus casseliflavus* (ex Vaughan et al. 1979) Collins et al. 1984 – Publication in the IJSEM: Naser et al. (2006c)
- Enterococcus saccharominimus* Vancanneyt et al. 2004c pro synonym. *Enterococcus italicus* Fortina et al. 2004 – Publication in the IJSEM: Naser et al. (2006c)
- Falcivibrio grandis* Hammann et al. 1984 pro synonym. *Mobiluncus mulieris* Spiegel and Roberts 1984 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1 – Original publication: Hoyles et al. (2004)
- Falcivibrio vaginalis* Hammann et al. 1984 pro synonym. *Mobiluncus curtisii* Spiegel and Roberts 1984 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1 – Original publication: Hoyles et al. (2004)
- Flexibacter aggregans* (Lewin 1969) Leadbetter 1974 (Approved Lists 1980) pro synonym. *Flexithrix dorotheae* Lewin 1970 (Approved Lists 1980) – Publication in the IJSEM: Hosoya and Yokota (2007a)
- Gaetbulimicrobium* J.H. Yoon et al. 2006a pro synonym. *Aquimarina* Nedashkovskaya et al. 2005h – Publication in the IJSEM: Nedashkovskaya et al. (2006f) [Rule 37a(1)]
- Gordonia nitida* Yoon et al. 2000 pro synonym. *Gordonia alkanivorans* Kummer et al. 1999 – Publication in the IJSEM: Arenskötter et al. (2005)
- Hemophilus paraphrophilus* Zinnemann et al. 1968 pro synonym. *Hemophilus aphrophilus* Khairat 1940 (Approved Lists 1980) – Publication in the IJSEM: Nørskov-Lauritsen and Kilian (2006)
- Hongiella* Yi and Chun 2004 pro synonym. *Algoriphagus* Bowman et al. 2003 – Publication in the IJSEM: Nedashkovskaya et al. (2007b) [Rule 37a(1)]
- Jannaschia cystaugens* Adachi et al. 2004 synonym. *Thalassobacter stenotrophicus* Macián et al. 2005a – Publication in the IJSEM: Pujalte et al. (2005b) [Rules 15 and 17]
- Kluyvera cochleae* Müller et al. 1996 pro synonym. *Kluyvera intermedia* (Izard et al. 1980) Pavan et al. 2005 – Publication in the IJSEM: Pavan et al. (2005)
- Lactobacillus arizonensis* Swezey et al. 2000 pro synonym. *Lactobacillus plantarum* (Orla-Jensen 1919) Bergey et al. 1923 (Approved Lists 1980) – Publication in the IJSEM: Kostinek et al. (2005)
- Lactobacillus cellobiosus* Rogosa et al. 1953 (Approved Lists 1980) pro synonym. *Lactobacillus fermentum* Beijerinck 1901 (Approved Lists 1980) – Publication in the IJSEM: Dellaglio et al. (2004)
- Lactobacillus curvatus* subsp. *melibiosus* Torriani et al. 1996 pro synonym. *Lactobacillus sakei* subsp. *carneus* corrig. Torriani et al. 1996 – Publication in the IJSEM: Koort et al. (2004)
- Lactobacillus cypricasei* Lawson et al. 2001 pro synonym. *Lactobacillus acidipiscis* Tanasupawat et al. 2000 – Publication in the IJSEM: Naser et al. (2006b)
- Lactobacillus durianis* Leisner et al. 2002 pro synonym. *Lactobacillus vaccinoferus* Kozaki and Okada 1983 – Publication in the IJSEM: Dellaglio et al. (2006)

- Lactobacillus ferintoshensis* Simpson et al. 2002 pro synon. *Lactobacillus parabuchneri* Farrow et al. 1989 – Publication in the IJSEM: Vancanneyt et al. (2005a)
- Lactobacillus suntoryeus* Cachat and Priest 2005 pro synon. *Lactobacillus helveticus* (Orla-Jensen 1919) Bergey et al. 1925 (Approved Lists 1980) – Publication in the IJSEM: Naser et al. (2006a)
- Lactobacillus thermotolerans* Niamsup et al. 2003 pro synon. *Lactobacillus ingluviei* Baele et al. 2003 – Publication in the IJSEM: Felis et al. (2006)
- Leuconostoc argentinum* Dicks et al. 1993 pro synon. *Leuconostoc lactis* Garvie 1960 (Approved Lists 1980) – Publication in the IJSEM: Vancanneyt et al. (2006c)
- Marinicola* J.H. Yoon et al. 2005c pro synon. *Roseivirga* Nedashkovskaya et al. 2005c – Publication in the IJSEM: Nedashkovskaya et al. (2005c) and S.C. Lau et al. (2006b) [Rule 37a(1)]
- Marinobacter aquaeolei* Nguyen et al. 1999 pro synon. *Marinobacter hydrocarbonoclasticus* Gauthier et al. 1992 – Publication in the IJSEM: Márquez and Ventosa (2005)
- Methanogenium frittonii* Harris et al. 1996 pro synon. *Methanoculleus thermophilus* corrig. (Rivard and Smith 1982) Maestrojuán et al. 1990 – Publication in the IJSEM: Spring et al. (2005a)
- Methylobacterium chloromethanicum* McDonald et al. 2001 pro synon. *Methylobacterium extorquens* (Urakami and Komagata 1984) Bousfield and Green 1985 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 4 – Original publication: Y. Kato et al. (2005)
- Methylobacterium dichloromethanicum* Doronina et al. 2000 pro synon. *Methylobacterium extorquens* (Urakami and Komagata 1984) Bousfield and Green 1985 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 4 – Original publication: Y. Kato et al. (2005)
- Methylobacterium lusitanum* Doronina et al. 2002 pro synon. *Methylobacterium rhodesianum* Green et al. 1988 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 4 – Original publication: Y. Kato et al. (2005)
- Novosphingobium subarcticum* (Nohynek et al. 1996) pro synon. *Novosphingobium resinovororum* (Delaporte and Daste 1956) Lim et al. 2007 – Publication in the IJSEM: Y.M. Lim et al. (2007)
- Pseudomonas chloritidismutans* Wolterink et al. 2002 pro synon. *Pseudomonas stutzeri* (Lehmann and Neumann 1896) Sijderius 1946 (Approved Lists 1980) – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 4 – Original publication: Cladera et al. (2006)
- Pseudomonas multiresinivorans* Mohn et al. 1999 pro synon. *Pseudomonas nitroreducens* Iizuka and Komagata 1964 (Approved Lists 1980) emend. Lang et al. 2007a – Publication in the IJSEM: Lang et al. (2007a)
- Roseomonas fauriae* Rihs et al. 1998 pro synon. *Azospirillum brasiliense* corrig. Tarrand et al. 1979 (Approved Lists 1980) – Publication in the IJSEM: Hesel et al. (2006)
- Salmonella choleraesuis* corrig. (Smith 1894) Weldin 1927 (Approved Lists 1980) synon. *Salmonella enterica* (ex Kauffmann and Edwards 1952) Le Minor and Popoff 1987 – Publication in the IJSEM: Tindall et al. (2005)
- Salmonella choleraesuis* subsp. *choleraesuis* corrig. (Smith 1894) Weldin 1927 synon. *Salmonella enterica* subsp. *enterica* (ex Kauffmann and Edwards 1952) Le Minor and Popoff 1987 – Publication in the IJSEM: Tindall et al. (2005)
- Salmonella enteritidis* (Gaertner 1888) Castellani and Chalmers 1919 (Approved Lists 1980) synon. *Salmonella enterica* subsp. *enterica* (ex Kauffmann and Edwards 1952) Le Minor and Popoff 1987 – Publication in the IJSEM: Tindall et al. (2005)
- Salmonella paratyphi* (ex Kayser 1902) Ezaki et al. 2000. synon. *Salmonella enterica* subsp. *enterica* (ex Kauffmann and Edwards 1952) Le Minor and Popoff 1987 – Publication in the IJSEM: Tindall et al. (2005)
- Salmonella typhi* (Schroeter 1886) Warren and Scott 1930 (Approved Lists 1980) synon. *Salmonella enterica* subsp. *enterica* (ex Kauffmann and Edwards 1952) Le Minor and Popoff 1987 – Publication in the IJSEM: Tindall et al. (2005)
- Salmonella typhimurium* (Loeffler 1892) Castellani and Chalmers 1919 (Approved Lists 1980) synon. *Salmonella enterica* subsp. *enterica* (ex Kauffmann and Edwards 1952) Le Minor and Popoff 1987 – Publication in the IJSEM: Tindall et al. (2005)
- Shewanella affinis* pro synon. *Shewanella colwelliana* (Weiner et al. 1988) Coyne et al. 1990 – Publication in the IJSEM: Satomi et al. (2007)
- Silicibacter* Petrusdottir and Kristjansson 1999 pro synon. *Ruegeria* Uchino et al. 1999 – Publication in the IJSEM: Yi et al. (2007) [Rule 37a(1)]
- Sphingomonas subarctica* pro synon. *Novosphingobium resinovororum* (Delaporte and Daste 1956) Lim et al. 2007 – Publication in the IJSEM: Y.W. Lim et al. (2007)
- Staleyia* Labrenz et al. 2000 pro synon. *Sulfitobacter* Sorokin 1996 – Publication in the IJSEM: J.H. Yoon et al. (2007x) [Rule 37a(1)]
- Stanielrella* Nedashkovskaya et al. 2005h pro synon. *Aquimarina* Nedashkovskaya et al. 2005h – Publication in the IJSEM: Nedashkovskaya et al. (2006f) [Rule 37a(1)]
- Staphylococcus pulvereri* Zakrzewska-Czerwińska et al. 1995 pro synon. *Staphylococcus vitulinus* corrig. Webster et al. 1994 – Publication in the IJSEM: Švec et al. (2004)
- Stenotrophomonas africana* Drancourt et al. 1997 pro synon. *Stenotrophomonas maltophilia* (Hugh 1981) Palleroni and Bradbury 1993 – Publication in the IJSEM: Coenye et al. (2004b)
- Streptococcus difficilis* corrig. Eldar et al. 1995 pro synon. *Streptococcus agalactiae* Lehmann and Neumann 1896 (Approved Lists 1980) – Publication in the IJSEM: Kawamura et al. (2005)
- Streptomyces arabicus* Shibata et al. 1957 (Approved Lists 1980) pro synon. *Streptomyces vinaceus* Jones 1952 (Approved Lists 1980) – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1 – Original publication: Lanoot et al. (2004)
- Streptomyces argenteolus* Tresner et al. 1961 (Approved Lists 1980) pro synon. *Streptomyces griseus* (Krainsky 1914) Waksman and Henrici 1948 (Approved Lists 1980) – Publication in the IJSEM: Z. Liu et al. (2005b)
- Streptomyces caviscabies* Goyer et al. 1996 pro synon. *Streptomyces griseus* (Krainsky 1914) Waksman and Henrici 1948 (Approved Lists 1980) – Publication in the IJSEM: Z. Liu et al. (2005b)

- Streptomyces chibaensis* Suzuki et al. 1958 (Approved Lists 1980) pro synonym. *Streptomyces corchorusii* Ahmad and Bhuiyan 1958 (Approved Lists 1980) – Publication in the IJSEM: Lanoot et al. (2005)
- Streptomyces chrysomallus* Lindenbein 1952 (Approved Lists 1980) pro synonym. *Streptomyces anulatus* (Beijerinck 1912) Waksman 1953 (Approved Lists 1980) – Publication in the IJSEM: Lanoot et al. (2005) [Rule 37a(1)]
- Streptomyces chrysomallus* subsp. *chrysomallus* Lindenbein 1952 (Approved Lists 1980) pro synonym. *Streptomyces anulatus* (Beijerinck 1912) Waksman 1953 (Approved Lists 1980) – Publication in the IJSEM: Lanoot et al. (2005)
- Streptomyces citreofluorescens* (Korenyako et al. 1960) Pridham 1970 (Approved Lists 1980) pro synonym. *Streptomyces anulatus* (Beijerinck 1912) Waksman 1953 (Approved Lists 1980) – Publication in the IJSEM: Lanoot et al. (2005)
- Streptomyces cochleatus* Nakagaito et al. 1993 pro synonym. *Streptomyces cinereorectus* Terekhova and Preobrazhenskaya 1986 – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1 – Original publication: Lanoot et al. (2004)
- Streptomyces distallicus* (Locci et al. 1969) Witt and Stackebrandt 1991 pro synonym. *Streptomyces colombiensis* Pridham et al. 1958 (Approved Lists 1980) – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1 – Original publication: Lanoot et al. (2004)
- Streptomyces flaviscleroticus* (ex Pridham 1970) Goodfellow et al. 1986 pro synonym. *Streptomyces minutiscleroticus* (Thirumalachar 1965) Pridham 1970 (Approved Lists 1980) – Publication in the IJSEM: Lanoot et al. (2005)
- Streptomyces fluorescens* (Krasil'nikov 1958) Pridham 1970 (Approved Lists 1980) pro synonym. *Streptomyces anulatus* (Beijerinck 1912) Waksman 1953 (Approved Lists 1980) – Publication in the IJSEM: Lanoot et al. (2005)
- Streptomyces griseus* subsp. *alpha* (Ciferri 1927) Pridham 1970 (Approved Lists 1980) pro synonym. *Streptomyces microflavus* (Krainisky 1914) Waksman and Henrici 1948 (Approved Lists 1980) – Publication in the IJSEM: Lanoot et al. (2005)
- Streptomyces griseus* subsp. *cretosus* Pridham 1970 (Approved Lists 1980) pro synonym. *Streptomyces microflavus* (Krainisky 1914) Waksman and Henrici 1948 (Approved Lists 1980) – Publication in the IJSEM: Lanoot et al. (2005)
- Streptomyces lipmanii* (Waksman and Curtis 1916) Waksman and Henrici 1948 (Approved Lists 1980) pro synonym. *Streptomyces microflavus* (Krainisky 1914) Waksman and Henrici 1948 (Approved Lists 1980) – Publication in the IJSEM: Lanoot et al. (2005)
- Streptomyces nigrificiens* Waksman 1961 (Approved Lists 1980) pro synonym. *Streptomyces flavovirens* (Waksman 1923) Waksman and Henrici 1948 (Approved Lists 1980) – Publication in the IJSEM: Lanoot et al. (2005)
- Streptomyces phaevoviridis* Shinobu 1957 (Approved Lists 1980) pro synonym. *Streptomyces phaepurpureus* Shinobu 1957 (Approved Lists 1980) – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1 – Original publication: Lanoot et al. (2004)
- Streptomyces roseodiastaticus* (Duché 1934) Waksman 1953 (Approved Lists 1980) pro synonym. *Streptomyces tricolor* (Wollenweber 1920) Waksman 1961 (Approved Lists 1980) – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1 – Original publication: Lanoot et al. (2004)
- Streptomyces roseoflavus* Arai 1951 (Approved Lists 1980) pro synonym. *Streptomyces fradiae* (Waksman and Curtis 1916) Waksman and Henrici 1948 (Approved Lists 1980) – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1 – Original publication: Lanoot et al. (2004)
- Streptomyces roseosporus* Falcão de Moraes and Dália Maia 1961 (Approved Lists 1980) pro synonym. *Streptomyces filamentosus* Okami and Umezawa 1953 (Approved Lists 1980) – Publication in the IJSEM: List of Changes in Taxonomic Opinion no. 1 – Original publication: Lanoot et al. (2004)
- Streptomyces setonii* (Millard and Burr 1926) Waksman 1953 (Approved Lists 1980) pro synonym. *Streptomyces griseus* (Krainisky 1914) Waksman and Henrici 1948 (Approved Lists 1980) – Publication in the IJSEM: Z. Liu et al. (2005b)
- Streptomyces willmorei* (Erikson 1935) Waksman and Henrici 1948 (Approved Lists 1980) pro synonym. *Streptomyces microflavus* (Krainisky 1914) Waksman and Henrici 1948 (Approved Lists 1980) – Publication in the IJSEM: Lanoot et al. (2005)
- Syntrophospora* Zhao et al. 1990 pro synonym. *Syntrophomonas* McInerney et al. 1982 – Publication in the IJSEM: C. Wu et al. (2006) [Rule 37a(1)]
- C. Wu et al. 2006 propose to transfer *Syntrophospora bryantii* (Stieb and Schink 1985) Zhao et al. 1990 (the type species of the genus *Syntrophospora* Zhao et al. 1990) to the genus *Syntrophomonas* McInerney et al. 1982 as *Syntrophomonas bryantii* (Stieb and Schink 1985) C. Wu et al. 2006, comb. nov. According to Rule 37a(1), bacteriologists adhering to this proposal should change the name *Syntrophospora* Zhao et al. 1990 to *Syntrophomonas* McInerney et al. 1982. However, *Syntrophomonas bryantii* (Stieb and Schink 1985) C. Wu et al. 2006 is not validly published [see above *Syntrophomonas bryantii* (Stieb and Schink 1985) C. Wu et al. 2006, 2335]
- Thermoterrabacterium* Slobodkin et al. 1997 pro synonym. *Carboxydotherrmus* Svetlichny et al. 1991 – Publication in the IJSEM: Slobodkin et al. (2006a) [Rule 37a(1)]
- Trichlorobacter* De Wever et al. 2001 pro synonym. *Geobacter* Lovley et al. 1995 – Publication in the IJSEM: Nevin et al. (2007) [Rule 37a(1)]
- Wautersia eutropha* (Davis 1969) Vaneechoutte et al. 2004 pro synonym. *Cupriavidus necator* Makkar and Casida 1987 – Publication in the IJSEM: Vandamme and Coenye (2004)
- Wautersia* Vaneechoutte et al. 2004 pro synonym. *Cupriavidus* Makkar and Casida 1987 – Publication in the IJSEM: Vandamme and Coenye 2004 [Rule 37a(1)]
- Weissella kimchii* Choi et al. 2002 pro synonym. *Weissella cibaria* Björkroth et al. 2002 – Publication in the IJSEM: Ennahar and Cai (2004)

Blaut. 2007. *Clostridium saccharogumia* sp. nov. and *Lactonifactor longoviformis* gen. nov., sp. nov., two novel human faecal bacteria involved in the conversion of the dietary phytoestrogen secoisolariciresinol diglucoside. *Syst. Appl. Microbiol.* 30: 16–26.
- Cleenwerck, I., N. Camu, K. Engelbeen, T. De Winter, K. Vandemeulebroecke, P. De Vos and L. De Vuyst. 2007. *Acetobacter ghanensis* sp. nov., a novel acetic acid bacterium isolated from traditional heap fermentations of Ghanaian cocoa beans. *Int. J. Syst. Evol. Microbiol.* 57: 1647–1652.
- Cloud, J.L., J.J. Meyer, J.I. Pounder, K.C. Jost, Jr., A. Sweeney, K.C. Carroll and G.L. Woods. 2006. *Mycobacterium arupense* sp. nov., a non-chromogenic bacterium isolated from clinical specimens. *Int. J. Syst. Evol. Microbiol.* 56: 1413–1418.
- Coenye, T., D. Henry, D.P. Speert and P. Vandamme. 2004a. *Burkholderia phenoliruptrix* sp. nov., to accommodate the 2,4,5-trichlorophenoxyacetic acid and halophenol-degrading strain AC1100. *Syst. Appl. Microbiol.* 27: 623–627.
- Coenye, T., E. Vanlaere, E. Falsen and P. Vandamme. 2004b. *Stenotrophomonas africana* Drancourt *et al.* 1997 is a later synonym of *Stenotrophomonas maltophilia* (Hugh 1981) Palleroni and Bradbury 1993. *Int. J. Syst. Evol. Microbiol.* 54: 1235–1237.
- Coenye, T., E. Vanlaere, E. Samyn, E. Falsen, P. Larsson and P. Vandamme. 2005. *Adeenella incenata* gen. nov., sp. nov., a novel member of the *Alcaligenaceae*, isolated from various clinical samples. *Int. J. Syst. Evol. Microbiol.* 55: 251–256.
- Collins, M.D., E. Falsen, K. Brownlee and P.A. Lawson. 2004a. *Helcococcus sueciensis* sp. nov., isolated from a human wound. *Int. J. Syst. Evol. Microbiol.* 54: 1557–1560.
- Collins, M.D., L. Hoyles, G. Foster and E. Falsen. 2004b. *Corynebacterium caspium* sp. nov., from a Caspian seal (*Phoca caspica*). *Int. J. Syst. Evol. Microbiol.* 54: 925–928.
- Collins, M.D., T. Lundström, C. Welinder-Olsson, I. Hansson, O. Wattle, R.A. Hutson and E. Falsen. 2004c. *Streptococcus devriesei* sp. nov., from equine teeth. *Syst. Appl. Microbiol.* 27: 146–150.
- Collins, M.D., J. Routh, A. Saraswathy, P.A. Lawson, P. Schumann, C. Welinder-Olsson and E. Falsen. 2004d. *Arsenicicoccus bolidensis* gen. nov., sp. nov., a novel actinomycete isolated from contaminated lake sediment. *Int. J. Syst. Evol. Microbiol.* 54: 605–608.
- Collins, M.D., A. Wiernik, E. Falsen and P.A. Lawson. 2005. *Atopococcus tabaci* gen. nov., sp. nov., a novel Gram-positive, catalase-negative, coccus-shaped bacterium isolated from tobacco. *Int. J. Syst. Evol. Microbiol.* 55: 1693–1696.
- Conrads, G., D.M. Citron, R. Mutters, S. Jang and E.J.C. Goldstein. 2004. *Fusobacterium canifelinum* sp. nov., from the oral cavity of cats and dogs. *Syst. Appl. Microbiol.* 27: 407–413.
- Conville, P.S., J.M. Brown, A.G. Steigerwalt, J.W. Lee, V.L. Anderson, J.T. Fishbain, S.M. Holland and F.G. Witebsky. 2004. *Nocardia kruczakiae* sp. nov., a pathogen in immunocompromised patients and a member of the "N. nova complex". *J. Clin. Microbiol.* 42: 5139–5145.
- Cook, A.E., M. Roes and P.R. Meyers. 2005. *Actinomadura napiensis* sp. nov., isolated from soil in South Africa. *Int. J. Syst. Evol. Microbiol.* 55: 703–706.
- Cook, A.R., P.W. Riley, H. Murdoch, P.N. Evans and I.R. McDonald. 2007. *Howardella ureilytica* gen. nov., sp. nov., a Gram-positive, coccoid-shaped bacterium from a sheep rumen. *Int. J. Syst. Evol. Microbiol.* 57: 2940–2945.
- Cooksey, R.C., J.H. de Waard, M.A. Yakus, I. Rivera, M. Chopite, S.R. Toney, G.P. Morlock and W.R. Butler. 2004. *Mycobacterium cosmeticum* sp. nov., a novel rapidly growing species isolated from a cosmetic infection and from a nail salon. *Int. J. Syst. Evol. Microbiol.* 54: 2385–2391.
- Corsetti, A., L. Settanni, D. van Sinderen, G.E. Felis, F. Dellaglio and M. Gobbetti. 2005. *Lactobacillus rossii* sp. nov., isolated from wheat sourdough. *Int. J. Syst. Evol. Microbiol.* 55: 35–40.
- Coton, M., J.M. Laplace, Y. Auffray and E. Coton. 2006. Polyphasic study of *Zymomonas mobilis* strains revealing the existence of a novel subspecies *Z. mobilis* subsp. *francensis* subsp. nov., isolated from French cider. *Int. J. Syst. Evol. Microbiol.* 56: 121–125.
- Cotta, M.A., T.R. Whitehead, M.D. Collins and P.A. Lawson. 2004. *Atopostipes suicloacale* gen. nov., sp. nov., isolated from an underground swine manure storage pit. *Anaerobe*. 10: 191–195.
- Cousin, S., O. Pücker and E. Stackebrandt. 2007. *Flavobacterium aquidurense* sp. nov. and *Flavobacterium hercynium* sp. nov., from a hard-water creek. *Int. J. Syst. Evol. Microbiol.* 57: 243–249.
- Crapart, S., M.L. Fardeau, J.L. Cayol, P. Thomas, C. Sery, B. Ollivier and Y. Combet-Blanc. 2007. *Exiguobacterium profundum* sp. nov., a moderately thermophilic, lactic acid-producing bacterium isolated from a deep-sea hydrothermal vent. *Int. J. Syst. Evol. Microbiol.* 57: 287–292.
- Cravo-Laureau, C., R. Matheron, J.L. Cayol, C. Joulain and A. Hirschler-Réa. 2004a. *Desulfatibacillum aliphaticivorans* gen. nov., sp. nov., an n-alkane- and n-alkene-degrading, sulfate-reducing bacterium. *Int. J. Syst. Evol. Microbiol.* 54: 77–83.
- Cravo-Laureau, C., R. Matheron, C. Joulain, J.L. Cayol and A. Hirschler-Réa. 2004b. *Desulfatibacillum alkenivorans* sp. nov., a novel n-alkene-degrading, sulfate-reducing bacterium, and emended description of the genus *Desulfatibacillum*. *Int. J. Syst. Evol. Microbiol.* 54: 1639–1642.
- Cravo-Laureau, C., C. Labat, C. Joulain, R. Matheron and A. Hirschler-Réa. 2007. *Desulfatiferula olefinivorans* gen. nov., sp. nov., a long-chain n-alkene-degrading, sulfate-reducing bacterium. *Int. J. Syst. Evol. Microbiol.* 57: 2699–2702.

- Cui, H.L., D. Tohty, J. Feng, P.J. Zhou and S.J. Liu. 2006a. *Natronorubrum aibiense* sp. nov., an extremely halophilic archaeon isolated from Aibi salt lake in Xin-jiang, China, and emended description of the genus *Natronorubrum*. Int. J. Syst. Evol. Microbiol. 56: 1515–1517.
- Cui, H.L., D. Tohty, P.J. Zhou and S.J. Liu. 2006b. *Halorubrum lipolyticum* sp. nov. and *Halorubrum aidingense* sp. nov., isolated from two salt lakes in Xin-jiang, China. Int. J. Syst. Evol. Microbiol. 56: 1631–1634.
- Cui, H.L., D. Tohty, P.J. Zhou and S.J. Liu. 2006c. *Haloterrigena longa* sp. nov. and *Haloterrigena limicola* sp. nov., extremely halophilic archaea isolated from a salt lake. Int. J. Syst. Evol. Microbiol. 56: 1837–1840.
- Cui, H.L., D. Tohty, H.C. Liu, S.J. Liu, A. Oren and P.J. Zhou. 2007a. *Natronorubrum sulfidifaciens* sp. nov., an extremely haloalkaliphilic archaeon isolated from Aiding salt lake in Xin-jiang, China. Int. J. Syst. Evol. Microbiol. 57: 738–740.
- Cui, H.L., Z.Y. Lin, Y. Dong, P.J. Zhou and S.J. Liu. 2007b. *Halorubrum litoreum* sp. nov., an extremely halophilic archaeon from a solar salt-ern. Int. J. Syst. Evol. Microbiol. 57: 2204–2206.
- Cui, Q., L. Wang, Y. Huang, Z. Liu and M. Goodfellow. 2005. *Nocardia jiangxiensis* sp. nov. and *Nocardia miyunensis* sp. nov., isolated from acidic soils. Int. J. Syst. Evol. Microbiol. 55: 1921–1925.
- Cui, X., P. Schumann, E. Stackebrandt, R.M. Kroppenstedt, R. Pukall, L. Xu, M. Rohde and C. Jiang. 2004. *Myceligeners xiligouense* gen. nov., sp. nov., a novel hyphae-forming member of the family *Promicromonosporaceae*. Int. J. Syst. Evol. Microbiol. 54: 1287–1293.
- Cui, Y.S., W.T. Im, C.R. Yin, J.S. Lee, K.C. Lee and S.T. Lee. 2007a. *Aeromicrobium panaciterrae* sp. nov., isolated from soil of a ginseng field in South Korea. Int. J. Syst. Evol. Microbiol. 57: 687–691.
- Cui, Y.S., W.T. Im, C.R. Yin, D.C. Yang and S.T. Lee. 2007b. *Microclunatus ginsengisoli* sp. nov., isolated from soil of a ginseng field. Int. J. Syst. Evol. Microbiol. 57: 713–716.
- Cunha, S., I. Tiago, A.L. Pires, M.S. da Costa and A. Veríssimo. 2006. *Dokdonella fugitiva* sp. nov., a *Gammaproteobacterium* isolated from potting soil. Syst. Appl. Microbiol. 29: 191–196.
- Dahle, H. and N.K. Birkeland. 2006. *Thermovirga lienii* gen. nov., sp. nov., a novel moderately thermophilic, anaerobic, amino-acid-degrading bacterium isolated from a North Sea oil well. Int. J. Syst. Evol. Microbiol. 56: 1539–1545.
- Dai, X., Y.N. Wang, B.J. Wang, S.J. Liu and Y.G. Zhou. 2005. *Planomicrobium chinense* sp. nov., isolated from coastal sediment, and transfer of *Planococcus psychrophilus* and *Planococcus alkanoclasticus* to *Planomicrobium* as *Planomicrobium psychrophilum* comb. nov. and *Planomicrobium alkanoclasticum* comb. nov. Int. J. Syst. Evol. Microbiol. 55: 699–702.
- Dai, X., B.J. Wang, Q.X. Yang, N.Z. Jiao and S.J. Liu. 2006. *Yangia pacifica* gen. nov., sp. nov., a novel member of the *Roseobacter* clade from coastal sediment of the East China Sea. Int. J. Syst. Evol. Microbiol. 56: 529–533.
- Daneshvar, M.I., D.G. Hollis, R.S. Weyant, J.G. Jordan, J.P. Macgregor, R.E. Morey, A.M. Whitney, D.J. Brenner, A.G. Steigerwalt, L.O. Helsen, P.M. Raney, J.B. Patel J.B., P.N. Levett and J.M. Brown. 2004. Identification of some charcoal-black-pigmented CDC fermentative coryneform group 4 isolates as *Rothia dentocariosa* and some as *Corynebacterium aurimucosum*: proposal of *Rothia dentocariosa* emend. Georg and Brown 1967, *Corynebacterium aurimucosum* emend. Yassin *et al.* 2002, and *Corynebacterium nigricans* Shukla *et al.* 2003 pro synonym. *Corynebacterium aurimucosum*. J. Clin. Microbiol. 42: 4189–4198.
- Davidov, Y. and E. Jurkevitch. 2004. Diversity and evolution of *Bdellovibrio*-and-like organisms (BALOs), reclassification of *Bacteriovorax starrii* as *Peredibacter starrii* gen. nov., comb. nov., and description of the *Bacteriovorax*–*Peredibacter* clade as *Bacteriovoracaceae* fam. nov. Int. J. Syst. Evol. Microbiol. 54: 1439–1452.
- Davidova, I.A., K.E. Duncan, O.K. Choi and J.M. Suflita. 2006. *Desulfoglaeba alkanexedens* gen. nov., sp. nov., an n-alkane-degrading, sulfate-reducing bacterium. Int. J. Syst. Evol. Microbiol. 56: 2737–2742.
- de Beer, H., C.J. Hugo, P.J. Jooste, A. Willems, M. Vancanneyt, T. Coenye and P.A. Vandamme. 2005. *Chryseobacterium vrystaateense* sp. nov., isolated from raw chicken in a chicken-processing plant. Int. J. Syst. Evol. Microbiol. 55: 2149–2153.
- de Beer, H., C.J. Hugo, P.J. Jooste, M. Vancanneyt, T. Coenye and P. Vandamme. 2006. *Chryseobacterium piscium* sp. nov., isolated from fish of the South Atlantic Ocean off South Africa. Int. J. Syst. Evol. Microbiol. 56: 1317–1322.
- de Boer, W., J.H. Leveau, G.A. Kowalchuk, P.J. Klein Gunnewiek, E.C. Abeln, M.J. Figge, K. Sjollema, J.D. Janse and J.A. van Veen. 2004. *Collimonas fungivorans* gen. nov., sp. nov., a chitinolytic soil bacterium with the ability to grow on living fungal hyphae. Int. J. Syst. Evol. Microbiol. 54: 857–864.
- de Bok, F.A., H.J. Harmsen, C.M. Plugge, M.C. de Vries, A.D. Akkermans, W.M. de Vos and A.J. Stams. 2005. The first true obligately syntrophic propionate-oxidizing bacterium, *Pelotomaculum schinkii* sp. nov., co-cultured with *Methanospirillum hungatei*, and emended description of the genus *Pelotomaculum*. Int. J. Syst. Evol. Microbiol. 55: 1697–1703.
- De Bruyne, K., U. Schillinger, L. Caroline, B. Boehringer, I. Cleenwerck, M. Vancanneyt, L. De Vuyst, C.M. Franz and P. Vandamme. 2007. *Leuconostoc holzapfelii* sp. nov., isolated from Ethiopian coffee fermentation and assessment of sequence analysis of housekeeping genes for delineation of *Leuconostoc* species. Int. J. Syst. Evol. Microbiol. 57: 2952–2959.
- De Clerck, E., M. Rodríguez-Díaz, G. Forsyth, L. Lebbe, N.A. Logan and P. De Vos. 2004a. Polyphasic characterization of *Bacillus coagulans* strains, illustrating heterogeneity within this species, and emended description of the species. Syst. Appl. Microbiol. 27: 50–60.
- De Clerck, E., M. Rodríguez-Díaz, T. Vanhoutte, J. Heyrman, N.A. Logan and P. De Vos. 2004b. *Anoxybacillus contaminans* sp. nov. and *Bacillus gelatini* sp. nov., isolated from contaminated gelatin batches. Int. J. Syst. Evol. Microbiol. 54: 941–946.
- De Clercq, D., S. Van Trappen, I. Cleenwerck, A. Ceustermans, J. Swings, J. Coosemans and J. Ryckeboer. 2006. *Rhodanobacter spathiphylli* sp. nov., a gammaproteobacterium isolated from the roots of *Spathiphyllum* plants grown in a compost-amended potting mix. Int. J. Syst. Evol. Microbiol. 56: 1755–1759.
- de Groot, A., V. Chapon, P. Servant, R. Christen, M.F. Saux, S. Sommer and T. Heulin. 2005. *Deinococcus deserti* sp. nov., a gamma-radiation-tolerant bacterium isolated from the Sahara Desert. Int. J. Syst. Evol. Microbiol. 55: 2441–2446.
- Dedysh, S.N., Y.Y. Berestovskaya, L.V. Vasylieva, S.E. Belova, V.N. Khmeleina, N.E. Suzina, Y.A. Trotsenko, W. Liesack and G.A. Zavarzin. 2004. *Methylocella tundrae* sp. nov., a novel methanotrophic bacterium from acidic tundra peatlands. Int. J. Syst. Evol. Microbiol. 54: 151–156.
- Dedysh, S.N., S.E. Belova, P.L. Bodelier, K.V. Smirnova, V.N. Khmeleina, A. Chidthaisong, Y.A. Trotsenko, W. Liesack and P.F. Dunfield. 2007. *Methylocystis heyeri* sp. nov., a novel type II methanotrophic bacterium possessing ‘signature’ fatty acids of type I methanotrophs. Int. J. Syst. Evol. Microbiol. 57: 472–479.
- Delgado, O., J. Quillaguamán, S. Bakhtiar, B. Mattiasson, A. Gessesse and R. Hatti-Kaul. 2006. *Nesterenkonia aethiopica* sp. nov., an alkaliphilic, moderate halophile isolated from an Ethiopian soda lake. Int. J. Syst. Evol. Microbiol. 56: 1229–1232.
- Dellaglio, F., S. Torriani and G.E. Felis. 2004. Reclassification of *Lactobacillus cellobiosus* Rogosa *et al.* 1953 as a later synonym of *Lactobacillus fermentum* Beijerinck 1901. Int. J. Syst. Evol. Microbiol. 54: 809–812.
- Dellaglio, F., I. Cleenwerck, G.E. Felis, K. Engelbeen, D. Janssens and M. Marzotto. 2005a. Description of *Gluconacetobacter swingsii* sp. nov. and *Gluconacetobacter rhaeticus* sp. nov., isolated from Italian apple fruit. Int. J. Syst. Evol. Microbiol. 55: 2365–2370.
- Dellaglio, F., G.E. Felis, A. Castioni, S. Torriani and J.E. Germond. 2005b. *Lactobacillus delbrueckii* subsp. *indicus* subsp. nov., isolated from Indian dairy products. Int. J. Syst. Evol. Microbiol. 55: 401–404.
- Dellaglio, F., M. Vancanneyt, A. Endo, P. Vandamme, G.E. Felis, A. Castioni, J. Fujimoto, K. Watanabe and S. Okada. 2006. *Lactobacillus durianis* Leisner *et al.* 2002 is a later heterotypic synonym of *Lactobacillus*

- vaccinostercus* Kozaki and Okada 1983. *Int. J. Syst. Evol. Microbiol.* 56: 1721–1724.
- Denner, E.B., M. Kolari, D. Hoornstra, I. Tsitko, P. Kämpfer, H.J. Busse and M. Salkinoja-Salonen. 2006. *Rubellimicrobium thermophilum* gen. nov., sp. nov., a red-pigmented, moderately thermophilic bacterium isolated from coloured slime deposits in paper machines. *Int. J. Syst. Evol. Microbiol.* 56: 1355–1362.
- Derrien, M., E.E. Vaughan, C.M. Plugge and W.M. de Vos. 2004. *Akkermansia muciniphila* gen. nov., sp. nov., a human intestinal mucin-degrading bacterium. *Int. J. Syst. Evol. Microbiol.* 54: 1469–1476.
- Derz, K., U. Klinner, I. Schuphan, E. Stackebrandt and R.M. Kroppenstedt. 2004. *Mycobacterium pyrenivorans* sp. nov., a novel polycyclic-aromatic-hydrocarbon-degrading species. *Int. J. Syst. Evol. Microbiol.* 54: 2313–2317.
- Devriese, L.A., M. Vancanneyt, M. Baele, M. Vaneechoutte, E. De Graef, C. Snauwaert, I. Cleenwerck, P. Dawyndt, J. Swings, A. Decostere and F. Haesebrouck. 2005. *Staphylococcus pseudintermedius* sp. nov., a coagulase-positive species from animals. *Int. J. Syst. Evol. Microbiol.* 55: 1569–1573.
- Dhia Thabet, O.B., M.L. Fardeau, C. Suarez-Núñez, M. Hamdi, P. Thomas, B. Ollivier and D. Alazard. 2007. *Desulfovibrio marinus* sp. nov., a moderately halophilic sulfate-reducing bacterium isolated from marine sediments in Tunisia. *Int. J. Syst. Evol. Microbiol.* 57: 2167–2170.
- Díaz, C., S. Baena, M.L. Fardeau and B.K. Patel. 2007. *Aminiphilus circumscriptus* gen. nov., sp. nov., an anaerobic amino-acid-degrading bacterium from an upflow anaerobic sludge reactor. *Int. J. Syst. Evol. Microbiol.* 57: 1914–1918.
- Dimitriu, P.A., S.K. Shukla, J. Conradt, M.C. Márquez, A. Ventosa, A. Maglia, B.M. Peyton, H.C. Pinkart and M.R. Mormile. 2005. *Nitrincola lacisaponensis* gen. nov., sp. nov., a novel alkaliphilic bacterium isolated from an alkaline, saline lake. *Int. J. Syst. Evol. Microbiol.* 55: 2273–2278.
- Ding, L. and A. Yokota. 2004. Proposals of *Curvibacter gracilis* gen. nov., sp. nov. and *Herbaspirillum putei* sp. nov. for bacterial strains isolated from well water and reclassification of [*Pseudomonas*] *huttiensis*, [*Pseudomonas*] *lanceolata*, [*Aquaspirillum*] *delicatum* and [*Aquaspirillum*] *autotrophicum* as *Herbaspirillum huttiense* comb. nov., *Curvibacter lanceolatus* comb. nov., *Curvibacter delicatus* comb. nov. and *Herbaspirillum autotrophicum* comb. nov. *Int. J. Syst. Evol. Microbiol.* 54: 2223–2230.
- Ding, L., T. Hirose and A. Yokota. 2007. *Amycolatopsis echigomensis* sp. nov. and *Amycolatopsis niigatensis* sp. nov., novel actinomycetes isolated from a filtration substrate. *Int. J. Syst. Evol. Microbiol.* 57: 1747–1751.
- Donachie, S.P., J.P. Bowman and M. Alam. 2004. *Psychroflexus tropicus* sp. nov., an obligately halophilic *Cytophaga-Flavobacterium-Bacteroides* group bacterium from a Hawaiian hypersaline lake. *Int. J. Syst. Evol. Microbiol.* 54: 935–940.
- Donachie, S.P., J.P. Bowman, S.L. On and M. Alam. 2005. *Arcobacter halophilus* sp. nov., the first obligate halophile in the genus *Arcobacter*. *Int. J. Syst. Evol. Microbiol.* 55: 1271–1277.
- Donachie, S.P., J.P. Bowman and M. Alam. 2006. *Nesiotobacter exalbescens* gen. nov., sp. nov., a moderately thermophilic alphaproteobacterium from an Hawaiian hypersaline lake. *Int. J. Syst. Evol. Microbiol.* 56: 563–567.
- Dong, Z., X. Guo, X. Zhang, F. Qiu, L. Sun, H. Gong and F. Zhang. 2007. *Dyadobacter beijingsensis* sp. nov., isolated from the rhizosphere of turf grasses in China. *Int. J. Syst. Evol. Microbiol.* 57: 862–865.
- Doronina, N.V., Y.A. Trotsenko, T.V. Kolganova, T.P. Tourova and M.S. Salkinoja-Salonen. 2004. *Methylobacillus pratensis* sp. nov., a novel non-pigmented, aerobic, obligately methylotrophic bacterium isolated from meadow grass. *Int. J. Syst. Evol. Microbiol.* 54: 1453–1457.
- Doronina, N.V., E.G. Ivanova and Y.A. Trotsenko. 2005. Phylogenetic position and emended description of the genus *Methylovorus*. *Int. J. Syst. Evol. Microbiol.* 55: 903–906.

Sekiguchi. 2007. *Bellilinea caldifistulae* gen. nov., sp. nov. and *Longilinea arvoryzae* gen. nov., sp. nov., strictly anaerobic, filamentous bacteria of the phylum *Chloroflexi* isolated from methanogenic propionate-degrading consortia. Int. J. Syst. Evol. Microbiol. 57: 2299–2306.
- Yamamura, H., M. Hayakawa, Y. Nakagawa, T. Tamura, T. Kohno, F. Komatsu and Y. Imura. 2005. *Nocardia takedensis* sp. nov., isolated from moat sediment and scumming activated sludge. Int. J. Syst. Evol. Microbiol. 55: 433–436.
- Yamamura, H., T. Tamura, Y. Sakiyama and S. Harayama. 2007. *Nocardia amamiensis* sp. nov., isolated from a sugar-cane field in Japan. Int. J. Syst. Evol. Microbiol. 57: 1599–1602.
- Yamamura, S., M. Yamashita, N. Fujimoto, M. Kuroda, M. Kashiwa, K. Sei, M. Fujita and M. Ike. 2007. *Bacillus selenatarsenatis* sp. nov., a selenate- and arsenate-reducing bacterium isolated from the effluent drain of a glass-manufacturing plant. Int. J. Syst. Evol. Microbiol. 57: 1060–1064.

- Yamashita, S., T. Uchimura and K. Komagata. 2004. Emendation of the genus *Acidomonas* Urakami, Tamaoka, Suzuki and Komagata 1989. *Int. J. Syst. Evol. Microbiol.* 54: 865–870.
- Yang, D.C., W.T. Im, M.K. Kim and S.T. Lee. 2005. *Pseudoxanthomonas korensis* sp. nov. and *Pseudoxanthomonas daejeonensis* sp. nov. *Int. J. Syst. Evol. Microbiol.* 55: 787–791.
- Yang, D.C., W.T. Im, M.K. Kim, H. Ohta and S.T. Lee. 2006. *Sphingomonas soli* sp. nov., a beta-glucosidase-producing bacterium in the family *Sphingomonadaceae* in the alpha-4 subgroup of the *Proteobacteria*. *Int. J. Syst. Evol. Microbiol.* 56: 703–707.
- Yang, H.C., W.T. Im, D.S. An, W.S. Park, I.S. Kim and S.T. Lee. 2005. *Silvimonas terrae* gen. nov., sp. nov., a novel chitin-degrading facultative anaerobe belonging to the 'Betaproteobacteria'. *Int. J. Syst. Evol. Microbiol.* 55: 2329–2332.
- Yang, H.C., W.T. Im, M.S. Kang, D.Y. Shin and S.T. Lee. 2006a. *Stenotrophomonas korensis* sp. nov., isolated from compost in South Korea. *Int. J. Syst. Evol. Microbiol.* 56: 81–84.
- Yang, H.C., W.T. Im, K.K. Kim, D.S. An and S.T. Lee. 2006b. *Burkholderia terrae* sp. nov., isolated from a forest soil. *Int. J. Syst. Evol. Microbiol.* 56: 453–457.
- Yang, S.H., K.K. Kwon, H.S. Lee and S.J. Kim. 2006. *Shewanella spongiae* sp. nov., isolated from a marine sponge. *Int. J. Syst. Evol. Microbiol.* 56: 2879–2882.
- Yang, S.H., J.H. Lee, J.S. Ryu, C. Kato and S.J. Kim. 2007. *Shewanella donghaensis* sp. nov., a psychrophilic, piezosensitive bacterium producing high levels of polyunsaturated fatty acid, isolated from deep-sea sediments. *Int. J. Syst. Evol. Microbiol.* 57: 208–212.
- Yang, S.J., Y.J. Choo and J.C. Cho. 2007. *Lutimonas vermicola* gen. nov., sp. nov., a member of the family *Flavobacteriaceae* isolated from the marine polychaete *Periserrula leucophryna*. *Int. J. Syst. Evol. Microbiol.* 57: 1679–1684.
- Yang, Y., H.L. Cui, P.J. Zhou and S.J. Liu. 2006. *Halobacterium jilantaiense* sp. nov., a halophilic archaeon isolated from a saline lake in Inner Mongolia, China. *Int. J. Syst. Evol. Microbiol.* 56: 2353–2355.
- Yang, Y., H.L. Cui, P.J. Zhou and S.J. Liu. 2007. *Haloarcula amylobytica* sp. nov., an extremely halophilic archaeon isolated from Aibi salt lake in Xin-Jiang, China. *Int. J. Syst. Evol. Microbiol.* 57: 103–106.
- Yassin, A.F. 2005. *Rhodococcus triatomae* sp. nov., isolated from a blood-sucking bug. *Int. J. Syst. Evol. Microbiol.* 55: 1575–1579.
- Yassin, A.F. 2007. *Corynebacterium ureiceleivorans* sp. nov., a lipophilic bacterium isolated from blood culture. *Int. J. Syst. Evol. Microbiol.* 57: 1200–1203.
- Yassin, A.F. and S. Brenner. 2005. *Nocardia elegans* sp. nov., a member of the *Nocardia vaccinii* clade isolated from sputum. *Int. J. Syst. Evol. Microbiol.* 55: 1505–1509.
- Yassin, A.F. and H. Hupfer. 2006. *Williamsia deligens* sp. nov., isolated from human blood. *Int. J. Syst. Evol. Microbiol.* 56: 193–197.
- Yassin, A.F. and K.P. Schaal. 2005. Reclassification of *Nocardia corynebacterioides* Serrano *et al.* 1972 (Approved Lists 1980) as *Rhodococcus corynebacterioides* comb. nov. *Int. J. Syst. Evol. Microbiol.* 55: 1345–1348.
- Yassin, A.F., H. Hupfer and K.P. Schaal. 2006. *Dietzia cinnamea* sp. nov., a novel species isolated from a perianal swab of a patient with a bone marrow transplant. *Int. J. Syst. Evol. Microbiol.* 56: 641–645.
- Yassin, A.F., W.M. Chen, H. Hupfer, C. Siering, R.M. Kroppenstedt, A.B. Arun, W.A. Lai, F.T. Shen, P.D. Rekha and C.C. Young. 2007a. *Lysobacter defluvii* sp. nov., isolated from municipal solid waste. *Int. J. Syst. Evol. Microbiol.* 57: 1131–1136.
- Yassin, A.F., F.T. Shen, H. Hupfer, A.B. Arun, W.A. Lai, P.D. Rekha and C.C. Young. 2007b. *Gordonia malaquae* sp. nov., isolated from sludge of a wastewater treatment plant. *Int. J. Syst. Evol. Microbiol.* 57: 1065–1068.
- Yassin, A.F., C.C. Young, W.A. Lai, H. Hupfer, A.B. Arun, F.T. Shen, P.D. Rekha and M.J. Ho. 2007c. *Williamsia serinedens* sp. nov., isolated from an oil-contaminated soil. *Int. J. Syst. Evol. Microbiol.* 57: 558–561.
- Yi, H. and J. Chun. 2004a. *Hongiella mannitolivorans* gen. nov., sp. nov., *Hongiella halophila* sp. nov. and *Hongiella ornithinivorans* sp. nov., isolated from tidal flat sediment. *Int. J. Syst. Evol. Microbiol.* 54: 157–162.
- Yi, H. and J. Chun. 2004b. *Nocardioides ganghuensis* sp. nov., isolated from tidal flat sediment. *Int. J. Syst. Evol. Microbiol.* 54: 1295–1299.

- Yi, H. and J. Chun. 2006b. *Flavobacterium weaverense* sp. nov. and *Flavobacterium segetis* sp. nov., novel psychrophiles isolated from the Antarctic. *Int. J. Syst. Evol. Microbiol.* 56: 1239–1244.
- Yi, H., K.S. Bae and J. Chun. 2004a. *Thalassomonas ganghuensis* sp. nov., isolated from tidal flat sediment. *Int. J. Syst. Evol. Microbiol.* 54: 377–380.
- Yi, H., K.S. Bae and J. Chun. 2004b. *Aestuuriibacter salexigens* gen. nov., sp. nov. and *Aestuuriibacter halophilus* sp. nov., isolated from tidal flat sediment, and emended description of *Alteromonas macleodii*. *Int. J. Syst. Evol. Microbiol.* 54: 571–576.
- Yi, H., P. Schumann, K. Sohn and J. Chun. 2004c. *Serinicoccus marinus* gen. nov., sp. nov., a novel actinomycete with L-ornithine and L-serine in the peptidoglycan. *Int. J. Syst. Evol. Microbiol.* 54: 1585–1589.
- Yi, H., H.M. Oh, J.H. Lee, S.J. Kim and J. Chun. 2005a. *Flavobacterium antarcticum* sp. nov., a novel psychrotolerant bacterium isolated from the Antarctic. *Int. J. Syst. Evol. Microbiol.* 55: 637–641.
- Yi, H., H.I. Yoon and J. Chun. 2005b. *Sejongia antarctica* gen. nov., sp. nov. and *Sejongia jeonii* sp. nov., isolated from the Antarctic. *Int. J. Syst. Evol. Microbiol.* 55: 409–416.
- Yi, H., Y.W. Lim and J. Chun. 2007a. Taxonomic evaluation of the genera *Ruegeria* and *Silicibacter*: a proposal to transfer the genus *Silicibacter* Petrusdotter and Kristjansson 1999 to the genus *Ruegeria* Uchino *et al.* 1999. *Int. J. Syst. Evol. Microbiol.* 57: 815–819.
- Yi, H., P. Schumann and J. Chun. 2007b. *Demequina aestuarii* gen. nov., sp. nov., a novel actinomycete of the suborder *Micrococccineae*, and reclassification of *Cellulomonas fermentans* Bagnara *et al.* 1985 as *Actinotalea fermentans* gen. nov., comb. nov. *Int. J. Syst. Evol. Microbiol.* 57: 151–156.
- Ying, J.Y., B.J. Wang, S.S. Yang and S.J. Liu. 2006. *Cyclobacterium lianum* sp. nov., a marine bacterium isolated from sediment of an oilfield in the South China Sea, and emended description of the genus *Cyclobacterium*. *Int. J. Syst. Evol. Microbiol.* 56: 2927–2930.
- Ying, J.Y., Z.P. Liu, B.J. Wang, X. Dai, S.S. Yang and S.J. Liu. 2007a. *Salegentibacter catena* sp. nov., isolated from the sediment of the South China Sea, and emended description of the genus *Salegentibacter*. *Int. J. Syst. Evol. Microbiol.* 57: 219–222.
- Ying, J.Y., B.J. Wang, X. Dai, S.S. Yang, S.J. Liu and Z.P. Liu. 2007b. *Wenxinia marina* gen. nov., sp. nov., a novel member of the *Roseobacter* clade isolated from oilfield sediments of the South China Sea. *Int. J. Syst. Evol. Microbiol.* 57: 1711–1716.
- Yong, J.J., S.J. Park, H.J. Kim and S.K. Rhee. 2007. *Glaciicola agarilytica* sp. nov., an agar-digesting marine bacterium from the East Sea, Korea. *Int. J. Syst. Evol. Microbiol.* 57: 951–953.
- Yoo, S.H., H.Y. Weon, B.Y. Kim, S.B. Hong, S.W. Kwon, Y.H. Cho, S.J. Go and E. Stackebrandt. 2006. *Devosia soli* sp. nov., isolated from greenhouse soil in Korea. *Int. J. Syst. Evol. Microbiol.* 56: 2689–2692.
- Yoo, S.H., B.Y. Kim, H.Y. Weon, S.W. Kwon, S.J. Go and E. Stackebrandt. 2007a. *Burkholderia soli* sp. nov., isolated from soil cultivated with Korean ginseng. *Int. J. Syst. Evol. Microbiol.* 57: 122–125.
- Yoo, S.H., H.Y. Weon, H.B. Jang, B.Y. Kim, S.W. Kwon, S.J. Go and E. Stackebrandt. 2007b. *Sphingobacterium composti* sp. nov., isolated from cotton-waste composts. *Int. J. Syst. Evol. Microbiol.* 57: 1590–1593.
- Yoo, S.H., H.Y. Weon, B.Y. Kim, J.H. Kim, Y.K. Baek, S.W. Kwon, S.J. Go and E. Stackebrandt. 2007c. *Pseudoxanthomonas yeongjuensis* sp. nov., isolated from soil cultivated with Korean ginseng. *Int. J. Syst. Evol. Microbiol.* 57: 646–649.
- Yoon, J., S. Maneerat, F. Kawai and A. Yokota. 2006. *Myroides pelagicus* sp. nov., isolated from seawater in Thailand. *Int. J. Syst. Evol. Microbiol.* 56: 1917–1920.
- Yoon, J., S. Ishikawa, H. Kasai and A. Yokota. 2007a. *Perexilibacter aurantiacus* gen. nov., sp. nov., a novel member of the family 'Flammeovirgaceae' isolated from sediment. *Int. J. Syst. Evol. Microbiol.* 57: 964–968.

- Yoon, J., S. Ishikawa, H. Kasai and A. Yokota. 2007b. *Persicitalea jodogahamensis* gen. nov., sp. nov., a marine bacterium of the family *Flexibacteraceae*, isolated from seawater in Japan. *Int. J. Syst. Evol. Microbiol.* 57: 1014–1017.
- Yoon, J., Y. Matsuo, S. Matsuda, K. Adachi, H. Kasai and A. Yokota. 2007c. *Cerasiococcus arenae* gen. nov., sp. nov., a carotenoid-producing marine representative of the family *Puniceococcaceae* within the phylum *Verrucomicrobia*, isolated from marine sand. *Int. J. Syst. Evol. Microbiol.* 57: 2067–2072.
- Yoon, J., Y. Matsuo, S. Matsuda, K. Adachi, H. Kasai and A. Yokota. 2007d. *Rubritalea spongiae* sp. nov. and *Rubritalea tangerina* sp. nov., two carotenoid- and squalene-producing marine bacteria of the family *Verrucomicrobiaceae* within the phylum *Verrucomicrobia*, isolated from marine animals. *Int. J. Syst. Evol. Microbiol.* 57: 2337–2343.
- Yoon, J., N. Oku, S. Matsuda, H. Kasai and A. Yokota. 2007e. *Pelagicoccus croceus* sp. nov., a novel marine member of the family *Puniceococcaceae* within the phylum *Verrucomicrobia* isolated from seagrass. *Int. J. Syst. Evol. Microbiol.* 57: 2874–2880.
- Yoon, J., M. Yasumoto-Hirose, A. Katsuta, H. Sekiguchi, S. Matsuda, H. Kasai and A. Yokota. 2007f. *Coraliomargarita akajimensis* gen. nov., sp. nov., a novel member of the phylum *Verrucomicrobia* isolated from seawater in Japan. *Int. J. Syst. Evol. Microbiol.* 57: 959–963.
- Yoon, J., M. Yasumoto-Hirose, Y. Matsuo, M. Nozawa, S. Matsuda, H. Kasai and A. Yokota. 2007g. *Pelagicoccus mobilis* gen. nov., sp. nov., *Pelagicoccus albus* sp. nov. and *Pelagicoccus litoralis* sp. nov., three novel members of subdivision 4 within the phylum *Verrucomicrobia*, isolated from seawater by in situ cultivation. *Int. J. Syst. Evol. Microbiol.* 57: 1377–1385.
- Yoon, J.H., K.H. Kang, T.K. Oh and Y.H. Park. 2004a. *Halobacillus locisalis* sp. nov., a halophilic bacterium isolated from a marine solar saltern of the Yellow Sea in Korea. *Extremophiles* 8: 23–28.
- Yoon, J.H., K.H. Kang, T.K. Oh and Y.H. Park. 2004b. *Erythrobacter aquimaris* sp. nov., isolated from sea water of a tidal flat of the Yellow Sea in Korea. *Int. J. Syst. Evol. Microbiol.* 54: 1981–1985.
- Yoon, J.H., K.H. Kang, T.K. Oh and Y.H. Park. 2004c. *Shewanella gaetbuli* sp. nov., a slight halophile isolated from a tidal flat in Korea. *Int. J. Syst. Evol. Microbiol.* 54: 487–491.
- Yoon, J.H., I.G. Kim, K.H. Kang, T.K. Oh and Y.H. Park. 2004d. *Nocardioides aquiterrae* sp. nov., isolated from groundwater in Korea. *Int. J. Syst. Evol. Microbiol.* 54: 71–75.
- Yoon, J.H., I.G. Kim, K.H. Kang, T.K. Oh and Y.H. Park. 2004e. *Bacillus hwajinpoensis* sp. nov. and an unnamed *Bacillus* genomospecies, novel members of *Bacillus* rRNA group 6 isolated from sea water of the East Sea and the Yellow Sea in Korea. *Int. J. Syst. Evol. Microbiol.* 54: 803–808.
- Yoon, J.H., I.G. Kim, T.K. Oh and Y.H. Park. 2004f. *Microbulbifer maritimus* sp. nov., isolated from an intertidal sediment from the Yellow Sea, Korea. *Int. J. Syst. Evol. Microbiol.* 54: 1111–1116.
- Yoon, J.H., I.G. Kim, P. Schumann, T.K. Oh and Y.H. Park. 2004g. *Marinibacillus campisalis* sp. nov., a moderate halophile isolated from a marine solar saltern in Korea, with emended description of the genus *Marinibacillus*. *Int. J. Syst. Evol. Microbiol.* 54: 1317–1321.
- Yoon, J.H., M.H. Lee and T.K. Oh. 2004h. *Porphyrobacter donghaensis* sp. nov., isolated from sea water of the East Sea in Korea. *Int. J. Syst. Evol. Microbiol.* 54: 2231–2235.
- Yoon, J.H., H.B. Lee, S.H. Yeo and J.E. Choi. 2004i. *Janibacter melonis* sp. nov., isolated from abnormally spoiled oriental melon in Korea. *Int. J. Syst. Evol. Microbiol.* 54: 1975–1980.
- Yoon, J.H., T.K. Oh and Y.H. Park. 2004j. *Kangiella koreensis* gen. nov., sp. nov. and *Kangiella aquimarina* sp. nov., isolated from a tidal flat of the Yellow Sea in Korea. *Int. J. Syst. Evol. Microbiol.* 54: 1829–1835.
- Yoon, J.H., T.K. Oh and Y.H. Park. 2004k. Transfer of *Bacillus halodenitrificans* Denariet al. 1989 to the genus *Virgibacillus* as *Virgibacillus halodenitrificans* comb. nov. *Int. J. Syst. Evol. Microbiol.* 54: 2163–2167.
- Yoon, J.H., S.H. Yeo, I.G. Kim and T.K. Oh. 2004l. *Marinobacter flavimaris* sp. nov. and *Marinobacter daejeonensis* sp. nov., slightly halophilic organisms isolated from sea water of the Yellow Sea in Korea. *Int. J. Syst. Evol. Microbiol.* 54: 1799–1803.
- Yoon, J.H., S.H. Yeo, T.K. Oh and Y.H. Park. 2004m. *Alteromonas litorea* sp. nov., a slightly halophilic bacterium isolated from an intertidal sediment of the Yellow Sea in Korea. *Int. J. Syst. Evol. Microbiol.* 54: 1197–1201.
- Yoon, J.H., S.H. Yeo, I.G. Kim and T.K. Oh. 2004n. *Shewanella marisflavi* sp. nov. and *Shewanella aquimarina* sp. nov., slightly halophilic organisms isolated from sea water of the Yellow Sea in Korea. *Int. J. Syst. Evol. Microbiol.* 54: 2347–2352.
- Yoon, J.H., S.H. Yeo and T.K. Oh. 2004o. *Hongiella marincola* sp. nov., isolated from sea water of the East Sea in Korea. *Int. J. Syst. Evol. Microbiol.* 54: 1845–1848.
- Yoon, J.H. and T.K. Oh. 2005a. *Sphingopyxis flavimaris* sp. nov., isolated from sea water of the Yellow Sea in Korea. *Int. J. Syst. Evol. Microbiol.* 55: 369–373.
- Yoon, J.H. and T.K. Oh. 2005b. *Bacillus litoralis* sp. nov., isolated from a tidal flat of the Yellow Sea in Korea. *Int. J. Syst. Evol. Microbiol.* 55: 1945–1948.
- Yoon, J.H., K.H. Kang, S.H. Yeo and T.K. Oh. 2005a. *Erythrobacter luteolus* sp. nov., isolated from a tidal flat of the Yellow Sea in Korea. *Int. J. Syst. Evol. Microbiol.* 55: 1167–1170.
- Yoon, J.H., S.J. Kang, S.Y. Jung, C.H. Lee and T.K. Oh. 2005b. *Algoriphagus yeomjeoni* sp. nov., isolated from a marine solar saltern in the Yellow Sea, Korea. *Int. J. Syst. Evol. Microbiol.* 55: 865–870.
- Yoon, J.H., S.J. Kang, C.H. Lee and T.K. Oh. 2005c. *Marinicola seohaensis* gen. nov., sp. nov., isolated from sea water of the Yellow Sea, Korea. *Int. J. Syst. Evol. Microbiol.* 55: 859–863.

- Zhang, Y.Q., W.J. Li, R.M. Kroppenstedt, C.J. Kim, G.Z. Chen, D.J. Park, L.H. Xu and C.L. Jiang. 2005b. *Rhodococcus yunnanensis* sp. nov., a mesophilic actinobacterium isolated from forest soil. *Int. J. Syst. Evol. Microbiol.* 55: 1133–1137.
- Zhang, Y.Q., P. Schumann, W.J. Li, G.Z. Chen, X.P. Tian, E. Stackebrandt, L.H. Xu and C.L. Jiang. 2005c. *Isoptericola halotolerans* sp. nov., a novel actinobacterium isolated from saline soil from Qinghai Province, north-west China. *Int. J. Syst. Evol. Microbiol.* 55: 1867–1870.
- Zhang, Y.Q., W.J. Li, K.Y. Zhang, X.P. Tian, Y. Jiang, L.H. Xu, C.L. Jiang and R. Lai. 2006. *Massilia dura* sp. nov., *Massilia albidiflava* sp. nov., *Massilia plicata* sp. nov. and *Massilia lutea* sp. nov., isolated from soils in China. *Int. J. Syst. Evol. Microbiol.* 56: 459–463.
- Zhang, Y.Q., P. Schumann, L.Y. Yu, H.Y. Liu, Y.Q. Zhang, L.H. Xu, E. Stackebrandt, C.L. Jiang and W.J. Li. 2007a. *Zhihengliuella halotolerans* gen. nov., sp. nov., a novel member of the family *Micrococcaceae*. *Int. J. Syst. Evol. Microbiol.* 57: 1018–1023.
- Zhang, Y.Q., C.H. Sun, W.J. Li, L.Y. Yu, J.Q. Zhou, Y.Q. Zhang, L.H. Xu and C.L. Jiang. 2007b. *Deinococcus yunweiensis* sp. nov., a gamma- and UV-radiation-resistant bacterium from China. *Int. J. Syst. Evol. Microbiol.* 57: 370–375.
- Zhang, Y.Q., L.Y. Yu, H.Y. Liu, Y.Q. Zhang, L.H. Xu and W.J. Li. 2007c. *Salinicoccus luteus* sp. nov., isolated from a desert soil. *Int. J. Syst. Evol. Microbiol.* 57: 1901–1905.
- Zhang, Y.X., C. Dong and S. Biao. 2007. *Planifilum yunnanense* sp. nov., a thermophilic thermoactinomycete isolated from a hot spring. *Int. J. Syst. Evol. Microbiol.* 57: 1851–1854.
- Zhao, J.S., D. Manno, C. Beaulieu, L. Paquet and J. Hawari. 2005. *Shewanella sediminis* sp. nov., a novel Na⁺-requiring and hexahydro-1,3,5-trinitro-1,3,5-triazine-degrading bacterium from marine sediment. *Int. J. Syst. Evol. Microbiol.* 55: 1511–1520.
- Zhao, J.S., D. Manno, C. Leggiadro, D. O'Neil and J. Hawari. 2006. *Shewanella halifaxensis* sp. nov., a novel obligately respiratory and denitrifying psychrophile. *Int. J. Syst. Evol. Microbiol.* 56: 205–212.
- Zhao, J.S., D. Manno, S. Thiboutot, G. Ampleman and J. Hawari. 2007. *Shewanella canadensis* sp. nov. and *Shewanella atlantica* sp. nov., manganese dioxide- and hexahydro-1,3,5-trinitro-1,3,5-triazine-reducing, psychrophilic marine bacteria. *Int. J. Syst. Evol. Microbiol.* 57: 2155–2162.
- Zhilina, T.N., R. Appel, C. Probian, E. Llobet Brossa, J. Harder, F. Widdel and G.A. Zavarzin. 2004. *Alkaliflexus imshenetskii* gen. nov. sp. nov., a new alkaliphilic gliding carbohydrate-fermenting bacterium with propionate formation from a soda lake. *Arch. Microbiol.* 182: 244–253.
- Zhilina, T.N., V.V. Kevbrin, T.P. Tourova, A.M. Lysenko, N.A. Kostrikina and G.A. Zavarzin. 2005. *Clostridium alkalicellum* sp. nov., an obligately alkaliphilic cellulolytic bacterium from a soda lake in the Baikal region. *Mikrobiologiya*. 74: 642–653 (in Russian); English translation: *Microbiology*. 74: 557–566.
- Zhilina, T.N., D.G. Zavarzina, J. Kuever, A.M. Lysenko and G.A. Zavarzin. 2005. *Desulfonatronum cooperativum* sp. nov., a novel hydrogenotrophic, alkaliphilic, sulfate-reducing bacterium, from a syntrophic culture growing on acetate. *Int. J. Syst. Evol. Microbiol.* 55: 1001–1006.
- Zhou, Y., X. Wang, H. Liu, K.Y. Zhang, Y.Q. Zhang, R. Lai and W.J. Li. 2007. *Pontibacter akesuensis* sp. nov., isolated from a desert soil in China. *Int. J. Syst. Evol. Microbiol.* 57: 321–325.
- Zhou, Y., J. Dong, X. Wang, X. Huang, K.Y. Zhang, Y.Q. Zhang, Y.F. Guo, R. Lai and W.J. Li. 2007. *Chryseobacterium flavum* sp. nov., isolated from polluted soil. *Int. J. Syst. Evol. Microbiol.* 57: 1765–1769.
- Zhu, H.H., J. Guo, Q. Yao, S.Z. Yang, M.R. Deng, T.B. Phuong le, V.T. Hanh and M.J. Ryan. 2007. *Streptomyces vietnamensis* sp. nov., a streptomycete with violet blue diffusible pigment isolated from soil in Vietnam. *Int. J. Syst. Evol. Microbiol.* 57: 1770–1774.
- Zitouni, A., L. Lamari, H. Boudjella, B. Badji, N. Sabaou, A. Gaouar, F. Mathieu, A. Lebrihi and D.P. Labeda. 2004. *Saccharothrix algeriensis* sp. nov., isolated from Saharan soil. *Int. J. Syst. Evol. Microbiol.* 54: 1377–1381.
- Zurdo-Piñeiro, J.L., R. Rivas, M.E. Trujillo, N. Vizcaíno, J.A. Carrasco, M. Chamber, A. Palomares, P.F. Mateos, E. Martínez-Molina and E. Velázquez. 2007. *Ochrobactrum cytisi* sp. nov., isolated from nodules of *Cytisus scoparius* in Spain. *Int. J. Syst. Evol. Microbiol.* 57: 784–788.
