This chapter first clarifies the definitions of some terms and expressions used in gender studies, which refer to social rather than biological differences between the sexes, followed by a brief background to the development of gender studies in demography. Recent findings in the key areas of demography—family, fertility and contraception, health and mortality, migration, aging—are then reviewed in a five-section survey of the literature on "gender and population," focusing on what are arguably the most promising lines of research. The gender system, or certain aspects of it, will in some cases be looked at as determinants of demographic behavior, whereas in other cases, the other side of the question will be examined: how do demographic behaviors modify gender systems? This is because the relation between the two aspects is not one-way but much more two-way, and it is important to highlight one or other of these two directions in the relation or their reciprocal linkages, as the case may be. The final section will consider the specific data and methods relating to gender and population research.

I. SOME DEFINITIONS

The word "gender" has only recently entered into demography. As Richard Udry (1994) points out, in a 12,000 title bibliography of the literature on marriage and the family from 1900–1964, the word gender is notable by its absence. In 1972, John Money suggested using the word *sex* for the biological distinction between males and females, and the word *gender* when discussing sex-specific behavioral differences (Money and Ehrhardt, 1972). Generally, the word gender is used to highlight the social development of relations between the sexes and to get away from the biological determinism implicit in the word "sex" or expressions such as "sex differences." The word "gender" also stresses the relational aspect: men and women are defined relative to one another, and neither can be understood other than by studying both (Watkins, 1993).

In social science terms, gender depends on three things: roles, socialization, opportunities. A *gender role* is a range of sex-specific and field-differentiated acceptable behaviors, perpetuated by *gender norms.* The bounds of acceptable behaviors differ for men and women: overstepping these bounds is penalized and, in any event, obstructed by the surrounding environment.

Where do sex-differentiated norms derive from? There are several theories, based variously on the influence of technologies; reproductive role differences, which in turn underlie the gendered division of labor; ideological theories; and, finally, those arguing for sex-differentiated behavior as simple historical accident (Bem, 1987). In the social sciences, gender is about differential social experiences that explain both between- and within-gender differential behavior. With these theories goes a biological theory of gender: sex hormones dictate sex-differentiated behavior and the development of the reproductive function among humans and animals, but in different ways. Biology and social experiences both have an influence, as shown by the undeniable historical changes in gender behaviors (Udry, 1994).

Karen Oppenheim Mason (1995) describes the socially constructed societal expectations for male and female behavior as a *gender system.* The expectations of a gender system prescribe a division of roles and responsibilities between men and women and grant different rights and obligations to them. The gender system comprises the complex of roles, rights, and statuses that surround being male versus female in a given society or culture. It has subcomponents, for example, it prescribes a division of labor and creates institutionalized inequality between male and female members of society to form a *gender stratification* that is measurable in terms of wealth, power, and prestige. The power dimension, for example, includes autonomy (the freedom to act as they choose rather than as others would have them act), control of material resources, and command of social honor or prestige.

But this is not to deny that sex-specific biological differences may shape men's and women's behaviors: a gender-neutral environment, if possible, would not produce a neutral society because the two sexes do not react in the same way to the same elements of socialization (Udry, 1994). Also, the individual behaviors of each sex (in variable form) are in great part owing to individual biological characteristics, which are also an explanatory factor of within- and between-gender variability (Udry, 1994). Generally, however, the gender system goes beyond the behavioral differences that can be expected of biological diversity alone and creates an injustice—that is, inequality between the sexes in power, autonomy, and well-being typically to the disadvantage of women, which change in time and space.

Improving women's status and reducing gender differences means increasing women's empowerment. The United Nations (UN) *Program of Action* produced by the *International Conference on Population and Development* (1994) lists actions to be undertaken in favor of women: to improve their political representation, education, health, participation in the labor market and social security systems; to eliminate poverty and discrimination of all kinds, including employment discrimination based on pregnancy status or the pledge not to have children, and stereotypes in the media and school textbooks; to make it possible to combine work and child-rearing; to give women full economic rights (e.g., to sell, buy, inherit, borrow, contract); to promote the setting-up of activist groups for women to foster women's awareness of their rights; to strengthen women's well-being, self-image, and self-esteem; and, finally, to provide consideration for women and children. All this involves male responsibilities and participation.

Women's increased empowerment is therefore measured in many and unaccustomed spheres, which open up new areas of research and require new data and new methods to evaluate the changes and their effects on demographic behaviors.

II. FROM WOMEN'S STUDIES TO GENDER STUDIES IN DEMOGRAPHY

From the 1960s, a handful of feminists (Blake, 1965; Ridley, 1968; Dixon, 1975; Germain, 1975) began showing that women's status has significant demographic implications. But it was chiefly from the 1980s that the issue entered the mainstream of demographic thought, although not yet a central variable of *transition theory* (see Chapters 68, 69). A series of studies have built up a clearer and more detailed picture of the significance of women's status as a multidimensional concept composed of autonomy, prestige, power, empowerment, access to and command of resources, etc. The framework for analysis devised by Christine Oppong and Katharine Abu (1986)—the so-called *seven roles* theory—clarified the different roles that women play (individual, conjugal, maternal, domestic, occupational, kin, and community) and helped shed light on the underlying dimensions of women's status and suggested methods of information collection and indicators that could turn the concepts into operational definitions. This activity of cerebration, theorizing, and development of working constructs was held back by the practice that had evolved in differential demographic analyses of using women's educational level and participation in the labor market as women's status indicators; this stemmed partly from practical considerations, some intellectual laziness, and inertia—seldom was the trouble taken to clarify the theoretical reference frame that set the limits of validity within which the selected data and indicators were usable for each study.

In each case, many of the concepts put forward implicitly referred to a male benchmark. Further, the concepts of women's status and social status were often used interchangeably, such that it gradually became seen as preferable to talk of *gender* rather than women's status, by explicitly including the comparison with men into the assessment of women's status.

The UN and its agencies, along with other international organizations involved in population and development policy, have made a big contribution to this process, which first revealed the importance of women's status as a determinant of demographic behavior and then clarified and developed the concept to accommodate gender systems. When the stages in this development and its gradual inclusion in the action programs drawn up by the UN for the three world population conferences in Bucharest, Mexico City, and Cairo are charted, it is striking to see the increased prominence given in them first to women (from 1974–1984) and then to gender, in 1994. This rising emphasis on women, finally resulting in a gender focus, comes chiefly from an awakening to the need to expand women's decision-making power over sexuality and reproduction, and to reduce male opposition to the idea, at the risk of seeing family planning programs collapse. The ideas, preferences, and expectations of women and men alike therefore had to be taken into account. This policy shift has had a significant influence on public opinions and research.

The International Union for the Scientific Study of Population (IUSSP) has played a key role in this development as an early adopter of issues around women's status, gender, and their relationships to demographic behavior (see Appendix 93–1). The IUSSP, first through the preparatory work for the Asker Conference and then through the activities of the scientific committees it appointed on the issue, has done much to raise demographers' awareness of gender issues, define and develop this field of research, devise theoretical frames of reference, and systematize empirical knowledge.

III. GENDER AND FAMILY

Marriage is the most common way to sanction the union between a man and a woman and is the origin of family formation. Historically, it has been used as means of creating wealth and power. The rules and norms governing marriage, divorce, conjugal relations, and the rights and duties of family members are important to each society. Very few countries anywhere in the world at present give the two sexes equal rights in relation to marriage, divorce, and family property. Put simply, institutionalized gender inequality still persists in most countries. There are still countries where the legal minimum age at marriage for women is 12 or 14, and millions of girl children are given in marriage in the world every year (UN, 1992). The spousal age difference, always to the man's advantage albeit to very varying degrees, is the simplest indicator of the unequal relationships within the union. These and other aspects of the gender disparity within the family have been extensively considered by Véronique Hertrich and Thérèse Locoh (1999) for developing countries, and by me for developed countries (Pinnelli, 1999).

One function of the family should be to protect its members, but in fact, violence and abuse are common within families, and the victims are invariably women. It may range from battering, burn injuries, and other types of assault on women (especially in connection with dowry disputes), through genital mutilations, child sexual abuse and psychological violence to spouse rape and murder (UN, 1989). Recent studies have shown that most family violence is perpetrated on the wife, invariably by the husband (Smyke, 1991), although mothers-in-law are also implicated to quite a high degree.

Beyond the male breadwinner–female housewife stereotype, gender relations within the family vary by family type (nuclear, cohabitation or long-distance union, step/blended, extended, kinship, tribal, polygamous) and life-cycle stage (courting, marriage or cohabitation, first childbirth, last child's home-leaving, labor market exit of aged partners, divorce or widowhood).

The developed countries have experienced big changes, especially in patterns of union formation: marriage is less frequent and more delayed, often after a period of cohabitation, and less stable. More children are born outside wedlock and to older mothers and increasingly often live with a social rather than a biological father or with a lone mother (Roussel, 1989; Pinnelli, 2001). This situation varies from country to country, with the economic and social situation, gender system, and institutional context. In southern Europe, for example, these trends are not yet particularly pronounced, because institutional support to families is limited (inadequate childcare provision, shorter maternity leave, tax system favoring legal families), because there is little assistance for young people made unemployed by the economic crisis, or because the gender system is more unfavorable to women (less autonomy, less work and more frequently interrupted careers, less political and administrative power) (Pinnelli, 1995, 1999). In contrast, changes in the family are more apparent where female labor force participation is more widespread and where the economic situation enables the formation of even nontraditional unions. That is not without adverse consequences for the life of women and children, however: out-of-wedlock children often have a lower birth weight and higher infant mortality than do in-wedlock children, notwithstanding that the rise in illegitimacy also reflects positive developments such as women's greater empowerment and autonomy. The increased instability of family situations has a negative influence on mothers' and children's physical and mental well-being (Pinnelli and Masocco, 1995).

Lone mother families resulting from union dissolution (break-up or divorce) are growing increasingly common, and women have difficulty juggling the children's needs with the need to work as well as assuming alone the physical, emotional, and economic family responsibilities in situations in which insufficient institutional support may be compounded by ex-husband or partner absence. Women and children bear the brunt of the increased instability of the new family patterns. But moving from studies on women to gender studies also means taking into account men's expectations and preferences to help understand and reconcile individual demands for personal happiness and responsibility to future generations.

Comparative analysis of male and female behaviors in the developed countries clearly reveals how women are torn among work, career, and family life and acknowledges the higher price they pay for the deinstitutionalization of marriage and increased instability of unions (Pinnelli *et al.*, 2003).

IV. GENDER, FERTILITY, AND CONTRACEPTION

1. Fertility

Karen Oppenheim Mason (1985) reviewed the literature on relations between gender systems and fertility in developing countries.

Little research has been done on how gender systems affect reproductive behavior, but there are concordant findings from case studies done in Bangladesh (Balk, 1994), Nepal (Morgan and Niraula, 1994), and India (Malhotra *et al.*, 1995) that both micro- and macrolevel changes in gender systems produce fluctuations in fertility and its intervening variables. The first of these used women's freedom of movement within the community, their authority within the home, the leniency of households toward their women, and their gender attitude as indicators of the gender system. The second considered women's freedom of movement and voice in household decisions on the use of contraception and fertility desires. The third took the relationship between female and male mortality, which preceding studies had shown to be a good proxy for *gender stratification*, and the proportion of economically active women. Further, various studies done in Bangladesh (Schuler and Hashemi, 1994) showed that involvement in programs to raise their standard of living enhanced women's literacy skills, earning abilities, and power and increased contraception use. However, the geographic and cultural coverage of these studies is limited, and it is not known whether identical findings would be made in less traditional contexts.

One intervening variable added to those designed to explain fertility patterns is son preference, which prompts "unlucky" parents to continue creating children until their sex preferences are fulfilled. A relationship has been observed between fertility decline and a lesser degree of son preference (Cain, 1993).

Studies based on evidence from the World Fertility Survey (WFS) and Demographic and Health Survey (DHS) analyzed the influence of women's education and employment on contraceptive behavior and fertility. The findings for education are robust and consistent with the hypothesis of an inverse relationship with fertility; those for employment are less so. Where employment fails to affect women's enhanced autonomy, power, or control of resources, fertility does not fall. Evidence from some studies, however, shows that individual-level measures of power and autonomy are unrelated either to fertility levels or to contraceptive use (Jejeebhoy, 1995).

In developed countries, with generally subreplacement level fertility, gender equality is associated with higher fertility (Pinnelli, 2001; Di Giulio and Pinnelli, 2003). This finding has surprised those who hypothesized that women's enhanced status led to reduced fertility. It suggests the converse—that women who acquire more autonomy and power more easily approach ideal fertility as measured by surveys on the number of children wanted, whereas others tend to have lower fertility (Pinnelli, 1995). In fact, the lowest fertility is found today in the southern European countries, where, as mentioned earlier, protracted economic crisis and youth unemployment are obstacles to first union formation and the lack of adequate institutional assistance is a disincentive to married women to have more than one child, notwithstanding the women's more traditional status in that location and its more pronounced gender differences.

2. Family Planning

Demographic research has long disregarded men's role in reproductive and contraceptive decisions; as a result, family planning programs in developing countries have been directed only toward women. One characteristic of contraceptive models in continuing very high fertility countries, therefore, is a lack of male involvement, evidenced by the infrequent use of male methods of birth control. This situation is only partly explained by the need for wholly reliable methods, because more medical research could have been directed toward male methods. The real problem is the failure to get men engaged with family planning programs. Too little attempt was made to encourage men and women to make joint decisions about their desired fertility, birth spacing, and the methods to be used to achieve that, or to tackle male abdication of responsibility or chauvinism.

A woman-centric approach may arguably be the most practical course, given that women do not want all the many pregnancies they have. But the evidence is that in fact women cannot solely take such key decisions for the family and society as family size: disempowered in so many spheres of both public and private life, they cannot act in this of their own volition. For instance, a study of women's and their partners' fertility and contraception demands and preferences in selected African countries revealed that men were less concerned than were women about fertility control, but that men's opinion prevailed over women's in moving from preferences to practice (Andro and Hertrich, 2001).

Another consequence of sidelining men from family planning programs is to have held back condom use by young people, women who cannot use the pill or intrauterine device (IUD) on health grounds, for example, or where there is a risk of sexually transmitted infection.

Getting men to engage more with contraception and family planning decisions also means involving them more in responsibility and care for children, prompting them to provide adequate economic resources for the needs of the large family to which they generally aspire, and, ultimately, inspiring them to limit their fertility.

In the long run, the success of family planning programs will depend on changing men's attitudes toward women, marriage, children, and the family, as well as on changing women's attitudes.

This means studying men's contraception and fertility desires, preferences, and behaviors in the same way as women's, as well as studying the interactions between the sexes. This is why fertility and birth control surveys, including, for example, the Family and Fertility Survey (FFS) and DHS, now systematically include a sample of men as well as the traditional sample of women, in recognition of the importance of recording data for both partners.

The contraceptive history of developed countries has taken a very different tack. Fertility control has been a male preserve, using such methods as condoms or coitus interruptus (a specifically male method), whereas women have contributed to reduce fertility through abortion (Dalla Zuanna, 1996). The 1960s, and especially the 1970s, with the spread of the pill, followed by IUDs and sterilization, signaled women's ownership of family planning. Falling abortion rates evidenced the gradual shift to more effective contraception methods. But also in the developed countries, the sudden emergence of AIDS put the merits of condom use and, more generally, negotiation with the partner for infection risk-free sexual activity back on the agenda. Involving men in contraceptive decisions has thus become as essential in developed as developing countries.

V. GENDER, HEALTH, AND MORTALITY

1. Child Health and Survival

Responsibility for the health of family members is traditionally left to women, but where there is a highly antiquated view of women's status and wide gender gaps, women are excluded from modern medicine, an act that has family-wide repercussions. It is in society's interests, therefore, that women should have access to modern medicine and the ability to get information and interact with the health system. A large body of research in fact shows that the gender system influences infant health and survival, both of which improve with mothers' empowerment. Islamic Middle Eastern countries, where women have little freedom of movement or autonomy, are those where, *ceteris paribus*, child health conditions are worst. This was reported by John Caldwell as long ago as 1986 and was subsequently confirmed by a series of studies (Oppenheim Mason, 1995) using micro- and macrolevel measures of the gender system.

Even the most approximate indicator—women's educational levels—bears out these findings, because the most well-educated women are more self-confident and resolute or are able to communicate with their partner. There is therefore a link between education and the intervening variables of infant survival, such as hygiene and utilization of health care provision, and that holds true even where socioeconomic conditions are controlled. The effect of women's economic participation is more contentious, however: although women's resources may help improve children's diet and health care, work may reduce their mother's available time and attention for them;

unsurprisingly therefore, the relation is found to be situation specific (Basu and Basu, 1991).

Excess girl child mortality has been observed in several countries, notwithstanding the greater biological weakness of boys (see Chapter 54). Some studies (Chen *et al*., 1981; Das Gupta, 1987) have evidenced girl child discrimination in relation to feeding and medical care. Excess female child mortality is a very robust proxy for sex discrimination against women.

2. Excess Male Mortality

As development has progressed, mortality generally has receded but excess male mortality has risen (see Chapter 54). Societies with no pronounced son preference are always found to have approximately 10% to 15% excess infant male mortality (Vallin, 1993). In developed countries, this excess male mortality then becomes significantly age specific, peaking at a very high level around the age of 65. Historically, however, and in developing country societies, age-specific excess female mortality has been observed, especially in infancy and at the reproductive ages (see Chapter 54).

Were lifelong excess male mortality to remain constant at its first-year level, gender-differential life expectancy would be approximately 2 years (Pressat, 1973). Arguably, therefore, a female survival advantage of 2 years could be seen as biologically normal, and a lower recorded difference in a given country could be attributed to women's disadvantage in treatment, diet, and economic participation, whereas a differential above 2 years reflects a male disadvantage.

Some of the male disadvantage stems from men's more aggressive, reckless, and less health-conscious behavior. But health and health care provision use surveys also evidence gender-differential attitudes: women are readier than men to acknowledge their unwellness and seek treatment, whereas men will seek treatment if they acknowledge their illness but are less ready to do so (Waldron, 1976, 1985). Arguably, that is a key explanatory variable of the sex-specific mortality differentials. But males are also more exposed to environmental risks (physical and psychological). A borderline case evidencing an exceptional male disadvantage is Russia, where the recent mortality crisis after the collapse of the communist system simply worsened the ongoing decline in the health situation since the mid-1960s (Shkolnikov *et al*., 1995a–d; Meslé *et al*., 1996, 1998). Even so, the female excess over male life expectancy at birth rose there from 9 years in 1965 to 14 years in 1995 (Meslé and Vallin, 1998).

A fascinating field of research straddling biology and sociology has opened up to encompass, beyond the often self-victimizing stereotypes of feminist studies, the highly meaningful causes of one of very few female advantages.

3. The Biological Role in Danger

Developing country infant and maternal mortality indicators bear an inverse relationship to care development and availability; conversely, in developed countries, where infant and maternal mortality rates are very low, no correlation is found with the intensity of care, which may be seen as excessive and unnecessary. There is in fact no evidence that the overmedicalization of pregnancy and childbirth produces more mother and child health and survival advantages. Women undergo very frequent checks and even risky analyses, labor is medically controlled, the frequency of caesarian sections is much higher than that which the World Health Organization (WHO, 1985) considers to be physiologically necessary, breast feeding has been reduced to a few weeks or abandoned altogether in many developed countries and is also declining in developing countries (for a short literature review, see Cesaroni and Pinnelli, 1999). Not only does this extreme overmedicalization of a function that is specific and exclusive to women bring no gain for either mother or child, it surely brings a psychological and emotional loss.

One factor that encourages overmedicalization of childbirth in developed countries is later motherhood: delayed first pregnancies are seen as medically delicate, so risk-avoidance controls and care are—consensually—increased. Birth deferral also exacerbates conception problems, evidenced by the steadily-growing recourse to assisted reproductive techniques, used increasingly—and increasingly earlier—when pregnancy does not rapidly follow the decision to procreate (WHO, 1985). This creates a general impression of a rise in sterility and infertility. But various studies (Mosher and Pratt, 1993; Beets *et al*., 1994) have shown that deferring the first birth until age 30 to 35 or even after, partly owing to women's rising educational levels and greater economic participation, is the structural cause of women's increasing procreation problems in developed countries. Whatever else, this difficulty helps to drive the market for medically assisted reproduction, with all its economic and psychological costs and the attendant risks of failure.

The inference from this example of the overmedicalization of birth is that greater gender equality makes it harder for women to accept and assume their biological role. They uncritically accept excess care provision as if pregnancy were a serious illness and not a natural fact of a woman's life, but seek to expedite a pregnancy that does not occur for being too long deferred (Leridon, 1992). They may need a greater ability at the right biological and social time in the life cycle to balance emotional fulfillment with social and career success, while preserving the priceless naturalness of motherhood as being a function specific to women.

VI. GENDER AND MIGRATION

There is scant information on gender and migration, because migration is still seen as a primarily male phenomenon. The stereotype is that women's migration follows that of their husbands, so most research is focused on male motivations and preferences. But women also increasingly frequently migrate of their own volition, especially never-married and very young women under 20 or older women aged around 45 to 50—especially those widowed, separated, or divorced. Historically, these movements were often thwarted by a range of circumstances: the gender division of agricultural labor assigned work requiring constant, ongoing care to women and more seasonal work to men, such that men were able, and women unable, to migrate. Furthermore, migration was seen as endangering their virtue, which would be thus placed beyond the control of parents and elders. Finally, women's lower average educational level reduced their employment opportunities and disadvantaged them against men (Makinwa-Adebusoye and Afolayan, 1995). But the situation has undergone rapid change, and an increasing number of women now migrate as free agents.

Going or staying is the outcome of a family survival strategy that decides who will migrate. It is important to consider this from the perspective of the microlevel, as well as at the macrolevel of social and cultural norms and employment policies that often disadvantage women. Women emigrate for education, which for many is the first step toward urbanization; as a permanent or occasional domestic worker or as a member in the sex trade, which is seldom permanent and less common than may be supposed; in farming, often in seasonal work, as is common in many regions of Latin America, Asia, and Africa; or in the act of joining their husband or a relative. Similar to men, women's migration is chiefly economic, especially when they are young, but less commonly is this the only reason. Women's children also accompany them, if not left with relatives. Personal and family considerations dictate the time and destination of migration (UN, 1994b). In international migrations, women suffer discrimination on three counts: class, race, and gender. Most work, usually in domestic service and childcare (by thus performing for reward some of the domestic and care duties of their female employers, they release these women to engage in other activities outside the home) and in shops. Working for lower pay and in less secure jobs, they nevertheless remit more money home than do men (Makinwa-Adebusoye and Afolayan, 1995). They have lower fertility than do nonmigrant women (Findley, 1999; Hugo, 1999).

Nonmigrant women are apt to be middle-aged mothers, resigned to their husband's emigration as a necessity. Where they already have some autonomy, it increases with the husband's emigration, and their situation may improve. Others, however, may find themselves in greater difficulty. Separation from the husband and the possible consequences are always stressful.

The personal and family lives, and the social and economic conditions, of women who migrate with or without husbands—but also nonmigrating women with migrant husbands—undergo major upheavals. The gender system changes in particular. Women who are significant wage-earners and also more reliable household breadwinners appreciably increase their value in the family. Migration changes the rules of care and attention provision and the models of intergenerational assistance. Migrant women have fewer children than do nonmigrant women and can play a leader role in fertility transition as models of innovation or sources of information on low fertility. This is true for migrant women and for the nonmigrant wives of migrant husbands: family structures change (Findley and Williams, 1991). Research has barely begun to consider migration from the migrant/nonmigrant woman viewpoint, and the subjects studied have only been touched on. It is clear that migration has many repercussions on the lives of women (work–life balance, well-being, education, social mobility opportunities, health, etc.), those for whom they are caregivers, and gender relations in the societies of departure and arrival. Research should inform all these aspects in the coming years.

Another important factor is changes in social structures and gender relations related to rapid urbanization. Gender structures shape women and men's involvement in management of the community, the extent of their representation in urban government, and how far their requirements inform urban development and organization. Structural adjustment programs, for example, have affected women's lifestyles more than men's: women have had to engage in paid work and reduce their family consumption. Women do most of the childcare and housework, but their demands on housing and essential services go unheeded. The house is often the center of productive activities. Women's greater physical and social vulnerability should inform the planning of community, housing, service, and transport development (UN, 1994b).

VII. GENDER AND AGING

Aging is a female topic in many ways: because at the older ages women outnumber men, because institutional support at the older ages is often deficient, because women are the main caregivers for older people, and because women's lower participation rates and lower-paid jobs expose them to a greater risk of old age poverty. Here, the gender perspective adds new areas for exploration, but research is barely at its beginnings. Consider a few examples of the gender-aging nexus. In some cultures, women are empowered by exiting reproductive age: they are then less subject to male authority and can engage in many activities prohibited to younger women. They no longer need to defer in the same way to men or dress or conduct themselves as modestly; they may disregard certain language taboos and speak more freely and with more authority; and they may move outside the home and travel much more freely than younger women. All this means that older women have the potential to challenge men in decision-making bodies, carry on commercial activities beyond their village, and work with others in organized activities. But, simultaneously, older women in traditional societies also often become protagonists in the transmission of gender norms that disadvantage females.

This contrasts with industrialized countries, where age tends to bring disempowerment for women. Granted, there are situations in which increased women's empowerment generally delivers greater well-being for older women: one example is care provision for older males, which falls to women through either tradition or demography (women are apt to care for their elderly spouses and males not, because generally in unions, the husband is the older and predeceases). When women are empowered in political decision making and local government, institutional assistance to families increases and this advantages all women (UN, 1993). This is a specific example of the mechanism of women's empowerment: here, it adjusts the balances in the gender system, enabling an improved quality of life for women without harming those needing care.

Gender role differentials may even decrease with age: retired men can help more with housework, whereas women can become more independent and outward-looking once the children have left home. This is borne out by various studies, although the results do not lend themselves to extrapolation (Arber and Ginn, 1995).

VIII. DATA AND METHODS FOR THE STUDY OF THE GENDER-DEMOGRAPHIC BEHAVIOR RELATIONSHIP

1. Stereotypes and Realities

Through an analysis of articles published in the first 30 years of the journal *Demography* since 1964, Susan Watkins (1993) showed how a preconceived and stereotyped view of the gender system underlies the bulk of the work. In a quarter of the literature references, this view is not expressly stated but implicitly shapes all demographic research from the type of data to be collected through to the choice of methods to be used, and the tables or more advanced analyses to be produced. The researcher's—even subconscious—assumption that the prevailing gender system model is the standard male worker/breadwinner with female housewife/homemaker-cum-child carer, will inform the type of data collected and analyses of it. For example, the fact that the information we have on economic activities is on formal for-gain work, and not on informal work or housework, although major contributors to the economy are normally assigned to women, is a direct product of the researchers' view of society and not mere chance or data-gathering issues.

2. Official Sources

The general population and household census is a fundamental source of information on total male and female populations in terms of many characteristics. Family surveys are good sources of national data, at least, and may cover the widest range of topics. For countries that systematically record vital events, these records are also a mine of information: many of the UN's social indicators are derived from them. Other statistics (e.g., tax, education, work, health, crime) can also be used. One problem with official statistics, however, is that women's status is a fairly low priority in the topics covered, and so often no useful information is collected on it. The way in which the collection of data on economic activity is informed by gender role stereotypes has already been mentioned. Moreover, in many cases, published data are not sex-disaggregated, which renders any gender analysis impossible.

Contextual analysis of a population's living conditions requires more than just collecting quantitative data. Defining a community's gender system means analyzing all the prevailing norms and values that may influence sex-specific roles, power, and value. That means referring to sources of information not normally used by demographers and bringing to bear legal, ethnological, and anthropological skills, in other words a firmly interdisciplinary effort.

3. Time Use Statistics

Time use statistics greatly inform the analysis of gender differences: a day comprises 24 hours, for men and women alike, and the use made of that time can provide much objective information about men and women's lifestyles, constraints, and preferences. Time use also clearly reveals the wide range of activities undertaken, especially all those carried out by women for the informal or family production of goods and services that do not enter into official statistics. The main issues with such statistics are the reliability of recording (daily time use logs are often vague), the categories of activity defined, the choice of reference period (risks of seasonal effects), time- and space-dependent comparability, and the cost of the surveys.

4. Wistat, a Database on Women

The year 2000 saw the publication of the fourth edition of *Wistat, Women's Indicators and Statistics Database* drawn up by the UN in conjunction with several of its specialized agencies.[1] This database provides a range of sex-specific or women-related information on specifically female matters (e.g., fertility) or other issues relevant to women's lives (e.g., childcare provision, environmental conditions that impact women's lives, like health service provision, availability of drinking water). The thinking is that women's status and the gender system cannot be studied separately from development. The database contains, for example, information on sex ratio at birth and at different ages; marital status; percentages of women ever married and never married, singulate mean age at marriage, and percentage ever married among persons aged 15 to 19. It also contains information about female household headship, contraceptive and unmet contraceptive demand; percentage of women requiring more than an hour travel time to the nearest facility providing family planning services or supplies; circumstances under which abortion is permitted; women and men's expressed ideal number of children for total, urban, and rural areas; age-specific fertility; and female population by age and number of children born alive. Other data include urban or rural residence, employment, foreign-born population, availability of safe drinking water and health services, life expectancy, infant mortality, child malnutrition indicators, smoking prevalence among persons 15 years of age and over, causes of death, HIV and AIDS, antenatal care, percentage of infants breastfed, percentage of births delivered by caesarian section, maternal mortality, learning and education, percentages of women teachers by level, women in international cooperation, youth work, commercial loans for women, unemployment, wages, maternity leave, years in which women acquired the right to vote and to stand for election, numbers of women ministers or deputy ministers, women in UN staff in posts subject to geographical distribution, date of ratification and entry into force of Convention on the Elimination of All Forms of Discrimination against Women (CEDAW), prevalence of violence against women by an intimate partner, and deaths from external causes. The geographical and time coverage of these indicators is improving year by year.

5. How to Measure the Gender System?

The first requirement in studying the gender-demographic behavior nexus is to translate the gender system concept into indicators. This is no easy matter, because it is a multidimensional concept. Gender stratification aspects (power, wealth, and prestige) have been operationalized by measuring women's situation relative to that of men: this has, for example, included evaluating autonomy (Dyson and Moore, 1983), power and control of material resources (Cain *et al.*, 1979), and freedom of movement (Morgan and Niraula, 1994). Power has been evaluated through six specific components: (1) sense of self and vision of a future, (2) mobility and visibility, (3) economic security, (4) status and decision-making power within the household, (5) ability to interact effectively in the public sphere, and (6) participation in non-family groups. The information was gleaned from personal interviews with different questions on each component (Schuler and Hashemi, 1994). Richard Udry (1994) used 19 measures of gender behavior, including marriage with a man, number of live-born children, a sexual orientation index, importance of career, importance of children, domestic burden sharing, a scale of typical sex-specific activity, importance of marriage, an index of femininity, the list of main interests, pleasure taken in child care, percentage of women in employment, a socioeconomic index, percentage of women in the work unit, and personality type. The International Labor Office devised a series of recommendations for the collection of data on economic conditions to highlight women's contribution to the economy and the obstacles to their integration in development: employment, unemployment, income, sex segregation, gender differences in emigration, time use, access to credit, housing, physical mobility; support networks, and access to training (Anker, 1980). Christine Oppong and Katharine Abu (1986) proposed indicators at the community and individual level for each of the seven roles played by women (occupational, conjugal, domestic, maternal, community, kin, and individual), relating to activity, time use, knowledge and skill acquisition, resource use, power, and decision-making ability. The indicators are equally applicable to men and women and support an analysis of gender differences.

Many of the individual indicators referred to are drawn from face-to-face surveys or participant observations. Information of this type tends not to be extracted from WFS, DHS,[2] or FFS-type demographic surveys or official statistics, where indicators usable for an evaluation of gender systems are few and limited. For this reason, the demographic literature often uses information on education and learning, employment, and age at marriage, as *proxies* for gender stratification indicators (Sathar *et al*., 1988; Jejeeboy, 1991; Chowdhury and Trovato, 1994). Demographers have recently begun to assess the validity of these proxy measures. It had been found that in some cases, the proxies do not give a proper representation of gender stratification: in Islamic society, for example, better-educated women may be confined to *purdah*,[3] that is, have severely constrained mobility, whereas less educated women are forced to try and earn a living in the most difficult circumstances and so become more independent decision-makers. However, the fact of working does not necessarily imply that a woman has greater power and autonomy if, for example, she cannot freely use her earnings or they are earned to be spent on necessities for the family.

6. Synthetic Macro Indicators Sensitive to Gender Inequalities

The *Human Development Report* (1995) uses two synthetic measures of gender inequality, the Gender-related Development Index, a multiattribute measure of longevity, knowledge, and access to resources (life expectancy, education, and income) expressed as an equally distributed equivalent percentage for female and male shares, and the Gender Empowerment Measure, developed out of three variables for women's participation in political decision making, access to occupational opportunities, and earning power (female share of parliamentary seats; share of women as senior officials, managers, and professional and technical positions; share of female nonagricultural wages compared with that of men). These indicators have a limited value, because they make no allowance for many aspects of gender inequality, such as within the family or in community life, and do not lend themselves to an evaluation of the situation in rural areas; nevertheless, they are useful for an overall evaluation of the gender system at the macro level.

Pavel Sicherl, in a 1989 book, suggested simple and effective methods for evaluating gender disparities by using aggregate statistical data, providing worked examples for four fields: education, employment, wages, and time use (Sicherl, 1989). He stressed the importance of taking into consideration the absolute values for men and women, the relative values of gender disparities, as well as both static and dynamic measures. He introduced the time-distance index, that is, the number of years necessary for women to catch up with a given level reached by men (using historical data or projections), as a dynamic measure of gender differentials. He nevertheless cautioned that the male position should not always be regarded as an objective to be achieved, because value judgments change over time with the importance attached to different aspects of the quality-of-life evaluation. His proposed overall measure of gender disparities was a weighted combination of static and dynamic measures. He counseled that the analysis should always be set within the broader reference frame of development, because although development will not automatically eliminate gender inequalities, neither is the simple elimination of gender differences sufficient to improve women's standard of living and eradicate poverty.

7. Plan of Research

Karen Oppenheim Mason (1995) posited that the ideal research plan for analyzing the gender system-demographic behavior relationship should combine multivariate with multilevel analysis that embraces both the macro- and microlevels (collective factors related to development, culture, norms, and institutions with individual social condition, attitudinal, and behavioral factors), within a cohort approach. It should encompass external determinants, intervening

[2] Albeit the Demographic and Health Surveys done in Egypt in 1995–1996 and Haiti in 2000 contained a long series of questions on women's status, which yielded many indicators of the gender system and women's empowerment.

[3] Which forbids women to leave the house at all or only to a very limited extent.

variables, and individual characteristics and should cover successive cohorts. The analysis should bear on four levels at which the gender system acts: (1) through community norms and values, (2) labor market characteristics, (3) the structure and characteristics of the family, and (4) individual characteristics and attitudes (Sen and Batliwala, 2000).

The longitudinal approach is not really workable at the microlevel today, because it is difficult to obtain data on gender systems at the individual level owing to recall problems and recording distortions. Nor is there any easy way to collect long historical and geographical series, even at the aggregated level. Prospective research can be started now but will only produce results some years hence. Aggregated data alone could be more easily used, but only by foregoing any study of the linkages between gender systems and demographic behaviors at the individual level.

Period fluctuation analysis allows intercultural variations to be substituted for intertemporal variations and can include a multilevel strategy by incorporating both individual information and community data. One problem with intercultural studies, however, is that the meanings of questions may often be determined by context. But they are always useful and particularly advisable whenever a comparison of different realities can give insights into which factors are specific to a given culture and which have a more general relevance and influence.

8. Methods of Qualitative Research and Experience of Development Projects

Traditional research is often time-consuming and unsuited to the rapid evaluation of gender systems, and their interactions with demographic behaviors usually seen over 10-year periods. How can we prevent development projects from repeating the disastrous historical mistakes that flowed from having ignored this dimension? Methods have been developed for a rapid evaluation of gender systems and the potential impacts of targeted programs. Such studies aim to gain insights into gender relations that are object to the project, understand gender-differential perceptions of the proposed activities, evaluate whether the institutions involved are capable of addressing the gender issues implicit in the project, and evaluate the project's potential gender impact on various categories of people. They are short-run studies (a few months) using a range of qualitative information and data collection techniques; are highly practice-oriented; are based on interviews with women, men, and the organizations involved; and use lists of criteria such as the Organization for Economic Cooperation and Development's Development Assistance Committee/Women in Development (1992), the *Checklist for Development Projects* (Pezzullo, 1982), the Key Questions from Chapter 3 of the *Handbook for Social/Gender Analysis* (Moffat *et al*., 1991), or the *Harvard Analytical Framework* (Overholt *et al*., 1985). The gender system is analyzed chiefly by observing the division of labor, access to and control of resources and services, participation in decision-making and organizational opportunities, women's sense of self and self-perception, and men's and women's opinions and expectations of the project (Gianotten *et al*., 1994). These same research strategies can be applied to a gender system analysis of family planning, reproductive health, or any other kind of demographic issue. More generally, social anthropology methods can be used to see through the target population's eyes rather than through the often Western or Westernized filter of the observer. In addition to the *rapid rural appraisal* techniques, these methods include critical analysis of the historic reports and data, key anecdotal evidence, *sondeos* (an interdisciplinary team of men and women technicians and social science researchers spend several days working in permuted pairs such that each technician eventually works with each researcher, discussing their observations and interviews at the end of the day; this method fairly quickly introduces new individuals in a domain, and creates an environment for highly dynamic, interdisciplinary learning), mapping, and observation. Participatory research methods, in contrast, aim to involve stakeholders in decisions affecting them and in project implementation activities (e.g., family planning or health). They include such methods as group interviews, projective techniques, case studies, guided group discussions, and learning fora. Data collection itself is often not possible with traditional methods owing to poor literacy skills and low educational levels, lack of organizational ability, and cultural isolation. In such cases, group discussions, collection of life histories, projective techniques, and content analyses are often the most appropriate methods (CIDA, 1989).

Many research strategies proposed for genderized development projects can be useful to gender and population research. For instance, research on the relations between gender systems and population must enlist many different methodological skills from demography, sociology, statistics, social anthropology, etc.

CONCLUSION

Starting with some clarification of the vocabulary used in gender studies, this chapter set out to show what a gender perspective can add to demographic research and, conversely, how demographic analysis can inform gender studies. It was seen that research theories, data and strategies must adapt to this new perspective. It is apparent from this overview that there is an ongoing ferment of development in theory and practice in the field of gender studies, not merely through academic teaching and research but also by the needs of economic development and family planning programs. Gender studies in demography also have useful operational spin-offs.

But tomorrow's research depends on today's teaching, and it is increasingly essential for gender to be systematically mainstreamed across demography teaching to train researchers and practitioners that are sensitive to these issues and capable of reflecting them in their work. That means making a specific effort not only to devise new programs but also to identify the methods most apt to create this new sensitivity. Appendix 93–2 reviews the learning methods that could be explored in this field in the years and decades to come.

APPENDIX 93–1

The IUSSP and Gender Issues

The IUSSP, the International Union for the Scientific Study of Population, has since the 1980s put a big focus on issues relating to women's status, gender, and their relationships to demographic behaviors. A series of activities on these topics, including publishing a literature review on "The Status of Women, Population and Development" (Federici *et al*., 1985) and holding an international conference on "Women's Position and Demographic Change in the Course of Development" (Asker, 1988), the proceedings of which were published in 1993 edited by Nora Federici, Karen Oppenheim Mason, and Solvi Sogner (1993), culminated in the IUSSP setting up a Scientific Committee on "Gender and Population"[4] in 1990.

Hitherto, the linkages between gender and demographic behavior had gone ignored in many fields of demographic research. The most pressing need was therefore to raise awareness on the issue. The committee first staged an international seminar on "Gender and Family Change in Industrialized Countries" in Rome in 1992 (Oppenheim-Mason and Jensen, 1995), followed by two sessions at the Montreal International Population Conference (IUSSP, 1993), one on "Women's Organizations/Interventions for Women:

[4] Cochaired by Karen Oppenheim Mason and Shireen Jejeebhoy, the committee's members also included Brigida Garcia, Ann-Magritt Jensen, Paulina Makinwa Adebusoye, and Catherine Pierce.

Their Impact on Fertility and Child Mortality" (Pierce, 1993) and the other on "The Process through which Female Education Affects Fertility and Child Survival" (Sathar, 1993), plus two further international seminars on "Women's Position and Demographic Change in Sub-Saharan Africa" (Dakar, 1993: Makinwa-Adebusoye and Jensen, 1995) and "Women, Poverty and Demographic Change" (Oaxaca, 1994: Garcia, 2000); it also contributed to a collective work on "Female Education, Women's Status, and Demographic Change in Developing Countries" edited by Shireen Jejeebhoy (1995).

In 1994, when the life of this first committee expired, the IUSSP set up a new Scientific Committee on "Gender and Population,"[5] which in turn programmed three international seminars on "Female Empowerment and Demographic Processes" (Lund, 1997, Presser and Sen, 2000), "Men, Family Formation, and Reproduction" in Buenos Aires in 1998 (IUSSP, 1998; Necchi, 1999), and "Women and the Labor Market in Changing Economies: Demographic Consequences" in Rome in 1999 (Dixon-Mueller, 2000; Garcia *et al.*, 2003), and organized two sessions at the 1997 Beijing International Population Conference (IUSSP, 1997), one on "Teaching Gender and Population" (Pinnelli, 1997) and the other on "Fatherhood: Recent Exchanges and Policy Strategies" (Presser, 1997); it also published a series of educational papers on "Gender in Population Studies."[6] Other IUSSP gender initiatives are also described in the book, *IUSSP Contributions to Gender Research* (IUSSP, 2001).

All these various activities have helped to define and develop this field of research, devise theoretical frames of reference, systematize empirical knowledge, and lay the foundations for a growing awareness of gender issues among researchers and teachers in demography. So successful did they prove that in 1998, the IUSSP Council queried whether a new committee was needed after the expiry of the second, compared with the benefits of mainstreaming the issue across all the traditional Scientific Committees. The IUSSP therefore tasked an exploratory mission[7] with producing an opinion on the matter. In light of its report, which stressed that although gender studies now enjoyed recognition in the scientific community, much remained to be done to ensure their continued presence on the future demographic research agenda, a new committee was set up in 2002.

[5] Cochaired by Brigida Garcia and Harriet Presser, its other members were Lawrence Adeokun, Richard Anker, Paulina Makinwa Adebusoye, Edith Pantelides, Antonella Pinnelli, Gita Sen, and Ferhunde Ozbay.

[6] A series of eight papers edited by Antonella Pinnelli on the labor market (De Graff and Anker, 1999), migration in Latin America (Findley, 1999) and in Asia (Hugo, 1999), mortality (Vallin, 1999), maternal mortality (Cook, 1999), the family in developing countries (Hertrich and Locoh, 1999) and in developed countries (Pinnelli, 1999), and materials and methods (Dalla Zuanna, 2000).

[7] Chaired by Therese Locoh, and comprising Maria-Eugenia Cosio-Zavala and Sally Findley (Locoh, 2002).

APPENDIX 93–2

Teaching Gender and Population

An International Objective

Raising awareness of gender issues is an internationally recognized objective. The *Program of Action* approved by the United Nations (UN) International Conference on Population and Development gives a central role to relations between gender systems, demographic behavior and sustainable development, in particular devoting a chapter to "Gender Equality, Equity, and Empowerment of Women." The UN's message is that starting or completing demographic transition and achieving sustainable economic development that is compatible with the survival of the planet are not possible without changes (among other things) to the gender division of roles and power relationships between men and women. Accordingly, the UN Program of Action places great importance on training. Chapter 11 on "Population, Development and Education" sets as an educational objective the promotion of a "greater responsibility and awareness on . . . gender equity."

Trainers

Who should provide demographer training to promote increased awareness of gender issues? Demographers are concerned with analyzing the determinants and consequences of demographic behaviors, and the gender system must be seen as both a determinant and a consequence of demographic behavior. This subject has only recently come onto the international scientific and political agenda, from its general absence from demographic training programs, which at best address the relations between women's status and demographic trends in very general terms.

To make it female-delivered provision (as was frequently done in research on relations between demographic behavior and women's status) not only risks ghetto-ization, but by no means ensures that the issues will be properly addressed, because it cannot be expected that female academics, whose gender experiences tend to differ widely from those of most other women, will have an awareness of the gender system that exists in actuality.

Objective

Genderizing demographic training is an immensely wide-ranging objective: the United Nations Program of Action talks of information on population and related issues being directed toward elected representatives at all levels: the scientific community; religious, political, traditional, and community leaders; nongovernmental organizations; parents' associations; social workers; women's groups; the private sector; qualified communication specialists and others in influential positions; age-appropriate education for young people, beginning in the home and continuing through all channels of formal and nonformal education; teachers; and all others involved in the planning of education and communication programs. The urgent need to address the demographic problem in developing countries is the reason for the importance attached to information and education, especially in these countries.

But, a culture of sustainable development and quality of life must also be spread in developed countries, and gender equity and population dynamics are a part of that. A first aim for a developed country could be academic training in the teaching of demography up to doctorate level and continuing training in statistics or demographic research bodies to increase *gender awareness* among statisticians and researchers, as well as in public enterprises, for public and private decision makers.

Examples of promoting continuing training have already been given, in the economic field, for appropriate reporting of women's economic participation both in the (formal and informal) market and out of the market, as well as in urban planning, to factor women's needs into community development (personal safety, as well as of children and older people, transport, socialization, etc.) in a way compatible with broader family needs. The same argument could be extended to other areas (e.g., work environment, services).

Education, both in the family and in the classroom, should remain a main focus of continuing training, because it fosters the gender socialization of the population. Women's enrolment and labor force participation are rising, whereas their socialization to domestic and family care roles is much less great. But men have become more socialized to these roles. The outcome will be dwindling numbers of adult men and women who have been educated to assume what were previously women's duties, with the foreseeable impact on child physical and emotional development, as well as the well-being of other family members, at an as-yet-unevaluated cost to society. Government education, health, and social affairs departments should put these changes at the top of their agendas and take the necessary measures to avoid a decline in personal and family life.

Contents

The topics that should feature in university-level "gender and population" training programs could broadly include:

Definitions and data at the macro and micro levels—*feminist studies*, (studies on women's status, for which there is already a long-established tradition) are often confused with *gender studies*, (i.e., the differences between men and women and the components of a gender system); the data available at the collective and individual levels determine the possible types of knowledge.

Qualitative methods of information-gathering on gender systems—participant observations, in-depth interviews, focus groups, etc.

Quantitative methods of analysis and synthetic gender system indicators—a strategic multivariate and multilevel analysis demands a wider array of methodological tools. Because a gender system is a multidimensional concept, composite indicators must be developed that account for the main dimensions of the system; that means using factor analysis, using multiple classification methods, and constructing latent variables (all methods that are little-used in many demographic research schools). Multilevel analysis methods address the need to consider several levels of analysis but are only in the earliest testing stages in demographic research.

Legal bases—for gender differential demographic behavior (e.g., family law norms where equal dignity is not granted to both sexes; different legal minimum ages at marriage, which is the first instance of the development of an unequal relationship).

Biological bases—of gender differences in demographic behavior.

Relations between gender systems and demographic phenomena—family; fertility, birth control, and reproductive health; health and survival; aging; and internal and international migrations.

Depending on the educational context in which the gender and population issue is set, the following related topics could be included:

Production and market—adding informal and domestic activities to formal work, looking at work patterns such as part-time and flex-time that are compatible with family care, factoring in men's and women's forms of work organization (individualistic, authoritarian and competitive for men, co-operative, interchangeable, flexible for women), taking account of institutional support to the family, etc.

Development programs—very often discussed only with men, the assumption being that women do not count; wrong decisions may therefore be taken simply by ignoring women's development input.

Environment—in developing countries, women manage the essential environmental resources such as water, wood, and food and spend many hours each day in getting them; they must therefore be involved in decisions concerning the use of these resources because wrong decisions can greatly add to their hardships.

These are some selected aspects of method and content. The latter vary widely with their reference historical, geographical, or social contexts. There is as yet no handbook that addresses all these issues—the series of papers published by the IUSSP (Pinnelli, 1999–2000) are merely a first step in that direction—but there is a wide variety of preparatory texts put out by international agencies and nongoverment organizations that have sought to genderize development programs or programs relating to the big areas of intervention, such as health, the environment, the economy, and agriculture. Many use case studies to illustrate the relations among gender, population, and development, because there is often too little research on which to base generalizations. Accumulated knowledge generally refers to developing countries and is especially valuable in identifying the obstacles to be overcome for a speedy completion of demographic transition.

Learning Strategies

Proposing new educational contents means deciding the most appropriate learning strategy. Teaching gender and population raises the issue of linkages with other subjects, because teachers and students alike have internalized from birth and throughout life ideas and stereotypes about the gender division of roles. If the aim of training is not just to transfer knowledge but also to raise awareness of the interrelationships between gender systems and population and to prompt empowerment to change them, the training method design must foster the challenging of deep-rooted ideas and stereotypes. This makes an educational psychology input vital to the development of discussions on the challenge and reconstruction of pre-existing knowledge.

The awareness of the difficulty that trainers have in this field is already clear to see in the training programs linked to the development projects run by United Nations agencies, in which the approaches are focused through the use of interactive and inclusive training strategies such as those based on case studies, video materials as a basis for discussion, and redesign, and role play.

The issue is couched in different terms in the academic environment, in which it is mainly about defining approaches by which to develop gender awareness among specialists training in population issues. One guideline could be a thorough review of academic curricula to genderize the contents. This would be the straight track to change mentalities and knowledge. But, of course, effective as that may be, there are objective limits to training on topics that are not about simple education-instruction learning but go to deep-rooted cultural issues.

The practical impossibility of this kind of approach (involving a paradigm shift that means overcoming fierce opposition from the considerable interests involved) has led to two other solutions: (1) introducing a specific curriculum comprising the most strongly gender-characterized topics, and (2) seeking out potential linkages between the different academic curricula as regards gender issues to devise systematic interfaces between the different areas of education. A credit-based system could address the evaluation issue.

This latter solution, which is a compromise to a complete refashioning of curricula, is arguably an acceptable short and medium term solution, because it would set in motion a valid process of reflection while avoiding ghetto-ization, which is the big risk of the alternative.

One possibility that springs to mind for academic education is to develop *cross-cutting training modules* as the common backbone for the different curricula concerned (history, geography, education theory, sociology, law, demography, economics, etc.), with a more specific focus on gender issues. Introducing elements of this kind could avoid resistance from educators with little knowledge of gender issues, because these modules would be taught by specialists.

Also highly relevant from the teaching viewpoint would be to bring in anthropological-cultural references to other cultures, those apt to promote an awareness that what may sometimes be absolutely unimaginable gender structures are a product of their cultures.

Obviously, from the learning viewpoint, the positive experiences of activities already carried out on the topic in developing countries should be brought in as these—as mentioned earlier—have highlighted the value of educational techniques that maximally involve those to whom they are addressed, specifically to facilitate an awakening to the powerful cultural connotation of gender structures (Pinnelli and Ajello, 1997).

CHAPTER

94

Economic Activity and Demographic Behaviors

GIUSEPPE GESANO

Istituto di Ricerche sulla Popolazione e le Politiche Sociali (IRPPS), Consiglio Nazionale delle Ricerche (CNR), Rome, Italy

INTRODUCTION

There are multiple relationships between economic activity and demographic behaviors, and these relationships are obviously reciprocal. The importance that most people attach to economic activity puts it at the center of the fundamental choices that heavily influence demographic evolution, especially regarding reproductive behavior and geographic mobility. In the opposite direction, among the different options and strategies in the individual and family life cycle, marriage, procreation, and changes of residence are all decisive stages in the lives of persons and families, and they in turn influence the choices made regarding participation in economic activity, whether it concerns the types of work or the time consecrated to work.

These relationships, which are cardinal at the individual level or at the level of elementary social groups (family, clan, village, etc.), may also be interpreted at the level of populations by a dialectical relationship between demographic trends and the changes in the labor market and in the economic system. In the same way as at the microlevel, these relationships are reciprocal at the macrolevel, with population dynamics influencing the supply of labor, both in quantity and in quality (from a demographic viewpoint), and employment opportunities contributing in the opposite direction to determining demographic events and flows, especially regarding migration.

The principal objective of this chapter is to take account of the complexity of the linkages between demographic dynamics and social and economic conditions. Given the difficulties encountered in the search for cause-and-effect relationships, it is undoubtedly better to conceive the ambivalence and the circularity of linkages between these two components of the human condition, which it would be vain to reduce to simple one-way relationships. In sum, it is perfectly clear that these relationships between economics and demographics are always established at two levels: at the microlevel, for individuals and families, and at the macrolevel, for the aggregates of population and the labor market.

In the next section of this chapter, the relationships between demographic behaviors and economic activity, both at the microlevel and the macrolevel, and the pertinence of discussing them in a treatise on demography will be emphasized. Then several elements that, without being rigorously demographic, are nonetheless necessary to deal correctly with this type of subject, will be provided regarding sources of data on the labor force and methods for analysis of gender differences in economic activity. Finally, given that the effects of women's economic activity on fertility have already been largely considered in other chapters in this treatise (most notably in Chapter 37), the next to last section will focus on the interaction between economic activity and migration, which undoubtedly constitutes the most significant relationship in the area that we are interested in here.

I. IMPORTANCE OF ECONOMIC ACTIVITY IN THE STUDY OF DEMOGRAPHIC BEHAVIORS

The goods and services necessary for the survival and well-being of individuals, families, and collectivities come from work, either of the population to which they belong or of another population with which it is linked. This results from a continuous circular process of transformation of vital energy into work, seeking to produce goods. These goods, in turn, are necessary to reconstitute the expended physical energy and to take care of the entire patrimony of material and nonmaterial elements at the disposition of individuals, families, and collectivities.[1]

It follows from this approach that human activities to be considered as productive are not limited to those covered by classical economic categories and official statistical definitions. We must reintroduce not simply the activities contributing to the reproduction of the labor force (both with regard to its daily restoration and the more formally demographic reproduction of generations) and the activities of general training and technical apprenticeship, to the extent that they produce value added in terms of human capital, both individual and collective.[2]

The relationships between economic activity and population dynamics depend on the level of well-being and the degree of complexity attained by a given society. This concerns the primary relationships between the availability of food products and several demographic variables (in particular, mortality, nuptiality, and fertility) (Livi Bacci, 1987) and can be extended to the hypothesis of a reduction in fertility linked to new patterns of consumption characteristic of the abundant society (Ermisch, 1983). The mobility of the population can also find its motor force in geographic variations in the availability of goods. This latter factor, although it has taken many varied aspects, is nonetheless common to the great historical migrations induced by famines (as well as being still sometimes present, here or there, in the poorest regions of the world) and to that part of current migration from developing countries or from eastern Europe that is based on the illusion of ample availability of goods and services in Western countries.

In addition, economic activity itself constitutes the principal if not the only source of individual and family income, although carrying out this activity implies certain operating costs for everyone and, in many cases, specific investment costs, borne by the worker himself.

Decisions concerning entry to the labor force, the type and conditions of work, and leaving economic activity are taken on the basis of comparisons of costs and benefits, in time and space. Possible changes of residence that may be required by the exercising of the economic activity further complicate the assessment of the explicit and implicit costs and the effective advantages or those expected in the future. Before they are rationalized at the individual level, such choices often result from obligations. In the family context, intentions and individual and collective expectations are heavily influenced by the definition of the roles and functions of different members of the household. Nonetheless, whatever decisions are in fact made regarding participation in the labor market of the potential labor supply of family members, they are made, consciously or not, as a function of a comparison of costs and benefits. This includes, on the one hand, the explicit costs (such as the cost of a baby-sitter who replaces the mother while she is at work) and the opportunity costs (such as forgoing the possibility of improving one's education and consequently improving later one's remuneration level) and, on the other hand, the benefits, not simply the immediate (salary payment) or future (retirement pension) economic benefits but also the hope for a more important role in the family and in society.

In this case also, the linkages with certain demographic aspects are explicit, even if they are less direct. The size and composition of families constitutes a powerful regulator of the labor force participation of individuals who belong to those families, as a result of a complex evaluation of the relative costs and benefits. Moreover, the alternative that women often confront between economic activity and motherhood shows

[1] It is important to note the degree to which this process comes into play in the succession of generations and thus carries, including in its most nonmaterial aspects, a universal dimension. In reality, we benefit today from the fruits of the labor of very distant populations in time or space, including those that preceded us in the past as well as those from the four corners of the planet with which we trade, directly or indirectly. From a sustainable development perspective, we must succeed, by our own work, in bequeathing to future generations a patrimony that is at least equivalent.

[2] "Every action that tends, directly or indirectly, to make possible the satisfaction of individual or collective economic needs, present or future, is an act of production and the person who accomplishes it is economically active" ("*Ogni azione che tenda, direttamente o indirettamente, a rendere possibile il soddisfacimento di bisogni economici individuali o collettivi, presenti o futuri, è un atto di produzione, e chi la compie esercita un'attività economica*") (Mortara, 1960:50). It is worth noting that accepting this argument implies that we must take into consideration the set of domestic activities, especially of women, that statistics and national accounting do not consider as productive.

clearly that this comparison of costs and benefits includes some important noneconomic elements. In a wider framework, it appears that there are substantial consequences, for example, for the level of reproduction of a population, that may flow from these decisions. The choice with regard to mobility, in all of its various forms and types, rests in an even more explicit manner on a comparative evaluation of advantages to be obtained and costs to be borne. This is true as much at the level of individuals as, in a more complex manner, in the family context, with solutions that inevitably tend to optimize the different components.

In decisions pertaining to participation in productive economic activity, a "time balance" comes into play in considering the hours devoted to work and complementary nonwork time. Although time at work is largely imposed from outside the household, its regulation can become an important variable in a family's search for organizational equilibria when the labor market provides opportunities for flexible schedules or part-time activities. It is apparent that this may be mutually correlated with the decision-making spheres regarding the raising of children and family assistance to the ill or aged. It is worth noting as well that certain forms of occupational mobility impinge on time allocation, with more or less impact, between the time devoted to work and time available for rest.

But taking time into consideration also has a broader dimension, extending to the life cycle, during which periods of economic activity and periods of inactivity, either temporary (holidays, illness, maternity leaves, unemployment, etc.) or structural (childhood, schooling and training, retirement), are interspersed. In the daily, weekly, and annual cycle, economic development has substantially reduced the time devoted to productive work. Labor force activity, especially if understood in the strict economic sense, has thus undergone considerable reduction: on the one hand, in favor of periods of training and, on the other hand, in favor of leisure and retirement.

In economically less-developed societies, in the past or even still at present, life and work largely coincide, and age constitutes at most only a weak regulator of the intensity and the quality of productive activity at the two extremes of life. In advanced modern societies, human capital training requirements and the accomplishments of labor unions regarding restrictions on age and labor time increasingly disassociate economic activity and personal life. For quite some time, however, participation of the population in economically productive activities has been conditioned by the different roles given to individuals as a function of their sex, age, marital status, family size, their position within the family, etc.

The relationships between population and economic activity are pertinent both at the microlevel (individual or family) and at the macrolevel. They should be analyzed from the two classical demographic perspectives: cross-sectional and longitudinal.

1. Micro Aspects: Individuals and Families

At the individual level, the study of economically active life in the context of the life cycle is the best approach for identifying the turning points and the factors regulating individual decisions regarding participation in productive activity. In considering the different steps in successive order, the first key transition point is that separating the training phase from the work phase, that is, in modern contexts, the school-to-work transition.[3] The distinction between these two phases has been progressively reinforced to the extent that the objective of the training has gone from a simple apprenticeship for a specific occupation to the constitution of a more or less complete cultural baggage. At the same time, this passage is also taking place later and later in the life cycle, with the extension of compulsory schooling and the widening desire to reach the highest educational levels.

In this domain, the access of young women to higher education is important from a demographic perspective. Not only does this reduce the participation of very young women in economic activity, but it also delays the age at which the woman becomes part of a couple and, quite often, delays the age at which she has the birth of her first child. In societies in which fertility is still high, schooling provides women with the cultural tools for access to models of controlled fertility via the mastery of birth control techniques. In addition, development of schooling may also give a woman access to nonhousehold employment, and hence, the necessary status to discuss, as an equal partner within the couple, the use of contraceptive methods, as well as to be able, if necessary, to live an autonomous life in case of widowhood, divorce, or repudiation.

The prolongation of the schooling phase has, however, also been responsible for the phenomenon of delay in becoming an independent adult, even if this is not the only reason. In this regard, patterns of

[3] The continuous transformation of structures and types of production and the growth of occupational mobility have resulted in a growing frequency of occupational training and retraining during the working life, beyond the initial period of schooling and training. In general, however, these additional training activities do not entail real career interruptions and hence do not play an important demographic role except indirectly, via the increased income or changes in residence that may result from them.

TABLE 94–1 Percentage of European Young Adults Living with their Parents, 1986 and 1994, by Age Group and Sex

Country	Ages 20–24				Ages 25–29			
	Men		Women		Men		Women	
	1986	1994	1986	1994	1986	1994	1986	1994
Central Europe	59.9	61.2	37.9	41.3	23.1	24.7	9.4	11.4
France	56.9	61.8	36.4	41.6	19.3	22.5	8.4	10.3
Germany	64.8	64.6	42.8	44.6	27.4	28.8	11.0	12.7
United Kingdom	57.2	56.8	33.8	37.0	21.9	20.8	8.6	10.8
Southern Europe	87.1	90.9	71.1	81.3	51.3	65.3	28.8	44.3
Spain	88.1	91.5	76.1	84.3	53.2	64.8	35.3	47.6
Greece	76.5	79.3	52.3	62.3	53.8	62.6	23.8	32.1
Italy	87.8	92.2	70.4	82.4	49.6	66.0	25.5	44.1

From Fêrnandez Côrdon, 1997:580.

behavior vary considerably among the advanced societies (Moors and Palomba, 1995), because of both objective reasons and customary and psychological reasons. In the former case, the availability of adequate housing in terms of size and cost and the attainability of jobs accessible to youth and appropriately remunerated are key aspects. With respect to the latter reasons, one relevant aspect, for example, is the willingness of young workers to accept jobs, at least temporarily, for work that does not really correspond to the level of preparation acquired while waiting for eventual access to more appropriate employment.

The demographic and socioeconomic counterparts of this turning point are known: whether they are apparent, such as residential mobility linked to independence, or more indirect, such as the possible beginning of a marriage-like cohabitation. Consideration of these aspects can explain in part the small number of consensual unions among youth in the countries of southern Europe. These youth, in contrast to their northern European counterparts (Table 94–1), tend to stay in their family of origin until they obtain stable employment or get married.[4] Moreover, the idea remains widespread in these societies that economic independence stemming from stable and well-paid employment constitutes an indispensable precondition to the starting of a real family.

In rural societies, in which the extended family prevails and in which work is distributed among all members of the family as a function of their roles and their capabilities, the passage from the training phase to professional life is not as marked, and the creation of a new household depends above all on nonindividual factors such as agreements between families or the prosperity of that particular year. In modern societies with low fertility, in contrast, the reduced number of children per family and the considerable availability of resources that parents can transfer to their children may encourage the formation of new families even in the absence of an inheritance or an independent income that are deemed necessary for the formation of a new family.

It is also important to emphasize the profound modification of relationships between women's economic activity and family formation: initially, in relation to the length of the status of being an autonomous unmarried person and, then, in the relationship between the timing of these two phenomena. Formerly, the low schooling of women and the primacy of their domestic and reproductive functions after marriage resulted in a pattern of female labor force participation rates by age that peaked at a very early age, followed by a very rapid and sharp decline after age 20, closely linked to age at marriage or age at the birth of the first child. The prolongation of the training period and then the effort to conciliate labor force activity with family tasks and responsibilities have modified the pattern of female labor force participation rates, giving a profile much closer to that of men.

The relationships between women's work and their reproductive behavior have been studied a great deal since the 1960s, that is, since the study of fertility differences in the presence of voluntary birth control has highlighted the capital importance of women's level of education and their occupational situation as explanatory variables. In reality, this situation becomes important when economic activity becomes nonagricultural

[4] The phenomenon of adult children who reside with their parents well into adulthood was analyzed from a comparative international perspective (focused on Japan, the United States, France, and Italy) by Hiroyuki Takahashi and Jeanette Voss (2000). It is also worth looking at the special issue of the *Journal of Family Issues* devoted to this subject and edited by Andrew J. Cherlin, Eugenia Scabini, and Giovanna Rossi (1997).

and nondomestic, that is, in an economically developed context, and especially if the society is not organized so as to allow mothers to reconcile economic activity with the demands of motherhood and the raising of children[5] (Killingsworth, 1983; Brinkmann, 1987).

Below we will deal with the relationships between geographic mobility and occupational mobility more thoroughly. However, the disassociation between personal and family life and professional life has consequences, including in terms of the differentiation of the places in which they occur. As a first effect, this implies very short distance mobility, notably in the form of daily commuting between home and work. But more substantial and more definitive moves are also linked to the evolution of one's career or to changes in place of work, enterprise, or occupation, and the beginning and the end of professional life, in particular, can bring about important changes of residence. On one hand, there is migration in search of new employment or at the beginning of one's career, and on the other hand, there are moves related to leaving employment, both to the place of origin (return migration) and to agreeable and warm localities, perhaps even to foreign countries, to spend long years of retirement there.

The relationship between economic activity and demographic behaviors becomes much more complex at the family level because of the juxtaposition and, sometimes, the opposition of different interests of family members. Thus, family choices regarding the work of the two spouses, with the resulting family situation influenced by whether there is one income or two, certainly have a demographic impact. This in turn affects the assessment of costs and benefits, time use, and the mutual division of roles and duties: in societies in which birth control is prevalent, strategies relative to the number and timing of births in the family life cycle derive in large measure from this set of elements.

Even more important are the family strategies pertaining to the duration and type of schooling to provide to each child (or, alternatively, whether the child should enter the labor market early), notably as a function of the child's sex and birth order. Patterns differ considerably according to the culture and inheritance rules. In traditional economies, girls and the youngest children are often sacrificed as part of this choice. In the current developed societies, certain difficulties encountered by youth when entering the labor market can, on the contrary, lead families to try to offer to their reduced number of children the option of continuing their studies, while hardly taking account of either their capabilities and their actual chances of success or of the strategic opportunity of the training that is undertaken.

It is absolutely necessary to take the family into account when considering occupational mobility strategies, taking into consideration the demands and desires of different family members. Choices thus often result from mediation among the interests of the principal actors, and in case of incompatibility, they can lead to conflicts and renunciations, including those pertaining to economic activity, on the part of the weakest members of the family.[6]

However, especially in societies in which unemployment and underemployment are high, temporary labor migration by one or several members of a family may constitute a survival strategy or one of relative enrichment in relation to the initial situation. After the great European emigrations of the first part of the 20th century (see Chapter 58), these strategies have henceforth been largely adopted in Third World countries, both at the level of the extended family or clan, via emigration of their most capable and entrepreneurial members, and at the level of nuclear families, via the temporary migration of the husband or wife, based on the employment opportunities that the host countries may offer (Piore, 1979).

2. Macro Aspects: Cross-Sectional and by Cohorts

The complexity at the microlevel of individual and family relationships between economic activity and demographic aspects is partially simplified at the macrolevel, but there are some specific issues that come into play when one takes a global approach. In particular, it is necessary to analyze the reciprocal influences that exist between, on the one hand, the size

[5] Beyond the existence of an adequate number of daycare centers and nursery schools that are economically accessible, the compatibility of their annual and daily schedules (as well as those of all schools) with work time is capital (Del Boca and Repetto, 2002). However, strong family structures and the proximity of residence of relatives or in-laws and economic inactivity of at least some of them can also facilitate work in the labor market by mothers, even in societies that are not well-equipped and well-organized in this domain.

[6] In the most intense and chaotic phase of urbanization in certain Western societies, abandoning the rural residence and activities may have temporarily penalized woman's explicit economic activity, putting her in the petit bourgeois role that made her the "angel of the hearth." Moreover, the type of activity and work schedules characteristic of early industrialization were hardly compatible with the traditional tasks of a family mother who, among other things, found that urbanization and family nucleation reduced the assistance that, in the countryside, she could receive from a much more extended family network.

and structure of a population and, on the other hand, the labor market and labor migration.

Thus, the vicissitudes that modify the magnitude and the distribution by age and sex of the fraction of the population more interested in carrying out a productive economic activity have effects on the size and on the types of labor supply, which, along with other conditions, appear in the labor market. In addition, precisely because it is a market, the reactions of the market and the autonomous changes in the demand for labor will have, in turn, consequences for employment, for labor supply, and probably—that which is of particular interest here—for certain demographic behaviors such as the formation of new families and choices regarding fertility and migration.

It is apparent that the study of this domain requires the combined expertise of a demographer and a labor economist. The former, among other things, not only provides the basic elements for the static and dynamic analyses of the populations in question but also makes available extremely useful analytical instruments for understanding the phenomena and their relationships. Among these instruments, notably, is the perspective provided by longitudinal analysis, which allows one to follow the continuous process of renewal of cohorts and the linking up of their experiences.

Starting from this postulate, Richard Easterlin (1987) developed, beginning in the 1960s, a hypothesis of differential success of cohorts, based precisely on the relationships that they have with the labor market as a consequence of their relative size. In very summary terms, the members of relatively small cohorts will face less internal competition when they enter the labor market and then during their careers, and they will thus experience greater and more rapid success than do members of relatively large cohorts. This success will allow them to begin their own families sooner and to have more children, thus resulting in larger subsequent cohorts. The inverse results for larger cohorts, and in the long run, this phenomenon should tend to smooth out demographic waves resulting from the alternation of more or less numerous cohorts of parents.[7]

This theory found a rather general verification in the American and north European baby boom that took place after World War II. But the profound restructuring of productive systems that occurred after 1973 undermined one of its implicit hypotheses, which rested on a demand for labor that was at least stable, if not growing. Moreover, the continual and prolonged reduction of European fertility since the middle of the 1960s led to an empirical contradiction of the theoretical result of a new cyclical quantitative equilibrium between the generations of parents and those of children. However, two aspects of the theory remain valid: the generational postulate and the hypothesis that there are reciprocal effects between the labor market and the population. In particular, the sudden structural and cyclical contractions of the demand for labor in the developed countries beginning in the 1960s may very well have been owing in part to the evolution of the level and timing of fertility. Indeed, the difficulties of entry to the world of work have increased for youth, and moreover, those entering the labor market, in their effort to begin their careers, come up against the crowding created by the larger generations that preceded them and that, by virtue of seniority, occupy and will continue to occupy for some time the best jobs in a productive system in which there has sometimes been a slowing of the growth of the demand for labor.

Cross-sectional differences between situations that occur simultaneously in different labor markets often result in labor migration. Demographic disequilibria and differences in the pace of economic development among European countries and, in their midst, among the different regions, effectively created after World War II different situations in their respective labor markets, situations that in numerous cases were brought back into equilibrium by temporary or permanent mobility of workers. At the theoretical level, a purely quantitative first approach to these phenomena has given way to sophisticated considerations concerning the qualitative characteristics of jobs most frequently offered to the immigrant labor force and to the theory of the "dual labor market" one reserved for native workers and the other available to immigrants (Stalker, 1995).

A hypothesis relevant here is that there is an ongoing process whereby employments at the top of the ladder first go to native workers and then to immigrants who came long ago, and this process leaves to recent immigrants the dirty and difficult jobs that are refused by workers already well-positioned in the labor market (Böhning, 1988). However, without fundamentally contradicting this hierarchy of employments, the most recent international migrations have demonstrated the inadequacy of this paradigm of the labor market in explaining the direct flows toward the west from countries of the south of the world and those of eastern Europe. Underlying this phenomenon is a strong and growing pressure of unemployment and underemployment in the countries of origin, as well as a general propensity in the destination countries to exploit immigrant labor, especially when that

[7] For a critical review of the Easterlin hypothesis, see Macunovich (1997).

labor is in the precarious situation of being irregular or clandestine.

II. THE LABOR FORCE: PRINCIPAL SOURCES OF DATA AND SOME ANALYTICAL INSTRUMENTS

The principle of the market on which economic activity is supposed to be based and regulated implies the existence of a demand and a supply, potential or effective. Statistical treatment of these concepts requires, however, precise definitions that vary in time and space as a function of economic structures, systems of production, and behaviors in use by the population.

To define in a universal way *potential supply* confronts the strong dependence that links the labor market to the cultural context, upstream of the social and economic spheres in which they are operating. A definition from the potential population reservoir in which the effective supply is very often formed seems, however, possible: its definitional terms change more slowly as a function of legal norms, usage, and actual behaviors of the population in its relationship to economic activity and with respect to the duration of the life-cycle stages that precede or follow the productive period.

With regard to legal aspects, there are numerous rules that establish the minimum age of entry into different economic activities, forbidding child labor and providing a legal framework for work by minors. For reasons of coherence, the minimum working age often corresponds to the maximum age of compulsory schooling, but special requirements exist for older ages for certain specific occupations. Conversely, there is generally no legal upper age limit to economic activity other than in the inverse form of a minimum age at retirement, which is very variable from one country to another and from one epoch to another. In addition, the minimum retirement age may be a function of the type of employment, and it can be exceeded by workers who wish to remain economically active beyond that age.

Empirically, the recent history of the most economically developed societies shows that there is a progressive raising of the age at entry to the labor force and a reduction in the age at exit. The delay at entry is obviously linked to the diffusion of higher education and its lengthening. The earlier exit is a consequence of both the nearly total coverage of workers by social security systems and the specific demands of restructuring of production systems. Briefly, the crisis of social accounts that is affecting the Western countries will in all likelihood impose drastic changes with regard to the minimum age of retirement and, thus, an important delay in the exit from economic activity by workers.

It is common in international comparisons to treat as the potential supply of labor a *population of working age,* often fixed between ages 15 and 65. For the economically developed countries, it would be more realistic to set the limits around ages 20 and 60, if account is taken of recent behavior of most workers. In the near future, however, it is very likely that the upper limit should be set at least at age 65 in these countries also, as a consequence of the more severe rules that appear to be imminent regarding retirement payments.

For a precise definition of the aggregates that interact in the labor market, texts of economic statistics or publications of the International Labor Organization (ILO) on sources and methods of labor statistics may be consulted.[8] It should not be forgotten, however, that even if the concepts can be clearly defined, it is still difficult to translate them into precise practical parameters, both because of their variability across societies and over time and because it is rarely possible to translate them into objective measurements.

Simplifying greatly, one can define the *(economically) active population* as that which, in a given time period, provides the supply of labor for the production of the goods and services that are taken into consideration in the system of national accounting approved by the United Nations, which includes own consumption of goods and services produced as well as market production of goods and services. A distinction may then be made between the *usually active population,* the population observed as such for a comparatively long time period via a general question on the individuals' usual work status, and the *currently active population,* more frequently referred to as the *labor force,* observed with reference to a short period close to the date of observation.

The *active population,* notably that which forms the *current labor force,* includes the *employed,* who were able to demonstrate the existence, during the reference period, of a relationship with an economic activity (whether or not this activity entails working for someone else, is currently ongoing or temporarily suspended for whatever reason) and the *unemployed (in the broad sense),* that is, those who did not have work during the reference period but were nonetheless

[8] In particular, see the Web site of the International Labor Office in Geneva. The definitions to be found there were adopted at the 13th International Conference on Labor Statistics at Geneva in 1982 and are still in effect today. See the following addresses: http://www.ilo.org/public/english/bureau/stat/res/ecacpop.htm; http://laborsta.ilo.org/appl/data/c3e.html.

available for work and had undertaken some action to find a job.[9] Among these *persons in search of a job,* there is usually a distinction made between *the unemployed in a strict sense,* that is, those who lost a previous job, and *persons seeking a first job.* Finally, persons of labor force age who are not in the labor force are asked if they would be willing to work under certain conditions (regarding place, position, schedule, salary, etc.), in order to identify the entire *potential labor force,* which, in addition to the actual labor force, includes *discouraged workers,* that is, the undeclared supply of labor that remains out of the labor force owing to current market conditions.

These definitions allow one to identify the corresponding categories in population censuses and specific surveys. During the operation of these data collection, the employment status of the interviewee is in general defined with reference to a precise period of time (often the week preceding the survey), close to when the data collection takes place, so as to avoid ambiguities and reporting errors. However, differences in data collection methodology can explain apparent inconsistencies between different sources. Employment survey data gathered by direct interview have rather good reliability. Conversely, censuses, which generally are based on self-administered questionnaires, tend rather to identify the occupational situation judged to be "normal" by the person in question (or the person providing the information for him) and thus runs the risk of providing less reliable information, notably with regard to transitory situations such as unemployment.

In many developed countries, employment surveys are systematically organized at regular intervals. This is notably the case in the European Union countries, for which Eurostat has made a major effort to ensure that statistics produced by different member countries are comparable. In general, these surveys are repeated several times per year (in the European countries, they are often quarterly) in order to take account both of current economic conditions and structural characteristics of the labor market. This entails sample surveys, which are implemented by using partially rotating *panels* to take into account the changes (and hence the flows) between the individuals' economic statuses observed from one survey to the next (or to the survey taking place at the same time the following year, to obtain annual flows).

A partial or complete description of the working life cycle can, however, only be obtained via follow-up analyses. Although there only exist some very partial examples, such analyses could be developed by relying, for example, on the databanks of social security institutions or else via retrospective surveys, with all of the relevant problems of reliability and extrapolation to the universe from which the surveys are drawn. In particular, the French "3B" survey (family biography, migration biography, and economic activity biography) sought to gather retrospectively the relations among events, both individual and family, for the three indicated areas. Unfortunately, difficulties in analyzing the data have limited the results to a few of the very many variables considered (Courgeau and Lelièvre, 1993).

Even if the *absolute quantities* describing the labor market and its evolution (such as the number of unemployed workers) often give an interesting view of economic activity, comparisons in space and time generally require construction of adequate *relative measures.* Moreover, these phenomena vary greatly as a function of the age and sex of those being considered, and because of this, it is necessary to differentiate the intensity measures. Hence, most often relative measures are used.

The *activity rate* (or *labor force participation rate*) is defined as the ratio of the active population to the total population. These rates are then calculated separately for each sex, now limiting the denominator to the population most susceptible to belong to the active population, that is, the *population of working age.* The *unemployment rate* (a measure more economic than demographic) is defined as the ratio of the sum of those seeking a first job plus the unemployed in the strict sense (those who, having lost a previous job, are actively in search of new employment) to the corresponding total number of economically active persons. With regard to employment, two measures may be calculated: either the rate complementary to the unemployment rate or the employment-to-population rate (the ratio of the employed to the total population at the same ages). It is thus important to specify what definition is used.

The profile of rates by age and sex will be described below. We should, however, note here that in addition to the obvious importance of the number of active individuals (employed or unemployed) per 100 residents of the same age, this indicator may also be considered as giving an image of the portion of the year spent by each individual of this age in the corresponding labor force status. In this specific interpretation, the sum of rates by age, cross-sectionally or better yet longitudinally, from the beginning of the working life until its end measures the average duration of the total working life. Table 94–2 presents an international comparison of these durations calculated from the age-

[9] The reference period for such actions is generally much longer than is the reference period for the definition of employment status.

specific activity rates estimated by the ILO (1997). It is interesting to note the differences between men and women, not only in terms of durations but also for the contrast between men who are shortening the duration of their working lives and women who are lengthening theirs. Moreover, the diversity observed across countries is growing over time.

This duration, in years and fractions of a year, can then be compared to the analogous durations spent in other economic condition or outside of the labor market, thus synthesizing the working life cycle in the more general context of the unfolding of life in its entirety, in its different socioeconomic contexts. For example, Fig. 94–1 shows, for each sex, the total durations of different economic statuses, calculated from the age-specific rates recorded in the 2001 Albanian census for those aged 15 to 64. This schema is interesting not only for the substantive results it shows but also as an example of application of a demographic approach to economic questions.

TABLE 94–2 Duration of Working Life by Sex in Some Countries (Total Activity Rate for Ages 15 to 64, in Years)

Country	Men			Women		
	1950	1980	2000	1950	1980	2000
France	46.2	40.5	36.3	20.0	27.1	29.7
Italy	48.1	40.5	38.0	14.3	19.1	23.9
United Kingdom	48.4	44.9	41.3	18.3	28.4	32.6
Sweden	45.7	42.7	41.4	16.8	34.7	40.0
United States	44.8	42.1	39.8	17.6	28.7	33.9
Japan	45.3	42.9	41.9	25.3	25.9	30.3

Calculated by the author using the International Labor Organization estimates (ILO, 1997).

One kind of analysis that is especially useful in macroeconomic studies is that of *stocks* of labor market aggregates and the *flows* into and out of the labor market that change these stocks. Both the basic principle and the principal components of such an analysis have obvious relationships with demography. However, the underlying logic often remains rather simplistic, unable to describe the internal complexity of the processes at work, because the aggregates cannot be adequately refined. Age is the key element that is usually ignored, both in the calculation of stocks and in the calculation of flows. Moreover, the data needed for this type of analysis are not always available (*panel* data are required or, in their absence, retrospective data). This means that for one of the flows (e.g., where the demographic component, which can be taken into account using more reliable data and recommended techniques, has the greatest impact), we

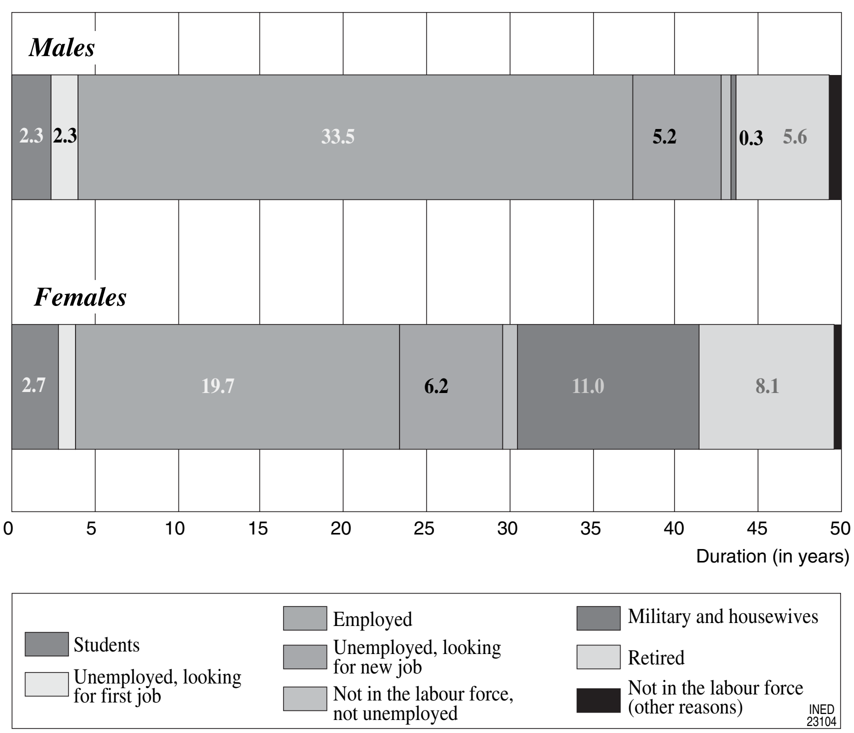

FIGURE 94–1 Total number of years between ages 15 and 64 spent in different economic statuses calculated from the Albanian Census data of 2001.

are left with competing pertinent hypotheses, in order to obtain the other flow as a residual, comparing the stocks over time.

If the necessary data are available, a more rigorous approach would consist of applying the method of multistate life tables to employment situations, thereby allowing one to take account of the articulation between economic activity and demographic parameters (Lalu, 1992). Thus, by use of panel or retrospective survey data, transition probabilities from one economic status to another may be calculated, according to age, sex, and, of course, the initial employment status. The concrete and theoretical problems to resolve when using this multistate life table method are well known: scarcity of the required basic data; arbitrary nature of the estimated probabilities, based on surveys that are generally limited and hence always representative of a specific reality; and hypothesis of stability over time of transition probabilities (even though it is known that the phenomena being studied may vary considerably with economic conditions). In addition, the process is assumed to be a Markov process, with no memory regarding previous moves, whereas it is known that certain states, such as unemployment, for example, tend on the contrary to repeat themselves with greater likelihood among certain individuals and largely bypass others.

Complete retrospective life-history surveys are theoretically much more appropriate for discerning reality in these cases. But these surveys present problems in data analysis and in the construction of indicators, problems that will not be discussed here (see Chapter 23 of Volume I). The advantage of such surveys compared with other sources of data is in their capacity to link events that occur in relation to different aspects of individual and family life. This greatly enriches the analysis. In particular, it becomes theoretically possible to link a person's working life history with his geographic mobility and his fertility and family history, and to identify interesting causal relationships. But this comes at the cost of difficult complications to overcome, as we saw regarding the French 3B survey discussed above (Courgeau and Najim, 1995).[10]

Given what we saw in second section, it should not be surprising that behavior regarding economic activity varies considerably by age and sex. It is also quite evident that the nature of these variations depends largely on productive and economic structures, on rules and norms of social organization, and on the acknowledged and recognized roles of individuals as a function of their sex, their marital status, or their age. It should, however, be made explicit that this argument makes sense only if one considers just the economic activities that are officially recognized and, hence, statistically observed. Otherwise, nearly all of the life cycle can be considered more or less as active for both sexes. In addition, and for the same reasons, it is only in the context of modern economies that activity profiles that are clearly differentiated by age and sex can be readily identified. In this context, an individual's economically active life is more clearly distinct from other roles within the life cycle.

Thus, in particular, males present a typical activity profile by age that has a unimodal curve and that over a large intermediate age range remains very close to 100% of the corresponding population. This central phase is surrounded by initial and final phases of entry and exit, respectively, that are more or less rapid and characterized by portions of logistic curves with two asymptotes, with growth that is initially positive and then negative. Outside of this curve there is, of course, first the training phase and then that of retirement: the rapidity of entry to and exit from work depends on the rules and on the actual behavior that guides these transitions between these two extreme phases and the intermediate phase characterized by a massive presence in the labor market. With the development of higher education and the growth of publicly funded retirement programs, recent changes have generally reduced the age interval during which economic activity rates remain at the highest levels and, on the contrary, have made the phases of entry and exit more extended and flexible.

Women's economic activity profiles were more varied in their form, depending on the social and economic contexts, and they have changed more than have those of men in recent decades. Fig. 94–2, which, by choice, refers to an already dated period (the beginning of the 1980s) so as to illustrate the different patterns of female labor force participation that were apparent then, shows how different the Finnish, Japanese, and Spanish patterns were. Since that time, in the advanced societies this diversity of women's situations has given way to a double homogenization, with female economic activity profiles becoming more alike among different developed countries and also becoming more like the male ones. Although there are more or less marked differences that still exist among women's activity levels, it is also the case that these levels reach more than 80% in certain countries of Northern Europe. In the less advanced societies, women's participation in economic activity showed a peak at young adult ages (especially when schooling

[10] Another example, although limited to aspects of employment status mobility, is given by Miguel Malo and Fernando Muñoz-Bullón (2003), who used data from the British Household Panel.

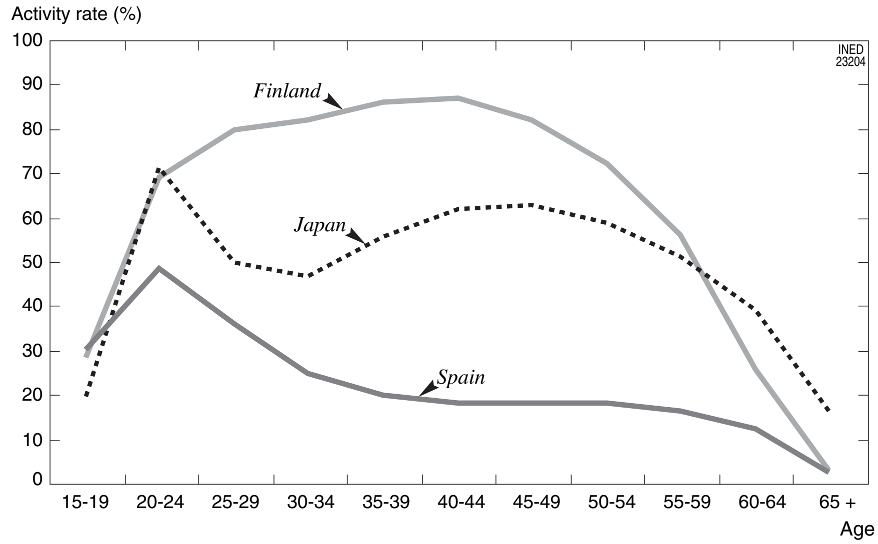

FIGURE 94–2 Women's economic activity rates by age group in three developed countries around 1980.

retarded in extending to these ages) before diminishing, after age 25, at the ages of marriage and childbearing, and as a function of the still quite distinct differentiation between the roles of wives and husbands. Likewise, normative and cultural factors resulted in variations in the right-hand side of the curves, showing women's activity rates depending on whether the exits from the labor force after age 25 were permanent (at least from the official point of view) or temporary, with a return to the labor market once past the life-cycle stage most encumbered by childbearing and the raising of preschool-age children. In the first case, the activity curve stagnated at a very low level up to the age of retirement (as in Spain during the 1980s), whereas in the latter case, a second maximum would be evident between ages 40 and 50 (as in Japan around 1980).

III. ECONOMIC ACTIVITY AND GEOGRAPHIC MOBILITY

In view of studying the numerous relationships between geographic mobility and socioprofessional mobility, the problem is to successfully identify which is the primary phenomenon and which is the induced phenomenon. Only in a few cases is the answer very clear: for example, it is easy to say that forced displacements and movement of refugees are indubitably the primary factor in relation to work changes that may flow from them. Retirement migration is, conversely, the immediate consequence of an important change in one's socioprofessional situation. In other cases, however, one should be able to analyze, case by case, the set of relationships between these two types of mobility.

Nora Federici (1974) made a nice distinction in differentiating between "physiological migration" and "pathological migration," according to whether geographic moves were pursuant to the normal evolution of social and professional life, or changes in socioprofessional status were consequences of a decision to migrate, respectively. Today, in economically advanced societies, it seems that physiological migration has prevailed, with socioprofessional mobility normally being the primary factor in relationship to possible geographic moves. On the contrary, in the relations between developing countries or regions and developed countries or regions, the determining factor regarding geographic mobility tends to be the need for a new equilibrium between population and resources. Thus, especially in periods of reduced labor demand, such movements are above all determined by push factors in the countries of origin, opening the way to typically pathological migration. In these cases, the decision to migrate precedes the possible change in socioeconomic and work status, which is at best but the principal objective of the move and an objective that is often far from being realized.

Table 94–3 shows a typology of the most common forms of geographic mobility as a function of the type of occupational and work mobility. It is ordered on a decreasing scale of importance and complexity of the move undertaken. However, especially for geographic moves, this does not constitute the only possible articulation, as there are numerous criteria that one can think of to classify the different forms of geographic mobility (see Golini, 1987). Likewise, the modalities

TABLE 94–3 Typology of Geographic Mobility as a Function of Occupational and Work Mobility

Occupational and work mobility	Geographic mobility					
	With change of place of residence				Without change of place of residence	
	International	Interregional	Intraregional	Local	Back-and-forth	Nonsystematic
Entry to the labor market for a permanent job	Permanent or long-term migration	Permanent or long-term migration	Permanent or long-term migration	Change of residence pursuant to change of status	Beginning of back-and-forth work movements	Beginning of nonsystematic work mobility
Entry to the labor market for a temporary or seasonal job	Temporary or seasonal migration	Temporary or seasonal migration	[unlikely combination]	[unlikely combination]	Beginning of back-and-forth work movements	Beginning of nonsystematic work mobility
Entry to the labor market for a precarious job	Migration "of fortune" (e.g., irregulars)	Migration "of fortune" (e.g., nomads)	Rural-urban and "fortune" moves	[unlikely combination]	Beginning of back-and-forth work movements	Beginning of nonsystematic work mobility
Permanent exit from the labor market	Different from of permanent return or of new migration	Different forms of permanent return or of new migration	Different forms of permanent return or of new migration	Change of residence pursuant to change of status	End of back-and-forth work movements	End of nonsystematic work mobility
Temporary exit from the labor market (nonemployment, long vacation, etc.)	Temporary or seasonal returns or new migration	Temporary or seasonal returns or new migration	Temporary or seasonal returns or new migration	[unlikely combination]	End of back-and-forth work movements	End of nonsystematic work mobility
Change of sector of economic activity	[rather frequent combinations]	[rather frequent combinations]	Rural-urban moves	Drawing closer of place of residence and new place of work	Change of destination and distance	Change of destination and distance
Change of work situation (employee/ independent)	[likely combination]	[likely combination]	[likely combination]	Drawing closer of place of residence and new place of work	Change of destination and distance	Change of destination and distance
Change of employer	[likely combination]	[likely combination]	[rather frequent combinations]	Drawing closer of place of residence and new place of work	Change of destination and distance	Change of destination and distance
Change of place of work (implantation, office, etc.)	Mobility in international enterprises or firms	Mobility in enterprises with multiple locations	Mobility in enterprises with multiple locations	Drawing closer of place of residence and new place of work	Change of destination and distance	Change of destination and distance
Change of occupational position (career)	[unlikely combination]	[unlikely combination]	Change of residence pursuant to change of status	Change of residence pursuant to change of status	[unlikely combination]	Change of destination and distance

given in each of the cells certainly do not claim to exhaustively describe the very large spectrum of individual situations that may in fact fit together with one or another combination of geographic and professional mobility. The modalities described in the table relate primarily to situations most often prevalent currently in developed economies.

Despite the impossibility of defining in a general way fixed relationships in the complete and logical sequence of linkages between the determining events of geographic and professional mobility, one can try to identify some typical cases, corresponding to mass phenomena and implicating large groups of individuals.

In the first place, the professional life cycle articulates itself in several fundamental steps that often include one form of geographic mobility or another. Thus, it is not only that labor market entry and exit can activate (or deactivate) systematic mobility (commuting and back-and-forth movements) or nonsystematic mobility precisely owing to the change in economic status or in the kind of work, but they create new social relations and new psychological and economic conditions as well as precise requirements for localization of residence that may induce more or less permanent and more or less distant geographic moves.

Only specific surveys can provide pertinent information on this particular linkage between these two types of mobility. The considerable internal migration flows and, in particular, the phenomenon of massive urbanization that, in the west, accompanied and marked the economic transformations of the Industrial Revolution, can, however, indirectly tell us about the amplitude of the link between these two phenomena. Abandoning the sector of activity of the family of origin—especially when it is the agricultural sector, where nearly always the place of residence and place of work are the same—constitutes in these cases the sign of a likely migratory move subsequent to entry to the labor market.[11]

From this perspective, something may have changed or is changing in the most developed countries. It is certainly the case that the great agro-industrial transformation in these countries has already been accomplished, and the next stage, in which the tertiary sector of the economy is dominant, tends to take place in the urban environment without any substantial new population movements. Further, the phenomena of decentralization of production and geographic redistribution of services reduce, if not reverse, the previous trends toward the concentration of workers in a small number of locations. As a consequence, entry into working life in sectors or industries are different from those where the family of origin may already be found, or subsequently, changes in one's sector during the working life less and less imply, by themselves, the need for a change of residence. In addition, the development of means of mass communication and transportation has no doubt been a factor in the sense of reducing permanent moves in favor of temporary and recurring moves.

Developing countries have not yet reached this stage. Not only do they remain characterized by ongoing urbanization, but almost always this urbanization is driven by the push of rural populations toward the cities. In the urban destinations, there is not a real demand for labor corresponding to the level of pressure brought to bear by the in-migrants. It is thus not the case in these countries that entry to the labor market motivates such large migratory moves: people are only prompted to migrate by an often false hope of securing a higher income via obtaining a job and by the illusion of being able, in the urban setting, to have opportunities that do not exist in the countryside. Migration precedes a possible access to economic activity and hence establishment in the urban labor market, but these remain uncertain as a consequence of the limits and precariousness of labor demand. Thus, one can see, from rural to urban areas, *migrations of fortune* (that is, people who migrate as an adventure), a phenomenon currently typical in many Third World countries, even if in the past it also, at least in part, marked the history of the growth of western cities and the depopulation of rural places.

Migrations of fortune have, moreover, always constituted an important share of international mobility, in which it is difficult to have a prior agreement between local employers and workers coming from more or less distant foreign countries. Often, in this case, the worker migrates essentially on the basis of some simple general indications regarding the possibilities of finding some kind of employment in the destination country.[12] Such possibilities may become reality, but only a posteriori, in the meantime exposing the immigrant to the risks of long periods of unemployment and serious problems of getting established in the new society.

[11] Catherine Bonvalet and Éva Lelièvre presented some interesting results on this subject in two articles published in *Population* in 1989 and 1991. Based on sample surveys, the 3B survey already mentioned and the survey *Peuplement et dépeuplement de Paris*, these results confirm the relationships between the socioprofessional mobility of children in relation to their parents and geographic mobility, particularly if the mobility involved Paris.

[12] In these processes an important role is traditionally played by the so-called migration chains that circulate information and descriptions, sometimes illusory, about the destination society in the places of origin, via those who have migrated previously.

When these phenomena occur very frequently and in the absence of policies or rules pertaining to immigration on the part of the receiving country, the end result is illegal immigration. However, whatever the temporal logic between geographic mobility and professional mobility may be, migration between different countries and between continents has lost its character of conquest, and colonization reflected by migration in past centuries and has become today the primary instrument for re-equilibrating labor markets on an international scale. As a consequence, the amplitude of the flows, their direction and even the means of mobility are, more or less explicitly, increasingly dictated by the requirements of labor demand. Repeat migration stems not only from an adjustment of the duration of the displacement to the duration of the demand for labor but also from the rules established by host countries that are opposed to the permanent settlement of foreign workers. Seasonal migration may seem to be outdated, in that it is primarily linked to agricultural work, but today it is re-emerging in relation to the typically seasonal nature of certain commercial activities (peddlers) and services (e.g., in the tourist sector).

Recently, economic, social, and political push factors have become more important in causing international migration flows that often go beyond the requirements and the rules of the destination countries. These countries, in turn, increasingly evaluate the need for accepting the immigrants, both as a function of an overall evaluation of their international relations and as a function of their own internal manpower needs. As a consequence, there is a growing difficulty in clearly distinguishing from among the total international moves those for work reasons and in singling the economic immigrants out from the total number of foreigners who live in a country.

In all of these cases, such an important move, in terms of both sociocultural distance and geographic distance, as it is implied by international migration (and this is also the case, to a slightly lesser degree, for many long-distance internal or inter-regional moves, especially when they involve moves from depressed regions to developing regions) is almost always accompanied by an even more important modification of the nature of the individual's economic activity. Often an entry to the labor market (stable, temporary, or precarious) is observed, accompanied by changes in economic activity (sector or industry, occupation or employment) that can be attributed to new entrance to a labor market that is totally different from that which prevailed at the place of origin.

But if the relationship between work and location is in these cases rather straightforward, strict, and exact, one must also ask what happens, in general, when for whatever reason the work stops. Of course, the reactions will be different according to the nature of the work interruption and the degree to which the migrant has been able to establish himself since immigrating. When the migrant's situation is precarious, a brief period of unemployment is sufficient to provoke a return to the place of origin (returning in failure) or a departure to another destination (stepwise or circular migration). However, systematic interruptions can be foreseen by the nature of the activity or by the legal framework in effect: in this case the result is a return flow of seasonal or temporary and repeat migration.

It is, however, the permanent exit from the world of work that often causes, in this situation, a definitive return move for retirement. At this stage, preference can be given to the linkages and interests maintained at the place of origin, especially in the case where local socioeconomic conditions have in the meantime improved thanks to the emigrants themselves, both by their monetary remittances and by their contribution in specific know-how or simply as part of the general evolution of standards of living.

Along with the natural and foreseeable consequences of retirement for the migration/work tandem, the favorable economic prospects and the longer life expectancy of the newly retired in our advanced societies has given birth to a new kind of migratory move, not yet massive but probably more selective, both in terms of age structure and social group as well as the destinations chosen. A first stage of this phenomenon can be identified in the American Sun-belt or on the Mediterranean coasts and islands, inhabited permanently or used systematically by number of retirees, for a tourism extended to the entire year.[13] Moreover, the process will evolve very rapidly, at least when the degree of aging of the populations of origin will be accentuated, if the favorable economic conditions for the elderly are maintained. In these cases, the magnitude of the move, far from being reduced, will be increasingly motivated by the desire to find a new place to settle as different and distant as possible from the place of residence during the working life, especially when that place is not particularly pleasant. This provokes an inter-regional or even international movement that cannot really be considered as labor migration, but which nevertheless is part of the considerable mobility of the population following changes in the relationships between individuals and the world of work.

[13] For an analysis of the literature on this theme from a European perspective, see Casado-Díaz *et al*. (2002), available at *http://www.shef.ac.uk/sisa/esf/EW_Bibliography.shtml*. One can also refer to King *et al*. (1998), as well as to the complete issue of the *International Journal of Population Geography* in which this article is found, because it is entirely devoted to international retirement migration in Europe, notably that coming from Great Britain.

Also at the boundaries of real migratory movements as such may be found long-distance mobility determined by the work itself or by certain modifications of aspects of its being carried out. At the lowest level, or even in the absence of occupational mobility, specialized labor services can be found which by their nature or the location where the work must take place induce a more or less prolonged and/or systematic dislocation between the places of work and of usual residence, very distant from one another. But stimulus to geographic mobility stems also from the type of economic structure in which the work is accomplished: being part of organizations or multinational corporations entails invitations and obligations to make international moves as a function of changes in one's duties or even transfers to the same job at a site situated in another country. Moreover, the same can be said, all things considered, in the case of belonging to firms or entities organized into decentralized units within a given national territory. In this case, there is a high probability that a work-related move will be positively correlated with the level of professional qualifications attained and will represent in addition an indicator of success for career progress.

Along with these long-distance moves, there is a lesser mobility linked to work and the labor market that develops. This mobility is lesser not in terms of the number of people involved, because at the lowest level it tends to be the normal situation for nearly all work activity. Rather, it is lesser in terms of the distances covered and especially the effects that are felt by the persons and social environments that are involved.

In this perspective, the most important event is the relocation of own residence as a function of the evolution of work. The drawing closer of the residence to the place of work or relocating as part of the process of adapting to a new standard of living pursuant to permanent entry, definitive exit, or promotion to a better and higher-paying job are the most frequent cases. Whether the magnitude of the move is regional or only local becomes less important with the development of means of transportation and communication on a large geographic scale. This in turn results in a disconnection, at least within certain geographic limits, of the choice of a place of residence from the location of the job, and the ultimate choice of residence may in the end result from factors that, in large part, have nothing to do with the place of work.

In such cases, even if the *living space* (*espace de vie*, following a nice definition by Daniel Courgeau, 1970) of the individuals involved only changes a little, we are nonetheless considering a change of residence, an infrequent and important event in the life course of a person or family. But beyond this almost rare mobility, one considers as a widespread and normal condition, owing to its ineluctable and habitual character, all recurring mobility, whether of a systematic or nonsystematic nature, that is closely linked to work and its changes: occupations that by their nature are undertaken in variable places, random mobility stemming from ongoing economic activity, and commuting between home and work.

From the same perspective, it may be said that with the declining role of agriculture or the disappearance of artisan workshops and also with the progressive exemption from the assembly line and from great industrial concentrations, economic activity is increasingly carried out as forms of communication. At the current stage, we are witnessing an exaltation of the physical mobility of persons. Very soon, progress and the diffusion of computerized telecommunications will perhaps allow information flows to increasingly attenuate the direct effects on location and on the geographic mobility of persons, thereby reducing mobility in relation to economic activity.

OVERVIEW AND CONCLUSIONS

This chapter sought to illustrate the complex and multiple relationships that link two essential aspects in the lives of individuals: *demographic behaviors* (as reflected in matrimonial, reproductive, migratory, and residential choices) and *economic activity,* notably *occupational* activity, seen from different angles: (1) means of production of the goods and services necessary for the survival and the well-being of individuals and their families, (2) major source of income, and (3) importance for time allocation (notably for certain stages of the life cycle). Because of the importance that each of these two aspects assumes in the lives of most people, the choices cannot be made on one side without taking the other side into account, so a compromise is struck, as a consequence of the attainments and the opportunity costs in each domain.

The study of the modifications of the life cycle and, under the circumstances, of the working life cycle, can provide interesting keys for understanding the changes that are taking place at present, regarding both the intensity and timing of demographic events and the time allocation and types of participation of individuals in economic activity. The full importance of the cultural and socioeconomic context is thus understood, especially the fundamental role played by the life stages that precede and follow the working life, that is, the phases of training and those which, in the advanced societies with some sort of social security system, coincide with retirement.

If, on the one hand, the family allows for a compensation between the capacities and aspirations of the individuals who are in it, thereby opening the way to more flexible and complex strategies with regard to demographic behaviors and participation in the labor market, the family is also, on the other hand, the place where the choices and the compromises between individual projects or plans are struck. Thus, it is essentially the compensation function that prevails in intergenerational relations, notably in favor of children during the training period (which in general also precedes their exit from the family of origin and formation of a new, autonomous family unit). But it is the dialectical confrontation and the function of interindividual compromise that govern survival strategies of families (and even of clans), notably via migration and residential choices.

Although the contradiction and the arbitrage between demographic behaviors and economic choices are evidently situated at the microlevel of individuals and families, there is also a confrontation between demographics and economic activity at the macrolevel: for a number of different aspects, the structure and the dynamics of the population interact with the state of the labor market and the conditions under which it is functioning. This interaction may be analyzed in terms of cohorts, for example, to inquire into or verify the hypothesis of Richard Easterlin of an influence of the relative size of successive cohorts and the resulting labor market competition on fertility behaviors. That interaction can also be seen cross-sectionally to measure quantitative disequilibria and qualitative disequilibria that demographic dynamics can provoke between supply and demand for labor and migration, which such disequilibria can induce.

The macro perspective also allows for better definition of the aggregates and measures relative to the labor market. In particular, it permits analysis of the different economic behaviors associated with differing economic conditions, as a function of the evolution of the cultural and socioeconomic environment, notably in the domain of the roles borne by women.

Finally, we saw, under numerous aspects, the importance of the relationships that the state of the labor market and its variations maintain with the different forms of geographic mobility of the population. There is a wide variety of relationships via which the evolution of productive structures and migration strategies both bring about substantial changes.

In conclusion, because economic activity and work form a specific part of the life of individuals and families, one which is distinct and circumscribed in time, the study of the relationships between demographic behaviors and economic activity constitutes a fundamental element of any population study seeking to identify different behaviors and to determine their causes. The joint study of demographic dynamics and of the evolution of the labor market is especially important in order to understand their mutual interactions and to foresee possible disequilibria as well as their likely consequences in terms of migration flows.

We may expect that in the future changes in the nature and timing of economic activity may modify, here or there, the nature or intensity of this relationship. However, so long as work remains a vital economic function, it will play a valuable social role and will remain a major means of success for individuals, thereby confirming the key position occupied by the relationships that it maintains with this other aspect of life, even more responsible for social worthiness and individual accomplishment, where demographic behaviors are defined.

Demography and Ethnicity

An Ambiguous Relationship

JEAN-LOUIS RALLU, VICTOR PICHÉ, AND PATRICK SIMON

INTRODUCTION

One of the most striking features of the end of the 20th century was the resurgence of the ethnic question in public debates, both in developing and in developed countries. Between conflicts interpreted from an ethnic perspective (the Balkans, central Africa), nationalist struggles (the Basque country, Quebec), and demands for ethnic identity by new minorities resulting from immigration, every country is currently affected by what is commonly known as cultural pluralism (Dieckhoff, 2000). Similar to all social sciences, demography is affected by the debate and is sometimes even directly involved, if only in its use of official and administrative categories.

Ethnicity is not easy to define. There are several definitions that refer to numerous concepts and theories of ethnicity (Poutgnat and Streiff-Fenart, 1995:93–133). Here we will retain the definition borrowed from Martin Bulmer (1996:35) that an ethnic group is "a collectivity within a larger population having real or putative common ancestry, memories of a shared past, and a cultural focus upon one or more symbolic elements which define the group's identity, such as kinship, religion, language, shared territory, nationality, or physical appearance." It is clear that race, defined by the criterion of "physical appearance," is included in this definition, and this would appear to be increasingly common practice in the field of ethnic relations. The concept of ethnicity emerged after World War II, whereas previously the concept of race was employed to include ethnic group and skin color (Kertzer and Arel, 2002b:12). Even though some authors denounce the confusion of race with ethnicity (see Oomen, 1997:58), we will retain Bulmer's definition as the issues associated with ethnicity (e.g., discrimination) also apply to race (racism).

There is extensive literature on ethnicity as a phenomenon deserving analyses and explanations in its own right, and producing theories that are often contradictory, swinging between essentialism (ethnic group as an innate reference) and constructivism (ethnic group as a social construction) (for some reviews of the theories, see Glazer *et al.*, 1975; Portes, 1984; Martiniello, 1995; Poutignat and Streiff-Fenart, 1995). Until recently, demography was hardly present in these theoretical constructions. Without reviewing the publications, we can quote three basic premises from recent works: (1) ethnicity is a determining social marker, in the same way as are social class and sex (Simon, 1983); (2) the essentialist definition is to a great extent rejected (Poutignat and Streiff-Fenart, 1995) in favor of a definition based on social and historical construction, and involving changing boundaries (Barth, 1969); and (3) despite the real difficulty of empirically measuring the concept of ethnicity, a difficulty that provokes caustic criticisms that go so far as to suggest all attempts in this direction should be rejected, it is increasingly acknowledged that greater efforts should be made in experimental formalizations to construct and mobilize categories closer to social and economic reality.

It is in connection with this function attributed to statistics (Desrosières, 1993) that demography has become implicated in research on ethnicity. Indeed, demographers have participated and contributed to the development of "ethnic statistics," defined here as the production and analysis of official categories such as are those provided by censuses and large surveys carried out by public statistical bodies. Even in descriptive works, it is obvious that the development of conceptual tools and categories at the source of these analyses are produced from a more or less explicit theoretical formalization. In this sense, the spread of theories of ethnicity in national social sciences has had a direct effect on the degree of acclimatization in the demographic research of ethnic categories in each country.

The use of ethnic categories is not without problems, and several works discuss the issue of the social and political significance of such categories (see Anderson and Fienberg, 1999; Zuberi, 2001). We will steer the analyses that follow in this perspective, by placing ourselves at four different levels: (1) attempting, by examining demoethnic analyses, to answer the question "why are demographers interested in ethnicity?"; (2) giving a brief overview of the diversity in the political and social use of statistical categories; (3) illustrating our words with the study of three cases where ethnic data have been used in the United States, Canada, and Great Britain; and (4) looking critically at the production of ethnic data in censuses.

I. WHY DEMOGRAPHERS ARE INTERESTED IN ETHNICITY

The answer to this question is not univocal or obvious insofar as demography is not fond of epistemological and theoretical reflection. The examination of demographic publications (particularly Anglo-Saxon) show that the ethnic variable is analyzed in association with population components supplied by censuses. Moreover, demographic manuals deal with the ethnic question in this perspective (see Beaujot, 1991:297). This type of analysis aims at studying the relative size of ethnic groups, their growth over time, and their socioeconomic characteristics. Research into integration has also drawn on this type of data in order to compare the economic performance of different ethnic groups, or that of the native population with that of immigrant populations (North American literature is very extensive: see Lieberson and Waters, 1988; Borjas, 1994; Halli and Driedger, 1999; Pendakur, 2000; for Europe: Coleman, 1994). The concept of "residual discrimination," which is defined as the persistence of economic differences even after human capital factors have been taken into account, could be empirically verified in these data (Renaud *et al.*, 1997).

Beyond the immediate interest for each variable that characterizes population, the theoretical interest in the ethnic variable for population sciences comes from the conception of the population system. To reproduce (or renew) itself, a population can only count on a limited number of mechanisms: the replacement of generations through natural growth or net migration. When the ethnic (or racial) composition of a population is a sociopolitical issue, the population dynamics of subgroups becomes a wide-spread field of research, as is the case in Canada and the United States (Bean and Frisbie, 1978). From a methodological point of view, the ethnic group constitutes a dependent variable that varies according to demographic variables. It is an essentially descriptive approach that, at first sight appears nontheoretical, but behind these analyses there is always a certain reference to a desired or desirable demoethnic balance. Population projections often serve as a warning to adopt more selective or restrictive immigration policies. Beyond these sociopolitical considerations, this type of analysis causes huge classification problems, as we will show later, as it is based on categories that are assumed to be fixed and invariable, a fiction that is contradicted by the fluidity of ethnic identities (Waters, 1990; Hout and Goldstein, 1994).

However, another response to the question "why is demography interested in ethnicity?" is not strictly demographic but more generally linked to social science concepts, which consider ethnicity as a factor in behavioral variations. The ethnic category is raised to the level of an explanatory variable of demographic phenomena. For a long time, the descriptive approach was preferred when ethnicity was used in the analysis of differential demography in the same way as sex, age, marital status, family structure, and social categories. Recently and increasingly, research in this area has been using statistics from multivariate analyses. Once again, despite the empirical character of the research, the interpretations most frequently borrow from culturalist theories (Piché and Poirier, 1995). Beyond the general criticisms that call the adequacy of these approaches into question (Poutignat and Streiff-Fenart, 1995:120–123), a more radical criticism suggests that ethnic categories are inappropriate for causal analysis and are carriers of a racist ideology if they are not placed in their sociopolitical context (Zuberi, 2001).

Migration is a distinctive case and deserves to be considered separately. For a long time, researchers were obliged to choose between a Marxist approach that rejects the pertinence of the ethnic variable and a functionalist, neo-liberal approach that considers the ethnic variable as a proxy for cultural factors. In the first case, migration determinants are of a macrostructural nature in relation to capitalist development. When Marxists deign to speak of ethnicity, it is considered as a smokescreen or as a secondary contradiction in relation to the war of the classes (Bonachich, 1999). In the second case, the accent is placed on the individual (microscopic approach), and ethnicity is most often presented as an obstacle to mobility (a retention factor) and an impediment to integration. For some time, authors have been trying to reconcile the two micro-macro approaches (Wood, 1982; Massey *et al.*, 1998:chapter 2) and introduce a communal level (the "meso" level) at which ethnicity is a strategic link. Thus, ethnicity acts as a networking factor in he field of migration at the point of origin, by participating in the organization of migration, and at the destination, by constituting itself as a channel of information for the other members who have remained in the country of origin and as an interdependent group within the community.[1] The concept of ethnicity has therefore become central to all contemporary theories on migration.

In any case, the importance of ethnic categories will always remain ambiguous. Ethnic categories can be useful to dominant groups (those who have the power to nominate) as classification tools in order to maintain the privileges and systems of racial segregation (Zuberi, 2001). Classification therefore aims to determine hierarchical statuses that stipulate who has or does not have political and civil rights, as was the case for the apartheid system in South Africa, racial segregation in the United States, and ethnic selectivity in Canadian immigration policies. Censuses are therefore used to count, classify, organize into a hierarchy, and control.

With the adoption by various countries of rights and freedom charters, programs for equal access to employment, and antidiscrimination measures (at the beginning of the 1960's), the role of censuses changed radically, as we shall see in the next section. The principle of these charters is that no specific group has intrinsic, normative, or cultural superiority over another. As a matter of principle, therefore, there is only one category of citizens. But in reality (and this is the role of the analysis of ethnicity), there really is an ethnic stratification. Classification therefore aims at determining which groups are disadvantaged (less equal) and which mechanisms are the basis of ethnic stratification. In this approach, the census is used to enumerate in order to highlight the stratification and to identify the target groups toward which equal opportunity programs should be aimed. Here the criteria are presumed to be objective (color, national origin, ancestral origin, language), and exogenous (defined by the statistical system or the researcher). Very recently with self-identification, the criteria have become subjective and endogenous. But regardless of whether the criteria are exogenous or endogenous, the ethnic categories can be used by minority groups to demand equal access to economic, social, and political resources.

In short, the intrinsically ambivalent nature of ethnic data must be emphasized, in the sense that, as we stated previously, they can confirm hierarchical organization, as well as be used in aiming for equality. Undeniably, ethnic inequality is present in every country of the world and ethnicity is a major principle for division within human society. It therefore seems difficult to analyze societies, or transform them (which is not, strictly speaking, the purpose of demography, but is also what it is used for), without taking their organizational principles into account.

In demography, the analysis of ethnicity is nearly always based on official data provided by censuses. An analysis of the types of data collected (or not collected) is very revealing of subjacent conceptions. The next section presents three case studies (United States, Canada, Great Britain) that illustrate the issues behind the statistics on origins. The last section presents a more technical discussion of the production of ethnic data.

II. OFFICIAL CATEGORIES AND THEIR POLITICAL UTILIZATION: A GREAT DIVERSITY

The linkages between political views and projects and the statistical categories that support them are present in every society (Nobles, 2000). In this respect, censuses are a special place in which views on race and ethnicity are confronted by official statistics. In this sense, censuses do more than reflect social realities, they also participate in the construction of these realities (Kertzer and Arel, 2002b:1). However, statistical constructions around ethnic categories cover a wide diversity, which makes any attempt at generalization difficult. This is essentially owing to historical and social specificities and the various procedures that are at the origin of racial and/or ethnic stratification. Conquests, annexations, redefinition of borders, or migration have placed certain groups in minority positions, whether they are old or recent minorities (Striff-Fenart,

[1] For a more detailed analysis of this concept, see Piché's contribution in this treatise (Chapter 84).

1997:3). To simplify, four cases could summarize past and present experiences regarding ethnic statistics. The first case *(counting to dominate)* has characterized a major part of historical experiences associated with colonialism. Although very widespread in the past, it still exists in some newly independent countries. The second case *(not counting in the name of national integration)* is associated with the republican perspective for which national identity is unique. Ethnic differences are therefore denied and should disappear through an unavoidable assimilation process. The third case *(counting or not counting in the name of multiculturalism)* is associated with counting or not counting but for reasons that have little to do with racist views or national unification, but rather with the increased appreciation of cultural mixing. The fourth case *(counting to justify positive action)* has appeared recently and implies a complete reversal of the racist and discriminatory perspective of the first case. Although the first three cases currently apply to the majority of countries, there is increasing pressure to recognize minorities and the necessity of ethnic statistics in order to document discriminatory practices.

1. Counting to Dominate and Exclude

Historically, this type of categorization was closely associated with the colonial situation, which was impregnated with racist ideologies and the issue of superiority/inferiority. According to colonial logic, the *others* should be collectively identified, and censuses (or administrative surveys in the case of the majority of African countries) are the most visible and most politically important tools for the state's statistical needs (Kertzer and Arel, 2002b:3). This approach characterized all the regions under colonial domination, particularly Africa and Asia but also eastern Europe. Generally, the approach employed categories that reflected racial and ethnic differences considered to be scientifically apparent and administratively pertinent (Uvin, 2002). Such a stratification essentially aims to recognize the rights of the dominant and to exclude the dominated from citizenship. In some extreme cases, racial or ethnic markers are recorded on identification papers: this was notably the case in *apartheid* in South Africa (Kertzer and Arel, 2002b:3), in Rwanda (Chrétien, 1997:18), and in Soviet controlled countries (Haug, 1998:13).

Regarding the postcolonial period, the paths taken by the newly independent countries were extremely diverse despite their very similar colonial situations. The case of Africa illustrates this diversity well. Although after independence, as we will see later, the majority of African countries opted to negate ethnicity in the name of national integration, some of them adopted an ethnicist approach by using ethnic categories as tools for domination. The comparison of Burundi and Rwanda is an exemplary illustration of the political stakes of statistical data. In the case of Rwanda, ethnic categories served as administrative markers in order to exclude the Tutsis from power, thus leading to a policy of numbers that tends to cover discriminatory practices (Chrétien, 1997:37). In Burundi, the reverse strategy was adopted: ethnicity is denied (therefore no questions in the census) in order to mask the unequal power structure and the system of mass exclusion (Uvin, 2002:166). In other cases, censuses are simply abandoned (Nigeria), or the results are not published (Mauritania) (Kertzer and Arel, 2002b:25).

Eastern Europe's experience should also be placed under the title of "counting to dominate". The Soviet experience regarding nationality is all the more interesting, as many authors see the similarity between the concept of nationality and that of ethnicity (Courbage, 1998:27; Arel, 2002b:802). Historically, the former Soviet Union was presented as a federal structure based on ethnic and territorial foundations (Abramson, 2002b:176). Nationality or membership of an ethnic group was recorded on each citizen's identity card (Haug, 1998:13). The Soviet empire's constitution is a unique historical case given the huge challenge of managing a multinational empire. Ethnic statistics are indeed used for imperial management here and follow from the colonialist logic of territorial extension (Blum and Gousseff, 1997:49). The colonial nature of the Russian territory raised the issue of the administrative and legal status of the *conquered people*, and social distinctions based on geographic origin (national or ethnic) become necessary in order not to give to the inhabitants of these regions the same attributes as those of the central regions. Censuses have played a key role in the establishment of precise nomenclatures enabling territories and nationalities to be associated, initially on the basis of ethnography (between 1897 and 1937) and then on a purely official, administrative, and legal basis (1839–1989) (Blum and Goussef, 1997:55–61).

With the collapse of the Soviet empire, the policy of numbers continued to dominate the debates regarding official census categories, but this time in the context of independent States. In post-Soviet censuses, the association between nationality and territory is maintained everywhere as the question of nationality continues to be linked with that of national sovereignty. Indeed, the legitimacy of independence is perceived as being based on the fact that the country constitutes the land of origin of the *titular nation*, that is, the ethnic nationality that has given its name to the state, hence the necessity of creating ethnic majorities via census statistics, which provokes struggles by different groups for recognition on the list of nationalities (Arel, 2002b:804–805). "Post-Soviet elites use the census to legitimize the right of titular nations to rule over their homeland, in perfect continuity with Soviet practice," according to Arel (2002:817). The case of Uzbekistan illustrates this continuity in the practice of national and ethnic categorization in which the policy of numbers persists even after independence (Abramson, 2002). As we will see later, taking into account the fact that these new states are emerging within a new global system of nation states, the necessary recognition of ethnic diversity will transform the enumeration practices of censuses (Abramson, 2002b:196). Moreover, these pressures also apply in Russia (Blum and Gousseff, 1997; Haug, 1998).

This said, it must be stressed that the approach of "counting to dominate and exclude" did not develop only in colonial situations. As we will see in greater detail, this issue has been present in countries of immigration such as the United States and Canada for a long time. For example, in Canada during the 19th and at the beginning of the 20th century, the racial issue was included in an immigration policy that aimed at excluding certain groups such as blacks and Asians. These racist criteria were not eliminated until the 1960s (Piché, 2003). However, although the racist issue has lost momentum or even disappeared in the official statistics of these countries, racial categories continue to be included in censuses, even though ethnic categories are dominant, but for reasons that are diametrically opposed and associated with the struggle against discrimination.

2. Not Counting to Unify and Assimilate

In contrast to "counting to dominate," many countries have opted not to count populations based on ethnic or national criteria. The justifications are not all identical, but in all cases, ethnicity as a basis for social stratification is rejected, either in the name of national integration, as is presently the case in many African countries, or in the name of the republican principle of national unity, as is the case in several countries in Western Europe. The case of west Africa is particularly interesting insofar as the scale of ethnic analysis, which was omnipresent during the colonial period, has been abandoned in the postcolonial period in favor of a nation-building ideology. Indeed, they have moved from a situation in which ethnic classification, invented by colonial administrators and ethnologists (Amselle, 1990:22), was used as a basis for social stratification to a situation in which the effort of developing and building a national identity is monopolized by the postcolonial state, which is involved in a modernization process that should result in the disappearance of ethnic awareness (Otayek, 2000:87, 90). In this context, ethnic analysis becomes taboo owing to the weakness of the state, which is trying to build a nation within borders drawn by the colonizers, borders that rarely take ethnic geography into consideration. For west Africa, analysis of ethnicity is all the more lacking as vast circular migratory movements have turned the region into an integrated economic space (Adepoju, 1988:60; Cordell *et al*., 1996:13). Membership of an ethic group is of little importance in this context, as long as labor needs remain high, and the concept of citizenship is of little importance in societies in which access to *social security* remains essentially within the family sphere and outside of state-controlled legislation.

Therefore, during this period, demographers ignored the ethnic variable in their analyses of censuses and surveys, even when the variable had been explicitly included in the questionnaires. It is only recently, notably in Côte d'Ivoire, that the concept of citizenship has come into effect and is used for exclusion purposes (Blion and Bredeloup, 1997; Dozon, 1997). It goes without saying that even if ethnic categories are rejected in the name of national integration, this does not mean that ethnicity is not included in political practices (Otayek, 2000:55). The situation is at the very least paradoxical: on the one hand, ethnic data are absent in order to avoid claims of ethnic identity and to promote national integration, and on the other hand, ethnic based policies are omnipresent.

The refusal to include ethnic categories in official statistics characterizes nearly all the countries of western Europe. According to a recent inventory, the reasons that these countries refuse to include a question regarding ethnic groups are mainly political, constitutional, and legal: this is the case notably of France, Germany, Spain, Belgium, Denmark, and Italy. It would seem that this information is not pertinent for Sweden, Switzerland, and Ireland and that there is no social demand for these types of data (Courbage, 1998:55).[2] The case of France deserves particular attention insofar as the debates there are particularly virulent. Indeed, in France, the question of using ethnicity as an analytical or simply descriptive category is far from being resolved as is confirmed by debates that are ideological and controversial in nature (Taguieff, 1991; Lorcerie, 1994). The frequently violent arguments between demographers testify to the difficulty of

[2] Other unitary states exist, such as Greece and Turkey, which, although proclaiming the homogeneity of the nation state, would not recognize the existence of minority groups on the territory or official statistics on these groups (Haug, 1998:13).

introducing the ethnic variable into the analysis of social reality. For some, the study of ethnicity is dangerous because of the risk of making it essential—and, in so doing, reducing social issues to biology (Blum, 1998)—and playing into the hands of the extreme right (Le Bras, 1998). For others, taking ethnic categories into account is necessary if we wish to understand the mechanisms at work in the exclusion phenomena based on national or ethnic origins (Tribalat, 1995). The rise in the assertion of identity highlights the inadequacy of traditional categories (French–foreign) in the study of the future of immigrants and their descendants, particularly with regard to discrimination (Simon, 1998).

It is necessary here to note the double standard of metropolitan practices in the colonies. Thus, France, Great Britain, and Belgium, which have refused to include questions regarding cultural or ethnic identity because of its incompatibility with their conception of a nation state, did not hesitate to do so in the colonies (Kertzer and Arel, 2002b:10). In the specific case of France, colonization, which creates a system of ethnic classification, constitutes a denial of republican universalism (Otayek, 2000:24–25).

3. Counting or Not Counting in the Name of Multiculturalism

The Latin-American experience is different from the majority of historical experiences discussed thus far. In this region, racial mixing is acknowledged in political and ideological views as a positive value and should therefore not cause a problem. Within this ideological context, there are two distinct statistical practices. On the one hand, in the majority of countries (e.g., Venezuela, Colombia, Cuba, Dominican Republic) the census does not enumerate by race or color (Nobles, 2000:66). On the other hand, and this is the case in Brazil, the use of the census in racial attitudes is particularly well developed. Thus, racial views are in a way used to promote multiculturalism, insisting on harmonious race relations, and statistical data serve to measure the population's degree of whitening (Nobles, 2000:43, 62). However, since the 1980s, numerous surveys have shown socioeconomic differences between the categories of *color*: we thus move from the idea of a radically democratic and nondiscriminatory society to an image of distinct groups that are discriminated against (Nobles, 2000:65).

4. Counting for Positive Action

All ideological constructions regarding notions of race and ethnicity are currently under pressure and being called into question. In particular, countries using statistical categories in order to dominate are being challenged by the minority rights movement and antiracist and antidiscriminatory ideologies. Although Africa seems so far to have avoided this movement (e.g., Côte d'Ivoire), the recognition of pluralism is imposing an increasing number of new statistical practices and risks transforming the enumeration practices of censuses. This is particularly true in the case of eastern Europe, where the issue of pluralism has appeared (Blum and Gousseff, 1997; Abramson, 2002; Arel, 2002b). Even countries such as France, which are characterized by the absence of ethnic statistics, are confronted by the increase in social demand for data requesting information concerning the integration of immigrants beyond the first generations (Striff-Fenart, 1997). A new issue is appearing in the countries of the European Union, supported by the Council of Europe, which expresses the need for reliable statistical data "to encourage peaceful intercultural relations and ensure the protection of national minorities" (Haug, 1998:11). Pressure in favor of positive action appears as much in Latin America, for example, in Colombia (Barbary, 2001) and in Brazil (Nobles, 2000), as in Asia, for example, in China (Courbage, 2002). We are progressing from the diversity of past situations to a pluralist model that tends to replace ethnic nationalism by a more civic nationalism (Dieckhoff, 2000:191).

Three countries deserve particular attention for having made this transition toward a pluralist model, they are the United States, Canada, and Great Britain. In these countries, ethnic diversity resulting from immigration has necessitated calling official views and statistical categories into question. Here we witness a complete reversal in views and policies, which now sees ethnic categories of censuses as tools in the fight against discrimination. The following section will present these three case studies.

III. STATISTICS OF ORIGINS: UNITED STATES, CANADA, AND GREAT BRITAIN

Countries that have introduced ethnic or racial classifications[3] in their statistical systems have all, in one

[3] Despite the scientific invalidation of "race" as a biological concept, it continues to be used as a descriptive category of populations in social practices and has been maintained in numerous international texts, the most famous being the 1948 Universal Declaration of Human Rights, and UNESCO's 1950 "Experts' Declaration on Race" (see Gayon, 2001). Based more on social perception than on improbable genetic variations, the "racial" categories des-

way or another, been confronted with the experience of population diversity associated with a political connection: slavery, immigration (postcolonial in particular), or the registration of minorities within the political borders of a nation state. The definition of the categories, the methods used for recording them, and the use made of them vary considerably among the countries, which underlines the weight of historical-national formations and the difficulty of providing a description and an analysis of classification methods independently of their political contexts (taken in the broadest sense). The experiences of the United States, Canada, and Great Britain make it possible to highlight certain constants in the models developed by immigration countries.[4] The omnipresence of the ethnic and racial reference not only concerns legal or social policy bodies, administrative bodies, the media, and collective representations, but it clearly distinguishes the demographic (and social science) research of these countries where the principal divisions place race and ethnic group at the same level as sex, age, and social category.

1. The United States: From Slavery to Multiple Race

The extraordinary development in the use of racial and ethnic categories in the United States is part of a historical continuity with origins that are in slavery and immigration. These two major facts are part of the United States' constitution. The new nation's first census, in 1790, used the categories that had already been used in colonial censuses. It includes a distinction of the population according to race and condition, with regard to slavery. This founding distinction continued until well after the abolition of slavery and the federation's 10-year censuses continuously included questions regarding the "race" of the territory's inhabitants (Anderson and Fienberg, 1999). To this fundamental distinction was quickly added differentiation according to ethnic origin, whose characterization was continually being refined during the development of mass migration and then during the period of assimilation in the years between the two wars (Schor, 1999), and after the success of the civil rights movement and the emergence of ethnic revival affecting the descendants of European immigrants of the beginning of the 20th century. In the extension of the civil rights movement that obtained the suppression of segregation policies (civil rights acts) and the establishment of affirmative action, a revision of the categories included in censuses became necessary (Nobles, 2000).

Indeed, affirmative action programs require a numerical comparison of the distribution of racial groups in the economy, housing, or education. The disparities within an equal representation serve as indicators of the size of the phenomenon and its eventual decrease or increase. However, the list of groups benefiting from these programs was officially set in 1977 by "Federal Statistical Directive 15" at four minorities: "Blacks," "Indians," "Hispanics," and "Asians." As a result, these four groups are subject to special treatment in censuses, either through a question regarding "race,"[5] or by a special formulation for "Hispanics."[6] The naming of target groups in affirmative action programs therefore reproduces the American society's racialization, as it aims to quash the negative effects of the circulation of racial prejudices. By doing this, it reinforces the racialization of the statistical system.

Jointly with the consolidation of racial taxonomy, a re-evaluation of categories used to classify immigrants and their descendants was undertaken. The combing operated by the question on foreign parentage was indeed of no use in describing the situation of immigrants who had arrived between 1880 and 1920. To study the identity demands of the *hyphenated Americans* in more depth and to re-establish genealogical links, another approach was required.[7] The concept of ancestry appeared within this context. Contrary to the double classification that resulted from individuals' place of birth and that of their parents, ancestry records the origin with which the respondent identifies, with reference to the nationality or the country of origin of the last ancestor born outside the United States. The U.S. statistical office carried out several

ignate phenotypic, physical, or chromatic markers that serve to distinguish individuals and outline populations. Some countries, such as the United States as we will see later (but also Brazil), officially use a racial classification. Others use proxies, such as "visible minorities" in Canada, or "ethnic group" in Great Britain. The sociological literature of ethnic and racial studies extensively uses the concept of race, thus conferring social or cultural acceptance on it. Simply put, race is what is produced by racism, dealing with the effects of racism therefore presupposes speaking of race, while being aware that this is not based on any objective distinction between humans. In a later section of this chapter, we will refer to ethnic and racial categories, without quotation marks, to evoke the classification used by the statistical bodies of the countries in question.

[4] For further developments, see Simon, 1997.

[5] With the following formulation in 2000: "What is this person's race? Mark one or more races to indicate what this person considers himself/herself to be" (the underlining is ours). The possibility of selecting more than one race appeared for the first time in the 2000 census. The expression "considers to be" emphasizes the subjective nature of the response.

[6] For background on the "Hispanic question," see Cholsin (1986).

[7] On the links between ethnicity and race in the United States' statistical classification, see Schor (1999).

surveys in 1969 and 1979 (Current Population Survey) that tested the questions on ancestry, and the question was introduced into the census in 1980.

From then on, ancestry was used as an elementary parameter for pinpointing ethnic groups in the United States. Although such groups do not benefit from differential treatment programs, their recognition through the census consolidates the development of the ethnic pluralism present in American society since the mid-1960s (Petersen, 1997). From a methodological point of view, the recording of declarations on individuals' origins is an innovation in the census. Beyond an objective evaluation of ethnicity, self-classification is based on the expression of identity. Indeed, by asking individuals to choose an origin or even several origins, the question presupposes a selection among the plurality of possible origins, according to criteria that largely elude statistical services. In other words, the responses to the question on origin indicate the *ethnic options* of individuals, to quote the title of Mary Waters' famous publication (1990) devoted to the analysis of data on ethnic origins.

The significance of data on race and ethnic origins poses a real epistemological problem for statistics and, in particular, for official statistics whose purpose is to authenticate the numerical size of the groups that make up the country's population. The variations in the declarations of ethnic origin in each census demonstrate the instability of identities and their sensitivity to current events, whether they are political, cultural, or social (Skerry, 2000). The interweaving of the collection of racial and ethnic data and affirmative action programs mainly provoke debates on the categories. Their legitimacy is rarely called into question as they have become almost natural in American society. The division of society into a racial pentagon is conceived as consubstantial and is never questioned (Lacorne, 2001).

In contrast, the debate surrounding the policy of affirmative action has weakened the statistical base and provoked changes in the method of handling racial groups. The introduction of the possibility of multiple choices in declaring race in the 2000 census formalized the change in society toward greater racial diversity. Indeed, the results (fewer than 7 million declarations of several races, 2.4% of the population) seem to demonstrate the resistance of racial boundaries, if not in reality, at least in the representations of individuals who favor an uncombined genealogy in their declarations (Grieco and Cassidy, 2001). Multiple choice for race has, however, opened the Pandora's box of the reliability of the declarations and definitively damaged the pertinence of the questioning (Perlmann and Waters, 2002). Although some consider that the low rate of racial mixing declared reinforces the pertinence of affirmative action, others predict that the convention of racial self identification will be called into question (Goldstein and Mourning, 2002).

2. Canada and the Visible Minorities

Since the beginning of the 1970s, the Canadian government has been professing a multiculturalism based on recognition of the population's ethnic peculiarities, associated with the exercise of specific rights for minorities within the confederacy. However, this conversion should not make one forget the particularly assimilation policies of successive governments faced with foreign immigration. The multicultural opening exists within the conflict between the two "founding peoples," France and Great Britain, since the promulgation of the 1867 Act of British North America that created the dominion of Canada.

A regular and detailed count of inhabitants according to their origins and first or usual language occupies a strategic position in the formation of Canadian identity and, in more concrete terms, in confederate political management. More recently, debates surrounding the emergence of a Canadianism that could be expressed in the same way as that of other ethnic groups, or be defined as a priority, is developing among the two founding peoples as a result of the pressure from large-scale foreign immigration.[8] The recording of origins in censuses has experienced numerous changes since the end of the 19th century. As well as nationality and place of birth, data on *ethnic group* and *racial origin* were collected until after World War II, when there was a return to *ethnic origins*. Opposition between a geographical-political definition of origin and a definition of ethnicity through *linguistic ancestry* has been seen in Canadian classifications from 1871 up to the last census in 1996 (White *et al.*, 1993).

The definition of ethnic origin developed dramatically between 1951 and 1991. Although the 1951 census was the first to offer a geographical definition of origin, the 1971 census introduced a series of significant modifications in the conceptualization and the formulation of ethnic origin. In particular, it marked the passage to self-counting. Origin is characterized as the "ethnic or cultural group [to which] the ancestor on the male side belonged upon arrival on the continent" (*Census Guide*, quoted in White *et al.*, 1993). The *Census Guide* recommends referring to the language spoken by this ancestor. In 1981, the reference to the ancestor on the male side was abandoned and replaced by a wider

[8] The concept of "foreign immigration" is a Canadian specificity and indicates all origins other than French and British.

meaning of ancestry. The concept of roots replaced that of descent in the guide's instructions. The use of a list of names, organized hierarchically according to the number of times they were used in the preceding census, was proposed in several censuses. This organization method in the form of origins listed in descending order resulted in competition between different groups to be recognized in the listing and to obtain, thanks to multicultural policy, a significant numerical representation. The pressure exerted by ethnic lobbies to modulate the formulation of the questions or to include one name or another started to multiply.

The multiplication of demands from the first nations led to the removal of the reference to the first ancestor to arrive on the continent. This step toward a broader concept of the Canadian population's origins also resulted in the acceptance of multiple responses in even the wording of the question. The result did not take long: multiple responses represented 11% of all responses in 1981, 28% in 1986, and 38% in 2001. The affirmative action programs included in the 1982 Charter, then in the Employment Equity Act of 1986, modified in 1996 (Equity Act, 1996), and the Multiculturalism Act of 1988 also had a significant effect on the data collected in the census. The inclusion of a "Black" category in 1986 responded to the Employment Equity Act, without it being really sufficient to cover the range of minorities that were likely to be discriminated against. Working on the same principle as the affirmative action programs, the act established quotas or numerical objectives to achieve equal opportunity. However, the Canadian census, contrary to the U.S. census, has not included a reference to race since 1951. The evaluation of the population concerned by the Equity Act revealed itself to be delicate, and the act introduced the concept of "visible minorities." By visible minorities, the concept of "nonwhite"[9] people is understood, that is, an all-inclusive list combining all individuals according to their country of origin but referring implicitly to visible attributes such as skin color or appearance.[10] In 1981, all visible minorities combined made up nearly 5% of the total population, by 2001 they had increased to 13%. This increase is essentially owing to high, mainly Asian, immigration in the 1990s.

After nearly a century of evolution, the categorization of ethnic groups has changed considerably. Origin is now clearly distinguished from language, it has lost its reference to the paternal line (awareness of gender inequality in Canadian society), and its reference to the first arrival on the continent (increase in autochthonous claims). Henceforth, it is turning toward a more subjective definition, closer to identification than ancestry, which in any case is very hypothetical. Taking into account multiple origins puts into perspective claims to reconstitute ethnically homogenous lines from the migration period up to the census date. The high levels of mixed marriages between ethnic groups should favor a more subjective definition of origin, because the identification of a specific ancestry depends on a grid of complex decisions that are specific to each respondent.

Increasing the relativity of origin as the expression of ancestry, the emergence of a *Canadian* category disturbs the classification usually used. For a long time regarded as inadequate, claims of Canadian origin have increased significantly. The introduction of a Canadian category in the list of ethnic groups was tested in preparation for the 1991 census. Nearly a third of respondents chose it to describe the origins of their parents or grandparents, and half chose it to describe their own ethnic identity (Pryor *et al*., 1992). Quite obviously, a process of indigenization consecutive to the date of the initial migration (more than 2 centuries for the founders) has greatly affected the Canadian population. This refusal to be included in the old ethnic distinctions by affirming a national identity can be explained as a reaction to the multicultural policy. The 1996 and 2001 censuses explicitly included the Canadian category in the section on origins. Nearly one-quarter of the population indicated it as their only ethnic origin in 2001, whereas 16% declared it in combination with another origin. A postenumerations survey on ethnic identity is carried out in conjunction with the census in order to provide an evaluation of the population's declaration and membership logic, beyond a national feeling that obviously destabilizes the statistical systems and public policies toward minorities.

3. British Postcolonialism

Although questions regarding race and language have been authorized by the Census Act since 1920, data on ethnic or racial ancestry have only been collected in the United Kingdom census since 1991. Up to this date, censuses had only recorded data on nationality and place of birth. These were used to establish statistics on ethnic groups with the short-lived introduction in 1971 of a question on parents' place of birth based on the model of the American census.

[9] More precisely "persons, other than natives, who are not of white race or who do not have white skin."

[10] The list of groups considered as "visible minorities" indicates visible perceptions as clearly as the terminology: "White, Chinese, South Asian, Black, Arab/West Asian, South East Asian, Latin-American, Japanese, Korean, Other."

However, the categories thus obtained did not correspond to the groups studied by the sociology of *ethnic and racial studies*, or to the population targeted by campaigns against discrimination. Created by the Race Relations Act (RRA) of 1976, the *Commission for Racial Equality* was given a mission "to work towards the elimination of discrimination; to promote equality of opportunity; to influence policy; and to develop and encourage research in the field of race relations" (RRA). From this point of view, public action and the development of tools of knowledge and surveillance appear closely related.[11] However, the development in the fight against ethnic and racial discrimination encounters many problems, the least of which is not the complete lack of quantitative information on the phenomenon. The concept of a minority, the usage of which spreads meteorically in public view, does not have a statistical basis. In the 1971 census, a question on the parents' country of birth, similar to that of the American census, was introduced. It was used as a basis for identifying minorities concerned with the RRA. However, the information thus collected is not really satisfactory, and from the point of view of the 1981 census, reflection on taking ethnicity into account began. A virulent argument began between those who support pinpointing individuals' ethnic and racial origin and those for whom such a process is not only prejudicial to individual freedom but also springs from scientific trickery. To the detractors of a question on ethnicity, Martin Bulmer (1980) responded by pointing out the relative imperfection of all measurement of social phenomena. By placing the specific issue of race in a more general perspective, he neutralized the controversy regarding the legitimacy of racial representation and only dealt with the technical issue.[12]

In parallel with the epistemological and ethical debate on the racialization of statistics, the Office of Population Census and Survey carried out a series of tests to develop the questionnaire on ethnic and racial origins. In the face of resistance, the idea was abandoned by the government, and the 1981 census did not include any questions on ethnic origin or parents' place of birth. After this first failure, the gaps in the information provided by the census on the situation of ethnic minorities caused major problems for the Commission for Racial Equality. The adjustment of local positive action policies required very accurate information that the census could not provide. As a result, the government asked the Office of Population Census and Survey to begin exploratory work again. This time, the changes in the census did not meet with any major opposition. The 1991 census therefore included a question regarding a person's ethnic origin (Coleman and Salt, 1996). The taxonomy used combined racial and ethnic elements, such as *White*, *Black-Caribbean*, or *Pakistani*. This confusion reflects the ambiguity in the definition of minorities in British legal texts.

In Great Britain, more so than in the United States, the borders between race and ethnic group appear to be extremely blurred. In most cases, these two terms overlap or are used one for the other. Thus, the RRA of 1976 defines discrimination as unfavorable treatment of a person on the basis of "racial grounds." The text uses an extensive definition of racial grounds: " 'racial grounds' [refers] to 'color, race, nationality (including citizenship) or ethnic or national origin.' " With criteria combining objective (place of birth, language of socialization, religion, culture, nationality, skin color) and subjective elements (identification of a real or imagined ancestry, feeling of belonging to a group), such a liability is hardly surprising. It reproduces the broad outline of the divisions inherited from the colonial experience and the construction of the British empire, while striving to match the most common representations in British society. This is why the "ethnic origin" category is biological, cultural, political, and social (Ballard, 1997).

Such a characterization indicates a continuity between British colonial classifications and those used for minorities settled in the United Kindgom. The fact that the majority of the immigrant populations came from former colonies of the empire reinforces the transposition of taxonomies. The colonial heritage[13] greatly modifies the management and position of immigrants in former empires. As Didier Lapeyronnie (1993:132) points out, the immigrant of colonial origin is a victim of a specific rejection, more racist than xenophobic, which "is born from the difficulty that is specific to universalistic and modern cultures of incorporating the particular experience of the colonized." The progression from colonialism to racism rises from a connection between the immigrant and the host society that precedes the migration. In this sense, the racialization of immigration statistics in Great Britain is situated in the extension of the classification formed

[11] Maire Ni Brochlain (1990:546–550) lists no less than seven reasons justifying the presence of an "ethnic question" in the census. These arguments all have, with no exceptions, an operational range. Here, knowledge is subordinate to action, it starts with a recognition of multiple "racial" discriminations in all aspects of social life, then the statement directs the initiatives taken by the services in charge of "ethnic minorities."

[12] A very "positivist" position, which he reiterated in the Office of Population Census and Survey publication that followed the 1991 census (Bulmer, 1996).

[13] On this point, British and French experiences show many similarities.

within the framework of colonial management and reactivated in immigration control policies.

The ambiguity of such a determination corresponds to the broad spectrum covered by the laws on race relations. Social intervention programs, in placing the fight against racial and ethnic discrimination at the centre of their concerns, have encouraged the racialization of statistics while polarizing social issues on ethnic-racial problems. The British experience once again illustrates the close links between racism and antiracism in their interdependent development. How can the terrible contradiction that is attached to any reparation be avoided? By refining the methods of pinpointing exposed minorities, the classification locks them into an autoreferential dynamic, excluding de facto other media of identification (notably socioeconomic).[14] In the same way as the United States—which began to take multiple declarations into consideration, opening the way to an apprehension of multiculturalism or intermixing—the census in 2001 also introduced a mixed position in a formulation that was even more explicit than the U.S. example by introducing a special heading. A question on religion was also added. However, there are no longer any questions on citizenship.

IV. THE VERY DIFFICULT USE OF ETHNIC DATA OR THE BIAS OF ETHNIC STATISTICS

The ideological and ethical aspects considered so far should not blind us to the simply methodological problems. It is necessary to ask about the quality of ethnic data and the specific methods of analysis that are associated to them, which conditions the legitimacy of their use and on which the image of the components of society depends.

Here we will only discuss the statistical aspects: data collection; the manner in which respondents can be situated in the categories, notably with the question of people of mixed race (for convenience, all persons of multiple or mixed ancestry will be so called, but the terms should be understood in the social and not the biological sense); and the presentation of information by statisticians who regroup and classify the data once more. The importance of data collection for these types of data is such that it is necessary to consider this stage in sufficient detail before moving on to the issue of analysis. Then we will consider analysis problems at a given time: estimates of data quality and common bias in these types of data. Last, we will look at the problems of studying population trends through ethnic statistics.[15]

1. Collecting Ethnic Statistics

The statistician's approach wishes to be objective (Goldman and McKenney, 1993; Goldmann 1997) by ensuring that the ethnic categories reflect the sociocultural reality of the various components of society. The statistician is involved twice: during the design of the questionnaire and during analysis of the data collected.

a. The Wording of the Question on Ethnic Origin

Before the questionnaire is written, the issue of the method of declaration of ethnic origin comes up: self-declaration by the respondents, declaration by the interviewer, or from a document (e.g., identity card, passport) that includes the origin, which was very common in the Soviet Union and still is today in countries that were part of it. Self-declaration conforms best to the freedom of the individual but is still not universally applied. The declaration method obviously affects the results (Telles and Lim, 1998).

The question on ethnic origin is usually presented as a list, closed or open. Experience has shown that not only do these lists differ from the terms used by anthropologists, but that they do not fulfill scientific criteria and that they mix different dimensions: racial, cultural, and national. Thus, one often comes across terms referring to race (skin color), language, and nationality with the names of ethnic groups. The United States divide the question into three: that is race (e.g., "White," "Black," "Amerindian," "Chinese"), Hispanic origin ("no/yes Mexican, Porto Rican"), and ancestral origin ("ancestry") of an ethnic-cultural nature (including nationalities and ethnic groups). In Great Britain (1991 census), a single question includes racial aspects and nationality in the terminology of the categories (e.g., "Black African," "Black Caribbean," "Indian," "Pakistani,") (Bulmer, 1996). Australia uses a question on ethnic origin in order to distinguish the aborigines and only introduced a question on ancestral origin in 1986 (and more recently in 2001). New

[14] Criticism aimed at ethnic and racial classification in the census and at the entire statistical machinery remains relatively widespread in Great Britain. It also comes from users who work in the field of discrimination, and who, although challenging the production of ethnic statistics, also set up systems for evaluation. For an example of this position, see Moore (1997).

[15] Although the issue of people's origins has been called many different names—ethnic origin, race, and ancestry in Anglophone countries—we always use the term ethnic origin for more clarity and because the problems of collection and analysis are the same regardless of the term used.

Zealand uses one ethnic question that can include nationalities ("ancestry") in the open category, and people of mixed race can tick several boxes.

At the level of the ethnic groups themselves, various inaccuracies are frequent: a group can appear on the list at the same time as one of its subgroups, particularly when the subgroup is sufficiently represented in the population for its size to be of interest. Certain names are more popular than scientific, and they often correspond to the manner in which the dominant group has named the other ethnic groups rather than the manner in which the ethnic group calls itself, a situation that was common in colonial statistics. Last, certain very minority ethnic groups do not appear on the list and can be specified in the "other" category if space has been provided. The list is sometimes very short and aims to group into large categories as is the case in Great Britain.

The considerations that determine the establishment of the list of categories proposed are not strictly anthropological but are associated with the demographic and social significance of the groups. However, they tend to carry the majority's a priori vision, represented by the administration and including the statisticians, and can make it difficult for respondents to accept the suggested categories and to identify themselves therein. It is therefore desirable that the list be prepared in collaboration with representatives of the different components of the population.

Because of the existence of various levels (race, nationality, ethnicity) of groups and subgroups in the proposed list, the order of the categories has a nonnegligible influence on the results. Alphabetical order can place very poorly represented groups at the top of the list, whereas ordering according to numerical importance is subject to the quality of prior estimates and variations with time. For this reason, it is frequently contested by various minorities. Statistics Canada's recent tendency has been to remove the list altogether and replace it with an open question consisting of four blank spaces (Canada, 1996 census: Goldman 1997:45).[16]

b. Mixed-Race and Multigroup Membership

The individuals who make up the population can belong to several ethnic groups at the same time owing to intermixing. Statisticians may wish to ignore this fact and insist that an individual be attached to one and only one group. Ethnic membership is therefore considered as a social (we attach ourselves socially to a community) rather than a genealogical phenomenon. Transmission of origin can therefore follow a patrilineal or a matrilineal tradition, or another method: social, emotional, etc. Statisticians can also decide at which degree of intermixing a person belongs to a community; the U.S. practice of *one drop blood,* according to which with 1/16 of black blood a person is black, has been the object of much criticism. The choice of single membership within a social context is not contradictory to the definition of ethnic origin as membership of a sociocultural group but has implications for analysis. Whereas a characteristic fixed at birth such as sex is (nearly) unchangeable, a social characteristic is subject to variation and to various interactions. The example of the 2000 U.S. census illustrates these aspects clearly. Few mixed-race individuals identified themselves as such and the declaration of ethnicity is therefore social rather than biological (African-Americans would seem to make up a social class). There is nothing to ensure that some of the people of mixed-race will not choose a different category in the next census.

If the declaration of mixed-race is allowed, it can be done in many different ways: ticking as many boxes in the list as necessary, describing in the "other" category, having several boxes in an open list as in the 1996 Canadian census, or dividing the question into two questions on parents' origins (with a double answer possible for each parent such as in the 1988 French Polynesian census). The approach of two questions on parents would be capable of reflecting the genealogical reality of the parents if they had at the most two origins, otherwise a question on each grandparent would be necessary. It is however not a biological racial reality (whose existence has been definitively invalidated) that we wish to identify, but sociocultural membership, a fact that justifies taking simplified representations into account.

c. Respondents' Answers

The respondents' answers represent the subjective aspect of ethnic membership. Choosing imposed declarations would not solve all the problems. In the absence of a document, the interviewer must decide on the origin of the persons and his/her opinion varies according to the interviewer's own origin—a member of a majority group, of the interviewed minority, or another (Telles and Lim, 1998)—and would influence the results (Davis, 1997). Coercive practices can cause an outright refusal to reply, either by avoiding the survey or by giving inaccurate information, which results in under-representation, a high rate of nonresponse, and a reduction in data quality.

The principal difficulties undoubtedly stem from the existence of groups that are divided into subgroups and people of mixed-race. Thus when two groups that

[16] The purists claim that even the few examples quoted in the title of the question can influence the results (Goldmann, 1997).

are in a relation of inclusion are present on the list, an individual might not read the list entirely. Some members of a subgroup not present on the list might wish to distinguish themselves from the main group that is listed and place themselves in the "other" group, clearly mentioning their origins or not. Persons of mixed-race have the choice among their various origins, which they can only mention if the questionnaire offers the possibility. If this is not the case, in order to show a dominant origin, they are obliged to omit their other origins. Last, because origins are of a social nature, sociodemographic factors such as length of stay, nationality, social situation, and cultural integration can influence the declaration.

In the field of ethnic categories, the collection method used is particularly susceptible to ambiguity between categories in which respondents can place themselves according to their perceived origins, and objective categories that reflect society as viewed a priori by statisticians. The trend is to give more freedom to the respondents and to move away from single answers (the United States recorded multiple answers in the 2000 census, see above) and to replace a list of hotchpotch categories that reflect the concerns of the majority with open responses.

2. Presentation of the Results

Although a table usually presents all responses, possibly including the most common responses to the open question and the different types of multiple origins when they can be declared as such, tables that compare different variables should, for practical reasons, group the origins in fewer categories. The groupings are usually done by geographical region or by cultural groups, unless particular origins are of specific significance because of their number or social position. If the questionnaire is designed for this purpose, one can still choose to continue separating people of mixed-race into one or more categories or integrating them into monoethnic groups at this level.[17]

[17] Only the method of dividing the question on origin into two questions on the parents makes it possible to calculate the dominant origin of mixed-race individuals: persons with three-fourths of an origin or one-half *a*, one-half *b*, and one-fourth *c*; however, if only two origins are required for each of the parents there will be ambiguity at this level. The question on individual origin does not make it possible to weight the different origins to which a person is attached, a one-half *a*, one-half *b*, and one-fourth *c* person appears to belong equally to three ethnic groups from ticks on a list or the counting of his/her origins in an open question. Placing mixed-race individuals into one single group is not mathematically correct and is based on the choice of hierarchical organization (or attribution priorities). Usually, high priorities are attributed to minority groups, which results in placing mixed-race individuals with them, but this choice does affect the results of the analysis.

Since 1991, New Zealand has been using a particularly interesting double analysis of ethnic categories associated with the existence of people of mixed-race. An initial analysis provides additive numbers. Statistics New Zealand has used, according to priority, a maximum of three ethnic groups mentioned by mixed-race individuals and published a table according to the number of origins: single and mixed-race by two or by three or more origins with the details of these origins (Statistics New Zealand, 1993). This implies category changes when grouped at a wider level: an English-Greek mixed-race individual is no longer of mixed-race if European origins are grouped. Another analysis of the data produced tables in which an individual is included in a category as soon as he/she mentions it. This method makes it possible for each component of the population to include all its elements, as well as those who share their origins with others, but the results are not additive.

As soon as the results are presented, the frequency tables of ethnicity and the analysis of open answers make it possible to consider changes to the list. As with any changes in nomenclature, it is important to preserve the comparability of the information with that collected in the past. However, poorly represented groups are sometimes withdrawn from the list, which causes problems in ascertaining to which group they will attach themselves, or sometimes groups that seemed well represented in the open question are added to the list. It would seem preferable to avoid withdrawing groups from the list, but adding also has an effect on the evolution of other groups. Individuals whose group does not appear on the list can change their declaration, detailing their origins in the open question or attaching themselves to a different group in various censuses. Individuals thus move from one category to another simply as a result of the imprecision of the categories (a phenomenon that should be distinguished from voluntary changes, see above), which results in population transfers between groups. However, the absence of a list obviously avoids any such changes.

In summary, even though the large number of ethnic groups cause coding and grouping problems for the presentation of the results, it would seem preferable, from an essentially theoretical point of view, to abandon the lists and to ask about ethnic origin in a completely open question. This would avoid the problems associated with the imprecision of terms and the inevitable changes to the list that this then entails. The second conclusion is more imperative: it is necessary to give mixed-race individuals the possibility of declaring themselves as such and to present them separately in the results.

a. Data Quality and Variations of Declarations of Origin

The populations that we wish to study through the question on ethnic origin are old, historic, or autochthonous minorities or are new minorities, resulting from migration. The phenomena studied are the socioeconomic and sociocultural (e.g., language, religion) characteristics and more generally social integration, which presupposes an analysis over time but which can be carried out through comparison between diverse components of a population by cross-section. This presupposes reflection on data quality.

Comparison of data on ethnic origin with other variables makes a relative verification of the quality of the answers possible. The most interesting variables are place of birth and original nationality. However, there are hardly any monoethnic countries, and multisecular migrations, including colonization, add to this confusion, although analysis by age or period does sometimes make it possible to distinguish old migrants (e.g., returning colonists). Religion and first language in particular also make verification possible; however, these concepts do not always overlap. Declaration of religion varies according to practice, and persons born in the host country or who migrated at a young age may not have spoken their parents' language enough to consider it as their first language.

Whereas up to now we have mainly considered that respondents declare their ethnic origin in its unchanging aspect (as an origin) and the objective aspect (in the sense of ethnic-cultural filiations reflecting social reality), we will now consider the cases in which this declaration is affected by other criteria and can change over time.

Individuals can refuse to be identified with a group of origin for numerous personal, social, or political reasons and attach themselves to a group that they believe is closer. A high social position can result in an individual attaching to a more favored group: artists, for example, tend to attach themselves to groups of exotic origins. This phenomenon particularly affects mixed-race people but is not exclusive to them. Thus, in Australia and Canada, people of all origins have started to declare themselves to be Australians or Canadians, respectively, in censuses (Pryor *et al.*, 1991, 1992). These phenomena generally tend to lower the socio-occupational levels of minorities. Measuring social distance, and socioeconomic characteristics in general is obviously biased if the definition of the population in which the characteristics are being measured is in itself social, in other words, if there is interaction between the social situation and the declaration of origin. More generally, a variant characteristic is measured, for example, socio-occupational situation, against an invariant characteristic, such as birth year, place of birth, and sex, but it is far more risky to do it in comparison to a characteristic that is itself variant, such as the declaration of a person's ethnic group.

The socioeconomic position of people of mixed-race is especially sensitive to this type of measurement. Their attribution to one or another of these groups in the context of a single category will affect the results of the comparisons. Thus, the tendency, through the interplay of priorities, is to include them in the visible minorities; by so doing, the intergroup distance in the measurement is reduced, as the mixed population would be more favored than the minority groups. The same is true if we consider that persons with faint kinship ties to an ethnic group do not belong to this group, whereas visible characteristics still distinguish them from the majority group and are therefore the cause of discrimination. The process is therefore reversed: underprivileged people are included within the privileged population. To measure a social phenomenon such as discrimination, it is necessary for the affected group to be fully counted, in other words that there be adequacy between the division of the population by the statistician and that caused by the discrimination itself.

With the existence of intermixing, ethnic groups take us back to set theory in mathematics. Mixed-race people belong to several groups, and comparison between subsets should include every individual from each group or the separate analysis of each intersection. Therefore, the solution lies either in including mixed-race people in all the groups to which they belong (this has been the case in New Zealand since 1991), which avoids the above mentioned bias (but a difference in proportion effect of mixed-race people remains in some groups), or in analyzing them separately.

Another source of inaccuracy is linked to the fact that the ethnic origin variable combines several generations whose degree of integration undoubtedly varies. It is therefore necessary, in the case of recent migration, to compare it with the place of birth to distinguish the migrant generation (first generation) from that of their descendants. If the parents' place of birth is available, it is also possible to distinguish migrants' children (second generation) from the following generations.[18] However, particular components of migra-

[18] One might also believe that discrimination is easier to measure shortly after the migrant's arrival, with compensatory phenomena coming into force after a while in sectoral or ethnic labor markets (Renaud *et al.*, 1997); it would therefore be more interesting to study recent migrants in a survey or from a question on residence a year before the census.

tion (such as the return of colonists) cannot easily be distinguished from nationality. Although nothing prevents the place of birth and ethnic group from being used simultaneously, when these variables are combined (or cross-tabulated) biases linked to ethnicity are found.

In summary, using monoethnic categories leads to the isolation of nonhomogenous populations, which are made up of people with double (or multiple) membership, and ethnic origin alone does not make it possible to distinguish different generations, which, added to the social aspect of the declaration of origin, can bias the estimate of social distance. Simultaneous approaches by variables not susceptible to biases linked to the social nature of origin appear necessary, and it would be useful to have information on parents' birthplace for populations resulting from recent migration.

3. Longitudinal Observation

It is also necessary to consider the difficulties in measuring the evolution of population components in the context of simultaneous variations in the quality of enumeration,[19] of natural growth, migration, and changes in declarations of origin. Declaration of ethnic origin can vary over short periods. In Australia, between the 1986 census and the postcensus survey, 15% of changes in the declarations of aborigines were observed (Howe, 1994). How can longer-term changes be measured?

The evolution of the population by ethnic group, all ages combined is first of all affected by the different composition of births and deaths with regard to the proportion of mixed-race people, which is interpreted differently according to the method of classifying them. A population that becomes mixed can lose, according to the method of classification used, some of its descendants, which can reduce and even reverse its growth.

The analysis of the evolution of an ethnic group is more precise if it is carried out by birth cohort through the method of expected population (by survival between t and t').

$$P^{t'}_{x+a} = P^{t}_{x} * S_{x,x+a}$$

where S = population's probability of survival (P);

x = age in t;
a = interval t,t'.

However, estimates of mortality by ethnic group often give controversial results, owing to the bias associated with the declaration of different origins for the same person in censuses (denominators) and in civil registration data (numerators), because the declaration is made by the relatives or neighbors of the deceased. This is a first illustration of the problems in using ethnic data for measuring demographic phenomena such as mortality and natality in order to measure demographic trends and socioeconomic characteristics. Indeed, in relation to a stable attribute (e.g., sex, place of birth . . .), a cohort increases or decreases (apart from mortality) only as a result of migration, but it is not the case with an unstable variable susceptible to changes in declaration such as ethnic origin. It is therefore difficult to decide whether the changes are due to migration or changes in declaration, which react one against the other as interference. The ethnic origin variable alone is not sufficient to measure migration. Because migration is frequently ascertained from other sources, we can therefore attempt, by difference, to estimate the changes in the declaration of origin. Ideally, migration data according to the same categories as those of the census or the survey should be available.[20] The use of ethnic group, in censuses, for example, seems to call for its use once more in other statistical fields: civil registration, migration, etc.

In the absence of a direct measurement of migration, changes according to place of birth or the nationality of origin provide an estimate of migration[21] when there is a good match between an ethnic group and these variables. In the case of censuses, migration can also be estimated with a question on former residence, directly for the arrivals and from the expected population for the departures (the difference between the population expected by survival between t and $t'$and population observed in t' who declared residence in the country in the question on former residence in t). The growth by birth cohorts, of an ethnic group that is higher than migration or higher than the growth of another variable that enables the size of this population to be estimated without ambiguity represents an increase in the declaration of this ethnic group in these birth cohorts, and vice versa, lower growth indicates a decrease in declaration.

Thus, in the absence of immigration, an increase in the cohorts of Australian aborigines has been observed since 1981, after a reduction, in the absence of emigration, between 1976 and 1981. In Canada, American Indians have recently experienced an increase owing to changes in the declaration of origin. In Yugoslavia,

[19] The methods of verifying the completeness of the enumeration are usually postenumeration surveys and comparison with other, for example, administrative, sources.

[20] Provided that that the categories are the same and that the declaration of origin is identical and stable.

[21] Provided that the statistical operations are similarly complete.

the Yugoslavs[22] increased between 1961, 1971, and 1981, but they decreased significantly between 1981 and 1991. These variations were often more than 10%. In Australia, the increase resulted from the adoption of laws that are more favorable to the aborigines. In Yugoslavia, the reduction resulted from an increase in competition between the nationalities, with political parties demanding each person to attach themselves to their origins (Mrdjen, 1992). Between the French Polynesian censuses (Baudchon and Rallu, 1993), significant variations are observed around the age of 20, when individuals move out of family homes and complete the questionnaire themselves without always taking into account the declaration that their former household head made when he/she completed the questionnaire on their behalf. The changes should also be considered in relation to migration, which is considerable at these ages.

The evolution of the population's ethnic components is interesting not only at a national level but also at regional and local levels in order to measure phenomena such as confinement and ghetto-ization. The problems that appear at national level can also be found at these levels (evaluation of enumeration quality, migration, and changes in declaration of origin) and necessitate, when the information is available, the same comparisons with stable attributes as at the national level.

Taking into consideration the difficulties of following the trend in numbers and the social nature of origins (e.g., susceptible to vary with the occupational situation), measuring the evolution of the socioeconomic characteristics of the population's ethnic components seems particularly hazardous. Admittedly, rarely are huge changes in declaration observed, but, for example, variations of 5% in the total number concentrated on certain social categories can be enough to make the assessment of the trend in levels of qualifications or occupation impossible.

Finally, the use of ethnic origin, which is not a stable attribute even though it is often considered as such, does not make it possible to separate the factors of change of ethnic groups. As in cross-sectional analysis, it is necessary to use together (or simultaneously) other approaches based on stable attributes in order to confirm the changes.

In conclusion, evaluating the ethnic origin variable is particularly delicate as it is based on different points of view regarding the composition of society, the statistician's objective viewpoint, and the more subjective viewpoint of individuals: that of the majority group and that of the minorities. It represents different realities, social for the statistician and genealogical or biological for others. The fact that the ethnic origin variable includes nonhomogenous populations, including individuals with double (or multiple) origins and of different generations, makes its use difficult, resulting in considerable biases in the measurement of social distance. Last, as an unstable variable, it does not allow a precise measurement of changes, particularly of migration. With regard to minorities resulting from recent migration, the individual's place of birth and that of the parents can be used at the same time as ethnic origin or preferably apart to improve the homogeneity of the populations studied and enable change factors to be analyzed.

It is surprising that current practice most often deviates from the appropriate methods: lists composed of terms referring to various dimensions, frequent changes in the list, imprecise treatment of people of mixed-race, delimitation of nonhomogenous populations, and approximate evaluation of changes without distinguishing the various factors; all of this leads to measurement of social distance and its evolution without the sources of bias even being mentioned. Compared with analyses of stable attributes, the analysis of ethnic origin can be an interesting complement or a source of bias, more especially so as the methods of collection and analysis are approximate. It remains, however, the only variable that enables autochthonous minorities or those whose migration dates back to three generations or more to be studied.

CONCLUSION

Demography has played a preponderant role in ethnic statistics. In so doing, it participates and has always participated in the *power of naming*. For this reason, complicated problems exist in the demographic analysis of ethnicity. The ambivalence still remains as, beyond the numerous problems of production and analysis of statistical categories such as described above, the essentialist and biologizing drift is still possible. Moreover, the increasing ethnic pluralism of modern societies, in association with the migratory flows of the past 30 years are a major challenge in that they question the old definitions of identity based on the idea of an ethnic nation and necessitate new approaches to citizenship (Bauböck and Rundell, 1998).

One of the major questions raised by the emergence of new ethnic minorities resulting from immigration concerns their position within the society and the

[22] Individuals declaring themselves to be of Yugoslav nationality, rather than Serb, Croat, or Muslim, etc., which should not to be confused with Yugoslav citizenship.

nation. In particular, the issue of economic integration finds its meaning in the fact that minority groups have to contend with discriminatory and racial obstacles in the labor market. The numerous antidiscrimination and antiracism measures have created considerable social demand for data providing information on the experience of immigrants and their descendants, and data that identify the groups who suffer most from the mechanisms behind ethnic stratification. Censuses continue to provide the best opportunity for producing such data, insofar as the so-called ethnic categories reflect, if only in an approximate way, new migratory realities. The trend toward self-identification in censuses and the evolution toward subjective and endogenous definitions must be interpreted in this sense.

The evolution of ethnic categories calls into question two traditions of demographic research concerning the use of these categories. Their changing and fluid nature decreases their causal value considerably and therefore makes it difficult to interpret the variations in behavior according to these categories. It is traditional, differential demography that is called into question here. But more fundamentally, the subpopulation approach, which is so dear to demography, must be abandoned as it becomes difficult, if not impossible, to follow ethnic groups from one census to another. Expressed in more technical terms, the comparability of ethnic categories is seriously disrupted by the new definitions. Nevertheless, that which is lost in comparability is gained in legitimacy and validity insofar as minority groups participate in the definition of the categories. Where demography can play a strategic role in studying ethnic groups is in its *statistical power* of information on ethnic inequality. The collection of ethnic data is only legitimate if it is not used to the disadvantage of minority groups (Pool, 1991:16) but serves to reinforce the policies and measures aimed at eliminating racist and discriminatory practices.

Genetics and Demography

ENZO LUCCHETTI AND LAMBERTO SOLIANI

Dipartimento di Genetica Antropologia Evoluzione, Università degli Studi di Parma, Parma, Italy

Dipartimento de Scienze Ambientali, Università degli Studi di Parma, Parma, Italy

INTRODUCTION

The collective genetic heritage (*gene pool*) of a population is made up of all of the hereditary information (*genes*) carried by individuals in the population. The goals of human population genetics are to study the structure of the gene pool, to identify the modes and mechanisms that control the transmission of genes from one generation to the next, and to track the underlying variations and their causes.

The intersection between demography and population genetics is clear: both fields study the structure of human groups and their evolution, distribution in space, and perpetuation over time. However, they differ in their approach to the topic. Demographers are interested in individuals and their behavior (e.g., the population structure by age, sex, marital status, survival or mortality, nuptiality, fertility, mobility), whereas population genetics focuses on the allelic structure of the gene pool and the probability of change over time in the relative frequency of alleles. Interaction between the disciplines is intrinsic to the phenomena themselves, especially with reference to the mechanisms and modes by which a population is perpetuated over time. On the one hand, genes are not independent entities; their dynamic can only be studied in relation to the characteristics and behaviors (notably demographic) of their carriers. On the other hand, demographic phenomena, such as individual behaviors, are partly determined by individuals' genetic heritage.

In the first section of this chapter, we review the main components of the genetic structure of a population. We then examine and assess the principal models used in population genetics. Next, we study the evolutionary mechanisms of population genetic structure, using both theory and examples. We conclude the chapter by discussing the important role that the study of family names can play in the intersection of genetics and demography.

I. THE STRUCTURE OF A POPULATION'S GENE POOL

The characterization of the collective genetic heritage of a population is based on the observation of *phenotypes*, manifestations of hereditary characteristics that can be discerned by the use of our senses or using available instruments. For example, *eye color* can have the *blue* or *brown* phenotype; for the characteristic *ABO blood type*, we distinguish the phenotypes *type A*, *type B*, *type AB*, and *type O.*

The phenotypic manifestation of hereditary characteristics is determined by the *genotype*, the set of genes that the individual received from his or her parents. For each autosomal characteristic[1] the individual has two genes, one inherited from the mother and one from the father. These two genes form the individual's genotype for this characteristic.

Alleles are different forms of the same gene or different hereditary information for the same characteristic. For the characteristic *eye color*, genetic information

[1] For clarity, this discussion will be limited to autosomal characteristics, characteristics that do not differ by sex.

TABLE 96–1 Characteristics, Phenotypes, Genotypes, and Alleles

Characteristic: Eye color		Characteristic: MN blood group		Characteristic: ABO blood group	
Alleles: C, c		Alleles: M, N		Alleles: I^A I^B, i	
Relationship: C, dominant; c, recessive		Relationship: codominant		Relationship: I^A and I^B, codominant; i, recessive	
Phenotype	Genotype	Phenotype	Genotype	Phenotype	Genotype
Brown eyes	CC, Cc	Type M	MM	Type A	$I^A I^A$, $I^A i$
Blue eyes	cc	Type MN	MN	Type B	$I^B I^B$, $I^B i$
		Type N	NN	Type AB	$I^A I^B$
				Type O	$i\ i$

might be *blue eyes* (*c* allele) or *brown eyes* (*C* allele); for the characteristic *blood type* there are three principal types of allele, designated by the symbols I^A, I^B, and i. An individual who carries two identical alleles for a given trait is called a *homozygote*; an individual whose genotype consists of two different alleles is called a *heterozygote*.

Different alleles have different capacities to determine phenotypes. An allele is called *recessive* when the information it carries is only manifested if the other allele is identical (condition of homozygosity); it is called *dominant* if its manifestation is independent of the other allele; and two alleles are *codominant* if, when present in the same individual, they interact to produce a phenotype different from that produced by either of the two alleles in homozygous condition (Table 96–1).

Studies of population genetics start by observing phenotypes (phenotypic frequencies) in order to deduce genotypic and allelic frequencies (Appendix 96–A). Allelic frequencies are the base parameter. A population is characterized by the relative frequency of the alleles in its gene pool, and studying the genetic evolution of a population means analyzing the internal dynamics that determine changes in allelic frequencies from one generation to another.

II. MODELS OF POPULATION GENETICS

Population genetics uses explanatory models to study changes in allelic frequencies. Even the most refined models are merely theoretical instruments and can never achieve a complete description of reality. However, models have been proven to be generally effective in identifying the forces and mechanisms of genetic evolution and analyzing their modes of action.

1. Panmixia

The simplest model, *panmixia*, assumes that evolution of the gene pool over generations is solely determined by allelic frequencies. The birth of a new individual (or the formation of a new genotype) is equivalent to two independent selections from the gene pool of the parent generation. If p and q are the frequencies of the A and a alleles of an autosomal bi-allelic system ($p + q = 1$), the probability that a new individual has the genotype AA is p^2, $2pq$ is the probability that the individual is an Aa heterozygote, and q^2 is the probability of aa homozygosity. The Hardy–Weinberg theorem, named after its inventors, describes the relationship between allelic frequencies (p, q) and genotypic frequencies, given by $(p + q)^2$. In the new generation, a fraction p^2 of individuals will have the AA genotype, a fraction $2pq$ will have the Aa genotype, and a fraction q^2 will have the aa genotype.

The model is stable: allelic frequencies remain constant across generations, and the underlying distribution of genotypes and phenotypes is also unchanging (panmictic equilibrium). A population that is initially unbalanced (i.e., with a significant difference between the observed genotypic frequencies and the frequencies expected based on the model) reaches equilibrium in the first generation for which the model's hypothesis holds. Equilibrium is then maintained as long as the hypothesis holds (Table 96–2).

2. Random-Mating Model

Populations perpetuate themselves via sexual reproduction, which requires the formation of couples.

TABLE 96–2 Panmictic Model

Allelic frequencies in the parent generation	Genotypic composition of the filial generation	Allelic frequencies in the filial generation
Allele *A*: frequency = p	Genotype *AA*: $p*p = p^2$	p_f = $(2p^2 + 2pq)/2 = \mathrm{p}$
Allele *a*: frequency = q	Genotype *Aa*: $2*p*q = 2pq$	
	Genotype *aa*: $q*q = q^2$	$q_f = \mathrm{x}$ $(2p^2 + 2pq)/2 = \mathrm{q}$

TABLE 96–3 Random-mating Model

Type of pairing	Frequency	Distribution of offspring according to genotype		
		AA	***Aa***	***Aa***
AA **AA*	p^4	p^4		
*AA** *Aa*	$4p^3q$	$2p^3q$	$2p^3q$	
*AA** *aa*	$2p^2q^2$		$2p^2q^2$	
*Aa** *Aa*	$4p^2q^2$	p^2q^2	$2p^2q^2$	p^2q^2
Aa aa*	$4pq^3$		$2pq^3$	$2pq^3$
aa aa*	q^4			q^4
Total	1	p^2	$2pq$	q^2

The reference model (random mating) assumes that couples are formed randomly with respect to genotypes (or phenotypes) and that their contribution to the perpetuation of the group does not vary systematically. Table 96–3 describes the model: the possible types of pairings (in terms of genotypes), their relative frequency, and the distribution by genotype of the progeny of each couple. It is clear that the condition of *panmixia* (random extraction of pairs of alleles) coincides with that of *random mating* (random formation of couples).

III. MECHANISMS OF VARIATION OF GENETIC STRUCTURE

These models assume that the population is large (theoretically infinite) and that individuals (classed by phenotype or genotype) all contribute equally to the formation of the filial generation, with each individual having an equal probability of coupling and no differences in fertility or mortality. They also assume that there is no *mutation* (passage from one allelic form to another), so allelic forms remain unchanged and that the populations are not affected by migration (or at least that there is no differential migration by phenotype or genotype). When these conditions are met, the population is said to be in panmictic equilibrium; allelic frequency (and genotypic and phenotypic frequency) are stable across generations.

There are several situations in which these hypotheses are not met.

1. Assortative Mating or Nonrandom Formation of Couples

We speak of *assortative mating* when the probability of couple formation is not independent of the phenotype (or genotype) of the partners. Assortative mating can act in a positive direction (if a couple is more likely to form when the partners are alike than when they are different) or in a negative direction (in the reverse case), and can act either completely or partially.

Positive assortative mating (when partnerships are more likely to form—or only form—between bearers of the same trait) does not cause variation in allelic frequencies, but it does imply a different distribution of genotypes and phenotypes than that expected under the panmictic model. In effect, the population is divided into several subgroups; couples form between individuals of the same subgroup. In the case of *complete genotypic sorting*, for example, the population is divided into three groups, each made up of individuals with the same genotype—*AA*, *Aa*, and *aa*, respectively. All children of *AA*AA* couples and *aa*aa* couples belong to the same groups as their parents, whereas children born to *Aa*Aa* couples are distributed among the three groups in a 1 : 2 : 1 ratio. In each generation, the frequency of heterozygotes declines, whereas the frequency of homozygotes rises. The *AA* and *aa* groups of homozygotes each increase by half the amount by which heterozygotes were reduced. Allelic frequencies, however, remain constant. After many generations, heterozygotes approach extinction, and almost all individuals are of *AA* or *aa* genotypes. The relative frequencies of these two genotypes approach p and q. At that point, the two remaining groups are completely separated, forming two distinct populations between which there is no exchange of genes.

Consanguinity, marriages between individuals with common ancestors, can be seen as a particular form of assortative mating: unions are formed between individuals carrying a higher than average proportion of identical alleles, with the proportion being higher the more closely the two individuals are related. These identical alleles have not only the same effect but also the same origin, because they are pairs of alleles that were present in the couple's common ancestors. Children born to consanguine marriages show a higher frequency of homozygous *loci* and a lower proportion of heterozygous *loci* than do other children. The probability that recessive alleles will be manifested at the phenotypic level increases, which explains the higher frequency of hereditary diseases among children of consanguine parents.

Negative sorting means that couples are more likely to form between individuals with different characteristics. Sex is the classic example, although the example is not quite correct: the two chromosomes X and Y, which jointly determine sex (XX for women, XY for men), can be seen as two allelic forms of a gene. Pairings only take place between individuals of the opposite sex. From these pairings, individuals of both sexes are born, in a 1 : 1 ratio. The system is stable, with the frequency of the two alleles constant at 0.75 and 0.25. Only two genotypes (or phenotypes) are possible (XX and XY), male or female, each with a frequency of 0.5.

2. Selection: Differences in Contribution to Subsequent Generations

Selection occurs when individuals' contributions to subsequent generations differ as a function of the genetic information they carry. Survival and fecundity, the two primary components of the biological capacity for reproduction, are largely determined by genetic heritage, although fertility also depends on many other factors, with socioeconomic and cultural factors playing a growing role.

The relative effective contribution to the formation of subsequent generations is measured using the *index of fitness.* A *fitness* of one is assigned to the individuals (or couples) who have the largest number of *successful offspring*, that is, children who survive and reproduce in turn. The value of the index of fitness for other groups is calculated by dividing their average number of successful offspring by that of the group with fitness 1. The *index of selection* describes the phenomenon from the opposite perspective and is calculated by subtracting the index of fitness from one. Selection is set at zero for the group whose contribution is largest and is equal to one for the group with zero contribution (fitness equal to zero).

Table 96–4 gives an example in which the average number of successful offspring varies by genotype and shows the relative values of fitness and selection for each group. For each successful child produced by an *AA* individual, *Aa* and *aa* individuals produce 0.75 and 0.5 children, respectively. It does not matter for the purpose of this example whether all *Aa* and *aa* individuals have lower effective fertility do than *AA* individuals or whether, for example, 75% of *Aa* individuals reproduce as do *AA* individuals and 25% do not reproduce at all, or the survival of children born to *Aa* individuals is 75% that of children born to *AA.*

TABLE 96–4 Indices of Fitness and Selection

Genotype	Average no. of successful offspring	Indices of	
		Fitness	Selection
AA	4	1	0
Aa	3	0.75	0.25
aa	2	0.50	0.50

Selection can act at different levels: in the formation of gametes, during the course of the definition of the genotype, or in the expression of the phenotype. It can act through mortality or differential survival, through differences in fecundity or fertility, or even through differences in the capacity to raise children after their birth. In all cases it influences the overall results through differential contributions to the perpetuation of the population. Because of the large reduction in infant mortality, the number of children born alive now provides a good estimate of fitness.

Categories (gametes, genotypes, phenotypes) that are associated with reduced fitness are submitted to *negative selection*; we speak of *positive selection* for groups with higher fitness. To indicate the object and the direction of selection, expressions such as *selection against the recessive allele, against the recessive phenotype, selection in favor of*, or *against heterozygotes*, are used. Appendix 96–B explains in more detail the effects of different types of selection on the genetic structure of a population.

Over the course of generations, the continuous action of selection reduces the frequency (or even completely eliminates) of the alleles being selected against and the genotypes and phenotypes formed by these alleles. Selections against the heterozygote constitute a special case, because this genotype contains different allelic forms (Appendix 96–B). *Selection against the heterozygote*, when it has a lower fitness than do the two homozygous genotypes, leads to fixation of the allele with a higher initial frequency. *Selection in favor of the heterozygote* (heterozygote with higher fitness than homozygotes), in contrast, leads to a stable equilibrium, determined by the intensity of selection against the two homozygotes independently of their initial allelic frequencies.

The direction of selection is not always constant. The eradication of malaria is a classic example of a process that has changed the direction of genetic selection. When a population is subject to both thalassemia and malaria, selection favors the heterozygote, to the detriment of the two homozygous forms. However, with the disappearance of malaria, selection acts against the thalassemia homozygote and, to a lesser degree, against the heterozygote.

3. Mutations

The expression *genetic mutation* signifies the passage from one allelic form to another. Mutations occur naturally in the course of the DNA replication that precedes the formation of gametes. Certain environmental conditions can influence the frequency of mutations or *mutation rate.* The most common effect of a mutation is the loss of a function: for example, an error in replication might cause an allele to lose the information necessary for the synthesis of an enzyme. Such a mutation is equivalent to the passage from the dominant allelic form to a recessive form: individuals that are homozygous with respect to the new allele are not able to synthesize the enzyme, and the reaction that requires its presence cannot take place in these individuals. Mutation in the opposite direction (*retro-mutation*), which confers a previously missing functional capacity on an allele, is less frequent but still possible.

Mutations change allelic frequencies. Given a rate of mutation μ from A to a, in each generation a number $p\mu$ of A alleles mutate to a. In subsequent generations, the allelic frequency p of A varies according to the equations:

$$p_1 = p_0 - \mu p_0 = p_0\,(1-\mu)$$

$$p_2 = p_1 - \mu p_1 = p_1(1-\mu) = p_0\,(1-\mu)(1-\mu) = p_0\,(1-\mu)^2$$

$$p_n = p(1-\mu)^n.$$

If, in addition to the mutations from A to a, retro-mutations also take place at a rate ν, in each generation μp A alleles mutate to a and νq alleles mutate from a to A. If the two quantities are equal, the allelic frequencies do not change. Equilibrium is thus determined by the values of the mutation and retro-mutation rates, not by the initial values of the allelic frequencies. In an equilibrium state

$$\hat{p} = \frac{\nu}{\mu+\nu} \quad \text{and} \quad \hat{q} = \frac{\mu}{\mu+\nu}$$

Mutation-Selection Interaction

A mutation that causes the loss of a function, such as the capacity to synthesize an enzyme, can lead to the phenotypic manifestation of defects or disease in the homozygote. In this case, there will be selection against the recessive phenotype. Selection tends to eliminate harmful alleles, whereas mutations continue to reform them. If s is the intensity of the action of selection and q is the allelic frequency of a, sq^2 individuals will be eliminated in each generation as aa homozygotes are struck by selection. Mutations will simultaneously recreate $\mu p \cong \mu$ new a alleles. Equilibrium conditions are defined by

$$\hat{q} = \sqrt{\mu/s}.$$

If there is complete selection ($s = 1$), the equilibrium frequency of a becomes:

$$\hat{q} = \sqrt{\mu}.$$

4. Individual Mobility and Migration

When individuals migrate, they take their genes with them. Depending on the characteristics of the sending and receiving populations and the intensity and direction of migration, migratory flows can modify the genetic structure of the populations involved. Models are used for reference in studying the effects of migration. Migration-induced variations are generally evaluated based on allelic frequencies in the gene pool of the receiving population as a whole (Appendix 96–C). Migration often leads to the constitution of subgroups within the receiving population; couples form preferentially within each subgroup (assortative mating based on origin). Usually, it requires many years, or even many generations, before groups of immigrants can be considered to be integrated into the receiving population to the point at which the hypotheses of the random-mating model can be applied to the population as a whole.

Migration may also influence fertility. The average number of children in immigrant families is often different from that of native-born families. Migrants may have higher fertility owing to the conservation of traditions specific to the population of origin or, fertility may be lowered by difficulties caused by migration itself.

Appendix 96–C illustrates some of the effects of migration on the genetic structure of populations. These effects can vary depending on the direction and strength of migratory flows, allelic frequencies in the populations in question, and, finally, the subgroup structure that develops in the host population. Models address one phenomenon at a time; they can be combined and integrated to describe interaction between different processes taking place in the same population.

Because migrants are not a random genetic sample of the population of origin, migration can also induce changes in the sending population. In the models considered here, migratory behavior is hypothesized to be independent of the genotype or phenotype of the individual, but it is nevertheless possible that genetic characteristics could affect the propensity to migrate. For example, migration by groups (family groups, groups of relatives, or inhabitants of the same village) can produce concentrations of specific genetic markers, which differentiate migrants based on their population of origin.

5. Genetic Drift

Genetic drift describes the effect of random variations occurring in a finite population with an intensity inversely proportional to the size of the group. The action of drift, which accumulates from generation to generation, can lead to fixation of one of the initial allelic forms. It is impossible to predict which allelic form will be fixed. In general, the allelic form with the highest frequency has the highest probability of being fixed; if several populations with the same initial allelic frequencies are considered (p for allele A and q for a), the most likely outcome is that allele A becomes fixed in a proportion p of the populations and a in a proportion q. However, this distribution is only the most probable distribution; the outcome in a given population cannot be specified a priori.

The *fixation rate* is a useful parameter for describing the dynamics of finite populations: it indicates the proportion of alleles established in each generation in a population, that is, the proportion of the population in which an allele is fixed.

Genetic drift reduces the internal variation in a population, thus limiting the possibility of adaptation; that is, in evolutionary terms, a population's capacity to survive in the face of environmental changes. At the extreme, when all individuals in a population have the same phenotype, environmental variation incompatible with this phenotype can lead to the extinction of the entire population. However, genetic drift increases differences between populations, by causing the fixation of different alleles in initially similar populations. One or more of these populations might contain an allele more capable of responding to environmental variation. Only these populations would survive, possibly occupying vacated ecological niches. Drift cannot be defined a priori as having positive or negative effects on a population's survival capacity; it produces an advantage in some cases and a disadvantage in others.

Migration counteracts drift by increasing internal variability and reducing divergence between populations. In the presence of migration, even at low rates, the index of fixation by drift decreases rapidly. Mutations also work in opposition to drift, but because mutation rates are generally much lower than are migration rates, their effects are even weaker.

IV. ANALYSES AND APPLICATIONS

The development of electrophoresis techniques has led to great advances in the observation of allelic frequencies. These techniques make it possible to observe polymorphism at the proteic level; today, DNA sequencing techniques have opened the way for new and more radical means of observing genetic variability, based on the sources of information as well as it manifestations.

1. Geographic Distribution of Allelic Frequencies

Graphing techniques can be used to establish the spatial distribution of allelic frequencies as a function of the geographic location of populations. Lines of equal frequency, analogous to level curves uniting points at the same altitude on a relief map, mark zones where populations share the same allelic frequency, and color and shadings distinguish geographic areas with different frequencies.

When these techniques are applied to the different regions of Italy (Fig. 96–1), zones with strong or weak diffusion of an allele are immediately visible, as is the existence of a gradient. In this situation, the distribution of allelic frequencies is the result of specific patterns of diffusion produced by both migration and factors of isolation. Environmental characteristics can also influence the frequency distribution. For instance, because the hemoglobin allele S confers a relative resistance against malaria, the distribution of the allele is associated with the presence of the disease.

The works of Arthur Mourant (Mourant, 1954; Mourant *et al.*, 1976) provide a remarkable set of observations on this subject. The monumental work of Luigi Cavalli-Sforza *et al.* (1994) is more up-to-date both in the data collected and in the methods used.

2. Evolutionary Reconstructions and the Relationship between Populations

The relationships between populations, and their genetic similarity (or distance), can provide information about their biological evolution. Clearly, two populations that have recently descended from the same

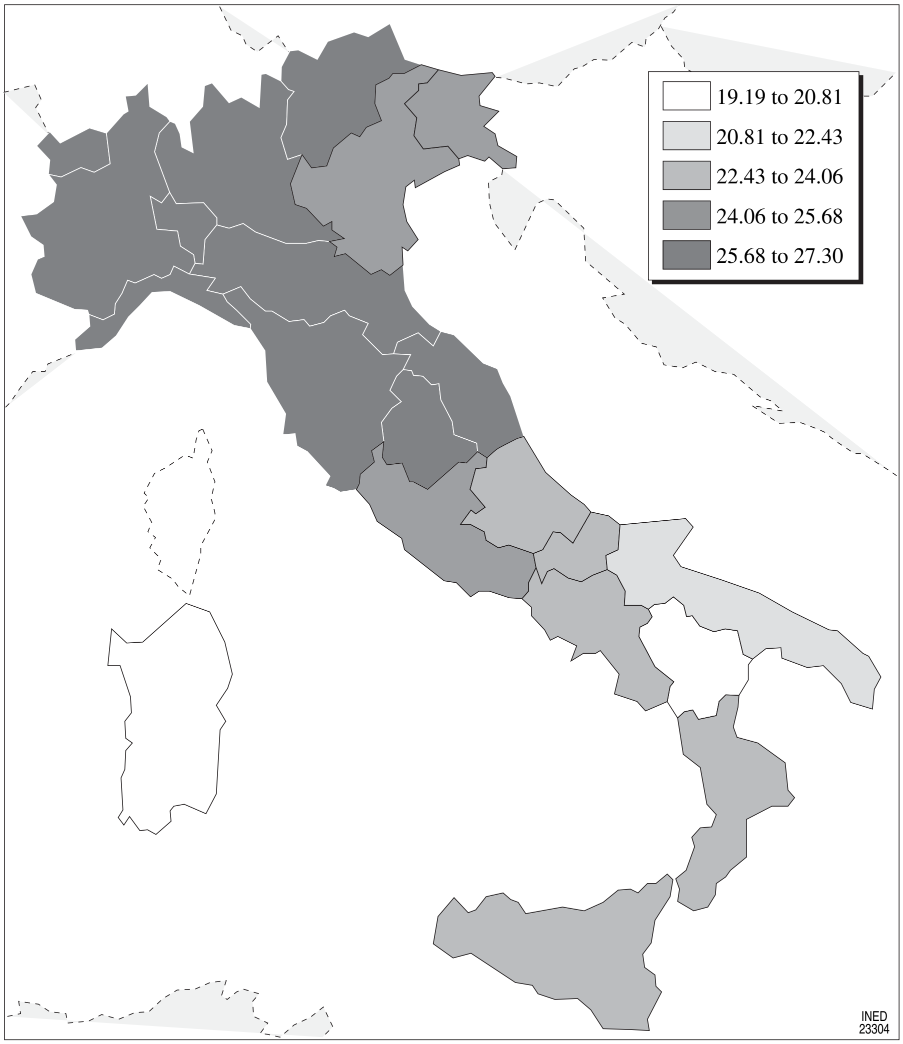

FIGURE 96–1 Average frequencies of I^A alleles (ABO system) in regions of Italy. (From Soliani *et al*., 1981.)

ancestral population will have similar allelic frequencies. However, populations that have been evolving separately for a long period will have more different distributions of allelic frequencies. It is even possible to estimate the time elapsed since the separation of two populations by hypothesizing a relationship between the degree of differentiation between the populations and the time necessary to develop this difference. That is, comparing the gene structures of populations makes it possible to formulate hypotheses about their evolution and the relationships between them. Conclusions should be accepted with caution; genetic similarity can result if populations are submitted to analogous factors of selection and does not necessarily imply a common evolutionary path. In addition, the relationship between genetic difference and time elapsed is not always linear.

3. Genetic Distance, Distance Matrices, and Methods of Representation

Indices of genetic distance provide a synthetic measure of divergence between the gene pools of different populations. There are numerous methods for calculating the genetic distance between populations; Jorde (1980) and Lalouel (1980) provide overviews of these methods that are both detailed and wide in scope.

One of the most commonly used measures of genetic diversity is Masatoshi Nei's *D* value (1972, 1978). Nei's *D* is calculated by using the probability of having identical alleles on the same locus chosen randomly from the gene pool of the two populations being compared, weighted by the probability of equality within each population. If p_{Ai} and p_{Bi} are the frequencies of the allele i in populations A and B, respectively, then:

$$I_{AB} = \Sigma p_{Ai} p_{Bi},\ I_{AA} = \Sigma p_{Ai}^{2} \text{ and } I_{BB} = \Sigma p_{Bi}^{2};$$

the normalized identity *I* is given by the ratio

$$I = I_{AB} / \sqrt{I_{AA} I_{BB}}$$

and the standard genetic distance is

$$D = -\ln(I).$$

Anthony Edwards and Luigi Cavalli-Sforza (1965) proposed a geometrically based method. Populations are represented by points whose coordinates correspond to the square roots of the allelic frequencies. Because the sum of the allelic frequencies of each system is equal to one, these points are located on the surface of a hypersphere with radius 1 and axes given by the square root of the frequencies. In a bi-allelic system ($p + q = 1$), the population-points are positioned on the circumference with the equation $x^2 + y^2 = 1$, with $x = \sqrt{p}$ pand $y = \sqrt{q}$. In a tri-allelic system $p + q + r = 1$, they are on the surface of a sphere. The distance between two populations can be defined as a function of the arc defined by the two points or of the length of the chord that joins them. The chord provides a linear distance and makes it possible to combine distances calculated from independent genetic systems (characteristics carried on different chromosomes) geometrically.

Researchers argue over the usage of genetic distances, the theoretical conditions required for validity of the measures, and the interpretation of results. However, both theoretical and empirical examples show a strong correlation between the different methods of calculating genetic distance, generally between 0.8 and 0.95 (Hedrick, 1975).

4. Graphical Representations

Distance matrices, constructed from the indices of diversity between populations taken in pairs, can be used to produce graphic representations which are easier to read and interpret than distance measures. The most common approaches are tree diagrams (or *dendrograms*) and topological maps.

The *dendrogram* describes the evolutionary relationships between populations. It assumes that currently existing groups are derived from the same ancestral population submitted to a series of splits, and that the cumulated genetic difference between two populations is a function of the time elapsed since their separation. Starting with the distance matrix, it is possible to retrospectively reconstruct the order of splits and the probable evolutionary paths (*phyletic trees*) traced by the populations. Different methods often produce different results; specialized techniques, such as bootstrap resampling (Efron, 1982), can be used to assess the credibility of the trees produced and to identify the most likely tree.

At the conceptual level, one problem with the dendrogram is that splits are generally not followed by complete separations between populations, and genetic flows, in the form of individual migrations, continue between groups belonging to different branches. Satisfactory methods taking into account these postseparation genetic flows do not yet exist.

Take, for example, the relationships between Italian regions, each characterized by allelic frequencies of the classic blood groups (ABO, MNSs, Rh haplotypes). We first recorded the average frequency of each allele in each region, then constructed the between-region similarity matrix. From there, we used the program Mega2 (Kumar *et al.*, 2001) to produce the dendrogram in Fig. 96–2, which describes the relationships between the gene pools of different regions. The uniqueness of Sardinia is immediately evident; a second division separates the southern regions from the center and north regions. These groupings are in turn progressively subdivided into distinct subgroups. The dendrogram as a whole reflects the geographic dispersion of the regions, their history, and the relationships that they have maintained over the past centuries fairly well.

Topological maps are based on methods such as principal components analysis and multidimensional scaling. In general, they provide good descriptions of the relationships between groups and are more informative than are tree diagrams when there are clear divisions among the groups or when the goal is to compare results obtained by using different data sets. Meaning is assigned to the axes afterward, and is often based on geographic position or ethnic origin, cultural identity and historic relations, territorial characteristics that impede or encourage relationships between groups, or migratory dynamics. Based on the organization of the population under study, topological maps can provide information on evolution. They do not necessarily assume that evolution has taken place in the form of a series of splits, with interruption of all genetic flows between the groups that result.

The topological representation in Fig. 96–3 is based on the same data used to construct the dendrogram in Fig. 96–2. The values of the first dimension of a multidimensional scaling analysis are plotted on the horizontal axis, whereas the second dimension is on the vertical axis. The first dimension can be easily interpreted as the north–south direction. Similar to the

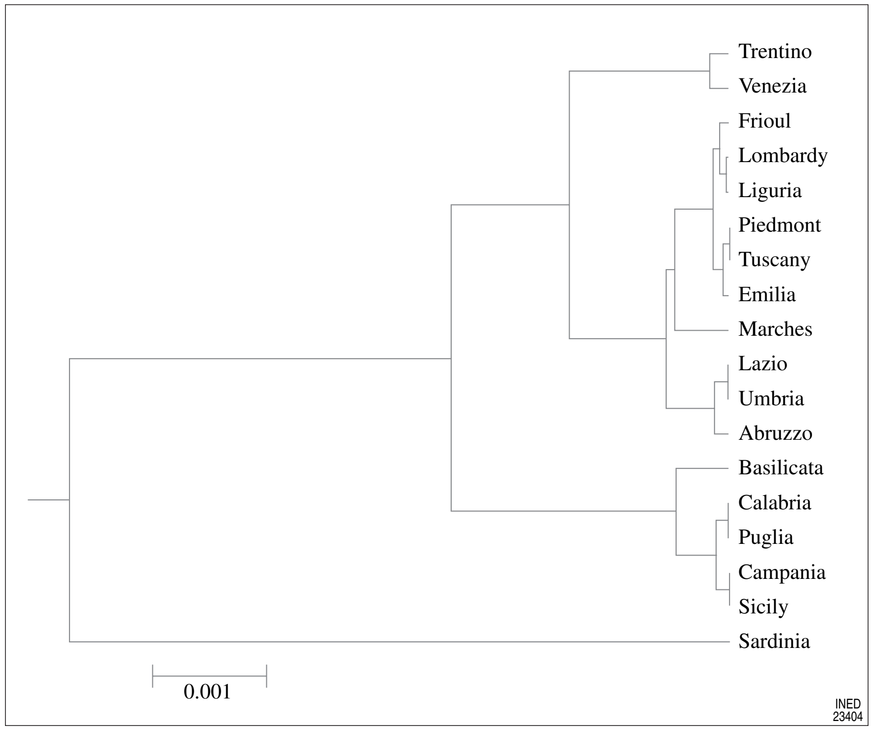

FIGURE 96–2 Dendrogram of relationships between Italian regions based on allelic frequencies of ABO, MNSs, and Rh blood groups. (From Soliani *et al*., 1982.)

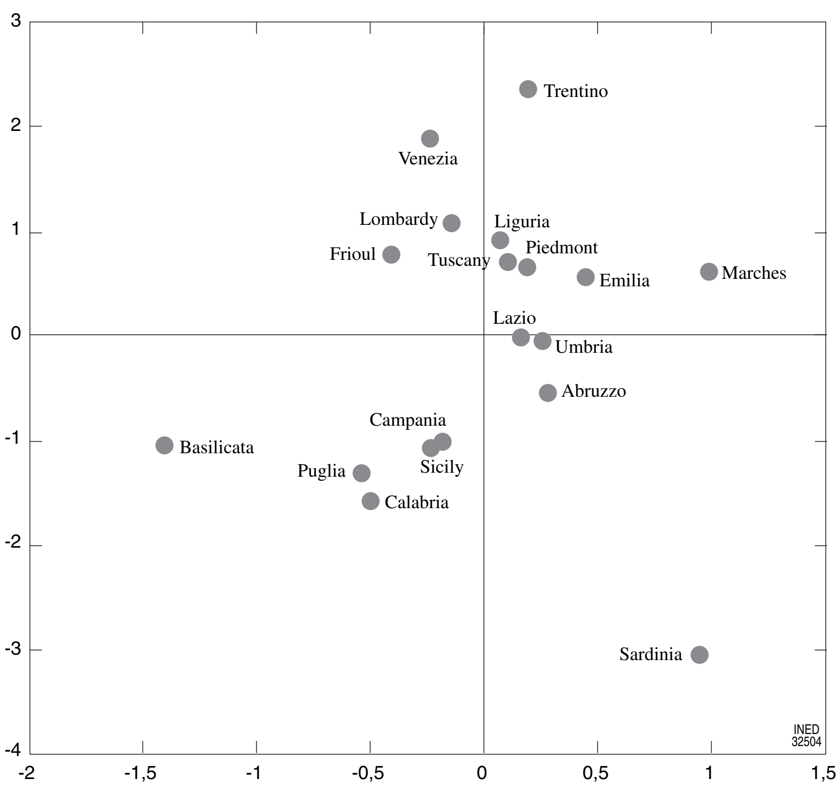

FIGURE 96–3 Topological representation of the relationships between Italian regions based on the similarity matrix of allelic frequencies (ABO, MNSs, and Rh blood groups). (From Soliani *et al*., 1982.)

dendrogram, the topological representation reflects the geographic distribution and the history of the regions. However, it describes the relationships solely based on the proximity of the points, without having to assign each region to a particular branch. Thus, for example, Liguria and Piedmont are closely linked both geographically and historically, but under the complete taxonomy of the dendrogram they were assigned to different subgroups.

V. BIODEMOGRAPHIC RESEARCH

When it comes to genetic evolution, human population biology shares many interests with the study of demographic evolution—the study of relationships between isolates and the groups that make up populations, and of variation over time and space. Scientists can study distributions of genic frequencies, by using erythrocytic and proteic markers and recent improvements allowing the observation of the sequencing of nuclear and mitochondrial DNA. This understanding makes it possible to make deductions about the origin and the evolution of human groups, and even to reach some conclusions about the origins of modern humans (Cann *et al.*, 1987; Cavalli-Sforza *et al.*, 1994).

Research on micro-evolutionary processes—the concrete mechanisms by which groups are transformed over time—as a function of sociodemographic behaviors is also very useful. In particular, it is necessary to consider changes in fertility, nuptiality, mortality, and migration, which can vary across populations and have reached new levels over the past few centuries.

An early area of research, which is now fairly old, studies demographic behavior in order to identify the mechanisms causing the evolution of genetic and genotypic frequencies: selection via differential mortality and fertility, migration, genetic drift, preferential mating, and subdivision of the population into isolates or subgroups. These biological and genetic transformations can be clarified and quantified by measuring evolution and demographic variation.

Consanguinity is one of the themes that has long been embraced by biodemography (Cavalli-Sforza and Bodmer, 1971; Conterio and Moroni, 1974). The type and degree of consanguinity as well as its incidence are tied to the age structure and the natural and migratory dynamics of the population. These factors in turn depend on social organization such as division into classes or castes, economic parameters such inheritance systems, religion, laws, traditions, and familial and collective customs. Studying the historical evolution of consanguinity and its variation over time and space, as well as differences in behavior within communities, makes it possible to evaluate the specific variations in the genetic structure of populations. Consanguinity is also important from a medical point of view, because it encourages the appearance of pathologies caused by harmful or lethal recessive genes; morbidity, disability, and infant mortality, in addition to morphological characteristics such as size, are closely correlated with consanguinity.

By studying union formation and modes of choosing spouses, it becomes possible to demonstrate that assortative mating by phenotypic characteristics or even social or cultural characteristics is taking place. Analyzing marital mobility, both within and between groups or populations, allows researchers to estimate a community's degree of isolation and to evaluate the effects of isolation on the evolution of genetic structure.

Migration has a strong influence on the evolution of the gene pool in a given geographic area. In genetics, the cumulative effect of continuous migration is important, even aside from the short-term effects of migration. Entries and exits have different impacts on the genetic pool. Emigrants are not a representative sample of the sending population, either socially or biologically. For the receiving population, the consequences for genetic heritage vary based on the life trajectories of immigrants, especially in terms of reproduction. Economic and social factors such as occupation, education level, marital status, and income affect both reproductive behavior and the likelihood of eventual integration into the receiving society. Thus, migratory flows must be analyzed at a fairly fine level, at minimum separately by sex and age group.

The nominative reconstruction of families, extended to entire populations or wide geographic areas, furnishes the most interesting, most complete, and most complex examples of interaction between demography and genetics or population biology. When it is extended to large territories and over several generations, it provides geneticists and population biologists with real-world experience ("real" populations whose outcomes can be followed over time) in which evolutionary forces and mechanisms, as well as their results, can be observed concretely.

This reconstruction takes the form of what we call "useful history" of a population, integrating demographic history, social history, and genealogical and genetic history.

The pioneering research in this domain was carried out on the population of Quebec in the 19th and 20th centuries (Charbonneau *et al.*, 1987; Desjardins, 1988; Bideau *et al.*, 1995). It represents a significant example of this type of approach because of the impressive number of individual records; the extent of the historical field covered; and the quantity of biological, medical, social, and economic characteristics considered. This research assessed the consequences of founder effects, the choice of spouse, the number of children per family, migratory flows, consanguinity, endogamy, and the evolution of isolates.

Because this analysis included information on hereditary diseases (Bideau *et al.*, 1979), it was possible to construct a map illustrating their spatial diffusion. "It is evident that the eastern regions are affected by rare diseases, mostly characteristic of the French Canadian population (tyrosinemia, spastic ataxia of the Charlevoix-Saguenay, intestinal atresia, agenesis of corpus callosum, myotonic dystrophy . . .). On the other hand, in the center and west regions, we find for the most part more common diseases such as Duchenne's disease, phenylketonuria, Friedreich ataxia, thalassemia. . . . Diseases including cystic fibrosis and fragile X syndrome are spread over the entire population" (Bouchard, 1993).

Demographic analyses, both aggregate-level and based on individual reconstructions, have shown that the region's population was produced by three waves of migration (from three founder effects?), which took place one after another in the three regions of Quebec between the 17th and 19th centuries. These immigrants, who were likely not a random sample of the French population of origin, gave birth to a population that was genetically different from the population of origin. The contribution of pioneering immigrants to the genetic pool is also clearly recognizable in reconstructions of ascending genealogies of the bearers of hereditary diseases: "A study of the first couples to arrive in the Saguenay (before 1842) demonstrated that after six generations, more than 20% of the first immigrants no longer had any descendants in the regional population, whereas 10% of them had more than 3000 descendants" (Bouchard, 1993).

Overall, the unique characteristics in the gene pool of the population under study can be attributed to (1) natural fertility that led to population doubling every 25 years, (2) distinctive modes of familial reproduction that encouraged the establishment of descendants of longstanding family lines, and (3) a relatively endogamous marriage market, all accentuated by (4) highly homogenous immigration.

Contrary to what is generally believed, studies have shown that closely consanguine parents were not significantly more common among carriers of rare hereditary pathologies. Because of differential reproduction patterns by founders within the population being considered, the risk of hereditary disease was diffused throughout the majority of the population rather than being concentrated in certain easily identifiable families or groups of descendants. Close consanguinity between spouses thus adds relatively little to the general risk of a given couple producing a child affected by pathologies owing to rare genetic mutations (Bouchard, 1993).

Research on reconstructed populations has slowed considerably since the 1980s because of the numerous and serious practical difficulties in organizing studies. Research is based on the collection of a large mass of data and requires costly long-term investigations and precise organization of data. In addition, it takes a long time to arrive at concrete results using these data. Genealogical reconstructions also demand a high level of competence in different scientific domains, leading to difficulties in collaboration and integration, and the substantial financial resources necessary for these studies are difficult to mobilize in a single field. Finally, because reconstructions necessarily apply to specific populations and periods, the results obtained describe specific situations and are not always easily generalized. Once carried out, however, this type of study can be highly productive, as evidenced by the example described above. Developments in computing and the expansion of available archives and computerized databases have opened new possibilities for the application of these methods, including in large present-day populations.

VI. THE ANALYSIS OF SURNAMES

In patrilinear societies, family names can be treated like allelic forms of a gene situated on the Y chromosome and transmitted through the male line. The origins of surnames are cultural. Since the codification of surnames and the establishment of rigorous norms of recording, however, the diffusion and population structure of surnames has been a product of the reproductive and migratory behavior of their bearers. (In many Italian regions and in a variety of European countries, family names were widely used starting in the 17th century.) Currently, the modes of diffusion of family names are analogous to those that prevail for genetic characteristics.

Surnames, which are inherited from the family of origin, define an individual identity that is both biological and cultural. At the population level, the distribution of surnames can help define the biological and cultural identity of different groups, as well as provide insight into the structural characteristics of the population itself.

The correspondence between family names and genes is obviously not complete. Problems arise from the polyphyletic origin of surnames: the same family name could form independently in different regions, and having the same family name does not always mean sharing the same origin. Illegitimacy, adoption, transcription errors, and legal changes, as well as the evolution of the language, introduce variations at the individual level, although they do not generally compromise the ability to characterize a population on the aggregate level. Finally, the length of time that is observable is not ideal: the history of family names is fairly brief compared with the long evolutionary period of allelic frequencies. Still, from the rich bibliography already available, it is clear that surnames and genes follow similar dynamics: conclusions derived from analyses using the two types of data are generally consistent (Lucchetti and Soliani, 1989; Zei *et al*., 1993).

Family names have the practical advantage of being easy, quick, and inexpensive to record and categorize. The record of surnames can be extended to cover the whole population and can often be directly obtained from lists that have already been established in various forms by various public and private institutions. Many of these lists now exist, and some are even computerized. Different sources of names can be used depending on the phenomenon being studied: stock data (censuses, population registers, lists of residents) or vital data (births, marriages, deaths) of people who are native to a certain area or have experienced certain events (marriage, birth, parenthood, death) in that area. By using historical registers (religious or civil), the record of family names can be extended into the past as well. A population's evolution, at least for the past few centuries, can be traced completely by observing actual movements in detail. It is thus possible to overcome the fundamental ambiguity of attempting to reconstruct the past from the present when experimental verification is not possible.

Frequencies of surnames form a system with high polymorphism, with a large capacity for characterization and differentiation. Systems of surnames can even be used to distinguish between neighboring populations, in which biological characteristics are generally not sufficient to identify significant differences (Lucchetti and Soliani, 1989).

1. Isonymy, Consanguinity, Matrimonial Structure

The use of surnames to analyze consanguinity is generally traced to George Darwin (1875), who estimated the frequency of marriage between cousins based on the incidence of isonymic marriages, or marriages between people with the same family name. Analyses of this type were carried out in numerous studies, based on a precise quantification of the relationship between consanguinity and isonymy (Crow and Mange, 1965). More recent applications address the repetition of surname pairs among spouses, thus extending the analysis to the marital behavior of the population as a whole. To uncover and assess population subgroups within which marriages take place preferentially, Gabriel Lasker and Bernice Kaplan (1985) calculate the number RP (for "repeated pairs") of repetitions in associations of spouses' last names according to the following formula:

$$RP = \frac{\sum [S_{ij}(S_{ij}-1)]}{N(N-1)}$$

where S_{ij} represents the number of couples in which the husband has the surname i and the wife the surname j and N is the total number of couples. The index RP varies between zero (each pair of last names appears only once) and one (all couples have the same combination of family names). The expected value $E(RP)$ for a random combination of family names is calculated by using the method proposed by Ranakut Chakraborty (1985). Comparing observed and expected values for a random sample makes it possible to measure the *nonrandom* component and thus to evaluate the influence of preferential choice on the formation of couples. Preferential choice is interpreted as an expression of subdivisions within the population (Mascie-Taylor *et al*., 1987). Applications to historical populations in Massachusetts (Relethford, 1992) have shown that the random component of RP is negatively correlated with the size of the population and with exogamy. The relative excess of RP is positively correlated with the size of the population, demonstrating a positive relationship between population size and internal stratification.

2. Family Names and the Internal Structure of the Population

The typology of the distribution of surnames supplies information on the internal structure of a population. Intuitively, there are two extreme situations: a population with few family names, all with a high degree of repetition, and a population with many family names, all rare. The first suggests a high degree of isolation, with no immigration of individuals from the outside: the survival of the population depends on local families, and the number of surnames declines over time, with the remaining names increasing in frequency. In the second type of population, the greater variety of surnames suggests the presence of immigration introducing new family names with low occurrence in the population.

The number S of different surnames in relation to the number N of individuals is a measure of the internal homogeneity (or variability) of a population. For populations of equal size, differences in the number S of patronymic forms stem from characteristics of the community, in particular on its level of isolation or openness.

The ratio S/N is a crude but simple indicator of a population's richness in surnames; a higher value implies a greater variety of family names. At the extremes, a ratio equal to one means that every individual in the population has a different last name, whereas values close to zero indicate that there are few patronymic forms and each is carried by a relatively large number of individuals. In the first case, the family name has great power to identify the individual within the population but can only rarely distinguish the population from other groups. In the second case, the family name cannot identify the individual within the group but is strongly predictive of the community that the individual belongs to.

The ratio S/N is defined based only on the diversity of patronymic forms in a population and does not always distinguish between different populations with the same level of variation. For instance, the ratio has the same value when there are S last names appearing with equal frequency in the population and when some of the S surnames are common whereas others are rare or unique.

Family names that appear only once (family names with frequency one) have a strong influence. In historical populations, especially isolated populations, the modes of transmission of family names and patrilocal customs meant that surnames with frequency one were mostly carried by women who had married in to the population. In present-day populations, however, family names with incidence one, or more generally with low frequency, are primarily associated with the mobility of single people, essentially men, who migrate for work reasons.

Numerous indices originally used in analyses of biological variability (genetic or ecological biodiversity) can be applied to the distribution of family names in order to describe the structural characteristics of a population. The probability that two randomly chosen individuals carry the same family name (Relethford, 1992) defines the random component of the internal isonymy of a group. As James Crow and Arthur Mange (1965) have shown, there is a specific relationship between this measure and the random component of the consanguinity in a population.

The frequency and distribution of patronymic forms can be used to evaluate a population's richness in surnames and even to estimate the importance of migratory flows. Ronald Fisher's α index (Fisher *et al.*, 1943), developed to assess an ecosystem's richness in species, measures the abundance of surnames in a population. The ν index developed by Samuel Karlin and James McGregor (1967) measures the rate at which new alleles appear in a population. When applied to surnames, it is interpreted as a measure of the rate of entrance of new names and used to estimate immigration.

Applications using historical data from the Parma Valley (Yasuda *et al.*, 1974) and Sardinia (Zei *et al.*, 1983), as well as on recent Italian (Piazza *et al.*, 1987), Sicilian (Scapoli *et al.*, 1997), and French (Darlu and Ruffie, 1992) data, confirm the credibility of this usage of family names. The results of this research are in agreement with observations based on demographic data.

3. Migration Matrices

By observing the distribution of surnames at different periods in the same group of populations, researchers can analyze changes in these populations as a function of migratory and reproductive behavior. For instance, Ellen Wijsmann *et al.* (1984) proposed an interesting method and applied it to historical data of Sardinia. The patronymic structure of several populations can be described using a matrix $\mathbf{N}$ of dimension $P \times S$, where P is the number of populations being studied and S is the number of names. Each row of the matrix corresponds to a population, and each column to a surname. Each cell element n_{pk} represents the number of individuals in the population p with family name k. The patronymic structure of the P populations observed at different times can be described using two matrices, $\mathbf{N_1}$ and $\mathbf{N_2}$, indicating times $t = 1$ and $t = 2$, respectively. If the P populations represent a relatively isolated system, $\mathbf{N_2}$ can be expressed as a function of $\mathbf{N_1}$ according to the relationship

$$\mathbf{N_2} = \mathbf{B} \times \mathbf{N_1} + \mathbf{E}$$

where the matrix $\mathbf{E}$ represents effects due to chance, or at least to causes other than migration and fertility. The matrix $\mathbf{B}$, a square matrix with dimensions $P \times P$, combines the joint effects of migratory and reproductive behavior. $\mathbf{B}$ can be decomposed into two matrices $\mathbf{R}$ and $\mathbf{M}$ such that $\mathbf{B} = \mathbf{R} \times \mathbf{M}$. $\mathbf{R}$ is a diagonal matrix: each cell r_{ij} describes the reproductive behavior in the jth population. $\mathbf{M}$ is a square matrix, also $P \times P$, in which each element m_{jk} indicates the proportion of individuals migrating from population k to population *j*. The elements of the main diagonal estimate the proportion of native born residents.

Ignoring **E** and assuming that only migration and reproduction are at work, we can write

$$\mathbf{N_2} = \mathbf{R} \times \mathbf{M} \times \mathbf{N_1}$$

where the value of each cell n_{pk} in $\mathbf{N}_2$ (the number of individuals in population p with surname k at time $t = 2$) is calculated by adding the number individuals with the kth name at time $t = 1$, reproducing at the rate of their population of origin, who migrate from each population to population p (including the quota m_{pp} of people originating in population p who stay in the same population). Ellen Wijsmann suggested a way of deriving **B** from the matrices of isonymy between the populations and then deriving **M**, which describes the probabilities of migration between the populations being considered. When applied to historical data from Sardinia, the method has produced results that are in good agreement with what is already known about migratory movements in the region.

4. Relations between Populations

Models and methods similar to those used for allelic frequencies can be applied to the study of family names and can shed light on the relationships between two or more populations. Indices of distance or of similarity can be calculated based on the probabilities that two individuals taken at random from the two populations have the same family name.

One of the most commonly used is the R_{ij} index developed by Gabriel Lasker (1977, 1985):

$$R_{ij} = \frac{\sum(S_{ik} \cdot S_{jk})}{2 \cdot N_i \cdot N_j}$$

where S_{ik} and S_{jk} are the number of individuals with surname k in populations i and j, respectively, and N_i and N_j are the total number of individuals in the two populations. R_{ij} is an index of similarity (of relationship): it is high when the two populations have a significant proportion of patronymic forms in common, zero when they have no patronymic forms in common.

To facilitate interpretation and comparison of values, other indices impose a constraint that the index of similarity of a population with itself be one. One of the most prominent of these indices is the index of "standardized isonymy" proposed by Kuan Ho Chen and Luigi Cavalli-Sforza (1983), which is calculated from the relative frequencies p_{ik} and p_{jk} of surname k in populations i and j:

$$R_{ij} = \frac{\sum(p_{ik} \cdot p_{jk})}{\sqrt{(\sum p_{ij}^2 \cdot \sum p_{jk}^2)}}$$

The methods of representation described for matrices of genetic distance can also be used for matrices of similarity obtained from family names. In general, results agree with those obtained on the basis of allelic frequencies. As noted above, these methods can also be used to compare neighboring populations with negligible genetic differences.

The diffusion of family names, in accordance with the geographic dispersion of their bearers, provides information on the history of populations. In particular, family names can shed light on the presence of groups linked by a common cultural-historical origin, or groups that are culturally differentiated owing to different ethnic origins or long periods of isolation. The application to the Italian population (Zei *et al*., 1993) has clearly shown correlations between the history of different regional populations, the influence of immigrants of different origins, and historic separations (Barbujani *et al*., 1991, 1992). Analyses carried out based on surnames are in good agreement with maps produced based on allelic frequencies (Piazza, 1988), as is shown in the examples described here.

These analytic methods have been applied to distributions of surnames in Italian regions (Lucchetti *et al*., 1996), constructed by using lists of telephone customers (Seat, 1993). The results of this analysis are presented in a multidimensional scaling representation (Fig. 96–4). The spatial distribution of regions in this figure echoes their geographic location, if the first dimension is graphed on the vertical axis (to identify the north–south direction) and the second dimension on the horizontal axis (to identify the east–west direction). The uniqueness of Sardinia is clearly visible—the region is characterized by very specific patronymic forms. Trentino and the Valle d'Aosta, where there are names of German and French origin respectively, are also distinctive. The southern regions are clustered in the lower part of the figure, whereas the northern regions are gathered in the upper section and Lazio, Abruzzo, and Molise are in the middle. On the other hand, Piedmont, Lombardy, and Liguria occupy unexpected positions based on their geographic location: the position of the regions of the industrial triangle demonstrates the effect of the powerful processes of migration coming from the southern regions.

The observation that north–south migratory flows are largely directed toward the industrial cities inspires an examination of the patronymic structure of the five principal metropolitan areas (Turin, Milan, Genoa, Rome, and Naples) separately from their

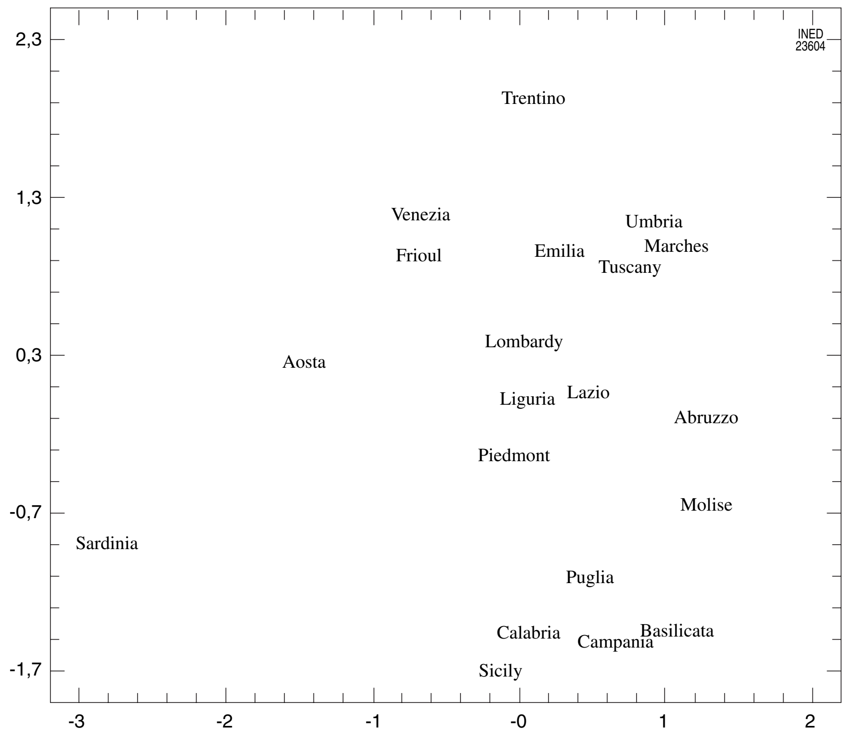

FIGURE 96–4 Division of Italian regions based on the distribution of surnames in 1993. (From Lucchetti *et al*., 1996.)

regions (Fig. 96–5). By using this refinement, the remaining parts of Lombardy and Piedmont rejoin the group of northern regions, whereas Milan and Turin fall even lower on the vertical axis than do their regions as whole in Fig. 96–4. On the other hand, Genoa, because of the greater dispersion of immigrants over the Ligurian territory, and Rome, toward which immigrants converge from all over the country, move very little in relation to their location in Fig. 96–4. Finally Naples, the arrival city for the flows of immigrants from the other regions of the south of Italy, is differentiated from Campania by moving even further toward the bottom of the figure.

The study of communal populations scattered over the Apennines (Parma and Piacenza in the north; Massa Carrara, La Spezia, and Genoa in the south), belonging to different provinces and linked to each other by various means of communication (railroad, roads, highways), reveals the direction of mobility and the contrasting effects of separation by the Apennines and connection by communication routes (Lucchetti *et al*., 1990).

Because data can be collected on the patronymic structure of a population in past centuries, analyses can be extended fairly far back in time. Research on the evolution of patronymic structures in parishes of the high Parma Valley (Lucchetti and Soliani, 1989) shows moments of rapid change alternating with periods of relative stability and highlights the effects of particular events, such as mortality crises or periods of war, and periods of marked isolation or rapid population growth.

5. Multidisciplinary Approaches: From Genetics and Anthropology to Demography and Sociology

"Current studies on family names, far from being limited to genealogy, are now a full part of the research domain. They facilitate an original decoding of both the historical and anthropological conditions that spurred the process of identification of individuals at different times in various parts of Europe." "Studying in turn the origins and the history of family names, their geographic distribution and the ties between genetic markers and family names . . . anthropologists, family historians, demographers, specialists in population genetics, and sociologists show the extent to which a multidisciplinary approach is necessary in order to explain the phenomenon of the family name." The project *Le patronyme. Histoire, anthropologie, société* (*The surname: History, anthropology, society*), published by the Editions du CNRS (Brunet *et al*., 2001), on whose

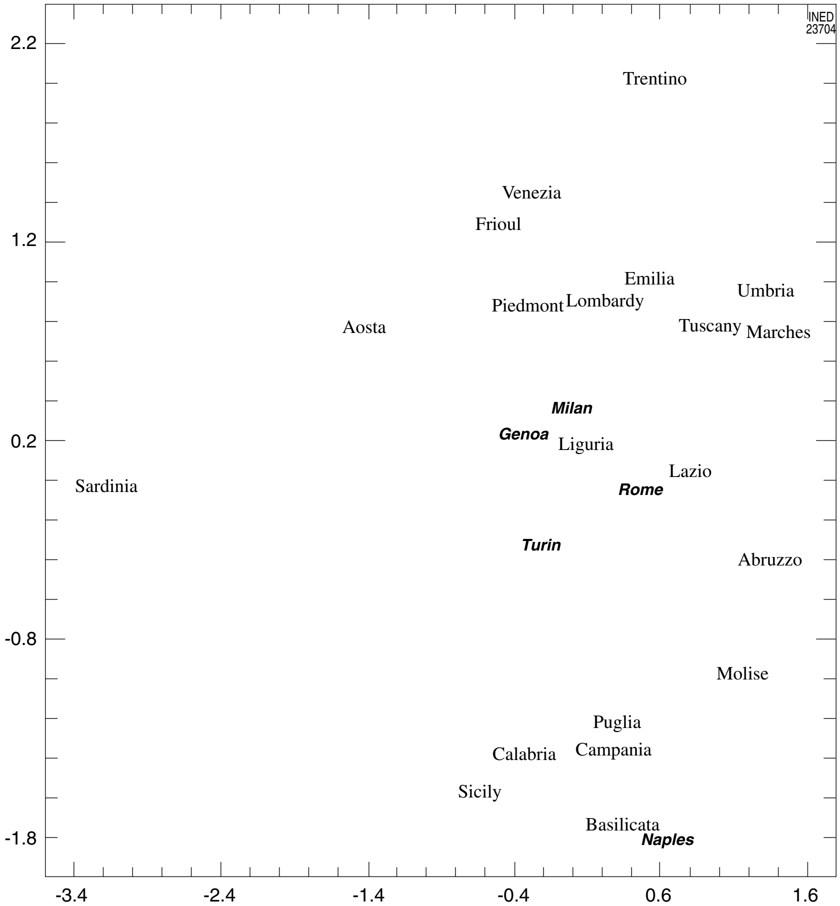

FIGURE 96–5 Division of Italian regions and five principal cities (Milan, Turin, Genoa, Rome, and Naples) based on the distribution of surnames in 1993. (From Lucchetti *et al*., 1996.)

cover these quotes are displayed, presents a large number of studies on the subject: "Based on concrete examples, from the Baltic provinces to Sardinia or the Moroccan Atlas, from the Flemish of France to the French of Quebec, this work offers a perspective without equivalent on the question of the origins and the evolution of the surname."

We take one of the diverse collection of articles as an example, both for the breadth of the field that it covers and for its demographic interest: "Immigration flamande en France au XIX^e^ siècle et au début du XX^e^ siècle."[2] In this article, European specialists from different disciplines show how characteristic family names of eastern and western Flanders diffused in the three French departments that were the closest, geographically and linguistically, to Flanders: the Nord, the Pas-de-Calais, and the Aisne. During the 19th century, there was preferential migration toward centers of labor, such as Paris, the Moselle, the Meurthe-et-Moselle, and Nantes. In addition to tracing the destination of migrants, the methods used make it possible to quantify their presence in specific zones and their dispersion over the course of the 20th century (Degioanni *et al*., 2001).

For the past few years, the major demography journals, including *Population*, have turned their attention to the usage of family names as an instrument of analysis, in particular for the study of migration. Italian migration to France has been analyzed in the framework of a collaboration between French- and Italian-speaking geneticists and demographers (Degioanni *et al*., 1996). They first reconstructed the distribution of family names in France and in Italy, using births from the vital registration system collected by National Institute for Statistics and Economic Studies for the 36,500 French communes, grouped by department, and marriage dispensations from the Vatican, grouped by diocese, for Italy. They then compared variations in the two series of distributions for the 50-year period

[2] "Flemish immigration to France in the 19th century and the early 20th century."

1891–1940 in order to estimate migratory flows from Italy to France. Despite the technical difficulties stemming from using these sources, the authors show that migration can be quantified using these methods, although in approximate fashion. Above all, these analyses clarify a number of points concerning the geographic origins of migrants, the direction of flows, and the time of migration, information that cannot generally be derived from census data. Residents of Piedmont and Liguria were the first to migrate to the south of France; starting in the early 20th century, they were followed by Venetians, many of whom moved toward the Garonne and along the Nantes-Rennes axis. Venetians and residents of Lombardy were also numerous in the Lorraine, and residents of Lombardy in Franche-Comté. Numerous groups from all over Italy, but especially from Emilia-Romagna, migrated to Paris. The zone around Marseilles attracted Italians from the center-south, especially from Lazio, Sicily, Sardinia, and Tuscany.

European demographic history societies occasionally follow along with the development of this new discipline, which applies easily accessible information to in-depth studies of the behavior of human populations, often impossible to analyze otherwise. As noted above, the analyses address the internal structure of specific communities and their demographic dynamics; the size of the marriage market and the modes of formation of couples; relations between populations; and the presence, intensity, and direction of migratory flows (Pizzetti *et al*., 2001). Further development of these research methods invented by anthropologists and geneticists, and their application, could be greatly encouraged by their diffusion among demographers and sociologists.

The evolution of human populations is the global result of a complex network of interactions between a number of different factors, often defined and analyzed in the context of different disciplines. Reciprocal forces overlap, cancel each other out, or reinforce each other in multiple and varied combinations (Livi Bacci, 1986). Evolution cannot be fully reconstituted through reductive approaches. When it comes to evolutionary and historical reconstructions, the phenomena under analysis can not be studied in a perfectly controlled manner or be subject to repeatable experiments in a laboratory. Studying these phenomena becomes a scientific challenge, and the credibility of the conclusions is rarely comparable to that of those obtained in the experimental sciences. The trust placed in these reconstructions depends on the convergence of multiple sources of evidence offering independent support to a given interpretation. The accumulation of new sources of evidence from varied research fields plays a vital role in creating a tight network of information to verify a proposed reconstruction (Ammerman and Cavalli-Sforza, 1986).

APPENDIX 96–A

Calculating Allelic Frequencies

Codominant Alleles

Calculating allelic frequencies is trivial when there are codominant alleles: because there is a one-to-one correspondence between genotype and phenotype, the alleles of each type can be directly enumerated and the relative frequencies derived from them. For example, for a sample of 1000 individuals (T = 1000), the following distribution of MN blood groups is observed:

TABLE 96–A

Group	Genotype	No. of individuals
M	MM	380
MN	MN	490
N	NN	130
Total		1000

The individuals in the sample carry a total of 2000 alleles (1000 × 2). The 380 individuals with phenotype M carry 380 × 2 M alleles, the 130 individuals with phenotype N carry 260 type N alleles, and the 490 individuals with phenotype MN each carry one M allele and one N allele. Of 2000 alleles in total, 1250 (380 × 2 + 490) are of type M and 750 (130 × 2 + 490) are type N. The allelic frequencies, generally represented by lower case p and q, are

$$p_{(\mathrm{M})} = (380 \times 2 + 490)/2000 = 0.625$$

$$q_{(\mathrm{N})} = (130 \times 2 + 490)/2000 = 0.375$$

More generally,

$$p_= \frac{2(MM \text{ homozygotes}) + MN \text{ heterozygotes}}{2{*}\mathrm{T}}$$

and

$$q_= \frac{2(NN \text{ homozygotes}) + MN \text{ heterozygotes}}{2{*}\mathrm{T}}$$

Because only two alleles are involved in the determination of the characteristic studied here, by definition $p + q = 1$.

The error involved in the estimation of the frequencies is equal to $\sigma_p = \sigma_q = \sqrt{pq/2T}$.

The existence of the Hardy–Weinberg equilibrium can be verified by comparing the observed genotypic frequencies to the frequencies that would expected given the relationship

$$\text{MM } (p^2);\ \text{MN } (2pq);\ \text{NN } (q^2)$$

Dominant Alleles

In the case of dominance, there is no longer one-to-one correspondence between phenotype and genotype. The direct counting method proposed above is no longer feasible, because homozygotes for the dominant allele cannot be distinguished from heterozygotes at the phenotypic level. We therefore assume that the population is in panmictic equilibrium, and the frequency of the recessive phenotype, that is, of homozygotes for the recessive allele, is assumed to be equal to q^2.

Take as an example a sample of 1000 (T = 1000) people composed of 350 people with blue eyes and 650 people with brown eyes. The allelic frequency q of c, the recessive allele determining blue eyes, is estimated by assuming

$$q^2 = \text{frequency of recessive homozygotes}$$

or, in other words,

$$q^2 = (350/1000) \quad q = \sqrt{0.035} = 0.187.$$

The frequency p of the dominant allele C is therefore given by the difference:

$$p = 1 - q = 1 - 0.187 = 0.813.$$

The error in this estimation is equal to $\sigma_q = \sqrt{(1-q^2)/4T}$.

Hardy–Weinberg equilibrium cannot be verified, because the hypothesis is taken as a given.

Calculating Allelic Frequencies using Maximum Likelihood Methods

Take the ABO blood type system as an example. Label the allelic frequencies of I^A, I^B, and i alleles p, q, and r, respectively ($p + q + r = 1$), and let n_1, n_2, n_3, and n_4 be their distributions into phenotypes A, B, AB, and O observed in a sample. Knowing the means of determination of phenotypes and the expected probabilities for each of them, we construct the probability function Λ, in which p, q, and r ($p + q + r = 1$) represent the unknowns. The values that maximize Λ are the most likely values for the allelic frequencies. The method also provides the estimation error.

TABLE 96–B

Phenotype	Genotype	Expected probability	Observed frequency of phenotype
A	I^AI^A and I^Ai	$p^2 + 2pr$	n_1
B	I^BI^B and I^Bi	$q^2 + 2qr$	n_2
AB	I^AI^B	$2pq$	n_3
0	Ii	r^2	n_4

$\Lambda = (p^2 + 2pr)^{n1}\ (q^2 + 2qr)^{n2}\ (2pq)^{n3}\ (r^2)^{n4}$

APPENDIX 96–B

Selection Models

Selection against the Recessive Phenotype

Selection against the recessive phenotype operates in the presence of diseases that are caused by a recessive allele *a* and are manifested in homozygotes. If selection is total, *aa* individuals do not contribute at all to the reproduction of the group, and population increase only comes from healthy individuals—*AA* homozygotes and *Aa* heterozygotes. However, individuals with the *aa* genotype continue to be produced as offspring of pairings between *Aa***Aa* heterozygotes as long as the population contains heterozygotes, who are healthy but carry *a* alleles.

Take a population in panmictic equilibrium, with the standard distribution of genotypes *AA*: p^2, *Aa*: $2pq$, and *aa*: q^2, where p and q are the allelic frequencies of *A* and *a*. When this population is submitted to a regime of total selection against the recessive phenotype, only *AA* and *Aa* individuals, a proportion of the population equal to $p^2+ 2pq = p(p + 2q) = p(1 + q)$, participate in reproduction.

The allelic frequencies within this fraction of the population are $p_1 = 1/(1 + q)$ and $q_1 = q/(1 + q)$: these become the allelic frequencies in the generation following selection. Clearly, $p_1 > p$ and $q_1 < q$: the frequency of allele *A* increasses, whereas that of *a* decreases. Similarly, in the next generation we have $q_2 = q/(1 + 2q)$, and after n generations of selection, $q_n = q/(1 + nq)$.

It is possible to evaluate the decrease in q at each generation or after n generations and the corresponding decrease in homozygous individuals *aa* carrying the disease caused by the recessive allele. It is also possible to calculate the number of generations necessary to reduce the initial frequency of the allele *a* by a given quantity given the regime of selection observed.

Selection with Respect to Heterozygotes

Selection against Heterozygotes

Selection against heterozygotes occurs when the contribution of heterozygotes to the formation of new generations is lower than that of the two types of homozygotes. To simplify, suppose that selection is total and that the two homozygotes have the same fitness:

TABLE 96–C

Genotype	Frequency	Fitness	Selection	Successful portion of the transmission
AA	p^2	1	0	p^2
Aa	$2pq$	0	1	
aa	q^2	1	0	q^2

Only *AA* and *aa* individuals ($p^2 + q^2 = 1 - 2pq$) participate in reproduction: within this group allelic frequencies are $q_1 = q^2/(1 - 2pq)$ and $p_1 = p^2/(1 - 2pq)$. In each generation the change in the allelic frequency q is given by

$$\Delta q = q_1 - q = [q^2/(1 - 2pq)] - q = [-pq(1 - 2q)]/(1 - 2pq).$$

When $\Delta q = 0$, the system is in equilibrium, with no changes in the frequency q over the passage of generations. The change Δq is zero if either p or q is equal to zero (if $q = 0$ and $p = 1$, all individuals are *AA*, whereas if $q = 1$ and $p = 0$, all are *aa*; in either case, there are no heterozygotes) or if the quantity $(1 - 2q)$ is zero, that is, if $p = q = 0.5$. The first two equilibrium conditions are stable, but the third is unstable. If $q > 0.5$, Δq is positive, that is, q increases from one generation to the next; if $q < 0.5$, Δq is negative and q decreases. Small random variations from the condition $q = 0.5$ are sufficient to spur evolution toward one or the other allele. If the two alleles in question have different frequencies when selection against the heterozygote begins, the allele with the higher frequency will reinforce its position. If the equilibrium condition, $p = q = 0.5$, is disturbed by random genetic variation, one of the two alleles will be reinforced. If selection against heterozygotes is introduced in several populations where the equality of frequency $p = q = 0.5$ initially was in effect, the two alternative alleles will each become fixed in approximately half of the populations; but the destiny of any given population cannot be predicted a priori.

Selection in Favor of the Heterozygote

Favorable selection toward the heterozygote takes place when heterozygotes have higher fitness than the two homozygotes.

The classic case of selection in favor of the heterozygote is that of thalassemia in a malarial environment. Thalassemia is a genetically determined disease that is less severe among individuals who are heterozygous with respect to the *t* allele responsible for the disease (thalassemia minor) and more severe among homozygotes (thalassemia major or Cooley's anemia). Selection takes place in a malarial environment because healthy individuals are more susceptible to malaria. Healthy individuals are subject to selection by malaria, and *tt* homozygotes are subject to selection by thalassemia. As a result, heterozygotes contribute most to the formation of the next generation.

TABLE 96–D

Genotype	Phenotype	Initial frequency	Agent of selection	Fitness	Selection	Successful portion of the transmission
TT	healthy	p^2	malaria	$1{-}s_1$	s_1	$p^2\,(1{-}s_1)$
Tt	thalassemia minor	$2pq$		1	0	$2pq$
Tt	thalassemia major	q^2	thalassemia	$1{-}s_2$	s_2	$q^2\,(1{-}s_2)$

Individuals $2pq$, $p^2\,(1 - s_1)$, and $q^2\,(1 - s_2)$ participate in reproduction; the frequency q of t alleles in the next generation will be:

$$q_1 = [(pq + q^2(1 - s_2)]/(1 - p^2s_1 - q^2s_2),$$

with

$$\Delta q = q_1 - q = -\,pq(qs_2 - ps_1)/(1 - p^2s_1 - q^2s_2).$$

The conditions where $\Delta q = 0$ correspond to the values $q = 0$ ($p = 1$), $q = 1$ ($p = 0$), and $= s_1/(s_1 + s_2)$. Selection in favor of the heterozygote produces a stable equilibrium condition (when $qs_2 - ps_1 = 0$), that is, when $q = s_1/[s_1 + s_2]$), which depends on the intensity of selection against the two homozygous genotypes. The equilibrium is stable, because when $q > s_1/(s_1 + s_2)$, Δq is negative and when $q < s_1/(s_1 + s_2)$, Δq is positive: in both cases the forces of selection work to maintain equilibrium, and there is no possibility of moving away from it.

APPENDIX 96–C

Migration and its Effects on the Genetic Structure of Human Populations

Island Model Migration

The island model describes the effects of constant unidirectional migration from a large population (a continent) toward a small population (an island). The model analyses the evolution of allelic frequencies in the smaller (receiving) population by assuming that the large population, because of its large size and the negligible influence exerted by the out migrations, does not experience significant change.

Let there be two populations, that of an island (i) and that of a continent (c), initially in internal equilibrium for a bi-allelic characteristic, with q_{i0} and q_{c0} being the respective initial frequencies for an allele a and m the proportion of individuals migrating from the continent to the island in each generation. The allelic frequency on the island becomes

After the first generation with migration: $q_{i1} = (1 - m)\,q_{i0} + mq_{c0}$;
After the second generation: $q_{i2} = (1 - m)q_{i1} + mq_{c0} = \ldots = (1 - m)^2q_{i0} + [1 - (1 - m)^2]q_{c0}$;
And, finally, after n generations: $q_{in} = (1 - m)^nq_{i0} + [1 - (1 - \mathrm{m})^n]q_{c0}$.

The proportion of natives among the residents of the island decreases with each generation. Over time, the island population will become more like that of the continent, and once the equation $q_{in} = q_{c0}$ holds the island population will no longer change from one generation to the next. The change Δ from the equilibrium value, initially $\Delta_0 = q_{i0} - q_{c0}$, becomes $\Delta_1 = (1 - m)(q_{i0} - q_{c0})$, $\Delta_2 = (1 - m)^2(q_{i0} - q_{c0})$, . . . , $\Delta_n = (1 - m)^{\mathrm{n}}(q_{i0} - q_{c0})$, declining by a fraction equal to $(1 - m)$ at each generation.

If the migration rate is known, allelic frequencies in the island population can be predicted. Reciprocally, if allelic frequencies at different times are known, they can be used to estimate the rate of genetic flow from the continent toward the population of the island.

This model has been applied to the North American population of African origin. This population is taken as the island population, subject to a steady arrival of genes from the much larger white population; movement in the opposite direction has very little influence on the white population. Typical allelic frequencies in the white and African-American populations q_{c0} and q_{i0} are known, so it is possible to estimate the average magnitude of genetic flows by generation, and from there to calculate the time necessary to reduce the remaining difference by half.

The R° allele (in the Rh system) has a frequency of 0.63 in the African population and a frequency of 0.03 in white populations; its frequency in current North American populations is estimated to be equal to 0.45. The length of the period of migration of genes toward the African population living in North America is estimated at 10 generations (approximately 300 years).

When the model is applied, the rate m of passage of genes from whites toward African-Americans is estimated to be 0.033 per generation; if this rate were held constant, another 10 generations would be required to reduce the initial difference between the two populations by half (Barrai, 1978).

The model can thus be applied to populations that live on the same territory and are separated by social, economic, or cultural factors rather than geography. In these cases, the two populations could be wholly or partly integrated at some future time.

Archipelago Model

The archipelago model accounts for migratory flows between several populations, analogous to a series of islands of an archipelago with migratory exchanges taking place in all directions. The model can be described by a matrix **M** of migrations, a square matrix with dimensions equal to the number of populations being studied, where each element m_{ij} represents the population of island i that immigrated during the previous generation from island j. The elements of the main diagonal $m_{ii} = 1 - \Sigma_{k \neq i} m_{ik}$ represent the number residents of island i who stayed on the same island during the next generation. A vector **q** describes the values of the allelic frequencies on the different islands, and the allelic frequencies of the next generation are calculated from the product of the vector **q** and the matrix **M**.

Because migration flows go in all directions, it is expected that the system will move toward an equilibrium at which allelic frequencies are the same on all islands and equal to $\bar{q} = \sum q_i / N$ (or a weighted average if the population sizes are different).

The model can be used to analyze changes in allelic frequencies in each population, the relative distance from equilibrium position, and the rate of reduction of the distance.

Migration, Isolation: Effects on Genotypic and Phenotypic Structures

The population that occupies a given geographic area is rarely a homogenous whole. Most of the time populations are divided into more or less separate subgroups. The problem is further complicated by large migratory flows.

Subdivision into groups influences the genotypic and phenotypic structures of the population: there are more homozygotes in populations subdivided into nuclei that are partially or totally separated from each other than in populations without subdivisions. Take, for example, a population formed from two isolates. Assume for simplicity that the populations are of equal size, and that both are in panmictic equilibrium with respective frequencies q_1 and q_2 for allele a. Within the two isolates the frequencies of homozygotes are q_{12} and q_{22} respectively; in the total population the frequency is $(q_{12} + q_{22})/2$. This frequency is greater than that expected when the population is taken as a homogenous whole: the frequency of the allele a in the whole population is the average of q_1 and q_2, and the expected frequency of aa homozygotes is $[(q_1 + q_2)/2]^2$.

Thus, fusing the two populations into a homogenous whole reduces the frequency of homozygotes and increases the frequency of heterozygotes. Conversely, the subdivision of the population into distinct groups is associated with an increase in the frequency of homozygotes and a reduction of the frequency of heterozygotes. The same phenomenon is observed in positive preferential mating. Specific statistics (Wright, 1968) are used to study the phenomena of division into subgroups (Whalund effect), both to detect the presence and intensity of structure and to predict its consequences. These methods focus in particular on migration, and the extent to which immigrants constitute partially distinct isolates within the receiving population rather than being integrated completely and rapidly into it.

HISTORY OF POPULATION THOUGHT AND POLICIES

Introduction to Volume IV

GRAZIELLA CASELLI, JACQUES VALLIN, AND GUILLAUME WUNSCH

Volume I looked at the central study of the discipline—the built-in mechanisms of population dynamics. Volumes I and II respectively addressed the determinants of the three big forces of population change (fertility, mortality, and migration). Volume III drew on all this groundwork to paint a broad panorama of the historical and geographical forces behind population processes and sketch out prospective future medium- and long-term trends. Volume III examined the biological, economic, social, and political consequences of population changes and, more generally, looked at the big issues facing society where these changes intersect.

But, should and can society as a whole try and shape the course of all of these processes? This is the central question in this fourth volume on population thought and policies. Volume IV will then go on to offer some insights into data collection methods and tools for demographic analysis.

Section I of Volume IV will address this issue of population thought and policies on three different levels, the first being the abstract level of ideas, the other two the concrete level of political realities, seen from two complementary angles: the broad concerns of a population policy and individual country case studies.

Before moving onto population policies as such, it was thought necessary to look first at the dominant thinking that shaped historical and contemporary population theory and informed the concerns of demographers, naturally, but more especially of philosophers, politicians, and the public. This short overview in two chapters is followed by a third on ethics as it affects demography. This first part concludes with an introduction to population policies proper. Because most of this work focuses largely on post-World War II developments, a historical review is given of pre-1940 population policies, while a few very basic reference points on the principles and context behind contemporary population policies are outlined in a very short chapter.

The major concerns of population policies (fertility, health, migration, age structures) are then considered in three parts, beginning with a world overview that takes in as far as possible the wide range of situations and policy approaches. This is followed by a comparative analysis of family and fertility policies pursued since World War II. Health policy is dealt with in the same way in the third part. The fourth part looks first at migration policies, then at policies concerned with population age structure.

But for all that it enables the topic to be considered in depth from a broadly comparative analysis standpoint, splitting the field up into these different subject chapters risked obscuring the fact that population change comes about as a result of the interplay between all these elements, and government attempts to shape population trends cannot ignore that: what they do (or do not do) in a sphere will affect population change only as it connects with the other factors in population change and hence with what they do (or do not do) in those other spheres. It was therefore thought necessary to amplify the subject approach with a fifth part containing country case studies to give an overview of all policies that have demographic consequences across all spheres. Eight chapters are therefore given over to as comprehensive as possible an analysis of the population policies pursued, purposefully or otherwise, over some 50 years in eight major countries, concluding with a survey of policies conducted at the international level to illustrate the unprecedented and at times quite decisive role played by the international community since World War II in the establishment of population policies.

P A R T

I

HISTORY OF POPULATION THOUGHT AND SHORT INTRODUCTION TO POPULATION POLICIES

GRAZIELLA CASELLI, JACQUES VALLIN, AND GUILLAUME WUNSCH

Although the word *demography* was a 19th-century invention (coined by Achille Guillard, 1855), population issues were a very early concern for human societies. The need to count people is lost in the mists of time. A major legacy has come down to us from the ancient world in this area, and no analysis of the population policies of our era can be undertaken without some mention of the history of ideas developed in different cultures down the centuries. The belief that births and deaths were ordained directly by a god, whose will alone determined their equilibrium or otherwise, left little scope for human population policies or even any real thinking on the matter, even when the mere fact of counting people was not itself taboo.[1] But philosophers from antiquity onward reflected on the theory, while administrators took censuses and, over time, the thinkers developed their ideas, explored the pros and cons of population growth, suggested to rulers policies or measures that might work toward the desired ends.[2] This is considered by Éric Vilquin in Chapter 97, in a concise but wide-ranging review of over 2000 years of history of population thought leading to the situation as it stood on the eve of World War II.

[1] The taboo on counting has religious connotations and is found in the Bible, but in both ancient and more recent history, has also often served as a cover for political strategies.

[2] A concern central to the work of the 18th-century Pastor Johann Peter Süssmilch ([1741], 1998), for whom "God's order" in no way precluded human intervention, provided it was consistent with what Providence ordained: the increased peopling of the Earth (Rohrbasser, 2001).

The difficulty of condensing into a single chapter so much history from so many different civilizations may be exceeded only by that of outlining the history of population thought in the few decades that followed, for at least three reasons. One is the indisputable difficulty a contemporary author, however learned, faces in objectively reviewing the development of fellow specialists' thought in light of a largely yet-unwritten history. But this standard difficulty is compounded by two things. Another is that this is among the most eventful periods in the demographic history of humankind—the most crucial phase of worldwide demographic transition, where population growth peaked. But it also witnessed a real growth spurt in the still very young discipline of demography, and a proliferation of new ideas and theories of all kinds. Paul Demeny tackles this in Chapter 98, on the trend in ideas on population since 1940, starting with an extensive look at the tools and materials readers can use to explore the matter in greater depth, and moving on to a more specific review of selected major concerns in contemporary demographic thought.

One consequence of the development of population science has been the increase in ethical issues surrounding the work of demographers, and the use to which the results of their research may be put, or perhaps even more so, the scientific or other use that may be made of the investigative techniques they employ. This sensitive issue clearly seemed to fit here, following on from the first two chapters of consideration on population thought, and as a prelude to the following chapters on population policies. François Héran therefore considers ethics and population in Chapter 99.

Part One concludes with two chapters that touch briefly on population policies proper. Plainly, these chapters concentrate mostly on developments in recent decades, seldom harking back to before World War II. But even modern population policies have historical roots, and a rapid review of population policies pre-1940 from Michael Teitelbaum in Chapter 100 informs the situation. Without preempting what follows, Stefano Baldi and Raimondo Cagiano de Azevedo sketch out in a concluding Chapter 101, some of the fundamentals of the principles and contexts on which today's population policies are based.

CHAPTER

97

History of Population Thought

ÉRIC VILQUIN

Institut de démographie, Université catholique de Louvain, Louvain-la-Neuve, Belgium

INTRODUCTION

Once a group of women and men develops the awareness to form a population which has a future of its own that transcends the overlaying succession of individual futures, some of its members will inevitably start thinking about how to manage this common history. Having perceived that the group has so far outlived the passing of individuals, they reflect on how best to ensure the same continuity in the future. Self-perpetuation is the aim of all populations! The mechanism of continual replacement that enables a population to endure over time (i.e., the combination of entries, births, and immigrations with exits, deaths, and emigrations) assuredly contains varying elements of inevitability or laws of nature that are relatively difficult to gauge and cannot but be endured. But humans would not be humans without a belief in their ability to shape a population, at least to some degree, as they have thought to do with so many other mechanisms in life and in the world; it is this specifically human conceit that is the source of progress. Our forebears were no more wearily resigned than we to the trends and vagaries of the components of demographic changes.

Population sustainability requires that the individuals comprising the population remain sufficiently healthy and survive long enough to contribute to population replacement. This in particular involves a sufficient proportion of the population managing to feed itself, protect itself day by day from the fatal stresses and strains of its environment, be sufficiently fertile, and be sufficiently untempted to emigrate. At what stage in the hominization process these basic considerations may have become expressly imprinted into the consciousness of some human being is not known and matters little. Suffice it to acknowledge that, long before writing and long before history, our remote ancestors certainly possessed the ability to conceive of population.

In order to influence the factors that shape their destiny, humans must assess their present situation, choose a goal to achieve or a course to follow, and frame an appropriate strategy. Where the future of the population is concerned, the point is to define a demographic ideal, measure how far one is from it, and decide how best to close the gap. The ideal population will be that whose absolute size, growth rate, and composition—judged by various criteria—are most apt to ensure both its long-term sustainability and its happiness; the strategy will be formed of a coherent set of effective, realistic, and legitimate ways of steering the population dynamics of the current population toward the ideal population characteristics. This means demographers, philosophers, and politicians—often one and the same—must work in conjunction.

If the aim of population sustainability and the strategic criteria of effectiveness and realism come down on balance to just plain common sense and calculation (sound demographic analysis), the same cannot be said of the aim of happiness and the criterion of legitimacy. What, within the bounds of the sustainability requirement, is a desirable population? Large or small? Dense or sparse? Increasing, stationary, or decreasing? Young or old? Homogeneous or heterogeneous (ethnically, socially, linguistically, politically, etc.)? In addition, which of the many effective and realistic policy approaches for achieving the chosen ideal characteristics should be selected? There is no scientific answer to this host of questions. Every society is deemed to have its own answers that square with the ethical choices and definition of happiness it has settled on; each individual, guided by his or her own conceptions of happiness and ethics, can formulate and express an opinion as to which population theory they would like to see the community follow. The history of population thought is a descriptive and comparative survey of theories that are, in the final analysis, only the demographic elements (where they exist and are overtly expressed) of belief systems of a much broader compass.

Advances in scientific knowledge have demographic consequences that must be taken into consideration by all subsequent population theories. So strong may be the influence of the underlying belief system, however, that all theories may not invariably do so. Also, demographic science has scarcely offered a description and explanation for all phenomena (which, indeed, no observer of human behavior can do, being unable to set up chemistry laboratory-style experiments), such that the gaps and uncertainties in knowledge leave a vast clear field for subjective and ideological argument, not to say theorists' own philosophies and personal psychologies.

Attempts have been made to apply different classification criteria to population theories, but none has become the standard. All told, a chronological classification is no more artificial than any other and suits the purpose here, barring the occasional liberty taken with the timeline. Also, rather than striving for a comprehensive survey—an equally hopeless and unfeasible endeavor—it seemed preferable to sketch out the history of population thought through an (inevitably personal) selection from among the most original and influential theories. Let me also stress that the main reason why Europe dominates this chapter is simply because European population theories have attracted significantly more analysis than those of other continents.

I. SOME OF THE EARLIEST KNOWN POPULATION THEORIES

We can ascribe to prehistoric populations a minimal implicit population theory: because the survival of the group depends on numbers,[1] it is essential to keep watch, and, if possible, act on, mortality, fertility, and migration; the pursuit of a more sophisticated social ideal than collective survival alone can only heighten nuance and add complexity to this type of concern. But it would be a mistake to conceive of a simple, coherent primitive population theory. The different situations and philosophies of the different peoples necessarily colored their thinking in this as in other fields: nomadic and sedentary communities were probably inclined to different demographic ideals; some may have been driven by the fear of underpopulation, others by overpopulation; all necessarily made their demographic choices agree with their religion, moral code, political organization, technology, psychology, and so forth.

[1] Volume of population, but also the specific absolute numbers of certain key subgroups: women (for reproduction), defenders (for war), producers (for the economy), and so forth.

Very few peoples in the ancient world gave expression to their population theories, at least in writing, which is the only sufficiently detailed and precise form. The interpretation of the archaeological remains left behind by preliterate peoples is too uncertain and approximate on this: the existence of (female and earth) fertility divinities in almost all nature-worshipping or primitive religions testifies only to an awareness of the importance of this factor for life and survival.

What theories are known, moreover, tend to be formulated by thinkers who may have been expounding only their personal ideas (e.g., Plato's theory is not universal for ancient Greece), although some admittedly influenced the behavior of their people. Care must be taken, therefore, not to generalize to all the great civilizations in the ancient world the smatterings of population theory that have survived for us in the works of their most renowned writers.

It would be impossible to survey all the religious, legal, philosophical, historical, or literary writings that fall within the ambit of demographic thought because they inform us about peoples' norms in relation to marriage, divorce, homicide, infanticide, sexuality, abortion, contraception, or their demographic agendas. What follows are merely examples of ancient theories which, in addition to their inherent merits, are deserving of special interest for the influence they may have on more recent theorists.

1. China: Confucius

Confucius (555–479 BC) codified and unified elements of long pre-existing theories, thereby investing Chinese civilization with a system of moral and political philosophy that left a powerful imprint on the rest of imperial history, permeating institutions and behaviors (Confucius, 1981; Gay-Sterboul, 1974).

The main aspects of Confucianism that affect the population are moral laws. They are not demographic in intent, but have demographic implications.

All Chinese—from beggar to emperor—are subject to the moral duty of filial piety based on the precept that the souls of the dead can only be kept alive (and favorably disposed to the living) in the afterlife by regular ancestral worship rites performed by their direct male descendants. For the man, therefore, reproduction is both a duty to his ancestors and a personal imperative. As an unbroken male line must be preserved at all costs, children must be produced in sufficient numbers to ensure multiple sons, and, in light of early mortality, ensure the survival of some children long enough to produce further children before dying. Given the extreme uncertainty of individual fertility and mortality, the only reasonable strategy is to aim for maximum fertility at almost any cost. Institutions and morality are therefore all ordered to that end. Its principal purpose being reproduction, marriage, arranged by families, sometimes before the birth of the young parties directly interested, is entered into only when the engaged couple have not only attained puberty, but are mature enough to bear and raise children. To further secure the birth of male offspring, a man may have concubines in addition to his wife. Repudiation of the wife is permitted and easily done; infertility is a normal reason for repudiation. A woman's life is justified only by bearing several male children to her husband. Bearing a female child is a failure, and it is understandable that, for the poor, a girl should be regarded as a superfluous burden that it is not unthinkable to rid oneself of. Remarriage by widows is frowned on, but that of widowers is a matter of course. Paradoxically, the art of loving, including contraceptive techniques, seems to have been cultivated by the elite in Chinese society, but it was strictly an indulgence of the nobility.

The emperor has duties specific to his function, which includes a duty of benevolence toward his subjects in return for their absolute obedience. He must ensure harmony and equilibrium in the working of the administrative and economic machinery of society through a realistic and fair policy. To this end, Confucius advises him to count the population in close detail: sex, age, social class, trade, and health are data that will enable the imperial government to accurately assess needs and resources. In fact, regular census taking was standard practice for the Chinese administration, so much so that it introduced for the purpose, at various eras and in different forms, hierarchically organized canvassing systems for the entire population, which at certain times provided more or less the same statistical services as a permanent population register.

Confucianism is a populationist theory. If the population is large, its work will ensure the welfare of all, the wealth of the country, and the emperor's power, provided there is a fair distribution of land and resources and the emperor treats his subjects benevolently. The success of this policy will be proved by the immigration of foreigners, further reflecting on the emperor's glory.

Confucius seems not to have expressly considered the demographic content of his moral precepts. He sees them as so absolute as to render any inquiry into the point or value of their consequences superfluous. He professes the optimistic belief that if all people, emperor and subjects alike, keep their place, perform their duties, and abide by the rules of moral conduct, the harmony of society and the world is assured.

Some of Confucius's followers glimpsed the possibility of a discrepancy between population growth and the finite character of natural resources: land that is farmed becomes exhausted, uncultivated lands decrease, people's needs increase, and so on. But they believed that overpopulation would result only from poor resource management, and the problem would be cured by a return to a sounder economic policy of low consumption, saving, and providence. There is therefore an optimum relationship between population and resources toward which the emperor's wisdom must steer the ship of state.

2. Greece: Plato and Aristotle

Two of ancient Greece's foremost thinkers developed somewhat similar population theories within the all-encompassing framework of a total political utopia. Plato (Vilquin, 1982; Plato, 1997) and Aristotle conceived an organization of society that was radically new in the Greek geopolitical context of their time: the city, a small territory centered on a single town, in which the citizens (free men) attended to public civil and military business while women and slaves did the work necessary for general life. They also formed part of a line of thought that questioned the traditional values of Greek civilization, beginning with religion and morality. The old morality based on ancestor worship, which made reproduction a religious duty to the family line, was in disarray, but was supplanted by a civic morality that made reproduction a civic duty to the State.

In his *Republic* and *Laws*, Plato (428–348 BC) conceives of a city whose organization and legislation strictly regiment each person's life so that no individual whim risks upsetting the eternal static equilibrium that constitutes the Platonic ideal.

Here, he develops the odd theory of the two fertilities formulated in his other philosophical works (in particular, the *Banquet*). Fertility of the soul is an exchange of thoughts between the minds of men. Its perfect form is the love between master and disciple, which is the vehicle for the transmission of science, philosophy, and the sense of beauty. It is Platonic love, with no sexual overtones. The other fertility is reproduction, reduced to a simple biological and social necessity. All the worst individual and social disorders, the attendant passions, crimes, lunacies, and rebellions are the result of commingling the two fertilities which should remain utterly discrete. Plato also sees the interplay of love and sexuality as the gravest threat to the harmony of his perfect city. So high are the stakes that the dissociation of the two fertilities must be inculcated in children at all costs, and any means by which to ensure that individuals respect it are acceptable.

Because reproduction is an entirely civic function, it is for the State alone to organize it. The State must regulate not only the institution of marriage, but also sexual relations, the "selection of sons" (Republic, III, 415 a–c)[2] (eugenics), and the education and guidance of children toward the different functional specializations that society needs. The State's power in these matters must be absolute and no personal, family, or other interest must compete with or challenge it. These premises therefore lead Plato into constructing an unwieldy, pettifogging, sometimes monstrous framework of demographic laws.

The only exception to the Platonic ideal of moderation, "right measure," even nonmovement, is the quest for physical (eugenics) and spiritual (philosophy) perfection on which no bounds can be set. The city must be neither rich nor poor, the population neither too sparse nor too numerous.

The *Republic*, the first description of Plato's great political utopia, is the product of this obsessional quest for "right measure"/moderation and eternal static equilibrium. Like all other aspects of the city (which should be "neither large nor small" V, 460 a), the population absolutely must be stationary. This obviously cannot be achieved if reproduction is left to the free will of individuals and families. All the strings of this infinitely delicate biosocial function must be completely in the hands of the State, that is, the aristocracy of the magistrates. This elite of scholars and sages knows and lays down the conditions for the happiness of the individual and the community, resulting in their absolute authority and the total obedience by all other citizens. The State's power is totalitarian: the State may compel, mislead, or brainwash. For the system cannot suffer the slightest discordance; total law and order cannot tolerate the slightest measure of individual fancy or initiative. This leads logically to Plato's abolition of property and the family, which could only stand in the way of the magistrates' authority. The objectives of a stationary population and eugenics dictate the laws.

There may be a community of property among all citizens, but it is not possible to talk of a community of women, since total separation of the sexes is the general rule, with marriage reduced to simple cohabitation ordained by the magistrates for a specific period. The magistrates must be perfect demographers: using calculations, which Plato does not explain, they must have point-in-time information on the number of newborns the city needs to ensure a constant, sustainable absolute size of population and its qualitative advancement. For that, the city ordains a given number of marriages. The couple will be designated by the drawing of lots (so that only fortune or the gods are to blame for dissatisfaction with the partner they acquire), but the draw will have been deftly manipulated to ensure that the best of men are partnered with the best of women—for the good citizen is physically healthy and attractive, politically docile, and psychologically predisposed to his or her allotted social function. To limit the production of weak or malformed children, Plato recommends that reproduction be authorized only within specified age limits (that vary somewhat from chapter to chapter). Like physically deficient babies, children conceived without the magistrates' authorization must also be eliminated (the technique of infanticide as practiced in Greece and mentioned by Plato was to expose children to the elements). The others will be raised collectively and conditioned to perform allotted duties to society and the economy. They will never know their parents or siblings, which will create problems for the eugenicists!

Plato is well aware of the difficulties that his magistrates will face in making the necessary prospective mortality and fertility calculations, and his chief fear is that a forecasting error may irreparably damage the entire edifice.

In the *Laws*, written 40 years after the *Republic*, Plato endeavored—frankly, with little success—to add a touch of realism to his great dream. Population stationarity and genetic selection remain the two main focuses, but there is a lighter touch to the social organization and laws. There is less duress and more incentive (rewards, penalties) and social pressure (taboos). Instead of abolishing the family and property, Plato neutralizes them: they will remain, but every care will be taken to see that they do not thwart the magistrates' social engineering. The problem of land distribution

[2] Like the Bible, Plato's writings have references independent of the page numbering, which are common to all editions and translations.

between citizens' families, which regularly exercised the Greek cities (sometimes to the point of civil war), is settled once and for all when Plato ordains that the city will only ever have 5,040 families. The land is fairly divided into 5,040 indivisible and nontransferrable lots, one per family, and this distribution is immutable and never to be challenged. Each lot must therefore have not only one owner, but also only one heir (male citizens only). This gives a new justification to the demographic laws: the magistrates must evaluate and manage the fertility of unions such that the total number of families neither increases nor decreases, and that each lot has one male heir only. Plato bitterly regrets the impossibility of ensuring that each union produces exactly one male and one female child that are fit to survive and reproduce, and so robust measures are called for: large families will surrender children to infertile unions, while supernumerary children will be taken out of society (by infanticide or, if adults, banishment). The magistrates, in charge of stationarity and eugenics, must gauge the city's short-, medium-, and long-term population requirements, and, on the basis of their calculations, issue mandatory orders: if the city is likely to suffer a shortage of children, they will enjoin reproduction for all for a specific period; in the event of a likely surplus, they will prohibit all sexual intercourse for a specific period. To enforce their orders, they will use a range of measures increasing in stringency from exhortation, through rewards and threats to compulsion. In the final degree of coercion, "nuptial inspectors" (i.e., matrons with authority over marriage) will have the power to enter homes to ensure that couples are obeying orders (!), exacting punishment on offenders.

Plato allows migration only as a last resort. Immigration is ruled out because of the danger of allowing into the city individuals not inculcated with its specific moral precepts from birth. Emigration (in fact expulsion under the guise of establishing settlements) is a means of ridding the city of undesirables of all kinds: individuals whose upbringing had not produced the desired outcome, antisocial elements, troublemakers or, quite simply, supernumerary individuals too old to be discreetly put to death as a baby would be.

Only in the *Laws* does Plato set the total number of the stationary population. Specifically, he sets the number of family heads at 5,040. Why this figure, rather than, say, 5,000? Because 5,040 is the product of the first seven whole numbers, which gives it precisely 60 divisors, including the first ten whole numbers and 12. For a philosopher fascinated by the arithmetical properties of numbers, the figure of 5,040 is that of the numbers of the same order of magnitude (wherein Plato probably situates "right measure") which best enables the population to be exactly subdivided into numerically equal groups and subgroups.

Averaged over time, each head of family must have a wife, a son (heir), and a daughter (who will marry a neighboring heir), so at all times there will be just over 20,000 free citizens. Strange as it may seem, at no point does Plato concern himself with the total population size of the city. He refers to slaves for the functions they perform, but considers neither their numbers nor their population dynamics. It was probably obvious to him that family heads, having absolute power over their slaves, would be capable of managing them like livestock in their best economic interests through a judicious and easily readjustable mix of commerce and breeding. The State had no need to concern itself.

The optimum population thus devised by Plato is not an economic optimum. There is no question of balancing population with land size, production, or consumption. The ideal absolute number is that which best enables the State to control the population, ensures that all the city's political institutions work to the best effect, and delivers a high level of satisfaction to citizens themselves in the fulfillment of their political offices (pledge of social stability). Overpopulation is a purely numerical concept: there is point-in-time overpopulation of the city when there are more than 5,040 male heirs.

Aristotle (384–322 BC) espouses Plato's theories in his *Politics* (Books II and IV). Certain aspects are nuanced and tempered, but the fundamental principles are no different (absolutism, stationarity). He fears population growth, but only because distributing the land and its produce among a growing number of individuals would impoverish some of the people, which can only result in social unrest. But he fears underpopulation no less, since it would deprive society of the economic advantages of the division of labor. He is no less authoritarian than Plato, for example in considering that the State could compel women to terminate their pregnancies if the number of children were deemed to be excessive.

3. Rome: Augustus

The Romans saw the issue couched in very different terms. Rome was the center of a sprawling empire that the Latin people had conquered by arms: Rome's view of the benefits of a large population was mainly from the standpoint of military might.

Augustus' predecessors had already noted the waning popularity of marriage and reproduction among Roman citizens. In the first century BC, the citizen class were finding the idea of a wife and children common. Spending one's wealth on festivals and banquets was a greater sign of status than keeping a family. As the literature, drama, and biographies of famous citizens attest, the unmarried state was fashionable among this class of the population, and there was no certainty of its replacement. The chief ambition of a young Roman citizen was to be adopted by a rich, aging bachelor and inherit his fortune. Augustus (63 BC–AD 14) thus found it increasingly hard to recruit young Romans of noble birth into the officer class of the army and to administer a rapidly expanding empire. Having clearly identified the sources of the problem, he promulgated a highly sophisticated set of laws to promote marriage and reproduction, and tackle what was hindering them. These laws (*lex Julia*, 17 BC, and *lex Papia Poppaea*, 9 AD, are the main ones) lay down a mix of generally financial deterrents against the declining morality of Roman society which lay behind a falling birth rate and the undermining of civic virtues. Adultery was severely punished. Cohabitation was automatically legalized. The financial advantages of being unmarried were scrapped. The ability to benefit under a will was radically reduced and in some cases abolished for single people, childless couples, women with fewer than three children, un-remarried widowers and divorcees. The confiscated portion legacies were allotted to large families. Parents with more than three children were highly favored.

These first laws failed to remedy matters, so Augustus introduced a 100-day delay between death and the vesting of the inheritance to give unmarried heirs the time to marry in order to claim their portion. But this final "tweak" seems to have added nothing to the effectiveness of this major body of demographic legislation. Circumventions and exemptions were quick to develop. Although they remained formally in force for several centuries, Augustus' laws failed to stem the decline of the citizen class. This may well be one reason why Rome found it increasingly hard to enforce its presence and authority at the far-flung borders of its vast empire. The fall of the Roman Empire may in part be due to the loss of demographic dynamism among its nobility.

II. THE DEMOGRAPHIC DICTATES OF SOME MAJOR RELIGIONS

1. Judaism and Christianity

For the Jewish people, the injunction in Genesis to "Be fruitful and multiply, and replenish (fill) the earth" (Gen.1.28 and 9.1.7), is both a commandment and a promise: let Israel be confident in its reproduction; God guarantees its fertility and continuance. God said to Abraham, "I will make thy seed as the dust of the earth [. . .] tell the stars if thou be able to number them [. . .]: so shall thy seed be [. . .] I will make thee exceedingly fruitful [. . .] I will bless thee and [. . .] will multiply thy seed as the stars of the heaven and as the sand which is upon the sea shore" (Gen.13.16; 15. 5; 17.6; 22.17), and He would promise the same to Hagar the Egyptian and her son Ismaël (the forebears of the Arabs), and to Isaac and his son Jacob (the forebears of the Israelites). Fertility thus has a dual ontology: human duty and divine blessing. God approves and favors the man who creates many children, but also, it is the man with whom He is well-pleased to whom He grants a large progeny.

Populationism was an obvious imperative for this broad mix of tribes threatened (and often vanquished) by powerful neighbors. Being unmarried was an unthinkable state; the patriarchs' polygamy found justification in the need to increase their cumulative fertility; infecundity was among the worst of misfortunes. As a particularly striking and spectacular demonstration of His intervention in the story of humankind, God makes an infertile woman fertile.

The Bible has many verses, often in the form of aphorisms, with clear populationist overtones—"In the multitude of people is the king's honour, but in the want of people is the destruction of the prince" (Prov.14.28); "Children's children are the crown of old men" (Prov.17.6)—which would be formalized into shibboleths by 17th-century populationist–mercantilists like Bossuet.

The Old Testament also gives an account of three population counts done in Israel (Num.1, Num.26, and 2Sam.24) which, as well as their obvious purpose of measuring the nation's military and economic might, have a sacred nature whose ambiguity long prevented any census being taken in the Judaeo-Christian world. This is because although, like Moses before him (Num.1, Num.26), King David was ordered by God to number the people (2Sam.24.1),[3] he was conscious of committing a sin entailing harsh retribution. One possible interpretation of this paradox would be that knowing the size of the flock is the exclusive prerogative of the owner: the king is only the shepherd; God alone is the Master. Perhaps also the multitude of descendants promised by God to Abraham is beyond any attempt at measurement. It is accepted that the sta-

[3] Another later account of this episode attributes the initiating of the operation to Satan (1Chr.21, 1–27). The census is nonetheless an impious act.

tistics presented as the findings of these censuses are purely symbolic figures.

Early Christianity expresses no views on population. It is chiefly about ethical matters, without regard for the strictly demographic implications of its moral precepts. Christian populationism is therefore only a logical consequence of the Christian attitude toward life, the individual, and love.

Respect for life, the prospect of resurrection and eternal happiness, trust in Providence, and condemnation of material gain are all implicit encouragements for individuals to reproduce. Christian morality is opposed to polygamy, divorce, abortion, and infanticide. While extolling the virtues of indissoluble, monogamist marriage, the apostle Paul saw the unmarried state and chastity as morally superior, but he was concerned with a small elite, not the population as a whole.

2. Islam

For Muslim believers, the Koran and the example of the Prophet are the sources of precepts that must be followed and are not open to interpretation. Islamic populationism has the same expansionist overtones as biblical populationism. Children are repeatedly described as a blessing from Allah and many precepts encourage men to marry and reproduce. Marriage is the normal state of the believer; to remain voluntarily unmarried is offensive. Early marriage is encouraged (the traditional Arab practice of prepubertal marriage is not prohibited), as is remarriage. Spouses are forbidden to live apart for long periods. Marital sexual intercourse is expressly praised. Traditional Arab polygamy is maintained, but now confined within strict limits: a man may not have more than four wives at once, and must treat them equally.

The natalist hue of these promarriage and -reproduction precepts is somewhat qualified by other tenets that specify a large number of periods of sexual abstinence (during menstruation, after widowhood, during periods of fasting and pilgrimage). Protracted breast feeding is strongly urged. Repudiation of a wife is easily done; a wife can also obtain a divorce, but with great difficulty.

The issue of contraception is not clearly addressed by the holy writings. It is therefore a field in which different schools have put forward different theories. For popular religion, permeated with pre-Islamic superstitions, contraception is impious. Infanticide is expressly proscribed, but abortion is not mentioned and is therefore also the subject of varied doctrinal positions.

III. THE MIDDLE AGES AND THE RENAISSANCE

1. The Fathers of the Church. The Reformation

In their treatises on morality and the documents of councils convened to condemn various heresies (Manicheism, Gnosticism), theologians from the early centuries AD up to the Middle Ages expounded on certain aspects of Christianity that merely reinforced its populationist hue: humankind must populate the Earth and Heaven, so fertility is the primary purpose of marriage; any sexual activity other than for reproduction is unacceptable, nonmarital sexual intercourse is unlawful, and abortion equals infanticide. The medieval Church exhorted monks and nuns to chastity while propounding fertility for married couples; it imposed celibacy on priests and made dissolution of marriage almost impossible. Most Christian writers followed St. Paul[4] and St. Augustine in believing that the ideal state for human beings is pure celibacy; the alternative for those unable to achieve or not called to it is fertility within marriage.

Saint Thomas Aquinas (13th century), perhaps the only doctor of the church to have thought in specifically demographic terms, was a firm advocate of a large and growing population as the foundation of the glory and prosperity of terrestrial kingdoms.

The Reformation, while not calling biblical populationism into question, did relax some of the unyielding rules of Catholic morality: divorce and remarriage were accepted subject to conditions, reproduction was not the main purpose of marital relations, and in the 20th century, contraception would come to be regarded as morally acceptable between spouses not acting out of pure self-interest.

2. Ibn Khaldoun

The Arab historian and statesman Ibn Khaldoun (1332–1406) conceived the idea of writing a vast universal history, starting with a methodological introduction: *Al Muqaddima* ("Prolegomena" or "Introduction," 1968). It is in this first volume of his major opus that he develops a cyclical theory of history, which he calls the "science of human sociability" and is the first tentative nontheological sociology. The dialectical relationship between wealth and population, taxation and psychology, plays a key role in it.

[4] See in particular the First Epistle to the Corinthians (1Cor.6, 13–20, 7, 1–9 and 7, 25–27) and the First Epistle to the Thessalonians (1Thes.4, 1–5).

Wealth and population are interdependent, but the substance of their relationship depends on the sociopolitical context. In the earliest stages of a civilization (settlement), the population grows. With increasing population density, division of labor lightens the burden on all, bringing a rising standard of living and increased efficiency of political, military, and economic institutions. The leaders follow the Koran, so taxation is minimal. Farmers therefore produce great wealth because they keep the profit of their labor. The social climate is naturally optimistic and highly conducive to rapid population growth. Economic and population growth enrich the State; governments are caught in the trap of excess and avarice and raise taxes. This is the start of the downturn in the cycle. Rising taxation gradually erodes producers' interest in working, and production falters, prompting the leaders to further raise taxes in order to maintain revenues. The population feels oppressed, and its original optimism fades into disenchantment and rebellion, which are not conducive to reproduction. Fertility drops while mortality and emigration are temporarily exacerbated by civil war, which brings the nation to its knees. The field is now open for a new and uncorrupt people to embark on a new cycle where growth will again be followed by the decline of civilization, wealth, and population.

IV. MERCANTILISTS AND PHYSIOCRATS

The implicit populationism of church doctrine seems not to have been called into question in the pre-Renaissance Christian world. But, with the Renaissance, a rediscovery of the thinkers of the ancient world, the development of centralized states and state-to-state relations, the discovery of the New World, the birth of capitalism, and many other innovations prompted intellectuals to revisit the dominant theories in all fields. By overlaying political and economic considerations onto the moral precepts, traditional populationism would then be given a more explicit and voluntaristic gloss by some and would be challenged by others. The old biblical aphorism that the glory and strength of the king are made by the number of his subjects became formal doctrine and would go virtually unchallenged for three centuries.

1. Mercantilist Populationism (16th–18th Centuries)

For theorists of monarchical absolutism, like Niccolò Machiavelli (1469–1527) (*Florentine Histories*, 1520–1526), the purpose of the political and social organization of a nation, the supreme goal of government of a people, is the power and wealth of the State (incarnated in the person of the monarch). Any individual concern for welfare comes second to this ideal of national greatness, which means that it is often sacrificed to it with glib fatalism. The population is an essential factor of the leader's political and military might: his advantage therefore lies in the population being large, and he must actively promote its growth.

The mercantilists developed additional, relatively new populationist arguments out of their economic theories. They argued that a nation's wealth lay in the quantity of gold and silver it possesses, and anything that draws these precious metals into the royal coffers is good for the State. The discovery and systematic conquest of America having brought a sudden influx of gold and silver into the Iberian kingdoms, the rest of Europe feverishly sought ways of siphoning off some of this windfall. International trade became the favored means of accumulating wealth. Each country was to produce the agricultural foodstuffs and industrial products necessary for the subsistence of its inhabitants as well as a surplus of manufactured goods to be sold at the highest possible price abroad.[5] Why this emphasis on manufactured goods? Because, on the international market, they are far more advantageous than foodstuffs: industrial activity is much more profitable than agricultural activity, costs less, and brings greater returns. Some even went so far as to see agriculture as being governed by the law of diminishing returns, while industrial returns increase thanks to the division of labor.

Where does population fit into this mechanism? A larger population contains more individuals who are not needed for agriculture and can therefore be employed in manufacturing. Population growth enables the development of an export industry, which is the only way to increase the wealth of the State. If wealth is gold, the way to get it is through population growth. This is what lies behind Jean Bodin's exclamation (in *Les Six Livres de la République* [Six Books of the Commonwealth], 1576) that "there is no wealth nor strength except in men." The population policy propounded by mercantilists was therefore first and foremost a pro-marriage, -large families, -immigration (preferably of manufacturing workers), and anti-emigration (except to populate the colonies).

[5] Some of these exports of manufactured goods may be used to cover imports of subsistence goods if the national production does not suffice. But the balance of trade, in gold, must remain positive (Cantillon, 1755).

The leading theorists of mercantilism are Jean Bodin (1530–1596) (*Les Six Livres de la République*, 1576), Barthélemy de Laffemas[6] (1545–1612) and Antoine de Montchrestien (1575–1621) (*Traité de l'économie politique*, 1616). Broadly, they believe the earth to be non-depletable, France underpopulated, and that a larger and better managed population could substantially enrich the king and the kingdom. Their population policy is promarriage and for controlled migration, and their economic policy focused on food self-sufficiency and the export of high added value manufactured goods. There are only benefits to population growth ("one should never fear there being a surfeit of subjects or citizens", says Jean Bodin in *Les Six Livres de la République*, 1576). At worst, should the nation's farmers be unable to supply sufficient foodstuffs, the State can always import food using the added wealth gained from the increased population. Montchrestien adds a significant nuance to classical mercantilist doctrine: the source of wealth is not just the population, but the population at work (*Traicté de l'oéconomie politique*, 1616), from which stemmed his preoccupation with an employment policy and advocacy for the restoration of the tradition of census taking (abandoned in Europe after the fall of the Roman Empire) to identify the shirkers and scroungers (those that cannot be put to work will be removed from the kingdom).

Colbertism is surely the most perfected form of demo-economic policy inspired by mercantilism. Colbert, Louis XIV's principal minister during the first part of his personal rule from 1661 to 1683, went to extraordinary lengths to foster population growth, industrialization, and exports, fearing neither to overturn customs and privileges, nor to oppress the populace. Notable among his many initiatives was the 1666 edict encouraging marriage and reproduction by granting tax exemptions to couples who married before the age of 20 and to families with at least 10 legitimate children. This statute was only rarely and poorly applied, and had to be repealed in 1683. Colbert's bid to drive out religious celibacy by limiting the numbers of priests, monks, and nuns, and raising the minimum age of female noviceship, had little more success. He encouraged immigration and banned emigration, except for settlement in the colonies (Canada). To increase the volume of work, he cut the number of public holidays and set up workshops for sturdy beggars. At the same time as reorganizing the navy and the colonies to increase French influence on the channels of international trade, he laid the costly foundations of a mainly export-oriented luxury goods industry manufacturing tapestries, silk and other costly fabrics, fine glassware, watches and clocks, and more. To maximize the export selling prices of these products, he used the prestige of Louis XIV and his court to constantly launch new fashions in clothing (ribbons, lace, accessories), which Europe's other courts would rush to imitate from suppliers in Lyons, Lille, and Paris. The well-oiled mercantilist machine was running smoothly and population policy was a big part of it.

To Colbert and his interest in population we also owe the regular publication of vital records in Paris from 1670 on, a failed attempt at a national statistical survey, and the testing out in Canada of the systematic collection of population data.

The very end of the 17th century witnessed the emergence of what may be called critical mercantilism, propounded by humanist philosophers (Fénelon (1651–1715),[7] Vauban (1633–1707),[8] and Boisguilbert (1646–1714)[9]) who agreed with the broad theory, but minus the totalitarian excesses that absolutism and Colbertism had produced. They believed that if the king's glory derived from population numbers, the misery of the populace could only tarnish it. Their concern for the population's standard of living led them to a major rethinking of orthodox mercantilism. They sought to restore the status of farming, unfairly neglected in favor of industry, to add morality to and lighten the tax burden, and to liberalize trade and the movement of goods to and from the home market. From there, they implicitly came to a new definition of national wealth: no longer gold reserves, but a well-fed, gainfully employed population.

In England and Germany, mercantilism coexisted with antipopulationist arguments informed by the fear of overpopulation, too varied to form a uniform school of thought. Thomas More (1478–1535) (*Utopia*, 1516) harked right back to Plato's stationarity and authoritarian communism, while the deeply pessimistic Thomas Hobbes (1588–1679) (*Leviathan*, 1651) doubted that emigration to the colonies would suffice to drain off the surplus population.

Few mercantilists accepted the possibility of a limit to the volumes of subsistence that national agriculture or international trade could supply, or the obvious ceiling that would set on population growth. The most highly developed such theory is that of the Italian Giovanni Botero (1540–1617) whose *Delle cause della grandezza e magnificenza delle città* (1593, repub. 1930)

postulated that the life of humankind depends on two factors: the *virtus generativa*, which is humankind's propensity to reproduce, and the *virtus nutritiva*, which is the ability to produce subsistence. Botero's axiom is that the former is naturally more expansive than the latter: humankind's tendency is always to increase to the maximum allowed by the available means of subsistence. Point-in-time food stocks set a maximum level to absolute population size. Once the population rises above this maximum, a range of ills (famine, plague, war) will drain off the surplus. A state that wishes to increase its population must therefore first work to increase its food production; an increase in population will automatically follow.

After the death of Louis XIV, theorists taking stock of his disastrous rule took on a gloomier tone. For some, the mercantilist machine created its own problems, and the glimmering fears of overpopulation, whose harsh control by famine and wars could be more humanely achieved by emigration to the colonies. For others, population growth certainly added to the state's wealth, but its attendant excesses, vice, urbanization, and capitalization were all adverse to reproduction.

2. The Physiocrats

A breakaway theorist from the mercantilist school, Richard Cantillon (1680–1733), set the foundations for a radical new philosophy—physiocracy—which was only to be fully developed during the latter half of the 18th century. Cantillon (*Essai sur la nature du commerce en général*, 1755) reasoned that the real source of wealth was land (through labor). Landowners hold the reins of the economy, labor, and the population. The economic allocation they give to their lands (agriculture, stock farming, or amenity) dictates the volume of subsistence produced, labor demand, and hence maximum potential population growth. Cantillon also points out that, for a given quantity of subsistence, population size is determined by lifestyle: a population accustomed to excess cannot increase as much as a frugal population.

The principle behind all physiocratic theories is that of a fundamentally good and balanced natural order. Governing consists in enforcing that natural order and restoring it when it is upset. The physiocrats are therefore diametrically opposed to the economic interventionism advocated and practiced by the mercantilists. The real wealth of a nation is not its gold reserves or its population, but its land and agriculture. Only the land generates wealth, producing more than goes into it (François Quesnay's [1694–1774] "net product"; the articles "Fermiers" and "Grains" in the *Encyclopédie*, 1756–1757; *Tableau économique*, 1758); all other activities merely adapt the goods extracted from the land, adding nothing to national wealth. Logically, therefore, the nation's happiness lies in a fertile land, well-exploited by a sufficient population respectful of the natural order.

Population growth is no longer the absolute priority that it was for the mercantilists. It is desirable only insofar as the land is underused. And there is never any need for a specific policy to promote population growth, which occurs spontaneously to the full measure permitted by the means of subsistence available: "The only limits to [population] increase are those set by subsistence" (Quesnay, "Fermiers," *L'Encyclopédie*, 1756); "There are always as many people as can be fed" (Mirabeau, *L'Ami des hommes*, 1756). The best-fit criterion between population and subsistence is a decent standard of living. Unlike classical mercantilists, the physiocrats saw no benefits to a large but impoverished population. The aim of government must be not population increase but increased agricultural output, which will generate population growth and raise living standards. Physiocratic policy is therefore an agricultural policy to develop a prosperous farming community and promote scientific agriculture. Victor de Mirabeau[10] (*L'Ami des hommes*, 1756) even professes a belief in limitless agricultural progress that will not only enable but automatically produce population growth with no drawbacks. But he also believed that the population of Louis XV's France was declining, for which he blamed the architects of royal despotism, unfair taxation, luxury, and underexploitation of the land. François Quesnay reasoned far more pessimistically that the population inevitably tends to increase beyond what the available means of subsistence can support, so that the wage will always be minimal and poverty inevitable. The legislature's main concern, therefore, should be the populace's quality of life, not its numbers.

The controversy over depopulation of the known world sparked off around 1720 by Charles de Montesquieu (1689–1755)[11] (*Lettres persanes*, 1721) and Robert Wallace (1694–1771)[12] would impel many European intellectuals to propound theories on the origins of population growth that were more conviction- than science-based. Has the world or European population increased or decreased since ancient times? Is the population of a given country increasing or decreasing? With no population statistics at hand, sub-

[10] Marquis Victor Riquetti de Mirabeau (1715–1789) was the father of the powerful revolutionary orator.

[12] See in particular his *Dissertation on the numbers of mankind* (Reed, 1969).

stantiation for views was sought from any useful source, and many drew on an implicit axiom that the population increases under sound government and declines under despotism.

Victor de Mirabeau's belief in the limitless possibilities of progress—not just in agricultural science, but science in general—to increase subsistence without restriction or maximum finds echoes in William Godwin (1756–1836) (*An Enquiry Concerning Political Justice*, 1793) and Marie-Jean-Antoine de Condorcet (1743–1794) (*Esquisse d'un tableau historique des progrès de l'esprit humain*, 1795), who were flatly opposed by Thomas Robert Malthus (*An Essay on the Principle of Population*, 1798). More realistically, Jean-Jacques Rousseau (1712–1778) (*Social Contract*, 1762) believed that there was a right relation to be kept between size of territory and population size (Book II, Chap. 10), but remained in favor of some population growth, seeing depopulation as a sure sign of degenerated government (Book III, Chap. 10).

3. Adam Smith

The extraordinary demo-economic rise of North America inspired the father of free-market capitalism, Adam Smith (1723–1790), to evolve a theory that pushes the mechanistic nature of population growth to the limit. Just as the production of goods is demand-driven, population changes are labor-demand-driven, with wages interfacing between supply and demand. A labor shortage that pushes up wages will have a knock-on effect on marriage and fertility rates, "the demand for men [. . .]necessarily regulates the production of men" (*An inquiry into the nature and causes of the wealth of nations*, 1776). Malthus was to adopt much of this approach.

V. THE FIRST DEMOGRAPHERS

Demography dates from 1662. Its founder, John Graunt (1620–1674) (Vilquin, 1976), and its earliest theorists (e.g., William Petty [1623–1687],[13] Edmund Halley [1656–1742],[14] Antoine Deparcieux [1703–1768],[15] Gregory King [1648–1712],[16] Louis Messance [1734–1796],[17] Jean-Baptiste Moheau [1745–1794],[18] Johann-Peter Süssmilch [1707–1767][19]) strove mainly to observe and describe the population, its composition and changes. Their ultimate goal was to uncover laws governing population akin to those being discovered in the natural sciences. And they did indeed highlight many statistical laws (sex ratio at birth, age- and cause-specific mortality, the relative invariability of the crude birth and death rates, etc.), which produced astonishment from within a wide audience. They argued that the scientific results of demography were essential to inform government choices and policy, but seldom ventured further into political or economic theorizing. Many gave the backing of science to the theory of geometric progression: the natural tendency of humankind is to multiply by geometric progression, but obstacles of many kinds act to make it grow much less quickly in reality. Johann Peter Süssmilch (*The Divine Order*, 1741) sees it as not only a natural but a divine law (as the title of his treatise clearly indicates) which it would be blasphemous to oppose; population growth is therefore inherently good since it is "ordained" by Providence; also, adds Süssmilch to still his own objections, there is plenty of room on the Earth.

Over time, the development, systematic production, and publication of population statistics, and advances in analyzing them, meant that caveats had to be added to population theories, which were now at risk of being scientifically disproved.

VI. THOMAS ROBERT MALTHUS

Thomas Robert Malthus had many forebears—he did not originate his theory. But so glaring a light did he shed on the law of population as to blind his ardent followers and fiercest detractors alike, setting off a furious debate that still rolls on today. Population cannot now be addressed without referring to Malthus and taking a stand on his thought. Sadly, Malthus's thinking, clumsily propounded by self-styled Malthusians, has also continually been deformed by rigid theorists more concerned with castigation than dispassionate examination. Emphatic refutations of the Malthusian system by some big names have been accepted as authoritative, and history's belated attempts to right the worst wrongs done to Malthus and his thought have not yet made sufficient inroads.

1. Thomas Robert Malthus (1766–1834), A Noble Intellectual

Born in 1766 into a family steeped in the utopian ideals that were the seeds of the French Revolution, Thomas Robert Malthus became a fellow of Cambridge University and a country parson after a broadly based education inspired by the educational theories of Jean-Jacques Rousseau. He was a man of nobility and rectitude, esteemed and liked. He had a reputation for wisdom without severity. Initially fired by his father's enthusiasm for all the social, reforming, and revolutionary ideas converging from all sides, both in France in the wake of the Revolution and in England then in the throes of turmoil, he nevertheless sought to distance himself from the dangerous optimism of some ideal society theories with the publication in 1798 of a pamphlet which caused a furor—his *Essay on the Principle of Population*. This was a bare-knuckle demonstration of the misguided theories held by Godwin, Condorcet, and other egalitarians or pre-Socialists on the causes of poverty and hence the means of eradicating it. Spurred on by the unexpected success of his pamphlet, he wrote a second edition (1803), which was both more developed and especially more meticulously documented with the collected "evidence" gleaned from his lectures and travels. From 1804 to his death (1834), he was a professor of history and political economy at the East India Company College, publishing, in addition to four new editions of his *Essay*, other significant works that rank him among the founders of the science of economics. He married late in life, at age 38, had three children, and seems to have lived his life by the virtues he preached.

2. Egalitarian Utopias

While almost all the political philosophies of previous centuries had been dominated by a single obsession (how to enrich the State or the Ruler), thinkers in the latter half of the 18th century were increasingly concerned with an issue of a very different order: how to stem the sharp rise in the number of poor. But rising poverty was nothing new. Renaissance England had witnessed an economic change that enriched the few by condemning the many to poverty: the land enclosures, which turned ploughed land to pasture, replaced corn by wool, cereal-growing by sheep-rearing. Sheep-farming is much less labor-intensive than crop-farming, forcing tens of thousands of displaced peasants to flee the land to huddle in poverty-stricken masses on the outskirts of towns. In 1516, Thomas More, in his *Utopia*, accused sheep of devouring men! As the canker continued to spread, Queen Elizabeth I revived a primitive form of social assistance in 1601–the poor laws. This body of legislation made each parish responsible for feeding paupers residing within their boundaries. Most English parishes discharged this obligation by levying a tax on ratepayers to provide bread to the unemployed and vagrants. Two centuries later, the poor laws were generally criticized for failing to prevent the unrelenting spread of poverty, despite the increasing cost burden they represented. The social visibility of poverty had reached unacceptable levels, and the remedies were clearly not working, which made poverty a universal subject of concern to philosophers and economists in the closing quarter of the 18th century.

Theories abounded, but some were keener to lay blame than try to understand why, while others preferred simply to dismiss something that they could not realistically conceive of. It was this latter attitude that shocked Thomas Malthus, and the subtitle of his *Essay* (". . . with remarks on the speculations of Mr. Godwin, M. Condorcet and other writers") is a thinly veiled statement of intent to lay bare the errors of Godwin, Condorcet, and others.

For these noble souls, poverty was all about the distribution of wealth. In an inegalitarian society, the arrogation of wealth for the benefit of the few is institutionally organized (in particular through ownership), plunging the many into abject poverty. Revolution will overturn these unfair institutions, at the same time sweeping away all obstacles to progress. With wealth then being fairly distributed, excess and poverty will be no more; also, humankind's biological and spiritual progress will lead it inexorably to an earthly paradise where the indefinite prolongation of human life will result in the diminishing and disappearance of the sexual instinct.

Poverty, thought Malthus, was too serious and acute a problem to be dealt with through such naive conjectures. And, refuting the theory of the indefinite perfectibility of mankind and society led him to develop his own explanation of poverty.

3. The "Principle of Population"

The centerpiece of his theory of poverty is encapsulated in a universal natural law, which many other writers (since renamed pre-Malthusians) had previously expounded, calling it even then the principle of population: the propensity of living species to multiply (driven by the instinct of reproduction) is at all times apt to exceed the Earth's capacity to produce the subsistence necessary to support that multiplication. The human species, like the animal species (a bold comparison for the time, which Darwin would draw on for support), is subjected by divine will to two forces pulling in opposite directions: the naturally powerful, fierce, and unreasoning instinct of reproduction is at variance with Nature's fundamental inability to produce means of subsistence at the same unchecked pace. The pattern of food production necessarily imposes its pace on population growth. The renowned geometric (of population) and arithmetic (of subsistence) progressions of increase that have elicited so much fruitless discussion are, as Malthus himself would point out, no more than rough depictions of the dizzying nature of the divergence between the two trends. He cites the example of the United States of America, a vast, wealthy, and clearly underpopulated country: its population doubles every 25 years, and even every 15 or 10 years in some regions. So long as neither space nor means of subsistence are lacking, therefore, the population naturally tends to increase in a geometric progression. Sooner or later, however, both space and means of subsistence will inevitably become scarce.

4. Misery, Its Causes and Remedies

The demands of the instinct of reproduction can be kept down to the level of food production possibilities in different ways, all of which will lead to the same necessary and inevitable result: that the Earth never has more than the number of inhabitants that it can feed. Animals—and, sadly, most humans—leave it to Nature to operate this check, and Nature has at its disposal only the grim means of ridding itself of the surplus of live-born individuals it lacks the means to feed.[20] Famines, epidemics, wars,[21] malnutrition, unhealthy living conditions, unemployment, and low wages,[22] all factors of premature death that Malthus refers to together as "positive checks," constitute misery. This is the first aspect of the thesis, the origin of misery. But a wide gulf separates Malthus's analysis from that of his detractors: the cause of misery lies not in human institutions that can be changed by revolution, but in a universal (divine) natural law that no revolution can change.

No living species can evade the principle of population, but misery—Nature's means of applying that law—is an inevitability only for animals. This is because Man's capacities for reason, self-assessment, and forethought give him other resources than to submit to Nature. He can take control of his life and replace the destructiveness of Nature (misery) with a preventive human strategy proper of ensuring that there are no surplus individuals condemned to an early death for want of subsistence; it is enough for them not to be born. Misery can be averted by rendering it redundant, that is, by replacing it with another way of keeping population commensurate with the means of subsistence: voluntary fertility control. All men have the choice of avoiding misery. They may (by default) be driven purely by reproductive instinct to produce more children than they can feed, or they may have only the number of children for whom they can decently provide, which, unless they are wealthy, will certainly lead to a smaller family size than in the former hypothesis. This is the second aspect of Malthusian theory: solving misery through the use of preventive checks.

As a Christian moralist, Malthus dismisses vice and acknowledges contraception as an effective but wrongful means of fertility control. All that remains, therefore, is marriage, but only after having acquired the means to support a family, remaining pure in the celibate state ("moral restraint").

The first way of applying this solution to the problem of misery in practice is to explain to those most patently in need of explanation—the poor—how their situation has come about: the natural mechanism of the principle of population and the false inevitability of the resulting misery; then to describe the solution to them, and urge and help them to choose wisely. For a liberal economist like Malthus, this is purely a policy of education, unsullied by restraint. No social or economic system (which he systematically reviews) offers any way of avoiding the choice between the preventive and destructive obstacles imposed by the principle of population.

[20] In the 1803 edition of his *Essay*, Thomas Malthus expressed this in the celebrated "Nature's feast" passage: "A man who is born into a world already possessed, if he cannot get subsistence from his parents on whom he has a just demand, and if the society do not want his labour, has no claim of right to the smallest portion of food, and, in fact, has no business to be where he is. At nature's mighty feast there is no vacant cover for him. She tells him to be gone, and will quickly execute her own orders, if he does not work upon the compassion of some of her guests. If these guests get up and make room for him, other intruders immediately appear demanding the same favour. The report of a provision for all that come, fills the hall with numerous claimants. The order and harmony of the feast is disturbed, the plenty that before reigned is changed into scarcity; and the happiness of the guests is destroyed by the spectacle of misery and dependence in every part of the hall, and by the clamorous importunity of those, who are justly enraged at not finding the provision which they had been taught to expect. The guests learn too late their error, in counter-acting those strict orders to all intruders, issued by the great mistress of the feast, who, wishing that all guests should have plenty, and knowing she could not provide for unlimited numbers, humanely refused to admit fresh comers when her table was already full." So great was the outcry caused by this passage that Malthus deleted it from later editions.

[21] Surplus consumers contending for too small quantities of space and food.

[22] Surplus demanders contending for an insufficient quantity of available jobs, and the jobs are allocated to those who accept the lowest wages.

5. Challenging False Solutions

If misery results from the principle of population, any putative solution of misery that does not go to the levers of that principle is unrealistic. Malthus systematically examines such various solutions as social revolution, public assistance, and private charity, and concludes that in every instance these are bogus remedies that in no way affect the conditions for application of the principle of population. They neither check the insensate drive of the instinct of reproduction, nor radically increase the productive capacity of the land, which are the only possible avenues to a real solution. A simple redistribution of existing wealth by whatever means changes neither the number of consumers, nor the quantity of subsistence available, nor the conditions in which both are produced. Justice and charity are lofty moral values, certainly, and Malthus in no way disavows them, but they can only alleviate specific misfortunes, solving the social problem of misery is beyond their ken. In the final analysis, palliating misery simply displaces it, replacing one set of poor by a larger number of new poor. Malthus's opposition to the poor laws of England is wholly consistent, therefore. Palliating the distresses of the poor allows them to reproduce without having the wherewithal to provide for their children, who will therefore increase the poor population. This Malthus summed up in a short phrase that set British society in uproar: "the poor laws create the poor which they maintain"! (*Essay*, 1798, p. 83).

6. Liberal Philanthropist or Cynical Reactionary?

The ease with which Malthus dismantled the false solutions outraged many who took their vengeance through smear campaigns, painting him as a cold and cynical reactionary. Although fundamentally an economic liberal, Malthus was no less fundamentally progressive. His foremost concern was to increase the standard of living for the whole population, and he was more than ready to compromise his economic liberalist principles so that the poor did not bear the brunt. He called for sweeping social reforms (democratization of education, medicine, savings, guaranteed minimum wage, etc.) to promote the rise of the poor up the social scale, in the belief that this would dispel the fatalism and resignation that stopped them from taking control of their own future.

Nonetheless, objectively speaking, Malthusianism relieves the governing and privileged classes from all responsibility for misery and its elimination, cutting the ground from under the feet of any revolutionary theorizing;[23] objectively, while ever people's standard of living is low, marriage and families are bourgeois privileges; it is also true that Malthus was an apologist for social inequality, which he saw as morally reprehensible but socially necessary as the only effective engine of human activity, work, and progress. His crusade against the putative right of the poor to be maintained at society's expense is little short of shameful. Much remains still to be said about the alarming repercussions of Malthusian theory.

VII. THE 19TH CENTURY–PRO- OR ANTI-MALTHUS

1. Malthusians and Neo-Malthusians

The very first Malthusians were naturally the bourgeoisie. Living handsomely on the profits generated by an unheeding, unquestioning capitalism, they arrogated wealth and power, right and respectability to themselves everywhere in Europe. Malthus providentially salved their consciences of any unease about the plight of the laboring classes. When French minister François Guizot made his celebrated "Make yourselves wealthy" speech[24] to the Chamber of Deputies (Lower House), the noble parliamentarians' ovation was given with no hidden agenda.

The 19th century saw the flowering of classical economic theories. All the writers in this vast movement were familiar with Malthus's *Essay* and, treating it as established scientific fact, drew arguments or at least inspiration from it on which to base and develop their views on the role of population in the mechanics of socioeconomic processes. Most were doomsayers who believed that the principle of population was an inescapable fact, and even sought to refine the case for it.

David Ricardo was a friend of Malthus, and a Malthusian: the "law of diminishing agricultural returns" (*On the Principles of Political Economy and Taxation*, 1817) reinforces the principle of population; wages act to regulate the population because, naturally settling at subsistence level, they embody the maximum means of subsistence to which the absolute size of population always necessarily adjusts. Many economists make the so-called wages fund theory a central article of faith: when the population increases, wages decrease, and wages can rise only if the population decreases.

[23] As was perfectly well understood by bourgeois governments and socialist purists, the former embracing Malthusianism as a fixed scientific truth, the latter showering insults on Malthus's head.

[24] Given on 1 March 1843.

John Stuart Mill (1806–1873) (*Principles of Political Economy*, 1848) also argued that the working population must restrict its numbers as the only means of achieving full employment with decent wages. From a given population density, any population growth brings the law of diminishing returns into operation and the standard of living falls. For Mill, the ideal tendency of the entire connection between volumes and prices (including population and wages) is toward a stable equilibrium.

Some argued that population was proportioned to capital stock, while others believed that capital accumulation and population growth were in competition. Jean-Baptiste Say (1762–1832) (*Catéchisme d'économie politique*, 1815) recommended "saving rather than procreating."

There was a broad consensus of liberal thought to reinforce the class theory element of Malthusianism. Malthus was cited as authoritative proof for the argument that the misery of the working classes was caused not by free-market institutions, but the ignorance and improvidence of workers, and that fertility regulation by the working classes would result in the elimination of misery without calling the principles of economic liberalism into question.

Jean Charles Léonard Sismonde de Sismondi (1773–1842) (*Nouveaux principes d'économie politique*, 1819) stood apart from this trend as a self-professed Malthusian who was opposed to economic liberalism. He believed that self-interested capitalism bore some responsibility for the emergence and spread of misery, and advocated legislative protection of workers against abuse. He was a somewhat unorthodox Malthusian, arguing that misery made the poor improvident and prompted them to reckless reproduction; foresight therefore had to be inculcated in them (education, saving), which would lead them to regulate their fertility.

This era also saw the development of neo-Malthusianism, chiefly through those who subscribed to Malthus's view that the poor must limit their family size to improve their lot, but without his moral scruples, believing that all or almost all means were justified to reduce fertility. More activists than theorists, they ran information campaigns to persuade the working class of the benefits of contraception. They included luminaries of the non-Marxist far left, feminists, and anarchists calling for a "womb strike" to choke off capitalism by depriving it of the "labour fodder, cannon fodder, and pleasure fodder" (Chapelin, cited by Bureau, 1920) which were its lifeblood! In England and France, these movements encountered draconian suppression by law and justice.

While English and French socialists were on the whole fiercely anti-Malthusian, some German socialists like Adolph Wagner (1835–1917) (*Foundations of Political Economy*, 1876) believed that regulation of working-class fertility was essential. But, believing the education in individualism and providence counseled by Malthus to be ineffective, they argued for State-imposed restriction of fertility, advocating measures, some of which foreshadowed the worst perversities of Hitlerism, like the forced castration of poor male children.

As if to validate Malthus, for whom the United States was the exemplar of a country where the principle of population had not yet taken effect, Malthusianism would not find a foothold in North America before the 20th century.

2. The Anti-Malthusians

On the fringes of liberal capitalism which had embraced Malthus's views as a revelation, some optimistic economists, like Frédéric Bastiat (1801–1850) *Harmonies économiques*, 1850), argued that the opportunities brought by industrialization and technological progress (division of labor, productivity growth) disproved Malthusianism and held out the prospect that subsistence would increase consequent on the rate (exaggerated by Malthus) of population growth.

The Church shared that optimism and overlaid it with theological arguments to refute Malthusianism, which it argued denied the affirmation of Holy Writ that the multiplication of living things, and mankind in particular, was a good thing and God's will (Genesis). Moreover, it was unacceptable for some men to be declared surplus and so eliminated (or prevented from being born). Malthusianism was a self-seeking and blasphemous theory. Society must strive to increase subsistence so that any nascent human being may come into life.

Following William Godwin, vehemently refuted by Malthus, the early socialists argued that misery was caused by the organization and functioning of society. Standing chronologically between Malthus and Marx, they were more concerned with repudiating what they saw as the heinous principle of population than constructing serious foundations for their own explanation and solution for misery.

Very broadly, the pre-Marxian socialists challenged the idea that the working class were to blame for poverty-creating overpopulation, and repudiated a theory that sought to justify the preservation of existing social structures with their glaring injustices.

Inequality of resource allocation, regardless of absolute population size, was what produced misery among some of the populace, and created a false impression of overpopulation. Some went further to argue that, were the working classes to follow Malthus's counsel and limit their family size, then far from improving their standard of living, social inequalities would actually widen, as the wealthy would arrogate to themselves all the benefits of the demographic slowdown.

The most utopian argued simply that an egalitarian, collectivist, or socialist society would spontaneously generate regulating mechanisms which would prevent population growth from outstripping the increase in subsistence (Charles Fourier, 1772–1837) (*Le nouveau monde industriel*, 1829). Pierre-Joseph Proudhon (1809–1865) (*Système des contradictions économiques*, 1846) ("There is only one man too many on Earth: Mr Malthus!") and Louis Blanc (1811–1882) (*L'Organisation du travail*, 1839) turn Malthus's argument on its head: misery causes overpopulation; when their standards of living rise, the working class will become provident and limit their fertility. They cited anecdotal evidence that the wealthy limited their family sizes to maintain their standard of living, while the working class living on subsistence level had nothing to lose or gain from an inegalitarian system.

Karl Marx (*Das Kapital*, 1867, Vol. 1) would draw together and give substance to the disparate arguments of the earliest socialists, without thereby clarifying the role of demographic variables in the socialist economy and society. He refuted the idea of a principle of population discrete from the economic context, arguing for a law of population peculiar to each society, and more specifically, to each mode of production. The misery of the working class was a necessary consequence of the capitalist mode of production.

The capital accumulated by individual capitalists comprises both constant (buildings, machinery, intermediate goods) and variable capital (stock of money exchanged as wages for the labor of workers). One effect of competition between individual capitalists is the invariable tendency for the constant to increase much more than the variable capital. Like capital, production increases, and so the economy should be able to satisfy the needs of an increased population. But the individual capitalist is coldly calculating and always more inclined toward labor-reducing investments that consign to unemployment workers who would otherwise have been employed in accumulating more capital. This is why Marx talks of a "relative surplus-population" (Book 1, Chap. 25, Sect. 3). In this way, an "industrial reserve army" (ibid) is formed, comprising not only workers unable to find work and those thrown out of work by mechanization, but also a whole range of other laborers without stable jobs, farm laborers ready to leave the land, and all society's rejects—(widows, orphans, the sickly, etc.).

This mass of unemployed labor is not only a by-product, but also an essential instrument of the capitalist mode of production; from it, individual capitalists source and return the labor they need, and consign their supernumerary labor according to the fluctuations in demand. The unemployed also press down on the wage demands of the active labor force, ensuring that rising wages do not undermine profit rates.

However, while Marx carries out a searching critique of the law of population of the capitalist mode of production, he is extremely noncommittal on the law of population in a socialist system, simply asserting that as private ownership of the means of production disappears, so too will the mechanism of relative surplus-population. His ostensible argument is that rising standards of living in an egalitarian society will reduce natality, but little more; Marx offers no theory of population. He does not consider the problem of population growth relative to the means of subsistence or even production; he analyzes only one aspect of it—relative surplus-population—but seems unable to carry this partial analysis over into the broader problem.

Ill-equipped with the bases of theory on this by its founder, Marxism can only signal its implacable opposition to Malthusianism by attacking it for objective complicity with bourgeois privilege and professing a dogmatic populationism, largely founded on a blind faith in progress, which, after the revolution, will no longer be held back by the private interests of capitalists and resource owners. Only Friedrich Engels, albeit taking a more optimistic view than Marx (socialist production would outstrip capitalist production), raised the possibility of an absolute surplus-population in a socialist society. But he believed in a socialist society's ability to carry out population no less than production planning, if need be.

Revisionist socialists accepted that contraception could bring immediate relief to the lot of the working population. But orthodox socialists argued that the poor should not yield to Malthus by limiting their family size, since he was merely an apologist for his own class and capitalism. Instead, they took refuge in Marxist theory, deferring the issue to the advent of socialism, when the problem would no longer arise since it was a problem specific to capitalism. Most claimed (but brought no proof) that socialism would admit steady population growth above that permitted by capitalism but far from the geometric progression of Malthus. They also rejected the law of diminishing returns as a Malthusian axiom espoused by classical economists.

Vladimir Ilyich Ulianov, popularly known as Lenin, took the Marxian view, describing neo-Malthusianism (*Pravda*, 16 June 1913) as typically "petty-bourgeois." Contraception and abortion are personal liberties, but strategically against the interests of the proletariat. This line of argument exerted a strong influence on socialist thought right up to the late 20th century.

VIII. MATHEMATICAL, BIOLOGICAL, AND SOCIOLOGICAL THEORIES

1. Logistic Growth

In about 1840, Adolphe Quetelet (1796–1874) who had met and corresponded with Malthus, thought to add the final touch to Malthusianism by making it a mathematical model. He tasked a young associate, the mathematician Pierre-François Verhulst, with formalizing a self-limiting geometric growth model. After a series of attempts, all unsatisfactory to Quetelet, Verhulst (1845, 1847) devised the "logistic function" as a common model of time-dependent population growth. The graph of this function takes the form of a sigmoid curve. After an initial phase of near-exponential growth, the population reaches its "normal" absolute size when all productive land is farmed; growth is continuous in time as long as new land can be put under crop, but slows more rapidly (proportional to the difference between current population and normal population) when it passes a point of inflection and approaches a horizontal asymptote, that is, a maximum absolute population size.

Rediscovered and popularized circa 1920 (Pearl and Reed, 1920), the logistic law has attracted increasing criticism for omitting too many key factors involved with population social and cultural development. Its explanatory capacity is of little value and its forecasting capacity highly unreliable. The few attempts to incorporate economic and psychological factors into logistic theory have been short-lived.

2. Biological Approaches

Herbert Spencer's (1852) biodemographic theory describes the antagonisms between the propensities of species to survive and to reproduce. He argued that development of the nervous system decreases the tendency to multiply in favor of self-maintenance. Fertility is inversely proportional to development of the organism. Accordingly, the least developed individuals will multiply, but being exposed to the principle of population, only the fittest will survive.

Francis Galton (1869) believed that differential fertility was present between races and social classes, and recommended that the process should be directed toward the development of a superior race.

Corrado Gini's (1934) cyclical theory assumes that the rising standard of living (among the higher social classes) diminishes reproductive energies. After World War II, Josué de Castro (1952) gave a similar theory a deceptive scientific veneer, which lasted only 20 years or so. He claimed that increasing protein intake in the diet led to sterility, while certain dietary deficiencies, by contrast, increased fecundability ("the poor are under-fed, but misery makes a fertile bed"), but no reliable scientific evidence was produced to give credence to these assertions.

3. Sociological Theories

Many sociologists have stressed the importance of population growth, especially increased population density, in the process of civilization, intellectual, economic, and social progress. For Emile Durkheim (1893), *inter alia*, population density is an essential driver of progress because it enables the division of labor. For Eugène Dupréel (1928), increasing density develops individuals' activity in all fields through the development of linkages between them; he also argues that a population that perceives itself as growing is imbued with optimism.

Another focus of concern for sociologists was to find an explanation for fertility decline in industrialized countries. Their many and varied theories involve growing individualism resulting from rising standards of living, women's economic activity, urbanization, rationalism, and so forth.

Arsène Dumont's (1890) theory of "social capillarity" argues that the desire for upward mobility leads to restriction of family size, since fertility is a financial burden that competes with other possible investments (see Chapter 92); the desire to secure higher social status for their children, moreover, will often impel parents to invest more in their education than in their number.

IX. OPTIMUM POPULATION

The basic idea underpinning the theory of the optimum is very simple: if a population can be considered as too small or too large, there must be an intermediate stage between underpopulation and overpopulation that is more balanced than these two extremes. Adolphe Landry (1934) saw the ultimate aim of demography as being to determine the theoretical conditions of this optimum and put them into practical terms for specific populations. The idea of an optimum is at least implicit in several older theories: the golden mean of China, Plato's static equilibrium, the optimum combination between population and subsistence or welfare theorized by Richard Cantillon and many others. But the concept of optimum population came under methodical study only from the 1920s onward.

Even the definition of an optimum raises controversial issues, for in fact it involves determining the main demographic characteristics (mainly absolute size) of a population that will maximize its happiness, the assumption being that happiness is not maximized where population is too high or too low. The crucial issue is, if not to define happiness, at least to select a reliable and preferably measurable indicator of it: longevity, individual income level, for example. Any change in one constituent of the definition of happiness will produce a shift in the optimum.

One source of this theory lies in the assertion of some classical economists that an increase in the absolute size of a population produces first an increase, then a decrease, in the return on its economic activities (Cannan, 1861–1935) (*Elementary Political Economy*, 1888). There is, therefore, an absolute size of population that will yield a maximum return on its activity. One objection to this line of argument is that there is probably a different optimum for the different activities of a population.

In economic terms, conjecturing a certain quantity of wealth produced by a certain quantity of population, for distribution among that population, the optimum may lead to conclusions with which its theorists themselves may be uncomfortable. By applying the laws of increasing and diminishing returns and the (average and marginal) productivity trends, it can be concluded that maximizing individual welfare depends on reducing the number of individuals who must share in the national wealth (where the wealth generated decreases more slowly than the population). But a new question arises (previously raised by Victor de Mirabeau, Jean Charles Sismondi, and others): is it better for a few to enjoy a very high level of welfare, or for a slightly lower level of welfare to be shared by a greater number? The economic optimum offers no answer to this question.

Optimum theory therefore leads to a dilemma: either a satisfactory definition of happiness is achieved through mostly nonmeasurable elements, for which no quantitative relation can be made with absolute population numbers and so no optimum absolute size can be calculated, or happiness is reduced to a quantifiable indicator, and that simplification unduly constrains the scope of the results. Some proponents of this theory have therefore accepted that between underpopulation and overpopulation—which can be defined—there lies a broad optimum area in which the choice of an optimum point is discretionary and depends on population- and time-specific, especially noneconomic, criteria to define that population's happiness.

Attempts to further refine the theory have been made with the concept of a dynamic optimum. Because the optimum is never achieved and constantly shifts with the continual changes in the context in which a population evolves, rather than matching absolute population size to a putatively fixed context, population development should be matched with the evolution in its environment. Although conceptually more pleasing, this new theory of the optimum resolves none of the technical contradictions of its predecessor: its key constituents are and remain unquantifiable; the optimum rate of change can no more be determined than the optimum absolute size.

Alfred Sauvy (1963) put an interesting gloss on the definition of the optimum: it is the absolute size of population that best permits achievement of the self-appointed objectives of a given society, from which a wide range of optima can be defined, linked to the various possible societal objectives: geopolitical supremacy (optimum power), population living standards (optimum welfare), economic efficiency, elimination of poverty, economic self-sufficiency, attainment of a philosophical ideal, and so on. Alfred Sauvy also sought to bring into the theory previously neglected elements like the linkages between the growth and changes in the structure of a population (his marked preference was for population growth from what he regarded as the all-around beneficial effects of the resulting rejuvenation of the population).

X. DEMOGRAPHIC TRANSITION

Population thought in the latter half of the 20th century was dominated by the theory of demographic transition. This theory, whose raw makings predate World War II (Landry, 1934; Thompson, 1929), grew out of the observation that all industrialized countries had, over approximately the last two centuries, followed the same demo-economic development from a starting stage (agrarian society) to an end stage (industrial society). As this trend seemed to be independent of the physical, economic, and political characteristics of the populations concerned, it was hard to resist the beguiling temptation to develop it into a universally applicable theoretical model, particularly so for the comforting answers it appeared to bring to the huge and distressing question mark raised by the demographic future of the Third World, and hence the planet.

Adolphe Landry (1934) divided time-dependent population change into three phases or "demographic regimes." In the primitive regime, the pressure of subsistence (or, more generally, the economy) on the population affected only mortality, not fertility. Nature was left to regulate the population by taking off the excess numbers. Through this process of "natural" adjustment, the population always tends toward the maximum supportable by available subsistence. Both fertility and mortality are very high. The absolute size of this population experiences very moderate long-term growth that is frequently and suddenly reduced by crises of excess mortality (epidemics, wars, etc.).

In the intermediate regime, scientific progress gradually improves mortality, while economic progress brings the population a standard of living that it aspires to maintain or further improve. This calculation leads to a measure of fertility regulation (initially through postponed marriage). The third stage, or contemporary regime, brings a sharp drop in natality, not just as a result of individual economic motives; this, said Landry, disproved the idea of a universal law.

Various later authors produced classifications somewhat different from that of Adolphe Landry, but the broad pattern remains unchanged, focusing chiefly on time-dependent sequences of fertility and mortality trends.

There are two aspects to the transition phenomenon. First, it is a transition from equally high mortality and natality to equally low mortality and natality. Between these two, spectacular economic progress brings major changes in the population whereby mortality and fertility are reduced by different and independent mechanisms. Second, there is a time lag between these two downturns, and it is the scale of that lag that determines the pace of transition, since it dictates the trend in the population growth rate. In most of the historical situations for which the theory tries to account, mortality decline has preceded fertility decline, such that transition has commenced with a relatively spectacular population growth and ended with population stationarity or even decline.

Following so many others, this theory was seized on as offering a universal model, and used in particular to predict the demographic future of the Third World (having recognized that its "demographic revolution" was the effect of mortality decline, while fertility remained very high). Its proponents therefore naturally looked closely for the signs of the onset of fertility decline. In some cases, feeling it to be too long delayed, they forced it in order to give credence to a theory that they deemed not only scientifically right but also politically expedient.

At the same time, the theory was attacked by demographers and historians as an over-simplification of the real and often quite different population processes of different industrialized countries. Their conclusion was that its lack of general value in describing the past applied equally to forecasting the future. They also stressed that the onset of transition in the Third World today is taking place in a radically different context from that of the onset of Europe's own transition at the end of the 18th century.

One major weakness of this theory is that it merely describes the course of a phenomenon but not its mechanisms, the factors involved, or the cause–effect relationships. The search for a theory to explain fertility decline is probably key to a renewed impetus for transition theory.

XI. MAJOR CONTEMPORARY DEBATES

At this close remove, a detailed review of the ferment of 20th century thought on population issues is clearly not possible. Interest in population issues will obviously be increasingly acute and widespread at a time in history of utterly unprecedented population events and situations: wars that wrought the greatest carnage ever, the largest scale genocide, the Third World population boom, the most coercive population policies, the inexplicable inconsistencies and collapse of fertility in wealthy countries, and more. The final quarter of the 20th century saw the average annual growth rate of the world population reach and exceed its historical peak. Scientists and politicians fear unbridled growth in the total numbers of humankind during most of the 21st century, which will be very unequally distributed between rival worlds. Population awareness is more than ever global, and population thought arguably more discrete than ever. The scale and pace of the demo-geopolitical upheavals in progress are fertile ground for the resurgence of theories of every kind.

Demographic load remains very much part of the world political agenda, keeping nationalist populationism very much alive.[25] The arguments propounded

[25] Michel Debré, French Prime Minister from 1959 to 1962, is said to have dreamed of a "France of 100 million people."

for it are varied: renewed fertility efforts, possibly combined with selective immigration, to prevent white Western Christian civilization from becoming a numerical minority, to ensure the survival of a language or a culture, to balance and outweigh others. The recurrent theme of improving fertility often cloaks fear of immigration and its social and cultural effects. In some cases, the exclusionary and racist overtones are clear: increasing the number of births so that society's needs do not have to be met from immigration, selecting only prospective immigrants that match the host country profile, driving out foreigners that cleave to their cultural identity, cleansing the nation.

One of the most hotly discussed topics of recent years among population theories is that of population and development (Chapter 86). The interaction between population growth and economic development is widely acknowledged as self-evident, but theories as to the meaning and nature of this relationship are irreconcilable and all the more strenuously argued (in particular at the big United Nations conferences: Bucharest, 1974; Mexico City, 1984; Cairo, 1994) where the stakes run into the billions of dollars! The wealthy who see population growth consuming the bulk of the crumbs they spare for the economic development of the Third World take comfort in the belief that funding family planning programs is much more effective and profitable than lending assistance for economic development; while the poor, who see themselves trapped in inescapable economic inferiority, feel that only an economic takeoff will help check population growth.

The industrialized world is engaged in a different, internal debate on population aging. The question is, in order to avert the collapse of pension and social security systems in the meantime, should fertility be encouraged to increase the contributor base for when the number of beneficiaries increases, or should the way the systems work be adjusted to changes in the shape of population pyramids?

It is also in wealthy societies that an almost total schism has silently come about between the sexual behaviors of couples and individuals and the codes of sexual morality propounded by the great religions, mainly Catholicism. The Roman Catholic Church, with what is often described as obdurate consistency, has regularly renewed its prohibitions on contraception (with the exception of "natural" forms of birth control), abortion, remarriage after divorce, and euthanasia (see, *inter alia*, Pope Paul VI's encyclical *Humanae Vitae*, published in 1968). But no more in the 20th century than in the 1st has it expressly linked its moral injunctions to demographic issues. In the debate on population and development, it argues that the Malthusian view is no more than a self-seeking blind refusal to help build a society of fairness and fellowship.

Malthusianism received a new lease of life after World War II with the emergence of environmentalism. The Club of Rome's (Meadows *et al*., 1972) work on the linkages between world population trends, forms of economic development, and the future of the planet's energy resources, was the starting point for a major extension of the Malthusian argument. The imperatives of prudence and providence apply both to human fertility (of rich and poor alike) and management of the natural heritage; uncontrolled demographic change foredooms the long-term, sound management of the earth. The most alarmist of these arguments gave rise to the radically new concept of the right of successor generations, but while it has become a bandwagon issue, its content has not really been spelled out.

What will inform population thought in the coming century? All the old lines of reasoning and argument will be more alive than ever. But, probably more than ever, the issues will be those of space and food, ethics and realism, urgency and indecision, differences and injustices.

History of Ideas in Population since 1940

PAUL DEMENY

Population Council, New York, United States

INTRODUCTION

Labor in industrial societies is highly specialized. A large proportion of gainful activities are directed—through exchange in economic and political markets—to the production of goods and services aimed at satisfying the needs of the day and the foreseeable future. Within the social division of labor, however, in modern economies a growing proportion of human effort is allocated to science: to activity aimed at a better understanding of natural and social phenomena and processes through observation, description, and the derivation of regularities. Some of these activities may be best seen as ornaments that an affluent society desires and can afford. What once may have been amateur pastimes only, now find systematic support within the walls of academia and in specialized research institutions. Thus, studies are devoted to uncover the architecture of ancient Pompeii, to chart the evolution of medieval music, or to fathom the origins of the solar system. Utilitarian arguments, narrowly construed, poorly justify such work: its aim is satisfaction of curiosity and aesthetic interest now elevated to the level of a social need.

The analysis of the state and dynamics of human populations, the core subject matter of the science of demography, may provide its practitioners intellectual stimulation and, when a job is well done, a sense of accomplishment similar to what those students of Etruscan vases or of distant galaxies might experience. But it is important to remember that what society demands of the study of population is far more directly tied to considerations of practical use. If the goal in describing demographic facts were simply satisfaction of curiosity—contemplation of intriguing numerical oddities and regularities in a mirror, as it were, held up to a population—demography no doubt would still flourish in any affluent society. It would be, however, a much more limited enterprise than what it is today. Society through its institutions—governments, foundations, international organizations and the like—seeks to have access to a polished and multifaceted mirror, providing an accurate demographic image, because it suspects, indeed knows, that what appears in the mirror is likely to be less than fully in harmony with the collective interest, or with the interests of various collective constituencies. Similarly, predictions concerning population change are sought because of the anticipation that demographic trends, evaluated by various value criteria, are less than optimal.

Optimality does not mean a state of bliss. The notion of demographically "less than optimal" merely implies that through appropriate collective rearrangements, improvements could be achieved. Optimality would be reached when this is no longer possible: that is, when, under the existing rules of the political system, proposed further rearrangements could not command support that is sufficiently strong for their adoption. Demographic knowledge is needed, and population research is socially supported, first and foremost because it is expected, directly or indirectly, to yield useful information to the political process searching for opportunities for social improvement. Awareness of this social need suggests a simple fourfold classification of the functions of demography and its practitioners. Demographers ask four types of questions that start, respectively, with the words: What? Why? With what effect? and, finally, What (if anything) can and should be done about it? In other words demography, and demographers, in their special domain focused on the state of population and its dynamics, provide *description*, investigate *causes*, study *consequences*, and engage in studies of *policy*. The massive volumes of this treatise address in great detail the topics delineated by this fourfold division. But while the classification just outlined is a useful device in thinking about and in understanding what demographers do, particular products of demographic research do not necessarily fall in just one of the four boxes identified by the classification. Description, explanation of causes, discussion of consequences, and even discussion of policy matters may be bundled rather than neatly separated. Still, one of those ingredients typically tends to dominate, suggesting the right pigeonhole. But as the present volume amply demonstrates, investigating the substantive issues as delineated above requires appropriate methods—instruments of research. Such instruments are sometimes imported ready-made from neighboring social science disciplines, but more often must be laboriously home-grown. The importance of such instruments in demography, and the appreciable share of research effort demographers devote to developing and polishing them, warrants that separate consideration be given to a fifth topic: *tools*. Most, although by no means all, demographic tools serve the goal of better description. Thus, discussion of research instruments may be thought of as subordinated to the topic of description.

I. LANDMARKS OF POPULATION THOUGHT SINCE 1940: AN OVERVIEW AND A LITERATURE GUIDE

At least two weighty reasons support the seemingly arbitrary period–demarcation line of 1940 indicated by the title of the present paper. First, the steady accumulation of demographic work, traceable back to the 18th century has markedly accelerated after 1940. A number of notable developments signaled this shift. These include the launching of a series of ambitious demographic studies at Princeton's Office of Population Research in the early 1940s under the sponsorship of the by-then moribund League of Nations; the extensive scientific activities of the Royal Commission on Population in Britain, set up in 1944; the establishment of the Institut national d'études démographiques (INED) in France; and the launching of the first two major specialized scientific journals in demography: *Population*, in 1945, under the auspices of INED, and *Population Studies*, in 1947, under the sponsorship of Britain's Population Investigation Committee. Other novel initiatives were also important. The United Nations established its Population Commission in 1946 to "provide advice and assistance on matters affecting or affected by population changes" (Trygve Lie, 1995). At the same time, to carry out population studies and to serve as a source of expert analysis and advice in population matters, the Population Division was created within the UN Secretariat. In 1947 the International Union for the Scientific Study of Population (IUSSP), originally founded in 1928, was reconstituted as an international association for individuals interested in population studies. The establishment of the Population Council in 1952 and the subsequent entry of private U.S. foundations, notably of the Ford Foundation and the Rockefeller Foundation, into the field of population gave impetus to the establishment of vigorous university-based demographic research programs in the United States and in a number of developing countries. The 1954 World Population Conference, held in Rome, marked the beginning of an influential series of international scientific congresses on population that were sponsored, respectively, by the United Nations and by IUSSP. Within individual countries, the immediate postwar years witnessed a greatly expanded role claimed by governments in economic and social matters that generated a strong demand for more timely and more extensive demographic data. National statistical organization supplying these data, in turn, set up research units for the analysis of demographic information. Thus, post-1940, within the social sciences demography became an established independent discipline.

A second consideration that justifies 1940 as a demarcation line in population studies is the strong shift in the subject of demographers' interest that can be best linked with that particular date. In the 1920s and 1930s there were two major preoccupations in the "cutting edge" of demographic research: interest in eugenics—(in changes, actual or potential, in population quality) and the related concern with low fertility in industrial societies, pointing toward eventual population decline. The trauma of World War II brought discredit to eugenics, resulting in the virtually total dissociation of demographers from work in that field.

And the unexpected upturn of Western fertility, that culminated in the postwar baby boom but was already evident in the early 1940s, made the concern with below-replacement fertility at least temporarily moot. At the same time, the accelerating tempo of mortality decline in the economically less developed world and the resulting dramatic acceleration of the rate of population growth, coinciding with the process of decolonization, shifted many demographers' interest to the study of population dynamics in the countries of Asia, Africa, and Latin America—a topic only marginally present in pre-1940 demographic research. The perceived negative economic consequences of rapid population growth greatly amplified demand for research on the demography of the developing world and also strengthened demographers' interest in consideration of the policy implications of their findings. This, in turn, generated demand for research on the factors influencing population growth and its proximate and underlying demographic and socioeconomic determinants, and stimulated demographers' involvement both in research on the nondemographic—economic and social—consequences of demographic change and in policy studies based on findings from such research.

Thus, ironically, at the same time that demographic studies gathered strength and demography became a recognized independent academic field, its disciplinary boundaries also became fuzzier and less well-defined. In descriptive demographic work, and in fashioning tools for that work, demographers are in possession of their own uncontested proprietary terrain. That is still true when demographers seek to explain a change in a particular demographic variable in terms of changes in some other demographic variable. But in searching for deeper explanations for population processes, demography must become an "interdiscipline": demographers need to acquire skills and cooperate with practitioners from other fields of study—from history, sociology, anthropology, economics, political science, to name only disciplines most evidently capable of contributing to a better understanding of demographic phenomena. Making use of a broad array of skills is even more of an obvious necessity in research on the consequences of population change and in the domain of policy studies; there, demographers are often only junior partners in interdisciplinary cooperation.

Not surprisingly, there is a tendency among demographers to resent this dilution of their professional identity and a preference for drawing narrower, hence clearer, boundary lines around their discipline. Doing so assures easy communication with colleagues and provides the familiar academic and intellectual comforts of conducting discourse only with the like-minded. Such discourse is important for advancing knowledge in the core areas of demography, and wise institutional design should assure that it is sufficiently fostered and protected. But the temptation to make it exclusive should be resisted; wise institutional design should also seek to stimulate an opening up of the cloistered world of demography to wider intellectual influences through interaction with other specializations. As is, few demographers would be brave enough to claim that existing arrangements in the ways demographers are trained, research is conducted, research results are scrutinized, published, and disseminated have found satisfactory solutions. Such solutions require maintaining a delicate and shifting balance between disciplinary exclusivity (with the attendant risk of marginalization in terms of the social significance of the resulting research products), on the one hand, and interdisciplinary cooperation (with the attendant risks of losing professional identity and intellectual overextension), on the other.

The ideas of demography are hatched in demographers' heads. If the ideas emerge from that locus—and often they do not—they may take the form of words, spoken in a classroom, or in professional debates, or in public forums. Each of these sources can be influential and important, but each of them is elusive and limited in outreach and permanence. Ideas in the scholarly world can be communicated fully satisfactorily only if they are committed to paper, pass critical peer review (admittedly a fault-ridden process), and get published in journals and books, accessible to anyone interested and open to sustained critical scrutiny. Thus, in a first approximation, an account of ideas produced by an academic discipline is a review of the published literature in that field. The references to the chapters in this treatise provide a comprehensive introduction to the important contributions to modern population thought and its grappling with the four questions noted above.

The limitations of such an introduction, however well intended, should be, nevertheless, evident. The first is the limitation of the present reviewer, but in most instances also of the other contributors, in terms of access to languages and in geographic outreach. The references cited here, and in most other contributions to the enterprise, are in English and French only. This is a bias only partially excusable by the fact that by sheer numerical bulk and by ease of access to demographers, irrespective of their geographic location, the terrain covered constitutes a disproportionately large chunk of the population literature.

The second bias is one of selectivity, that reflects, once again, limitations of the reviewer's, and also of other commentators', outlook and judgment, but is also imposed by the sheer size of the literature that carries demographers' ideas. One bibliographic research tool familiar to demographers, *Population Index*, now (unfortunately) defunct, even if professing selective coverage, carried many hundreds of new citations every year, and has done so during the entire period of the six decades under consideration here. The *Review of Population Reviews*, published by the Paris-based organization CICRED lists the contents of some 80 journals in the field of demography. *POPIN*, the population information service maintained by the United Nations Population Fund, provides extensive databases on population publications. It also offers a *Worldwide Directory of Population Institutions* which lists, for example, more than 100 population research and training institutions both in China and in India.

Clearly, the short overview offered below cannot claim to be representative. The aim, instead, is to illustrate main strands of population thinking that appear to have been especially important in population policy debates during the last six decades or during parts of that period. As has long been the case in the natural sciences, contemporary social science work tends largely to ignore publications that are not of recent vintage. The overview below seeks to avoid that practice by paying attention to significant work during the period covered regardless of date of publication.

Where should the reader look for enlightenment about the flow of ideas in the field of demography that is far more detailed than what follows below and that also permits forming a judgment uninfluenced by a guide? Those with ample time would be well advised to settle in the reading room in a well-equipped library and to leaf through the proceedings volumes of IUSSP's General Conferences. These are held every four years (and special conferences sometimes in-between) and the raw (unedited) papers presented at each meeting fill either a single massive tome, or more often two or three, and on occasion up to six, hefty volumes, and, more recently, a CD-Rom, which is deceptively slim but offers equally rich fare. Their content is obviously too sprawling to be sampled and characterized here, but their inspection and selective perusal would well reward the critical reader (who may also imagine hopping from conference to conference in places like Rome, Vienna, Stockholm, New York, Ottawa, Belgrade, London, Mexico City, Liège, Helsinki, Manila, Florence, Delhi, Montreal, Beijing, Salvador de Bahia, or Tours) The papers in most cases are volunteered by IUSSP's members, subject only to the restriction that they fit a fairly accommodating overall topical frame. Thus, the content of these volumes gives a good representative picture of what demographers, or the institutions that support their research, have been interested in, hence considered important, during the post–World War II decades.

A similarly simple recipe for an exploratory excursion in pursuit of modern ideas on population would be perusal of past volumes of specialized journals. The reader would have the advantage of being exposed only to material that had been filtered through a competitive process for limited space and had been subjected to prior editorial screening and revision, albeit of varying severity. Those with ample yet not unlimited time at their disposal could apply themselves to a subset of what is available in this genre and go through only some of the journals, such as (a) INED's *Population* (completing in 2005 its 60th annual volume), preferably with a side excursion to INED's ambitious monograph series appearing under the general title *Travaux et documents* (and, more recently, titled *Les Cahiers de l'INED*: some 150 volumes since the inception of the series); (b) *Population Studies* (in its 59th year); (c) *Demography*, the journal of the Population Association of America (in its 42nd year); (d) *Population and Development Review* (in its 31st year) and its eleven book-length supplements on special topics; or (e) *Genus*, the population journal with the greatest longevity. Reading the book review sections of the journals just cited (unfortunately, not all of them are engaged in providing this service so essential for the good health of a discipline) also would be a rewarding guide into the population literature that takes the form of books and monographs.

Turning to books that provide a comprehensive overview of the field and experienced guidance combined with original scholarship can be an efficient way of avoiding the hazards of a random walk across the periodical literature. Eminent examples of this genre include Alfred Sauvy's *Théorie générale de la population* (Sauvy, 1956, 1969), and classic French and American population textbooks in population, such as Adolphe Landry (1949), Philip M. Hauser and Otis Dudley Duncan (1959), Donal Joseph Bogue (1969), and William Petersen (1975). A less ambitious book is a "reader," offering selections of special merit from the periodical literature, with sometimes extensive, sometimes perfunctory commentary that imposes some coherence on the works presented. The main merit of such books is that they provide easy access to items, typically mostly journal articles, that readers otherwise may find difficult to locate—a problem that is now being solved by access to specialized literature through the Internet, such as through the indispensable journal storage *JStore*. Some recent examples include, each with a focus or special emphasis on economic aspects of population, Nancy Folbre (1996), Paul Demeny and Geoffrey McNicoll (1998), T. Paul Schultz (1998), and Julian L. Simon (1997).

As a rigorously edited early guide to key issues that occupied demographers in the past, the UN-sponsored study *The Determinants and Consequences of Population Trends* (United Nations, 1953) is still indispensable. The follow-up volumes to that project (United Nations, 1973) are also valuable, as are the volumes commissioned as back-up materials for the UN's first large intergovernmental conference on population, held in Bucharest in 1974 (United Nations, 1975). In general, the United Nations, primarily through work in its Population Division, its Statistical Office, and through its specialized agencies (more recently especially the UN Population Fund), is a steady producer of population reports, analyses, and statistics that find wide use in the field of demography. The United Nations, often through its regional economic and social commissions, also is a frequent convener of specialized population meetings, typically resulting in valuable technical publications with contents either produced within the organization itself or contributed by invited academic researchers.

In contrast to the United Nations' work, with its resolutely internationalist outlook, country-specific examinations of population issues sponsored or initiated by national governments reflect the special interests of domestic constituencies. Reports of this type, often published annually—such as part of, or a supplement to, compendia of up-to-date national demographic statistics—have long been a steady presence in the population literature in most industrialized countries.

More recently, their equivalents on a regional level have also increasingly made an appearance, as organizations with access to strong professional staff resources, such as the Organization for Economic Cooperation and Development (OECD), the Council of Europe, or the European Commission, publish general surveys of the population of their member countries or report on special population–related issues of their region. Despite their national or regional frame of reference, the best examples of these products should be of substantial interest to students of population everywhere.

The same remains true, despite a degree of inevitable obsolescence, of two especially ambitious national programs aimed at examining population issues at a particular point in time. The first of these, the work of Britain's Royal Commission on Population, which stretched over a period of four years, was already mentioned above (Great Britain, 1949). Its papers, rich also in technical–analytic material, constituted six volumes. The other, carried out in the United States, was the Commission on Population Growth and the American Future (1972). Its report was based on deliberation that took nearly as much time as did its British predecessor's, and was backed up by eight large volumes of research papers, covering demographic, social, economic, and spatial aspects of population growth, and discussing the relationship of demographic growth to such issues as resources, environment, and governance. The considerable scientific merits of the work of the two commissions notwithstanding, both projects turned out to be somewhat ill-timed, hence less influential on policy matters than could have been expected. The perceived problems that prompted these enterprises were polar opposites: in the first instance it was low fertility and the prospect of population decline; in the second, the problem of sustained high fertility and the resulting rapid population growth and the prospect of an increasingly negative influence of these phenomena on the quality of life. Both expectations proved to be misguided. As a member of the Royal Commission is said to have observed (Grebenik, 1997), the Commission was established when there was lots of money and few babies, but issued its report when there were lots of babies but little money. The American effort encountered similar interference from hard-to-predict demographic trends. When the enterprise was conceived, the U.S. baby boom—which at its peak brought total period fertility rates above 3.5—was still a reality. By the time the Commission's report was published, the baby boom was history and the total fertility rate was below replacement.

Ideas about population include ideas by practitioners in the field of population studies about how well, or how unsatisfactorily, the discipline is performing its main functions: producing and disseminating important and sound research findings. Such stock-takings, assessments, criticisms, and forecasts of future developments by demographers are often influential in protecting the field from unhealthy tendencies, provide guideposts for new directions, or at least enhance demographers' self-awareness about problematic aspects of their work. Even more optimistically, they prompt academic decison makers and administrators in allocating funds for population research more wisely and with deference to unpopular ideas.

The genre typically takes the form of an essay; sober analysis is often combined with expressions of controversial personal views and occasionally filled with polemics. Some examples are Dennis Hodgson (1983, 1988), who, using the example of the theory of demographic transition, documents a shift in demographic research from a social–scientific to a policy-oriented stance; Paul Demeny (1988), who assesses and criticizes the institutional arrangements that tend to relegate policy-oriented research to performing ancillary functions to existing population programs in the Third World; Samuel H. Preston (1989), who identifies deficiencies and conflicts in the diagnosis of population problems; Dirk J. van de Kaa (1991) who discusses emerging issues for demographic research agendas in Europe and the ambiguities of the role of the demographer as a scientist and as an actor concerned with socially useful results; McNicoll (1992), who complains that increasing sophistication in the analysis of population processes has been accompanied by a lessening of interest by demographers in the larger, related questions of social and behavioral change; Simon Szreter (1993), who argues that further intellectual progress in fertility studies, a key area of demographic research, requires emancipation from the idea of transition and its associated obsolescent methodology; and Greenhalgh (1996), who finds that demography's sophisticated methods and noted achievements are undercut by outmoded thinking rooted in modernization theory and analyzes the tension between demography's use for applied purposes and its claims to being a science.

Round-numbered institutional anniversaries occasioned much self-examination in a similarly critical vein. *Demography*'s 30th birthday was marked by several such essays, notably by Keyfitz (1993), who examines the influence of population journals and comments on the tension between researchers wishing to focus on conclusions about substantive matters and those pursuing technical questions of methodology; and by Preston (1993), who discusses the scope of demography and the various research approaches that can legitimately claim that label, and identifies promising research areas in which demographers can be expected to be called on to address issues of national and international concern. From INED's 50th anniversary celebration sprang a volume (Chasteland and Roussel, 1997) containing some 20 highly informative articles assessing national experiences in demographic research and discussing the future of demography. Particularly notable among these are two contributions by the editors of the volume, and essays by Ronald Lee, Samuel Preston, Alain Blum, and Graziella Caselli. Marking the first half century of the publication of *Population Studies*, the closing issue of volume 50 of that journal published an equally important set of articles examining the achievements, status, and prospects of various subfields of demography. The lead essay, by John Caldwell (1996), questions the extent to which demography is a social science (and gives a less than conclusive answer) and examines how changes in the outside world affect what demographers do and what and where they publish.

A recent comprehensive appraisal of the field of population studies that surveys contemporary thought on demographic processes in their multifarious connections to social phenomena at large is offered by *The Encyclopedia of Population* (Demeny and McNicoll, 2003). Population issues are often defined fairly narrowly, focused on description of the core demographic processes or, in a policy context that was dominant in the second part of the 20th century, on rapid population growth and measures to curtail it.

An aim of the *Encyclopedia* is to make a compelling demonstration of the need for a more universal interpretation of the subject matter. Even a partial listing of the topics covered by the nearly 300 contributors of this 2-volume survey suggests the breadth of contemporary population thought. The topics include the entrenchment of very low fertility and the growing problems of old-age support; the retreat from marriage and the diversification of family forms; the new medical technologies affecting reproduction and longevity; the resurgence of a variety of infectious diseases; increased South-North migration and refugee movements; the press for women's equality and fuller reproductive rights; a widened array of environmental effects of demographic dynamics, notably climate change; and global shifts in the relative population size of countries.

The *Encyclopedia* also gives attention to the evolutionary bases of human development and behavior, with insights drawn from genomic research and from comparisons with other species. Many of these topics have ethical debates associated with them—long-standing, like abortion and asylum-seeking, or newfound, like genetic engineering and animal rights—debates that are unlikely to be satisfactorily advanced without expert input from demographers. And the traditional interest in population history and prehistory also brought new findings and interpretations during recent decades, settling some controversies and raising others. All this territory is staked out in the *Encyclopedia*.

In a somewhat different genre, the present series, *Demography: Analysis and Synthesis*, also offers, as was noted above, a broad overview of the population field. There, the coverage is less encompassing, but with the advantage that the narrower focus permits greater in-depth treatment of the various topics. These two recent works demonstrate that any attempt in a single chapter that would aspire to offer a comprehensive survey of population covering the last 60-odd years could necessarily excel only in superficiality. To avoid that pitfall, my assignment must be interpreted as one calling for drastic selectivity. The ambition of the present chapter is not to duplicate specialized discussions of population thought but to focus selectively on some major issues that the in-depth but piecemeal approach may have missed. The prime opportunity for that is offered by examining the bearing of population dynamics on public policy as perceived by those studying demographic issues during the last 65 years. In doing so, I seek to distill some of the major themes in population thought from the literature cited above.

II. THE GLOBAL POPULATION PROBLEM

The study of demographic dynamics as a scholarly pursuit has its own considerable intellectual and aesthetic rewards to both researcher and consumer of demographic research. But such study acquires social importance only to the extent that particular patterns of population change are proven to affect, or are perceived to affect, social welfare differently: some patterns are, or are thought to be, better than others. Such differences raise the possibility of deliberate, purposeful modification of the demographic status quo in a mutually agreed direction that enhances the common welfare. If the cost of such an engineered change is less than the improvements obtained, ameliorative collective action—crafting beneficial population policies—becomes a potential possibility. Population thought in the second half of the 20th century has been preoccupied by exploration of the opportunities modified demographic trends might offer for enhancing human welfare.

Population policies are often discussed with reference to particular countries. This is the case also in the present treatise. Although the choice is in many ways natural—states are the locus of many important political decisions affecting demographic behavior—a country-by-country study may miss some important policy issues and leave their common underlying logic unexplored.

In the early 1940s, students of population anticipated the emergence of two kinds of population problems in the post–World War II years. One was the continuation of below-replacement fertility observed in almost all countries of the Western world during the 1930s, implying negative rates of population growth in the coming future. To the extent that this was seen a "problem," it clearly required responses to be determined by the affected countries themselves.

A second type of problem was seen as a global or at least a broad regional one: emerging as a result of exceptionally rapid rates of population growth in countries where fertility was still traditional (i.e., "high" in comparison to Western levels) but mortality was declining. Economists as well as demographers expressed doubt about the ability of many low-income countries to cope with a rapid population surge. Some concluded that the economic and social consequences of mortality improvements will not be sustained or will even be reversed unless rapid fertility decline also ensues.

By the late 1940s, the first type of the anticipated postwar problem seemed to evaporate quickly as birthrates rose in most low-fertility countries. Although the magnitude of this "baby boom" varied from country to country, vigorous pronatalist policies no longer seemed justified. Indeed, at the height of the baby boom, in some instances, notably in the United States where period total fertility rate reached 3.7 in 1957, serious consideration was given to policies that would actively seek moderation of population growth.

Predictions about accelerating population growth in the less developed world were, however, on a firmer footing. What fueled this growth was an often-precipitous drop in the level of mortality—a welcome development. But a doubling or even tripling of population size by the end of the 20th century was likely to set back already low living standards or at least greatly retard their improvement. To a significant extent, mortality decline was sparked and sustained through the adoption of new methods of controlling infectious disease, greatly aided by international aid programs. This suggested that international programs could and should also be designed to bring birthrates down faster than could be expected in the absence of deliberate intervention. An acceleration in demographic transition, it was argued, would speed up economic development.

This was not a universally shared view. In an influential article published in 1949, Alfred Sauvy argued that the global population problem is a false problem; indeed the notion of world population is largely devoid of meaning. The politically relevant units are the sovereign countries; only countries can assess their own problems and find their own appropriate solutions.

Yet many of the newly independent developing countries of Asia and Africa were not well prepared to pay sufficient attention to potentially deleterious demographic changes or to mount effective programs that could modify these changes for the better. An elaborate set of economic–demographic projections prepared by researchers at INED (Balandier, 1956) showed the magnitude of the economic difficulties that accommodation of rapid population growth would involve, and the potential alleviation of that burden if fertility decline were to follow more closely the falling rates of mortality. For example, the INED projections showed that the population of India and Pakistan (within the borders prior to the independence of Bangladesh) with constant fertility would grow from 460 million in 1955 to 1.3 billion by the year 2000. Early and rapid fertility decline would result in a population of 866 million in the year 2000: still a rapid growth by any historical standard, but presumably more conducive to economic development. (The actual 2000 population of these countries is estimated by the United Nations as 1.288 billion: a result that reflects both a lower mortality trajectory than was assumed in the INED projection and an appreciable decline of fertility in the last two decades of the 20th century.)

Concerns with the harmful effects of rapid population growth manifest in academic studies and eventually also in developed countries' public opinion and in official policy formulations by economic development agencies, national and international, were not only humanitarian. Economic instability and impoverishment in the less developed countries were deemed as having potentially ominous consequences in the context of Cold War rivalries. Quite apart from the latter consideration, sharpening income inequalities among countries were seen as a source of international instability. And, in the long term, the growing imbalance between population sizes in the low-growth regions as compared to regions experiencing rapid demographic growth had unwelcome geopolitical implications.

The search for policy instruments suitable for accelerating the fertility transition in less developed countries led to extended and sometimes acrimonious debates. Much of this discussion among countries, with the conspicuous exception of China, which found its own unique solution for the population problem, was conducted in academic forums in the developed world, primarily in America. The developed world of course had relatively low fertility and much historical experience on why birthrates fell. Social science analysis was virtually unanimous in interpreting this experience. The explanation centered on the role of changing structural conditions of the economy, conditions to which microlevel units of the population readily responded, in demographic as well as in other matters. Demand for smaller families was seen as the primary force determining birthrates; the means by which couples regulated their fertility was not unimportant, but was seen as a distinctly secondary factor. If the demand were strong enough, fertility would be low, even if birth control technology were primitive. A transition to low fertility presupposed changing preferences, and such preferences were responses to market signals. If policy were to have an explicit role, it would be through reinforcing those signals through appropriate institutional arrangements. The specifics of the needed socioeconomic arrangements were known and well elaborated. They were development oriented in a broad sense: the demographic side effects were essentially by-products of the overall design.

But assembling the policy instruments so identified into a coherent development strategy of institutional-structural reforms, reforms justified also by demographic objectives, remained a task inconsistent with the spirit of post–World War II development philosophy. In promoting development, governments came to see their roles not in supporting institutions harnessing the market, but in replacing the market in key developmental tasks through specific goal-oriented categorical programs. In the matter of population policy, the rapid postwar progress in the technology of birth control provided an appealing, apparent shortcut for achieving fertility decline through programmatic means. Markets, it was held, could not be relied on to bring that technology to those wishing to practice birth control. Governments could, instead, organize free delivery of birth control information and provide effective means for preventing births to all those who wished to plan their families. Surveys indicated that there existed a substantial latent demand for such services. Satisfied customers, in turn, would serve as role models, bringing new clients to the program.

The effectiveness of family planning programs in reducing fertility remains a matter of controversy. According to international guidelines, programs recruit their clients on a strictly voluntary basis. By accepting the service voluntarily, clients demonstrate that they value that service. But some of the more successful programs, notably in Asia, tended to increase acceptance by often heavy-handed methods of persuasion, and, in the especially important case of China, by coercion backed by legal sanctions. Where fertility fell in less developed countries with active family planning programs, it is typically found that program-provided free services account for a large percentage of those practicing contraception. This result is then often taken as an indicator of success in reducing aggregate fertility. But what would have happened in the absence of the program is conjectural, hence routinely ignored. Some less developed countries that lacked government programs also experienced major falls of fertility: Brazil is a conspicuous example. Similarly, if programs have seemingly only minor success in reducing fertility, this can be taken as evidence that the program is inadequately financed, organized, and managed: greater efforts would have led to better results.

Family planning programs as they were commonly conceived had a strong resemblance to health programs. But given the special priority accorded to family planning services in foreign assistance, typically they were organized as a separate "vertical" program, or kept administratively distinct within the broad health program. The justification for such treatment was that while clients of family planning services are recruited because the program satisfies their individual needs, the program also serves a national developmental need by helping to reduce aggregate population growth and hence deserves priority. Once a family planning program is organized, its managers and professionals form a natural advocacy group strongly interested in the program's sustenance. Invoking the public interest in lowered fertility, as distinct from simply serving the needs of the program's clients, has long served as a key supporting argument in that endeavor.

Over time, this developmental prop has eroded. This was in part a result of criticisms of the intrinsic scientific merit of the argument but most of all a reflection of the extensive decline of fertility that has occurred, a decline often attributed to the success of the family programs themselves.

Accordingly, the development rationale of family planning programs was gradually dropped and was replaced by the argument that the programs satisfy important health needs and help people exercise a fundamental human right. The Cairo conference formalized this shift: even though the name of the conference for the first time included a reference to development, scant attention was paid to that concept. Family planning programs were redefined, instead, as reproductive health programs, responding to a broader range of women's health needs, such as prevention of unsafe abortions and sexually transmitted diseases, including HIV/AIDS. But beyond this, new emphasis was put on some requirements that would contribute to women's empowerment: reduction of infant and maternal mortality and improvement in girls' education and women's opportunities for employment and political participation. Although the connection was not highlighted, these are conditions that are likely to help reduce the birthrate through stimulating the demand for smaller family size. The Cairo conference, in effect, reverted to some key elements of earlier population thought, advocating a demand strategy for reducing birthrates.

The future of family planning service programs—the centerpiece of the dominant population thought since the late 1960s—is thus left in a somewhat tenuous state. Without invoking a collective interest in a wider practice of birth control, it is not clear what level of priority should be accorded to such programs as just one part of publicly financed health programs, or indeed relative to any other social welfare programs that also serve demonstrable human needs. Not surprisingly, there are increasing efforts in national programs to rely on the market to facilitate access to contraceptives and to provide program services on a fee-for-service basis.

III. THE PROBLEM OF BELOW-REPLACEMENT FERTILITY

During the second half of the 20th century, debates about both population policy and consequent programmatic action were centered on the issue of rapid population growth in the less developed world. Toward the end of this period, however, a quite different demographic phenomenon began to attract increasing attention: aggregate fertility levels that are inadequate for the long-run maintenance of the population. Analytically, the potential population policy issue raised by low fertility is identical to the problem inherent in rapid population growth: it is caused by the disjunction between the sum total of individual reproductive decisions and the collective interest in a long-run demographic equilibrium. But this time individual aspirations generate a deficit rather than an excess in population growth. The syndrome, is not entirely novel: it was detectable in fertility trends in the West, especially in Europe, in the 1920s and 1930s, and in some instances, notably in France, even earlier. But in the decades immediately following World War II, the baby boom seemed to make the issue of low fertility moot. Indeed, by any historical standard, population growth was rapid during the second half of the 20th century, even in the developed world. Europe's population, for example, grew during that period from 550 million to about 730 million.

The baby boom was, however, a temporary interruption of the secular downward trend in fertility. By the 1970s, the net reproduction rate was at or below unity in most countries in Europe and also in the United States. In the U.S., fertility stabilized at or very close to that rate, but in Europe, fertility continued to decline. By the beginning of the 21st century, the average total fertility rate was 1.4. Such a level, if maintained indefinitely, would result in a population loss of one-third from generation to generation, that is, roughly, over each period of some 30 years. In some countries, notably in Southern, Central, and Eastern Europe, period fertility rates were at low levels without historical precedent for large populations. If continued, in the absence of large compensatory immigration this would not only lead to rapid population decline but also result in very high proportions of the population at old ages. It might be expected that in the affected countries such prospects would generate not only concern, but also vigorous remedial policy action.

By and large, however, this response has not been evident. Most governments, as well as the general public, tend to view below-replacement fertility with an equanimity quite unlike the alarmed reaction that the same phenomenon elicited when it first emerged between the two World Wars. And explicit pronatalist policies, common in the 1930s, are conspicuous by their absence. There are a variety of reasons explaining this indifference.

First, the preeminent population issue confronting policymakers in the post–World War II period was rapid global population growth. Programs aimed at moderating fertility in the developing world received assistance or at least encouragement from the rich, low-fertility countries. Although the rationale was modified over time, such assistance and encouragement has continued, as indeed substantial further population increase in the less developed countries is still anticipated in the early decades of the 21st century. Even though population issues tend to be sui generis, reflecting differences in demographic behavior country-by-country, there was, and remains, a perceived dissonance between fertility-lowering assistance to other countries and engaging in action at home serving the opposite aims. Faulty logic notwithstanding, the international terrain has not been favorable for domestic pronatalism.Second, the natural rate of increase—the difference between the number of births and the number of deaths—is still positive in many of the countries with fertility well below replacement. This is the result of age distributions that reflect past fertility and mortality, and notably the effects of the postwar baby boom, that still favor population growth. While this momentum effect is temporary, the long-term implications for population decline and population aging are only dimly perceived by the general public and provide an excuse for inaction on the part of policymakers.

Third, when those long-term demographic effects are understood, a calmer attitude still prevails. There is an inclination, reinforced by increasing concern with the quality of the natural environment, to regard a degree of demographic "decompression" as a not necessarily unwelcome prospect, especially in countries with already dense populations. And it is assumed that the economic and social disadvantages that might be imposed by a declining population can be effectively dealt with through institutional adjustments and social policy measures other than measures aiming for a higher birthrate. A demographic policy often regarded as potentially helpful in this regard is encouragement of immigration. That willing immigrants are available to compensate for low birthrates is taken for granted—a realistic assumption in high-income countries.

Fourth, there is a vague expectation that the population decline, impending or already begun, will in due course trigger corrective homeostatic mechanisms, leading to a spontaneous rebound in the level of fertility. Another baby boom may not be in the offing, but fertility may rise sufficiently to once again reach, or at least approximate, replacement level. Governments, it is assumed, would be ill-advised to interfere with this natural process by trying to increase birthrates and then seek to fine-tune them at the desirable steady-state level. According to this view, a laissez-faire fertility policy is justified since, apart from broad upper and lower limits, governments are not competent to determine what constitutes an optimal fertility rate, or growth rate, or population size in any given year, decade, or even longer time interval.

Finally, even if the will were there, there is a paucity of effective pronatalist policy instruments. Exhortation from governments is not promising, and in any case unlikely to be tried in a democratic polity. Restrictions imposed on access to modern contraceptive technology are not politically acceptable and would be certain to fail. This leaves the traditional levers of social policy: dispensing material incentives and disincentives so as to increase the willingness of couples to have children. Such incentives can be engineered by the government through fiscal measures, such as differential taxation, provision of services in kind, or both. This approach was tried in the interwar years, but with limited success. After World War II many similar measures continued to be applied; in fact, with the steadily expanding welfare state, they were often upgraded and their scope, too, was extended. However, they were no longer considered "pronatalist" but were absorbed within the more encompassing frames of family and general welfare policy. The new label partly reflected a political–ideological preference, but in part also the fact that some distinctive features of pronatalism—such as differential rewards that favored large families, and non-means-tested or even regressive allocation of family and child benefits—were generally no longer acceptable.

Although the redistributive policies of the contemporary welfare state are biased in favor of the elderly and the poor, government-organized transfers to parents of children, or to children directly (such as through publicly financed day-care services and free or subsidized education often beyond the secondary school level, which lessens the cost of children to parents), are substantial in all low-fertility countries.

Indeed, it is typically assumed that existing family and welfare policies sustain fertility above a level that would ensue in their absence. Accordingly, making these policies more generous—socializing an even larger share of child costs—is often seen as a means toward increasing fertility, whether as an outright policy objective or, more in the prevailing spirit of the time, as an unintended but welcome by-product. Such extension, however, is difficult, given the fiscal constraints of already overcommitted welfare states. And more to the point, the net effect of family-friendly redistribution of incomes and provision of services is uncertain. It is notable that in the United States, where such schemes are distinctly less well funded than, for example, in Western Europe, fertility is, nevertheless, relatively high.

In recent decades, in modern industrial economies, the participation of women in the formal labor force has expanded rapidly. This tendency, reflecting market forces, but also encouraged by government policy (partly as an antidote for deteriorating dependency ratios as the population becomes older), is likely to continue. Among the factors explaining the low level of fertility despite general material affluence, many observers point to the double burden on women of both raising children and working outside the home. To the extent that higher birthrates are seen to be socially desirable, the derived policy prescription is to adopt measures that make motherhood and women's labor force participation more compatible. The higher fertility in countries (notably in Scandinavia) where such measures are strongly applied, compared to countries (especially those in Southern Europe) where they are largely absent, suggests that enhanced compatibility (through day-care services, flexible work hours, liberal sick-leave allowances, and the like) is an effective pronatalist policy even if motivated by other considerations. But it is far from clear whether the fertility differential so generated is high enough to bring the total fertility rate back to replacement level. Steady labor force participation of women during the child-bearing years can certainly be made compatible with having one child or even two. It is likely to be far less compatible with sustaining, or even increasing, the proportion of women who have more than two children. Many career-oriented women voluntarily remain childless; many others prefer a single child. It follows that, to achieve average replacement-level fertility, the proportions of such women need to be counterbalanced by high enough proportions of women who have chosen to have three, four, or more children. There is little indication at present that policies directed at enhanced compatibility achieve that result.

When fertility is high, as it still is in most developing countries, it is a safe prediction that with economic development it will eventually decline, at least to replacement level. In the long term, apart from out-migration, the only alternative is higher mortality. The record of the high-income countries indicates, however, that replacement-level fertility is not a necessary resting point. Once fertility is lower than that, predictions become highly hazardous. European and East Asian experience suggests that fertility has a tendency to settle below an average of two children per woman, hence tending toward sustained population decline. The question, to which no good answers exist at the dawn of the 21st century, is "how far below?" "Scandinavian"-style family policies may stabilize fertility only modestly below replacement—around a total fertility rate of 1.8. That would imply a fairly moderate relative shortfall of births compared to deaths, and population stability in rich countries with such vital rates could be fully or almost fully compensated with a modest level of controlled immigration. Population aging would be then kept within relatively narrow limits, which postindustrial economies could readily adjust to. The demographic weight of such countries within the global total in the foreseeable future would continue to shrink, raising possible problems of a shifting geopolitical balance. Still, such demographic configurations would be likely to push the day of demographic reckoning beyond the policy horizons that governments feel an obligation to be actively concerned with. Pronatalist interventions would find at best a marginal place on governments' policy agendas.

On the other hand, fertility levels in the lowest-fertility countries—countries with a total fertility rate of 1.3 or below around the turn of the 20th century—might stabilize at that level or even shrink further, reflecting the decentralized and uncoordinated decisions of individuals and individual couples. Such an outcome might also foreshadow future reproductive behavior in countries in which fertility is still fairly close to replacement level. This would create a qualitatively different demographic situation for which there are few precedents in modern history. It would represent a clear threat to the continuing viability of the countries affected. Compensatory immigration flows would have to be so large as to be inconsistent with any reasonable degree of cultural and ethnic continuity. Alternatively, population aging in the absence of immigration would create virtually unsolvable challenges, and likely there would be a drastic loss of relative geopolitical status. Spontaneous homeostatic mechanisms may not come into play to save the day, or may do so too sluggishly to matter. A radical rethinking of fertility policy would then become a necessity for social—and national—survival.

Ethics and Demography or Macrodemus and Microdemus in the Country of Ethicists

FRANÇOIS HÉRAN
Institut national d'études démographiques (INED), Paris, France

Macrodemus and Microdemus were long-standing members of the same research center. They were both demographers, but it was hard to believe they were both in the same profession. Macrodemus practiced macrodemography, Microdemus microdemography.[1]

Macrodemus spent most of his time processing the data series on births, marriages, and deaths from around the world, which he received via the Internet from national statistical offices, official health organizations, and the United Nations Population Division. He was an expert in formal demography, as his English-speaking colleagues put it, and also a fan of demographic projections. Reputed for his rigorous analyses, he had learned demography from Nicodemus and Mathodemus, and was eternally grateful to his masters. Macrodemus had never observed or interviewed anyone in his life. He saw the world from high above and far away. He believed that one could learn about human subjects all the more easily by studying them in the aggregate and at a distance.

Microdemus was 10 years younger than Macrodemus. Trained by Epidemus and Geodemus, he liked to explore the field on foot, observe behaviors at length, and converse with men and women of all ages and ranks. He was fond of stating that a researcher's first task was, using the 18th-century phrase, to "know society." This meant possessing not only the art of conversation but also the knack of getting on with all social groups, the ability to discover the exotic in everyday life, to decipher the words of all tribes, to construct and deconstruct institutions, and to reveal the hidden side of things. He felt a special attraction to fringes and margins, where, in his view, the fate of society was determined. While not disdaining quantitative analysis, he was convinced that qualitative analysis was the key to human behavior.

Macrodemus and Microdemus were not the Center's best-known researchers but, to use the language of sociologists, they embodied the two "ideal types" at the opposite poles of its activity. Other researchers filled the space in between.[2] Some covered

[1] These demographers should be of either sex. In the French text, I have given them masculine-sounding names and have used male gender agreements, in the hope that female readers will be happy not to be identified with such overly typical male characters. Apart from that, I borrow the following guideline from the Quebecois textbook by André Duhamel and Noureddine Mouelhi (2001, p. vi): "The masculine form is used here to refer to both sexes, without discriminating between men and women, and for the sole purpose of streamlining the text."

[2] They often came in pairs: Epidemus and Biodemus, Ecodemus and Geodemus, Agrodemus and Cosmodemus, Paleodemus and Neodemus, Calodemus and Mesodemus, Erodemus and Gynodemus, Iatrodemus and Necrodemus, Oligodemus and Polemodemus, etc.

a very broad spectrum by switching effortlessly from macrodemography to microdemography and vice versa: they could analyze data covering the entire planet in the morning and follow an interviewer testing long questionnaires on fertility practices in a distant suburb in the afternoon. But there were few of these hybrid, semi-micro/semi-macro people around. Most often, the distribution of labor at the Research Center was polarized between the two models. The two worlds coexisted without really mingling. Macrodemus and Microdemus were, so to speak, caricatures, but they merely embodied extreme forms of widespread practices.

The inclination of the Center's researchers toward macro- or microdemography was not determined by their original disciplines. None had been initially trained in demography. All had discovered it while working in another discipline: sociology, economics, history, political science, geography, statistics, epidemiology, biology, or more seldom, social psychology and anthropology. But some had hastened to forget their initial training in order to enter into a jealous marriage with demography, while others were repeatedly unfaithful to it by cultivating a strong interest in social science or the life sciences: they thought it natural to put demographic analysis in a broader framework.

This divergence in practices and cultures had a deep structural influence on the Center. Both groups invariably focused their research on human subjects, but their relationships to the subjects were radically different. The approach to ethical issues was substantially altered in consequence—so much so that one might ask whether demography had a specific ethic or whether, instead, each type of demography had a separate ethic.

The philosophical tale told in this chapter seeks to answer the issue I have just defined. It shows that the discovery of ethics by demographers is a laborious process, marked by advances and setbacks. To provide a better grasp of these difficulties, we shall deliberately begin our reconnaissance trip in the company of a hardline "macrodemographer": Macrodemus. He seems to be the antithesis of the ethically concerned, because he sincerely believes that his working style poses no particular ethical issues. We shall follow him in his unlikely and involuntary visit to Ethics Island. This initiation voyage will give him the opportunity to make many discoveries, until the day when, like Robinson encountering Friday, Macrodemus finds a companion in the guise of Microdemus. He eventually understands that they will need to join forces to face the ethical challenges of tomorrow.

I. FIRST EXPLORATION OF THE ETHICISTS' ISLAND

When our story begins, at the start of the Third Millennium, Macrodemus has not yet met Microdemus. Through circumstances beyond his control, which it would be superfluous to recount here, Macrodemus has landed unexpectedly on an unknown island with his laptop computer—and no hope of return. He has taken refuge at the top of a promontory, where he has gradually built a rugged shelter. Thanks to wireless Internet, he continues to receive and process his beloved data. Through the same channel, he fulfills contracts for national and international organizations and receives his salary and research funds. Macrodemus is a modern Robinson. He has made the unsurprising discovery that the island is inhabited. He has promptly introduced himself to the locals, but without arousing any feelings among them except polite attention. He accepts this indifference and rarely leaves home.

Macrodemus has not taken long to discover that the island is called Ethics Island and is dominated by an elite of formidable experts: the Ethicists. They are subsidized by the island's governor for the task of addressing all the moral dilemmas arising on the archipelago, and even beyond. The Ethicists describe the dilemmas, exacerbate them (a good dilemma is a life-or-death dilemma), and sometimes try to resolve them. They produce a prolific literature, in which several debates rage. The most prominent have seats in houses for the initiated, called "Ethics Committees," which the governor consults periodically. The Ethicists practice the cult of ancestors but do not elevate them to the same degree of divinity as sociologists do. They venerate founding fathers from the late 18th and early 19th centuries: Immanuel Kant, founder of the ethics of duty; and Jeremy Bentham and John Stuart Mill, founders of utilitarianism. But the cult of Aristotle—for whom virtue is the quality of virtuous men and must be nurtured through education—still has its followers and is even enjoying a certain revival.

At the start of each academic year, the Ethics Island bookstores display stacks of textbooks and collections of readings that ethics professors recommend to their students. Almost all of these works are in English (Mackie 1977; Singer, 1993; LaFollette, 2000; Thomson, 2000). [CB: order cites late to early year]A few manuals in French, imported from Quebec, have slipped into the list (Duhamel and Mouelhi, 2001).

Macrodemus is not a big reader and, to tell the truth, his intellectual curiosity before landing on the island was very limited. But one day, in a moment of forced idleness (the macrodata he was expecting had not been delivered on time), he fought off his boredom by taking refuge in a bookstore. There, he struck up a conversation with a very learned and highly persuasive young salesgirl, Philarethes, who invited him to browse the works of the Ethicists.

This was a discovery for Macrodemus. The issues addressed were the life-and-death issues recurrently raised by events in the news. The Ethicists pondered the legitimacy of certain actions such as preventive war, capital punishment, suicide, euthanasia, abortion, tissue and organ removal for grafting, recovery of stem cells from excess human embryos, gay marriage, and gay parenting. Macrodemus was surprised to discover that some authors discussed these sensitive issues in an intelligible, lively manner. Philarethes advised him to purchase a remarkable encyclopedia.[3] At home, he started reading it in small installments, and this prompted him to buy more books in the months that followed.

From these readings, Macrodemus derived some simple ideas:

- Ethics is a critical questioning of the principles that guide our choices and actions. It has a practical goal: the point is not only to wave principles around but also to act in accordance with them.
- Ethics is meaningful only for players who are in a position to make responsible choices: totally constrained actions are not choices and cannot be subjected to ethical assessment.
- Ethics questions the moral legitimacy of our actions, whether private or public. The issues raised are at two levels: meta-ethics and applied ethics.

Applied ethics covers the practical dilemmas already listed. Meta-ethical issues touch on the principles for distinguishing good actions from bad actions. In particular:

- Does the value of actions lie in those actions or in their consequences? If we ought to judge them by their consequences, what time frame should we take into account: the near future, the next generation, or future generations? And on what portion of humanity should we assess the effects of the action: myself, my immediate circle, my partners, strangers, neighbors, or all of humanity?
- Can we fail in our duties (e.g., abiding by contracts or respecting truth) to save a person's life?
- How should we define the welfare that we ought to promote, given the number of persons and the diversity of their conditions? Is it the growth in aggregate welfare, the growth in welfare per capita, the alleviation of suffering for the less fortunate, the definition of a basic quality of life, economic justice, the universal respect for the individual, the fulfillment of personal aspirations in all their diversity—or something else?
- Are there absolute or sacred values that apply to all persons and are, strictly speaking, unchallengeable, that is, impossible to discuss?
- What is the moral value of an action that is good for me but unacceptable to others?
- Can the same society harbor several moral systems?
- Is every individual free to define the good to which he or she aspires—in which case the State should remain neutral and impartial toward individual preferences—or should the State rank priorities and steer behaviors in accordance with a vision of collective welfare?
- Should we entrust to experts or specialized institutions the task of examining or even resolving our moral dilemmas?

Macrodemus understood that the distinction between applied ethics and meta-ethics was classic but not crystal clear, owing to a necessary alternation between the two registers: the dilemmas of applied ethics can be settled only by relying on a thoughtful, critical vision of principles, while principles are revised or deepened with the occurrence of practical cases that raise new issues.

The list of questions raised by ethics is not improvised. As the young bookseller confirmed, they had taken shape in the course of long discussions that had begun in antiquity and had intensified in the late 18th century. As religious references faded, two major families of theories had emerged (Table 99–1). Because of their relationship, marked by sharp mutual criticism, they would polarize the field of ethical reflection until our time. At one end was the Kantian ethic of duty (or "deontologism"). It does not define the nature of Good but subjects the rules of action to the universalization test: a rule is moral only if it can be universal, which means not instrumentalizing persons but respecting their dignity in all circumstances (Table 9–2). At the other end stood "consequentialism,"

[3] *Dictionnaire d'éthique et de philosophie morale* edited by Monique Canto-Sperber (1996). Updated in 2001, reprinted in 2004 in paperback (two volumes of 1,000 pages each), it has 330 entries, averaging eight pages, with a detailed bibliography for each. Two hundred sixty authors contributed, including many from outside France; the indexes are very helpful. There is a glaring gap between the dictionary's international quality and the weakness of ethics teaching in the French education system, in both mainstream and vocational programs. The situation is entirely different in English- and Spanish-speaking countries.

TABLE 99–1 The Leading Theorists of Ethics, from Antiquity to the Present

Author		Main work and date of publication	
Aristotle	(384–322 BC)	*Nicomachean Ethics*	320 BC
Pyrrho of Elis	(360–272 BC)	No writings (views known via Sextus Empiricus)	—
Marcus Aurelius	(121–180)	*Thoughts*	180
Thomas Aquinas	(ca. 1225–1274)	*Summa theologiae*	1273
Baruch Spinoza	(1632–1677)	*Ethica, ordine geometrico demonstrate*	1677
David Hume	(1711–1776)	*Enquiry concerning the principles of morals*	1751
Immanuel Kant	(1724–1804)	*Kritik der praktischen Vernunft* (Critique of practical reason)	1788
Jeremy Bentham	(1748–1832)	*An introduction to the principles of morals and legislation*	1789
Immanuel Kant	(1724–1804)	*Grundlegungen zu einer Metaphysik der Sitten* (Foundations of the metaphysics of morals)	1797
Jeremy Bentham	(1748–1832)	*Deontology*	1834
John Stuart Mill	(1806–1873)	*Utilitarianism*	1861
Henry Sidgwick	(1838–1900)	*Methods of Ethics*	1874
Francis Herbert Bradley	(1846–1924)	*Ethical studies*	1876
George Edward Moore	(1873–1958)	*Principia ethica*	1903
Émile Durkheim	(1856–1917)	*L'Éducation morale*, lectures given in 1902	1925
Richard Mervyn Hare	(1919–2002)	*The Language of Morals*	1952

TABLE 99–2 The Three Versions of Immanuel Kant's Categorical Imperative

Original German	English translation
Handle so, daß die Maxime deines Willens jederzeit zugleich als Prinzip einer allgemeinen Gesetzgebung gelten könnte.	Act only on that maxim whereby you can, at the same time, will that it should become a principle of universal law.
Handle so, als ob die Maxime deiner Handlung durch deinen Willen zum allgemeinen Naturgesetze werden sollte.	Act as if the maxim of your action was to become, through your will, a universal law of nature.
Handle so, daß du die Menschheit sowohl in deiner Person als in der Person eines jeden andern jederzeit zugleich als Zweck, niemals bloß als Mittel brauchst.	Act in such a way that you always treat humanity, whether in your person or in the person of any other, never simply as a means, but at the same time as an end.

which judges actions (or the rules of action) not on their intrinsic value but by measuring their consequences as a function of a specific good to be promoted (welfare, pleasure, happiness, utility, etc.). The main variant of consequentialism was the utilitarianism of Jeremy Bentham and John Stuart Mill, which aimed at the "greatest possible happiness for the greatest number of people," asserting that each person should "count as one and only one."

Examining the list of major ethical questions, Macrodemus had the feeling that some might directly involve his discipline or that he could have a say in the manner of addressing them. In particular, the number of humans seemed to be a key element in utilitarian ethics. However, a search of the bookstore's database with Philarethes failed to yield any reference work that presented a balance sheet of the relationship between ethics and demography. The young bookseller admitted there was a gap here.

Macrodemus's attention was drawn to a singular fact: contrary to a widespread belief, ethics was not principally concerned with issues of sexual morality. Most Ethicists were even convinced that these issues were secondary. Some leading religions stubbornly continued to place them at the center of their doctrine, but the entire history of moral philosophy was a long, patient effort to emancipate ethics from this religious dominance. The divine commandments could not constitute an autonomous source of ethics. For either the divine commandments were moral because they were already consistent with preexisting ethics, or they arbitrarily gave God the exclusive privilege of defining good and evil, which made human ethics superfluous. A divine commandment is an absolute truth, literally undebatable, in the sense that it is impossible to discuss, being sheltered forever from public debate, under the sole control of authorized exegetes; it therefore cannot have the slightest ethical value. There was no absolutist ethic but only absolutism *tout court*. The same reasoning applied to the references to "natural law" or "anthropological invariants," which in fact were merely variants of the argument from authority, often applied to sexual relationships or family configurations. True ethics could not rest on divine or natural foundations.

Macrodemus had never thought about these issues too hard. In conversing with Philarethes, he had the feeling that the Ethicists' approach, unlike the naturalist or religious approaches, maintained a relationship to truth that was very close to the scientific spirit: truth is not given, but is built up through a succession of proofs and counter-proofs. It must be subject to debate. It was not relativism. Some truths were now established, such as the Earth's rotation around the Sun, or the primacy of the respect due to the human person. But the only reason why they had been established is that they had been conquered. They would always need to take account of the novel issues that the latest events would keep raising.

But Macrodemus's curiosity had its limits. His interest in Ethicist literature mainly satisfied his concerns as voter or consumer, as patient or parent. He confessed to Philarethes that, as a demographer, he felt little concern for the Ethicists' dilemmas. The young bookseller conceded that demographic issues occupied only a tiny space in this vast literature. Macrodemus thought he understood why. The demographer is never in a position to resolve the life-or-death dilemmas explored by the Ethicists. He always arrives after the battle, after the action. He can, of course, estimate the losses due to war or genocide, identify the share of suicides in death statistics, count the number of abortions, measure the effects of medically assisted procreation on fecundity and fertility, and so on. More generally, he is bound to take an ever-greater interest in new reproductive methods, in new forms of union, in lives extended by medicine or cut short by violent deaths, and he does so chiefly in order to understand these phenomena and assess their impact on population dynamics. But when he steps in, the moral dilemmas have already been settled—or discarded. Unlike the physician, psychologist, or social engineer, the demographer does not operate on bodies or souls. He decided nobody's fate. To borrow the term used in ethical analysis, demography is not an "interventionist" science. It is only exceptionally associated with clinical or therapeutic trials. It even disregards the in vivo experiments of social psychology. We can say of the demographer what Proust said of the statistician: he takes a "bird's eye view," because his goal is not to find out about an individual life—even less, to influence its course—but to grasp the aggregate of all the existences that compose a population.[4] From his refuge on his promontory, Macrodemus appreciated this commanding position and was not about to abandon it.

One exception, however, caught his attention. While the Ethicists were very discreet about demographic issues, some chimed in with the ecologists in stressing the responsibility of present generations toward future generations. This topic took up some room in textbooks on environmental ethics (Pojman 2005). Monique Canto-Sperber's dictionary had an interesting entry on environmental ethics (Birnbacher [2001] 2004). But Macrodemus felt the issue had been treated rather superficially: the philosophers' plea for sustainable development still referred to a "population optimum," an old notion long since abandoned by demographers. Indeed, where should one locate this alleged population optimum, if not somewhere in the huge space between an underpopulated territory and an overpopulated territory? These, in turn, were extremely fuzzy concepts soon made obsolete by the passing of time. Demographers were not uninterested in the interactions between resource renewal, population size, and human welfare, but most were aware that the issue largely spilled over the field of demography. Just look at the Millennium Goals defined by the United Nations, in which demography took up only a limited share. The leading international researchers in those early 2000s (such as Amartya Sen [1987] and Joseph Stiglitz) were primarily economists with a thirst for justice; they made very limited use of demography, which mainly served as a backdrop for them. True, the ethical issues they raised did find some resonance among specialists of population studies in the developing countries, but without producing a definition of a robust ethical system for demographers.

Philarethes had listened to this speech intently. She did not seem to approve it entirely. But Macrodemus

[4] At the end of *Time Regained*, in the aftermath of World War I, the narrator reviews the social trajectories of the various characters: "Of course, circumstances and individual character have always a share in the matter and it was in quite different ways that Legrandin [. . .] had in his turn penetrated this *milieu*, that Odette's daughter had become related to it, that Swann and finally I myself, had entered it. [. . .] But, from the bird's eye view of a statistician who ignores reasons of sentiment and the avoidable imprudences which lead to the death of an individual and only counts the number of people who die in a year, one could observe that many people starting from the same environment as that with which the beginning of this narrative has been concerned reach another quite different and it is likely that, just as in every year there are an average number of marriages, any other well-to-do and refined bourgeois *milieu* would have furnished about the same proportion of people like Swann, like Legrandin, like myself and like Bloch [. . .]" (Proust, [1927] 1967, p. 346; English trans. 1931, with one amendment).

did not want to linger. He took his leave, promising to resume the discussion again some day.

II. THE DREAM OF MACRODEMUS

One fine day, Macrodemus received a visit from an Ethicist. People had found out about his activities. He was handling computer files produced by the processing of individual data. He should urgently declare them to the ethics committee with authority in such matters, under pain of being found in breach of the law. Macrodemus had no choice but to undertake the necessary formalities, which, all in all, were rather modest.

But he was in for a shock. He had thought he was above all suspicion. The issues pertaining to the black box of individual-data collection were of little interest to him: he had never administered a questionnaire in the field (unless in an earlier life, or as occasional supervisor in an exotic district). He obtained his material from statistical offices, on the principle that they had one single task: that of supplying him in a timely manner with the impeccable files that his sovereign science required. The files had to contain the complete list of unions and their children and, more generally, the exact calendar of all events (so that he could fill out all the half-lozenges of the Lexis diagrams). He had trouble understanding why it was so hard to obtain the exact chronology of migrations: why wasn't it routinely included in the files of all the statistical offices, with the variables clearly describing the origins of each flow? He could not imagine the efforts and transactions involved in producing demographic information. He readily believed that it was enough to remind every player (citizens, foreign residents, civil registrars, doctors, police, etc.) of what the public interest required. Overwhelmed by the force of his arguments, the authorities would finally decide to introduce the right questions into the right schedules, in order to collect impeccable responses and deliver them in the proper format to the demographer. One day, exasperated by the inertia of officials and the failures of statisticians, Macrodemus had not hesitated to publish an open letter in the press solemnly enjoining the authorities to follow his recommendations for producing better statistics.

Recommendations was one of his watchwords. Macrodemus had a very simple way of characterizing the social exchanges needed to produce data. It was a balanced theory of rights and duties. A single duty: that of the authorities to provide the relevant data. A single right: that of the demographer to receive them. To cope with the gaps, biases, and disparities in data from country to country, Macrodemus believed a two-step approach would suffice. First, you analyzed the deficiencies by identifying the data that should have been available and those that were not. Then, you promulgated the national or international recommendations that made it possible to remedy them—by insisting, for example, that a particular country add a specific question to a given register or identity document. The rest was a matter of willingness and enforcement. If the recommendations were not followed, it is because the authorities were incompetent or craven.

Occasionally, Macrodemus had a dream, that of an ideal data collection. It was an unmediated operation without the participation of a statistical office, survey department, or interviewers—a flow of data springing directly from the population to feed his computer. No ethics committee, no authority protecting individual data. And this dream extended to all of humanity: he saw on his screen a unified global system of vital statistics—or, better yet, a planetary population register—that would provide him in real time with all the data and indicators he needed. A large title appeared on the screen: "Universal predetermined harmony of data," written in a new language that he instinctively understood: demospeak. But his euphoria was short-lived. No sooner had Macrodemus started to query the database than the screen went fuzzy and displayed blinking failure messages: "Data concealed!" (by the populations surveyed) and "False data!" (owing to the incompetence of statisticians). Oddly, men and women refused to be counted with the same docility as livestock. They didn't want to be corralled, branded, or tracked. They demanded explanations. Strange words streaked across the screen: "consent," "non-response," "private life," "information technology and civil liberties," "borders," "informal," "irregular." Unfilled questionnaires fluttered in the skies, eventually cluttering up the screen. The awakening was rude.

Macrodemus would have liked to shake off this nightmare, but the vision returned, relentlessly. He lacked a field culture, a personal experience of the organization, and, ultimately, a genuine statistical culture to understand that data come from people, that they are burdened by transaction costs, and that the demographer's art is to be able to work with human data—in other words, imperfect data.

III. WHEN MACRODEMUS FANCIED THAT DEMOGRAPHY COULD MAKE A MOCKERY OF ETHICS

Each year, Macrodemus declared his data files to the Ethicists, irritated at having to comply with what he saw as a superfluous obligation. An idea occurred to him: wasn't there a radical means to expedite the issue of the links between ethics and demography by asserting outright that true science couldn't care less about ethics? After all, the goal of science—and this applies to demography as to any other discipline—is not to maximize human happiness but to augment the quantity of knowledge, irrespective of the use that humans make of it. Science is unconcerned by good and evil. It must only untangle truth from falsehood, and this quest for truth presupposes total freedom of research. Let's be Nietzschean, for heaven's sake! Let's assert the gay science beyond good and evil!

Energized by this revelation, Macrodemus donned Zarathustra's clothes and started traveling across Ethics Island preaching the theory of Superman—the Superman of science, naturally.

But the Ethicists were not impressed. They were experienced and subtle folks. It was even said that they had taken power on the island after the fall of a local autocrat, the "Super-scientist," who had compiled a database of all the islanders without telling them. The Ethicists promptly reminded Macrodemus that his claim to autonomy ignored some crucial points:

- To engage in an activity with no concern for its consequences on one's fellow-humans is, in itself, to take an ethical position, however negative.
- Declaring the free search for truth as an unconditional value is to defend its universal character, which is already an ethical position (we know, since Kant, that a rule of conduct is moral if it can be made universal, that is, if it can be adopted by all without harming anyone).
- The unconditional search for truth cannot prevent us from entering into conflict with other values, given the multiplicity of reference systems in our societies. But a researcher who ignores value conflicts would leave the task of settling them to others—moral philosophers, jurists, legislators, journalists. He would therefore lose the autonomy to which he claims title.
- In social science, data do not spring naturally from the soil. The source of sources is always the persons whose declarations are collected, whose administrative data are gathered, or who need to be observed for relatively long periods. This raises issues of consent, anonymity, secrecy, and information access.
- As people are not things but actors, they voice opinions, implement strategies, and interpret their own history: all these viewpoints, as well, belong to social reality, and deserve to be heard. Objectivating the researcher's viewpoint with respect to the actors' viewpoints is a scientific requirement that also has an ethical impact.
- Scientific activity is both individual and collective. On the one hand, the researcher legitimately seeks to establish his or her reputation in a competitive world. On the other, many agents and institutions are involved in the data production and processing chain. This raises issues of intellectual property and recognition, which are ethical issues as well.
- Knowledge production has a cost, if only to pay for professionals with the time needed to conduct research and methodical investigations. But the relationship with employers, orderers, and financers (very often governmental or international agencies) creates a tension between responsibility and freedom that has an ethical dimension.
- Science does not boil down to an intransigent quest for truth. It is also a path to fame and honors—resting on a pedestal that may be national or international, duly controlled by the profession or broadened to the extreme by the media, at the risk of upsetting the internal ranking of scientific values. Should one counteract distortions of this kind or, instead, exploit them? Does the publication of unverifiable but stimulating tests have its place in the advancement of research? All these issues touch on professional ethics.
- More generally, we cannot skirt around the relationship between science and society, which inevitably has an ethical dimension. Despite many doubts, we expect that scientific research, if anything, will help to increase collective welfare rather than decrease it, to strengthen personal rights rather than erode them. We could, of course, imagine a Nietzschean position that consists in denying the universality of personal rights and privileging a knowledge elite situated beyond good and evil. But this pretension to a superior amorality is itself an ethical position that, as such, must be open to discussion and refutation.

It was decidedly impossible to elude the Ethicists' grasp. Demography was admittedly a temperamental, freedom-loving science, but it could not waive its ethical duties. There had to be an alternative. Our macrodemographer did not give up. The Nietzschean model being of no help, he resolutely embraced a new strategy: outwitting the Ethicists at their own game. They wanted ethics? They would have it!

An opportunity arose: the authorities invited him to give a lecture in a series on "Ethics and society" at the Island's Grand Theater. Macrodemus embarked on intensive preparations. As he did occasionally in times of great need, he started to read some books, but this time without assistance from Philarethes; the young bookseller had defended her doctoral thesis and, apparently, taken another job. Macrodemus spent a whole month polishing his arguments. On the day of the lecture, he was ready.

IV. WHEN MACRODEMUS IMAGINED THAT DEMOGRAPHY WAS ALREADY ETHICS IN ITSELF

Before a large audience of invited guests, Macrodemus began his lecture. Ethics and science were inseparable. But some disciplines meet this requirement better than others, starting with demography. It was, for Macrodemus, the most ethical of the social sciences. It described the general dynamics of the population in a fully neutral, unbiased manner. The distance it spontaneously took from persons made it perfectly harmless. *Primum non nocere* (First, do no harm) proclaimed the Hippocratic oath in its Latin version. Well, Macrodemus argued, the observance of this great principle was enough to make demography ethically self-sufficient. No need to call on the Ethicists: demography was ethics through and through.

Macrodemus was convinced of the radically innocuous character of his activity. The demographer in a research center was neither an administrator nor a judge, neither a healthcare professional nor a social worker. He never handled personal files for the purpose of deciding people's fates but worked only on derived statistical files, which were always anonymized. His statistical activity could therefore have no effect on people, either negative or positive.

Indeed, Macrodemus noted, this neutrality was not specific to demographic analysts working on aggregate data. It also applied to researchers mining individual data, even when the data were of administrative origin. The main factor was not the nature of the source, which could be administrative (e.g., the justice ministry, the interior ministry, or a social-protection agency), but the purpose of the new file was that it was compiled for knowledge purposes, ruling out all intervention concerning people and, from this standpoint, totally disinterested. The demographer practiced better than anyone the art of detachment, far from human agitation.

And Macrodemus challenged his listeners: do you think that the subject of demography is life, love, death, and exile? If that were true, it would be terribly intrusive. In reality, demography talks of other things: births, unions, deaths, and migrations. The demographer is an alchemist who converts the milestones of human life into a prosaic series of dates. Hence, like the ancient sage who rises above to contemplate the restless world and seizes the order of things under the chaos of passions, the demographer remains impassible. He can study infant mortality without shedding a tear on the fate of children. If he counts abortions, it is without taking sides. If he tries to enumerate migrants, it is not to proclaim that there are too many or too few of them, but to measure the impact of migration flows on the demographic or social dynamics of the countries of origin and destination. If he tries to individually identify the old people who break longevity records, it is not out of love for the very elderly but to improve the quality of the data that will allow a modeling of the final phase of life tables. In short, demography is not sentimental.

Indeed, Macrodemus noted wryly, any listeners who fancied going up to his office one day would soon realize this. There's nothing more disappointing that a demographer's office: a computer, statistical compendia, files, a few memos. No cell holding a few guinea-pig inhabitants awaiting interrogation. The demographer lived outside the world. By spending his life handling aggregate series, like a hermit reciting his prayers, Macrodemus had no need to make contact with the anonymous individuals peopling his tables of figures. So what if he was told that such remoteness from the field was unthinkable in most other social sciences—anthropology, social psychology, sociological observation? He accepted this singularity and saw it as a guarantee of objectivity. Macrodemus was not unaware that a population consists of men and women in flesh and bones. But he had no reason to take an interest in people in themselves. Their sole value was as units of account or as underlying elements of variables allowing the construction of anonymous statistical relationships. The data-collection process was so heavily delegated and decentralized that the demographer, working at the end of the chain, could ignore its existence, although he might recall it when the quality of the data fell short of his standards.

It would soon be time for a break. The seminar organizers opened the floor to an initial discussion. A listener thought this conception of the demographer's profession was terribly narrow and reductionist. Macrodemus replied that an office researcher could make an excellent demographer provided he did not move out of his field of competence and remained clearly aware of his power and its limits. Demography had to be reductionist in order to be productive: depersonalization was the price to pay to construct an overall view of the population that remained beyond the reach of individual scrutiny and ensured the researcher's ethical neutrality.

Another attendee declared that, quite to the contrary, Macrodemus's vision did not lack grandeur. It was reminiscent of the contemplative reduction exercises practiced in antiquity, which marked the beginnings of the scientific approach (Box 99–1). Macrodemus accepted the comparison as a good omen. He cited the work of his friend Bibliodemus on the genesis of German demography in the 17th

BOX 99–1 The origin of the demographic viewpoint: the scholar's detachment, according to ancient wisdom

Greek and Roman philosophers, particularly the Stoics, practiced spiritual exercises that reflected their determination to remove themselves from the world by contemplating it from above and from afar. Imagine, they wrote, that you rise above the Earth until it is reduced to a sphere. Seen from on high, persons are merely particles, individual lives merge into a population, and you will see the hustle and bustle of humans give way to regular movements. Scipio's dream, described by Cicero in Book VI of the *Republic*, is the best-known example of this thought experiment. Pierre Hadot has shown that it fit into a long tradition of spiritual exercises of ancient philosophy, ranging far beyond Stoicism.

Emperor Marcus Aurelius, for example, quotes this "fine saying," which he attributes to Plato:

> That he who is discoursing about men should look also at earthly things as if he viewed them from some higher place; should look at them in their assemblies, armies, agricultural labors, marriages, treaties, births, deaths, noise of the courts of justice, desert places, various nations of barbarians, feasts, lamentations, markets, a mixture of all things and an orderly combination of contraries. (*Thoughts*, VII, xlviii)

The lofty Stoic perspective converges with the Emperor's viewpoint here. Significantly, the list includes the decisive events that were later to interest demographers: births, unions, and deaths. In the same period, the Romans had raised census and registration methods to a level of perfection that was not to be reproduced until the Renaissance. In particular, they shifted from an enumeration of noble families to the exhaustive count of individuals, issuing birth certificates to enable the Empire's subjects to prove their age (Nicolet, 1988).

More generally, the Ancients asserted the prerogatives of "theoretical life" or "contemplative life," which allows a handful of free men to observe the battles of interests among the multitude without taking part in them. The contemplative detachment of the wise man, as cultivated and celebrated by the Greeks at a very early stage, played a crucial role in the history of Western science by asserting the social figure of the scientist as disinterested researcher.

century. Stoic thought, which best embodied this distancing, had significantly influenced Leibniz and his disciple, the Protestant minister Johann-Peter Süssmilch, a keen student of demography. For the latter, the regularities of demographic phenomena could be contemplated and understood only from the standpoint of God, who is located at the "geometral point of all perspectives." It is from there that we perceive the "divine order,"that is, the optimal order of the world, which combines—or so Süssmilch believed—the best birth and death rates imaginable (Rohrbasser, 2001). Provided it was duly secularized, this point of view remained valid.

It was objected to Macrodemus that the notion of modeling scientific detachment on divine detachment reflected a very elitist approach. But Macrodemus countered with the example of John Graunt, the man who inaugurated demography by tabulating deaths in the city of London. In his seminal essay of 1662, Graunt expressed his satisfaction that demographic computations enabled a mere citizen of London, a merchant by profession, to have access to a comprehensive science and hence be elected to the Royal Society. Very early on, the pioneers of demography realized that tabulation and computation gave everyone access to a totalization capacity hitherto reserved for kings or theologians. The divine gaze on the demographic order of things was now within reach of the lowest commoner, provided that he mastered the appropriate techniques.

To a sociologist who asked him what he thought of Émile Durkheim's approach, Macrodemus explained that demography realized almost effortlessly the ideal proclaimed by Durkheim in 1894 in *Les Règles de la méthode sociologique* (The Rules of the Sociological Method): it spontaneously treats social facts "as things," it does not let itself be thrown off course by players' motives, and it steers clear of preconceived ideas and value judgments.[5]

[5] Émile Durkheim's *Le Suicide* (1893) is the textbook example of a statistical analysis that may be conducted in the absence of the interested parties or their close circle (note, however, that Durkheim mentions in *Le Suicide* an important collection of letters left by persons who committed suicide and that he returns to it at the end of the work, taking care to check that these testimonies do not contradict his typology of suicides). Throughout his career as sociologist and anthropologist, Durkheim remained a desk-bound scholar, remote from the field. When he agreed to run the Commission for welcoming Jewish refugees from Russia in World War I, he performed his duty with dedication, but confided to his close friends that he suffered from this change of register: "To decide people's fates on the basis of written reports without seeing the interested parties leaves the door so wide open to error that it makes me shudder. We're working in the live flesh, a job that's not for me" (Durkheim, 1998, letter to Marcel Mauss, March 12, 1916).

V. UNIVERSAL, IMPARTIAL, AND NEUTRAL?

After the break, Macrodemus resumed his presentation. He explained that the demographer treated people in a universal, impartial, and neutral mode. Universal, because in good demography everyone counts. Impartial, because results are not influenced by the observer's position and interests. Neutral, because the goal is not to describe what must be but only what is. And Macrodemus set out to elaborate these three points.

He began by quoting a remark by Jacques Vallin at the beginning of an introduction to demography: "We cannot count individuals or compile statistics about them unless we treat them as if they were all the same" (Vallin 1992). This statement contained a dual concept: individual enumeration and a fertile reductionist approach. The notion of enumerating individuals may seem simple but it is not self-evident. For a long time, authorities counted intermediate management units (houses, lineages, hearths, concessions, etc.) or pivotal individuals (freemen, men fit to bear arms, taxpayers, producers, the faithful, *de jure* citizens, natives, etc.). The notion of counting identically people of either sex and of all ages—without discrimination by status or origin, and irrespective of the price that can be assigned to them in the market for economic or social values—is a late development. It first emerged in Rome in around the second century AD (Nicolet, 1988). It did not reappear until the 18th century.

To realize this, we need only look at the lifelines in the Lexis diagrams: demographic analysis rests on the individual, not the family; it is not intrinsically family centered but individualist.[6] Family and household statistics are a useful but fortuitous extension of the demographer's work. Reproduction indicators, for example, do not start by separating couples that reproduce from those that do not; they aggregate individuals of the same birth cohort and try to see if this set collectively produces enough children to replace the cohort. The fact that some individuals remain childless and others have an above-average number of children does not influence the construction of the reproduction rate, although it is a useful element to take into account when explaining behaviors. In sum, the demographers' reproduction indicators can operate just as well in a Platonic society that collectivizes children as in a liberal society that individualizes them. What matters is the end result of reproduction at the cohort level. This is because demographic analysis bypasses ready-made social groups. It is content with placing individuals on a time axis. The cohort is only a time grouping that ensures a formal equivalence between persons. The equivalence principle likewise amalgamates persons born locally and those who have arrived from elsewhere, that is, natural increase and net migration, interpreted as two growth factors of a population. By the following year, demographic accounting incorporates the two additions into the reference population, because it naturally assumes that one existence is worth another, whatever its origin.

In its very principle, Macrodemus stressed, demography treats individuals as units of account, without weighting them in advance by any factor whatsoever. Such a notion presupposes an equivalence principle defining the membership of all individuals in a common humanity (Desrosières, 1993; Boltanski and Thévenot, 1991). Now this natural presupposition of demographers (shared with many statisticians) did not appear until late, at the same time as the emergence of the individual as an autonomous subject of rights and duties in moral philosophy. Macrodemus underscored the strange affinity here between the demographic calculus and the utilitarian calculus championed by Bentham and Mill: both procedures implement a principle of accounting universality that attests to an equal regard for all members of humanity.[7]

In the second part of his presentation, Macrodemus set out to show that he had adopted some of the Ethicists' basic ideas. The first was that all moral theories begin by defining a reference population whose members possess equal dignity. For Aristotle, the group consisted of free citizens, excluding slaves and half-breeds. For the Founding Fathers of the American Constitution, Blacks and slaves could not be counted on a par with Whites and freemen. The Australians did not start counting Aborigines until 30 years ago. And one could give further examples. By contrast, with utilitarian philosophy, the definition is as broad as possible. It potentially extends to all of humanity and even beyond. Macrodemus did not share the prejudice, still widespread in France, that saw utilitarianism as an economic ideology centered on selfishness and the pursuit of personal interest. He was sufficiently conversant with the founding texts of utilitarianism to understand that it was, in fact, a resolutely altruistic moral philosophy. In the phrase borrowed by Bentham from Francis Hutcheson, ethics sought "the greatest happiness of the greatest possible number" (Bentham [1781]). The balance of ills and goods should be

[6] Contrary to the argument defended by Rémi Lenoir (2003).

[7] Later, as we know, economic theory dealt a severe blow to the civic and community dimension of utilitarian calculations by reducing "utility" to a purely economic function (Pareto's "ophelimity") and treating every individual as an entrepreneur, including when he decides to form a union and have children. But that's another story.

assessed for the aggregate social body and ultimately for all of humanity, as each individual had an equal claim to welfare, regardless of his or her condition. Bentham defined the principle of the computation of benefits and negatives ("pleasures" and "sorrows") in a famous phrase—"everybody to count for one, nobody to count for more" (Bentham [1781])—later endorsed by John Stuart Mill (1861).

All things considered, it was a subversive idea, the product of a long history, of which Macrodemus could provide only an outline. It is potentially embodied in Stoic cosmopolitanism and, in an altogether different manner, in the equivalence established by Christianity between the children of God, all of whom were identically marked by original sin and the possibility of redemption. The notion that each person counts is expounded in the American and French declarations of the rights of man. It was fulfilled in the implementation of universal suffrage ("one man one vote"), which was accepted only at a late stage, in the face of stubborn resistance (Rosanvallon, 2002). For a long time, people thought it impossible to reduce the heterogeneity created by dependency relationships (master/slave, white/black, settler/aborigine, master/servant, man/woman, native/immigrant, etc.). The right to vote was denied for this reason to the homeless, the poor, servants, women, former slaves, indigenous inhabitants, and so forth, and most countries still deny it to immigrants—an archaism that will eventually disappear like all the others. The paradox is that universal suffrage without a means test or weighting was a path to emancipation whose access was denied to the subordinate categories, on the grounds that they were not sufficiently emancipated. They were judged too dependent on dominant groups or heads of families (just as, today, immigrants are barred from the electoral process on the grounds of their presumed dependence on foreign interests). By deciding to count everyone without discrimination, irrespective of their legal status, demographic statistics embedded in the core of its practices a universalist principle. It is also the principle of democracy on the march, which it sometimes takes one step further—even if this means having to face the old condemnation (dating back to Edmund Burke) of the "atomization" of the social bond triggered by the "rise of individualism."[8] Each person counts as one and only one: an unexpected consequence of this utilitarian formulation is that the reference individual cannot place his own interests above those of others when seeking to assess the consequences of his action. The obligation to grant the same weight to everyone, including to oneself, takes the impartiality requirement to the extreme. The utilitarian calculus must logically produce the same collective results, whatever the actors' positions.[9]

The negative part of Bentham's precept ("nobody to count for more") establishes a leveling principle: for the demographer as for the utilitarian philosopher, enumerated human beings are neither big nor small, neither powerful nor destitute. In a further stage, of course, demography, expanded into social statistics, takes heterogeneity into account by introducing all sorts of variables that differentiate situations and behaviors, but it does so a posteriori, by attaching these values to bases initially regarded as equivalent. It is precisely because it uses an equal, neutral background that it can measure differences, detect inequalities and, accordingly, objectify the variations in the probabilities of access (such as differential mortality). This initial leveling is anything but trivial, as attested by the resistance from people of quality, who are not fond of being quantified.

Macrodemus saw another proof of the impartiality of demographic calculus in his refusal to weight the planet's inhabitants according to their distance. Seen at a remove, the world no longer offers a privileged vantage point separating nearby peoples from faraway peoples. Again, this was a break from our habits. We have a natural tendency to weight the existence of human beings according to the distance between them and us. Adam Smith had already posed the question: if an earthquake destroyed China and its millions of inhabitants, would the English be affected? The famous apologist for the Chinese mandarin expresses the same notion: if I can make a fortune by simply pressing a button that remote-destroys a Chinese mandarin whom I've never met, would I hesitate for one second? And in its present version, the apologist for the bomber or cruise missile says the same thing: it is easier to obey an order to kill anonymous populations at a distance than to execute nearby or visible individuals point-blank. A modern variant: we feel more interest and compassion for victims that television brings close to us than for invisible victims.

[8] Edmund Burke, in *Reflections on the French Revolution*, castigates "the metaphysical and alchemistical legislators" who "have attempted to confound all sorts of citizens, as well they could, into one homogeneous mass [. . .]. They reduce men to loose counters, merely for the sake of simple telling, and not to figures whose power is to arise from their place in the table" (Burke [1790] 1980, p. 398).

[9] This impartiality constraint, a sort of "veil of ignorance" before its time, is an equivalent of Kant's universalization test: a point of view that is not interchangeable with another person's point of view cannot have moral value. That is why the present defenders of the utilitarian theory staunchly deny that it allows the sacrifice of the fate of a random individual to the benefit of an impersonal collectivity, as frequently objected by Ethicists of Kantian obedience.

The issue is all the more acute today with the disappearance of physical obstacles to information gathering and transmission in our global village. There remains a pure distance, the psychological or cultural distance, which measures our real degree of interest in others. It is taken into account by the media, who select images from information agencies depending on what they expect to be the level of public interest. The giant tsunami that devastated the South Asian coasts on December 26, 2004, causing almost 300,000 deaths (a figure whose size was not known until several weeks later), captured the attention of Western media for a sustained period. The event triggered an unprecedented solidarity movement, coordinated by the United Nations, which had castigated the selfishness of the leading countries. Was it the number of victims that succeeded in offsetting the effect of distance? Would we have shown equal concern if the victims had not included many Western tourists? How would we have reacted if the catastrophe had mainly struck a poorer region less attractive to tourists, such as East Africa? The principle of "everybody to count for one" is at variance with our general propensity to measure the value of human life in terms of its physical or social distance. In this convergence with the Benthamite imperative, the demographic approach shows its solid ethical foundation.

A recent episode had particularly shocked Macrodemus. The intrinsic impartiality of the demographic approach had been undermined during the preparation of the 2000 U.S. census, at the end of the Clinton presidency (Anderson and Fienberg, 2001). The Census Bureau had suggested improving the census coverage by performing in-depth surveys in the most disadvantaged urban areas. Republican members of Congress had objected, fearing that this improvement would increase the electoral weight of the Democratic Party, which has a stronger presence in these districts than the Republican Party. The census results determine electoral redistricting in a country that takes for granted that minorities should be locally represented by elected officials of the same ethnic origin. Even as the partial defense of political interests was intruding into data collection, it was the Census Bureau that was accused of political partiality: the contradiction was such that the Bureau's director preferred to resign. The ethics of demographic and statistical neutrality had been openly violated, since the electoral weight and partisan weight of individuals had been taken into account to determine whether they were worthy of entering demographic statistics or not. For Macrodemus, this example simultaneously illustrated the dangers of too close a connection between the collection of demographic data and political organization, of which the United States offered an extreme example.

Macrodemus proposed strengthening the impartiality principle by extending it from spatial distance to temporal distance. This extension was a logical consequence of demographic analysis. A generation that wants to make an unbiased assessment of the impact of its behaviors should not place its own interests above those of future generations. The only way to achieve true impartiality would be to neutralize temporal proximity in the same way as physical proximity. The Ethicists who had pondered the issue were wondering about how to make present generations sensitive to the interests of future generations, which, by definition, are composed of distant, anonymous, and unknown beings. For Macrodemus, demography could play a decisive role in instilling such awareness. The calculation of reproduction rates, combined with long-term demographic projections, is indeed consistent with this impartial perspective that puts the interests of all generations on the same footing: it places inter-generational links in a dynamic framework that, by construction, grants equal weight to the players and output of successive generations, whereas economists do just the opposite: taking our preference for the present for granted, they apply discount rates to long-term investments, devaluing the distant future to the benefit of the near present.

Macrodemus refrained from giving other examples. He concluded his lecture with a call for mutual recognition of demographers and ethicists. Our objectives are the same, he assured.

Macrodemus was warmly applauded. The Ethicists had listened to his presentation in silence. They announced that a young Ph.D., recently promoted spokeswoman for the Higher Council of Ethicists, would respond. Macrodemus was surprised to recognize Philarethes, the young lady who had welcomed him a few months earlier in the Island's general bookstore.

VI. THE LIMITS OF THE ETHICAL CONTENT OF MACRODEMOGRAPHY: THE ETHICISTS' RESPONSE

Our guest, Philarethes began, has just made an interesting contribution to research ethics. His thesis is simple: the demographic approach is universal, detached, impartial, indifferent to personal cases, and disinterested. Do these qualities suffice to proclaim the intrinsically ethical value of demography? I don't think so, and here's why.

First, your ethics, dear Mr. Macrodemus, are essentially negative. You quoted the abstention phrase at the start of the Hippocratic oath: *Primum non nocere*. But that's just the beginning of the ethical approach, a basic reminder of what we Ethicists call the Golden Rule: "Do not do unto others what you would not have done unto yourself." Does doing no harm suffice to meet all one's obligations? Surely not.

Second, you tell us that the demographer practices ethics spontaneously, without having to give it a thought. Now an ethics worthy of the name cannot remain tacit. It must be practiced cognizantly, and rest on principles that can be stated and discussed publicly. "Everybody to count for one" may be a mere advertising slogan concocted by communication agencies in charge of launching a census. We now need to give it meaning.

Third, the invocation of ethical principles cannot be confined to self-justification. Many demographers and statisticians are convinced they are serving the public interest. The notion that one could suspect their attachment to the ethics of neutrality seems radically inappropriate and unfair to them. Convinced that their practice can harm no one, whether by its goals or by its methods, they reckon that their only problem is to get the public to share this belief, and that a large share of so-called ethical issues are, in fact, just communication problems. In sum, their practices are good; all that remains is to advertise the fact. This is to ignore that the ethical approach is relational. It's built up through interaction with colleagues, partners, the public, and limited partners—not proclaimed on a solitary basis. Where are the documents that constitute your ethics code and regulate your dealings with your interlocutors?

Philarethes took the example of the impersonal, anonymous character of data. She quoted one of the few French statisticians to have explored these issues: "The need to know individual data and the need not to take an interest in them are the basis of statistical confidentiality" (Padieu, 1991, p. 38). The problem is that the second need does not have the same status as the first. It's a form of abstention obtained automatically, without special efforts. In practice, the statistician working on thousands of individual recordings has no merit in obeying this rule. If he happens to handle individual files that have not yet been anonymized (e.g., when updating a longitudinal survey), we can easily imagine that his attention may be drawn here and there to a person displaying a rare characteristic (a woman with 10 children, a household with exceptionally high income, an exotic place of birth, a TV show host, etc.), without this ephemeral attention leading to public disclosure. We may find this situation fairly reassuring. If respect for confidentiality had to rely solely on the virtue of each person whose work involved handling the data, we would doubtless have reason to worry (with 500 people processing 5,000 individual data files each, the risk that at least one worker will commit an indiscretion is high). The fact that the manager of a statistical operation has no interest in divulging an individual datum offers the best possible protection. But this is more a consequence of data-protection arrangements stipulated by law than of a personal ethical disposition. Let's not overestimate the moral merits of the statistician who merely respects statistical confidentiality: this secrecy depends very little on his moral qualities.

Philarethes expressed her skepticism about the demographer's intrinsic impartiality. Far from being cosmopolitan, demography had often lent itself to nationalist manipulations. To say the least, demography did not escape the tendency for each country to focus on its own problems and to reduce enumerations to the "accounts of power." In many European countries, international migration boiled down to the immigration question, that is, the place of foreigners "on our turf,"—a real problem, admittedly, but one that was far from exhausting the issue. The United Nations' sustained use of demographic data, thanks to the compilation and harmonization undertaken by its Population Division, clearly showed that demography spoke the same language on all continents and practiced the same methods everywhere, but the UN's work was not itself without incidence on the fate of nations. And Philarethes gave an example inspired by one of her past conversations with Macrodemus.

The latest UN 50-year projections revealed that Yemen might overtake Russia in population size, making it one of the world's demographic giants. Paul Demeny, demographer at the Population Council and editor of the journal *Population and Development*, relied on these projections in a doomsday article that used this scenario—Russia overtaken by Yemen—as the symbol of the demographic threat from the Muslim world to an old Europe resting on privilege (Demeny, 2003). The article had a public impact. And the Yemeni authorities were able to exploit this unexpected publicity to obtain a mega-loan from international monetary organizations. The problem is that some demographers specializing in the Arab world challenged the quality of the data used: it turns out that Yemen's fertility rate is not seven to eight children per woman but rather five, which means that its demographic transition is already well under way and that its future growth would be less robust than what the UN projections announced (Courbage, 1999).

I don't have the means to settle this dispute among demographers, Philarethes hastened to add, but I'm struck by the fact that the international image of an entire country and, consequently, its economic fate can be so dependent on the uncertainties surrounding the demographer's calculations. I thought, she added, that the statistician could frame his measurements in a "confidence interval." Isn't there a statistical ethic that the demographer should have followed in this case? In any event, the notion that the remote handling of demographic macrodata protects local populations from all intervention (benevolent or malevolent, it makes little difference) is clearly refuted by such an example. Generally speaking, the main justification for demographic coverage of the planet since World War II has been that the data gathered should allow an expansion of action programs in developing countries—for reducing fertility, combating HIV/AIDS, or intervening in migration flows. This is not reprehensible in itself, and is perhaps even positive, but we must conclude that the practice of demography is not without consequence to the fate of the countries concerned and that the demographer would do well to reflect on it.

Philarethes paused. We need to go further, she continued. You stressed the demographer's impartiality, his indifference to social weightings, his lack of interest in individuals. But impersonality, when linked to bureaucratic indifference, is a double-edged quality. It can, depending on circumstances, provide people with the most efficient protection possible or cover up the worst excesses. The demographic study of populations largely owes its neutrality toward individuals to the fact that it retrieves the standardization work already performed by society: the main life events have been ritualized, then recorded, by the Church (series of baptisms, marriages, and burials), before being recovered by civil registration officials (births, marriages, deaths). Today, the information is sent by postal mail or computer networks to statistical institute delegations, then centralized and put through the statistical number-cruncher. Survey data follow similar paths. The whole process unfolds, as Alfred Schütz put it, "like a letter in the mail," through channels that are not those of interknowledge or personal exchange but require a new form of trust, which has become crucial in our societies: "systemic trust" (Luhmann, 1989), that is, a reasonable confidence by individuals in the proper functioning of an anonymous bureaucracy.

You are not unaware, she went on, that one of the most mind-boggling phenomena of contemporary history is the ease with which ordinary people ensured the success of the final solution perpetrated by the Germans against the Jews, as if it was a mundane business matter. An army of functionaries and employees contributed to it by applying measures of which many were—in Raul Hilberg's concise phrase—"of a bureaucratic nature, anchored in routine, habit, and tradition" (Hilberg, 1985, p. 219). This required not only the contribution of railroad employees and police officers but also that of ordinary clerical workers "attached to the respect of form" and for whom the Jews "were only a word in a subheading of their files." A careful examination of the evidence reveals that "normal procedures were applied to abnormal situations, as if the decisions were in no way extreme." One had to hate the Jews in order to decide to persecute them, but (contrary to what Daniel J. Goldhagen imagines) it was not even necessary to hate them in order to contribute to the smooth functioning of the persecution machine. Human problems were kept at a distance, largely neutralized and de-realized: they became technical problems. Correcting Hannah Arendt's famous phrase on Eichmann, Raul Hilberg concludes that the "banality of evil" operated at the ground level rather than among top decision makers: they were fully aware of what they were doing, and knowingly relied on the inexhaustible resources of bureaucratic and "systemic trust" (Hilberg, 1985). In sum, a core of hate surrounded by a gigantic halo of indifference proved capable of fueling the enterprise of extermination.

Macrodemus wanted to interrupt her. He couldn't stand this penchant of the Ethicists for continually referring to History's worst misdeeds, as if statisticians or demographers were potential murderers.

But the Ethicists' spokeswoman had anticipated the objection: I know what you feel—you feel miles removed from such horrors, and you think this historical reference merely shrouds the issue we're discussing in useless pathos. You're wrong: this old history, which neither you nor I have known, will never be over. It gives us a permanent lesson, namely, that indifference to people as guaranteed by automated procedures has no ethical value in itself. It may protect the people concerned as it may protect their persecutors. Ordinary bureaucrats, Hilberg writes, acted "with deep indifference toward the nature and consequences of the acts performed" (Hilberg, 1985, p. 233). Let us apply this vigilance to demography (Selzer and Anderson, 2001; Selzer, 1998; Rémond, 1996). In ordinary times, the demographer's distanced, neutral treatment of persons has a negative ethical virtue: it does not harm people. In times of crisis, the reverse is true: neutrality can become reprehensible. It is neither beneficial nor detrimental, neither good nor bad.

And, to support her statement, Philarethes went back to census files and population registers. The notion of anonymity is more complex than you think, Mr. Macrodemus. Anonymized data may remain indirectly personalized if they include uncommon local or individual identifiers. If your file shows a doctor in a given age group with a given number of children in a particular locality, it's easy to track him down through a medical directory. Small groups localized with too great a precision are vulnerable to identification attempts. Also, the demographer, as you well know, does not always work on anonymous files. Increasingly, he uses longitudinal files, which, by definition, require the long-term archiving of individual profiles. Population registers (in some countries), residence-permit registers, social-insurance databases, and so forth are also long-term databases accessible to demographers and requiring special protection. There's nothing reprehensible about working on such data, provided that proper confidentiality precautions are taken. But all this requires special protocols. Plain routine won't do.

Philarethes offered a final argument. The demography practiced by Macrodemus did not embrace all of demography. The Ethicists were receiving ever more requests for consultation from demographers who combined macro-analyses and micro-observations. Witness this recent example: French statisticians are thinking of setting up, for research purposes, a vast cohort of children, similar to the Millennium cohort in Britain. The project would track 10,000 to 15,000 children from pregnancy to adulthood by combining direct surveys of parents, collection of biomedical data from children, information retrieved from social-protection agencies and schools, and environmental information gathered by means of sensors installed in homes. An undertaking as multifaceted and as long-lasting in its purpose takes us far, very far, from the national or planetary macrodata dear to the demographers of yore. It requires special ethical arrangements. The researcher no longer keeps human subjects at a distance but follows them closely throughout their lives: this raises serious issues of consent and confidentiality.

It's an extreme case, you will say, but we could mention simpler operations that consist in deepening macrodata by means of a microsurvey. One example is the international program for checking, individual by individual, the civil-registration records of all residents of a country who state their age as 110 or older. The demographer of mortality embarks on this type of operation because he wants to make a detailed description of mortality distribution at the oldest ages; he wants to see how it operates at the farthest tip of the population pyramid, where even the largest populations are inevitably reduced to a handful of individuals. Don't tell me, Mr. Macrodemus, that there's an unbridgeable gap between macrodemography and microdemography. On the evidence, they are tied by a continuum that is being explored in ever-greater depth. Moreover, who can fail to notice that the macrodemographer's field is narrowing? Marriages, which he stubbornly keeps tabulating as he did 30 years ago, have ever less significance, owing to the increase in cohabitation without marriage. If he wants to capture the informal chronology of union formations, he must go and ask the interested parties directly by means of a questionnaire. The chronology of migrations poses the same problem. The macrodemographer must ally himself with the microdemographer to update our knowledge base on the evolution of demographic behaviors. The ethics of macrodemographers and microdemographers will increasingly converge.

Philarethes offered her conclusion in the form of a question: dear Macrodemus, you're a demographer, but have you ever asked yourself why? There are a host of reasons for wanting to count the men and women who inhabit our territories. We may want to count because the interested parties want to be taken into account. We may want to count because of a desire to understand. We can count to assess needs, to measure what separates real-life situations from our ideals of justice. We can count because we want to speculate on the probability of survival and estimate the yield on annuity investments. A government may count to render accounts of its management. It may also count to control, and sometimes to exclude. In short, one may have the best reasons and the worst reasons to count. One thing is certain: nobody counts for the sheer pleasure of counting. Falling back on a technicist position does not dispense you from asking yourself about the purpose of your work and, ultimately, about its impact on the population and minorities.

The lecture was about to end. Macrodemus had neither the strength nor the time to reply to Philarethes. That would come later, no doubt. He returned to his outpost, firmly resolved to limit his contacts with the Ethicists to a bare minimum. However, the future would decide otherwise.

One fine morning, when Macrodemus was seasonally adjusting a Maltese or Cypriot series, there was a knock on the door of his workshop. He recognized an old colleague, whom he'd lost sight of, but whose name he still remembered. It was Microdemus.

Microdemus, too, had washed up on the Ethicists' island and had heard about the hermit on the promontory. He explained to Macrodemus what he was doing: a longitudinal survey on migrations between the islands of the archipelago and the mainland, based on a long questionnaire combining sociodemographic and economic questions, plus a series of qualitative interviews. He was looking for framework data, which Macrodemus perhaps could supply. That was the beginning of their relationship.

Macrodemus and Microdemus had very little in common. But the fact that they both lived abroad brought them close. They discovered that they were complementary. Microdemus told Macrodemus he had settled in the plain, near a village, where he was living in a house open to all visitors. He had trekked up and down the island and held long conversations with the Ethicists—including Philarethes, whom he knew well. He urged Macrodemus to get out of his workshop and explore the island at length. Soon, their relationship became more informal. They called each other by their abbreviated names, Mic and Mac. Each initiated the other in his science. The couple they formed was sometimes reminiscent of Robinson and Friday, sometimes of Bouvard and Pécuchet. As nothing in their appearance told them apart, the children nicknamed them Tweedledee and Tweedledum. In fact, they had become inseparable.

VII. DIALOGUE BETWEEN MACRODEMUS AND MICRODEMUS ON CHANGES IN DEMOGRAPHIC SURVEY METHODS

I wonder where demography's heading, Macrodemus confided to Microdemus one day. At times, I feel like a dinosaur, the last of the Mohicans. My master, Mathodemus, who still drops by to see me from time to time, is desperate; he feels his lifetime's teachings are lost, and that no one will ever be trained in demographic analysis anymore.

I don't share his pessimism, answered Microdemus. They're still training analysts, but of a new kind, who put demography in the broader context of social statistics. They can no longer merely adjust for structural effects by constructing "typical populations" free of disruptive events. They try to analyze files of individual data and to subject them to multivariate analyses that take durations into account and go beyond mere description, toward a form of statistics that is ever more explanatory.

But is it still demography? Macrodemus retorted.

It's still demography if it tries to shed light on the genesis and evolution of demographic behaviors: births, unions, deaths. But the novelty is that these behaviors are now viewed against a backdrop comprising a wide range of social, economic, educational, and institutional factors. The analysis of individual files requires new analytical techniques. So Mathodemus lamented the decline of demography? One could counter his complaint with a symmetrical one: is it conceivable that a demographer trained 30 years ago by Mathodemus, who had developed his expertise 15 years earlier, might never have subsequently received the slightest additional training to supplement his technical capabilities? Can we accept the notion of a researcher not enriching or upgrading his methods in 30 years? Tell me frankly, Mac, what new methods have you learned since your initial training? Have you, for example, familiarized yourself with duration models, which our young doctoral students and new recruits effortlessly master today?

Macrodemus carefully avoided answering. The idea of incorporating a training plan into his career plan had never occurred to him. He simply replied:

Why, then, change methods of demographic analysis that work? Sex and age will remain sex and age, fertility and mortality distributions will always need to be modeled, and Lotka's equations are here to stay.

It's the relationship to people, to human subjects, that's radically changed, Microdemus continued. The researcher must now keep close track of behaviors and question respondents in depth. This means asking for their cooperation and, ever more often, their informed consent. As you well know, Macrodemus, the new demographic behaviors elude official recording. Marriages no longer comprise all unions; families are reconstituted; new kinship ties emerge; people adopt children in lieu of biological children or, on the contrary, to add to the number of siblings; couples now form without cohabiting, calendars are getting complicated, complex ties are developing between demographic events (unions, separations, births, recovery of children) and the various paths followed by individuals (educational, residential, migratory, occupational, health-related). Length of life, quality of life, and number of persons are interacting variables. How can you possibly grasp all this richness by the sole grace of official aggregate data? Ever more often, demographic information must be obtained directly from the interested parties. To know what's going on, you have to go and ask people—it's that simple. You have to ask them questions about informal or unofficial behaviors. You need to jog their memories to reconstruct past events that have generated present situations. In short, you need to establish a new kind of relationship with people.

That's precisely what worries me, Macrodemus reacted. How do you make sure that people aren't making things up?

It's very hard to make things up. Responses given at random in a questionnaire would immediately be spotted as aberrant and removed from the data file. If they're simply errors, we can screen most of them through consistency checks upstream, inserted into the computer-aided personal interviewing (CAPI) programs activated during the interview; or we can correct them downstream through consistency checks that restrict the field of compatible responses. The problem doesn't lie there. Rather, it's in the respondents' tendency to standardize, minimize, and simplify (male bluff is not a prejudice; it explains many gaps between male and female responses). We accordingly need to estimate response bias, for example by benchmarking to external framework data or, more subtly, by combining different questions.

OK, but there are other sources of bias. I imagine there are a lot of things that people don't dare admit to you?

Only avowable practices are avowed, Microdemus conceded, but that's true of any survey or administrative record: income surveys never reveal tax evasion or embezzlement. If you want to study deviant or clandestine practices, you need other investigation methods. In fact, we draw a distinction between the private and the intimate. Respondents quickly understand that a question about private life (date of first-union formation, for example, or ex-spouse's occupation) is not prompted by an unhealthy personal curiosity but reflects a scientific inquiry of general import. If the questionnaire is well designed, if the survey managers are clearly identified as working in the public interest, then the operation will come across as professional and legitimate, and the ethical issue for us will be, instead, not to abuse the trust that respondents readily tend to place in us.

But, Macrodemus insisted, some surveys go further, like surveys on drug addiction, sexual behavior, and abortion. How do you manage?

I was coming to that. Such surveys are always tricky, of course. They need to follow precise protocols, guaranteeing confidentiality and anonymity (extreme cases may involve erasing individual contact information at the start of the telephone conversation). They must be conducted for a public-interest purpose: AIDS prevention, fight against discrimination, identification of target beneficiaries of a social program, and so on. That purpose must be stated fairly: for example, one must not announce a benefit that could only be, at most, an indirect consequence of the study. Above all, the surveys must win the informed consent of the persons concerned, when the topic is sensitive, that is, when it may reveal membership in a vulnerable or stigmatized minority, or offend the sensitivity of interviewees by the very fact that the question is asked. "Informed consent" means written and duly verifiable consent. If all these conditions are met, it becomes possible to ask intimate questions concerning—as it were—private life within private life. That said, each question must be proportionate to the questionnaire's overall purpose. This means, by the way, that the purpose must be clearly stated to respondents: the questionnaire plan must not throw them off balance in the process.

That seems obvious, Macrodemus.

Not all that obvious, said Microdemus. You'll find questionnaire theorists who, on the contrary, recommend jumping from one subject to another during the interview, on the assumption that the answers will be more spontaneous and more authentic.

Indeed, Macrodemus recalled, I had a visit one day from an interviewer working for a private firm, who questioned me in the manner you mentioned about my tastes and attitudes in a wide variety of areas. It was heavy going.

Actually, it's an entirely different conception of surveys, consistent with the psychologists' vision. The point is not to go and see people to gather the sociodemographic information they have, but to design the survey situation as a revelation experiment in itself: the interviewer isn't trying to collect your information but to trigger and analyze your reactions. The ethics of the questionnaire as we practice it in sociodemography generally excludes this type of experimental relationship. We don't see the respondent as the subject of an experiment: he's cooperating with us to produce missing information. He's almost a coproducer of data, so, even if it's technically difficult, the least we can do is to give him a summary of the results at the end of the survey.

It's an approach that suits me fine, Macrodemus concurred. I have a better understanding, now, of all the preparation and pedagogy that this type of survey requires. On the other hand, I'm more skeptical about the subjective questions that are increasingly common in these questionnaires.

You mustn't confuse them with the general opinion questions scattered throughout polling-company questionnaires such as "What do you think of School in general? of the Justice system? of the Police?" and so on. What respondents can describe accurately are their reactions to an event or an institution that we've just discussed with them (a recent divorce, their kid's school, the healthcare facility they've used). It's interesting to compare properly contextualized judgments and assessments with the corresponding objective practices. On this score, sociologists have learned a lot from American ethnomethodologists. They now believe respondents are not "cultural dopes," but are capable of describing what they do, and the survey designers must make intelligent use of this accountability.

What do you think of surveys on values, taken as explanatory factors of demographic behavior?

It's problematic, Microdemus admitted. Typically, these are batteries of fairly standardized questions. Some are even patented and cannot be reproduced without paying royalties to their inventor. Their purpose is to reveal people's deep-rooted attitudes, arranged in classic antagonistic pairs such as progressive/reactionary, tolerant/closed, individualist/collective, hedonist/ascetic, idealist/materialist, and so forth. In a way, it's a return to the system we were discussing before, that is, the transformation of questions into small experimental devices for gathering subjects' live reactions. I find the explanatory power of these typologies limited or relatively tautological: Why do some people expect morals to change? Because they're more open to moral change. Why do young couples want fewer children? Because they have a mindset that drives them to have fewer children. The notions of materialism, individualism, or hedonism seem too general and very moralistic to me.

Gérard Calot, a top expert in macrodemography if ever there was one, freely resorted to this type of explanation to account for the evolution of demographic behaviors.

True, said Microdemus, but he was aware of the weak scientific status of this type of explanation. When he had to write a scientific article about the decline in fertility, he simply made a cautious allusion to it. In fact, when you jump off the platform of demographic technique with your two feet and you have no sociological baggage whatever, you tend to use such spontaneous explanations as a parachute. If you believe in the "decline of fertility," you're sure to explain it by the decline in moral values, if not of civilization. Adolphe Landry was already complaining about this in *La Révolution démographique* back in 1934. And he painted a very grim picture of moral decay. Pornography, he assured, had already invaded the smallest French villages (he was targeting the movie industry and the image industry). What would he say today?

Are you telling me, Macrodemus asked, that you're against putting questions on values in a questionnaire on demographic behaviors?

No, Microdemus replied. If I had to choose, I'd prefer introducing the issue in the questionnaire itself, so I could check its relevance scientifically, rather than introducing it surreptitiously into the commentary on the data, as an uncontrolled heuristic resource. Like any sociologist, I'm reasonably Weberian. I think the special problem in social science is the need to study actors' values without indulging in value judgments, to take their moral standards seriously without lecturing them. Values do indeed exist, in more or less crystallized forms. They can function as intermediate drivers of action—as vectors or obstacles. I just think you should always inquire into their origins and, most important, never turn them into a deus ex machina that explains everything without ever being explainable. One of the ethical requirements of social science, in my view, is to abstain from judging actors' behavior by one's own moral values. There's nothing more insufferable than a researcher posing as an altruistic ascetic to disqualify someone else's hedonism and selfishness. That's how old folks have been judging the young since earliest antiquity, and how the rich judge the poor. An adult demography should shun this type of bias altogether, which would make it fall back on the glibness of common sense.

I don't feel targeted by such diatribes, Macrodemus mumbled. Personally, I prefer to explain the demographic by the demographic, as Durkheim explained the sociological by the sociological. All the rest is fluff.

You're wrong, countered Microdemus. It's not because the explanation of behaviors is subject to pressure from spontaneous and uncontrollable psychological theories that you should fall back on sex and age and never step outside the frame. I wholeheartedly applaud your indignation at a researcher who neglects structural effects, selection bias, or calendar effects. Identifying them is a vital prerequisite. But it's never more than a prerequisite. The notion that you need to "explain the demographic by the demographic" proceeded from a strategy to autonomize the discipline in the 1960s and 1970s. A similar phenomenon occurred in other social sciences: Durkheimian sociology, of course, but also pure Walrasian economics and structural anthropology. It belonged to a necessary moment in the development of demography. Today, the notion of pure demography has not vanished but it fits into a broader vision of social phenomena, where the groundwork for demographic analysis gives way to a wider social analysis. Concretely, this means that at both ends of the sequence running from questionnaire design to statistical processing, demographic behaviors are now incorporated into a complex of socioeconomic and sociocultural factors that put individuals back into their context. Demographic analysis is no longer separated from statistical modeling in general. It does make its specific contribution: a privileged attention to the calendar of events, to interference between demographic events, and to the interaction between age effects, period effects, and cohort effects. However, it does not cut itself off from statistical models with a wider descriptive and explanatory intent, such as duration models, multilevel models, and ceteris paribus regressions.

And, Microdemus insisted, that's where the Ethicists call us to account. With each successive survey project, they clearly see that most demographers now work on individual data, produced from surveys, where events and durations are studied in the light of social, educational, economic, health or cultural information—and, ever more often, combined with information on knowledge skills, preferences, intentions, motives, values, and habits. It's demography seen from below that now complements demography seen from above.

Microdemus drew an analogy with the work of historians. In their recent study of the immense historiographical output on World War I, Antoine Prost and Jay Winter (2004) observed that the history of the war long gave precedence to the viewpoint of diplomats and officers, while soldiers and civilians remained invisible. Historians studied "war without warriors." It was only in 1959, 40 years after the conflict, that the perspective began to change: under pressure from amateur historians, who were veterans themselves, professional historians have finally trained their spotlights on the men who had fought the war and the populations that had been subjected to it. Generals and diplomats have given way to soldiers and the populace, "the war seen from above' has been replaced by "the war seen from below" (Prost and Winter, 2004, p. 27–33). *Mutatis mutandis*, demography has followed a similar path—and so, incidentally, has a large sector of sociology. The changes in behavior have forced researchers to modify their way of looking at things and their perspective.

To support his claim, Microdemus cited the results of the Demography 2000 international online survey, conducted between October 1999 and 2000 among 637 demographers and population-studies researchers (Chasteland *et al.*, 2004, p. 142). Respondents were asked to name the main factors of change in demography from a long list provided. Their top three picks accounted for 48% of total responses: "development of information technology," "use of new categories from other disciplines," and "techniques borrowed from other disciplines." This was a clear acknowledgment of the force of external pressures on demography. More than other social sciences, population studies now combine very diverse techniques: collection of statistical data, collection of individual data, and the event-history or longitudinal approach. These methods were long separate. Social scientists who handled aggregate statistical data seldom practiced the intensive methods dear to sociologists of the family or anthropologists, and vice versa. On the one hand, you had large numbers, the standard questionnaire, the cross-section, and anonymity; on the other, interknowledge within a community, the qualitative interview, long-term tracking, and the personalized relationship based on trust. The two worlds are now joined. Individual data can now be mass-processed; lifelines can now be tracked for years, even for an entire lifetime (through long-term cohorts or administrative registers).

An ever-richer content, ever more intensive observations, ever longer tracking: these changes inevitably have ethical implications. Until now, demographers focused on just a few traces of our existence: a snapshot in the population censuses, and a few milestones in civil-registration documents. They can now capture entire lives in their webs. At the scientific level, this move toward multiple competencies and comprehensiveness must be encouraged as long as it produces knowledge, but it clearly adds to the researcher's moral obligations: the more information he or she extracts from respondents, the more explanations and guarantees he or she must give them.

In fact, Microdemus continued, the researcher's interest coincides here with the individual's interest. As you realize, the most grandiose observation systems remain at the mercy of popular consent. If they are targeted by a media campaign, they will be discredited.

I know something about that, Macrodemus acquiesced. There have been no census data for the Netherlands since 1971 or for Germany since 1987. I also learned that these antienumeration campaigns were aimed not so much against the census itself as against the plan to match it with population registers.[10]

It's not just the census, Microdemus added. In France, the population census is well accepted, despite the increasing difficulty for enumerators to enter buildings. The systematic recording of social-

[10] We cannot cite the suspension of the German and Dutch censuses to justify the expansion of population registers (argument sometimes used in France), for it is precisely the potential enhancement of the registers through the census that has caused problems. In the Netherlands, the first significant protests were triggered by the 1971 census, in university towns; they pointed to the danger of collating the census and population registers. In the preparatory tests for the 1981 census, the authorities observed such high rejection rates that they decided to call off operations. In West Germany, the 1983 census faced identical opposition for the same reasons: the protests were sparked by the automatic transmission to town halls of a page from the census schedule for the purpose of updating the population registers. The Constitutional Court ordered a halt in census preparation until passage of a law to protect personal data, which took place in 1985. The government authorized a new census in 1987, accompanied by a large-scale advertising campaign, but the Green Party called for a boycott, widely followed in the "alternative" neighborhoods of Berlin and university towns. Since then, the Länder and the federal government have failed to reach agreement to finance a new census.

insurance contributors (the notorious "Safari" plan) had to be halted in 1976 after a press campaign. Do you remember? They set up the Tricot commission, after which Parliament passed the Information Technology and Civil Liberties Act in 1978, establishing the like-named Commission. What strikes me, Macrodemus concluded, is the vulnerability of the databases used by demographers. Whether it's the census or administrative files, these data are as solid yet as vulnerable as a deposit bank. If you build a trusting relationship with the customer, they grow bigger and more beautiful. But if the public withdraws its trust, you get instant panic: the system collapses, and for a long time. Hence the usefulness of High Authorities for protecting the data: they remind us that censuses, administrative registers, and continuous surveys are arrangements requiring specific review and protective action. Personally, I've always argued that these watchdog bodies in each country should rely on the cooperation of statisticians and demographers, and should help, in exchange, to protect their work from frivolous claims.

But how do these high authorities, Macrodemus asked, follow the changes in morals and questionnaires? Do they easily accept the new survey style now prevailing in demography, which seems to be driving the researcher's curiosity ever further?

I won't conceal from you, Microdemus responded, that they have trouble following. The example of the problems encountered by the Family Survey associated with the 1999 French census is illuminating (Héran, 2005). The survey nearly went under: the High Authority that reviewed the questionnaires in 1994 didn't understand why a demographer would be interested in cohabiting unions of less than six months (these were necessarily "affairs"), in "living apart together" couples (they were not real couples), in the complete calendar of unions and separations (that stirred family secrets), and in adopted children (more secrets to protect). The survey managers had to negotiate some wordings and search the jurisprudence themselves to demonstrate the legitimacy of these questions. Now some far more formidable issues are being raised by the new generations of surveys.

Such as?

I'll only mention a few. How do you obtain the informed consent of "statisticized" people when part of the information is gathered unbeknown to them by cross-tabulation with administrative files? How do you guarantee anonymity if the longitudinal survey requires you to store personal data for long periods—up to an entire lifetime? Is it enough to deliver general information when the source files are opened, or do you need specific information for each new series of connections? How do you obey the neutrality imperative if the extension of the observation period tends to modify the behavior observed? Can you avoid intruding in private lives if the questions end up covering all aspects of life? Should respondents be told in advance how long the operations are expected to last? As you see, a lot remains to be done to settle these issues without jeopardizing the interests of science or the interests of individuals. One approach under consideration (which Benoît Riandey is promoting in France) is to develop encryption systems that segment the identification numbers. They allow citizens filling out administrative forms or survey respondents to enter sensitive information in one section of the questionnaire; that information will be inaccessible to the administrative body but can be decrypted by a properly authorized third party.

VIII. RESEARCH ETHICS: AN EPIDEMIOLOGICAL MODEL ILL-SUITED TO DEMOGRAPHY

In the hope of finding out more, Macrodemus and Microdemus surfed the Web looking for documentation that would give them a more practical answer to their questions. In their search, they discovered a variety of ethics more targeted than the one practiced by the Ethicists—which, in principle, should have been more relevant to them. Its name was "research ethics," a booming specialty in English-speaking colleges and universities. Did it offer guidance on the ethics of demographic research?

Macrodemus and Microdemus soon realized that research ethics was strongly anchored in the life sciences. It was only just beginning to spread to the behavioral sciences, in particular the disciplines that conducted experiments on humans, or that subjected them to intensive, long-term monitoring, such experimental psychology, cognitive psychology, and anthropology. The sciences that resorted to demographic and social statistics were virtually absent from this group, because they did not conduct real-life experiments but only thought experiments.

Microdemus paid a visit to the Ethicists' main bookstore. He found the research ethics guide written by the director of bioethics programs at the University of Montreal (Doucet, 2002). It was a remarkable summary of the regulations and legal arrangements successively adopted in Europe, the United States, and Canada. The guide pointed out in passing that the founding texts suffered from several imprecisions or terminological confusions, which ultimately revolved around the legitimate definition of science:

- Often, in international ethics texts, the term *research*' is used for "experimental research" and the expression *research subject* is simply a shortcut for "subject hired for experimental research purposes." This is misleading, as experimentation does not designate all research but only one of a number of research methods. The social sciences claim the right to use other methods. Macrodemus was happy to note that the Montreal specialist began by citing statistical modeling for descriptive and explanatory ends, and regarded it as a full-fledged scientific approach (practiced even by hard sciences such as astronomy). He also mentioned qualitative observation methods, of which Macrodemus was not very fond: these sought to reconstruct and understand the logic of behaviors using various techniques such as detached observation, participant observation, directive interviews, comprehensive interviews, focus groups, and the analysis of documents produced by actors and institutions. From one method to another, the researcher's relationships with human subjects are extremely variable. However, if the relationship is properly defined and controlled, the qualitative approach need not be experimental in order to qualify as scientific.
- Some ethical regulations do not merely reduce research in the general sense to "experimental research" but go further by equating the latter with "intervention-based clinical research," which covers pharmaceutical trials (as well as clinical trials of medical devices and surgical trials). The purpose of such tests is to measure the pharmacological and clinical effects of a product and establish at what level of effectiveness and safety it is absorbed by the subjects in the experiment. This marks the maximum degree of intervention by research on the human body. But there are experimental research studies that, so to speak, act not on the body but on the mind. This is true of experimental psychology, which conducts experiments in laboratories and natural environments. It is also true of studies involving the administration of tests or exams—a standard practice in education science and sociolinguistics. More broadly, any administration of a questionnaire to a sample of subjects may be qualified as experimental, since the same person is invited to respond to a series of questions (or give multiple-choice answers) and, reciprocally, a series of persons is invited to respond to the same question.
- Conversely, intervention on the human body is not necessarily synonymous with scientific intervention. There are forms of innovative care that use untested methods, whose main purpose is not the advancement of science but a therapeutic procedure of last resort (often, compassionate care). Such procedures are referred to as "experimental treatment," insofar as it involves a "procedure that is performed for the direct and immediate benefit of the recipient, but that, in scientific terms, has not yet fully proved its worth" (Law Reform Commission of Canada, 1989, quoted by Doucet, 2002, p. 148). Now it is not always easy to distinguish intervention-based clinical research from such innovative care not validated by science. The confusion is all the greater as clinical research is itself generally conducted on patients undergoing treatment and has not yet obtained the scientific validation that normally follows the experiment. To draw the sharpest possible distinction between the two types of intervention, clinical trials are no longer qualified as therapeutic research in North America because the expression may lead patients to believe that the research will have an immediate therapeutic effect on them. The term *clinical research* is now used instead of *therapeutic research*: the scientific connotation therefore outweighs the medical connotation, but the degree of intervention on the body may be of equal scope in both cases.

Microdemus had to read the texts twice to grasp the meaning of all these distinctions, which he tried to explain to Macrodemus. He understood the basic point: research, scientific research, experimental research, and intervention-based research are realities that communicate but do not blend. Research ethics must be careful to clear up these terminological confusions, which mirror confusions in the areas covered. The ethical principles that apply in one case are not necessarily valid in the other.

Likewise, Microdemus noticed that ethical guidelines were structured according to dichotomies ill-suited to demographic research: research was described as quantitative or qualitative, with human subjects or without human subjects, clinical or explanatory, with or without therapeutic (or diagnostic or medical) purposes, and so on. These distinctions were combined with a distribution by field, which, for example, allowed Hubert Doucet to devote the chapters of his textbook to four categories of research: intervention-based clinical, epidemiological, genetic, and qualitative (Doucet, 2002). But, Macrodemus wondered, where does demography fit into these typologies?

Into non-medical research, of course, but (to use the official Canadian phrase) was demographic research conducted with human subjects or without human subjects? Macrodemus had never really thought about it. He had the impression he was working on human subjects and at the same time without them. Admittedly, at a certain point, the subjects had had to participate in order to supply the basic information; the government had had to ask them to fill out census schedules, population registers, civil registration forms, or survey questionnaires, unless the declarations had been filed by friends or relatives, registrars under oath, or doctors. Operating at the end of the chain, Macrodemus also realized that individual data sometimes had gaps that needed to be filled by editing or imputation methods. But he preferred to leave this tinkering to the specialists at the national statistical offices. All that a macrodemographer asks of a statistical institute is the timely delivery of a clean file that meets the requirements of accounting consistency. Little does it matter to him to know the efforts and compromises needed to extract the data from the population.

On occasion, when he had to end a set speech with a lyrical flourish or answer a radio-show caller who insisted on describing his personal case, Macrodemus held in reserve a phrase that he would utter in an earnest tone: "Let's never forget that behind the indicators, you have people." This dash of humanism was always welcome. It was an inexpensive way to counter the unfortunate impression given by the demographer's impersonal treatment of the data, with decimals of children and mean life expectancies. But Macrodemus no longer dared use his fine phrase after Microdemus politely noted that it had no connection to any professional practice. For the true precept informing Macrodemus's practice was none other than Aristotle's old adage: "There is no science except of general things." A private individual could never be more than an anonymous purveyor of data for him. To study the individual as such was to run the risk of sinking into a bottomless pit, as we can clearly see from Jean-Paul Sartre's unfinished and desperate attempt in *L'Idiot de la famille* (The Family Idiot): the singular human subject (Gustave Flaubert, in this case) is infinite, and thousands of pages are not enough to describe him (Sartre, 1970–1971). To turn the human subject into an object of science, one must reduce him, and, ultimately, reduce him to insignificance. Microdemus found Macrodemus better inspired when he forthrightly defended the advantages of reduction instead of indulging in humanism or personalism.

In fact, while demographic research always needs human help, even when working on highly aggregated data, we must admit that this reliance is more systemic than individual. It is channeled through largely institutional and depersonalized mechanisms. Initially, individuals know that the registration of their existence (or death) by the authorities incorporates them into a broader enumeration. By the end of the process, when the demographer steps in, there is no personal dimension left. We can see this clearly in the borderline example of demographic analyses of world population: each of the world's 6.4 billion inhabitants is included in the tabulation and counts as one, but there is no way they can give the researcher their consent whenever they are "statisticized." Where should we classify this human yet impersonal science, which, on the one hand, can take all human beings as its object, through a vast compilation of individual data, and, on the other, never intervenes on the body and never performs experiments on human subjects? Where should we put a discipline that works both with human subjects and without them? The textbooks on research ethics offered no answer.

Macrodemus and Microdemus tried to determine in which cell research ethics placed social-science research. They realized that it was wrongly classified under qualitative research, on the pretext that it was not biomedical research of an experimental nature. "Qualitative" was a euphemism for "nonquantitative" and "nonexperimental"—in other words, "nonscientific." In countries such as Canada and the United States, the ethics committees set up in each university hospital no longer simply examined biomedical projects; they had ended up examining social-science research projects. This extensionist approach had been implemented in Canada by the Tri-Council Policy Statement (1998) devoted to "Ethical Conduct for Research Involving Humans," the three councils being specialized in medical research, natural sciences and engineering, and social sciences and humanities respectively (Doucet, 2002). To cover the three research fields, the Canadian authorities prescribed the "proportionate approach to ethics assessment," that is, "the more invasive the research, the greater should be the care in assessing the research." If the risk for individuals was minimal, one could authorize expedited review (called "simplified" review in France).

At first, it was thought that projects in sociology and anthropology, owing to their very limited potential harmfulness, would benefit from these streamlined procedures. But they were often viewed with great suspicion by committees of experts trained exclusively in the experimental sciences. As Doucet notes, these experts' incomprehension of social science is not so much at the ethical level as at the scientific level. They are worried not about the immorality or danger of social-science research projects but about their methodological weakness. They fail to see how causality links can be proven without using the experimental method. They fear that, in these conditions, research will give free rein to an ideological or subjective analysis, especially since social science jargon can be worryingly obscure whereas it is supposed to describe realities known to all. Because of their scant familiarity with social science, experts in experimental science tend to assess sociodemographic projects in terms of their common sense or prejudices.

Microdemus was deeply shocked by the notion that an approach was irretrievably subjective if it did not implement the experimental method. In his view, demography provided proof of the contrary: a social science, it was neither qualitative nor experimental, yet a science all the same, at least as much as economics and social statistics. To define the proper ethical approach for it, shouldn't demography be placed somewhere between experimental research and qualitative research? But Microdemus noticed that the research-ethics manuals had installed another discipline in this intermediate space: epidemiology. Did this mean that the ethical approach for epidemiology could be extended to demography?

As noted earlier, Microdemus had received some training from Epidemus. He had a rough idea of the relationship between demography and epidemiology. They do have in common the fact of being focused more on populations than on the individual. But the resemblance stops there. Epidemiological studies can treat human subjects using methods as interventionist as those of clinical trials. In fact, epidemiology is not consistent on this count: it can perform observation studies as well as experimental studies:

- The observation studies conducted in epidemiology may have a purely descriptive intent (measuring the distribution and propagation of health statuses to steer the allocation of healthcare expenditures) or, more ambitiously, they may seek to explain (by identifying behaviors or risk factors that play a decisive role in the etiology of illnesses). In ethical terms, these observation studies are interventionist or invasive when they involve taking biological samples from human subjects. The ethical problem becomes particularly sensitive if the samples consist of genetic material: the information gathered concerns not only the individual's identity and origins but also those of his blood relatives, who become, de facto, complementary subjects of the study.
- As for the epidemiologists' experimental studies, they are interventionist in the full sense of the term: they rely on the same principle as clinical trials. The difference is that causality is measured by comparing groups of subjects. The variations in health status induced by new products are not validated separately for each individual but established on a probabilistic basis at the group level. They must be statistically significant. For this purpose, the experimenter chooses the subjects on whom the medical procedure is performed and compares the changes in their status to those of the group that has not undergone the procedure. A crucial aspect of the method is that statistical causality must be measured by identifying insofar as possible the effects attributable to other factors at work.

Microdemus was tempted to place demography on one of these two branches. It could not be on the experimental studies branch. Should he conclude that demographic methods had more in common with those used in the epidemiologists' observation studies? On closer inspection, he saw that the latter could apply three types of protocol: cross-sectional studies, cohort studies, and case-control studies.

The only protocols found in identical form in demography were cross-sectional studies: they consisted in gathering the sociodemographic characteristics of a given population from all its members at the same time (these characteristics are either explanatory factors or variables to be checked), as well as information on health status, individual behaviors, and environmental data (interpretable as risk factors). By contrast, demographers did not conduct comparative cohort studies. Epidemiologists use them to detect changes in health status (or even deaths) associated with a risk factor. For this purpose, they conduct a long-term observation of two groups of subjects, one exposed to the risk factor, the other not. These studies are generally performed on small samples of patients treated in a hospital ward. The demographer preferred nationally representative samples, with as large a set of potential explanatory variables as possible. In this respect, he was close to the sociologist or social statistician.

This plunge into research ethics had greatly excited Microdemus, who had tried to interest Macrodemus in it—but in vain. Macrodemus had not examined a science other than his own in a long time. He let Microdemus conclude. No, the demographer's methods were not congruent with those of the epidemiologist. They were not interventionist, nor did they give precedence to groups of patients or subpopulations exposed to risk factors. They could not be subjected to the same ethical requirements, except for cross-sectional surveys.

But what were those ethical requirements? They were particularly strong for intervention-based clinical research and, from there, had been extended to other epidemiological studies. The Nuremberg tribunal, which had judged Nazi criminal doctors after World War II, had defined the main guidelines (known as the

Nuremberg Code), later broadened by the Helsinki declaration and various international resolutions (Box 99–2). These principles were stated as follows. No experiment on human subjects can be performed without their informed consent. They must not be coerced; in particular, they should be free to leave the scientific experiment at any time. Vulnerable individuals—children, the elderly, the mentally ill, the handicapped, the homeless, immigrants, members of disadvantaged categories—needed special protection: they could not be asked to participate in a medical experiment unless they were the intended privileged beneficiaries and unless the experiment could not be conducted first on other categories of individuals. The three principles were, therefore, securing informed consent, respecting the subjects' autonomy, and protecting vulnerable minorities.

The ethics committees' extensionist approach consists in applying these clinical-trial guidelines to epidemiological studies in general, including the least intervention-based. The main adjustment involves taking into account the collective or "populational" dimension of epidemiological studies. The informed consent of groups (via their legitimate and recognized representatives) is obtained in the same way as individual consent; the autonomy of groups (or communities, to use the standard North American term) is respected in the same way as personal autonomy. The groups likely to benefit most from the study are made to carry the bulk of the survey burden; reciprocally, steps are taken to ensure that the vulnerable groups are not burdened with studies that do not specifically concern them and in which they would only serve as guinea pigs.

This extensionist approach may seem exaggerated. Its explanation lies in the fact that some epidemiological studies are effectively performed on the bodies of subjects or patients, with procedures resembling those

BOX 99–2 Morals, ethics, deontology: semantic drift

The word *ethics* traces its roots to late antiquity; it derives from the Greek è*thos* (morals). In linguistic terms, *ethical* is the Greek counterpart to the word of Latin origin *moral*—its "didactic and literary equivalent," says the French dictionary *Le Robert historique de la langue française* in its discussion of the French forms *éthique* and *morale*. Ethics, therefore, is nothing other than morals, and professional ethics is the moral code of a profession. Academic English has given precedence to the term *ethics* and its derivatives, later imported as such into France (where this Anglicism revived the outmoded usage of *éthique*). In France, there is a perceptible difference in register between "ethics" (*éthique*) and "morals" (*morale*): the first has a more formal connotation, referring to the set of principles that enables us to decide between good and bad conduct; by contrast, *morale* tends to be confined to more informal usage, the assumption being that morality is a routine discourse or a discourse from authority enunciated in the first degree, without a clear knowledge of the underlying principles. Hence the expression *faire la morale*—to give someone a moral lesson.

To denote the corpus of moral rules that a profession defines for its internal use, English-speaking countries use the phrase *professional ethics*; Romance-language countries tend to use *déontologie* (deontology) or its cognates. The vocabulary varies according to whether the national language is Romance or Germanic: *code de déontologie* in French, *codice di deontologia* in Italian, *código de deontología* in Spanish. Deontology, in this sense, is simply the systematic exposition (*logos*) of duties (*deonta*): a compound that did not exist in classical Greek, since it was coined by Jeremy Bentham in ca. 1820. Bentham already mentioned it as a known term but used in a special meaning that persists to this day among English-speaking moral philosophers: they apply the qualifier *deontological* to theories that, like Kant's philosophy, make the unconditional fulfillment of duty the supreme criterion of good action; this is in contrast to consequentialist theories, which judge the moral value of action by its consequences on general welfare (the best-known consequentialist theory being utilitarianism).

In the English-speaking countries, the equivalent of "deontological codes" or "charters" is designated by a variety of roughly synonymous expressions: code of ethics, code of professional ethics, code of ethical practice, code of practice, code of conduct, code of professional conduct, code of good professional conduct. French often replaces code (*code*) with charter (*charte*), to denote that this is not a set of laws but a document freely adopted by an institution or profession. More recently, the expression *livre de style* has made its way into the Francophone press. This is a literal translation of the United States style book, initially a compendium of typographic rules, in which newspapers now gather not only their rules of writing and conduct, but all their ethical rules.

of clinical trials. But this is not always so, far from it. One must therefore attenuate the extensionist assessment approach by requiring ethics committees to abide by the principle of "proportionate approach to ethics assessment" set out in the Canadian Tri-Council Policy Statement.

But could one really curb the Ethicists' propensity to extend their powers of review to all sorts of research? Microdemus was openly skeptical. The Ethicists were not known to give up easily. What he heard from Canadian and U.S. epidemiologists seemed to indicate, on the contrary, that the tendency to generalize a legal or ethical procedure beyond its initial scope of application was irrepressible. If abuses of power had already been committed in extending ethical rules from the clinical to the epidemiological fields, there was reason to fear the effects of an additional extensionist thrust, which would result in demographic studies being placed under the jurisdiction of ethics committees specializing in epidemiology.

Clearly, Macrodemus and Microdemus concluded, demography did not have a place in the divisions drawn by the research Ethicists. The unsuitability of epidemiological standards was blatant as regards the procedures for obtaining informed consent. If a control model imitating clinical trials were applied to sociodemographic research, the obtaining of consent would become the default standard, and a research project would not escape the requirement except by special waiver, if it proved its harmlessness for human subjects. In demographic studies, the opposite prevails: the subject's consent is taken for granted, and is sought only in exceptional cases (when the data gathered are sensitive or too localized, or when a longitudinal survey makes it necessary to store names and addresses). It is generally assumed that questionnaire respondents have agreed to reply. It is also assumed that by declaring their personal data to civil registration officers, individuals accept once and for all that their lives are amalgamated along with those of thousands of others into anonymous overall statistics (in some countries, the civil registration forms advise people of this statistical use of their data). It would be absurd to ask demographers to obtain the individual consent of all the subjects taken into account whenever they calculate birth and death rates. Contrary to epidemiological studies, obtaining explicit consent is therefore not the rule but the exception in standard demographic research.

Macrodemus and Microdemus had no trouble concluding. Because it is centered on biomedical studies, research ethics has serious difficulties in specifically addressing the issues raised by demographic studies. It tends to draw them either toward the camp of qualitative methods, as practiced by social anthropology, or toward the camp of epidemiology, which in turn is drawn toward clinical trials. In both cases, research ethics misses its target. Another approach was therefore needed. But Macrodemus had no time for this: he had just received superb macrodata that required immediate processing.

IX. STRENGTHS AND WEAKNESSES OF ETHICS CODES

Time was going by. Like Saint Simeon on his pillar, Macrodemus was riveted to his suspended workshop. Too busy with his survey, Microdemus had spaced his visits but their e-mail exchanges had continued.

One day, while searching the Web for a reference on data quality, Macrodemus ended up by mistake on the site of an international statistical association, which published a code of professional ethics. The document referred to other guidelines and, by following the thread, one could peruse most of the codes of professional ethics promulgated in the past half-century by national and international associations of statisticians. The latter had been followed by associations of sociologists and anthropologists.

At first glance, this internal regulation literature had seemed more concrete to him than the Ethicists' speeches. He alerted Microdemus, who voiced a great interest in the discovery. Microdemus broached the topic with the Ethicists he knew, starting with Philarethes. What did she think of the ethics literature? Oddly enough, she didn't think much of it, despite her passing mention of it in the lecture/debate at the Grand Theater. The Ethicists barely cited it in their works. Professional ethics was just a narrow segment of applied ethics. Rarely did it discuss the deadly dilemmas that the Ethicists had made into one of their specialties. Moreover, the rise of professional ethics had begun long ago, as far back as the Hippocratic oath. There had been a rebirth in late 19th-century America—and, in between, a prophetic remark by Chancellor Francis Bacon in the early 17th century.[11]

[11] As early as 1605, in his astonishing treatise on the organization of science, Bacon explained that "duty," defined as the good rendered to society, comprises two parts: duties toward the State and the duties of professions and vocations. The theory of these duties should include a section on the "frauds, cautels, impostures, and vices of every profession." Instead of leaving the subject to satirists, we should make a serious and realistic study of it, for we cannot defend virtue without a good knowledge of evil: "we are much beholden to Machiavel and others, that write what men do, and not what they ought to do" (Bacon [1605] 2000, p. 216). This realistic program of professional ethics was promising, but Bacon never pursued it.

The phenomenon had not awaited the recent revival of moral and political philosophy, or the proliferation of ethics chairs in universities. For some Ethicists, this self-regulation enabled the professions enjoying exorbitant power—such as doctors, journalists, police, and insurers—to do two things: first, to protect themselves against customers increasingly worried about their abuse of power; second, to finally conduct an external communication campaign, albeit of little ethical value.

For Macrodemus and Microdemus, the Ethicists' disdain, if anything, spoke well for professional codes of ethics. Our two demographers didn't like radical speeches on good and evil. The modesty of the professional-ethics enterprise was a good sign for them. They were interested to discover a lecture by Jean-Marie Delarue, a jurist who had extensively frequented statisticians[12] (Delarue, 1998). It put professional ethics in perspective, as one of the many forms of regulation, alongside law, contract obligations, and private regulations. If I break the law, I expose myself to punishment by public authority. If I breach a contract unilaterally, I will be sanctioned on the initiative of the other party. If I ignore the regulations that surround me (internal regulations in businesses, schools, hospitals, condominiums, nonprofit groups, supermarkets, concert halls, sports facilities, Internet forums, etc.), I will be called to order, or even excluded, by the people—generally private individuals—tasked with preserving order. But if I infringe the code of ethics of the profession, I expose myself primarily to censure by my peers. This can range from a simple reprimand to disciplinary proceedings, and my peers can apply sanctions on their own initiative or in response to a user's complaint. The code of ethics is therefore a new source of normativity whose special feature is that it is basically internal to an organized group; more accurately, it provides internal prevention of possible external challenges. René Padieu notes, however, that the different sources of normativity communicate: the ethics codes prepared by professionals may precede and inspire laws.

Macrodemus and Microdemus started to read the codes of statistical ethics available (Box 99–3). They fell into two categories.

Some (such as the code for *administrateurs* [senior statisticians] of the French National Institute of Statistics) covered the entire process of a statistical operation, stating the guidelines to be followed at each step: how to define the initial framework, construct the data, ensure representativeness, administer proof, verify that the results are significant and of general import, prevent interpretation errors, inform readers of the implications and limits of the published figures, recognize one's mistakes and, lastly, make it possible to conduct a scientific critique.

[12] A member of the Council of State, Delarue was the former chairman of France's National Council for Statistical Information, the body in charge of vetting all questionnaires in official statistics.

But the codes of international associations followed another plan: they went through the long list of the statistician's partners—subjects interviewed, colleagues, employers, sponsors, and the general public—and stated the duties to be fulfilled toward each. Here is a summary of the prescriptions that appear in most of these codes:

Obligations toward the discipline:

- promote advancement of research and dissemination of knowledge;
- defend freedom of research;
- refuse contractual provisions restricting freedom of research;
- promote research-friendly conditions;
- welcome young generations of researchers.

Obligations toward colleagues:

- fully acknowledge their contribution, cite them;
- read them;
- avoid all plagiarism;
- do not exploit other researchers (particularly young ones waiting to fill positions);
- provide training;
- avoid over-personalizing relationships, which could create dependency situations;
- avoid all discrimination (by sex, origin, age, sexual orientation, or religious, labor-union, or political affiliation, etc.);
- foster equal opportunity in hiring and promotion.

Obligations toward persons participating in the research (survey respondents):

- ensure that the persons' physical, social, and psychological welfare is not adversely affected by the survey work, or, if so, to the least possible extent;
- particularly for persons of precarious or vulnerable status due to age (children, the elderly), health (illness, handicaps), social marginality (prisoners, homeless, illegal migrants, etc.), hardship caused by a special event (separation, death of a close relative, abortion, domestic violence, etc.);
- work to minimize the disruptions caused by the survey operations; special attention should be given to the possibility of appropriate compensation (its relevance, type, and amount, bearing in mind that national traditions diverge on the issue);

BOX 99–3 Specialized organizations and codes of professional ethics

1. Selected organizations and committees specializing in professional ethics in the social sciences

American Statistical Association (ASA), Committee on Professional Ethics

Social Research Association (SRA), United Kingdom

2. Ethical guidelines and professional ethics in statistics and epidemiology

International Statistical Institute (ISI), 1985. *Declaration on professional ethics.* http://www.cbs.nl/isi/ethics.htm

United Nations, Statistics Commission, 1994. *Fundamental principles of official statistics*

International Council of Scientific Medical Organizations (CIOMS) and World Health Organization (WHO): *International guidelines for ethical review of epidemiological studies*, Geneva, 1991 (under revision, 2004).http://www.cioms.ch/frame_1991_texts_of_guidelines.htm

3. Ethical guidelines and professional ethics in social science

Social Research Association (SRA), 2003. *Ethical Guidelines*

American Statistical Association's Committee on Professional Ethics

UNESCO, 1994. *Ethical guidelines for international comparative social science research in the framework of M.O.S.T.* (Management of social transformation). Paris.

The Research Council of Norway, 1994. *Guidelines for research ethics in the social sciences, law and the humanities.* Oslo.

Institute for Employment Studies, 2004. —*Respect Project: An EU Code of ethics for socio-economic research.* Project funded by the European Commission's Information Society Programme (IST). Brighton. http://www.respectproject.org

4. International bioethical guidelines (chronological order)

Nuremberg Code, 1947, judgment by U.S. military tribunal against Nazi doctors (text regarded as starting point of ethical guidelines on experimentation).

English version: http://ohsr.od.nih.gov/guidelines/nuremberg.html

World Medical Association

Declaration of Helsinki, Recommendations guiding physicians in biomedical research involving human subjects, adopted by the 18th World Medical Assembly, Helsinki, Finland, June 1964 (text regularly amended in later Assemblies, latest ed. 2004).

Website: http://www.wma.net/e/policy/b3.htm

International Bioethics Committee (IBC)

Universal Declaration on the Human Genome and Human Rights, Paris, UNESCO, 1997. http://www.unesco.org/ethics.

Council of Europe

Convention for the protection of human rights and dignity of the human being with regard to the application of biology and medicine (Oviedo, 4 March 1997), European Treaty Series, no. 164, 1997.

Council for International Organizations of Medical Sciences (CIOMS) and World Health Organization (WHO): *Manila Declaration*, 1981. *Proposed international guidelines for biomedical research involving human subjects*, Geneva, 1982. Revised edition: *International ethical guidelines for biomedical research involving human subjects*, Geneva, 1993. Website: http://www.cioms.ch/draftguidelines

5. National bioethical guidelines

Commission for the Protection of Human Subjects of Biomedical and Behavioral Research, Washington, D.C. (U.S.):

Research involving prisoners: Report and recommendations, and Appendix, 1976.

Research involving children: Report and recommendations, and Appendix, 1977.

Research involving those institutionalized as mentally infirm: Report and recommendations, and Appendix, 1978.

The Belmont Report: Ethical principles and guidelines for research involving human subjects, 1978, Washington DC: U.S. Government Printing Office. http://ohsr.od.nih.gov/guidelines/belmont.html

Medical Research Council (MRC), Natural Sciences and Engineering Research Council (NSERC), Social Sciences and Humanities Research Council (SSHRC), Ottawa (Canada)

Tri-Council Policy Statement: Ethical Conduct for Research Involving Humans, 1998 (with 2000 and 2002 updates).

Website: http://www.pre.ethics.gc.ca/english/policystatement/policystatement.cfm

Comité Consultatif National d'éthique pour les sciences de la vie et de la santé (CCNE), Paris (France).

Publishers *Cahiers du CCNE*.

Website: http://www.ccne-ethique.org

- alleviate the survey burden (duration, mental burden, psychological burden, guilt); obtain the informed consent of persons, including in the exceptional cases where the survey work is compulsory for reasons of public interest. These should be defined by an independent, legal body, democratically mandated to decide whether the survey should be compulsory: problem of surveys conducted in prison at the request of the prison director; problem of surveys conducted in non-democratic countries with the visible support of the authorities, and so on;
- inform persons of the degree of anonymity and confidentiality, which must be as high as possible. In exceptional cases (longitudinal surveys requiring long-term storage of personal details), obtain their informed consent;
- inform persons of the purpose of the study;
- do not give them illusory hopes of positive, immediate effects;
- make sure that the use of an informant in the household is relevant, is approved by other household members (wife describing her husband's characteristics, or vice versa), and concerns objective facts only—not opinions or judgments;
- make sure that the use of a proxy (informant) has a legal basis (for example, guardian, parent, or licensed caregiver for a handicapped person) if the interested party cannot give his/her consent;
- provide them with every guarantee that the information gathered will not be supplied to subsequent respondents, to the authorities, or to third parties in general;
- take special precautions when questioning children, by obtaining both parental consent and permission to question them in private, without parental pressure;
- do not offend persons' ethical and religious sensitivities; if the survey arrangements conflict with special rules (e.g., men's refusal to have their daughters or spouses questioned individually by men), adjust the survey arrangements in consequence, without losing sight of the survey objectives and without condoning potential discriminatory behavior;
- abandon the survey if it proves impossible to conduct without infringing personal rights.

Obligations toward sponsors and employers

- clarify the contractual arrangements for research by specifying the nature of the relationship with the customer, reciprocal expectations, type of services to be provided, timetable of operations, financial arrangements, authorized use of results by sponsor, right of researchers to publish them freely and re-use them later;
- inform sponsors beforehand of inherent limitations of methods used, as well as ethical restrictions on data access or use;
- do not accept orders that would impose methods or even results consistent with the sponsors' wishes, or enable them to block or delay discoveries they did not like;
- do not seek to undercut competitors by accepting an order whose budget precluded compliance with basic scientific standards;
- mention support from orderers and sponsors in the research publications.

Obligations concerning data quality

- refuse participation in research contracts without prior determination that you will be able to use or produce data of sufficient quality to answer the questions raised (this implies bringing together all the required competencies in the research team);
- give full information on data-collection method, so other teams can criticize it later;
- be attentive to data selection and construction biases, particularly when the data have been compiled by organizations for nonresearch purposes;
- verify data quality even if the results seem plausible at first sight;
- do not engage in international comparisons without assessing the variations due to the diversity of definitions, collection methods, and processing methods among countries.

Reading the good advice contained in the codes of statistical ethics, Macrodemus thought that demography, as a branch of social statistics, could readily adopt some of them. His highly technicist view of the profession led him to prefer the first expository method, the one that tracked every step of a statistical operation. As noted earlier, the notion that the data had to be built and negotiated through a complex network of social relationships was rather alien to him. But, in his defense, we must admit that the good advice dispensed by the statisticians' codes of professional ethics were curiously diverse. Some were extremely general, while others went too far into the details.

The general precepts could elicit unanimous approval. Do not harm the people whose data you handle, combat fraud and deceit of every kind, be honest and modest in your attempts at interpretation, recognize your mistakes if need be, respect other people's work, give each his due, quote your sources, colleagues, and sponsors fairly—who could object? The problem was how to put all these precepts into practice. Should oversight procedures be set up? If so, at what step in the statistical process? Early on, at the research-project review stage? In a later phase, when editorial committees vet planned publications? Or periodically, when researchers come up for evaluation? Should ethical vigilance be distributed among the different players involved in data production, or should it be concentrated in the hands of a committee acting on behalf of the entire institution? Should violations be sanctioned?

The detailed recommendations set out in the codes posed the opposite problem. They described the "how," but starting from principles that were not unanimously accepted. Macrodemus was not convinced, for example, that a code of ethics should go into details about the methods for administering proof or measuring significance. These methods not only sparked disagreements between statisticians, epidemiologists, and demographers, but also were hotly debated within each of the three tribes. Adapting such codes to the needs of demographers required much fine-tuning.

Macrodemus and Microdemus continued their exchanges. By dint of seeing each other, they had evolved. They began to understand that you cannot examine the links between ethics and demography without scrutinizing the nature of the demographic discipline itself. The professional ethics of demography had to vary depending on whether demography was practiced in a macro or micro approach. But that did not justify splitting the discipline in two and assigning separate ethics to each. Ever more commonly, demography was practiced in a macro perspective enhanced with micro approaches. Long-term cohorts offered a good example. This shift entailed an increasingly delicate alternation between statistical individuals and real persons. To cope with this difficulty, demographers concerned about professional ethics had to build their toolboxes by combining elements of different origin. They had to respect the ethics of other disciplines whenever they took part in interdisciplinary projects, but that was not enough. Macrodemus and Microdemus set themselves the goal of developing an original synthesis that would address the entire spectrum of ethical issues raised by demographic research, whatever the degree of proximity to human subjects.

They rolled up their sleeves and went to work.

Acknowledgments

History of Population Policies up to 1940

MICHAEL S. TEITELBAUM
Alfred P. Sloan Foundation, New York, United States

It is possible to interpret the title of this chapter in such a broad sense as to be utterly unmanageable. "History of population policies up to 1940" may be interpreted, especially in English, to mean all the ways in which, over the millennia from antiquity to the onset of World War II, human societies have debated and/or influenced the demographic forces that are changing them. Such a breathtaking scope could encompass essentially the whole of the history of present-day human societies. Each society in some sense contemplates whether it will survive, and embodies at the very core of its culture a set of institutional arrangements and belief systems that have a powerful impact on demographic phenomena, including religion(s), family structures, economic systems, political systems, and so forth. At this level of generality, a history of population policies becomes a global history of humanity.

In French usage, the term "politiques de population" normally has a more restricted meaning, limited to actions taken by the state (for discussion, see Prost, 2002, Chapter 13). For the purposes of this chapter, it therefore seems wise to limit the frame of our attention to those actions taken by states that are deliberate, that is, in which conscious decisions have been taken to create or modify societal arrangements with the expressed intention of affecting the rates of fertility, mortality, or migration, and thereby the trends of demographic growth, decline, or composition. The key ingredient then is volition and intent, or at least an awareness of the demographic impacts of political, economic, and cultural arrangements that are proposed or implemented. The requirement that such actions be taken by states means that population policies in this sense are to be found mostly since 1800, once the modern state had emerged and began to consider demographic characteristics as elements of military power or as sources of poverty or prosperity.

Even so constrained, the topic remains a sweeping one. Throughout human history, governments have taken actions to affect demographic change in ways that serve their interests. As Éric Vilquin noted in Chapter 97 of this volume, the political implications of this subject have been a topic of discussion by political philosophers, historians, and others during many periods of recorded human history, going back to the empires and city-states of antiquity. Moreover it has constantly engaged the attention of some of the intellectual giants of human history, from the Classical Greeks and Old Testament scribes of the Mediterranean to the classical economists of 19th-century Europe.

A common theme has been that larger populations imply greater power for the State, whether ruled by monarch, prince, emperor, chief, leader, president, or premier. Such perspectives are surely understandable, given that much of human history has been one in which societies struggled to survive by producing enough children to compensate for high mortality rates, and in which the number of soldiers or warriors commanded by the state had much to do with collective security and survival. Such a theme tended to dominate discussions of the subject in the ancient world, but also during the period of three centuries (16th–18th centuries) when mercantilist ideas dominated European perspectives. The 19th century saw sharp challenges to these assumptions that a bigger population is better, with Malthus and others arguing that unrestrained population growth spelled poverty and instability. But by the late 19th century into the 1960s, there was a return to the idea that population growth implied strength and prosperity. These ideas waned again due to concerns about the population explosion of the last half of the 20th century and the rise of environmentalist sensibilities, only to reappear in the 1990s as fertility rates fell to very low levels in much of the industrialized world.

While discussions about population policies have been part of much of history, the high point of such debates can be found during the two centuries from roughly 1800 to the present. Although there were strong ebbs and flows of concern during this period, both about whether population growth was too low or too high, these debates were not closely tied to the deep ideological rifts about political and economic policy that dominated this period. The 1930s and 1940s, for example, were decades dominated by fundamental (and ultimately catastrophic) conflicts among the leaders of fascist Germany and Italy, liberal democracies such as France, the United Kingdom, and the United States, and the authoritarian communism of Stalin's USSR. Yet the rhetoric and policy frameworks on population questions among this diverse array of leaders and countries tended to parallel one another in very significant ways. Moreover, within liberal democracies themselves, there was a surprising level of consensus among otherwise disputatious groups of political radicals, progressives, socialists, conservatives, and reactionaries.

I. ORIGINS: FROM THE ANCIENT WORLD TO MALTHUS AND MARX

1. Ancient Roots

Given space limitations, I can touch only lightly on discussions of population issues before the 19th century. The earliest recorded discussions on the subject, appearing in writings from ancient Greece, the Bible, and India, tend toward emphasizing the advantages of larger populations for military and economic power. The Old Testament includes several relevant passages, including the oft-quoted "Be fruitful" blessing in Genesis,[1] still cited today by religious pronatalists, and a precursor to mercantilist ideas appearing in Proverbs.[2]

Yet Genesis also points to the necessity of limits on numbers that can be supported by a given set of resources. Indeed, the historic separation of Lot and Abraham is attributed to such resource constraints.[3]

In ancient Greece, the historian Herodotus wrote as early as 440 BC of a conscious policy of pronatalism among the kings of Persia,[4] and Aristotle reported that the Spartan city-state under Lycurgus embraced explicit pronatalist laws such that ". . . the father of three sons shall be exempt from military service, and he who has four from all burdens of the state" (Aristotle, *Politics*, Book II, Chap. 9). Others noted that in classical Athens there were laws against celibacy and only fathers of legitimate children could appear as orators before the people or hold certain military commands (cited in Hutchinson, 1967, p. 9).

Yet Plato and other Greek philosophers saw the ideal state as consisting of a constant number of citizens numbering 5,040. The precise number was selected perhaps for mathematical reasons, but the general idea of a constant number of citizens on this small scale was likely seen as both sufficient for self-defense while small enough to maintain efficient governance and equal division of limited property. Aristotle argued that political leaders must

> . . . take care that the increase of the people should not exceed a certain number; and in determining that, to take into consideration those children who will die, also those women who will be barren; and to neglect this, as is done in several cities, is to bring certain poverty on the citizen, and poverty is the cause of sedition and evil. (Aristotle, *Politics*, Book II, Chap. 6)

In his comments on the pronatalist policies of Lycurgus in Sparta, Aristotle noted that it was "evident . . . that if the people increased there must many of them be very poor" (Aristotle, *Politics*, Book II, Chap. 9). In

[1] "God blessed them and said to them, 'Be fruitful and increase in number; fill the earth and subdue it. Rule over the fish of the sea and the birds of the air and over every living creature that moves on the ground'." Genesis 1:28 (New International Version)

[2] "A large population is a king's glory, but without subjects a prince is ruined." Proverbs 14:28 (New International Version)

[3] "Now Lot, who was moving about with Abraham, also had flocks and herds and tents. But the land could not support them while they stayed together, for their possessions were so great that they were not able to stay together. And quarreling arose between Abraham's herdsmen and the herdsmen of Lot. . . . So Abraham said to Lot, 'Let's not have any quarreling between you and me, or between your herdsmen and mine, for we are brothers. Is not the whole land before you? Let's part company. If you go to the left, I'll go to the right; if you go to the right, I'll go to the left.' " Genesis 13:5–8 (New International Version)

[4] "Next to prowess in arms, it is regarded as the greatest proof of manly excellence to be the father of many sons. Every year the king sends rich gifts to the man who can show the largest number: for they hold that number is strength" (Herodotus, *The History*, Book I, Chap. 136, cited in Hutchinson, 1967, p. 8).

this juxtaposition of population size and poverty, Aristotle anticipated many of the debates of the 19th century.

Perspectives on such matters in Rome were quite different. Instead of limiting its boundaries to those of a small city-state, and dealing with any population increase through trade and emigration, the Roman conception was of a growing population that would expand Roman territories via military power. Subsequent maintenance of the resulting empire required continued demographic increase. The goal of increases in the numbers of potential soldiers to serve imperial interests was reflected in Roman legislation (Hutchinson, 1967, p. 13–14).

2. Medieval Pauses

The classical tradition of thinking and practice regarding population matters diminished in Europe during the Middle Ages. Medieval thinkers generally believed that population growth was a sign of God's benevolence, and considered large families as one of his blessings (Spengler, 1942, p. 4–5, cited in Hutchinson, 1967, p. 15). The classical tradition was, however, maintained to some degree in the Arab world; in the 14th century, the eminent Arab historian Ibn Khaldun devoted an entire chapter of his *Prologomena* to a discussion of demographic change (Hutchinson, p. 15–16). He argued that the economic well-being of a society would be promoted by population growth, and described how states can promote the fertility of their subjects through wise and lenient government.

With the Renaissance, demographic discussion reemerged in the West as well. Already, during the 15th century, Francesco Patrizzi of Siena argued that while a large population might be desirable, this was so only with sufficient resources to support its numbers without mass poverty. In the 16th century, Niccolo Machiavelli was characterizing population increase as desirable for the monarch (Machiavelli, *The Prince*, Chap. 10). but also noting that demographic increases in excess of available resources would be constrained by poverty, disease, floods, plagues, or famines (Machiavelli, *Discourses*, Book I, Chap. 1 and Book II, Chap. 5, cited in Hutchinson, p. 16–17). Six decades later, the French political theorist Jean Bodin argued further for the virtues of larger populations as a source of political stability for the state and monarchy.[5] In 1588, the Jesuit thinker Giovanni Botero produced a treatise on population that both advocated a large and growing population as a source of strength and security for the state, while anticipating by two centuries the arguments of Malthus that the power of human reproduction exceeds the potential of agricultural subsistence.[6]

[5] Bodin was not only a theorist, but also counselor to the Duke of Anjou and a member of the Parliament of Paris.

3. From Mercantilism to Marx

European economic and political thought was dominated, for much of the three centuries from 1500 to 1800, by mercantilism. In this tradition, the population controlled by a monarch determined the power of his or her monarchy. For Frederick the Great, "the number of [the] people makes the wealth of states." People represented the monarchy's source of labor and soldiers, and hence the monarch was right to intervene to maximize the rate of population growth and to limit outmigration.

By the 18th century, utopian thinking had embraced mercantilists' view that population size was a principal determinant of wealth and prosperity. But they rejected the mercantilists' support for absolute monarchy, arguing instead that mankind could be perfected such that there would be no need for coercive social institutions, land could be held in common, and the resources produced by the application of the population's labor to the land distributed on the basis of need. Thus in their view, any level of population size and growth would be consistent with continuing progress. Among the leading utopians were the Marquis de Condorcet, William Godwin, and Daniel Malthus, the father of Thomas Robert Malthus.

A very different stream of thinking evolved first among physiocrats such as François Quesnay. Like the utopians, they opposed the authoritarian interventions favored by the mercantilists, arguing instead for what they termed "laissez-faire." Land rather than labor produced economic surplus, and hence the utopians erred in arguing that excessive population growth would lead to poverty. The physiocrats were the first to seek out and use the then-emerging data on demographic patterns produced by John Graunt, Edmund Halley, William Petty, and Gregory King.

The arguments of the physiocrats were influential with the classical economists who came to dominate the economic thinking of British political leaders by the early 19th century. For Adam Smith, David Ricardo, and Thomas Robert Malthus, there were three factors of production—land, labor, and capital—but of these only land was of a fixed supply. Hence increased

[6] Discussed in some detail in Hutchinson, *op cit*., p. 18–20. Botero, like Bodin, did not limit his role to theoretical writings. He served as Secretary to Federico Cardinal Borromeo, longtime Archbishop of Milan, and as an aide to the ruler of Savoy.

inputs of labor or capital applied to the land would lead to diminishing returns, with resulting limits on agricultural and industrial production.

It was Malthus who focused most deeply on the demographic dimensions. His first *Essay on the Principle of Population*, written in 1798, was a polemic deficient in empirical evidence, and directed principally against the utopian writings of William Godwin, Marie-Jean Antoine de Condorcet, and Malthus's own father Daniel. The perfected human society of the utopians was not possible, he argued, because without conscious constraints the basic biological propensity toward sexual behavior and unlimited reproduction would overwhelm the limited increases that could be extracted from the land.

Criticisms of his first Essay prompted Malthus to undertake more serious research and analysis, incorporated into subsequent revised versions. He estimated that a country with an excess of land relative to its population might double in size every 25 years. However, in more typical situations in which land was not in surplus, population growth would be limited by what he termed "positive checks" such as "sickly season, epidemics, pestilence, and plague." The alternative to such terrible positive checks was logically "prudential restraints." By this he meant both "moral restraint" such as late marriage accompanied by celibacy outside marriage and "immoral vices" such as promiscuity, prostitution, homosexuality, birth control, and abortion. Of these, only moral restraint was acceptable to Malthus, a former Anglican curate (Teitelbaum, p. 179–180). No humane society could ignore the need for prudential restraints, as the alternatives would necessarily be increased poverty, starvation, and suffering as the positive checks came into force.

While Malthus opposed both contraception and abortion on moral grounds, those who decades after his death called themselves "neo-Malthusians" embraced his arguments about the links between excessive population growth and poverty, but promoted use of voluntary means of fertility control. Their embrace of Malthusian arguments led to sharp rhetorical clashes between them and those on the left, who argued that the cause of poverty was not excessive population growth, but rather an economic system that failed to equitably distribute the output of economic activity.

Both Malthus and the neo-Malthusians, in turn, came under concerted fire from Karl Marx and his associates. For them, poverty was caused by capitalism, which allowed owners of capital to siphon off part of the surplus product produced by labor. Under socialism, these workers' products would be provided to the workers, thereby eliminating poverty. Hence any number of people could be supported, as people were at once producers and consumers; this was a view shared with the utopians, although Marx was otherwise quite critical of the utopians' views.

II. FROM THE 19TH TO THE 20TH CENTURY

This all-too-brief summary of more than two millennia brings me to the two centuries since 1800, which I will examine in more detail. The dramatic declines in both mortality and fertility that characterized this period were the topic of much debate and concern. The theory of the demographic transition (discussed in Chapters 68 and 69 of Vol. III), which came to prominence during the 1930s, explained these trends as consequences of forces of modernization such as industrialization and urbanization. (For detailed descriptions of the theory and empirical tests thereof, see Coale and Watkins, 1986; Teitelbaum, 1984.) Yet, contrary to the timing patterns implicit in the theory, it was the agrarian and rural France of the 18th century that experienced the earliest recorded sustained declines of fertility (van de Walle, 1974)—at least a century earlier than that of Great Britain, the pioneer and crucible of the Industrial Revolution, and even further in advance of rapidly industrializing Germany (see Chapter 69, Vol. III).

Evidently there were no obvious systematic patterns in the timing of such fertility declines, but all industrializing societies ultimately did experience fertility declines, some in the 19th and others in the 20th century. Moreover, despite the large differences among these societies in their histories, religions, languages, politics, and cultures, a few common population issues, which were of key concern during the period from 1870 to World War II, can be identified. It may be useful to categorize these political themes as follows:

Strategic demography, nationalisms, and the "Volk"
Concerns about poverty
The embrace of science: the rise and fall of eugenics and Social Darwinism
Taxes, medals, family allowances

1. Strategic Demography, Nationalisms, and the "Volk"

Perhaps the most common theme related to demographic change within Europe after 1870 concerned its implications for nationalism, national power, and related imperial interests. This has been described previously by the shorthand term "strategic demography" (Teitelbaum and Winter, 1985), a perspective that was most vigorously expressed in France.

The early decline of French fertility beginning in the middle of the 18th century coincided with a period in which the relative power and influence of France initially rose and then plummeted. By the late 19th century, France had declined in relative terms from perhaps the dominant state in Europe to one struggling to compete with the surging power of Britain and Germany. Of course the same century saw deeply destabilizing developments in France,[7] but it is perhaps unsurprising that many leading 19th-century French intellectuals focused instead on the early French fertility declines, and the resulting diminishment of the size and dynamism of the French population, as a central cause of the decline a nd "decadence" of France that they perceived to be underway.

While such concerns were present during the first half of the 19th century, they came into full cry following the French military collapse before the armies of Prussia in 1870–1871, which culminated in the creation of both the German Empire of Bismarck and the French Third Republic. In the ensuing final decades of the 19th century, the French Assembly considered numerous legislative proposals with pronatalist intent, clearly population policies in the restricted meaning discussed earlier. These included tax exemptions for heads of large families, tax surcharges and state appropriation of inheritances for unmarried adults and the childless, and restrictions on voting rights of unmarried men aged 26 to 40. While many such policies were proposed, the unstable coalitions that characterized the Third Republic meant that few of these provisions were adopted, and some of those that were passed were later rescinded.

In 1896, a coalition of prominent French intellectuals and politicians founded the National Alliance for the Increase of the French Population (*Alliance nationale pour l'accroissement de la population française*). This quickly emerged as an energetic and effective lobby group that framed numerous legislative proposals and pressed them on members of the government and the National Assembly.

By 1900, a resolution to create a commission on depopulation gained support from over 130 members of the French Senate. This commission, which began its work in January 1902, took only six months to conclude that the "prosperity and grandeur of France" required financial incentives to encourage French couples to increase their fertility (Beale, 1911, p. 171–267, as cited in Quine, 1996). Within a decade, this view had become the norm in France, as evidenced by the emergence of a broad-based Parliamentary Group for the Protection of Natality that by the election of 1914 had attracted more than half of the deputies in the National Assembly (Quine, 1996, p. 66).

Germany and Great Britain experienced their fertility declines much later than in France, and both elite and mass attention to low fertility also appeared much later. While in the 1870s the political class in Paris was actively debating the causes and consequences of French fertility decline, the British equivalent was more focused on the perceived dangers of too-high fertility in increasing poverty levels, with active debate especially about the merits or otherwise of the neo-Malthusian arguments and activism then underway in London.

In Italy, where fertility declines also occurred far later than in France, there was little visible support for promoting births until the 1920s, with the rise to power of Benito Mussolini's fascists.[8] Indeed, Mussolini himself had embraced neo-Malthusian ideas only 9 years earlier, just before the onset of World War I (Wanrooij, 1990, p. 79, as cited in Quine, 1996, p. 25). Yet in the ensuing slaughter, Italy lost over 680,000 soldiers (vs. 765,000 British and nearly 1.4 million French), and notwithstanding Mussolini's 1913 embrace of neo-Malthusianism, one of Mussolini's central goals after taking power in 1922 was to increase the population of Italy.

In a famous speech in 1927 and an essay published in 1928 titled "Il numero come forza" ("Numbers as Force"), Mussolini articulated a rejection of neo-Malthusian principles in favor of expanding the Italian population by at least 25% or 10 million (Mussolini [1928]). The goals were almost textbook examples of strategic demography: to increase Italian economic power by counteracting underconsumption in the economy; to secure Italian national security in a European neighborhood populated by 90 million Germans, 200 million Slavs, and much larger populations controlled by the empires of Great Britain and France; and to provide military manpower for the dispatch of colonial settlement abroad that was intrinsic to the heirs of

[7] The French Revolution of 1789, the Terror of the mid-1790s, the rise to power of Napoleon Bonaparte (1799–1815) and the depredations of the Napoleonic wars, the Bourbon restorations of 1814–1815, the revolution of 1848, and the defeats at the hands of Prussia during of the Franco-Prussian War of 1870–1871.

[8] Indeed, Mussolini became *Il Duce* (Leader) of Italy a year before Hitler's first attempt to seize power in Germany in the failed Beer Hall Putsch. By the time Hitler, another survivor of World War I, became the *Führer* (Leader) of Germany, Mussolini had ruled Italy for more than a decade.

the Roman Empire. The Italian fascists would lead to the rebirth of a "young and fertile race," the "national resurrection" of a powerful New Italy.

2. Concerns about Poverty

As noted earlier, there were long-standing concerns about poverty resulting from high rates of fertility and population growth, concerns that became more visible during the first half of the 19th century in response to the writings of Malthus, his followers, and his critics. Such concerns were most visible in Great Britain, where Malthusian ideas originated and then generated sustained interest and debate for many decades.

Indeed, one of the ironic twists that has heavily affected population debates over the past two centuries is the fact that Marx resided in London during the 1870s when the neo-Malthusians launched a highly public and energetic campaign, of which Marx was presumably aware. The radical leaders of the movement deliberately sought to test British laws prohibiting publication of information about birth control by openly reprinting a half-century-old text by an American physician, Charles Knowlton, *The Fruits of Philosophy*. This was one of the first test cases, in which Charles Bradlaugh and Annie Besant openly announced the book's re-publication, were arrested, and then in 1877 tried in a highly visible trial that was amply covered by the British press. This very public campaign by the neo-Malthusians may have something to do with Marx's exaggerated denunciation of Malthus and his theories, a denunciation which, as subsequently interpreted by Marxians, produced a century of controversy that to some degree still continues.

Meanwhile, in Germany, one of the leading Marxists of the period, Karl Kautsky, published a book arguing that in reality there was no conflict between Marxist and Malthusian theory. "The two," he asserted, "are not in principle incompatible"(Kautsky 1880, p. 166–192). For this, Kautsky was bitterly excoriated by none other than Friedrich Engels, close confederate and coauthor of Marx, and by then the defender of Marxian orthodoxy. In 1910, Kautsky recanted his apostasy, thereby solidifying the notion on the left that Malthusian theory was fundamentally reactionary (Kautsky, 1910, Chap. 15–16).

Support for Malthusian and neo-Malthusian ideas was more muted in France, without doubt due to its early fertility declines. Yet even in France, a neo-Malthusian society *(Ligue de la régénération humaine)* was founded in 1896, along with other efforts to promote the practice of birth control. Indeed these organizational efforts occurred during the same year as the founding of the National Alliance, and their near-simultaneous appearance may not have been unrelated.

Italy, unified only in 1871, was a latecomer to industrialization, modernization, urbanization, and the demographic transition. Its population was largely agrarian and poor; indeed even by the late 1930s, nearly half of the economically active population worked in agriculture. Its fertility and mortality rates had not shown signs of decline until close to the turn of the 20th century, and remained high throughout World War I and into the 1920s. The average rates disguised large regional disparities: the North experienced rapid industrialization and relatively early declines in both fertility and mortality, while the South was dominated by low-productivity agriculture performed by peasant farmers who sustained long-standing patterns of high fertility and high mortality.

By the turn of the 20th century, these conditions of deep poverty in the South led to increasing interest among Italian intellectuals and reformers in Malthusian ideas, and eventually to the development of a small but active movement supporting the adoption of contraception. In 1912, two leaders of this movement (Luigi Berta and Secondo Giorno) were brought to trial for publication of an allegedly obscene manual titled *L'arte di non far figli: neomalthusianismo pratico* (The Art of Not Having Children: Practical Neo-Malthusianism), of which some 27,000 copies had been sold. Like the London trial of Charles Bradlaugh and Annie Besant 35 years earlier, this Milan trial provided much free publicity to the cause, and in the end resulted in acquittal. Berta and Giorno promptly founded a new neo-Malthusian League and, until the onset of World War I, published a periodical with the evocative title *Educazione sessuale: rivista di neomalthusianismo e di eugenica* (Sexual Education: The Journal of Neo-Malthusianism and Eugenics).

3. The Embrace of Science: The Rise and Fall of Eugenics and Social Darwinism

The 19th century was in many ways the century in which science was first embraced enthusiastically by both the elite and the mass public, in part attributable to the evolutionary ideas of Charles Darwin. Many of the natural and social scientists who rose to prominence in this period played a powerful role in stimulating interest and concern about low fertility and depopulation.

In France, the national harbinger of concern about low fertility, early alarms came from prominent social scientists such as Frederic Le Play, a sociologist, engineer, and founder (in 1856) of the Society of Social Economy, and Paul Leroy-Beaulieu, professor at the College de France and founder and editor of *L'Économiste française*. While they differed in their prescriptions (with Le Play urging a domestic pronatalist strategy while Leroy-Beaulieu advocated French colonial expansion and the annexation of Tunisia), they agreed that the decline of France relative to Germany would continue unless the growth of the French population could be augmented.

More biologistic explanations were popular across the English Channel, most notably in the rise of eugenics. The word itself was a neologism created in 1883 by the English polymath Sir Francis Galton (1822–1911) from the Greek "noble in heredity." Galton, a cousin of Charles Darwin, was himself one of the most prominent scientists of his day: he was a founder of modern psychology, the creator of now-standard statistical correlation and regression analyses, inventor of identification via fingerprints, as well as a geographer, explorer, and meteorologist.

Galton and his followers took many steps beyond where Darwin had trod. Their core argument was that modern science for the first time made it possible to improve the human condition by cultivating "desirable" inherited traits and eliminating "unsuitable" ones. Eugenics and its supporters formed part of a larger intellectual current called Social Darwinism, in which the evolutionary insights of Darwin were to be applied to human societies, which came to be seen as subject to the same Darwinian natural laws of "struggle for existence" and "natural selection of the fittest."

Contrary to current-day perceptions of that period, in these early days there was nothing intrinsically reactionary or right-wing about such ideas. For decades surrounding the turn of the 20th century, the lure of nominally scientific, eugenic, and Social Darwinist ideas attracted fascists, socialists, liberals, racists, and feminists alike. Ultimately, however, both eugenics and Social Darwinism were captured by the forces of reaction, racism, and fascism, and both were fatally discredited by the horrors perpetrated by Nazi Germany. (For a comprehensive treatment of the intellectual and political history of the eugenics movement, see Kevles, 1995.)

Although French intellectuals did not embrace eugenics as enthusiastically as did their British colleagues, those in France who were supportive of eugenics sought to closely align themselves with the pronatalist advocates led by the National Alliance. The founder (in 1896) and president of the alliance, Jacques Bertillon led a large French delegation to the First International Eugenics Conference at the University of London in 1912, and an alliance cofounder Charles Richet served as vice president of the French Eugenics Society, also founded that year (Quine, p. 67).

In Italy too, the pronatalist enthusiasms of Mussolini and the Italian Fascist Party drew on a substantial body of arguments and claims emanating from Italian intellectual and scientific circles. In particular, the fascists embraced the ideas of Italy's most prominent anthropologist, Giuseppe Sergi, who long before the founding of the Italian Fascist Party had embraced the then-burgeoning notions of "scientific racism." In 1900, Sergi had put forward the argument that the Italian "race" had inherited from its Roman forebears an innate drive toward empire, a disposition toward conquering and colonizing lesser "races." These "imperial Italian race" notions converged with related intellectual currents supporting the rising influence of eugenics and Social Darwinism.

In 1913 (just after the Milan trial of the Italian neo-Malthusians Berta and Giorni), eugenics had converged intellectually with pronatalism and Social Darwinism in the founding of *Comitato Italiano per gli Studi di Eugenica* (Italian Committee for the study of eugenics), which in 1919 became the *Società Italiana di genetica e Euginica* (*Italian Eugenics Society*). The intellectual leaders of this group were Guiseppi Sergi and the demographer Corrado Gini. In 1912, Gini (1884–1965) had published his *I fattori demografici dell'evoluzione delle nazioni* (Demographic Factors in the Evolution of Nations), in which he argued for a comprehensive set of pronatalist policies to enhance the economic prosperity and military security of the Italian nation. These included positive incentives such as welfare benefits and tax reductions to those who bore many children, negative incentives imposed on the unmarried and married but childless, and in general encouragement toward early marriage and large families.

The fascist government under Mussolini embraced many of these ideas, including both Sergi's notions of the "imperial Italian race" and Gini's prescriptions as to how its innate imperial proclivities might be facilitated by increased fertility.

4. Taxes, Medals, Family Allowances

Many of these ideas, promoted effectively by advocacy groups (e.g., the National Alliance in France), were translated into formal government policies during the first decades of the 20th century. In certain cases, these ideas resulted in the emergence of population policies during the chaotic political-economic period of the interwar years and during World War II. The three most prominent instances of this phenomenon occurred in France, Italy, and Germany.

a. France

In France in 1913, the French parliament enacted a new family allowance act advocated by pronatalist groups, which provided substantial payments to fathers for each child between the ages of 3 and 13. In 1914, French income tax rates were modified to reduce taxes imposed on larger families. However, many of these provisions were delayed by World War I, and the family allowances adopted in 1913 were allowed to diminish in real terms with inflation.

After the chaos and mass slaughter of the war, it is ironic to note that in 1919, in the French Senate debates on the Treaty of Versailles, the French Premier and Minister of War Georges Clemenceau saw fit to address himself to the strategic threats posed by low French fertility:

> The treaty does not say that France must undertake to have children, but it is the first thing which ought to have been put in it. For if France turns her back on large families, one can put all the clauses one wants in a treaty, one can take all the guns of Germany, one can do whatever one likes, France will be lost because there will be no more Frenchmen. (*Journal Officiel: Débats du Senat*, 11 October 1919, p. 1625–1626; as cited in Tomlinson, 1983)

Following its election in 1919, the center-right government formed by the *Bloc National* created a *Conseil superieur de natalité* to develop new pronatalist policies. It also overwhelmingly passed legislation to prohibit "antinatalist propaganda," and adopted criminal penalties against providers of abortion. In 1920, the *Conseil superieur de natalité* organized the first national celebrations of *Journée nationale des mères de familles nombreuses* (National Day for Mothers of Large Families), which became Mother's Day in 1928 and Mother's Festival in 1941, during which some 30,000 mothers with five or more children received bronze, silver, or gold medals recognizing their service to the French nation. These celebrations were emulated two decades later by the Vichy Government. Later that same year, legislation was adopted that imposed a 25% surcharge on unmarried males and females over age 30, along with a 10% surcharge on childless marriages of 10 years or more in duration. In 1921, special train fares were legislated for large families, and in 1922 large families received preference to rent apartments in subsidized public housing (Talmy, 1962, vol. 1, p. 162–165, and Tomlinson, 1983, cited by Quine, 1996, p. 74.).

During the 1920s, French pronatalism developed from elite activism to a mass movement. There was a coalescence among national political movements ranging across much of the political spectrum, religious defenders of both the family and traditional values, and widely dispersed local and regional groups promoting aid to families. Many of the latter had their roots in clerical circles, yet reflected the goals of the lay Catholic establishment. Their memberships reached some 300,000 persons by 1930, far outnumbering the 40,000 supporters of the secular National Alliance for the Increase of the French Population. Though they differed in particular ways, they shared a common commitment to increase financial support for French families so as to facilitate increased childbearing.

In 1932, this loose coalition achieved a major success with passage of the Family Allowance Act. The act made compulsory the payment of family allowances *Allocations* that had been introduced voluntarily by many industrial employers. Most of the financing continued to come from employers, but by 1938 nearly two-thirds of the 9 million industrial workers in France received such supplementary payments. These payments could be substantial relative to earnings, especially at the lower end of the social scale, although the nominal amounts varied during the economic crisis of the 1930s and during World War II, and their real value often declined when inflation accelerated.[9] Still, following World War II, an unskilled French worker with three children received a family allowance equal to half his pay, while the allocation to a factory worker with five children exceeded the average wage for such occupations (Prost, 1989, p. 155).

Finally, in 1941 the Vichy government organized festivals of family culture that included a Mother's Day celebration in Reims under Maréchal Philippe Petain's patronage. Some 21 years after the 1920 celebrations organized by the *Conseil superieur de natalité*, the collaborationist Vichy government reflected continuity with the practices of earlier nationalist governments by awarding medals to women with large families: bronze for women with 5 or 6 children, silver for those with 7 to 9, and gold for those with 10 or more (Teitelbaum and Winter, 1985, p. 38–39).

b. Italy

In Italy, during the mid-1920s, Mussolini's government declared *una battaglia delle nascite* (battle for births) to be conducted on many fronts. In 1926, a celibacy tax was imposed on unmarried men. It was portrayed as an evolution of a tax imposed by the Roman Emperor Augustus, but may well have been based more immediately on the model of the 1920

[9] Even so, following World War II an unskilled French worker with three children received a family allowance equal to half his pay, while the allocation to a factory worker with five children exceeded the average wages for such occupations (Prost, 1989, p. 155).

French income tax surcharge imposed on men and women who were unmarried and on married couples with no children. The Italian celibacy tax was based on both income and age, and for unmarried men between 35 and 50 represented an income tax surcharge of fully 25% plus an additional flat-rate tax. The fascist government openly discussed additional measures, including a tax on married couples with few children, annulment of marriages that were childless after 5 years, exclusion of unmarried and low-fertility persons from attractive public sector employment, and the appropriation of wealth left by persons with no direct heirs or inherited by unmarried heirs (Quine, 1996, p. 41).

In his 1927 speech, Mussolini had forecast that under the influence of fascist pronatalist policies, the Italian population by 1950 would have increased from about 40 million to 60 million. Yet it was not to be, and by 1950 the population of Italy was still only 47 million (United Nations, 2003). The war could not be blamed for this failure as in 1938, in the build-up to World War II, the regime acknowledged that its battle for births had failed, and indeed that Italian fertility and marriage rates had continued to decline over the preceding decade.

c. Germany

But it was in Germany that the most aggressive, and finally, the most disastrous political measures were taken by the Nazis. As Paul Weindling comments (1988, p. 111), these measures were derived partly from the comparison made in 1921 by Oswald Spengler of low fertility to a "racial senescence." This idea which was then adopted by the German doctor, statistician, and demographer Richard Korherr in his study of the German fertility decline, the 1928 edition of which was honored with a preface by Benito Mussolini himself, while the preface of the 1935 edition was written by Heinrich Himmler (moreover, Richard Korherr later became head of the SS Department of Statistics).

It is not possible to disassociate the Nazi regime's population policy from its racial policy, which was a combination of three principal beliefs: the superiority of the "Aryan" race, the primacy of the state's interests over those of the individual, and women's main function being motherhood. These beliefs led to the three most ferocious political campaigns of the Nazi government: the sterilization and extermination of millions of "non-Aryans," the promotion of population growth among "racially pure" Aryans, and settlement of the resulting increasing number of Aryans in lands conquered by the German army or liberated through ethnic cleansing.

It is undoubtedly the second of these three campaigns, the promotion of growth among the racially pure Aryan population, which should be discussed here, even though the other two beliefs aimed at, and produced, direct demographic consequences. From the beginning of the Nazi regime, in 1933, interest-free loans were given to young married couples on the condition that they met the necessary racial conditions (being Aryan) according to the criteria established. These loans were also partly viewed as a means of creating employment for the millions of young unemployed males, as another condition was that the women showed proof of having been employed for at least 6 months and that they undertook to stop working once married. These loans were financed by the creation of a tax on unmarried men and women who earned a certain income, a "tax on single people," obviously copied from the Italian fascist legislation of 1926. The loans were provided for 8 years and the repayment capital was reduced by 25% on the birth of each child (McIntosh, 1983, p. 63).

The Nazi regime did not prohibit contraception or induced abortion before 1941, possibly to enable the eugenic use of these methods. However, from the very beginning, the government considerably limited distribution and access to birth control methods by closing all the family planning clinics and by prosecuting abortionists. The Nazis also harshly repressed people who were guilty of *Rassenschande* (racial shame), that is, sexual relations between Aryans and non-Aryans. Even more severe punishment was reserved for homosexuals, including among the Nazis themselves.

At the same time, a vigorous ideological campaign was undertaken in order to convince German women of their duty to produce many German children. The entire panoply of the formidable Nazi propaganda machine was mobilized to convince German women that motherhood was their sacred duty to the German state and its people. Oddly enough, given its rhetoric in support of the German family, the regime even encouraged Aryan Germans to have illegitimate children, provided that it was in the context of racially pure sexual relations (Bleuel, 1973, p.148–179, quoted by McIntosh, 1983, p. 62).

Did this policy have a major and durable influence on German fertility? Measured by the total fertility rate, fertility in Germany had, by the end of the 19th century, declined far less than in neighboring countries in Western Europe. Indeed, in France, the first country to experience fertility decline, nationalists used the high fertility rate in Germany as an explanatory factor for the military disaster in 1870 against the Prussians (Teitelbaum and Winter, 1985, p. 18–30). During the

1920s, after the defeat of Germany in World War I, German fertility fell to a level comparable with that observed in France and elsewhere in Europe. The total fertility rate (admittedly prone to significant variations due to postponing or bringing forward the fulfilment of desired fertility) fell in Germany to a level below the replacement of cohorts during the mid-1920s, before dropping to the historical low of 1.6 children per woman in the same year as Adolf Hitler came to power in 1933. Under the reign of the Nazis, the total fertility rate in Germany increased over a few years to 2.4 in 1939 at the beginning of World War II, but fell to less than 1.6 by the end of the war.

SUMMARY

Population policies, in the restricted sense of conscious actions by states to affect demographic trends, occupy an important place in the history of the 19th and 20th centuries. As the modern state evolved during this period, two foci of population policy emerged, relating first to military power of the state relative to its neighbors or competitors, and second to demographic trends internal to the state, relevant to perceived problems of poverty and population "quality."

Demographic components entered strongly into 19th-century debates about the sources of poverty and prosperity, especially in the passionate disputes among Malthusians, neo-Malthusians, and Marxians. Beginning around the 1870s, concerns began to emerge (especially in France) about "strategic demography," that is, threats to the state resulting from fertility decline. By the turn of the 20th century, parallel concerns about perceived decline in population quality appeared. Such concerns, perhaps exacerbated by the mass slaughter of the "lost generation" during World War I, attracted growing and broad-based enthusiasm for the new "science" of genetics and race, among intellectuals and politicians alike. During the 1920s, such concerns came to be co-opted by political movements of the right, including Social Darwinism. During the 1930s, such ideas flowered in some countries, ultimately morphing into the murderous depredations of the Nazi movement and its supporters elsewhere. Meanwhile, during the same decade more benign alarms spread about the by-then very low fertility rates experienced during the Great Depression.

By the end of World War II, ideas about differential "biological quality" on which Social Darwinism, eugenics, and scientific racism were based had been discredited by the Nazi genocides. Yet concerns persisted about the implications of very low fertility, with many governments adopting policies designed to increase fertility, as well as supporting the creation of demographic research efforts such as Institut national d'études démographiques (INED) in France and the Royal Commission on Population in the United Kingdom.

CHAPTER

101

An Introduction to Population Policies

STEFANO BALDI AND RAIMONDO CAGIANO DE AZEVEDO

Permanent Mission of Italy to the United Nations, United Nations Plaza, New York, United States

Facoltà di Economia, Università degli Studi di Roma "La Sapienza," Rome, Italy

As expanded on in the preceding chapter, the history of our societies shows that population policies, which tend to influence the size, structure, or dynamics of the population, even though they have not always been explicitly presented or perceived as such, are deeply rooted in the past. While being developed they are based, consciously or not, on ideological, military, or social grounds. Formerly, although it still happens nowadays, such policies were based on hypotheses or positions of superiority of one group vis-à-vis another one. In any case, it must be emphasized that they are developed somewhat independently from the actual circumstances that prevail at the time when they are adopted, and consequently from the possibility of implementing them, an aspect which is beyond the scope of this chapter.

Religion is an important source of inspiration for population policies. Persecution has been perpetrated in its name, sometimes leading to massive emigration of minorities, the creation of new human settlements in certain regions in the world, or even to the extermination of whole groups of the population. Religion has also been an important source of legislation in terms of private life regulation—marriage, family building, and reproduction.

Military motivations, particularly in the past, have been ground for nationalistic and imperialistic policies. The various motivations behind those two policies, that is, defense of the national territory for the former and expansion of zones of influence for the latter, have had the same effect: they tend to entail high pressure on the population. In the past they were often used as central themes in governmental policies and action in the developed countries, and even nowadays, they have provided motivation for the governments of certain developing countries.

Moreover, ideological factors have influenced the implementation of population policies—and still do. The major migration flows related to ethnic and racial discrimination provide recent examples of such a close relationship between ideologies and populations. Moreover, history is full of instances when abuse of political power was used to alleviate inequality and linguistic differences. The effects on population policies resulting from different schools of thought are subtler: for example, nowadays, the idea of a stationary population or of zero growth has had significant effect, both implicit and explicit, over population policies.

Most prominent among matters related to population policies, are those relating to fertility and reproduction, particularly two specific models, family policy and family planning. Family policy refers to a set of measures, rules, and behaviors that regulate the relations between governments and families, usually so that families can expand. Family planning, though not in opposition to family policy, is based first and foremost on a view of quality of life in which health and social conditions in human reproduction tend to be emphasized; when it is of a stronger type, family planning may include demographic objectives clearly expressed in quantitative terms.

The real difficulty, in defining a population policy, comes from the fact that most political actions eventually have direct or indirect effects over the population. Moreover, population policies cut across several sectors, affecting as they do many different areas, or interacting with them.

In fact, the following statement is quite right: "Population policy involves a good deal more than making family planning centers available to the rural poor. It also involves more than a recognition that poverty is a root cause of high fertility rates" (Dasgupta, 1995).

Actually, every nation will take political measures that affect the population and the size of families. However, it is sometimes useful to speak of population policies only in those cases when governments make explicit statements about those being their objectives. In many countries, population or family policies are only implicit within social policies and are not dependent on the demographic situation.

> Most countries have never had explicit and coherent policies on population, although all aspects of demographic change are affected by many government actions, usually taken for other reasons. The range of policies affecting population characteristics is so large that full consideration would include virtually all aspects of social and economic policy. (Pressat, 1985, p. 177)

I. DEFINITIONS, OBJECTIVES, AND COMPONENTS OF POPULATION POLICIES

Population policies may have various, multiple objectives—population size or more frequently, growth pace, age structure, geographic distribution, and so forth.

A policy can be considered an instrument for identifying the main objectives, combined with a specific set of means to reach them. The success of a policy is closely dependent on the capacity to relate objectives to the means available. Population policies are sets of various measures taken by a government with a view to influencing the size, growth, structure, and spatial distribution of the population.

Among other possible approaches to population policies, two definitions seem of particular relevance:

1. Strictly speaking, a population policy is a deliberate, purposeful policy aimed at influencing the number of the population in a given country. For example, a pronatalist policy will aim at increasing the size of the population, whereas a Malthusian, antinatalist policy would aim at reducing the size of it, or at least at bringing down the fertility rate and consequently the growth pace.
2. Broadly speaking, a population policy is a set of laws and other measures that directly or indirectly, deliberately or unconsciously affect the population, both in qualitative and quantitative terms.

According to point 3.5 in the Programme of Action of the International Conference on Population and Development, which was held in Cairo in 1994:

> At the international, regional, national and local levels, population issues should be integrated into the formulation, implementation, monitoring and evaluation of all policies and programmes relating to sustainable development. Development strategies must realistically reflect the short-, medium- and long-term implications of, and consequences for, population dynamics as well as patterns of production and consumption. (United Nations, 1995a, p. 14)

The characteristics of a population may be affected by policies that are implemented in a wide variety of sectors (health, housing, employment); consequently it is important to draw a distinction between those policies that have an indirect (or implicit) demographic effect and explicit ones that directly aim at (and were designed with a view to) affecting the population. Population policies have widely differing origins and substantially different effects, depending on their targets (housing policies, health policies, employment policies). A very good example is provided by policies directly aimed at reducing child mortality and in the area, significant success has been achieved within the social and health policies adopted in the latter part of the 20th century.

Mortality, fertility, and migration are the main components of population policies and represent the three facts that determine the quantitative evolution of the population. Whereas mortality and fertility rates may change in a gradual way, migration, both internal and international, may cause sudden variations in the structure of the population. Migration can be considered the most flexible of the three factors in implementing population policies, though it may also have negative effects over social stability when it is exceedingly massive.

The main methods that can be used to change the level of fertility rates include (a) measures relating to women's status; (b) systems on the protection of children, youth, and high-risk groups; (c) education and information; (d) strategies for an improvement of the distribution of the population; and (d) family planning and reproductive health services.

It is only recently that governments have started explicitly considering population issues as a stake in public policies, and in some countries there is still a tendencyto view population policies solely in terms of growth control.

Most population policies are adopted at the national level, although ongoing international debates on the subject clearly have strong influence over the attitude of national governments, particularly through the major international conferences (we shall return to this point at the end of the chapter, but the reader is also referred to Chapter 120 of this volume for further details on that point).

"An important first step in formulating population policy is to identify population problems and policy measures on the basis of population studies and research" (United Nations, 1993, p. 204). As with many other policies, implementing a population policy often implies hazards and requires occasional adjustments. A major factor is that population problems, cutting as they do across national borders, from a local scale take on an international one, which makes institutional responses still more complex.

II. THE RELATIONSHIP BETWEEN POPULATION POLICIES AND POPULATION THEORIES

1. Different Types of Population Policies

Roughly speaking, there are two major groups of population policies: the policies devised with a view to limiting population growth, and those aimed at encouraging growth or slowing down decrease. The former are usually called "Malthusian."

Population theories provide the basis for population policies to be adopted. According to Christopher Wilson and Roland Pressat (1985), "a population policy requires a clear, explicit statement of aims and a plan, backed by a theoretical framework, of how to achieve these aims" (p. 177). Concern is often expressed about governments interfering, through population policies, in this type of sector which is so intimately related to human private behavior. The debate on how justified any intervention in that area can be is a long-standing one. Among the wide variety of answers from various authors, the following, by Alfred Sauvy, seems to offer the most appropriate conclusion: "Interference exists anyway" ("L'intervention existe en tout état de cause") (Sauvy, 1966, Vol. 2, p. 371).

2. Policies Aimed at Limiting Population Growth

Those population policies that aim at addressing issues related to size of the population deal with growth rates rather than with the size itself.

In some cases, governments can implement antinatalist policies by adopting measures to encourage contraception. Basic measures taken to control population growth usually include supplying free contraceptives and campaigning for contraception. However, other initiatives, which vary from one cultural and religious context to another, may also affect the growth of the population. The most significant ones include rules on legal minimum age at first marriage, and laws concerning divorce or remarriage.

Governments' attitude to migration may also affect the growth of the number of the population and even its composition. If the overall legal framework is in favor of immigration, it may become a factor in accelerating population growth. In many cases, as in the United States or Canada, it may also delay the aging process, as a result of the specific contribution of young immigrants. On the contrary, those countries that allow large numbers of people to emigrate may consider such strategies as a means to alleviate demographic pressure. Permanent migration, which is now usually due to economic factors, still has significant demographic consequences. We return to this subject in Chapter 110, which is on migration policies.

Women's education has significant influence over fertility, in that it entails such effects as postponing first marriage, bringing the demand for children to lower levels and increasing contraceptive use (United Nations, 1995e). Any measure that encourages women's employment also has an indirect, though significant effect over decline in fertility rates.

3. Policies Aimed at Increasing the Size of the Population (or Slowing Down Its Decline)

Policies aimed at increasing population size are usually adopted by governments that are concerned with the negative evolution of the population growth rate (or even an actual decrease in the size of the population). Several methods and mechanisms (financial, fiscal, social ones) can be used to implement such policies, while taking into consideration the various factors that influence them (see Appendix 1).

Many different financial and fiscal means can play a role in encouraging population growth—low interest rate loans, benefits for young people and large families; benefits and assistance to working mothers (e.g., by allowing mothers to have paid leave), benefits for families based on the number of their children; cutting income taxes (in proportion with family size); allowances for the birth of a child (with amounts increasing proportionately to the size of the family); subsidizing day care and nursery schools.

Many social measures (concerning housing, schools, health care, and employment) can also be taken with a view to encouraging population growth—for example, the creation of special conditions for young couples renting or buying an apartment or house, access to information on modern contraceptive methods, or measures encouraging part-time employment.

Most of those measures or provisions are part of the so-called welfare state, which is currently being reappraised, and consequently should be reexamined in many developed countries, particularly in Europe.

Letting immigrants in is another possible option aimed at increasing the size of the population, though the issue is now an extremely controversial one, particularly among developed countries.

The psychological environment may also play a part in the success of population policies, particularly when they are aimed at increasing the population. Moreover, where raising children is concerned, the parents' expectations play an important part. In a society in which employment is so uncertain and the social cost of a child so high (in terms of education), parents are psychologically deterred from increasing the size of their family, even though their living standards may be quite acceptable.

In trying to stimulate birthrates, pronatalist policies sometimes aim at countering certain negative effects of population decline, particularly in relation to labor supply, human capital, and cultural heritage.

The Soviet Union under Stalin (in the 1930s) provides one example of implementing a staunchly pronatalist policy. Pursuant to the Marxist theory—which in fact does not differ much from mercantilist views, at least on this point—Stalin's pronatalist policy was based on the idea that population growth could be viewed as a stimulus to economic progress. In recent years, pronatalist policies have been implemented, to varying degrees, not only in such countries as Taiwan, South Korea, and Singapore (as will be expanded on in Chapter 103), but also in some extremely poor African countries.

4. The Adoption of Population Policies and Their Efficiency

An increasing number of countries are concerned with their population growth rates, and adopting policies aimed at solving the problem; and in international fora more and more developing countries have been expressing their preoccupation with the consequences of population growth (United Nations, 1996).

Though the proportion of countries that wish to effect major changes about the pace of their population growth has not much changed (Table 101–1), that of those countries who deem their growth rate exceedingly high has much declined: only 25% of the countries thought so at the beginning of this century, as against 83% only five years before!

The perception of fertility levels is approximately the same. The small proportion of countries that find their level of fertility satisfactory has significantly increased, rising from 11% to 18% in 25 years (Table 101–2). However, the proportion of countries who deem their fertility rates too high has also sharply risen to as much as 45% in 1996 (those countries represent 70% of the world population) (United Nations, 1997–2002). The evolution is clearly in close relation to the fact that fertility is declining in developing countries just as a growing number of governments are enforcing fertility regulation policies.

Health policies affect mortality and morbidity, and in the last few decades a favorable evolution of those two demographic variables has been observed. Life expectancy has been increasing everywhere in the world since World War II. However, few countries consider that the mortality level is wholly satisfactory. A survey by the United Nations on governments' atti-

TABLE 101–1 Governments' Views on Their Population Growth Rate (1976–2001): The Proportion of Countries (%)

Year	Satisfactory	Minor change desired	Major change desired	Total	Number of countries
1976	23	45	32	100	150
1986	16	45	39	100	164
1996	15	44	41	100	193
2001	15	44	41	100	193

Source: United Nations, 2002.

TABLE 101–2 Governments' Views on Fertility Levels (1976–2001): The Proportion of Countries (%)

Year	Satisfactory	Minor change desired	Major change desired	Total	Number of countries
1976	11	53	37	100	150
1986	13	46	41	100	164
1996	15	40	45	100	193
2001	18	38	44	100	193

Source: United Nations, 2002.

tudes toward mortality rates (United Nations, 1998) has shown that in 1992, 67.4% of countries considered their level of life expectancy as unacceptable. Most of those countries were developing ones, and their life expectancy levels are still quite far below those prevailing in developed countries.

In the mid-1970s the vast majority of governments (89%) considered that the spatial distribution of the population was inadequate (Table 101–3); the policies conducted in the last 25 years, however, have reduced such dissatisfaction, as the proportion of countries that wish to encourage further evolution in the area has gone down to 66%. Moreover, the majority of the problems that governments have had to face resulted from difficulties in dealing with urbanization, and the policies aimed at slowing down the growth of large cities have generally proved ineffective. Above all, it has been admitted that "the major urbanization problems of developing countries have little to do with the absolute size of the individual cities, but result from the failure to manage rapid urban population growth" (United Nations, 1993, p. 38).

The significance of censuses and surveys in formulating coherent population policies will depend on how often they are conducted (10-year intervals between censuses cause serious problems), and how comparable and analyzable they are. Another crucial element, particularly for developing countries, is the governments' level of commitment to population policy, as reflected in the way they develop national plans.

Two important aspects should be briefly mentioned: the relationship between population and development policies on the one hand, and population policies and environment on the other hand.

Development and environment are taking an increasingly important part in developing and formulating population policies. The relationship between population policies and environment has also been included in point 3.27 in the Programme of Action adopted at the International Conference on Population and Development in Cairo in 1994: "Implementation of effective population policies in the context of sustainable development, including reproductive health and family planning programs, require new forms of participation by various actors at all levels in the policy-making process" (United Nations, 1995a, p. 19–20). Unfortunately, the 2002 Johannesburg Conference failed to mention population issues in any explicit way.

TABLE 101–3 Governments' View on the Adequacy of the Geographic Distribution of the Population (1976–2001): The Proportions of Countries (%)

Year	Satisfactory	Minor change desired	Major change desired	Total	Number of countries
1976	11	37	52	100	150
1986	11	43	46	100	164
1996	29	30	42	100	192
2001	34	27	39	100	193

Source: United Nations, 2002.

The relationships between population and development are ambiguous. They depend on the social system, which may motivate individual, family, and social group strategies in various ways. At national level, development may have little influence over population growth in the short term. At lower levels, even over short periods of time, development plans that affect job creation may have strong influence on the evolution of the population through migration (United Nations, 1993, p. 6).

Another aspect of population policies currently under discussion is how they relate to local authorities. Many decisions relating to population issues depend on the local context (at the village, town, or region level) and, due to subsidiarity, efficiency requires a degree of decentralization in implementing them. The parties involved, the methods, and the areas of intervention of population policies clearly vary according to which levels are concerned. At the world and major regional levels, the United Nations and the cooperating institutions of the major zones (based on common geopolitical interests) are concerned with the large international migratory movements as well as the impact of conflicts and major shortages. At intranational levels, local authorities (from communes to federated States) and certain private institutions (e.g., large corporations) take an interest in those decisions that may have repercussions on the future of their populations (or workers, or customers). However, this chapter is focused on the national level, and we consequently deal mostly with governments' population policies, though it should be kept in mind that the most appropriate solutions to the problems and conflicts of interests caused by demographic evolution are not always to be found at the State level only, particularly where migration is concerned. The success of population policies implies political commitment, at local, national, and international levels.

5. Examples from Some Developing Countries

During the past two decades, the Governments of many developing countries have recognized the importance of for-

> mulating and implementing comprehensive national population policies. Many countries, however, do not have effective national population policies, while others have formulated policies that are not broad-based, comprehensive, integrated, multisectoral and adaptable to their socio-economic needs. Furthermore, although some countries have officially enunciated a population policy, it is not strongly supported by policy makers, planners, government officials and/or the general public. Other policies have not succeeded because they are not backed by proper legislation, plans of action, institutional arrangements and effective programmes and projects. (United Nations, 1993, p. 203)

In developing countries that are experiencing economic difficulties serious enough to affect the development process, it is particularly difficult to formulate any development program. For example, the implementation of authoritarian family planning methods in India only yielded rather uncertain results from a demographic point of view (see Chapter 113, which is on India). Likewise, in neighboring China, imposing family planning as a basic national policy required strenuous efforts, before the "one couple, one child" principle was eventually enforced in 1979 (see Chapter 112).

Despite the ethical and political reservations that necessarily come up concerning some of the measures that were taken, it must be admitted that China's population policy has been more efficient than India's, at least once it is acknowledged that the mortality and fertility transition in the former, which occurred much faster than in the latter, was a result of its population policy. However, such success perhaps was due to the economic, social, and cultural environment, rather than the population policy, strictly speaking. The example of India (particularly as far as certain States, such as Kerala, are concerned), as well as that of China, shows that the effects of population policies are all the greater as they are backed with such balanced economic growth as equitably benefits the different social classes. If the evidence of economic and social development is to be accepted as a prerequisite for an efficient population policy, then anti-Malthusian positions are eventually challenged. The evolution has been very clear in many countries, and still more so at the level of international relations (as is discussed in Chapter 103 of this volume).

Actually, except for China, very few governments have adopted coercive fertility policies, whether for ethical reasons or for the sake of efficiency. Most have chosen the opposite method, based on incitement and persuasion. In the latter part of this section are important illustrations of this, through various country case studies (Chapters 112–119).

6. Concerning Developed Countries

Two different concerns have characterized population policies in developed countries in the last few decades: foreign immigration and fertility decline, both of which have direct consequences over population aging. Consequently, most population policies explicitly adopted in those countries focus on those two aspects.

The case of France (which is discussed at length in Chapter 119) provides a good example of a country that implemented a pronatalist policy. To various degrees, other countries, such as Belgium, Luxemburg, Germany, and the Netherlands, also have chosen to enforce the same policy. Roland Pressat (1991) has very aptly summarized the situation of France:

> The French family policy is still currently broadly inspired from the principles contained in the Family Code, though a very large number of amendments and additions have been made to the earliest provisions established during the war. At the heart of the system lies the principle of various benefits paid in cash—prenatal or maternity benefits, family allowances from the birth of the second child on. . . . (p. 34)[1]

In the past the debate on population policies often took an ideological turn, between Malthusian and anti-Malthusian proponents. Only in recent times have the United Nations conferences on population (in 1984 and 1994) eventually achieved international consensus on the fact that population policies (or social policies that affect population dynamics) form a decisive part of development policies.

III. THE ROLE OF INTERNATIONAL ORGANIZATIONS AND AID IN PROMOTING POPULATION POLICIES

Though we shall not anticipate Chapter 120, in which the action of the international community is expanded on at length, this introductory chapter on population policies just cannot be concluded without mentioning, if only briefly, the part played by international organizations in that area.

The most comprehensive analysis of population policies at the world level was conducted by the United Nations (1996, 2002), which tried to summarize

[1] La politique familiale française s'inspire encore actuellement dans les grandes lignes des principes contenus dans le code de la famille et cela après les très nombreuses retouches et compléments apportés aux premières dispositions prises pendant la guerre. Le principe de l'octroi de diverses prestations en espèces est au coeur du dispositif: allocations prénatales, de maternité, allocations familiales à partir du 2e enfant. . . .

every government's perceptions of and every country's approaches to population policies. Every general policy is described in its institutional framework. Furthermore, demographic evolution, the size and age structure of the population, mortality and morbidity, family and fertility, international migration and spatial distribution, urbanization, and women's status are briefly described. That comprehensive survey, published in three volumes, makes it possible to compare the direct measures adopted by the different countries, and through which they implement their population policies.

Considering the nature and contents of population policies, as could be expected, many international organizations (particularly those of the United Nations system) are stakeholders in those issues. Most prominent is the UN Secretariat, through the Population Division of the Department for Economic and Social Information and Policy Analysis (DESIPA) in New York, while the United Nations Population Fund (UNFPA), whose headquarters are also in New York, is the most substantial source of aid funding for population-related matters. The United Nations Development Programme (UNDP) in New York offers a large number of aid programs to developing countries. Among the specialized agencies, the World Health Organization (WHO), the International Labour Organization (ILO) and the International Organization for Migration (IOM), all three of which are based in Geneva, and the Food and Agriculture Organization (FAO), whose headquarters are in Rome, have paid particular attention to the issue of population policies. The World Bank also plays an important financial role in population and development policies. "An increasing number of countries actively seek to work with the Bank on population policies—and borrow from it as well" (World Bank, 1994). At the regional level, the Council of Europe, based in Strasbourg, France, must be mentioned, as well as Eurostat for the production and dissemination of demographic data.

Many non-governmental organizations (NGOs) have played a vital role in population and development policies. They were pioneering in that area at a time when governments, restrained as they were by political, ideological, or bureaucratic considerations, were not in a position, or were unwilling, to take action (Sadik, 1991, p. 245). They played a crucial role in many countries in the implementation of aid programs. Organizations such as the International Planned Parenthood Federation (IPPF), the Population Council, the Pathfinder Fund, and the Rockefeller Foundation have been using extensive networks to disseminate their ideas and programs; on the other hand, religious organizations have had significant influence on population policies (or decisions) in many countries, and not only those where religion is a State institution. Religious organizations, to various degrees, are actively in favor of population growth.

The specific international conferences of the United Nations that have been held every 10 years since 1974 have also drawn the attention of governments to population policy issues; in fact, it was only after the 1970s that these issues were first recognized as essential in the development process. During the first conference, which was held in Bucharest in 1974, the first Population World Action Plan was adopted, and a relationship between population and development was thus officially recognized for the first time. During the Mexico City Conference in 1984, the Action Plan was amended so that the demographic evolution that had occurred since 1974 could be taken into account. The most important point included in the recommendations was on the development of population policy objectives. The 1994 Cairo Conference was titled "International Conference on Population and Development" (whereas for the first two conferences the word *development* was not mentioned in the official title, which included only the word *population*). For the first time the issue of population was viewed as part of the larger development issue (Najam, 1996), and the Conference adopted an Action Plan covering the next 20 years. The idea of one more conference on population in 2004 was rejected by the relevant authorities in the United Nations system.

APPENDIX 101–1 Table of Factors, by Sector, that Influence Population Policies

Agriculture	Soil preservation and land tenure
National defense	Recruitment and distribution of troops
Economic policy	Natural resources conservation, full employment, investment adequacy, land development and management
Education	School age limits, reduction of obstacles to girls' education
Finance	Fiscal systems (in particular, tax deductions for families), direct and indirect taxes, local taxes, access to credit and income opportunities, particularly for women
Industry and commerce	Concentration of companies, decentralization of industrial zones
Home affairs	Population census, registry offices, policies concerning abortion
Justice	Legislation on marriage and divorce
Housing and town planning	Building low-rent blocks of flats, distribution of flats, rent regulations and town planning management
Public health and population	Health policies (particularly directed at mothers and children), immigration, naturalization, abortion, contraception, population policy coordination
Employment	Full employment, welfare system, women's working conditions, pension systems, immigration, training programmes
Public works and telecommunications	Fares for transport and communications public services (trains, postal services), infrastructure
Civil service	Staff recruitment and distribution

P A R T

II

FROM FERTILITY CONTROL TO FERTILITY SUPPORT

GRAZIELLA CASELLI, JACQUES VALLIN, AND GUILLAUME WUNSCH

Paul Demeny pointed out in Chapter 98 that two big developments converged to focus population policy thinking on population growth issues in the aftermath of World War II. In the northern sphere, the baby boom temporarily masked fundamental questions already being asked in some countries, especially France, about what happens after demographic transition. But, in the wider world more especially, the onset of very rapid transition in Third World countries propelled the problem of rapid population growth to the top of the agenda, as spreading health improvements in these countries led to a faster rate of mortality decline than ever observed in any developed country, and a subsequent population explosion. The focus of concern then turned to excess fertility, to the point where northern public opinion was apt to accuse the South of endangering planetary equilibriums through unrestrained reproduction. This was in clear disregard of the fact that developing countries, like northern ones historically, needed time to add the new concept of fertility control to their very recent health improvements. Even so, this context focused population policy on fertility control, if not basic family planning.

This volume on population thought and policies plainly had to break away from this narrow and skewed approach; hence the historical chapter (Chapter 100) reviewing developments in population policies before 1940, placed at the end of Part I. More especially, however, in the belief that fertility is anything but the one issue of a population policy, Parts III and IV also separately address the other spheres that population policies cut across: health, migration, and age structures. But, because their dominance of the agenda in recent decades has tended to overshadow the fact that demography is not synonymous with fertility, this part (Part II) first addresses policies that deal with fertility and the family.

Until recently, the issue has been essentially very different in the developing and developed countries. Over the past half-century, the (presumptively excess) fertility of developing countries is what has exercised the international community, whereas low developed country fertility has, in most cases, only become a much more recent government concern. In fact, there are two different issues here, which are addressed separately: the developing countries are addressed in Chapters 102 and 103, and the developed countries in Chapters 104 and 105.

In Chapter 102, Thérèse Locoh and Céline Vandermersch give a wide-ranging review of fertility control policies implemented in Third World countries. It is an issue that has long been the focus of more ideological than scientific debate, but has ultimately been universally acknowledged as essential to economic and social development, notwithstanding that, at the same time, birth-control policies proper have had less real impact where not closely connected with social and cultural improvements in society in particular. But with or without policies, the second phase of demographic transition—fertility decline—is now everywhere under way, and well advanced in many countries. In some, it has even exceeded policy aims of replacement-level fertility. Some countries that were still only recently grappling with too-rapid population growth are now concerned at the prospect of population loss, and some have already made policy U-turns. This is the issue addressed briefly by Magali Barbieri in Chapter 103.

It is an issue that has long bedeviled many European countries, some of whom have long-standing fertility-support measures in place. Two questions remain open to debate, however: whether to let matters take their course, or try and curb the fall, or even reverse the trend, to restore a replacement capacity that has been largely eroded by current developments? Gustavo de Santis charts the history of fertility-support policies in the industrialized countries in Chapter 104. The other question is whether it is possible to pursue really effective policies that also respect fundamental human rights? A meticulous demographic analysis by the late, lamented Gérard Calot of the results of pronatalist policies in some countries where they were most openly pursued addresses this issue in Chapter 105.

102

Fertility Control in Third World Countries

THÉRÈSE LOCOH AND CÉLINE VANDERMEERSCH

Institut national d'études démographiques (INED), Paris, France

The fertility decline that has occurred in the majority of developing countries is indisputably one of the major events of the last 50 years (see Chapter 69, Vol. III). Concern regarding the rapid growth of world population began at the end of World War II. The developed countries were especially worried by the deceleration in their growth and had, up to that point, shown little interest in the developing countries which, at that time, constituted two-thirds of the world population and were not yet known as the Third World. From the 1960s, population forecasts established by the United Nations' Population Division have shown the growth potential of all the underprivileged countries of the planet, and over the last half-century world population has increased at the unprecedented rate of nearly 2% per year (see Chap. 77, Vol. III). Nevertheless, the increased control of fertility currently witnessed everywhere is occurring at different rates, and present situations are extremely diverse (see Chap. 69 and 71, Vol. III). At the beginning of the 21st century, the annual population growth of Third World countries is still, on average, 1.5% and as high as 3% per year in some of them. On a map of the world, Africa clearly appears as the last continent with high fertility (see Figure 69–9 of Chap. 69, Vol. III). Overall, Asia and Latin America have fertility levels that are significantly lower. There is no longer a uniform Third World with high fertility that can be compared to a developed world that has completed its demographic transition; we now have Third Worlds. Some countries have fertility levels that are comparable with those of the old European and North American countries; others, mainly in Africa, continue to value large families and still have relatively stable fertility levels.

This evolution, which we will discuss briefly in the first section of this chapter, is largely a result of general development policies that caused a decline in mortality, mainly in child mortality; an increase in education levels, particularly those of women; and an improvement in health and social infrastructures; but it is also the result of policies and programs created to reorient the fertility levels that we will discuss in this chapter.

In the second section, we will trace the evolution of fertility policies and the central role played by the United Nations which, during the four large conferences on world population, made an essential contribution in raising awareness of the population dynamic of developing countries, in developing theoretical knowledge on the factors that determined it, and in implementing national and international birth control policies and programs. We will then demonstrate how governmental opinions regarding policies on fertility control have developed. In the third section, we will discuss the means by which numerous countries implemented fertility control policies, in the forefront of which is the spread of contraceptive methods within family planning programs. In the fourth section, we will analyze the evolution of contraceptive practices in the three continents of the Third World, using a few countries as examples. In conclusion, we will mention some of the emerging issues regarding fertility control policies, for the governments of Third

World countries as well as for the whole international community.

I. SINCE 1950 FERTILITY HAS DECREASED BY HALF IN THIRD WORLD COUNTRIES

In 1950, the total fertility rate (TFR) was a world average of 5 children per woman. In 2002, it was only 2.8. The average completed fertility of women has therefore more or less been halved in 50 years, mainly due to the decline that has occurred in Third World countries (Table 102–1) where the total fertility rate has decreased from 6.2 to 3.1 (United Nations, 2002c). This is an extraordinary change that presupposes considerable changes in family dynamics and individual behavior in these societies. Figure 102–1 clearly illustrates the scale of the trend in the 1950–2000 period. Admittedly, sub-Saharan Africa and some Middle Eastern countries have so far resisted the general decline, but their fertility transition also began a few years ago (Locoh and Hertrich, 1994). East Asia and Latin America are the two developing regions for which the changes in fertility have occurred most rapidly.

Figure 102–1 summarizes the 50 years of change (see also Appendix Table 102–1). There are considerable differences between continents, and between subregions within the continents. But what is particularly striking is the similarity of the levels at the beginning of the period, between the different regions of the developing world (all with a TFR of between 5.5 and 6.5 children per woman), and the divergence in their current situations which have led to a TFR of 1.8 in China to 5.6 on average for the sub-Saharan African countries as a whole.

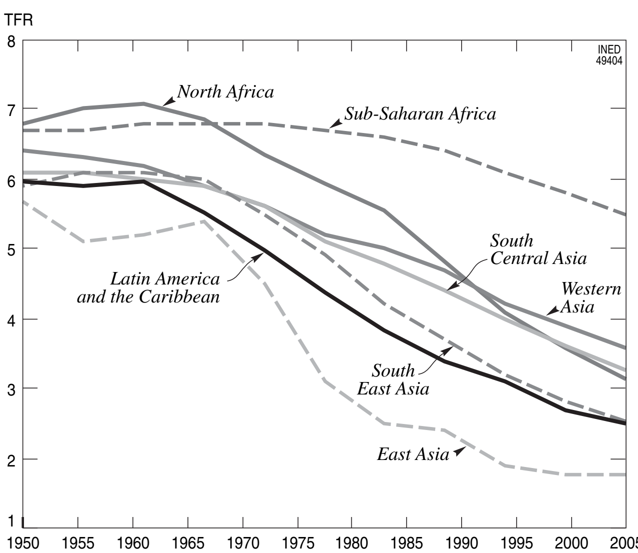

FIGURE 102–1 Total fertility rate, regions of the developing countries, 1950–2005. (Source: United Nations, 2003a.)

In Latin America, temperate South America (Argentina, Chile, Uruguay) has been characterized by relatively low fertility (3.5 children per woman) since the 1960s. But Central America and tropical South America at that time still had a rate of over 6 children per woman. Mexico only began its rapid fertility transition in 1970. The Caribbean began its transition with 5 children per woman. Fifty years later, in a rapid movement, the differences had diminished and in 2002 the total fertility rate remained at 3 children per woman only in Central America (United Nations, 2003a). Thus, significant gaps remain between the countries of the Latin American subcontinent. Guatemala, Honduras, Haiti, Bolivia, and Paraguay have rates of over 4 children, while Cuba, Trinidad and Tobago, and other small states of the West Indies have rates below 1.8 children per woman, which places them with the countries that are at the end of their fertility transition (United Nations, 2003b).

The changes were even more rapid in Asia, where the average rate was of 2.6 children per woman in 2002. The country that first springs to mind is the immense country of China which, following an initial unsuccessful attempt to introduce family planning (during the 1960s, see below), implemented a draconian program of birth limitation in 1970. This country, or rather this subcontinent, has succeeded in decreasing its fertility from more than 6 children per woman to fewer than two 2 between 1965 and 2000 (1.7 children in 2002). Other countries in East Asia also have experienced similarly spectacular changes. This is the case of Taiwan and South Korea (TFR of 1.3 according to the most recent estimate). Fertility levels had already started to decelerate in Hong Kong in the 1950s. The current fertility level is the outcome of a spectacular decline (1.2 in 2000).

TABLE 102–1 Trend in Total Fertility Rate (Number of Children per Woman)

Region	1950–1955	1960–1965	1970–1975	1980–1985	1990–1995	1995–2000
World	5.0	5.0	4.5	3.6	3.0	2.8
Developed countries	2.8	2.7	2.1	1.9	1.7	1.6
Developing countries	6.2	6.0	5.4	4.1	3.4	3.1

Source: United Nations, 2003a.

Generally, Southeast Asia is also following the same process if we disregard disaster-stricken countries such as Cambodia (TFR of 4 according to 2002 estimates), or very isolated countries such as Laos (TFR of 4.9 in 2002). Vietnam (TFR of 2.3 in 2002) is very advanced on the path to fertility control, as the example of its great Chinese neighbor was quickly followed in North Vietnam with the adoption of public health and family planning programs, extended since 1973 to South Vietnam.

In South Central Asia, that is, the Indian subcontinent, the fertility decline has been slower and there are numerous disparities, including between the Indian States. This country, which like China is a subcontinent in itself, is a mosaic of people and cultures, and the differences in fertility levels reflect this. The northern Muslim states still have fertility levels of 4 children per woman, while the state of Kerala, where the income level is more or less comparable, has a total fertility rate below 2 children per woman (IIPS and ORC Macro, 2000). In the region, Sri Lanka has been a frontrunner, with a sustained practice of family planning since the 1970s. Fertility, which has decreased regularly, was only 2 children per woman in 2000 (United Nations, 2003b). Another spectacular example is that of Bangladesh, a country that the media periodically projects as one of the poorest countries in the world; there the total fertility level declined from 6.4 children per woman in 1970 to 3.6 according to the most recent estimates (United Nations, 2003a). This is an example that contradicts the idea that only an improvement in economic conditions can lead to a deceleration in fertility (Adnan, 2002).

In Western Asia, changes in fertility have been slower, decreasing nevertheless from 6.4 children in 1950–1955 to 3.8 children according to a 2002 estimate made by the United Nations. Several countries (Cyprus, Israel, Turkey, Lebanon) now have fertility levels below 3 children per woman, while Yemen, Iraq, and the Palestinian territories remain, for diverse historical reasons, countries with high fertility (5.5 children and more in 2002). The former Soviet republics that belong to this geographic zone (Armenia, Azerbaijan, Georgia) have particularly low levels of fertility, under 2 children per woman. Iran, with a very rapid decline (from 6.5 children in 1980–1985 to 2.5 in 2002) contradicts another generally accepted idea according to which the Islamic religion is a systematic obstacle to fertility reduction. (Tunisia and the other North African countries also contradict it.)

Africa remains the continent with the highest fertility levels. Since the 1980s the first fertility declines have been observed in some sub-Saharan African countries and in all the North African countries. The continent is no longer as homogeneous as it was in the past, in terms of fertility levels. West Africa (the Sahel, the countries on the coast of the Gulf of Benin, including Nigeria, the most populous African country with its 115 to 135 million inhabitants) and East Africa (the Great Lakes, Tanzania, Zambia) are the two regions where fertility remains high (on average around 5.5 children per woman) despite the first signs of decline which have been observed, particularly in Kenya (see below). Southern Africa (South Africa and neighboring countries) is resolutely committed to fertility decline. It has decreased from 5.7 children on average in 1950–1960 to 3.3 children in 2000. Central Africa is a paradoxical case, where fertility has traditionally been lower than in the other African regions. It experienced a slight increase in the 1950–1990 period. This increase has been attributed to the improvement in health systems, which has resulted in a decrease in the incidence of sterilizing diseases that were widespread in some provinces of these countries. Finally, North Africa, which was still more fertile than the rest of Africa around 1950 (more than 7 children per woman on average), now has fertility levels close to 2 children per woman. Fertility in Tunisia has experienced a sustained decline since 1966 when it opened the door to modernity; Tunisia's success has been ensured by social development programs associated with one of the Third World's first family planning programs (around 1965). The other two North African countries, in very different political situations, are in the process of catching up with Tunisia.

The fact that nearly all of the African countries are currently involved in this process of fertility decline, even though some of them have made much more progress than others, confirms the universality of the second phase of the demographic transition, that is, fertility decline, which generally responds to the mortality decline that occurred during the first phase (see Chap. 68 and 69, Vol. III).

This decline in fertility in the regions of the world where, up until the beginning of the 1950s, large families were the rule, is revealing of the social and economic progress that has occurred since World War II. It is no surprise that, with a few exceptions,[1] the poorest countries are the last in this process.

Societies have slowly accumulated fertility control knowledge and practices. But the effective techniques that are now available, even in the poorest countries, were not at our disposal before the second half of the

[1] The oil-producing countries of the Persian Gulf (Saudi Arabia, Iraq, Kuwait, Oman), which are among the countries with the highest gross national product (GNP), are also countries with high fertility.

20th century. And since the 1950s the international community, expressing itself through large conferences organized by the United Nations and its agencies, has seized the issue of fertility control and has progressively included it in its programs and policies.

II. THE ELABORATION OF FERTILITY CONTROL POLICIES

After a brief reminder of the emergence of policies for controlling fertility, we will discuss the key role played by international organizations in their development, the arguments in their favor, and the evolution in governmental attitudes.

1. The Emergence of Fertility Control Policies

a. From Ancient Practices . . .

While the populations of developing countries have always been concerned with controlling their fertility, up until the 20th century it was most frequently in order to guarantee their survival and if possible their growth, in very unfavorable conditions of high mortality and all kinds of hazards (e.g., climatic events, epidemics, raids, or wars) that affected them. On the whole, high fertility was preferred to ensure the renewal of clans, lineages, and family groups that shared common objectives. As formerly in the countries of the North, before the initial progress made on mortality, families and couples were generally concerned more with having a sufficiently large family than with limiting it.

Historians of ancient populations have testified to concerns regarding birth limitation in some societies, well before modern times. Infanticide, the exposure of newborns, and induced abortion have existed in many societies of the North and the South as a means of avoiding imbalances between the production of food and the number of mouths to feed. In China, for example, studies carried out on fertility within marriage tend to prove that fertility was, during the pretransitional period, lower than it was in Europe, and we have proof of the existence of birth limitation practices, induced abortions, and the use of various substances for avoiding pregnancies (Zhao, 2002; Campbell, 2002).[2]

These studies support the hypothesis that birth limitation measures were present, at least in some circles, in pretransitional populations. Withdrawal was also a method used within all societies and was practiced by couples well before any family planning program. The same is true for induced abortion, mostly illegal. In many societies couples practiced and still practice in some countries, particularly in sub-Saharan Africa (Page and Lesthaeghe, 1981), postpartum abstinence of varying duration, intended to ensure a greater likelihood of survival for the child already born by arranging a sufficiently long interval between two births. This was a clear expression of the desire to control fertility, well before modern birth control methods became accessible.

But in many Third World countries, as was the case in developed countries, the main lever for intervening in reproduction was without contest, until the 1960s, social control on the formation of first union by young adults. In some countries, for example in North Africa, the recent decline in first union formation is a major factor in the fertility decline (Ouadah-Bedidi and Vallin, 2000), as the early marriage of women in previous decades was an essential element in the very large families observed there.

b. . . . to the First Fertility Reduction Programs

The conjunction of the discovery of effective contraceptive methods and the special attention given by the international community from the 1960s onward to the speed of population growth, rapidly encouraged some Third World countries to create or simply support programs for encouraging fertility reduction[3] and family planning. From this period onward, some large countries announced objectives for fertility reduction. From the beginning of the 1950s, India, with the assistance of international experts, adopted the first large-scale family planning program in the Third World (in 1952). Fertility reduction was its main objective (see below, Chap. 113). China, following an initial inconclusive family planning program (1956–1962) committed itself at the beginning of the 1970s to a very coercive program for controlling sexuality and fertility, under the rule of Zhou en Lai, to limit population growth as quickly as possible (Attané, 2002). Political control and police control of the Chinese population was consequently used to achieve this national objective (see Chap. 112).

[2] "China has a long history of using medical substances and other measures to induce abortion and to prevent pregnancy. Potions were used to cause abortion 2000 years ago. Medical substances and prescriptions that were believed to prevent or terminate pregnancy or cause sterilization were detailed in many medical writings published during the last two millennia" (Zhao, 2002, p. 756).

[3] At least initially because recently, certain countries of the South have been showing concern at the excessive decline in fertility and have opted for policies to increase fertility (see Table 102–2). The question is reviewed in more detail in Chapter 103.

In Latin America, where several countries had already started their fertility decline in the 1970s, the most common objective was fertility reduction but also a more equal distribution of the benefits of development (Guzman, 1994). This was the case of Mexico, for example, where fertility control programs were based on ambitious health policies (see Chap. 114).

In North Africa, Tunisia is another example of early focus on fertility control policies and Habib Bourguiba, after some equivocation, took a clear position in 1968 supporting a slowing of population growth and the establishment of family planning services (Vallin and Locoh, 2001b; Gueddana, 2001). The same occurred in Kenya, which implemented a national family planning program in 1967 and in Ghana in 1969 where the first African document defining a population policy based on quantified objectives for reducing population growth appeared. However, in sub-Saharan Africa, with the exception of these two countries, family planning was barely discussed until the 1970s. Some private organizations, one of the main ones being the International Planned Parenthood Federation (IPPF), and denominational organizations (notably Protestant churches, by the means of health centers that they controlled) were the first to offer contraceptive services, and not without opposition. Faced with governments that were mainly reticent, the first programs, both private and public, announced only the objectives of well-being for families and couples and the possibility of having the desired number of children, rather than demographic objectives for fertility reduction. In the Francophone countries of West Africa, which were for a long time the most reticent toward any ideas of birth limitation, only "programs for family well-being" were spoken of until the 1980s, and in the same period in Zaire (now called the Democratic Republic of the Congo) only the "program of desirable births" was mentioned.

2. Toward Fertility Control Policies: The Role of the United Nations (1950–2000)

The idea of adopting policies with the aim of slowing population growth is a very recent one. It was initially introduced into international circles by the richest countries, at a time when, having largely finished their transition and significantly slowed their natural growth, they became concerned with the acceleration in the population growth of the poorest countries. The population policies in the Third World countries were, from the beginning, designed within the context of the complex relationships between rich countries and poor countries, which initially did not facilitate their adoption by the governments concerned.

Given the influence of the United Nations' large conferences (United Nations, 2003b) in the evolution of governmental positions, it is legitimate to trace the evolution of ideas regarding fertility control policies in five stages, separated by the large international meetings. They set the rhythm for the last half-century and provided reports on the debates that animated both the international community and the decisions adopted by population specialists and then by political leaders.

a. The 1950–1970 Period and the Awareness of the Speed of Population Growth in the Developing World

During the first years of the United Nations' existence there were still many gaps in demographic data, notably in a certain number of developing countries that did not traditionally record data on population. The possible link between population growth and economic development was not yet a widespread idea. However, the first requests for assistance in data collection came from Brazil, India, Indonesia, and Thailand (United Nations, 2003b, p. 11).

The first World Conference on Population took place in Rome in 1954. It was co-organized by the United Nations and the International Union for the Scientific Study of Population and brought together demographers, rather than governmental representatives, as was later the case (Lebrun, 1985). During this meeting, an ideological debate was initiated between the Western countries and representatives of the USSR, with the latter supporting the opinion that rapid population growth was only a problem in the capitalist countries and that the real issue was the unequal distribution of wealth between the wealthy and the exploited. Indeed, during the years that followed, the incentive to investigate the effects of rapid population growth in the Third World countries came from the United States. In a famous publication, Ansley Coale and Edgar Hoover (1958) estimated that in India, reducing fertility by 50% would, in one generation, increase income per capita by 40% more than in the absence of this fertility reduction.

In the early 1960s, several developing countries began paying more attention to population growth and adopting family planning programs. This was the case of India, first of all, whose government in 1959 gave its support to the adoption of all family planning methods, including sterilization. The Egyptian government implemented a national family planning program in 1962. Other programs were initiated by private organizations in Pakistan and Singapore. These different initiatives took place at the time when the United Nations Population Commission, in an important declaration on population policies, proclaimed that each country was responsible for establishing its own population policy and programs. It also declared that the United Nations should provide, to any government that requested it, assistance in managing population problems. In 1962, the United Nations General Assembly called for a special effort to be made in the research into the linkages between population growth and economic development.

This was what was done in the Belgrade conference in 1965 where, as in Rome, the participants represented themselves rather than governments. The same ideological separations were expressed, with some placing doubt on the legitimacy of the United Nations' involvement in population policies and particularly in the implementation of family planning programs. However, approximately 20 national family planning programs were presented and discussed during this conference (Macura, 1986). A few years later, the International Conference on Human Rights, held in Tehran in 1968, explicitly included access to family planning as a human right. The conference asserted that parents have the right to freely decide the number of children they would have and the spacing of their births. This declaration encouraged movements in favor of the spread of family planning, but it also gave governments formal notice to provide couples with the means of planning their families.

Parallel to these debates in the international arena, important progress was being made in the area of contraception. The contraceptive pill and the intrauterine device (IUD or coil) provided women with new possibilities for controlling their fertility, which would significantly increase and diversify the provision of family planning services.

b. 1970–1980: A Decade Marked by the Creation of the UNFPA and the Bucharest Conference (1974)

The 1970s began with the creation of the United Nations Fund for Population Activities (UNFPA) (recently renamed the United Nations Population Fund). Its mission was not only to develop research and knowledge as did the Population Division, but also to support activities likely to have a direct influence on demographic variables, in particular fertility. In 1972, more than 50 countries committed themselves to contributing to UNFPA's funding. This new decade was marked by a renewed approach to population issues within international circles, issues that have become a major stake in international development strategies.

The International Conference on Population held in Bucharest in 1974 was prepared from within this perspective. This time, it was not a meeting of experts only,[4] but of individuals commissioned by their countries to represent their governments' positions. An ambitious World Plan of Action for Population was conceived by the United Nations Population Division. Notably, it proposed quantitative objectives for the deceleration of population growth. This plan and the position of the Population Division caused impassioned debates between supporters of vigorous actions in favor of the adoption of family planning programs and those, mainly from Third World countries (in particular, a group led by representatives from Algeria and Senegal), who were strongly opposed to it. They were defending a firm ideological position which affirmed that it was development that would lead to a slowing of population growth, and not the reverse. The slogan "Development is the best pill" summarized their position. Furthermore, the issue of the sovereignty of the decisions of each state regarding population was a very sensitive one for these newly independent countries that did not want restrictions on their freedom to act, a freedom for which they had paid so dearly, by allowing quantitative objectives for the control of their population growth to be dictated to them.

The conference therefore ended without retaining the quantitative objectives proposed by the experts for slowing growth. The final declaration recalled that the ultimate objective of the World Plan of Action was development and not the control of population growth. Nevertheless, the idea of reacting to this growth acquired a new legitimacy during this conference. At the same time, an increasing number of developing countries started resorting to international population assistance, some for programs to integrate the population variable into development and others for programs to increase the provision of family planning.

c. 1980–1990: A Decade Less Marked by Ideological Positions, the Mexico City Conference (1984) Draws Lessons from Ongoing Programs

At the beginning of the 1980s, fertility showed signs of easing in numerous developing countries (other than in sub-Saharan Africa), although in the majority of cases, contrary to the slogan of Bucharest, this phenomenon could not be attributed to an improvement in the economic situation. The international commu-

[4] In parallel, they had their own forum and their debates would play an important role in the decisions of the political representatives present at the conference.

nity, having taken note of 10 years of experience of introducing family planning programs into various social contexts, began to discuss the association between population growth and development with more moderate positions than it had in 1974.

The Mexico City conference in 1984 was firmly prepared by four regional meetings. That of Arusha, for the African continent, was a very important stage, and the Kilimanjaro Declaration (CEA, 1984) was adopted there. It recalled the rights of States and couples to freely decide their options regarding fertility but also the legitimacy of family planning programs to fulfill the new aspirations of individuals regarding the size of their families. This position was adopted by the conference during discussions in Mexico City. The reference to the right of individuals to have access to contraception was greatly stressed and resulted in a consensus, including that of developing countries which, in Bucharest, had been reticent to the idea of supporting family planning programs.

Compared to the Bucharest debates, some surprising reversals of positions of some governments were observed during this conference. The African states, sensitized by the Arusha debates, became much more favorable to the idea of making family planning programs available. The same applied to some Latin American states which, up until then, had remained rather conservative on the issue, due to the influence of the Catholic Church. On the other hand, the United States, supporters in 1974 of the adoption of strong fertility control in developing countries, had a different position and declared that they would not support any family planning programs that included the practice of induced abortion. This was due to the United States government's concern with satisfying the conservative right-wing, which had been returned to power.

d. 1990–2000: From Family Planning to Reproductive Health: The Cairo Conference (1994)

The International Conference on Population and Development (ICPD), the last conference of the 20th century was held in Cairo in 1994 (United Nations, 1995). Armed with the experience of previous conferences, the United Nations Population Division actively prepared this meeting, preparing national reports on population, convening meetings of experts on priority issues and, via the United Nations regional representations, organizing meetings on each continent to encourage regional consensuses (United Nations, 1994). New partners including charitable nongovernmental organizations (NGOs) and feminist movements played a key role in this conference. The former came in force to present their action and to lobby government delegates. The latter used the preparatory meetings in a masterly manner to integrate their legitimate claims for women's rights and demands for equality into the new Cairo Plan of Action. Up to that point, in the official documents relating to world population, the improvement of women's status was included mainly as a method of achieving demographic objectives and, more particularly, family planning objectives. The Cairo document adopted a new tone that was firmer on the principle of male and female equality, more open with regard to areas in which the conference should intervene in favor of women, and more precise in the actions that were recommended. The concept of women's empowerment was the cornerstone of the argument. The concept of reproductive rights was proposed, and it was clearly declared that equal rights for men and women was an objective in itself (United Nations, 1995, Chap. IV) and not only one of the methods of ensuring fertility reduction.[5] Thanks to this new approach, the document bravely tackled a certain number of crucial problems: infanticide, rape, trafficking of women, sexual harassment, and more. In fact, this was the first population conference where sexuality was openly discussed.

Furthermore, reproductive health, the new concept developed in the Cairo program, which includes family planning, maternal and infant health, sexual health, and particularly the prevention of AIDS, has, since the Cairo conference, irrigated every program carried out under the aegis of UNFPA, which remains the United Nations' main organizer of population programs. Fertility programs are increasingly justified by arguments for health and their integration into the health system of developing countries is reinforced, notably by the synergy between AIDS prevention programs and family planning programs.

3. Fertility Control Policies: Why?

Over the last half-century, the United Nations Conferences have included debates based on figures but which were often also impassioned, bringing together researchers and decision makers, scientific objectives, and geopolitical aims. The fertility control of Third World countries has made great progress, but it still remains one of the objectives of the international community at the beginning of the 21st century. Family planning and fertility control programs draw their legitimacy from two main arguments: that of the

[5] The new directions in favor of equality between men and women which were adopted by government representatives in Cairo found increased support in the following year during the Beijing conference (1995).

control of population growth and that of health and well-being, which is popularized by the expression "reproductive health."

a. Reducing Population Growth

Inspired by the trend of Malthusian ideas, numerous demographers and economists since the 1950s have estimated that the planet's population growth, mainly that of developing countries, was untenable and should be controlled for fear of a serious imbalance between population and resources. The analysis of Ansley Coale and Edgar Hoover (1958) on India's development clearly illustrated this point of view. During the 1970s (with the Bucharest conference, 1974) supporters of increased fertility control based on the adoption of quantitative objectives for growth, contained in a world plan of action for population, put forward these demographic arguments, insisting on future imbalances between population and resources. Developing countries based their counterattack on this (see Point B-1, below). The theme of the growing tension between population and resources remains one of the major arguments for the legitimization of population programs and policies. It was recently enriched (notably following the Rio de Janeiro conference on the environment in 1992) by the concept of protecting the environment and the urgency of preserving global public goods, such as water and air, which although they are not measured in terms of commercial value, are no less essential to the survival of the planet. It is therefore no longer only the prolific populations of the South, which contravene the balance between population and available resources, but also the rich countries that are predators of the environment due to their consumption methods. This is a novel view on the balance between population and resources that the rich countries are unlikely to acknowledge.

b. Promoting Well-being and Reproductive Health

Since the 1990s and the Cairo conference, population specialists, under the aegis of the UNFPA, have taken reproductive health as the key concept. It integrates family planning in the more general perspective of the respect of the rights of individuals with regards to reproduction and health promotion of mothers and children, but also that of the population as a whole, through combating sexually transmitted diseases, one of the main ones being AIDS. This new direction for the legitimization of fertility control makes it possible to refocus the objectives of demographic control in developing countries within a global strategy of social well-being (Seltzer, 2002). In the context of the AIDS, epidemic which is devastating developing countries, and with the reinforcement of numerous studies that expose the links between the survival of children, women's health, and better control of fertility, this new perspective has garnered a large consensus. It has also made it possible for feminist movements to develop arguments based on the respect of human rights and the reminder that sexual and fertility choices are one of the principal expressions of these rights and that promoting reproductive health can only help in the struggle for equality between men and women (Locoh, 1997; United Nations, 2002c).

The justification for the adoption of fertility control programs is based on research that has exposed the beneficial effects of these programs in terms of the survival of women and children. The reduction of infant mortality, maternal mortality, and adolescent fertility, which should result from these programs, are also essential arguments for their spread.

4. The Evolution of Governmental Attitudes Regarding Fertility Control

Fertility statistics are, at the beginning of this new millennium, available in the majority of developing countries. In countries where the national structures for collecting data are deficient, the demographic and health surveys (DHSs) have nevertheless made it possible to obtain measurements of trends over the last 15 years. This is notably the case for sub-Saharan Africa. These data make it possible to measure the road traveled (Figure 102–1), both by the population that has changed its behavior and by the national organizations for bilateral and multilateral cooperation that incited the change. The debates aroused by the world conferences made it possible to compare experiences and to benefit from successes and failures. These debates played a major role in the evolution of programs for fertility control. Nevertheless, very different tendencies continued to inflect population policies in developed countries. Since 1976, the United Nations have been carrying out a period survey on governments' assessment of the demographic situation of their countries and their positions regarding fertility, mortality, and migration (United Nations, 2003b). In 1976, 47% of Third World countries estimated that their fertility was too high, while 45% judged it to be satisfactory. In 2001, 58% (60% in 1996) considered their fertility to be too high, and 35% considered it to be satisfactory (Table 102–2).

For 25 years, the responses of developing countries have been evolving toward an awareness of the responsibility imposed by their fertility dynamics (Table 102–3 and Figure 102–2). In the first survey, the highest proportion of countries that considered their fertility as being too high was in Latin America (Latin

America 59%; Asia 46%; Africa 38%). In 2001, numerous Latin American and Asian countries had reached a level that they considered satisfactory. In Asia, where spectacular fertility declines had occurred, according to the 2001 survey 17% of countries considered that their fertility was too low (compared to 5% in 1976). The proportion of countries that consider their fertility too high has increased most in Africa (from 38% in 1976 to 77% in 2001).

While in 1976, 67% of African governments, 56% of Latin American governments, and 32% of Asian governments declared that they did not intervene in fertility levels, in 2001 only 23%, 36%, and 24% of these governments, respectively, still had the same attitude (Table 102–4). Government intervention to reduce fertility has become common practice over the last 25 years. Of the 145 developing countries, 85 (59%)

declare having programs aimed at reducing fertility. There were only 40 (34%) of them in 1976.

It is a sign of the times and of the success of previous programs that the proportion of countries that declare having programs for encouraging fertility has slightly increased since 1976 (from 5% to 8% in 2001) (see Chapter 103) and they are all Asian countries (Table 102–5). However, this does not mean that every polemic regarding these programs has disappeared, especially concerning their demographic argument. But generally, family planning programs are at the very least included within the framework of the improvement of women's health and the respect of individual choice. According to the most recent survey by the United Nations (United Nations, 2002b), 84% of developing countries gave direct support to the provision of contraceptive products and 10% gave indirect support (via NGOs).

The opinions expressed by the governments during the United Nations surveys should be considered with some caution, as they may not correspond to solid commitments, but the trend is clear and the fertility decline of the majority of countries concerned bears witness to the behavioral changes of individuals, generally accompanied by policies related to the issue, sometimes in a coercive manner and sometimes simply as an incentive.

III. POLICIES FOR FERTILITY CONTROL. WHICH METHODS?

Since the leading article by Kingsley Davis and Judith Blake (1956), the analysis of fertility determinants largely has been based on different biological, social, economic, and cultural forces, which can be used to weigh a population's fertility level. These analyses form the substratum of the fertility control policies that were developed from the 1960s onward. The work of John Bongaarts (1978) on the proximate determinants of fertility has had a great influence on the research and implementation of programs. This author identified four proximate determinants of fertility: average age at first union, birth spacing practices (postpartum abstinence and breast-feeding), contraceptive use, and recourse to induced abortion. These determinants are themselves influenced by economic and sociocultural factors (see Chapters 37, 38, Vol. I). This model has made it easier to identify the different measures likely to affect fertility levels. The range of methods used, the direction of the discourse aimed at popularizing them, and the stakeholders responsible for their implementation have resulted in very diverse policies, which are not, as is sometimes believed, limited only to the creation of family planning centers. The use of contraception has indeed been the spearhead of fertility reduction in the Third World, but it has been most effectively adopted in the areas where an arsenal of other accompanying measures have also been applied.

After having stressed the importance of development policies (A) to the success of fertility control policies, in this section we will successively examine (B) the adoption of statutory measures, (C) information and communication campaigns, (D) the choice between incentive measures and restrictive measures, (E) the choice of family planning services, and (F) the problems of funding the programs.

1. Development Policies: An Essential Role

To encourage fertility reduction, which is the objective of the majority of population programs in developing countries, the policies implemented are generally made up of a combination of direct action (information campaigns, family planning programs, various incentive and restrictive measures) and more general measures, arising from development policies. Without these indirect measures, it would not have been possible to implement the direct policies, or they would have had little effect.

Public health policies (dealt with in Chap. 106, 107, and 108) first spring to mind. They resulted in significant progress in survival, and above all, in the survival of children. In the Third World countries as a whole, the decline in infant mortality has significantly contributed to changes in the behavior of couples, and in contraceptive use. The higher the infant mortality, the more difficult it was to accept changes in the ideals that valued high fertility. To date, in sub-Saharan Africa, the high level of infant mortality has been one of the main obstacles to the adoption of fertility reducing behavior. The general improvement in the effectiveness of health systems has also been a centerpiece of the establishment of family planning programs, which are increasingly frequently integrated into health structures. In Mexico, for example, fertility control programs are based on the health services established at a very decentralized level and which had long ago won the confidence of the population (see section E, below). This is also an essential element in the success of the Bangladeshi program (Fauveau, 1994) and that of China (Attané, 2002).

Progress in education—above all, female education—has been another essential factor that has had a demonstrable effect on fertility. In all countries where education has flourished, fertility has begun to decline (United Nations, 2003c) and in proportion to the level of education achieved. The effects of education are both direct and indirect. Educated women and men better understand the available fertility control methods and experience fewer contraceptive failures. It is also easier to recruit trained personnel for contraceptive services. Moreover, educated people marry later, either because they are continuing their education or because they are able to more effectively resist any pressure from their family and wish to reach adulthood before embarking on married life. The increase in women's marrying age is perceptible in numerous developing countries (Westoff, 2003) and plays a significant role in fertility decline. This is a direct effect of the increase in education. Furthermore, educated people have different aspirations for their children and this changes the expectations that they have of them. Men and women create their families by seeking quality rather than quantity of children, are better equipped to protect their health, and are prepared to spend significant amounts on their education; all of these factors indirectly support fertility reduction.

The improvement in female schooling forms part of the battery of measures that aim to promote equal status between the sexes. Development policies in the wider sense are also part of it. Women's access to employment, legislation that protects them from economic and sexual exploitation, the ban on violence toward them, and the adoption of equitable (or better, egalitarian) laws regarding inheritance, marriage, and possession of land and goods are also development policies that are favorable to controlling fertility. But despite the efforts of activist groups and governments' declarations of intent, the problems remain acute in this area. Family planning programs, which can be one of the best expressions of female empowerment and of their ability to freely make decisions about their reproductive life, can also flout women's rights (Locoh, 1997). One only needs to remember the improper sterilizations in Latin America and the ban on having a second child in China, which results in little girls being abandoned or in selective induced abortions; both of these practices are also common in India (Arnold *et al.*, 2002).

In a more general way, in order for family planning programs to be effective, there must be a combination of conditions at the level of both social and economic development: the existence of a legal authority to apply the laws adopted and priority given to infrastructural investment, road systems and trade, as well as contraceptive supply. These conditions are most frequently found in towns than in rural areas, where progress in infrastructure development and in the area of population programs is slower. This results in less frequent contraceptive use in rural areas in a transitional period where urban inhabitants are already involved in the process of fertility deceleration. Urbanization is both the cause and the consequence of development. In cities, marriage occurs later due to a higher level of education, there is more information available and more opportunities to call traditional family systems into question, and there are more problems involved in maintaining a large family, which encourages city dwellers and migrants to change their traditional family ideals. Children are considered less as a resource (extra hands for working on the land) and more as an expense (expenditure on schooling, health). The very rapid urbanization of developing countries has therefore been one of the causes of fertility decline. In some countries, the active policies of regional planning have led to a reduction in the disparities between urban and rural areas. These policies have indirectly supported the implementation of family planning programs.

According to the culture, experience, and proposed objectives (health of mother and child, well-being of families, limiting population growth), or according to the pressure applied within partnerships with funding countries, the decision makers of developing countries, often assisted by international experts,[6] have implemented population and family planning programs with a combination of various ingredients: statutory measures, incentive and restrictive measures, information or persuasion campaigns, the establishment of infrastructure providing contraceptive methods, as well as global development policies which have affected, to varying degrees, each of the proximate determinants of fertility.

2. The Adoption of Statutory Measures

a. Legislation on Age at Marriage

In any fertility control program initiated by a government, the legislative measures must be adjusted to create conditions that are favorable to the achievement of fertility control objectives. A first area is that of age at marriage, which is generally regulated by the law. First union formation, which is not always a formal marriage, is an important factor in fertility. In many developing countries, early marriage of young girls is valued. Thus, the average age at first union is 18 years in West Africa and around 20 years in East Africa and it was earlier still 40 years ago. South Asia (India, Bangladesh, Pakistan) is a region where girls still marry early (see Chap. 28, Vol. I). The increase in age at marriage is generally one of the most reliable predictors of a future decline in fertility. It also indicates an increase in the education level of women, their greater participation in paid employment where it is possible, and generally, a good indication of progress in female autonomy and in a greater freedom in matrimonial choices.

By delaying the legal marrying age, fertility can be affected particularly in countries where the culture or the religion are firmly opposed to births out of wedlock, which is the case in all Muslim countries and in many Asian countries. This was the case in Tunisia, for example, where the increase in the legal marrying age was an effective means of birth limitation (Ben Salem and Locoh, 2001). It led to a decrease in early marriages and also consequently a decrease in births among very young mothers. But the adoption of legislation delaying the legal marrying age is generally an expression behavior changes that have already occurred. This is the case in Morocco where the amendment to the Moudawana, proposed by King Mohammed VI at the end of 2003, increased the legal marrying age from 15 to 18 years for females, whereas the average age at first marriage was already far above this new legal minimum. The increase in the legal age at marriage was one of the efforts used by the Chinese government beginning in 1973 to control fertility. In 1980, a new law on marriage increased the age to 20 years for females and 22 years for males. Moreover, this has been associated with measures for separating married couples, for varying lengths of time, by assigning them to distant production units (Banister, 1987). In sub-Saharan Africa, on the other hand, where cultural traditions tend to be tolerant of births out of wedlock, legislative measures on marrying age have had little effect.

But legislation on the minimum legal marrying age, while it can induce a change at the beginning of a society's modernization process, is far from being the only factor in the increase in age at marriage, which is an essential driving factor, with the adoption of contraception, in fertility reduction. This increase is one of the main expressions of the sociocultural evolution of a society and sometimes of the increasing difficulty of young people in establishing their economic autonomy in family making, as is the case in North Africa (Ouadah-Bedidi and Vallin, 2000) and even in sub-Saharan Africa since the end of the 1990s (see Chap. 27, Vol. I). In the majority of developing countries where fertility decline has occurred, the proportion of young girls married before the age of 20 is low and decreased during the period of fertility decline.

b. Control of Access to Family Planning Programs

The establishment of programs for fertility control[7] should also result in the adoption of appropriate legislation. Some countries are very reticent to open the doors of family planning centers to unmarried adolescent girls. This is notably the case in Africa, where some countries also require the husband's permission to provide contraceptive services to married women. However, under pressure from international bodies these restrictions have been officially lifted in many countries, even though there are still occasions when the staff refuse to provide contraception to young unmarried women.

At the level of statutory measures, all the laws, decrees, and decisions made by health ministries concerning the importation and sale of contraceptive products should also be mentioned on the one hand, as well as the services and staff entitled to prescribe contraception, on the other hand. These regulations

[6] Due to the weight of international funding allocated to family planning programs, international expertise is still very much present, despite the fact that a growing number of national specialists have been trained.

[7] For example, this was the case in numerous African countries that had been colonized by the French as they had inherited the notorious law of 1920, intended to combat the fall in the birth rate in France which forbade any propaganda in favor of contraception.

TABLE 102–6 Distribution of Third World Countries According to the Legal Conditions for Induced Abortion in 1999

condition access to the various contraceptive methods available. In some countries, the distribution of the pill is very restrictive,[8] while elsewhere it is delivered widely, by ancillary medical personnel, through community-based distribution. The restrictions can also affect the type of contraceptive products receiving marketing authorization. The contragestive "morning after pill" (RU 486), considered as an abortive, is still rarely authorized. Sterilization, which is definitive, has been the subject of restrictions and regulation in many countries. In Brazil, for example, where the feminist movement vigorously denounced the improper recourse to caesarean sections and to the sterilizations that frequently followed, laws were adopted in 1998 to better control these practices (Berquó and Cavenaghi, 2002, 2003).

c. *Legislation on Induced Abortion*

In many countries, induced abortion remains an offense and is the object of repressive legislation or is restricted to certain situations, according to a grading of risks recognized as justifying induced abortion. A recent inventory[9] (United Nations, 1999; Appendix Table 102–2) lists the regulations in the developing countries of Africa, Asia, and Latin America. In each of the Third World continents, approximately half the countries apply very restrictive legislation to induced abortion, and the others apply relatively flexible criteria (induced abortion possible in order to protect the woman's physical or mental health).

Penal sanctions for induced abortion have been removed in a certain number of Third World countries. In Tunisia, a precursory country, induced abortion was authorized in 1965 for women with five children, which was a great innovation for a Muslim country. In China, within the context of the single child policy, induced abortion is not only permitted but is imposed in cases of unplanned pregnancies (Attané, 2000). The issue of legislation on induced abortion remains, during international conferences, a bone of contention that positions its supporters against conservative countries, among which is the United States, and representatives of religious authorities (see Chapter 35, Vol. I). The United States have notably withdrawn all support from the population programs of developing countries, which include induced abortion as a birth control method. Nineteen countries in Africa, 11 countries in Latin America, and 5 countries in Asia relaxed their legislation between 1994 and 1999 (see Appendix Table 102–2).

d. *Creation of National Population Commissions*

These rules and regulations are increasingly being adopted within the wider context of the definition of a population policy, highly encouraged by the United Nations authorities on population. In the 1990s the UNFPA supported the design and the adoption by governments of documents defining their policies with regard to population. Coordinating bodies, generally dependent on ministries in charge of planning, were established to supervise the implementation of fixed objectives. The centralized and hierarchical organization of the bodies responsible for applying the decisions regarding birth planning, at both national and regional levels, can also give rise to regulations and possibly to the adoption of laws. This is the case in China (Huang, 1992, quoted by Attané, 2000; see also Chap. 112), in India (see Chap. 113), and in Mexico (Cosio-Zavala, 1994; see also Chap. 114), but not in Brazil (Martine, 1996).

When the objective of fertility control is integrated into a population policy and legislative measures are

[8] The restrictions relate to those authorized to prescribe (doctors only?) and to the clients (married women but not young girls, for example).

[9] Communicated by Agnès Guillaume (Meeting on Population Policies, CEPED, October 17, 2003).

adopted, it remains for the governments to support (and sometimes impose) their application through information and persuasion programs, or incentive and restrictive measures.

3. Information and Communication Campaigns

The adoption of fertility control methods in societies where, more often than not, large families were considered as a resource had to be encouraged by campaigns of information and communication, and sometimes even pure propaganda. It was necessary to let the population know of the existence of contraceptive methods, give information on how to access them, and convince individuals (the campaigns were mainly aimed at women) of the justification of planning their births. All the tools of modern communication, posters, radio, and television were placed at the service of the campaigns in some countries. India, Indonesia, Bangladesh, the Philippines, China, and Mexico, to name only a few large countries, carried out large intensive poster, radio, and television campaigns (Faria and Potter, 1995). In Mexico, for example, the national family planning program was constantly supported by information campaigns regarding population that used various methods of communication: publicity posters, radio, television, meetings in work places, schools, and clinics. Awareness and practice of contraceptive methods became common, even in rural areas. In Brazil, the success of the *telenovelas* and the campaigns led by well-known singers lobbying in favor of birth spacing are well known. But in other countries, other media, appreciated locally (e.g., puppets, theater, and concerts) were also used. These campaigns are targeted according to sociological context. In Latin America the campaigns are often centered on the delay of entry into reproductive life and are aimed at young people. Elsewhere the theme of limiting fertility to two or three children was preferred. In China, however, coercion rather than communication was used.

In sub-Saharan Africa, birth spacing that makes a long and intensive period of breast-feeding possible is still the most frequently used method for controlling fertility. The practice of postpartum abstinence also exists in some societies. In Yoruba land, in Nigeria, for example, a female must abstain from any sexual relations with her husband while she is breast-feeding, most frequently for 18 months to two years. These associated practices explain why the interval between two births in Africa is usually between two and a half and three years. Faced with the little success of campaigns promoting the use of modern contraception, information campaigns have sometimes used these spacing customs, valued culturally, to develop their argument in favor of fertility control. These campaigns include lobbying for prolonged breast-feeding, which lessens the probability of a new pregnancy.

The cultural obstacles to contraception often are based on a population's religious beliefs. We are aware of the Catholic Church's traditional opposition to any form of birth control other than continence. In theory, Catholic couples can only resort to periodic abstinence, which has a high risk of failure. This is how some countries (such as Mauritius) developed information on this contraceptive method, which remains marginal in the progression of fertility control. In Muslim societies, where there is no such structured hierarchy as in the Catholic Church, the governments or those responsible for family planning programs have attempted to obtain declarations from the Imams, who have a well-established moral authority, in favor of birth control. This was achieved in Egypt, Iran, Algeria, and Tunisia, for example (Gueddana, 2001; Ladier-Fouladi, 2003; Ouadah-Bedidi, 2004).

The UNFPA has also encouraged governments to introduce modules titled "Education in Population and Family Life into school syllabuses", in which information on population issues and the control of population growth are provided. The information regarding fertility control is more or less explicit, depending on the culture.

These actions have indeed resulted in increased awareness of the existence of contraceptive methods within all the developing countries. They are essential to breaking down reluctance regarding a particular method and to ensuring adequate use by clients. But the gap between knowledge and use remains a characteristic of some programs (Curtis and Neitzel, 1996). It is particularly clear in sub-Saharan Africa, where contraceptive use is still very low despite widespread knowledge of the existence of these methods. The information is necessary but frequently insufficient to make families change their practices, especially when they are not accompanied by improvements in the standard of living, increased opportunities for children's education, and pensions for elderly people. In some programs, therefore, more direct incentive or restrictive measures have been used.

4. The Carrot and the Stick: Incentive Measures and Restrictive Measures

Incentive measures have mainly been aimed at those prescribing contraception (Cleland and Mauldin, 1991). Bonuses to family planning agents, depending on the results obtained, are given in a certain number of countries. In Mexico, for example, bonuses were distributed to doctors and family planning agents, according to their performance evaluated in terms of family planning clients recruited in health centers. The frequency of female sterilizations in this country, condemned many times by feminists, is undoubtedly not unconnected to the financial incentives given to the medical personnel (Potter, 1999). But incentives have also been aimed at people who have accepted to use contraception. In India, during the 1970s in the large-scale male sterilization campaigns, where clients were recruited for vasectomies around the large stations and then operated on in nearby buses, those who accepted the operation were given radio sets and a small payment (Mauldin and Sinding, 1993). More recently, advantages in terms of retirement pensions were provided to families that had limited their fertility (United Nations, 2002a).

Again in India, restrictive measures have been used in some States, even as far as adopting measures to terminate the employment of civil servants who had had a third child. This radical measure caused Indira Gandhi to lose her position as Prime Minister in 1977, and the measure was then revoked (see Chap. 113). In Indonesia, programs of reciprocal surveillance and denunciation of those who did not respect contraception objectives within local communities were put in place. There were also campaigns of distribution of contraceptives by military personnel, a barely disguised method of coercion.

But it is China that springs to mind when considering coercion carried out on the population to oblige fertility control. No other country had gone so far. The family planning policy, which in 1979 became the single child policy, was implemented by force. To achieve the fertility reduction decided in the 1970s, a complete battery of measures was adopted, at the level of married life as well as in the practice of contraception. In order to apply these measures, the Chinese government did not hesitate to resort to a drastic supervision of the population, to police control, and encouragement of denouncement. The responsibility of local administrative bodies in the achievement of the objectives of the population policy was clearly outlined. Increase in the legal minimum age at marriage and the frequent separation of spouses (e.g., due to individuals being sent to distant manufacturing units) reduced their cohabitation. Police surveillance of females of reproductive age was established in workplaces to check that they were not pregnant. In rural areas, political leaders were in charge of this surveillance and were sanctioned in cases of unplanned births in their administrative entities. The single child policy led to unprecedented coercive measures, to the extent that a couple must seek permission to try for a child, within the limits of the objectives assigned to each township or administrative entity. This control of reproduction upsets family life and contains the seeds of a demographic imbalance in terms of sex ratio and cohort size (see Chap. 112).

5. The Infrastructure Chosen for Family Planning Services

To intervene in fertility control, governments have defined extremely varied strategies. The administrative and political tradition of each country, the cultural sensitivity, the existing infrastructure, and the advice of international bodies of experts are all parameters to be taken into consideration in the implementation of fertility intervention programs. Two intervention strategies were jointly tested: entrusting the diffusion of fertility control methods to designated structures like the IPPF clinics (where it was their specific objective) and integrating family planning services into existing health services.

The first attempts to distribute family planning were frequently carried out by voluntary associations grouped into federations around the IPPF. This organization played an essential role in the initial experiments of establishing family planning services in developing countries. Based on voluntary participation and a network of volunteers associated with publicity campaigns, the national structures were created. They received constant financial support (from the IPPF, various other foundations, and the UNFPA) but also support in the form of training and supply of contraceptives. They were generally the fermenting agent that led to changes in the attitudes of frequently reticent political leaders that then resulted in the adoption of fertility control programs and policies. This has been the case particularly in Africa where, at the beginning of this establishment (in the 1970s), the health care system and a large section of medical personnel were reticent to accommodating family planning services.

The need for the population to clearly identify the objectives and be provided with adequate services by specifically trained personnel justified the establishment of programs via specific family planning channels. When family planning services are completely integrated into the public health infrastructure, there is a risk of conflict between the main objectives of public health and the provision of contraception. The risk is greater when there is a shortage of health resources. Moreover, international donors that play a major role in many of the developing countries' family planning programs fear that the funds provided for controlling fertility will end up in other sectors, which do not conform to their objectives. In each society, fertility control policies are based on decisions that sometimes support the preeminence of specific services with considerable autonomy, and sometimes the health ministries controlling the whole family planning services organization.

Mexico: An Example of an Ambitious Family Planning Program Provided by Effective Health Services

It was during the 1960s that Mexico became concerned with its high population growth. Indeed, population growth was slowing and the fertility level, over 6.8 children per woman in the 1950s, was resulting in a massive surge of young people into the employment market. In 1973, a general population law was adopted, attesting to the Mexican government's interest in population problems and specifically in fertility control. Official family planning programs were therefore established in order to provide families with information concerning contraceptive methods and to provide them with the means of using them (Cosio-Zavala, 1994, p. 213–214; see also Chap. 114).

In 30 years, the total fertility rate was reduced by half: from 6.8 children per woman in 1960–1965 to 3.1 in 1990–1995 (United Nations, 2003a). This rapid decrease was largely due to the National Family Planning Program, established in 1977. Several factors contributed to the success of this program. On the one hand, contraceptive methods were distributed by using a powerful network of health centers, clinics, and hospitals controlled by social security institutes and the Health Ministry. On the other hand, the population had confidence in its medical units, and the advice provided on family planning was quickly accepted (Gautier and Quesnel, 1993). In Mexico, where the medical system is mainly composed of large public establishments, the provision of modern contraceptive methods by health services was very effective. A special effort was made in the provision of family planning services by rural medical units and clinics based in small rural localities, particularly from 1980 onward (Cosio-Zavala, 1994).

New users were recruited while giving birth in the hospital, where medical and paramedical personnel offered them an IUD or sterilization, which are the most common methods in Mexico. Personnel received financial incentives according to the number of new family planning users that they recruited. Official programs played an important role in providing rural families and impoverished urban families with accurate information and contraceptive services. It must be stated that the frequent recourse to sterilization (31% of women of reproductive age in 1997), made possible by the considerable medicalization of family planning services, is certainly an effective means of controlling population growth but its nearly definitive effect on women's reproductive ability is severely criticized by those in favor of respecting reproductive rights.

6. Funding the Programs

The issue of funding Third World countries' fertility control efforts is a crucial one. Although the majority of these countries have given high priority to these policies, they are faced with a structural shortage of resources in every area. The implementation of legislative and statutory measures, the incentives and disincentives, the infrastructure (buildings, access to services, etc.), and local salaries are partly provided by the governments concerned. But the expansion of family planning services would not have been possible without the considerable mobilization of the international community. This consists, in more or less equal parts, of bilateral aid, multilateral aid (via UN organizations), and from international NGOs such as the IPPF, as well as some large foundations (e.g., Rockefeller, Ford, and Mellon). The training of staff, provision of contraception, monitoring and evaluation of programs, and research into contraceptive methods have been the subject of very large programs, in which international donors have contributed considerably.

Table 102–7 summarizes the contributions of the various donor countries to population programs in 1998. These programs include family planning, education regarding population, support for both population policies and demographic data collection, and programs for preventing the spread of sexually transmitted diseases and HIV/AIDS. Programs on fertility and contraceptive use are the main ones supported. The United Kingdom and the United States alone account for half of the aid provided. They are followed by the countries of Northern Europe who place a very high priority on population issues in their aid to developing countries. Finland, Sweden, and Norway devote more than 5% of their international aid to supporting population programs. France, Italy, and Japan, in contrast, place little priority on population issues in the support that they provide. Steven Sinding (2002), in a review of the effects of international funds on fertility decline, concludes that it is difficult to demonstrate a statistically significant link between the external funding of programs and fertility decline. Nevertheless, several examples confirm the effectiveness of international funding when it is given to governments that are greatly committed to program implementa-

TABLE 102–7 International Population Funding (in Millions of U.S. Dollars) and Proportion of Funding for Population Programs in International Aid Provided by Each Donor Country, 1998

Source: Seltzer, 2002, p. 38.

tion. This is the case of Bangladesh, Kenya (from the 1980s onward), and Indonesia (during the 1970s).

The external funding provided to programs can in no way substitute for internal efforts, but they can provide the supplement that makes it possible to reach the critical mass necessary to reinforce the effectiveness of fertility control policies. Without the incentive of international aid, some governments would have been less inclined to adopt fertility control policies.

IV. FORTY YEARS OF PROGRESS IN CONTRACEPTION

The majority of fertility control programs, most frequently called Family Planning Programs, were established from the 1960s onward. It was from this period that scientific progress in contraception resulted in the availability of contraceptive methods of unprecedented effectiveness like the pill and the IUD, which considerably facilitated the implementation of such programs. Initially supported by NGOs, notably the IPPF, these programs were progressively integrated as development planning tools by some young independent precursory states (India and Tunisia, e.g.). Stimulated by UNFPA, these programs grew in scale from 1970 and became the most important section of the population policies of most developing countries.

1. The Progressive Generalization of Contraception in Asia and Latin America, the Delay in Sub-Saharan Africa

Appendix Table 102–3 (Seltzer, 2002) makes it possible to measure the progress between the first observations of contraceptive practices (between 1970 and the end of the 1980s according to country), and the most recent ones (at the end of the 1990s, apart from some exceptions) for the majority of developing countries. According to this comparison, sub-Saharan Africa still stands out from the large-scale movement of the spread of modern contraceptive use, but in other regions of the world, contraception is high in the majority of countries. For example, let us take an arbitrary threshold of 25% of contraceptive prevalence among women aged 15 to 49 years. In Asia, only Cambodia, Laos, Pakistan, and Mongolia are below this threshold. In North Africa and the Middle East, only five countries are under the threshold (Sudan, Iraq, Yemen, United Arab Emirates, and Oman), and in Latin America only two (Haiti and Bolivia). On the contrary, in sub-Saharan Africa only a small minority exceeds this 25% threshold: South Africa, Botswana, Cape Verde, Kenya, Namibia, Mauritius, and Zimbabwe.

Figure 102–3 illustrates the progress in contraceptive prevalence among married women aged 15 to 49 in some countries of the three Third World continents, chosen either for their population size or because of the originality of their experience. The starting dates depend on available data.

a. Four Asian Countries: China, India, Bangladesh, Philippines

For Asia, four countries are represented (Figure 102–3a): China, India, Bangladesh, and the Philippines. The contrast between China and India, the two most populated countries of the world, is striking.

China

In China, following the adoption of the single child policy and the associated coercive measures, the overwhelming majority of women are obliged to use contraception. In 1983 contraceptive prevalence reached 70% and in 2000 it was over 80% (see Chap. 112).

India

On the contrary, although India's birth limitation program was adopted in 1952, and it had at certain

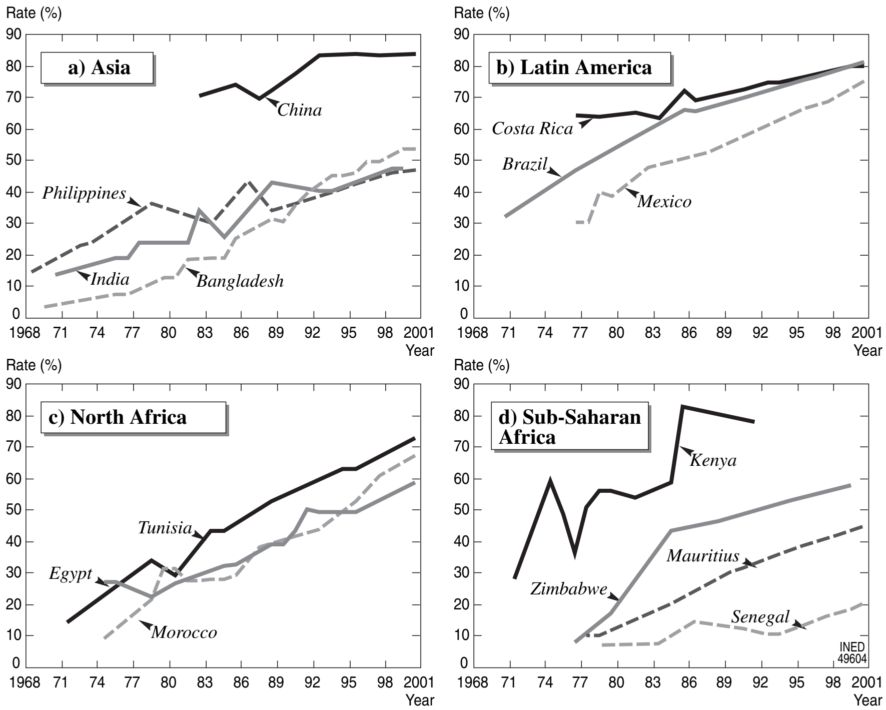

FIGURE 102–3 The trend in contraceptive prevalence among married women (aged 15–49), in some Third World countries; all methods combined.

periods experimented with coercive measures, contraceptive use has progressed slowly. The first data available show a contraceptive prevalence of 15% in 1970, and since 1989 when it reached 40%, its progress has slowed and is currently at 48% (women aged 15–44). Sterilization is the main method used (27% of married women in 1986, 36% in 1992). The programs' optimistic objectives, explicitly announced in successive plans, have never been reached at the forecast date (Bhat, 2002). India's birth limitation policy, although vigorous and sometimes coercive, has not had the anticipated effect (Srinivasan, 1998). Indeed, in this huge country, the differences are very marked between the advanced Southern states (notably Kerala and Tamil Nadu), and those of the North (Gujarat, Rajasthan, Utar Pradesh) (see Chap. 113).

Bangladesh

Bangladesh is one of the world's poorest countries, with a high infant mortality rate of 79 per 1,000 in 1995–2000, relatively low urbanization, and a population that is 90% Muslim and still values the tradition of the seclusion of women (*purdah*) inside the family home, and the prohibition of public contact with any unrelated males (Adnan, 2002). The median age at first marriage among women aged 25–49 is 15 years (Robinson, 2001). However, the rate of contraceptive prevalence has increased from 8% in 1975 to 54% in 2000 (Figure 102–3A), and fertility has been reduced by half between 1960 (7.1 children per woman) and 2000 (3.6 children per woman). Since the country's independence in 1971, the government has always placed a high priority on the objective of reducing fertility and on successive family planning programs. These have been significantly supported by international donors. It seems that the programs have not only made contraception available to couples requesting it, but they have also contributed to encouraging the population to adopt the limited family model (Cleland *et al.*, 1994).[10] The pilot studies and interventions in the Matlab zone demonstrate for the first time that providing quality family planning services in a rural area can result in a high increase in contraceptive prevalence and a significant decrease in fertility (Robinson, 2001). The main architects of this success were field personnel, area supervisors, family planning assis-

[10] Since 1977 Bangladesh has accommodated the famous Maternal and Child Health and Family Planning project, developed in Matlab. This project has been used as a laboratory for numerous health and family planning operations in developing countries. In particular, it has been demonstrated there that family planning services, even in an environment of great poverty, can be very effective provided that they are accompanied by close monitoring of the population, as is the case in this zone (Caldwell and Caldwell, 1992).

tants, and particularly, family assistants from the local area. Furthermore, the literacy of women has increased considerably, including in rural areas. The average age at first marriage has increased little, but the practice of induced abortion has played a certain role in fertility reduction (Islam *et al*., 1998).

However, the beginning of fertility decline preceded the setting up and the full development of experimental and governmental family planning programs. Factors external to the programs therefore encourage the population to reduce its fertility (Adnan, 2002). Massive changes in economic, social, and family structure appeared in rural Bangladesh in the second half of the 20th century. The level of women's education has improved, which tends to favor the decline in infant mortality. Economic difficulties have also contributed to changes in fertility preferences. The density of the population has increased considerably since the 1950s, increasing the number of farmers without land and favoring emigration to towns. Furthermore, poverty forced a large number of women to break away from traditional seclusion in order to look outside the home for a means of providing for their families. It is therefore a conjunction of constraining economic factors and an effective family planning program that explains the success. In spite of the maintenance of a very costly system for the wide distribution of contraceptives, the progress in family planning is now stationary and fertility was stagnating at a rate of 3.3 children per woman in 2000.

Philippines

In the Philippines, contraceptive use was, between 1970 and 1980, higher than in any of the other South Asian countries, such as India and Bangladesh, and this was partly due to the common practice of withdrawal and periodic abstinence, which are the only methods recommended by the Catholic Church. These two methods still represent, at the end of the 20th century, a third of contraceptive practice. Since the mid-1980s, the progress of contraception has been slower than in other Southeast Asian countries. Marilou Costello and John Casterline (2002) consider that there are not enough organizations that encourage contraceptive use and that a certain number of regulations continue to favor large families (maternal leave, lack of pensions, tax advantages only after the fourth child, etc.). It is also possible that the majority of the population, both Catholics and Muslims, are attached to a certain pronatalism. However, the experience of Latin America for Catholics, and of Iran and North Africa for Muslims, demonstrates that belonging to a pronatalist religion does not prevent the population from detaching itself from high fertility norms.

b. Three Latin American Countries: Mexico, Brazil, Costa Rica

For Latin America, we have selected two large countries, Brazil and Mexico, and Costa Rica, a smaller country that has had a very original population policy since the 1970s (Figure 102–3B). Latin America entered into the era of voluntary fertility control earlier than did the Asian countries presented above, but once again, we have three contrasting situations.

Mexico

In Mexico, the evolution of contraceptive prevalence was supported by clear political will declared in 1975 and implemented through a very dense network of public and private health services (Gautier and Quesnel, 1993). Based on the public health infrastructure which had the confidence of the public, very ambitious programs were adopted. They were particularly dependent on the cooperation of the medical staff, motivated by the attribution of advantages linked to the performance of the programs (Potter, 1999). Between 1977 and 2000, the prevalence rate was increasing regularly (from 30% to 77%), half of it by recourse to sterilization (see below) and minor but stable use of traditional methods. See Chapter 114.

Brazil

In Brazil, the transition occurred not through governmental programs or a clearly defined policy, but through a change in attitude regarding fertility, within the population as well as the medical profession, which was in favor of sterilization. Since around 1985, a rapid fertility decline has occurred, partly due to the production of contraceptives in the country itself and their distribution by the private sector and private family planning centers (Rutenberg *et al*., 1987), but particularly due to the practice of sterilization, which has become commonplace. Following caesarean sections, which are very common in Brazil, doctors tend to offer sterilization, and in Brazil this is the main method of limiting births. Women are prepared to adopt it as a convenient and inexpensive method of limiting fertility. In 1996, 77% of married women aged 15 to 49 used a form of contraception and among them, 52% had been sterilized, twice as many as were using the pill. Although induced abortion is illegal, it is still practiced in every sector of society. In 1990, there were 44 induced abortions for every 100 live births (Bozon and Enoch, 1999).

Costa Rica

As a consequence of firm political decisions and despite limited resources, Costa Rica has implemented very effective health policies that have resulted in a greater decrease in infant mortality than in other, better equipped countries (Caldwell, 1986). These decisions, the objectives of which were to reduce the inequalities between social classes, also indirectly had a beneficial effect on the adoption of contraceptive methods. With a contraceptive prevalence of 80% among married women, Costa Rica is the most advanced country in Latin America with regard to fertility control (Ghai, 1997).

c. Three North African Countries: Egypt, Tunisia, Morocco

In Africa, the differences between North Africa and sub-Saharan Africa are striking, both in the field of contraception as well as in their overall demographic situations (Figures 102–3C and 102–3D).

Egypt

Just like India, Egypt adopted a national family planning policy very early (1952), which the successive leaders of the country have continually supported. The activities to control population growth have associated programs for the direct distribution of contraception with activities to promote development (schooling, job creation, improvement of public health) (Kamran, 2002). Contraceptive prevalence has certainly increased to reach nearly 60% of married women in the year 2000, but at a slower rate than in other North African countries, even though they grasped the idea of controlling fertility through contraceptive practice later than Egypt.

Tunisia

Like Egypt, Tunisia adopted a policy for controlling population growth earlier than did its neighbors, based on a remarkable economic and social development effort (Vallin and Locoh, 2001a). Even though, for a long period, the increase in age at marriage affected fertility decline more than contraception did, contraceptive use increased regularly and had reached nearly 70% in 2000. Initially, the IUD was the main method used and has only recently begun to be replaced by the pill. Political will has constantly been reiterated in favor of the family planning program, and efforts to reach all sections of the population have been remarkable. One of the key reasons for this success is that 10 years before the adoption of a population policy, President Bourguiba had promoted the adoption of a modern personal status code, which was very favorable to the improvement of women's status. This essential document made it possible from 1965 for Tunisia to lift a number of obstacles to the adoption of a family planning program.

Morocco

Another experience is that of Morocco, which is in the process of achieving the same performance in terms of contraceptive prevalence after a delayed start. The pill is the main contraceptive used there (32% of women were using contraception in 1995). Indeed, up to 1975 fertility remained stable, with low contraceptive use (around 5%), despite a population policy that was favorable to a reduction in population growth. The rapid adherence of couples to contraception seems to be explained by economic factors, the start of a long-term crisis coupled with the spread of information regarding contraception by migrants returning from the northern countries, and the arrival of women in the labor market (Courbage, 2002). Algeria is another example of a delayed but rapid adhesion to the use of modern contraception (Ouadah-Bedidi, 2004).

d. Sub-Saharan Africa: Some Countries in Advance, the Majority Delayed

In sub-Saharan Africa, some countries resolutely committed themselves to active and effective policies. The most advanced is now South Africa, with a contraceptive prevalence of 61% in 1998 (Udjo, 2003) followed by Zimbabwe (nearly 60%) and Kenya (around 40%). They represent the countries, still quite few in sub-Saharan Africa, that are relatively advanced in their fertility transition (Sibanda, 1999). In Zimbabwe, the government has made special efforts to establish family planning centers in rural areas and to set up an effective contraceptive distribution network at the community level. The action of this infrastructure seems to explain part of the fertility decline.

With these exceptions, all the problems of underdevelopment combine to impede family planning programs in sub-Saharan Africa. The education of women is progressing slowly; children's health, after recording significant progress is now on the decline, in particular under the effect of AIDS; and the few resources of the states are insufficient to provide health services, and more so family planning services. It must be stated that, where fertility is declining, it is less as a result of the effective distribution of family planning than as a result of changes in the aspirations of families. The impoverishment of adults leads them to revise the traditional value placed on large families. And it is in the cities, more than elsewhere, that they have the desire and the means to reduce fertility. Where it is available, contraceptive practice is progressing rapidly. But there is also an increase in the number of induced abortions, in almost always disastrous conditions (Guillaume, 2000, 2003).

Kenya

Kenya was the first African country to adopt a national family planning program and was one of the countries with the highest fertility in the world until 1970–1975 (see also Chap. 115). It was only with the 1975–1979 five-year plan that a reduction in the rate of population growth was officially made an objective by the government. In accordance with a phenomenon frequently observed at the beginning of demographic transition, Kenya experienced a transitional fertility increase due to the improvement in health levels (decline in infertility) and the decline in traditional practices (particularly protracted breast-feeding). During the last quarter of the 20th century, this country then set out on the path of increased fertility control, with very rapid reductions in cities, but also significant decline in rural areas, verified by the results of three demographic and health surveys (1988, 1993, 1998). Contraceptive use in Kenya is one of the highest in sub-Saharan Africa. Nevertheless, family planning services are far from fulfilling the needs of spacing or limitation expressed by the women in the surveys.

A very considerable reduction in infant and child mortality and the rapid increase in education for young girls, associated with the establishment of good quality family planning services, have played a determining role in the acceleration of fertility decline. Furthermore, in 1976, a law set the minimum legal marrying age to 18 years for women and 20 for men (Sala Diakanda, 1991). In this country, the work of NGOs and Protestant organizations was a determining factor in the establishment of family planning programs, in parallel with the government's efforts (see Chap. 115).

Senegal

The evolution of contraceptive prevalence in Senegal (less than 15% in 2000) is, on the other hand, close to that which prevails in numerous sub-Saharan African countries: the late introduction of contraception, with varying degrees of reticence on the part of the authorities, the recent adoption of policies aiming to control fertility, weakness of programs, and the population's resistance to call into question the primacy of the value placed on procreation (Pison *et al*., 1995). Yet again, it is through spacing methods (long periods of breast-feeding, and in some societies, postpartum abstinence), far more than through contraception, that fertility control occurs in Africa, except in some countries, and in the cities (Locoh, 2002).

Mauritius

In Figure 102–3D, an atypical country has been included. The small island of Mauritius has for a long time been a pioneer in contraceptive practices, but with strong emphasis on so-called natural methods, already mentioned with regard to the Philippines. Here again, the influence of associations with the Catholic Church can be found at the beginning of the programs. The success of Mauritius in fertility control is also due to its more general development policy, which has resulted in a rapid increase in the population's standard of living, notably in their access to health services and education (Hillcoat-Nallétamby, 2002; Widmer, 2004).

2. Differentiated Contraceptive Choices, According to Continent

Fertility control in developed countries was implemented mainly through limited technical and often risky means (withdrawal, condoms and female condoms, and also the Ogino method); in many cases, these were unsatisfactory for sexual fulfillment (notably withdrawal). The frequent failures led to numerous induced, often illegal, abortions, with all the dangers that they involved for the physical and mental health of women, when induced abortion itself was not the main means for controlling natality as in the countries of Eastern Europe.

The scientific discovery of effective and reversible contraceptive methods radically changed the provision of family planning from the 1960s onward. Couples in developing countries benefited from these methods where they were available and encouraged. Certainly it was first of all necessary that the couples or the individuals wished to limit their fertility (with the exception of countries that coerce individuals, such as China), but once this bridge had been crossed effective contraceptive methods enabled them, in theory, to carry out their plans with fewer risks and with less constraining methods than were available to couples in the northern countries to reduce their fertility.

Today a broad range of contraceptive methods is offered by service providers to their clients, but in reality, political, economic, or cultural choices have led to each family planning program promoting some methods over others. Depending on each region in India, Africa, and Latin America, the provision of family planning is very different. The training received by family planning agents; the advice that they give, or which is provided by the media; the availability of methods or, inversely, shortages in stock; and the cost of procuring contraception are all factors that affect demand and individual preference. A summary of the methods used in the three large Third World regions, Asia, Africa, and Latin America, shows to what extent the choice of method differs from one to the other (Table 102–8 and Figure 102–4; see also Appendix Figure 102–1).

According to the latest available surveys, on average 6 out of 10 married women in developing countries use one form of birth control or the other, with more in Asia and Latin America (65 and 69% respectively), but many fewer in Africa (only 25%). The most popular method is sterilization (22% of married women). Nearly one in every three women in Latin America and nearly one in every four in Asia are sterilized, while in Africa this practice is completely marginal (2%). Then comes the coil (or the intrauterine device [IUD]), used by 16% of women and especially popular in Asia (20% of married women). In Latin America and in Africa, the pill is more popular than the IUD, but it is least likely to be used in Asia. Despite the intensive campaign in favor of condoms, carried out jointly by family planning programs and in HIV/AIDS prevention programs, only 3% of married women use them. This low prevalence rate can be compared to that of male sterilization (3%), which is only slightly higher (4.4%) in Asia, providing proof of the persistent reticence of men to take responsibility for fertility control. Among the other methods is the injection (Depo-provera), the prevalence of which could increase in Africa due to the prestige associated with the medical act of an injection and the possibility of using it without the knowledge of people around. Finally, the distribution of Norplant (subcutaneous placing of a contraceptive that lasts five years on average) is so far very low.

TABLE 102–8 Prevalence of contraceptive methods (%), among married women aged 15–49, by large regions (latest available surveys, from around 1997)

Method	Developing countries	Africa	Asia	Latin America
Pill	5.9	7.1	4.8	13.8
Injection	3.1	4.2	2.9	3.0
Intra-uterine device (IUD)	16.3	4.9	19.6	7.4
Female sterilization	22. 0	2.2	24.8	29.5
Male sterilization	3.6	0.1	4.4	1.6
Traditional methods	5.4	5.3	5.0	8.9
Vaginal barrier methods	0.2	0.1	0.2	0.3
Condom	3.1	1.1	3.4	4.2
Other modern methods	0.6	0.2	0.7	0.1
All methods	60.2	25.2	65.8	68.8
No method	*39.8*	*74.8*	*34.2*	*31.2*
	100	100	100	100

Source: United Nations, 2002a.

In the statistics, the so-called traditional methods include the so-called popular methods (based on knowledge of local pharmacopoeia and on customary practices) and the diverse variants of the periodic continence method (Ogino, temperature, etc.). They represent on average 5% of contraceptive practice in the Third World, with the exception of Latin America, where they make up 9%, a probable expression of the influence of the Catholic Church in certain circles of the continent. Figure 102–4 shows the distribution of modern contraceiption and traditional contraception (i.e., various pharmacopoeia, Ogino, etc.) for each country presented.

V. WHAT ARE THE RESULTS?

Some countries in Asia achieved their fertility reduction objectives to such an extent that their growth is not ensuring cohort replacement; other countries such as Tunisia are on the same path. Some have even adopted policies encouraging fertility and others could soon follow (see Chap. 103). Let us attempt rather to evaluate the part played by policies for controlling fertility reduction in the decline observed over the last 50 years.

Fertility has fallen in the majority of developing countries, mainly due to the generalization of contraceptive practices, and to a lesser extent due to the delay in women's first union formation. Fertility control policies were developed in the majority of countries during the last half-century, and, in parallel, through conferences, discussions, and program evaluations, the community of population specialists have so strongly insisted on the necessity of these policies that we are inclined to credit them with the successes obtained. Yet a study of the demographic and social history of some countries, a comparison of the paths that they have taken, and the arsenal of measures used could lead to questions regarding the specific role played by fertility control programs and policies. Were they the decisive factors in the reductions observed? Or were there other, less immediate but essential, economic, social, and cultural factors behind this behavioral revolution?

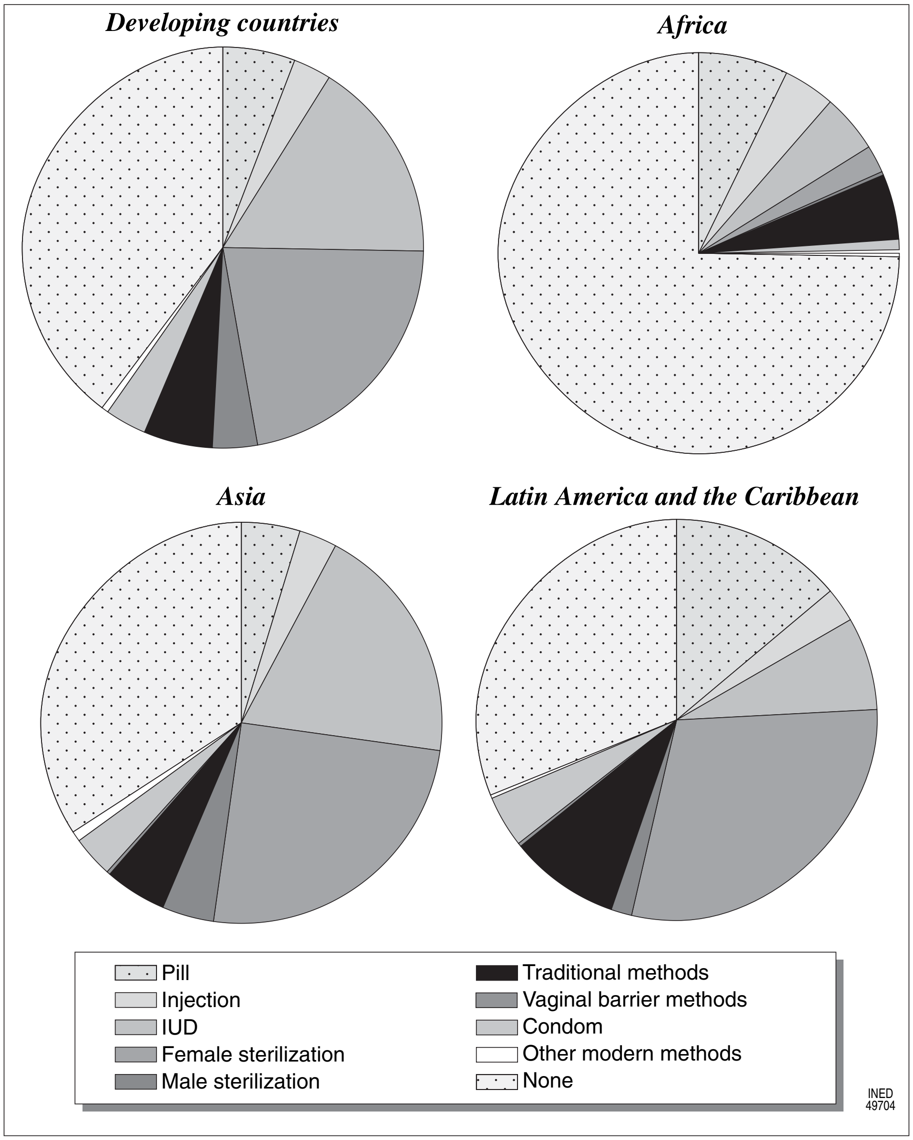

FIGURE 102–4 Prevalence of contraceptive methods, by large regions (latest available surveys, from around 1997). (Source: United Nations, 2002b.)

Historically, the efforts to encourage fertility control have sometimes considerably preceded the definition of governmental policies and the establishment of family planning programs. In Egypt, the first *fatwa* in favor of birth limitation was issued by the Egyptian religious authorities in 1937 (Fargues, 2002). In Bangladesh, the fertility decline preceded the establishment and development of the main governmental family planning programs (Adnan, 2002). In Tunisia, the personal status code promulgated by Bourguiba in 1956 had, before any concerns regarding controlling population growth, profoundly changed the status of women and thus prepared the ground for future population policies outlined only after 1965. The policies aiming to affect fertility generally proved themselves to be effective when they were on favorable ground, often prepared by economic progress, the education of women and their entry into the labor market, urbanization, and the development of health infrastructure which initiated the decline in infant mortality.

The meager results of population policies implemented in sub-Saharan Africa, despite the considerable resources, give the *a contrario* confirmation. In the majority of countries, progress at the economic and social levels is meager when it is not called into question. Infant mortality remains too high when it is not increasing due to the AIDS epidemic and the decrease in public health resources. Adult illiteracy and the lack of infrastructure for spreading contraceptive information and methods are still obstacles. While in the large cities fertility continues to fall rapidly, it is mainly because the economic crisis has convinced city dwellers that they can no longer ensure the well-being of large families and that family planning programs are available there. In rural areas, only some countries have been able to establish effective programs.

A comparison of national experiences will make it possible to demonstrate the difficulty in making a univocal diagnosis of the effect that fertility control policies have had.

Brazil and Mexico

All the countries that have succeeded in their fertility transition or that are in the process of doing so have not had fertility control policies on the same scale. Some of them, such as Brazil, have not had an explicit one. Comparing this large country with the other Latin American giant, Mexico, is instructive. Both currently have equivalent fertility levels (around 2.3 children per woman) and high levels of contraceptive use among married women (77% in Brazil, 70% in Mexico). Mexico applied governmental programs with significant incentives on the mobilization of medical personnel all over the country and on female sterilization as the main method of birth limitation. Brazil, without an explicit policy, and without a governmental program, achieved more or less the same result, and also made large-scale use of female sterilization (which is nevertheless forbidden). It did this through the spread of medical advice and promotion of sterilization after caesarean sections (see above). The entry of women into the labor market, and the already established tradition of education led women to reduce the size of their families. The motivation to have fewer children was present and was satisfied by private supply outside any specific policy.

Tunisia and Algeria

Other comparisons are essential, such as that of Tunisia and Algeria, the two neighboring North African countries. Tunisia had, from 1965, begun a fertility control program and is often quoted as an example of a successful fertility control policy (Vallin and Locoh, 2001a), but Algeria, which had, up until 1980, refused to commit to fertility reduction policies, and whose family planning programs have constantly suffered from the excuses of successive governments and insufficient infrastructure, currently has a fertility level that is very close to that of Tunisia (2 children per woman). The two countries have experienced a spectacular decrease in first union formation and, in Algeria, the mass education of women associated with the economic and political crisis has precipitated changes in behavior and the adoption of family ideals that are radically different from those of preceding generations.

Tunisia remains an example of good practices that have integrated population policies into development policies leading to the completion of the fertility transition. Economic and social progress has gone hand in hand with the development of programs for contraceptive distribution in the whole country. The first greatly contributed to the increase in age at first marriage, which has played a major role in fertility reduction; the second has given couples the means to control fertility within marriage. Although Algeria has taken a different path from that of Tunisia, it has arrived at the same point in terms of fertility, but not in terms of well-being. The existence of effective family planning programs in Tunisia has been a factor of well-being that Algerian women have not benefited from in the same way. It may also be true that without the example of Tunisia and its family planning programs, the changes in Algeria might have been slower.

Pakistan and Bangladesh

These two large countries, which were one until 1970, have followed very different paths. The poor performance of Pakistan in terms of fertility control (5 children per woman and 24% of married women practicing contraception) contrasts with the success of Bangladesh (3.6 children per woman and 54% of married women practicing contraception, see above), that nevertheless was handicapped by great poverty. Here again, the comparison pleads in favor of the effectiveness of population policies when social development policies are associated with them. In Bangladesh, these conditions were met and fertility control policies, carefully defined after a period of experimentation according to social context, coincided with an increase in female literacy and women's progressive entry into the labor market in employment outside of the family circle, providing them with relative autonomy. While the fertility control programs were impressive, they were not the only cause of the fertility decline. Social progress, demographic pressure on available land, and poverty among families strengthened the incentive measures of the programs.

During the same period, the situation was very different in Pakistan. Fertility decline was delayed. Zeba Sathar (2002) considers that the main reason for this was the "*ineffectiveness of the population policy and the State and the inability of the private sector to meet . . . the demand for good quality family planning services*" (p. 349). But she adds that the economic progress made has not set social changes in motion. Women's status is practically unchanged. For example, only one woman out of ten is literate. *"These factors block any rapid change in fertility desires and in women's motivation to control their fertility"* (Sathar, 2002, p. 349). While fertility control policies have been failing, development policies have also failed to support them.

And China . . .

We have not discussed the effectiveness of fertility policies in this final section. The case of China might be viewed as an example of a completely successful fertility control policy, but it was necessary to apply conditions that have not been used elsewhere and on such a scale and at a high cost to the population. The population's indoctrination, the permanent surveillance of their activities, and the application of sanctions to offenders were possible only through administrative and police control of the population, and a large-scale repressive arsenal. It must also be noted that substantial progress has been made in public health, and this has resulted in a rapid decline in infant mortality. Here again, programs other than fertility planning programs were necessary. In India, where fertility control policies also recommended very tough repressive measures, the population, through democracy, successfully resisted them, an act not possible in China.

All the experiences in fertility decline are unique. In examining the various national experiences of the past 50 years, it becomes obvious that policies aiming to reduce fertility were not the determining factor, but they did play a role in accelerating the process, in cases where the population was motivated to better control its fertility. By disseminating information, by making effective contraceptive methods available to family planning clients, and by giving legitimacy to a desire to control fertility, these policies became truly effective.

In some cases, fertility decline will probably be a consequence of a lack of economic and social policies, rather than the implementation of fertility control policies. This is observed in Africa, where fertility decline results more from the pressure of poverty than from the effects of family planning programs or other governmental fertility control measures. Here again, the stakeholders' motivation is essential. The economic crisis, which has become structural in the majority of countries, pushes men and women to change their fertility ideals.

Would the decline in fertility have occurred in the same manner if the international community had not seized the issue and had not designed, encouraged, or financed governmental policies pertaining to the subject? Undoubtedly. But it would have taken longer for the reduction to start, and the process would have been more difficult for those wishing to limit their family size. The most satisfactory results, at the macroeconomic level as well as that of the population's well-being were achieved when economic development and social policies were combined with and strengthened by fertility control policies.

Toward a Policy Turnaround in Low-Fertility Developing Countries?

MAGALI BARBIERI

Institut national d'études démographiques (INED), Paris, France

Apart from the West and Japan—a special case in Asia because of its early industrialization—the countries or territories whose fertility reached replacement level (2.07 children per woman) by the 1980s were in East and Southeast Asia (with the exception of Cuba and a few other sparsely populated Caribbean islands). To be more precise, these countries are Singapore, South Korea, Hong Kong, Macao, and Taiwan. Whereas the governments of the last three countries appear only mildly concerned by the socioeconomic consequences of their low fertility levels, Singapore and South Korea are sufficiently worried to have discontinued the strict population control policy instituted 30 years earlier. Despite their low demographic weight (4 and 47 million inhabitants, respectively, in the year 2000), the way in which the policies adopted by these two countries have evolved deserves special attention. Culturally acceptable for Asian populations, the route they take paves the way for many other countries in the region that have already caught up with them (China, Thailand, and Indonesia) or that will soon catch up (North Korea and Sri Lanka). Policies chosen by these pioneer countries may also present a more attractive alternative for other regions of the South, likely to reach low fertility levels at some point, than those developed in the West.

Faced with low fertility, Singapore and South Korea share similar concerns. The solutions chosen by each to rectify the situation are polar opposites, however: whereas Singapore has taken a resolutely pronatalist line, albeit with characteristics that clearly distinguish it from family policies implemented in the West, South Korea, instead of attempting to influence reproductive behavior, has developed policies essentially designed to lessen the socioeconomic consequences of fertility decline. These two options will be examined in turn, after a brief reminder of each country's previous policy features.

I. SINGAPORE

From the time of independence (1965), the government of Singapore viewed demographic growth control as a crucial element of its development policy. Population growth had reached an all-time high between the two preceding censuses, with an annual average of 4.3% between 1947 and 1957 (Figure 103–1). A stringent policy was adopted in 1966. Aiming to reduce the number of large families, it was linked to the slogan: "Stop at two!"; abortion was legalized, and became widely available at very low cost; female sterilization was encouraged after the second birth, and women who went ahead with it were offered a broad range of fiscal and social advantages (priority access to housing, and health services and education for themselves and their children), as opposed to couples with more than two children who, on the contrary, were penalized in these same areas.

This policy was set up within a highly favorable context. Economic growth was strong and sustained. It reached an average of 7% annually during the 1960s and 1970s, and generated a gradual improvement in living standards, such that in 1987, the average income per person was similar to that of Japan, and was superior to those of Spain and Italy. In addition, health

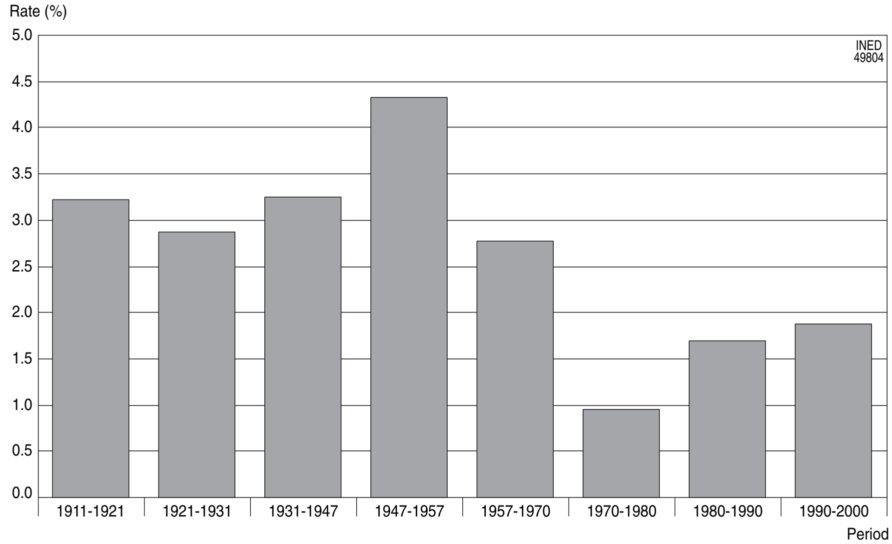

FIGURE 103–1 Intercensal average annual growth rate for the Singapore population, 1911–1921 to 1990–2000. (Source: SDS, 2001.)

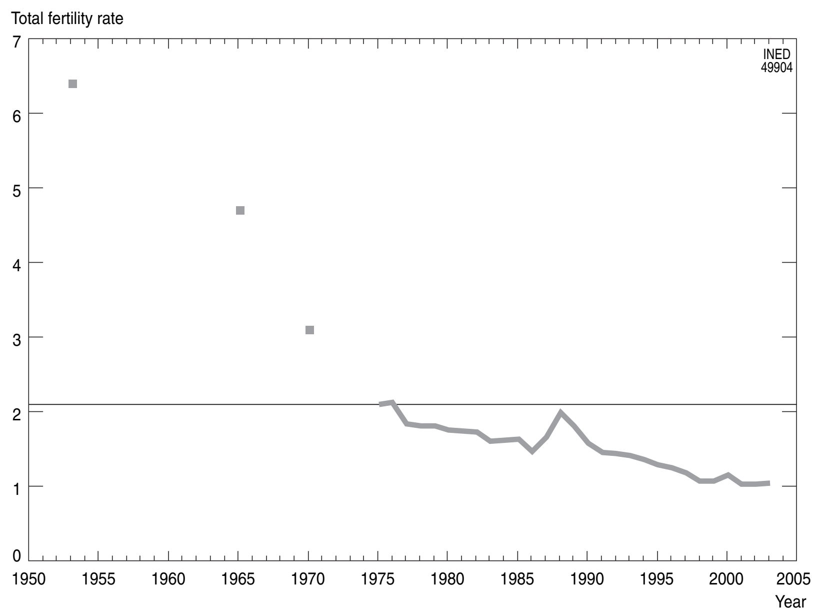

FIGURE 103–2 Fertility evolution in Singapore since 1950. (Source: International Data Base, U.S. Census Bureau. Retrieved June 20, 2004, from http://www.census.gov/cgi-bin/ipc/idbsprd)

improvements were considerable: life expectancy at birth reached 73 years in 1987, and infant mortality was lower than in the United States, the United Kingdom, and West Germany. This general situation encouraged very rapid fertility decline, and the total fertility rate (TFR) plummeted from 6.5 children per woman in the mid-1950s to 1.4 in 1986, after crossing the 2.1 threshold for the first time in 1975 (Figure 103–2).

From the mid-1970s onward, the government has been concerned by the fertility decline's effect on population age structure, especially on the ratio between the working population and the elderly. For the first time, in 1978, the demand for labor exceeded the offer. This prompted deliberations within the government that culminated in setting aside birth limitation policies and adopting a series of strictly pronatalist measures from 1984 onward.

This new policy's goal was to stabilize fertility above replacement level through an increase in three-child families. Some measures are similar to those introduced in the West: tax incentives, housing subsidies, ease of access to the best state schools, and so on, but they were implemented alongside other original policies. Thus, for example, as fertility decline was partly attributed to an increase in age at marriage and the growth of female celibacy, the government developed programs designed to help young people meet each other and form unions through activities worthy of the best marriage bureaus.

Its discriminatory nature, however, was the most striking aspect of this new policy. In 1984, the Singapore prime minister's address inaugurating the new population policy emphasized the importance of encouraging the most educated women to increase their fertility (Lee *et al.*, 1991; Teo, 1995). At the start, therefore, university-educated women were the only ones to benefit from the advantages associated with the arrival of a third child. Conversely, the least educated women (who had not finished secondary education or whose spouse had not) continued to be offered economic benefits if they agreed to be sterilized before having a third child. It soon became clear, in political discourse, that these measures were designed to encourage population growth within the dominant ethnic community, that of the Chinese, at the expense of Indians and Malaysians. These were not the groups who expressed their opposition to the government's family policy, however; it was rather women with some education (completed secondary school) who demanded the same advantages as the most educated women.

Their demands were satisfied by the adoption of a new program that substituted income level for education level as the condition of admissibility, and dropped the deterrents placed on the least privileged couples. "Have three or more if you can afford it!" became the slogan for this program. The economic and social incentives were generalized, and a special effort was made to encourage early births (additional fiscal advantages for women having a second child before the age of 28 years). Finally, all women with fewer than three children who applied for an abortion or sterilization were compelled to attend a counseling session especially aimed at dissuading them.

Up to the present day, this pronatalist policy does not appear to have born fruit: as the 21st century dawns, the TFR is fluctuating around 1.4 to 1.5 children per woman, the average age at reproduction is steadily increasing (from 27 years in 1980 to almost 31 years in 2000) (Singapore Department of Statistics [SDS], 2002a), and the proportion of third or higher births is still falling (from 55.5% of births in 1980 to 16% in 2000) (SDS, 2002a). Bolstered by its experience during the 1960s and 1970s, however, the Singapore government remains confident in its capacity to modify reproductive behavior in the end, and is continuing this course of action, even introducing a new program in 2000 to reinforce the measures developed since the end of the 1980s. This policy approach is made all the more interesting by the fact that it is being implemented in a context of very strong population pressure, with densities today reaching more than 5,000 persons per square kilometer (Figure 103–3) and an annual population growth rate close to 2%, two-thirds of it from sustained immigration (SDS, 2001).

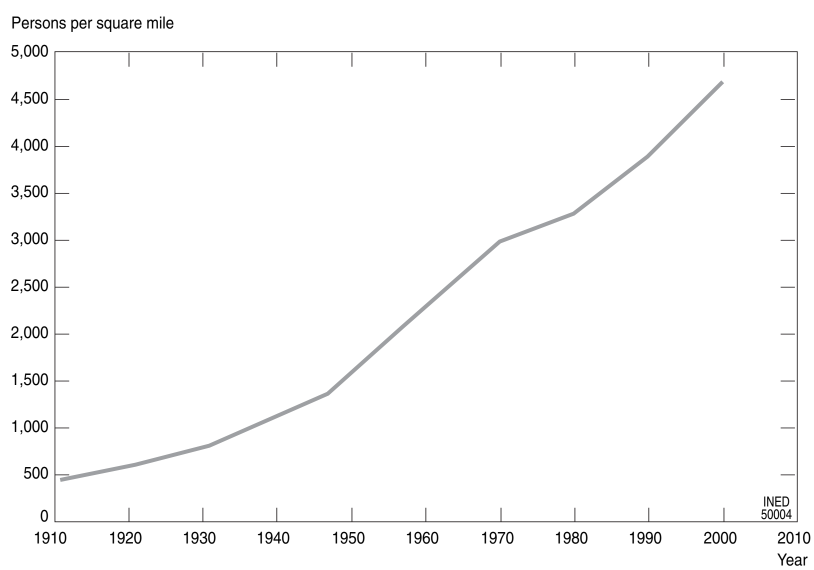

FIGURE 103–3 Evolution of population density in Singapore since 1911. (Source: SDS, 2001.)

II. SOUTH KOREA

Like Singapore, South Korea's current population policy marks a complete break with that of the 1960s, but the approach taken is an entirely different one. In 1961, South Korea was the third country, after Pakistan in 1953 and India in 1958, to develop a birth control policy to facilitate the country's economic development. Initially, the program focused on family planning education and the promotion of modern contraceptive methods, using local health professionals specifically trained in these areas. In 1981, family planning program developments were accompanied by new measures, articulated around a set of fiscal and social incentives designed to encourage birth limitation, similar to those introduced in Singapore. The government committed substantial funding to support this program, multiplying by 10 the budget allocated to it (Kwon, 2001).

From the 1960s onward, sustained economic growth reached an average annual rate of 8% and remained at this level for 30 years. At the same time, mortality was falling steadily: between 1960 and 1995, life expectancy at birth rose from 55 to 73 years and the infant mortality rate dropped from 56 to 13 per 1,000. In 1988, population policy had achieved its original goal: the TFR, as high as 6 children per woman in 1960, had fallen below replacement level (Figure 103–4), and the rate of contraceptive use was up to 80%, compared with 25% in 1971 (Kwon, 2001). Within the government, therefore, voices were heard lamenting the negative consequences of the population policy implemented during the three previous decades.

Various types of issues were raised, including some related to changing population age structure (Figure 103–5), associated with a rapid increase in the dependency ratio and of the proportions of elderly (the proportion of children under 15 years halved between 1960 and 1995, whereas that of the population aged 65 years and over more than doubled and is set to double again between 1995 and 2010), and others concerning reproductive health, with the disturbing prevalence of selective abortion by sex (Cho, 1996). The sex ratio at birth, which had remained at about 105 boys for 100 girls until 1982, began to rise, reaching 116 in 1993 (Figure 103–6). More troubling still, this increase was particularly strong for lower birth orders, increasing from 108 to 117 for second births, and from 129 to 191 for third births in the space of only five years (between 1985 and 1990), despite criminal lawsuits against doctors practicing selective abortion (three years imprisonment and fines of up to 12,500 American dollars).

In 1996, a new policy strategy was adopted, breaking with that implemented 35 years earlier. In contrast to the approach developed in Singapore, however, the Korean government decided to invest in counteracting the negative economic and social consequences of low fertility rather than attempting to modify reproductive

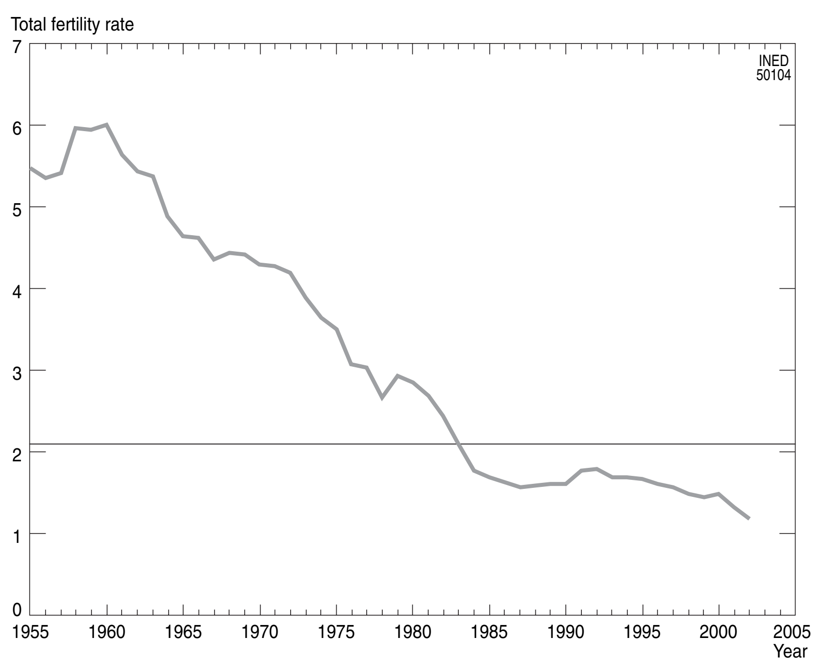

FIGURE 103–4 Fertility evolution in South Korea since 1955. (Source: Before 1975: Coale *et al.*, 1980; after 1975: Korea National Statistical Office. Retrieved June 22, 2004, from http://www.nso.go.kr/eng.)

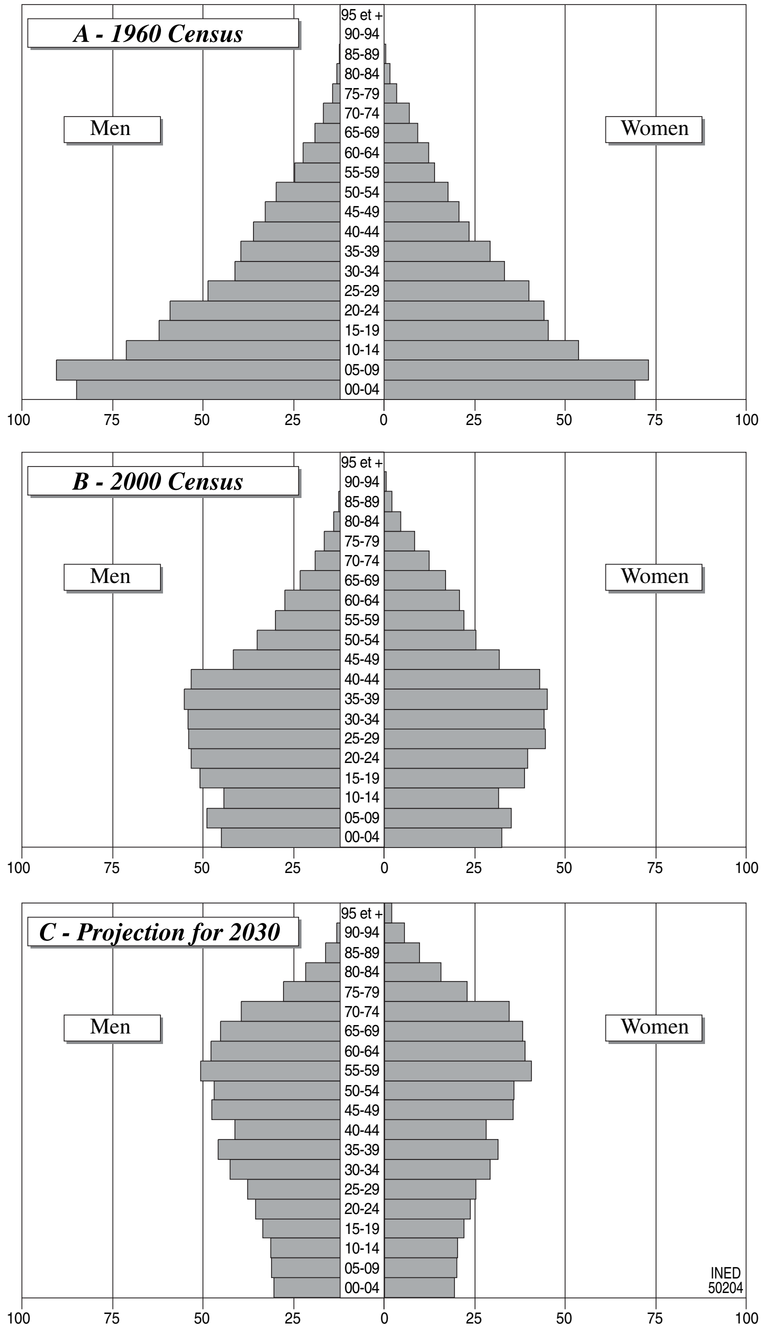

FIGURE 103–5 Population pyramids for South Korea in 1960, 2000, and projected for the year 2030. (Source: National Statistical Office: census results and projections. Retrieved June 22, 2004, from http://www.nso.go.kr/eng).

behavior. Supporters of this new perspective believe the efforts made to raise fertility levels by Western and other Asian countries, such as Singapore, Taiwan, and Malaysia, to be in vain. The strictly demographic aspect of Korean policy is thus limited to restructuring the family planning program and adopting legislation designed to fight discrimination against girls, whereas the new policy essentially operates within the area of employment and in the creation of social support policies for the elderly.

The family planning program was reformed with the aim of improving the quality of care and diversifying the contraceptive methods available; until then, the main investment was in sterilization—the only

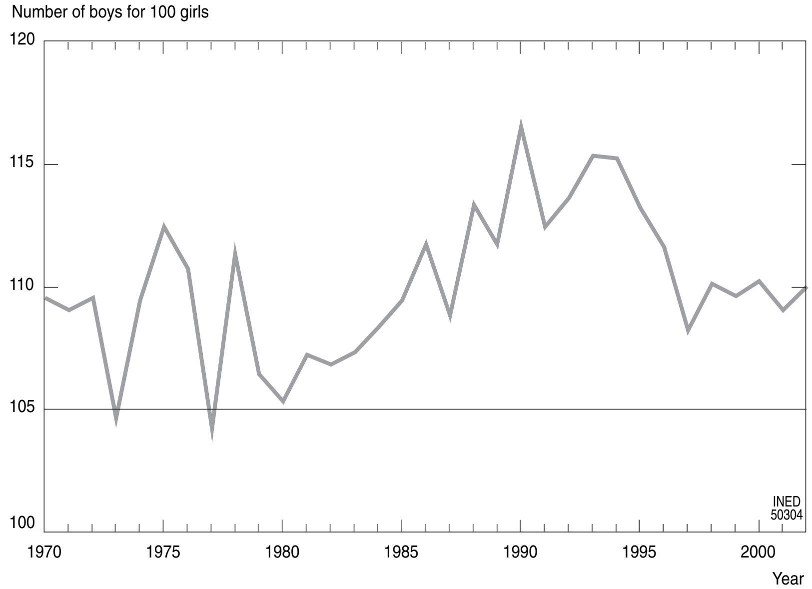

FIGURE 103–6 Evolution of the sex ratio at birth since 1970, South Korea. Source: *Ibid.*, Figure 103–4.

practical low-cost method. The goal was no longer to increase the contraceptive prevalence rate but to reduce the number of abortions, whose proportion had risen from around 25% of births in 1970–1974 to almost 50% in 1985–1991, and to improve coverage for the benefit of economically disadvantaged women and adolescents by extending family planning services to all aspects of reproductive health, especially those concerning sexually transmitted diseases. The program shared one point in common with Singapore's discriminatory policies, however: the poorest women were encouraged to be sterilized after their second child and became almost the only ones to benefit from fertility control measures. For the rest, family planning services were left increasingly to the private sector, although contraceptives continue to be reimbursed by Korean social services.

In years to come, South Korean population policy may turn to more resolutely pronatalist measures. For the moment, pressure on the labor force is certainly weaker in South Korea than in Singapore; the active population is still growing, although more slowly; and its proportion of the total population is now stable, after a steady rise between 1960 and 1995 (from 55% to 71%). According to the estimates, this proportion should nonetheless drop by 5 to 6 percentage points in the course of the next 20 years, at the same time as the demand for labor increases, producing a deficit of over a million jobs in 2020. Insofar as the Korean government does not wish to encourage immigration for social and political reasons, altering reproductive behavior may become a government priority once again.

III. OTHER LOW-FERTILITY COUNTRIES

Although other low-fertility Asian countries are showing fewer signs of discarding earlier birth control policies than Singapore or South Korea, there is nonetheless evidence of a change in direction. Certainly, China and Indonesia, the largest of them, are not yet ready to reverse their policies in favor of higher fertility, as demographic inertia leaves them concerned about the socioeconomic consequences of population growth in the medium term. Although characterized by the lowest fertility rates in the world (0.9 children per woman, according to the most recent estimates) but politically part of China, the territories of Macao and Hong Kong also show no interest in supporting any upward reproductive trend. Elsewhere, however, the fact that governments are discarding the strictest aspects of birth control programs, and are cutting spending on national family planning programs more generally, can be interpreted as the first signs of a turnaround in demographic policy (Mason, 2001). These types of changes are visible in Malaysia, Thailand, the Philippines, and especially in Taiwan where they are the most striking.

From the 1960s onward, Taiwan introduced many noncoercive measures to reduce fertility. The TFR fell below 2.1 as early as 1984 (Figure 103–7), and new programs were created in 1989, and reinforced in 1992, which moved away from the earlier policy approach. The two-child family continued to be encouraged, but the government developed a set of measures promoting

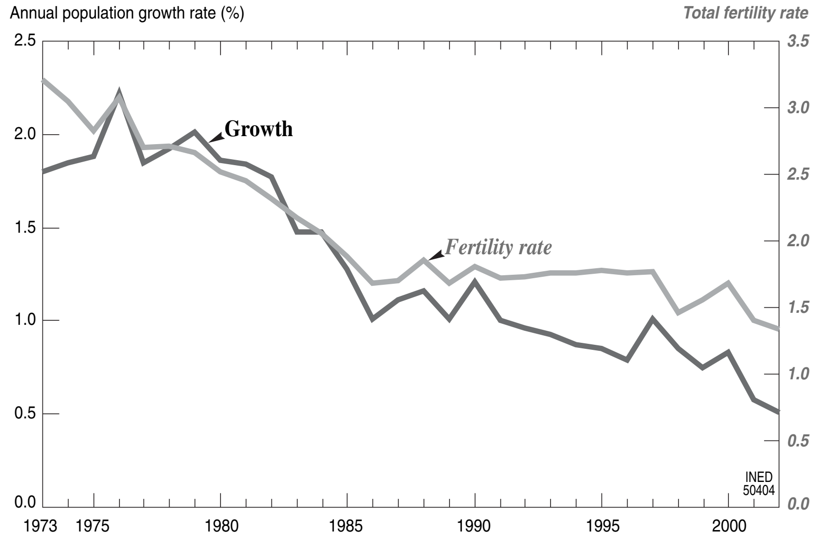

FIGURE 103–7 Population growth and fertility in Taiwan, 1973–2002. (Source: Republic of China, Statistical Yearbook of the Republic of China, 2003, Table 8, p. 11 and Table 15, p. 28.)

family values and programs supporting marriage among young people, rather like Singapore. With a population growth rate cut by four in 20 years (Figure 103–7) and considered satisfactory (Zhenghua *et al*., 1994), the goal was not so much rapid population increase as the gradual stabilization of fertility around replacement level. As the fertility curve illustrates, these measures could not reverse the TFR's steady decline. The most recent official statements, however, which simply reiterate their support for marriage, show that the government is still cautious about adopting pronatalist measures (Retrieved May 25, 2004, from http://www.moi.gov.tw/english/PopulationAffairs.asp).

In Taiwan as elsewhere, this type of policy is accompanied by the transfer of family planning services to the private sector or by their integration into the health services. More and more frequently, rather than reducing population growth, policy stresses the need to diversify and improve the quality of family planning services. Like Taiwan, one after the other—Malaysia, the Philippines, and Thailand—have abandoned quantitative goals with respect to fertility or demographic growth, and new concerns are emerging in spheres that, earlier, were at best considered peripheral but were most often completely absent from population policy.

The United Nation's International Conference on Population and Development held in Cairo in 1994 signaled a break in this respect, promoting concepts such as women's status and improving gender relations and reproductive health, which Asian countries increasingly take into account in their population policies. From that point on, these programs, previously directed exclusively toward married women, attempted to include adolescents and single women of all ages. Indonesia is a perfect example of this. During the first thirty years of its existence, its national family planning program ignored adolescents and unmarried women; still today, however, whereas the fertility level has just fallen below replacement, a profound change is emerging in government priorities. Aiming not only to make contraception available to all women, irrespective of marital status, it also intends to involve men, ambitiously aspiring to reach a level of male contraceptive use of 10% by the year 2010. Moreover, the fact that Asian governments have taken up the reproductive health concept has led to a growing integration of family planning programs into health services; it has also made it possible to direct resources previously devoted uniquely to reducing fertility levels to other areas, the first of which is the battle against sexually transmitted diseases in general, and the HIV/AIDS epidemic in particular.

CONCLUSION

The Singapore government's dynamic pronatalist policy is an exception among low-fertility Asian countries as a whole. Most are still cautious, not only about engaging on this extreme course, but even about relaxing their antinatalist policies established during the period of strong demographic growth. The historical and political context accounts more for this situation than do either the current demographic characteristics or the predicted course of population and components. Singapore does not differ significantly from South Korea, Hong Kong, or Taiwan in terms of its fertility levels, the present or future proportions of its elderly population, the population pyramid as a whole, or the estimated date at which total numbers will start to fall. It is understandable, on the other hand, that governments are loathe to envisage a radical policy reversal in countries where demographic inertia is still strong—where, in other words, the population's past evolution means that it will continue to increase strongly in future decades despite low fertility levels, as in Thailand (25% increase projected between 2000 and 2030)—or simply where the numbers involved, even if only a small proportion of total population, represent a huge demographic mass, as in China (more than 180 million persons between 2000 and 2030) or Indonesia (more than 70 million).

Outside Asia, countries whose fertility is likely to reach replacement level in the short term are still scarce. With the exception of many Caribbean islands and others in the Pacific, where geographic isolation lends a positive perception of the negative population growth predicted for 2030, the few countries where TFR will drop below 2.1 children per woman by 2010–2015 are distributed between Latin America (Costa Rica and Brazil), the Middle East (Lebanon and Iran), and North Africa (Tunisia). These are the candidates for an about-turn in population policy. Elsewhere, changes in reproductive behavior have been slow or late enough that the proportion of persons aged 65 years and over and the projected dependency ratios for the next half-century remain favorable for economic growth.

CHAPTER

104

Pronatalist Policy in Industrialized Nations

GUSTAVO DE SANTIS

Facoltà di Scienze Politiche, Università di Messina, Messina, Italy

INTRODUCTION: WHAT IS PRONATALIST POLICY?

Pronatalist policy is a complex and coherent system of measures designed to promote fertility. Essentially two avenues can be taken to portray pronatalist policy: start with government stated objectives or measure the empirical effects of selected policies. Both approaches, however, have significant drawbacks.

In Gérard Calot's opinion (Chap. 105), France is probably the only developed democratic country to have adopted explicitly pronatalist policies with some continuity through time, before significantly moderating its position on the issue in recent years. In 1995, however, Miroslav Macura, Mitchell Eggers, and Thomas Freijka (1995) created a more extensive list of pronatalist countries for the period 1976–1991; along with France, at least part of the time, were Bulgaria, the former Federal Republic of Germany, Greece, and Hungary.[1] Jonathan Bradshaw, John Ditch, Helen Holmes, and Peter Whiteford (1993) included Luxemburg, Norway, France, and Belgium in the group of countries showing the greatest generosity toward large families.[2] Shortly afterward, however, the same (or almost the same) group of authors extended the list to include Germany (Ditch *et al.*, 1998b). Anne Gauthier and Jan Hatzius (1997), in contrast, only mention France and Belgium as explicitly pronatalist countries, whereas Didier Blanchet and Olivia Ékert-Jaffé (1994) listed Austria, Hungary, Czechoslovakia, Bulgaria, and France.[3] Since then, Anne Gauthier (1999, 2002) has proposed yet another classification, and such examples could be further multiplied. In a word, it is not easy to classify countries in terms of their degree of support for fertility. For instance, governments respond to questionnaires on the topic sent regularly to them by the United Nations (United Nations, 2002) in ways that do not always correspond to what is actually done, and the traditional typology of industrialized countries (see, e.g., Esping-Andersen, 1990; Reher, 1998) does not always make it possible to group together countries with similar fertility policies.

Besides, an examination of the panoply of measures actually implemented in different countries, and a comparison of them with the declared intentions,

[1] It is true that this list includes countries which, at least during the period concerned, were not "developed and democratic," as the condition used by Gérard Calot in Chapter 105 would imply; a good part of them are nonetheless developed countries.

[2] According to Anne Gauthier (1996b), this classification is based on observed results, not on stated objectives.

[3] The criterion used here to identify pronatalist countries is the concentration of measures on families with a second or third child. The same authors, however, suggest an additional criterion—the economic relevance of this assistance, which, at that time in the countries cited reached between 10% and 19% of the average wage. In a second group of countries (Germany, the Netherlands, Norway, Poland, Austria, Japan, USSR), financial assistance to families also increases with the number of children, but to a lesser extent (from 1% to 11% of the average wage), thereby indicating, according to these authors, objectives that fall between pronatalism and redistribution (see below).

shows that pronatalism is in any case scarcely mentioned and that it is perhaps not even the main objective and is just one among many other goals, such as women's health protection, promotion of mother's labor force involvement, support for living standards in relatively large families, and so forth.[4] In order to classify these projects within a pronatalist framework, the relationship of cause and effect must be identified and measured. Already an extremely difficult goal to achieve within the social sciences in general, however, it seems virtually unattainable in this particular case, given the problem of defining the independent variable (population policy) and of establishing the criteria of analysis of dependent variables.

According to Jean-Claude Chenais (1985), four indicators could be used to achieve this:

- Cohort total fertility rates
- The period total fertility rate (TFR), also recommended by Gérard Calot (2001)
- The rate of natural increase
- Population age structure

From a strictly demographic viewpoint, cohort female reproduction (as defined in Chapter 19) is probably the ideal dependent variable. Despite this, studies rarely take it into account for a number of reasons, one of which being purely practical: as making policy decisions and evaluating their consequences are generally short-term undertakings, the long period of time needed to measure cohort fertility is hardly compatible with the brief duration in which policies are generally of relevance (including the population policies of interest to us here). The possible alternatives fulfill different criteria. The last two, moreover, take account of the need to provide results that are easily understood by the general public which, in democratic systems, elects the government and guides their policies, including those in the population sphere. One consequence of the problem of choosing between the possible indicators, at least while the four of them are not evolving in the same direction, is to provide arguments for government leaders who prefer to postpone their actions.

Writing about the various approaches, Anne Gauthier and Jan Hatzius (1997) distinguish four methods of investigation, according to whether they are based on

[4] For measures currently implemented in Europe, see *The Clearinghouse on International Developments in Child, Youth, and Family Policies* (http://www.childpolicyintl.org/). Sleebos (2003) provides a synthesis of these measures and of their possible effects on fertility (see Palomba and Menniti, 1994, for a similar effort, ten years before). It should not be forgotten, however, that many family policies evolve rapidly and not necessarily in the same direction, either in time, or from one country to another (Gauthier, 1999, 2002).

1. Opinion polls ("In a given context, what type of population policy is acceptable, or desired, or effective?" "Would you change your demographic behavior if the government took this particular measure?") (Moors and Palomba, 1995);
2. Quantitative intercountry comparisons that have not been formalized within a statistical model that tests hypotheses, checks correlations, or the like (Chap. 105; Chenais, 1985, 1996);
3. Formal quantitative comparisons[5] (Ékert, 1986; Blanchet and Ékert-Jaffé, 1994; Gauthier et Hatzius, 1997);
4. Individual data (Blanchet, 1987).[6]

The first method often focuses on a particular policy measure, while the three others have generally been used up to now only to evaluate the global results of the whole system operating in one country or another. Moreover, as it collects no data on real variations in demographic behavior following the adoption of new laws, the first approach can go no further than informing us of respondents' opinions and intentions in the face of new events that are purely hypothetical ("Would you have, or would you have had, a [another] child if . . .?") (De Santis and Breschi, 2003).

In fact, to identify specifically (potentially) pronatalist measures, or the most important ones at least, the different authors frequently choose what is probably the only feasible approach in the current state of knowledge: to restrict themselves to those that appear logically most closely linked to reproductive behavior. It is important to remember, however, that this choice carries a strong risk of losing sight of potentially important elements. It could be argued, for example, that all governments always implement demographic policies to some extent, though often implicitly rather than explicitly, in the way the fiscal system treats families (according to the number, the work situation, and kinship relationships of their different components, for instance), in the provision of free or subsidized services (child care, education, medical care, etc.), and the like (Chap. 105). Besides, attempts have often been made to study and quantify the financial impact of current legislation on families by composition and

[5] Supposedly a far superior method to the preceding one. As already mentioned, however, it should not be forgotten that the dependent variable is not self-evident and that population policy is composed of a wide variety of courses of action, often difficult to measure and intrinsically impossible to compare (economic support, career support, leave, provision of various services with different territorial or social coverage, etc.): translating all these measures into quantitative terms can sometimes give the researcher a false image of objectivity.

[6] Which nonetheless often employ simulation methods. Other studies based on microdata have been evaluated in Gauthier, 1996a.

income (Franco and Sartor, 1990) and, from the slightly different angle of intergenerational accountancy, the age profile of economic exchanges between individuals and the State, also an indirect indicator of the protection offered to minors and their families (Jägers and Raffelhüschen, 1999; Sartor, 2004a).

At times, macroscopic effects have been underscored[7]: in Chapter 105, for instance, Gérard Calot cites two classic examples of strong variations in marriage associated with the current economic climate: one observed in Austria in 1987 (linked to a modification of family taxation) and the other in Sweden in 1989 (linked to new retirement pension reversion laws). Jean-Claude Chenais (1996, 1998) also holds the policy context responsible for fertility differences in Sarre between the years spent under French administration (1945–1977) and the period that followed, after uniting with Germany; or those between East German and West German fertility up to reunification in 1990, and so on.

The case of Sweden's recent fertility revival (followed by its decline) also seems to belong to the realm of unexpected demographic consequences of political economy policies. In Sweden, working women receive a maternity allowance equivalent to a certain percentage of their most recent salary. Therefore, if a woman reduces her workload (e.g., by going part-time) when her first child is born and becomes pregnant a second time, her new allowance will start from a lower salary level. To correct this shortcoming, from 1984 onward women with successive births have been guaranteed an allowance at least equal to the preceding one, as long as the subsequent birth occurs within 30 months of the one before (Näsman, 1991; Rønsen, 2004). The resulting effect on fertility in the early 1990s, however, when the TFR rose above replacement level of 2.1 children per woman, appears to have almost disappeared today; since 1996, Swedish fertility has hovered between 1.6 and 1.5 children per woman.

Measures adopted to protect certain social categories, like single mothers in the ex-GDR in 1976 (Vukovich, 1993), or in the United States today (Gauthier, 1996a), provide interesting cases of unexpected and perverse consequences. In this type of situation, a fear, partly reinforced by the facts, is that concentrating assistance on specific groups will encourage individuals to place themselves voluntarily in protected categories in order to take advantage of these legally sanctioned benefits. Thus, in the concrete case mentioned here, the worry is that such measures will encourage women to have children outside legal marriage (and, especially in the American case, without looking for work).

Thus, pronatalist policies are extremely diverse in the approach they take and in their content. Without wishing to deal with all these aspects, I will attempt in the following text first to clarify the relationship between pronatalist and social policies, and, in a second section, to classify pronatalist policies essentially in terms of their content while also taking into account several other complementary criteria.

I. PRONATALIST POLICY, SOCIAL POLICY

Ignorance of the real cause of fertility decline discourages the adoption of pronatalist measures that, at least in terms of long-term fertility levels, are costly and only moderately effective (see, e.g., Olivia Ékert, 1986; Didier Blanchet and Olivia Ékert-Jaffé, 1994; Anne Gauthier and Jan Hatzius, 1997; Rønsen, 2004) or virtually ineffective (Demeny, 1987, 2003; Ditch *et al*., 1998a). Results are slightly more visible, on the other hand, over a shorter duration (see, e.g., Näsman, 1991) or when it involves reducing disparities between different social classes (Ékert-Jaffé-Jaffé *et al*., 2002).

In addition to doubts about their effectiveness is the public's poor appreciation both of what is really happening (despite insufficient fertility levels, the population in industrialized countries is generally still growing) and of the possible consequences which, not perceived as completely negative (as a decrease in population numbers can reduce pressure on resources and the environment), are therefore seen as insignificant, remote, and not requiring urgent action (Frinking, 1985; Vukovich, 1993). There is a potential lack of motivation, therefore, at the base of the rare explicitly pronatalist policies implemented.

Arising more generally out of the arguments usually used to justify public action, there is also some ambiguity about how to confront the problem (Sartor, 2004b).[8]

[7] There have probably also been many other cases where the effects, less evident or more diffuse in time, have gone almost unnoticed or, at least, for which it is more difficult to find clearly identifiable causes.

[8] I will not discuss here the question of knowing the extent to which public actions are decided through the power exerted over collective preferences by a minority. This interpretation is basically the one suggested by Samuel Preston (1984), who provides a plausible explanation for the inadequate support given to fertility by modern States: that the elderly, now the dominant group, use up resources that they do not wish to see redistributed to younger generations and their families (for a review, see Gauthier, 1999, 2002). Similarly, Peter McDonald (2002) expresses his astonishment that the young do not create pressure groups to obtain more state resources for family formation, and Olivia Ékert-Jaffé *et al.* (2002) consider that it is possible to assess the effects of social policy on the fertility not only of the whole population, but also for population subgroups affected differently by the various measures.

On the one hand, there are "market deficiencies": most individuals wish to behave in one way (in this case, to have an adequate number of children), but individual behavior does not conform to this ideal for various reasons. For instance, although surveys indicate that approximately two children is the ideal in almost all developed countries (although this has perhaps started to fall more recently: see Goldstein *et al*., 2003), the actual TFR is most often significantly below this level. This gap between ideals and actual behavior could be attributed to the operation of the market economy which, by encouraging short-term interests, inadequately compensates those who, by having children, are on the contrary investing in the long term (McDonald, 2002).

At an entirely different level, the state may instead be perceived as a protector, aware of, and concerned by, the long-term consequences of individual behaviors whose repercussions are not necessarily clear to the individuals themselves. This is the justification for compulsory pension plans, for example: left to themselves, individuals would not accumulate sufficient savings during their working life and would find themselves unexpectedly impoverished in their old age. The same could also apply to fertility: individuals prefer to have few children (or none at all) because they do not clearly appreciate the effect that low fertility will have on their quality of life during old age (Rendall and Bahchieva, 1998). This is also made all the more true by a predicted population composition imbalance: superficially, having children no longer seems necessary to guarantee comfortable retirement years, as alternative social protection systems now exist. These can only function, however, with a relatively regular succession of cohorts and therefore if the collapse in fertility is not generalized.

This basic ambiguity about the state's role in fertility, in turn influenced by the bad memories left by the pronatalist policies of many totalitarian governments, is also responsible for the lack of clarity concerning legitimate ways of curbing fertility decline. What seems sure is that such measures can never be presented in the form of punishment for those who fail to do certain things (e.g., the tax on celibacy introduced by the fascist regime) (Ipsen, 1997), but only as advantages for those who do them (e.g., cheap loans for young couples or facilitating access to housing); these advantages must be carefully justified, especially by invoking the need to cover part of the cost of more expensive lifestyles, thereby truly giving individuals the freedom to make choices for which they would otherwise be penalized.

Intervention through prohibitions is also becoming increasingly rare and politically delicate (prohibiting contraception, abortion, divorce, etc.). It is therefore preferable, and even essential, to give priority to incentives, encouragement, and guidance, while completely respecting individual liberty. Concretely, this means making certain individual choices more attractive than others, whether by using financial incentives or other mechanisms.

Beyond the simple question of numbers, family and society are also interested in ensuring that future generations do not fall below a certain threshold, particularly with respect to the quality of health care and education. This often translates into the provision of certain free or subsidized services, such as medical visits, schooling, and the like. Legislation aiming to reach this qualitative goal, however, also demands a heavy parental investment (through extending the duration of schooling, e.g.) and may lead to the interiorization of these values by families themselves (Moors and Palomba, 1995). In some cases, therefore, this legislation may end up reducing fertility excessively, because, when limited resources are available, investing more in each child means cutting down on the number of children.

Added to this potential conflict between quality and quantity, highlighted at the family level by Gary Becker (1960, 1981), is the controversial question of the family's role and women's position in society: do children thrive more if they are cared for, at least during early childhood, by the family (especially the mother) or in an appropriate institutional setting[9]? In the first option, mothers are encouraged to reduce their outside commitments, at least during the first years after the birth, although this creates a potential conflict with their professional aspirations (Chenais, 1998; McDonald, 2002); in the second, substantial investments are made in nurseries, child care centers, and other early childhood facilities. More often however, countries oscillate between the two options and move somewhat in both directions.

The population question is subtly linked to that of social policy, which has reached sizeable proportions in all developed countries (absorbing between 18% and 33% of gross domestic product [GDP]); this often generates some confusion between the two spheres, pronatalist and social, in terms of means and goals. Thus, families with children are often granted economic and administrative benefits, at least as long as they do not exceed a certain income threshold, beyond which these advantages diminish or disappear completely. However, as mentioned, social policies are

[9] Linked to this is the following controversial issue: are the best institutions private (as in Anglo-Saxon countries) or public (as is generally the case in continental Europe)?

often the camouflage used by governments to have fertility support measures accepted by a sceptical public opinion: having children is expensive and leads to a reduction in living standards, at times below the poverty line and, officially, the state intervenes only to prevent this happening.

Finally, it is just as important to consider the individuals toward whom population policy may be directed. The traditional family of the past was ordinarily represented by a family head (male, economically active) who benefited from any services offered by the State or his employer (such as family allowances, medical services for himself and his family, etc.). With the disintegration of this family form and the multiplication of alternative lifestyles that do not exclude having children, defining the beneficiaries, and even the typology of interventions, has become difficult since, as already mentioned, they often implicitly conceal a bias in favor of certain family types. Paying a salary to housewives, or at least to mothers who stay at home, for instance,[10] tends to exclude working mothers; if it is a fixed amount, a monthly allowance allocated at the birth of a child tends to penalize working women (who have to give up their salary, at least for a time); if it varies according to the woman's salary, on the other hand, it tends to benefit the wealthiest social classes. This explains at least part of the extreme care taken when adopting different measures, their variability through time and space, and perhaps also the caution over introducing index-linked measures. This is a sort of recognition of the need for perpetual revision of the bases and criteria of public intervention in fertility.

For European Union countries, a final dimension is worth bearing in mind. The European Union has no direct experience with family policy issues; nor does it have a shared definition of the family. But it is competent in many areas closely linked with the family and fertility, like that of labor force activity (which, e.g., interacts with maternity in terms of maternity leave) and of sexual equality, which motherhood should not threaten. The relationship between national governments and membership of the European Union is certainly a complex one, and if national policies in this domain converge much less than might have been expected, or do not converge at all, this is not by chance (Gauthier, 1999, 2002). In the future, however, it is possible that the problems shared by all European Union countries—the inadequacy of intergenerational exchange first among them—will end up homogenizing their policies to some extent.

[10] Which can occur, even implicitly, in terms of fiscal policy: for example, by granting a tax reduction or allowance for dependent wives.

II. A POSSIBLE CLASSIFICATION OF PRONATALIST POLICIES

A detailed analysis of fertility support measures adopted in different countries is impossible in the space of a few pages because of the frequent changes of direction, the complexity of different legislations within which specific actions simultaneously pursue a variety of goals (demographic, social, spatial redistribution of resources, etc.), and the lack of comparability between contexts (diversity of per capita income, variations in women's full- or part-time labor force involvement, etc.). (For a more complete account, see the sources cited in note 4 and the references at the end of the chapter.)

Table 104–1 brings together the elements of a framework and calendar for pronatalist practices, in the broader sense of support or protection for motherhood. As can be seen, the earliest interventions go back to the end of the 19th century. Up to the 1960s, measures gradually became more generalized (e.g., from a few groups of women to all women) and were reinforced, extending the period of compulsory or optional abstention from work and increasing economic support. Since then, trends have been less well defined, particularly for financial constraints, imposed by the already precarious state of many public budgets. In general, however, parental leave (often unremunerated) has been extended, allowing one

TABLE 104–1 Main Historical Stages of Family Policy Measures in Industrialized Countries

(1) 1870–1929	First paid maternity leave Prophylactic health measures for mothers and children Financial support for mothers in need
(2) 1930–1944	Allowances for workers with minor children Pronatalist policies in several countries
(3) 1945–1959	Universal family allowance Extension of maternity leave Other measures (preventative, health, and housing)
(4) 1960–1974	Higher family allowance for the poorest, means tested
(5) 1975–1995	Further extension of maternity leave and other benefits for working parents Articulated and integrated family policies (in several countries) Development of preschool child care services Public financial assistance for the poorest families

parent to spend time with the children as long as they have not reached a specified age, often 8 years old. Measures taken in this sphere are somewhat less linked to the economic and political climate; although they increased more slowly than other types of social spending during the 1960s and 1970s, they also proved more resistant to spending cuts during the 1990s, especially in the countries subject to the budgets restrictions imposed by the Maastricht Treaty.

All industrialized countries have strictly economic policies supporting families with children, although these diverge widely in their intensity and characteristics; some of these are presented in Table 104–2. Under the classic hypotheses of perfect competition (whose main assumptions include the rationality of parents/consumers, perfect prediction of the future, and the existence of a perfect captial market with no liquidity constraint), most of these actions should give perfectly equivalent results. In particular, allowances at birth or when the child reaches a given age,[11] monthly benefit payments, tax exemption, and the creation of a retirement credit for mothers can all be translated into a given sum of money expressed in current monetary value, taking account of the frequency of events and their distribution through time. However, the classic theses of marginal economics do not adequately represent the reality of industrialized countries today, for the manner in which the allowances are paid is of consequence for both the lawmakers and their beneficiaries (De Santis and Breschi, 2003).

In addition, many possible secondary regulations complicate any evaluation of potential benefits; among these, and not mutually exclusive, may be found the family's socioeconomic circumstances,[12] the wife's occupation (or sometimes the husband's, if the wife does not work), the children's birth order, the presence of two parents, the use of certain public services,[13] the existence of maximum and minimum transfer limits, and so on.

The presence of children (or of family responsibilities) is often a reason for tax exemptions. In the past, these exemptions often took the form of reduction in

[11] Among the European Union countries, this type of payment is made in Belgium, Denmark, Finland, France, Ireland, and the United Kingdom.

[12] The exclusion or reduction of benefits for the better-off is now an almost universal criterion, especially because of growing restrictions on budget balancing.

[13] Sometimes offered in place of cash transfers. For instance, mothers in Germany receive a child care allowance during the first year if they do not send their child to a state nursery.

taxable income. Because of progressive tax rates, however, this solution was more advantageous to the wealthiest families. Although justifiable from one point of view,[14] it was difficult to defend politically, especially during a period of reduction in public spending. Nowadays, transfers are most often made as fixed amounts and, usually, via tax credits only available to taxpayers.

The question of maternity leave and payments is particularly delicate both for compulsory and optional periods (Table 104–3). Most frequently, maternity benefit rates are linked to salary levels before the birth, although sometimes there are preset inferior and superior limits. Introduced in order not to discourage fertility among working women, this measure has various potential drawbacks. In particular, working women draw the greatest benefits from these measures, though some measures may discriminate among them at times by offering greater advantages to employees, notably those in the public sector.

The overall result, therefore, is to render the assessment of transfers rather obscure, linked probably to the absence, even in France, of a complete picture of the system. It is almost impossible for a family to calculate ex-ante (and even often ex-post) the total value of transfers received. To make meaningful international comparisons, therefore, estimates for specific family types are often employed; the problems remain, however, especially because countries' ranking changes, sometimes radically, with the passage from one family type to another, or with taking into consideration a more limited or broader range of services. As Table 104–3 suggests, for example, countries vary enormously in terms of the provision of child care services; for the youngest age group (0–2 years) these services cover from 2% to 60% of the population concerned, and in the following group (3–5 years), between 28% and almost 100%. The price itself is also very variable: free of charge in France and Belgium, services have to be paid for in the other countries. As costs generally change with family income, calculating the average cost is not easy, although estimates suggest that it may reach 36% of the average salary in Greece (and exceed 20% in Ireland and the United Kingdom).

These figures do not reveal all the differences, however—such as in spatial coverage and timing (with or without flexibility), in the quantity and quality of services provided by the institutions (such as meals), in preferential conditions of admissibility, and such like. All these variables are hard to quantify, but extremely relevant in terms of real support for families.

An additional reason for the poor comparability of family policies (among which we should look for potentially pronatalist measures) between industrialized countries (or even only between the European Union countries described here) is associated with housing policy. Such policies are usually aimed toward the most underprivileged population groups but, as family size enters into the assessment of needs, the largest families are often recognized as the most impoverished and therefore become the main recipients of such policies. These measures, however, are in turn relatively complex, and are often linked, in addition to the family's economic status assessment, to such factors as housing type (e.g., only social housing) or geographic situation (e.g., only zones with substantial pressure on housing).

Taking all these types of action into account as far as possible, Table 104–4 gives the list of European countries, ordered according to their level of family support (or more precisely, to 20 two-parent families with one to three children, not necessarily representative of families of this type). Although subject to the arbitrary nature of many choices, the gap between countries appears enormous in some cases: Luxemburg has a clear lead, followed by France and Belgium, who are practically equal. At the opposite extreme are Greece, Italy, Spain, and the Netherlands (with a net deduction on families instead of a transfer in their favor).

It should not be forgotten, however, that the variables researchers tend to examine do not include hidden transfers from the state to families through the provision of two free (or subsidized) services, namely health and education. Integrating these two elements into the calculation leads to the conclusion that even the least pronatalist countries (such as Italy) actually make positive rather than negative net transfers to families, as shown in Table 104–4 (Sartor, 2004a). This does not mean, however, that the table order would be upended if these advantages were also taken into account, as European countries are relatively homogeneous when it comes to taking responsibility for health and education expenses. The considerations about costs related to dependent children for which families actually remain responsible (for both direct expenses and opportunity costs) remain valid, but these costs would be far higher if families also had to pay for the medical expenses and schooling provided for their children.

[14] Despite their shortcomings, studies on the cost of children seem to suggest an increase in cost with the increase in family living standards (Ékert-Jaffé, 1994) and that of mother's income (opportunity costs; Gauthier, 2002).

TABLE 104–3 Maternity and Paternity Leave, and the Proportion (%) of Children in Nurseries or Preschool in Europe (ca. 2000)

Countries	Leave			Percentage (%) of children in nursery or preschool

CONCLUSION

Despite countless analyses and multiple attempts at explanation, the real causes of fertility decline still remain obscure. On the basis of these facts, some believe that any attempt to intervene to change these effects may be useless, and possibly counter-productive (Demeny, 1987).

European countries seem to have chosen to act in all reasonable directions: economic intervention, creation of child care services, career support for mothers, and so forth. But partly because of limited means, partly because of confusion surrounding goals (much more often social or redistributive that pronatalist), and partly through erratic application through time, attempts made up until now have not met with great success apart from a few fertility rebounds linked to specific situations. TFRs react only mildly, if at all, to the efforts governments make to influence them. Part of the explanation may be that the support received by families, even in the most favorable systems, covers only a small fraction of the expenses they face.

To successfully invert the downward trend of fertility over the last several centuries, if indeed that could be achieved, cultural, organizational, and financial inputs must reach far in excess of those that Western nations have agreed to up until now.

CHAPTER

105

The Effect of Pronatalist Policies In Industrialized Countries

GÉRARD CALOT

Institut national d'études démographiques (INED), Paris, France

During the 20th century, few industrialized countries implemented policies that had the explicit objective (or the explicitly declared objective) of influencing fertility. If dictatorships and other totalitarian regimes[1] that resorted to coercive methods of varying severity are excluded, the list is especially short. By confining ourselves to democratic countries which, over a long period, created legislation whose explanatory memorandum constantly and expressly mentioned, among other concerns, worries regarding a sufficient level of fertility, France is about the only example (see Chapter 119). Even then, the strength of pronatalist motivation, which was very marked at the end of World War II, has become very blurred in this country during the last two or three decades.

It is necessary, however, to remember that some countries—through what is called family policies, presented as targeting exclusively social objectives—adopted legislation which, in many cases, is not fundamentally different, in their content or their methods, from those presented elsewhere as targeting both social and demographic objectives. Indeed, even though some deny it, all the countries implicitly apply family policy measures, even if it is only in the way that the number of children is taken into account with regard to obligatory deductions (income tax, in particular), and social benefits, or in regard to education, care for little children (crèches, nurseries), or the budget on child health.

[1] Such as that of Nazi Germany, for example, which in the 1930s developed a pronatalist policy and succeeded in achieving some increase in fertility (see Chap. 100).

The general issue discussed here is the effect of policies on fertility: whether they are policies which at least partly aim for such an effect or policies with purely social objectives which can indirectly affect fertility. Beforehand, I will make some remarks on the possibility of assessing demographic effects. I will then deal with the issue raised by using the example of the increase in French fertility after World War II (Sect. 2), the case of Sarre (Sect. 3), a comparison of West and East Germany (Sect. 4), and a more general comparison of the trends observed in Western Europe (Sect. 5).

I. THE DIFFICULTY OF LINKING CAUSES AND EFFECTS IN SOCIAL SCIENCE

In demography, as in the other fields of social science, the impossibility of organizing provoked experiments makes it difficult to irrefutably connect causes and consequences. While analysis allows, exceptionally, for presumptions to be established, it is clear that causal certainty is, and will always remain, beyond reach.

Generally, it is on the basis of a temporal analysis that attempts to estimate effects are made: such a cause appears at a given date or is likely to exert its effects on a given scale from such a date; the study of the variation of this scale before and after the pivotal date can shed light on any possible effects. The diagnosis established is based, implicitly or explicitly, on the gap between the trend actually observed of the indicator considered and that which would have been recorded, but which is by definition not observable, in the absence of the cause studied.

The trend of the considered indicator that would have been recorded in the absence of the cause studied can be estimated under three specific circumstances.

1. Before the pivotal date, the indicator varies little, but over quite a short time interval, after the pivotal date, the indicator begins to increase or decrease significantly, and is then maintained without any significant variations near its new level. The shorter the interval is with the highest variations and the closer it is to the pivotal date, the more authority we have to attribute the recorded change in level to the considered course. In other words, this favorable circumstance is that for which the effect is immediate and massive on a scale that varies relatively little before and after sudden and significant variations in levels.
2. One case that is similar to the previous one is that of regular variation before the pivotal date in the indicator (e.g., in an appreciably linear manner); then over quite a short time interval, after the pivotal date, it increases or decreases significantly and then follows a regular trend comparable to that which prevailed before. The effect is therefore estimated by the gap between the extrapolation of the previous trend and the new trend.

   These two situations correspond to the case where the indicator considered has a considerable inertia before and after the appearance of the cause studied, and where the effects produced are limited to a change in level without a change in the rate of the chronological trend.
3. Another case, different from the preceding ones, is that in which a second demographic entity exists which has not been submitted to the cause studied and which, apart from that, is homogenous to the first entity. After the appearance of the cause in the first entity, a study of the trend in the considered indicator in the second entity provides an estimate of the trend that would have occurred in the first entity in the absence of this cause. This favorable circumstance occurs when a control group serves as a reference in the absence of a cause.

It is rare to be in one or the other of these situations. The exceptional historical and geographical specificities must be taken into account in order to estimate the effects. Note that with regard to the medium- or long-term effects on fertility, only the third situation is likely to provide some indication.

As an illustration, let us consider the following two examples:

1. The effects of legislative changes in Austria (changes to the law regarding income tax) and in Sweden (changes to the law regarding reversion pensions), which resulted in sudden variations in the number of marriages (Figure 105–1);
2. The effect of World War II on fertility in France and Switzerland on the one hand (Figure 105–2), and Sweden on the other hand (Figure 105–3).

Considering the scale of the variation recorded over a period of only a few months, the curve of the monthly number of marriages in Austria and Sweden, after correcting for seasonal changes, is significantly invariant (Figure 105–1). Moreover, at both ends of this period, the levels are identical, which indicates the very specific nature of the cause (in both cases, the advantage of being married before December 31). We are therefore in the first situation with a particularly transitory cause.

If the war period of 1940–1945 is excluded, the comparison of trends in the total fertility rate (TFR) in France and Switzerland between 1930 and 1955 shows a relatively significant parallelism, with the French indicator exceeding the Swiss indicator by 0.4 children per woman (Figure 105–2).

In both countries, fertility was decreasing slowly between 1930 and 1935. The slight increase observed in France from 1936 and which was accentuated in 1939 was abruptly interrupted by World War II and the invasion of the country. Although a certain increase was observed from 1942, the spectacular jump that marked the beginning of the phenomenon that became known as the baby boom did not occur until 1945. Swiss fertility stopped declining in 1937 and increased slowly up to the middle of 1940, followed by a rapid and massive increase until the end of 1945. Then, in parallel to the trend in French fertility, a reflux occurred, with the Swiss rate returning to between 2.62 and 2.30 children per women between 1946 and 1955, while the French rate was between 2.98 and 2.67.

This is how during the war, Switzerland, spared the hostilities, experienced its baby boom, which occurred on exactly the same scale as that of France: the difference between the TFR of 1946 and 1939 was 0.82 children per woman in Switzerland and 0.83 in France. But the French baby boom, prevented by the war, only occurred after the liberation. The great difference between these two countries is that the rate observed in 1946 was achieved by an exceptional increase in the French rate in the space of one year (the TFR increased from 2.15 in May 1945 to 3.14 in April 1946), while in

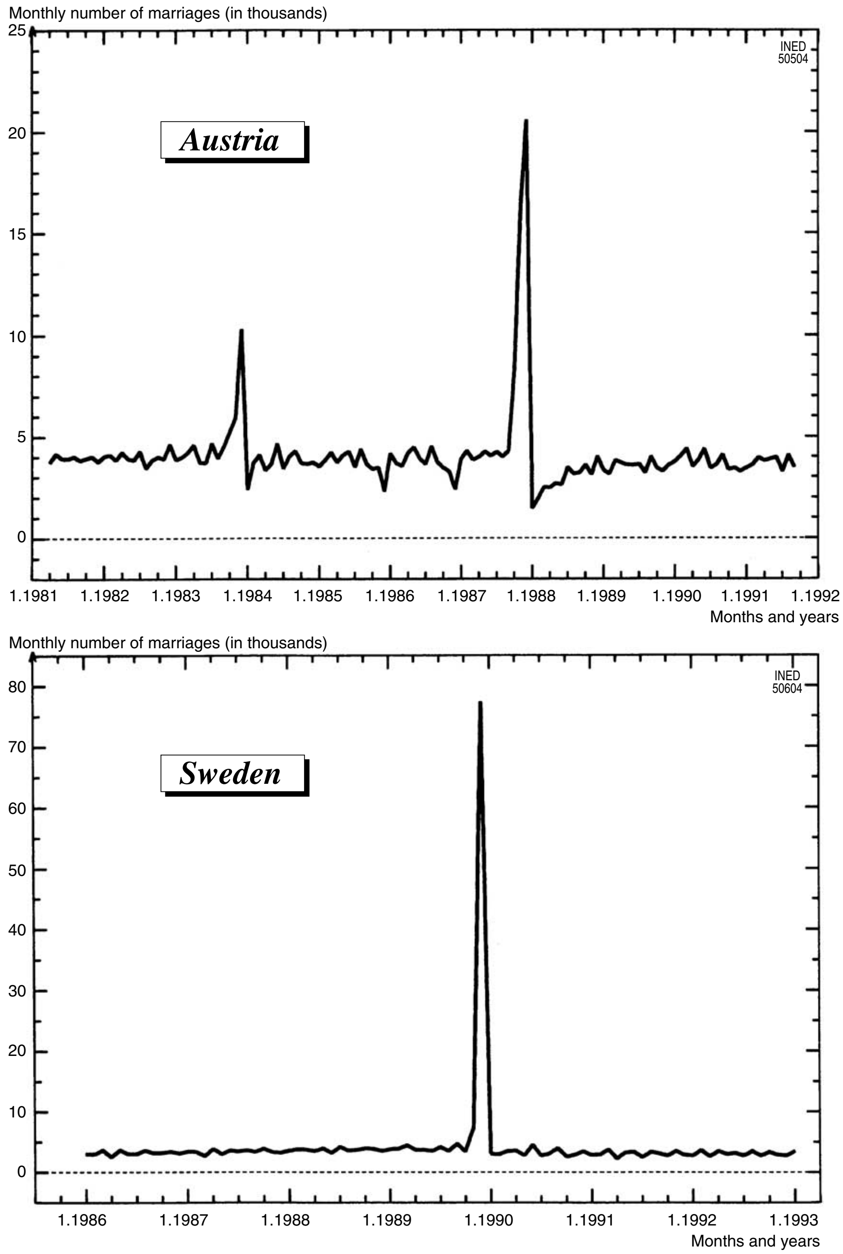

FIGURE 105–1 Monthly number of marriages corrected for seasonal variation: Austria 1981–1991 and Sweden 1986–1992. (Source: Population database of the Observatoire démographique européen [ODE], sardon@ined.fr)

Switzerland it was the result of a regular progression over the course of 6 years.

We are therefore led to believe that the Swiss fertility trend provided a pertinent reference to what would have been the progress of French fertility if the war had not taken place. In these conditions, the vigorous increase in fertility that occurred at the end of the war, in France as well as in the majority of countries that took part in the conflict, could well have been influenced by the war only in its timing but not in its nature, and not even in its scale: it corresponds to a trend, which certainly no contemporary had foreseen, but which could probably also have occurred earlier and spread over a longer period if peace had been maintained.

This presumption is corroborated by examining the fertility trends of Sweden, the other European country that was spared World War II (Figure 105–3).

We observe that the parallelism between the French curve and the Swiss and Swedish curves after 1945 correspond to a greater difference, around 0.15 children per woman, than during the 1930s (the gap

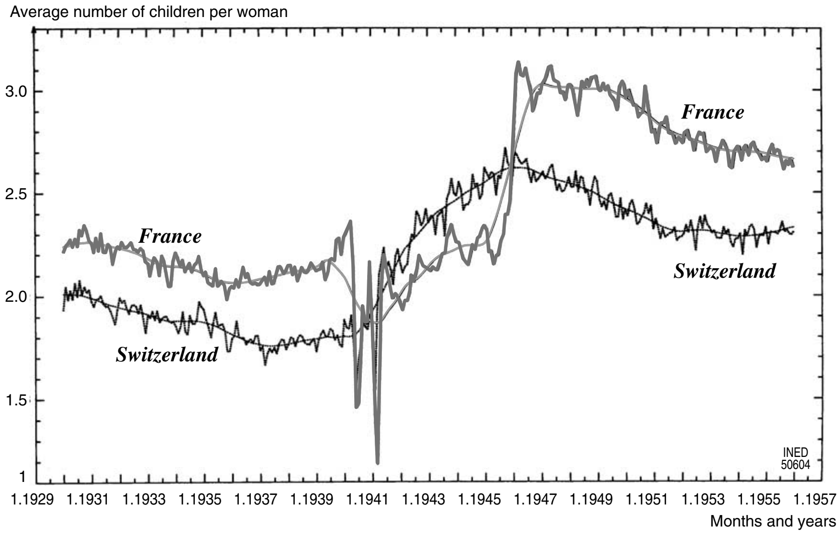

FIGURE 105–2 Trend in monthly TFR in France and Switzerland from 1930 to 1955. Data corrected for seasonal variation and data smoothed by moving average graduation (Hoem and Linnemann, 1988). (Source: Population database of the ODE)

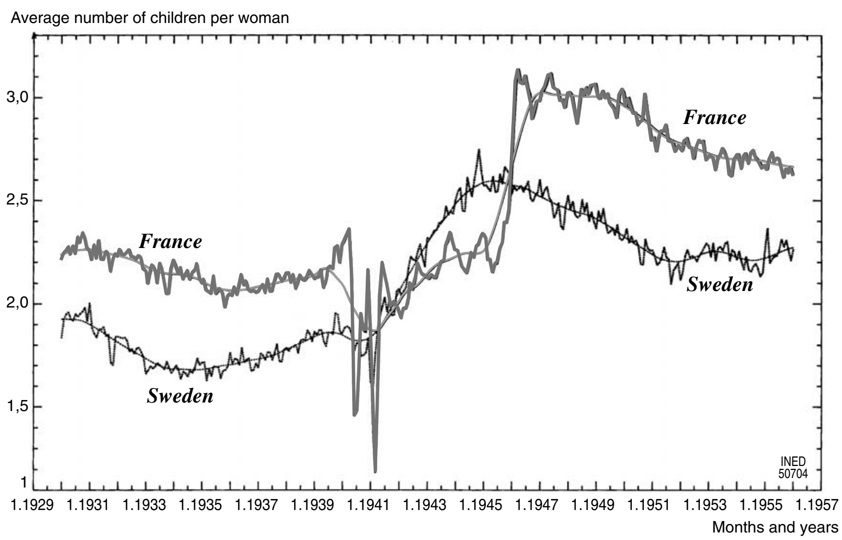

FIGURE 105–3 Trend in monthly TFR in France and Sweden from 1930 to 1955. Data corrected for seasonal variation and data smoothed by moving average graduation (Hoem and Linnemann, 1988). (Source: Population database of the ODE)

between the French rate and the Swiss one was on average 0.29 children per woman during the 1930–1939 period, and 0.44 during the 1946–1955 period; compared to the Swedish rate, the gap is 0.38 and 0.52, respectively).

II. THE RISE IN FRENCH FERTILITY AFTER WORLD WAR II

The principles of a particularly active policy in favor of families was defined in a decree established in 1939, known as the *Code de la Famille* (The Family Code) (Dalloz, 1995), with the clearly defined objective of maintaining fertility. But it was not possible to implement the policy until the liberation, in the context of a social security system made up of three branches: illness, old age, and the family. It consisted of the provision of considerable benefits to families. The funding of the family branch relied on employer contributions and was based on a 9% rate of deduction from salaries.

From 1945, all salaried employees benefited from these services. But it was not until the end of the 1950s

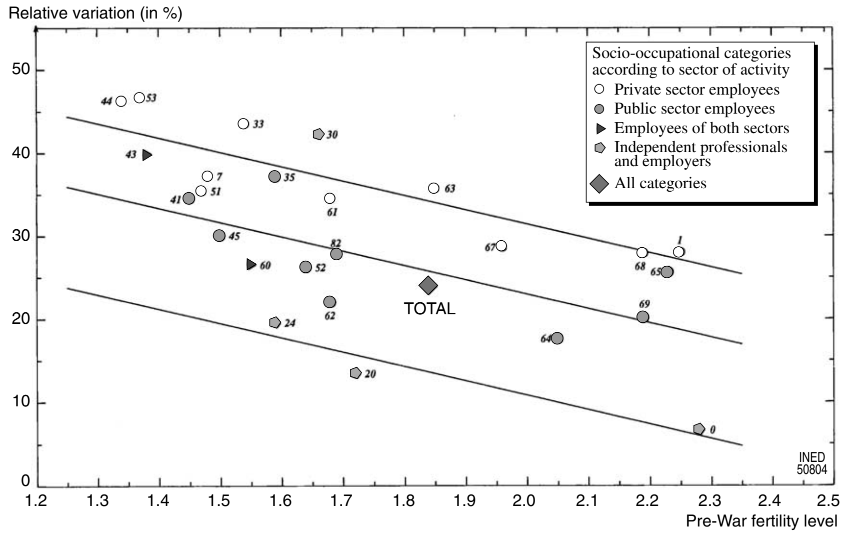

FIGURE 105–4 Variations in fertility between socio-occupational categories in France according to the 1962 family survey. Correlation between the relative variation of fertility between the pre-war period and the post-war period and the pre-war level. Fertility measured by the average number of children after 10 years of marriage. Fertility level corresponding to the marriage cohorts of 1920–1934, and 1940–1951 respectively. The code numbers in the figure refer to INSEE's classification of occupational categories. (Sources: Febvay, 1959; Deville, 1972; Lery, 1972)

that the system of family benefits was extended to nonsalaried workers: farmers, tradesmen and craftsmen, employers, and independent professionals. This very specific historical occurrence makes a differential analysis of fertility according to socio-occupational categories possible (data obtained from family surveys carried out during the censuses of 1954 and 1962). Furthermore, the establishment of a family benefits system represented a greater improvement in income for private sector employees (industry and trade), who only received modest benefits before the war, than for state and public sector employees, who already received family benefits before the war, but at a lower level than before 1945.

Undoubtedly, all the socio-occupational categories recorded an increase in fertility between the pre-war period and the post-war period. But at equal pre-war fertility levels, to what extent was this increase influenced by the implementation of this new family policy? More precisely, at equal pre-war fertility levels, was the increase virtually identical within each of these three groups (private sector, public sector, and nonsalaried employees) and significantly different from one group to another?

In Figure 105–4, a point for each socio-occupational category represents the correlation between (**A**) the relative variation of fertility between the pre-war and post-war period, and (**B**) the pre-war fertility level. The fertility levels, before and after the war, of each of the socio-occupational categories was measured by the average number of children after 10 years of marriage in the marriage cohorts of 1920–1934 and 1940–1951, respectively (Febvay, 1959; Deville, 1972; Lery, 1972).

Within each of the three groups, the points of the graph are ordered[2] according to a linear trend, with the three trend lines being virtually parallel. As expected, at a given pre-war fertility level the private sector employees recorded the highest fertility increase. They are followed by the public sector employees, then the nonsalaried workers.

The gap between the adjustment line corresponding to the private sector and that corresponding to the public sector is around 9 points, the gap between the latter and that corresponding to nonsalaried workers is around 12 points. If we could attribute the gap between the two extreme groups to the difference between the legislation applied (this naturally constitutes a hypothesis), we come to the conclusion that the effect of implementing the 1945 family policy was to increase fertility by around 20% from what it would have been without the family policy, that is, by 0.4 children per woman for a fertility level that would otherwise have been 2.0 children per woman. This

[2] Liberal professionals, a particular socio-occupational category made up of nonsalaried professionals, demonstrated a fertility increase between the pre-war and the post-war periods that was exceptionally high, considering their pre-war level. This anomaly could be due to the high standard of living of this socio-occupational category, which would make them less sensitive to the effects of the family policy.

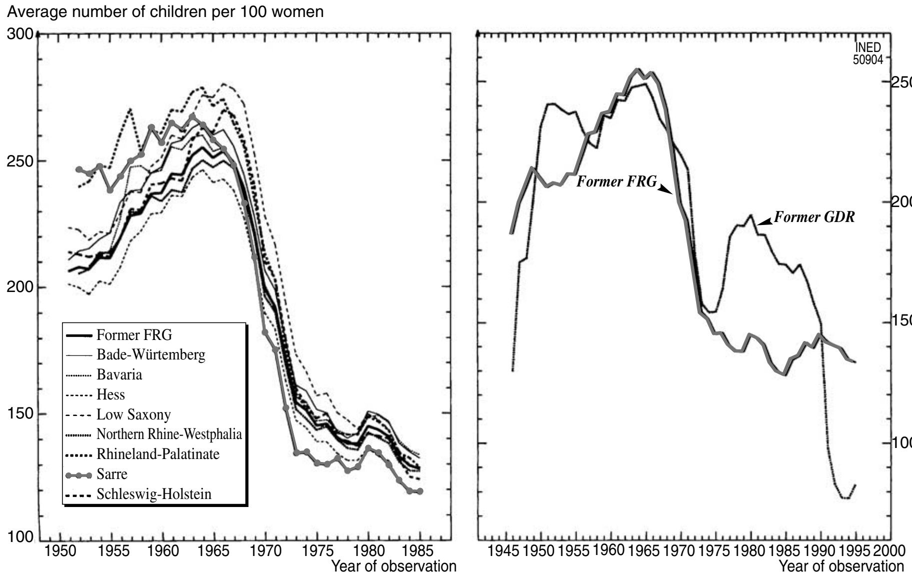

FIGURE 105–5 Trend in TFR in Germany, in the *Länder* of the West from 1951 to 1985 (graph on the left) and in both East and West Germany from 1946 to 1995 (graph on the right). (Sources: for Sarre, Schwartz, 1978; for both East and West Germany, Monnier, 1989; for updating these data and for the other *Länder*, Population database of the ODE)

conclusion is obviously weak: for example, one could object that the fertility changes that occurred within a given socio-occupational group could also be due to changes in the social recruitment of this category.

III. THE FERTILITY TREND IN SARRE

After World War II, Sarre remained under French control until a referendum was held in 1955 which led to its entry into the Federal Republic of Germany as a Landon January 1st 1956. For ten years, the French family policy was applied to the population of Sarre which, following a transition period, became subject to the legislation of Federal Germany which was less favorable to families. It is also interesting to compare the fertility trend in Sarre with that of the other Länderof West Germany (left part of Figure 105–5). If the French family policy implemented in 1945 had an effect on fertility, it should be possible to observe this effect on the demography of Sarre.

Figure 105–5 shows the fact that at the beginning of the 1950s, Sarre had one of the highest fertility levels among the eight *Länder* considered[3] and that from the 1970s it had one of the lowest levels, and even the lowest in 1985.

[3] The three entirely urban *Länder* of the former Federal Republic of Germany (Berlin, Bremen, and Hamburg) have been excluded from the analysis.

This result does not establish the certainty of the effectiveness of the French policy, but it supports the presumption of its effectiveness.

IV. THE FERTILITY TREND IN THE FORMER GDR AND THE FORMER FRG

The graph on the right of Figure 105–5 shows the trend of the TFR in the former Federal Republic of Germany (FRG), and in the former German Democratic Republic (GDR). Undoubtedly, in many aspects, the two halves of Germany were separate up until 1989, in their political and socioeconomic system above all, but also in the population's standard of living, the rate of female employment, the care of young children, the situation with regard to housing, and so forth. On many levels, the fertility of the two countries was very different, particularly with regard to age at motherhood and the proportion of births outside marriage. However, we cannot ignore the striking similarity in the fertility levels of both countries between 1957 and 1973. Furthermore, around 1970, these two countries were similar in the fact that their TFRs were the lowest in the world.

In 1975, the government of the GDR created a group of social measures explicitly aimed at increasing fertility; thereafter, the two rates separated quickly, that of the East surpassing that of the West by 0.4 to 0.5 children per woman from 1977 to 1985. Then, the fall of

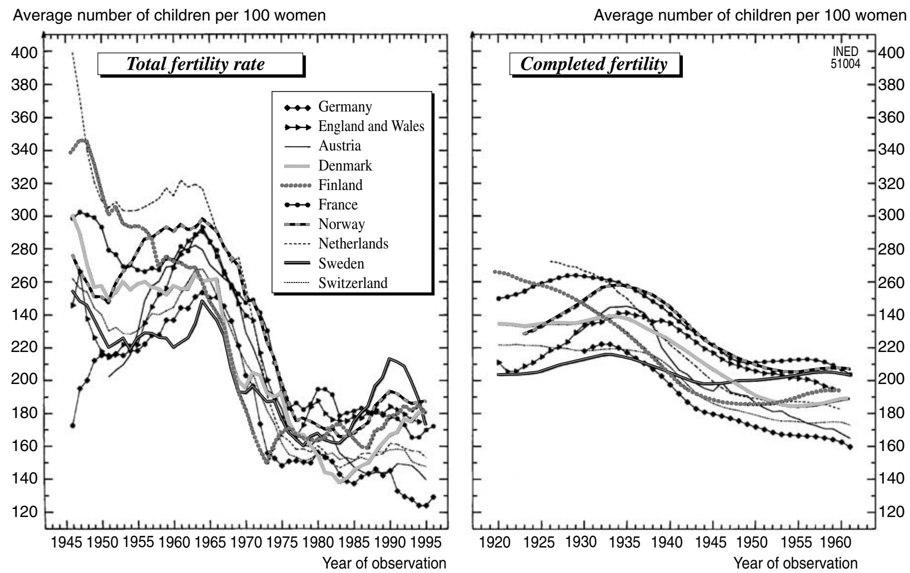

FIGURE 105–6 Trend in TFR (left graph) and the completed fertility of cohorts (right graph) in Northwestern Europe from 1946 to 1995. (Source: Population database of the ODE)

the Berlin Wall, the collapse of the Communist system, and the unification of the country completely overturned the situation.

While it is clear that analogical reasoning certainly does not make it possible to assert that the FRG would have recorded a trend similar to that of the GDR if it had adopted the same measures in the same period, it seems less dubious to suggest that the GDR would probably have experienced a similar trend to that of the FRG in the absence of the measures taken in 1975.

V. THE FERTILITY TREND IN NORTHWESTERN EUROPE

Since World War II, the countries of Northern and Western Europe have reached an increasing degree of similarity in population trends: the most striking trend inflections appear simultaneously and according to increasingly comparable terms. In particular, the massive decline in the TFR, which occurred between the mid-1960s and the mid-1970s, is very similar from one country to another (left side of Figure 105–6). Consequently the peculiarities in the trends, notably the exceptions to the parallelism, at least when the exceptions are quite significant, reveal national specificities that we need to identify and then attempt to explain.

The long-term demographic effectiveness of the French family policy appears, vaguely but probably, in the fact that in the TFR and, more especially, in the completed fertility from the cohort born in 1920 to that born in 1960, France had one of the highest levels in Europe (Figure 105–6). It is naturally impossible to quantify this effect on the basis of Figure 105–6 alone.

Close examination of Figure 105–6 shows, on the other hand, that the four Scandinavian countries (Denmark, Finland, Norway, Sweden) are distinguished by a clear increase in their TFR since the beginning of the 1980s. The most striking case is that of Sweden where the period of increase (1983–1990), which raised the rate above replacement level, was replaced by a period of decline of a virtually identical scale, from 1991. In terms of completed fertility, the Scandinavian peculiarity results in a lesser decrease of the curves, and even a near-invariance for Sweden: the Swedish curve crosses the curves of nearly all the other countries, which shows a decrease of at least 0.5 children per woman between the female cohorts born in 1930 and those born in 1960. While Swedish women born around 1930 were the least fertile females on the continent, their daughters, with a fertility level similar to that of their mothers, have one of the highest fertility levels in Europe. This is probably due to the indirect pronatalist effect of social policies, particularly those aiming to facilitate the compromise between professional life and family life.

CONCLUSION

At the end of this brief discussion of some remarkable changes in fertility in Europe, let us add some indications of general interest on the effects of policies that support fertility. As was mentioned at the beginning of this chapter, coercive measures, particularly those that consist of reducing fertility control by limiting access to contraception or induced abortion have been excluded from this discussion.

First of all, each time that the opportunity arises (exceptional, it is true) of evaluating the effect on fertility of policies aiming to improve the living conditions of families (regardless of the reasons, partly demographic or exclusively social), the resulting conclusion invariably includes a positive effect on fertility levels.

Secondly, this effect is generally modest. While the TFR could react with some intensity to such and such a change in legislation, cohort completed fertility would not have changed considerably. The maximum effect that can be expected from an active family policy over the long term is probably of a few tenths of a child per woman. Earlier we provided an idea of the scale of the effect of the French family policy implemented after the liberation. Econometric work carried out in France by Olivia Ékert (1986), came to the conclusion that the total compensation of the cost of a child could increase completed fertility by around 0.5 children per woman.

According to our previous considerations, it appears that no country could have avoided the two considerable variations in fertility observed during the 20th century (the baby boom of the 1940s and the baby bust of the 1965–1975 period) through appropriate policies. It is only on the fringes that changes could have been made.

However, for the female cohorts born around 1960, the difference that separates the completed fertility of the cohorts from replacement level, which can be taken as a reasonable demographic objective (maintaining the adult core of the population at its current number, which implies a slight population increase and a certain aging, due to the increase in average life span), generally remains in Europe within the scope of the possible effects of family policies. It is therefore possible to obtain simple replacement fertility in Western Europe.

It is true that many of our contemporaries are repelled by a policy for stimulating fertility, either because they consider that governments should not intervene in this most personal of issues, that of family choice, or because they condemn any objectives that are similar to those of previous totalitarian regimes. It is possible, however, that the changes that affect the balance between ages, particularly with regard to social security and particularly to pensions, will result in the disappearance of some of these objections.

Insofar as an active family policy is inevitably expensive for the public purse, what needs to be determined is whether the benefits that we might obtain from higher fertility are worth the cost. But that, in truth, is another discussion.

III

HEALTH POLICIES AND THEIR DEMOGRAPHIC IMPACT

GRAZIELLA CASELLI, JACQUES VALLIN, AND GUILLAUME WUNSCH

From man's appearance on the Earth up to the 18th century AD—that is, for tens of thousands of years—humankind never escaped the clutches of a stark mortality pattern: over a quarter of newborns did not survive infancy, and the mean length of life barely exceeded 25 years.

Less than three centuries have brought immense progress and unprecedented social change. The new mortality regime gives current populations a life expectancy two to three times longer than their predecessors, and this is probably a continuing trend. Some countries are plainly well in the lead, while others are still lagging, but all have moved forward and the general trend is extraordinary. And the last half-century has been the most decisive period of recent centuries. The great leap forward was a post-war achievement, brought about by the spread of antibiotics, the general introduction of social security systems in the developed countries, and the launching of large-scale health improvement programs in Third World countries.

Have health policies delivered? They aim to, so should they be credited with the outcomes achieved? Plainly, they are far from the only contributory factor to the recent mortality decline, and it would be foolhardy to claim them as directly and uniquely responsible. First, without the startling medical progress of the last 150 years, the situation today would still be very far short of where it actually is. Admittedly, this progress itself can be credited to health policies in the broad sense through investment in research, and the gains of that progress have been so great only because of health policies that spread the benefits to the general population. But it would be rash to conclude from this that merely taking medical research and current health policies forward will necessarily bring all populations of the world rapidly up to the level of the current trailblazers.

But, what do we mean by a "health policy"? This is not the place in which to rehearse the definitions of health,[1] nor dwell at length on the simple fact that a health policy is the deployment of society's resources to improve public health. But this simple approach can go down many different roads (Pradeau, 2004). More especially, it can focus on very different degrees of involvement by the State (or other public institutions).

A strict economic liberalism approach might consist in a policy based solely on the idea of a market for health populated by players who were production (pharmaceutical firms, etc.), service (hospitals, private clinics, fee-for-service health professions), or retail (pharmacies, etc.) undertakings, and consumers (people with health problems, or healthy individuals concerned with prevention). The purpose of health policy would then be, as in other public policy spheres, to regulate that market in order to maximize system efficiency by optimum management of resources that can never be equal to the vast needs for improvement of public health. The limits of such an approach need little explanation.

Still in terms of the basic functions of the State (Montesquieu, [1758]; Constant, 1815) that are compatible with free enterprise, health policies may include the efforts of government bodies to regulate certain occupations that have a responsibility to society, which can include the health professions. Government will then decide what skills are required to carry on these occupations and the legal framework in which they can be exercised. It may also order the different levels of occupation hierarchically, or prescribe specializations and, finally organize how they should be coordinated or work together.

The basic functions of the State may also require some aspects of the prevention or treatment of some diseases to be seen as a public policy imperative identical or similar to national defense, for which public health policies must be framed. It was one of the earliest approaches of this kind that helped to contain most effects of the major epidemics through the enactment of sometimes quite harsh public injunctions, like isolation or the establishment of quarantine lines to tackle the plague or cholera. The concept of public health is also what lay behind the late 19th- and early 20th-century political concerns with hygiene, followed by the introduction of compulsory vaccination schemes or sectoral policies to tackle specific diseases, like tuberculosis or syphilis, considered as social evils which the State or, more generally, the authorities, had a duty to tackle.

Taking public involvement one step further, health policy can be spelled out in terms of concrete objectives and deliverables. With regard to infectious diseases, for example, the idea rapidly gained ground that a policy objective could be not just to tackle, contain, and limit the consequences of a disease, but quite simply, to eradicate it entirely. So, the World Health Organization (WHO) set, and eventually achieved, the objective of eradicating smallpox.

Health measures may also aim to provide more specific protection to groups at particular risk. Special maternal and child welfare programs, and statutory protection for workers against work-related accidents or occupational diseases, are cases in point. The same concept was even extended to maximize the benefits when, for example, informed

[1] Which can be found in various chapters of the Treatise, in particular Chapters 40 ("Health, Illness and Death," by Catherine Gourbin and Guillaume Wunsch), 41 ("Measuring the State of Health," by Catherine Sermet and Emmanuelle Cambois), and 80 ("Lengthening of Life and the Population Health Status," by Jean-Marie Robine and Carol Jagger).

by the Chinese barefoot doctors scheme, the WHO's Alma Ata conference adopted the primary health care strategy designed to redefine health policy priorities for the benefit of the poverty-stricken populations of the Third World.

Public involvement goes yet a step further when the objective becomes more all-embracing, as in the health section of some countries' population policy statements: setting target dates and percentages for cutting the infant mortality rate, or even hard targets for life expectancy gains. This kind of objective has even been included in some WHO programs under the "health for all 2000" initiative.

But the surprisingly unrealistic title of this initiative itself was merely a partial reflection on a worldwide scale of the major development made in the concept of health policy by social democracy and more so by communist regimes. It is a concept that requires the State—either directly, as in the United Kingdom and communist countries, or indirectly, through special purpose welfare agencies, as in France and the Scandinavian countries—to pay the full cost (or at least a very big share) of health care for the entire population in order to minimize social inequalities in illness and death while maximizing the general health and life expectancy of the population.

Finally, at the maximum degree of public involvement, a health policy may be based on the legal recognition of a real right to health for all, although this involves little practical commitment given the many factors in individual health that are largely outside political control and policy action. A constitutionally entrenched right to health will remain mere lip service unless legislation or regulation lays down the dividing line by time and circumstances of what is and what is not possible, in order to define where the duty of the state and authorities really lies, which is little different from setting more or less achievable targets.

These various concepts that can underpin health policies have only gradually emerged during a history of health that often receives only a passing mention in attempts to trace the history of population policies (including in the opening chapters of this volume). In Chapter 106 of this third part, therefore, Jacques Vallin and France Meslé briefly review the history of health policies to inform an understanding of current issues. In Chapter 107, the same authors then consider the strategies deployed in recent decades, and in Chapter 108, they review the measurement of real health policy outcomes. This assessment can obviously not be wholly satisfactory, as measurement in this field suffers from a lack of data, aggravated by the growing complexity of the issue in our modern societies. In Chapter 109, therefore, Viviana Egidi and Vittoria Buratta discuss the monitoring systems that need to be put in place before health policy outcomes can be properly assessed.

Origin of Health Policies

JACQUES VALLIN AND FRANCE MESLÉ

Institut national d'études démographiques (INED), Paris, France

In its broadest sense, health policy may be defined as a collective action to improve a population's health status, irrespective of the type of collective entity responsible for the action, and without awaiting direct central-government involvement. Even if we accept this definition, there are two obvious prerequisites to such action: (1) the population (or at least some individuals) must be, or believe themselves to be, capable of combating disease and death; (2) society must be sufficiently organized to produce institutions capable of and willing to make a collective contribution to bettering the population's health status. Both conditions seem to have existed at the very birth of the great civilizations whose writings have come down to us. Indeed, the first prerequisite was undoubtedly met at a rather early stage of prehistory, since an examination of skeletons has shown that, by the Neolithic, humans knew how to reduce fractures by immobilizing broken bones and preserving their alignment (Sournia, 1997).[1] As to whether the second precondition was met, we must let our imagination run. However, as far back as the first known writings, medicine already had an effective presence; it was sufficiently structured for us to conclude that, from earliest antiquity, most societies had begun to sketch out a health policy, if only through the organization of the medical profession. True, this embryonic arrangement probably never led to the implementation of a health policy (in today's full sense of the term) before the 19th century. No doubt it was necessary to wait until health issues attained their full magnitude, and access to medical care became sufficiently effective to overcome major natural constraints. Nevertheless, current health policies are the culmination of a long maturing process that moved in step with the construction of human societies.

[1] "But as some overlaps between the two fragments remain, we can conclude that [man] did not know how to exert a traction at both ends that would have restored a perfect alignment. We are even more hesitant about assessing cranial trepanations, which were partly healed in the individual's lifetime. [. . .] Was their significance religious or rather therapeutic? [. . .] The question will probably never be answered"(Sournia, 1997, p. 10).

I. ANTIQUITY, MEDICINE, AND RELIGION: FROM IMHOTEP TO GALEN

1. Egypt

The oldest medical text in the world is undoubtedly the Edwin Smith papyrus, written at the start of the Old Egyptian Empire, that is, in about 3000 BC. It is a true classification of external pathologies methodically arranged from head to foot. Each chapter described a clinical case with exploratory methods, statement of diagnosis, and therapeutic recommendations. This form of medicine (in which gynecology[2]

[2] "Egyptian doctors could identify uterine prolapse (for which pessaries were applied), metritis, vulvitis, and uterine cancer, fought by means of local injections, purges, and aromatic fumigations whose composition is unfortunately not known." They could also establish "an early diagnosis of pregnancy by observing the comparative growth of two plants, one irrigated with water, the other with the urine of the woman assumed to be pregnant" (Sournia, 1997, p. 26). This role of gynecology in the medical concerns of the time was certainly linked to the relative sexual freedom in ancient Egypt, where women enjoyed considerable autonomy and played a major part in social, political, and religious life.

and surgery featured prominently) was, to some degree, effective, although it did not hesitate to rely heavily on the divining art. We have relatively full information on the subject in other papyri, most of which are copies of older ones. The corpus indicates that medical science was already very elaborately organized. Its best-known figure is unquestionably Imhotep, scribe, sage, poet, astrologer, architect (designer of the stepped pyramid of Saqqarah), and priest and vizir of Zoser (2630–2611 BC), as well as of three other pharaohs, but, most importantly, a physician whose thought long influenced the entire ancient world.

The position occupied by this practitioner at the highest level of the State is not entirely accidental. At the time, and throughout Egyptian antiquity, doctors belonged to the civil-service elite. They were members of a highly organized, hierarchic corporation comprising physicians-in-chief, chiefs of physicians, inspector-physicians, physicians-in-chief of the North and South, court physicians, court inspector-physicians, and, at the very top, physician to the Pharaoh. They were paid a fixed salary, practiced free of charge, and were assisted by a series of auxiliaries of different rank (nurses, nursing aides, etc.). This organized profession, embedded in the core of government, presumably focused its energies not on the populace but on a set of individuals whose status was reflected by the rank of the caregiver. Nevertheless, it had a very visible presence among miners and workers at the giant construction sites set up to build temples and pyramids, who risked many accidental traumas.

In sum, Egypt had (1) a rather extensive, well-codified medical science handed down from generation to generation, and (2) an organized medical profession incorporated into the machinery of State and used (at least in part) to dispense care to workers in major construction projects. These features constitute, in essence, an embryonic health policy. As in many other areas of social life, Egyptian society tightly controlled health care resources and codified their use. So much so that, recounting these facts, Jean-Charles Sournia (1997) asks: "Why is it that minds capable of writing, in 3000 BC, a sensible and useful treatise on small surgical operations were succeeded by lackluster heirs, capable only of recopying manuscripts handed down by their fathers?" (p. 31). Was the immobility of minds not imposed by the monopoly exercised in this sector, as in so many others, by an omnipotent State, nearly frozen inside structures resting on an equally static society? The author carefully avoids settling the issue, arguing that the reverse scenario is just as possible. In our view, human mental processes are such as to make the first possibility more likely.

2. Mesopotamia

Mesopotamia, too, saw the very early advent of a rather sophisticated and organized form of medicine, but one less directly subordinated to political authority. By contrast, illness was chiefly viewed as punishment for a transgression, and the main purpose of a medical examination was to discover the sin and identify the spirit responsible for the ailment. Yet, as Jean-Charles Sournia notes (1997), "moral transgressions were compounded by causes of physical impurity: putting one's feet in dirty water, [. . .] touching an unclean body, etc.," (p. 19), which could sometimes produce more realistic diagnoses. Therapies based on such foundations were naturally of uneven effectiveness, but, as in Egypt, surgery was the prime option (reducing fractures, dressing wounds, cataract treatments, urethral probe, etc.); there was also medication with plants and other substances, mineral or organic. Physicians were not functionaries, but the State paid their fees, as indicated on the famous Hammurabi Stele, which sets rates for different procedures. Many tablets also attest to the abundance of periodically updated lists and classifications. At the very least, therefore, we can conclude that there were official efforts to regulate health care activities.

3. Ancient China

"His main concern was that the populace should have enough to eat and that the rites of mourning and sacrifices should be properly observed. By the greatness of his soul, he won the support of the people; by his honesty, their trust; by his diligence, their successes; by his justice, their happiness." Thus did Confucius (551–479 BC) (1981, quoted by Hoizey and Hoizey, 1988, p. 33) pay tribute to King Wu, founder of the Zhou dynasty (12th century–221 BC). Confucius does not explicitly list health among the King's concerns in regard to his people, but he probably could have, for as in the Pharaohs' Egypt and Hammurabi's Mesopotamia, medicine was already an organized profession in Zhou China. There were *jiyi* (physicians for ailments) and *yangyi* (physicians for wounds) while the *shiyi* (food doctors) kept watch on nutrition. The *Yi King*, written in the fourth century BC, was an already very detailed medical treatise gathering knowledge partly recorded in older texts. Most important, principles of hygiene and prevention were being formulated as early as this period. It is hard to determine the precise extent to which the authorities were involved in organizing medicine and applying its principles to the well-being of the populace. But we do know, for example, that during the era of the Warring Kingdoms (fourth and third centuries BC) the growth of towns led to the construction of sewers (Hoizey and Hoizey, 1988, p. 44). Sanitation was thus already an issue in public health policy.

4. Greece

Everyone has heard of the Hippocratic Oath, still taken today by medical graduates when they begin practicing. Whether Hippocrates (460–370 BC) actually wrote the text himself is of little importance.[3] Unless it had antecedents unknown to us, it marked a new step in the implementation of a health policy, insofar as it may be regarded as the first outline of a code of medical ethics. While produced by the profession itself, the code clearly sought to control the actions of the profession in the collective interest, even if compliance relied entirely on an appeal to practitioners' moral sense.

Hippocrates was so successful that he influenced medical education in Europe until the 19th century and was almost universally recognized as the father of medicine. Yet his reputation undoubtedly rests less on his own discoveries and the 60-odd texts attributed to him than on his genius as a teacher and the popularity of his famous aphorisms, which summarize in a short, proverb-like sentence each principle suited to different pathological conditions. The aphorisms had to be learned and, most important, recited by heart, particularly in the schools of Cos and, later, Thessaly, founded by Hippocrates at a time when classroom materials consisted merely of parchment for teachers and wax for students. The method was hugely successful:

> Not only were Hippocrates's aphorisms studied until the 18th century, but many teachers wrote a host of treatises more or less closely adapted from those of Hippocrates. Until the 19th century, teachers prepared phrases that were easy to remember, like those of the old master of Cos. (Sournia, 1997, p. 39)

The founding of medical schools, distant ancestors of our modern universities, was also a vital asset for introducing health policy.

5. Rome

The Romans did not have a high opinion of the medical profession, whose practice they largely entrusted to slaves (often Greek, as the Romans held Greek medicine in high esteem). Nevertheless, the Romans left traces in the long march toward the introduction of health policies. The most important, in all probability, is not the work[4] of their best-known physician, Galen.[5] This is despite the fact that, in the second century, he dominated ancient medicine, showed great skepticism toward many treatments (by advocating the notion that nature was the supreme healer), and developed a remarkable synthesis of philosophical doctrines concerning medicine. Setting aside the Chinese example mentioned earlier, the Romans' chief contribution was to found a sector of critical importance in any public health policy: sanitation. The planning rules for all cities in the Empire included highly efficient sewage systems, public latrines, and fountains for distributing drinking water. Some cities appointed and paid doctors (known by the Greek name of *archiatri*) to care for the poor and assist them during epidemics; campaigning armies enlisted the services of physicians and surgeons. Health care establishments called *valetudinaria* (the first known hospitals) were set up for veterans and the infirm.[6] The existence and proper functioning of such buildings, structures, and services required a powerful and well-managed administration. Their disappearance in the ruins of the Roman Empire is yet another indication of their role as health-policy components.

Lastly, even if its economic concerns (annuities) were rather far removed from health care issues, we must give a mention here to Ulpian's table.[7] It was an ancestor (admittedly a very imperfect one) of today's life tables,[8] a key instrument for tracking changes in mortality and hence the effects of health policies.

Despite the Byzantines' efforts to preserve the heritage of the Ancients, in our area of interest as in many others, the West lost track of it almost entirely. The West did not rediscover its roots until the Arab conquest and the shock of the Crusades.

[3] Jean-Charles Sournia (1997, p. 40) regards this as highly unlikely.

[4] *De anatomicis administrationibus, De usu partium corporis humani, De sanitate tuenda, De temperamentis et facultatibus simplicium medicamentorum, De locis affectis.*

[5] As it happens, Claudius Galen was Greek. He was born in Pergamon in AD 131 and died in 201.

[6] However, Jean-Noël Biraben (1990) argues that the first true health care institution for the ill (*nosocomium*) in the West was founded in Rome in 380.

[7] Ulpian (170–228), jurisconsult, pretorian prefect under Alexander Severus.

[8] *"It is uncertain whether the figures in Ulpian's table are intended to represent the expectation of life or the present value of an annuity of 1. However, it is worth noting that the figure at birth, namely 30, is about the level previously cited for the duration of life in ancient Greece and Rome"* (Dublin *et al.*, 1949).

II. MIDDLE AGES AND RENAISSANCE: FROM AVICENNA TO AMBROISE PARÉ

1. The Arab-Muslim Contribution

In the seventh and eighth centuries, the Arabs conquered all the southern regions of the ex-Roman Empire, and Asian lands far beyond. It is the scholars of the Muslim world, at its apogee after the conquest, who were largely responsible for recovering the ancient medical heritage and transmitting it (with enhancements) to the Medieval and early Renaissance West. The main figure in this transmission was unquestionably Avicenna.[9] His Canon (*Quanum fit'tibb'*) is a systematic review of all the diseases known at the time. Admittedly, Jean-Charles Sournia sees it as an "obscure hodge-podge from which we can deduce nothing of use to patients" and, while expressing his esteem for Avicenna, he saves his admiration for Avicenna's far less famous predecessor Rhazes (850–923). Yet Avicenna remains the emblematic and still very widely celebrated embodiment of the role played by Arab-Muslim civilization in the development of medicine and public health. His contribution was twofold. First, it served as the scientific link between the ancient world and the medieval gestation period that heralded the Western Renaissance. Second, it enriched the concept of hospital inherited from the Roman *valetudinaria* by linking it closely to the teaching of medicine.

By the eighth century, the caliphs, followed by emirs and sultans, were opening hospitals in their cities. The Caliphate of Cordoba alone seems to have had 40 hospitals. These often-spacious establishments were divided into wards, including one for the insane, and were equipped with pharmacies and libraries, in itself, a considerable improvement on ancient models. Most important, in 932, Caliph Al-Muqradir instituted a compulsory examination as a prerequisite for practicing medicine. Students could prepare for the exam by completing an internship with a teacher to whom they paid tuition, or by attending a teaching hospital. The second option soon became very popular. Students were required to examine patients and then hand them over to more qualified assistants; the teacher would confirm the diagnosis and prescribe the treatment. Thus, for four centuries, "the Muslim world had teaching hospitals, which the Christian West did not establish until the eighteenth century" (Sournia, 1997, p. 80). However, this crucial component of all health policies did not involve the authorities except at the regulatory level. Most of the resources came from public charity. Strongly encouraged by the Koran, which prescribed almsgiving as a duty, such donations provided hospitals with generous endowments.

2. In the West: from the Founding of Universities to the Discovery of the Human Body

Founded on the ruins of the Roman Empire, the Christian West was fragmented, politically and administratively destructured, and ruralized. It would no doubt have lost all memory of ancient learning if the monasteries had not carefully preserved some traces of it in their libraries. But the elements of medical science salvaged by the monks were confiscated by the Church. Despite the brilliant and innovative experience of the Salerno School,[10] the Church clung jealously to its monopoly of knowledge, virtually refusing to make it available for treating patients and, even less so, for promoting public health.

Neither the founding of the first universities[11] nor their vigorous flowering in the 13th century nor the growing number of hospitals changed this situation to any significant extent. The universities took too long to distinguish between faith and reason, and to condescend to comparing theory and reality. As for the growing number of hospitals, often run by the Church, they never set any missions for themselves other than religious: these included charitable functions (taking in the poor) and (even more often, and for a long time) the organization of pilgrimages.[12] The hospitals provided no care and no instruction. In case of need, the only solution was to summon a doctor from outside. Paradoxically, the only specialty to record some progress in this period was surgery. From the treatment of wounds to the extraction of stones and even

[9] Abu Ali ibn Abdellah ibn Sina, known as Avicenna, was born in 980 in Bukhara (in present-day Uzbekistan) and died in 1037 in Ispahan (Iran), "exhausted by his work and the joys of the flesh" (Sournia, 1997, p. 77). In almost 200 works, he recorded his extensive knowledge of subjects as varied as astronomy, mechanics, acoustics, music, optics, philosophy, and medicine.

[10] A unique school in Christian Europe, Salerno accepted students of all faiths; its faculty consisted of lay practitioners who taught nothing but medicine, separately from philosophy. For two centuries (11th and 12th), Salerno was the only glimmer in the long deep night that shrouded scientific medical analysis at the time.

[11] Bologna and Montpellier contend for seniority, as both were likely founded in the 12th century. Valencia, Oxford, Paris, Naples, Padua, Cambridge, Toulouse, and Salamanca followed soon after, in the 13th century.

[12] The words *hospital* and *hotel* derive from their function of welcoming "hosts," whether pilgrims or not.

trepanation, the methods, instruments, and indications became more sophisticated, while the first steps were taken toward the use of anesthetic gases. Held in contempt by the medical profession and entrusted to barbers (of whom the "short-robed surgeon-barbers" and "long-robed surgeon-barbers" formed the intermediate cadre and the elite, according to their degree of training), surgery advanced thanks to the relative intellectual freedom of its practitioners and their proximity to the realities of the human body.

However, the Late Middle Ages did witness the enactment of some public measures to cope with the plague in Italy. These anticipated the more significant gains achieved in the field during the Renaissance. In 1348, the Doge of Venice appointed three civil servants *pro conservatione sanitatis* to combat the spread of the plague (Bourdelais, 2001b, p. 7). "In 1374, Genoa and Venice refused entry in their ports to ships from infected localities and, in 1377, Ragusa actually decreed one month's isolation, soon extended to 40 days. Quarantine [. . .] was born" (Bourdelais, 2001b, p. 8). A half-century later, in 1423, the quarantine system was strengthened in Venice by the establishment of the Lazaretto: one of the islands in the lagoon (the island of Santa Maria di Nazareth, whose name was distorted into *lazaretto*) was set aside to accommodate persons at risk of contamination (Biraben, 1976).

Starting in the 15th century in Italy and the 16th century throughout the rest of Western Europe, the Renaissance finally awakened the scientific spirit of a world in which it had long slumbered, stifled by dogma, tradition, and prohibitions. In medicine as in other fields, religious dogma was questioned; while respect for the Ancients persisted, their ideas were assessed, criticized, and judged. One of the most important transgressions for medical progress concerned the human body. Artists paved the way when Michelangelo dared to depict a fully naked Christ, but doctors went even further by finally daring to dissect corpses (a procedure hitherto regarded as sacrilegious) and obtaining permission to perform dissections in public for teaching purposes. Anatomical knowledge took a spectacular leap forward, its dissemination aided by the talent of the greatest masters (Michelangelo, Dürer, and Leonardo da Vinci) and the brand new invention of printing.

Paradoxically, surgeons were initially excluded from this change, as they were forbidden to dissect. Their art nevertheless continued to advance, most notably by developing techniques to address an entirely new challenge: firearm wounds. The most famous surgeon in France was Ambroise Paré (1509–1590), thanks to his abundant writings: beyond his own contributions, they encompass just about all of the surgical knowledge of his time.

However, neither physicians nor surgeons could fully exploit the fresh knowledge of human anatomy, not only because they knew virtually nothing about the functioning of the organs they were discovering, but also because their operations were hampered by restrictions due to the risk of infection.

III. THE 17TH AND 18TH CENTURIES: CONTAINMENT OF MASS EPIDEMICS AND DECLINE OF FAMINE

In contrast with this scientific development (which was as spectacular as its practical effects were limited) public-health measures were being introduced by the Late Middle Ages, as described above. They became increasingly specific during the Renaissance and, most of all, the 17th and 18th centuries. Despite their lack of clearly stated theoretical foundations, these measures proved ever more effective in stifling mass epidemics, while government action in non-health areas largely contributed to the decline of famine.

1. From the War on Plague to the Organization of Public Health

The 16th century saw a generalization of the measures introduced by some Italian towns to combat the plague in the previous century. The succession of plagues in Europe during this period led governments to enact health regulations and establish the means to apply them, namely, the creation of a health police, the establishment of special health institutions, and the development of health statistics.

With the accumulation of experience gained from specific measures implemented in various localities, full-scale plague regulations of general import were devised in Western Europe in the early 16th century; this new strategy spread to Northern Europe in the second half of the century. At the same time, the war on plague shifted from the local level to the regional or national level. In France, for example, the provincial *parlements* (judicial assemblies) began by codifying the regulations of the main towns before extending them to the entire province (Biraben, 1976). Provisions typically included isolating persons who were contaminated or who risked being contaminated (this went as far as building specialized hospitals to confine plague victims without, however, providing them with medical care); the radical cleansing of infected places (incineration of furniture and clothing, etc., and even demolishing roofs in order to "aerate" houses); more general measures for urban sanitation, such as street-sweeping; the establishment of professions specializing in handling patients and corpses, including the notorious *corbeaux* ("crows," i. e., undertakers); and strict rules for separate burial. These plague regulations are the ancestors of all the health regulations later promulgated to combat epidemics, food risks, and, most recently, pollution hazards.

Health offices with nearly dictatorial police powers were set up to enforce these regulations. By 1504, in Milan, a Special Health Council had life-and-death powers. France, in different periods, introduced health captains and health provosts with archers under their command. "The health offices, vested with dictatorial powers, did not play as exclusive a role as Jules Guiart believed (1933), but they certainly made an important contribution to eradicating the plague" (Biraben, 1976, p. 143).

The plague also contributed indirectly to the birth of health statistics. Sometimes, it prompted the authorities to conduct censuses ahead of (or in the wake of) an epidemic.[13] More importantly, it provided the opportunity to underscore the value of a continuous, systematic registration of deaths by administrative offices. At first, the registration was designed to count plague victims; it was thus confined to the latter and took place sporadically. But by the 16th century, in London, it became a systematic, recurrent enterprise that produced the "bills of mortality" from which John Graunt (1662) compiled his celebrated *Observations*, the documents that marked the birth of demography and epidemiology.

The history of the last outbreak of the plague in Western Europe, halted in Marseille in 1722, is emblematic of the success of these public health policies. Owing to a lax enforcement of the plague regulation, the port was contaminated by the arrival of a ship whose name has remained famous: the *Saint-Antoine*. But the epidemic was quelled thanks to the enactment of draconian measures, culminating in the total blockade of more than a hundred towns and villages of Provence and Languedoc, including all of Marseille. At the time, the key decisions were taken at the national level. On September 14, 1720, the Regent himself banned all travel into and out of Marseille, and even ordered the disinfection of mail.

[13] Two examples: "In late 1587, under the threat of plague, the town of Apt ordered a census of mouths to feed"; "On a larger scale, in 1720, as soon as the town was threatened by the Marseille plague, Chancellor Ranchin ordered a census before the outbreak of the disease and another in 1722, after the epidemic, for assessing the extent of its toll" (Biraben, 1976, p. 108 and p. 109).

2. Toward a More Extensive State Control of the Health of the Population

In the 18th century, the authorities became increasingly concerned about the health of their populations, albeit in rather different ways from one country to another. In the Germanic countries, the State acted directly by setting up national institutions in charge of enforcing regulations on the medical professions, handling epidemics, administering hygiene measures, and disseminating new ideas about health. This arrangement was called "medical police" by Johann Peter Frank (1745–1821) (1779), whose views about the need to apply coercive regulations to achieve a healthy population were revived by the Third Reich (Hick, 2001). However, its role was not confined to policing. A special cadre of medical functionaries was in charge of the following:

> supervising medical workers in the administrative territory under their control, examining the health of the inhabitants, [. . .] training midwives, providing free care for the poor, dispensing emergency care and reporting outbreaks of epidemics, conducting surveys and recommending hygiene remedies, [. . .] and performing topographic, climatological, and nosological analysis of the locality. (Hudemann-Simon, 2000, p. 153)

In England, this move toward health policy took a very different form, which relied on the already old foundation of the 1601 Poor Law. First, it was the towns that were vested by the royal authorities with responsibility in the area; second, rather than setting up a health policy, the main goal was to offer the poor a basic access to health care in tandem with purely economic assistance. (In particular, their employment in public works was paid for in kind or in cash.) The influence of Malthusian ideas led to a radical revision of this strategy in the 19th century (Robinson, 2002).

3. The Role of the Authorities in the Decline of Famine and Massacres

Even if this diverts us momentarily from the concept of health policy per se, we cannot discuss 18th-century Europe without at least briefly mentioning the role of organized States in the decline of famines and massacres.

At the margin of health policies themselves, governments largely contributed to the decline of famine, without necessarily working toward this goal in explicit fashion. Local, regional, and national authorities sought to contain the plague, but they also sought to reduce the uncertainties of food supply for the populace. To prevent food shortages, local and provincial authorities, followed by central governments themselves, fought the speculation that often aggravated the early stages of famine by requisitioning grain stocks and controlling their distribution in the markets (Cabourdin *et al.*, 1988).

Particularly in this period, officials contributed significantly to "abating the fear of wheat crises" (Chaline, 1998, p. 25) by enacting policies to stimulate agricultural production and food imports. Meanwhile, the improvement of roads and the gradual abolition of internal customs barriers played an important role in reducing swings in local and regional food supply.

The paradox of the age was that, even as warfare became increasingly deadly and involved ever larger armies, the formation of central States considerably reduced the number of local disputes, and especially that of their direct and indirect civilian victims. Without minimizing the scale of the horrors that marked the 19th and 20th centuries, the consequences on mortality rates remained "far milder than the utter demographic disaster caused, in their time, by the Hundred Years War for France or the Thirty Years War for the [Holy Roman] Empire, with their combination of massacres, epidemics, and famines" (Chaline, 1998, p. 28).

This digression has taken us a fairly long way from health policies, but the direct and indirect role of governments in the period was sufficiently significant for its impact on mortality and health status to be recalled here.

IV. THE 19TH CENTURY: HOSPITALS FOR THE SICK AND HYGIENE FOR ALL

The two major public-health innovations in 19th-century Europe consisted in (1) finally steering hospitals toward caring for the sick and toward the teaching of medicine, and (2) emphasizing the virtues of hygiene, both public and private.

1. From the Paupers' Hospital to the Medical Hospital

For centuries, hospitals, which were essentially ecclesiastical institutions, only provided accommodation, most notably for travelers (pilgrims), the poor, the infirm, and the sick (in particular, the insane), without ever dispensing medical care. Their charitable functions for the poor expanded over time, but so did their social-protection functions. When Louis XIV established the *Hôpital Général* (consolidating *La Salpêtrière*, the *Grand Hôpital de Bicêtre*, the *Hôpital de la Pitié*, and the *Hôpital Scipion* in Paris), he was pursuing a threefold objective:

> health-related (preventing the sick poor from spreading their diseases by begging), civic (putting back to work unemployed people who, in their idle state, had taken to begging), and religious (teaching them the principles of religion they did not know, and thus enabling them to win salvation). (Biraben, 1990, p. 26)

Until the late 18th century, the hospital's overriding function was merely to shelter the indigent and the mentally ill. Some prominent exceptions did begin to emerge, such as the French Hôtels-Dieu and, most significantly, England's voluntary hospitals (Hudemann-Simon, 2000).

It was practically not before the late 18th century that the Western hospital finally became a health care facility and that medical treatment gradually became its prime mission, with the teaching of medicine as an important related activity. The first hospital in the modern sense of the term, the *Allgemeine Krankenhaus*, was founded in Vienna by Emperor Joseph II in 1784, drawing on the English and French experience. The institution was chiefly a care facility, built and administered in conformity with medical standards: its architecture included ventilation and natural lighting; patients were grouped by diagnosis; separate rooms were provided for contagious patients, convalescents, and healthy individuals; and there was a single patient per bed. The intake was no longer restricted to paupers, and a category of fee-paying patients was instituted. The hospital also became the university's teaching center for medical training (Hudemann-Simon, 2000, p. 86–87). This model was soon copied all over Europe.

In France, the Revolution abruptly destroyed the old system just as it was starting to reform. The Convention's decree of 22 Messidor Year II (July 11, 1794) nationalized hospitals, deprived them of income from farms and real estate, and put them up for sale "to terminate the charity hospital for good" (Imbault-Huart, 1996, p. 56). In so doing, however, it halted the first attempts to introduce medicine in the hospital. At the same time, all academies and schools of medicine, surgery, and so forth were abolished. However, by 14 Frimaire Year III (December 2, 1794), a decree by the Thermidorian Convention, inspired by Antoine Fourcroy, reorganized medical education by associating it with the hospital. According to Jean-Charles Sournia (1989), this decision was the true starting point of the process that transformed "an institution dedicated to misfortune into a scientific instrument." This is somewhat of an exaggeration. In reality, the shift occurred very slowly. Not until the end of the 19th century did the hospital as health care facility prevail over the hospital as poorhouse in France, which lagged far behind England. There, the transition was an uninterrupted and far swifter process that began with the voluntary hospitals.

While paupers were obviously not excluded from hospitals, they were increasingly admitted for the sole purpose of receiving medical care. On the other hand, in the same period but in other European countries as well, under the influence of economic liberalism and Malthusian ideas, the poor lost the benefit of financial relief and even medical assistance at home that had been gradually instated in earlier centuries. In England, for example, the Poor Law Amendment Act of 1834 reduced relief and tightened the eligibility criteria, which led to a sizable reduction in the number of "physicians for the poor" (Hudemann-Simon, 2000).

2. Jenner and the First Vaccinations

The 18th century had imported into Europe the Chinese technique of "variolization," which consisted in protecting humans by inoculating them with smallpox pus. Wang Tang, prime minister of the Song emperors in circa 1000, cited the use of variolization for the dual purpose of reducing mortality and preserving women's beauty (Hannoun, 1999, p. 11). The practice, which had spread along the Silk Road to Constantinople, was brought back to England in 1715 by Lady Mary Montague, wife of the English Ambassador to Turkey. However, it met with scant success outside the United Kingdom, where William Black had even developed a plan for general inoculation. In France, Charles-Daniel de La Condamine (1754) wrote "smallpox decimated us, inoculation brands us with a vintage."

The variolization method encountered some success in Parisian circles (Hannoun, 1999), but its rationale was hotly contested on account of the risks incurred, and its use remained rather limited. Inoculation was not officially accepted until 1763, and the first inoculation clinic was not established until 1799, just when Jenner's vaccine was arriving from England. In 1796, Edward Jenner (1749–1823) discovered vaccination, which provided the same result with less risk through inoculation of vaccine (cowpox) (Jenner, 1798). The 19th century thus had at its disposal a less aggressive, more effective method that may be regarded as the true ancestor of all modern vaccines. It met with swift success in all countries. In England, 6,000 people had already been vaccinated by 1800; the following year, the number reached 100,000 (Jenner, 1801). The first vaccinations on the Continent took place in Geneva and Vienna in April 1799 (Faure, 1994). Talleyrand, the French Minister of Foreign Affairs, allowed an English doctor to introduce the stocks in France, and the first vaccination was administered in 1800. Ministers and leading politicians joined the propaganda committee founded by the Duc de la Rochefoucault-Liancourt. "Pinel,[14] Guillotin,[15] the new École de santé in Paris, and General Bonaparte were its main advocates. Entire schools and regiments volunteered to be vaccinated" (Sournia, 1997, p. 214). According to the Interior Ministry, the number of vaccinations rose from 150,000 in 1806 to over 750,000 in 1812 (Biraben, 1979). After a relative decline, the figure stabilized at 500,000 to 600,000 a year (Faure, 1994). The phenomenon was a milestone in the history of health policies, as it marked the first preventive-medicine campaign. However, because of significant accidents and the persistence of smallpox, it also sparked the public's first rejections of prevention. "This first successful preventive-medicine operation created a lasting climate of incomprehension and reciprocal distrust between doctors and the populace" (Faure, 1994, p. 134). We shall return to the actual effectiveness of this first experiment in vaccination, which became the focus of the scientific debate on the role of medical progress as the driver of the decline in mortality (see Chap. 108).

In any event, vaccination became compulsory in most European countries, starting with Greece in 1825, joined by Germany in 1874, England in 1883, Italy in 1888, and Austria-Hungary in 1891. Only France awaited the 20th century, passing legislation in 1902 to introduce mandatory vaccination (Rollet-Échalier, 1990).

3. The Age of Hygienists

In the late 17th and early 18th centuries, well-known doctors from several European countries had recommended specific actions informed by the Hippocratic tradition, which held environmental conditions responsible for endemic and epidemic diseases. The measures included draining marshes and peat bogs, ensuring the circulation of water, cleaning houses, and changing the air in dwellings and places of assembly (Bourdelais, 2001). In the 19th century, with the rapid industrialization and urbanization of European countries, but also with the outbreak of cholera in 1832, these ideas were vigorously revived and began to influence government policy. As contagion mechanisms had not yet been identified, hygienists blamed epidemics on "poisons" in the

[14] Philippe Pinel (1745–1826) was appointed chief physician at Bicêtre Hospital by the Convention in 1793.

[15] Joseph-Ignace Guillotin (1738–1814), professor of anatomy and philanthropy, was inspired to invent the guillotine for humane motives.

environment, and recommended the reduction of "miasmas" (contaminated atmospheres) in water, air, dwellings, and elsewhere. By acting on these living conditions, governments could therefore take steps to improve the survival and health of the populace, especially the poor. These goals motivated men such as the French physician Louis-René Villermé (1782–1863) (1840), cofounder of the *Annales d'hygiène publique et de médecine légale*, and the British lawyer Edwin Chadwick (1800–1890) (1842), a very influential adviser to the British government.

These ideas led to the widespread construction of sewage and potable-water networks. In Paris, the first covered sewers date from the 14th century, but the construction of a full-scale, citywide underground system began in 1850. In London, cesspits gave way to continuous wastewater drainage thanks to the construction of the first sewers in 1844.

In England, Edwin Chadwick secured passage of the Public Health Act in Parliament in 1848. The legislation established the Central Board for Health; it required boroughs (and not just the main cities) to provide drainage, potable-water supply, waste collection, street paving, and other services, and it required the opening of health boards in all localities with a mortality rate exceeding 23 per 1,000.

In every country concerned, however, this policy met with stiff resistance, particularly with regard to raising the necessary funds, and when it ran counter to the interests of businesses and wealthy private individuals (Szreter, 1993). But the movement triggered by hygienists without rock-solid scientific arguments found its fulfillment in the Pasteurian revolution.

V. 1880–1945: FROM PASTEUR TO THE WELFARE STATE

Apart from the initial attempt at vaccination, health policies until the end of the 19th century could rely on little more than relatively questionable scientific foundations and medical techniques. The cholera outbreak even rekindled fears of the great epidemics of the past, and underscored the lack of knowledge of the causes of diseases. It was only in the 1880s, with the discoveries of Louis Pasteur, that the resources of modern medicine were truly established, paving the way for increasingly effective policymaking. These new weapons for combating disease and death also fortified the notion that the authorities should bear some responsibility for equalizing the odds of survival by making the benefits of the new technologies available to the largest number of people.

1. Louis Pasteur: Victory over Infection and the Advent of Prevention

The first studies that triggered this revolution were unquestionably those of the physicist Louis Pasteur (1822–1895). He began by examining beer yeast in the 1860s; then he investigated a silkworm disease whose cause he identified as a microscopic organism. In 1878, the year after his discovery, Pasteur published his *Théorie des germes* ([Theory of Germs] Pasteur, 1878); that same year, Charles-Emmanuel Sédillot coined the term *microbes* to denote them (1804–1883). In quick succession, Pasteur developed anthrax vaccine (Pasteur *et al.*, 1881) and rabies vaccine (Pasteur, 1885). Contemporaneously, Robert Koch (1843–1910) discovered the tuberculosis bacillus in 1882 (Koch, 1882) and the cholera vibrio in 1884 (Koch, 1886). And this was only the start of a long series of discoveries that, in the 19th and 20th centuries, led to the production of vaccines against many infectious diseases (Table 106–1).

These discoveries immediately won the support of hygienists, who largely helped to popularize both the new underlying ideas and their value for improving public health. The hygienists argued their case before

TABLE 106–1 Chronology of Diseases for Which a Vaccine Was Developed

Eighteenth century		**Twentieth century**	
Smallpox inoculation[a]	1715	Pneumococcus	1911
Vaccine	1796	BCG (tuberculosis)	1921
		Diphtheria	1923
		Whooping cough	1926
		Tetanus	1927
Nineteenth century		Yellow fever	1932
		Typhus	1941
Rabies	1885	Influenza	1944

the medical and political communities. Health policies could now resolutely engage in two programs previously foreshadowed by hygienists and henceforth scientifically recognized: prevention through vaccination and asepsis procedures. The first considerably reduced the incidence of infectious diseases; the second enabled surgery to reach full efficiency at last. Germ theory eventually led to the discovery, in the mid-20th century, of sulfonamides followed by antibiotics, further strengthening the arsenal of medicine and health policies against infectious diseases.

Vaccination soon became a major issue in public health policies, which typically sought to combine information or incentive campaigns with mandatory measures. The concept of compulsory vaccination had already been invented, as noted earlier, in connection with Jenner's vaccine. France was one of the very last European countries to adopt the method, by passing the 1902 Act. The concept was revived to protect the population from a number of infectious diseases as the vaccines against them were successively developed. However, in a country like France, public reluctance was fairly strong. In France, for example, the distribution of vaccines was encouraged, but the only new vaccine made compulsory before World War II (against diphtheria) did not become so until 1938 (Rollet-Échalier, 1990, p. 206); in Britain, the only official action to disseminate it was an incentive campaign (Parish, 1965).

Even before the advent of antibiotics, Pasteur's discoveries also confirmed the presuppositions of the Hungarian obstetrician Ignaz Semmelweis (1818–1865) (1847) and the English surgeon Joseph Lister (1827–1912) (1867) on the means of protecting their procedures from the danger of infection by applying a maximum of antiseptic measures. Pasteurian sterilization enabled asepsis to replace antisepsis. The ensuing renewal of surgery was all the more consequential because of the discovery, in the mid-19th century, of safer, more effective methods of anesthesia. Freed from the risks of infectious complication and the impossibility of sparing the patient from excessive pain, surgery took an unprecedented leap forward between the wars.

The absolute weapon against infectious diseases seemed to have been discovered at last with the introduction of sulfonamides in the 1930s and, even more decisively, antibiotics during World War II. In 1932, Gerhard Domagk found a substance capable of selectively killing pathogen bacteria; this led to the market release of the first sulfonamides in 1935. But, as early as 1928, Alexander Fleming (1881–1955) (1929) had discovered penicillin, whose production did not actually begin until 1942.

2. From the First Provident Funds to Social Security

In traditional societies, some institutions (most notably the Church in the West, more seldom the civil authorities) consistently devoted special attention to the poor. But their health was never the main issue. It scarcely elicited the interest of governments except insofar as they sought to exercise a health-police function aimed more at protecting society than at treating the poor. In the late 19th century, the conjunction of rising socialist ideas and the new medical weapons born of Pasteur's discoveries fostered the emergence of a new health strategy. Its ultimate stage was the coverage of health care costs by the community. Previously, apart from some aspects involving public health, individuals were alone responsible for their health care. They had to bear the cost themselves, and were almost entirely dependent on family solidarity in case of illness or accident.

With the expansion of the salariat and the rise of a collective consciousness of the working masses fueled by the dissemination of Marxist ideas, new forms of solidarity developed. Individually, manual and clerical workers lacked the income, and, even more, the capital, to cope with health contingencies or the usually disastrous consequences of a disabling accident that deprived them of work. But the risks could be substantially cushioned if their burden was managed collectively. These circumstances led to the early forms of social insurance on the margins of (or incorporated into) the nascent labor organizations in the 19th century. By the mid-19th century, many mutual assistance societies were already active. France, for example, had nearly 4,000 in 1860, covering more than 500,000 members (Comiti, 1997). Meanwhile, the action of labor unions had led employers, spontaneously or under State coercion (including court rulings and new laws), to recognize their liability for occupational accidents and diseases. To protect themselves against the risks arising from this liability, employers, in turn, set up special insurance funds.

The State intervened fairly quickly to regulate, sometimes to slow down, and more often to hasten the march toward the collective coverage of illness and accident risks. But the Welfare State was not attained until the second half of the 20th century. To measure the road traveled, we can, for example, read the works of Louis-Adolphe Thiers (1850), speaking on behalf of the *Commission de l'assistance et de la prévoyance publique* (Commission on Assistance and Public Provident Insurance):

> A healthy, hard-working man, endowed with ordinary intelligence, who does not indulge in every vice, can, through his

> labor, in our civilized societies, meet his various obligations, barring fortunately accidental circumstances such as illness, an unemployment spell, a hailstorm, or a flood. Society's effort to assist the healthy man in these accidental occurrences is a noble concern that it should pursue in its providential function, and that its virtue demands; the degree of success will be equal to the esteem that [society] deserves. But, apart from these exceptional occurrences, the society that would seek, to whatever extent, to take charge of the fate of a group of its members would turn them into idlers, rabble-rousers, and trouble-makers, at the expense of all hard-working and peaceful citizens. (Thiers, 1850, p. 31–32.)

Thus the important point, for Louis-Adolphe Thiers, was that the State should control the mutual assistance societies to which it provided support, so as to avoid such slippages.

The true foundations for modern social-protection systems were laid in Germany in the 1880s, under the influence of Chancellor Otto von Bismarck. An initial law introduced the first compulsory sickness-insurance system in 1883. This was followed in 1884 by an occupational-accident protection system, and, in 1889, by a law on old-age and disability insurance. However, unemployment insurance was not established until 1927 under the Weimar Republic, just two years before the Great Depression.

France took much longer to move from mutual assistance societies to a more general system at the national level. Admittedly, ever since Colbert, who had established a sailors' insurance fund under Louis XIV, the State had intervened directly to set up specific funds for civil servants, military personnel, miners in 1894; rail workers in 1909–1910; and female factory workers and female farm workers in 1910. But *assurances sociales* (social insurance) was not introduced until 1928–1930, followed by legislation on family benefits in 1932. Even so, it should be stressed that, in 1936, the medical insurance established a few years earlier covered just over one-third of the population, and the reimbursement rates were very low. The factory workers and farm workers collecting pensions under the new system represented a mere 20% of the population aged over 60 (Comiti, 1997). It was only in 1945 that the government began to extend the system with a view to introducing a universal right to health care.

Sweden was far ahead on this issue, since, as early as the 1910s, it laid the foundations of a social-protection system for the entire population (Olsson Hort, 2001). By contrast, during the same period, the United States continued to apply a very free-market approach to health policy.

In many sectors, World War II led European societies toward reform and even reconstruction. One such sector was health. The 19th century had separated health policy from social policy, transformed the hospital for paupers into a hospital for care. The second half of the 20th century blended these two concerns into a single quest for the reduction of social inequalities and, in particular, the unfairest of all: inequality in the face of illness and death. Europe adopted the broader framework of the Welfare State, responsible for providing all citizens with access to decent living conditions, from cradle to grave, in all areas: education, housing, work, leisure, retirement, and so on. Health care accordingly became an entitlement, and the State now had to ensure its availability to all.

In the health sector, two new systems were born from the ruins of war. The first was not a genuine innovation in conceptual terms, as it was directly inspired by the Bismarckian model. In fact, it was a generalized version of the latter. It rested on the establishment by the State of compulsory sickness-insurance funds ("regimes"), managed by the "social partners" (employers' organizations and labor unions) and financed by social contributions, which are assessed mainly on earned income. The regimes sign agreements with health care provider partners in the public and private sectors, such as hospitals, doctors in private practice, and pharmaceutical firms. In consultation with the State, they define compensation rules and the medical fees charged to patients, as well as procedures for their total or partial reimbursement. The State sets the rules and ensures the system's overall balance, but does not intervene in its management unless exceptional circumstances require it. Citizens are granted a right to health in the form of a health care entitlement, but patients are free to choose their providers. This is the system adopted in Austria, Belgium, France, Germany, and the Netherlands, among others (Letourmy, 2000).

The other system is modeled on the Beveridge Plan,[16] implemented in the United Kingdom in 1946–1948 (Harris, 2001). It rests on the primacy of a public health care sector, largely funded through taxes (the private sector is not, however, eliminated: it remains open to patients who can afford it). Citizens have access to it free (or nearly free) of charge, but the choice of entry point is restricted. The government directly controls its financing, supplied in the form of fiscal allocations to institutions and fees to physicians, which are proportional to the number of persons enrolled on their lists. The authorities also control medical care, provided in public-sector facilities. This British model has been reproduced in Ireland, the Nordic countries, Italy, Spain, Portugal, Greece, and

[16] Named after Sir William Beveridge (1879–1963), author of the eponymous report filed in 1942 and published in 1943.

elsewhere. In fact, it is not too different from the totally State-controlled system set up in the Soviet Union before the war and by all the Communist regimes of Central and Eastern Europe from 1945 onward.

By contrast, the United States still does not have a universal protection system, although efforts to help some population categories have been made in recent years (most notably, the introduction of Medicare[17]). Private insurance or, at best, insurance agreements between employers and employees are the only way to pool health care risks in the United States.

In contrast, the notion of a universal right to health (or at least of the need to reduce the huge disparities at the global level) largely informed the creation of the World Health Organization (WHO) and shaped its program goals. This process occurred even as the colonial powers themselves were beginning to show concern about the health of indigenous populations (the plundering of resources was partly giving way to the development of local production, which required a healthy workforce). The spectacular medical progress since the late 19th century had raised the hope that industrial countries would be able to make their citizens equal in the face of death. Likewise, it seemed realistic to espouse the goal of offering the disinherited inhabitants of the Third World the benefits of the cheapest new technologies. This would enable them, if not to attain the highest life expectancies, at least to substantially narrow the gap with the richest countries, without waiting for the Third World to reach the same level of economic development.

For 30 years—the period from 1945 to the first oil shocks of the early 1970s, known in France as "Les Trente Glorieuses" (Fourastié, 1979)—the ideals of social security and third-worldism have forged ahead, largely inspiring national and international health policies, as long as the extended economic prosperity after World War II lasted. With the global economic crisis of the 1970s, the comeback of economic liberalism, the fall of the Soviet Empire, and the imbalance of age distributions generated by the decline in European fertility well below the replacement rate, those major advances have reached their limit. The Welfare State is pilloried in the northern countries, while drastic structural adjustments are forced on the southern countries. In the northern countries, health care systems are, if not openly questioned, at least subject to ever tighter budgetary constraints. In France, for example, a supply-control policy (involving the rationalization of budgetary choices, health care planning, and the definition of a "health care map") has given way to an even harsher policy of spending control (cutbacks in benefits) to avoid an excessive rise in contributions, which are increasingly contested. In some southern countries, particularly in sub-Saharan Africa, tottering health services have been dealt a fatal blow with the eruption of HIV/AIDS.

These developments make an overall reappraisal of health policies more necessary than ever.

[17] Medicare was established by an act on July 30, 1965, under Lyndon Johnson's administration (Corning, 1969). The system offers free hospital care to retired workers over 65 who have worked for more than 40 quarters, and to their spouses (Card*et al.,* 2004).

CHAPTER

107

Health Policies:

What Strategies? For Whose Benefit?

JACQUES VALLIN AND FRANCE MESLÉ

Institut national d'études démographiques (INED), Paris, France

Infirm of constitution, prey to constant pain, he shunned external help from medicine to follow instead the regime he had thought out for himself; he liked to say that his health, his longevity, was his work.

Victor Delbos (1971) on Immanuel Kant (1724–1804)

Health gains throughout history have been dictated by advances in two conjoined directions: the development of increasingly efficient new technologies, and their spreading use. The former requires investment that is scientific (in medical, pharmaceutical, and technological research) and industrial (to produce medical equipment of all kinds). The latter is more exacting still, requiring not just investment in training (of health professionals and the public) and infrastructure (care and preventive health facilities, health administration), but ensuring that all citizens have access to health provision and benefit from appropriate preventive measures. History has also shown that market forces clearly cannot deliver both with optimum outcomes. There are at least minimum aspects of health policy that are basic functions of the State—public health protection/enforcement, compliance with codes of practice, organization of prevention, and so on—and this minimum level of collectivist care is almost certainly nowhere near enough. Much could be said on the issue of whether the State is best placed to deliver an objective like the "health for all" objective called for by the World Health Organization (WHO), assuming that objective is not wholly unrealistic per se. In any event, the State is not the only relevant actor. Arguably, it may be more helpful at this point simply to review the different objectives and strategies of current health policies, and the actors and policy instruments involved.

I. OBJECTIVES AND STRATEGIES

A recurrent theme of the preceding chapter's historical review is that public health policy objectives may be very wide-ranging. A treatise on demography could start by distinguishing objectives with demographic impacts (mainly via mortality, and incidentally reproductive health as the determinant of fecundity and fertility) from those that are only remotely (e.g., for diseases or disabilities with no survival effect) or wholly (e.g., purely economic cost control or containment) unconnected with population dynamics, unless they negatively impact survival gains by restricting health resources. On that basis, this chapter would address only the former, treating the others as off-topic. Arguably, the dividing lines between these categories are too vague to be strictly demarcated, although the main focus will obviously be on the former.

The objectives of a health policy (or program, or measure) could also feasibly be distinguished by sphere of action (public health protection/enforcement, medical prevention, care provision, etc.) to consider the scale and type of aims (protecting the general population against certain risks, closing glaring health gaps, or meeting all individual health needs collectively by across-the-board health resources funding). Not only are these two criteria too inextricably linked to completely unravel the individual strands, whether starting from sphere of action or degree of involvement, but also any attempt to give even a halfway logical presentation of them means moving seamlessly between the two. At the risk of setting what may at times be somewhat arbitrary or vague limits, therefore, this chapter will endeavor to move linearly from issues around the general protection of a population from collective external risks to those around the curing of acute diseases or transient injuries, then improvements in the quality of years gained, to conclude with the reduction of certain glaring inequalities, and finally the collective payment of the total cost of health for all.

1. Public Health Protection/Enforcement

Granted that 20th-century society no longer needs protecting from many of the health risks present in earlier centuries, there remains an array of specific and general measures to protect the population against various health risks, some of which place mandatory requirements on individuals.

a. Protection from Criminal Assaults

One aim of enforcement action has a connection with the topic of this chapter, in that one of its functions is to protect citizens from criminal assault, and the demographic issues of such protection are less marginal than might be thought. Not only is the significant decline in exposure to this type of risk since the establishment of organized States a matter of record (Chesnais, 1976, 1981, 1985), but also the violence to which some populations are still exposed (e.g., those populations in countries where the State is either weak or disregards human rights) argues strongly for the importance of this objective. For example, Colombia's nonaccidental violent death rate in 1988 was 16 times that of Costa Rica (Ruiz and Rincón, 1996), while in 2000, its homicide mortality was still 10 times higher than that of the United States (Chesnais, 2003). The most exposed countries are also often those where reliable statistics are most lacking. Policies may differ widely even between long established democracies. The rules on carrying weapons are a case in point, and in this respect, human life is surely far better protected in most western European countries than in the United States.[1]

b. Supervision of Prostitution

Vice squads also partially pursue health objectives when, for example, conducting checks on the health of sex workers to protect that of the clients. This was a major concern in Europe before treatment was available for syphilis and other venereal diseases. In particular, this concern was behind the early debates on brothels and the various ways they were regulated in different countries at different times (Nor, 2001). It is very much on the agenda today in countries affected by HIV/AIDS. In Thailand, for example, the government has made condom use compulsory in brothels under threat of closure (P. Caldwell, 1995). In sub-Saharan Africa, wherever HIV/AIDS has wrought most havoc (which is also where the dividing lines of what constitutes prostitution are sometimes very unclear and varied in practice), such enforcement activities are far more difficult to carry out.

c. Epidemiological Surveillance at the Borders . . .

One key branch of modern public health protection/enforcement is also the product of tackling major epidemics down the ages. Health surveillance at national borders, which is its direct descendant, although now increasingly low-key, is still very real. Travelers must prove that they have been vaccinated against diseases that vary with their country of origin. The WHO keeps an updated database on countries of the world by reference to the presence and scale of contagious endemic diseases.[2] This database effectively operates as a sort of international public health protection/enforcement measure, since for three diseases at least (cholera, plague, and yellow fever), each country must report every case diagnosed to the

[1] Homicide mortality is much higher in the United States than in western European countries (Fingerhut and Kleinman, 1990; Chesnais, 2003), and most homicides in the United States are gun-crime killings; there is a strong probability that this high firearms-related component is directly related to their very widespread prevalence in the population (Shahpar and Li, 1999).

[2] This systematic international tracking system, carried out by the Communicable Disease Supervision and Response Unit, currently covers 15 diseases (anthrax; avian influenza; Crimean Congo, Dengue, and Ebola hemorrhagic fevers; hepatitis, influenza; Lassa fever; meningococcal disease; plague; Rift Valley fever; SARS [severe acute respiratory syndrome]; smallpox; tularemia; and yellow fever). The WHO maintains a website with continually updated information (http://www.who.int/csr/disease/en), as well as world maps showing the current status of each disease (http://www.who.int/globalatlas).

WHO.[3] It is this information, possibly supplemented from other sources, that individual countries use to decide for which diseases a certificate of vaccination is required to enter their territory. An unvaccinated traveler may be forced to submit to immediate vaccination or other appropriate preventive measures (e.g., taking medicine). But these routine measures may be tightened up at any time to address a particular threat, as was recently seen with the emergence of SARS (WHO, 2003).

d. . . . and Inland

But epidemiological surveillance does not stop at the border; it also accounts for much of the administrative activity of public health agencies. In France, for example, while it may have been largely supplanted by other tasks, the main function devolved on county health and social action authorities (DDASS) and the special staff of medical health officers that run them was to monitor for emerging epidemic risks and take all necessary steps to stop them from spreading. The general use of vaccination and effective antibiotics have considerably reduced the priority given to this function, but the lineup of legal and administrative measures remains in place, ready to be reactivated if need be. Here too, public enforcement activity relied heavily and still relies on the information collected through compulsory notification systems: not just the obvious cause-of-death notification (in France, cause-of-death certificates are sent first to the DDASS medical officers), but also diagnosed cases of certain infectious diseases. In France, for example, 22 infectious diseases (plus, recently, childhood lead poisoning) are still subject to compulsory notification (Table 107–1) (Antoniotti *et al.*, 2002). In 1998, the *Institut de veille sanitaire* (approximately equal to the United Kingdom's Health Protection Agency) was set up to alert the authorities to emerging threats to public health (Bonnici, 2003).

TABLE 107–1 List of Compulsorily Notifiable Diseases in France

Infectious diseases	
Botulism	Meningococcal cerebrospinal meningitis and meningococcaemia
Brucellosis	Locally contracted malaria
Cholera	Imported malaria in the overseas departments
Diphtheria	Plague
African hemorrhagic fever	Poliomyelitis
Typhoid and paratyphoid fever	Rabies
Yellow fever	Suspected Creutzfeldt-Jakob disease and other human transmissible subacute spongiform encephalopathies
Acute hepatitis B infection	Tetanus
HIV infection at any stage	Mass food poisoning
Legionella infections	Tuberculosis
Listeria infections	Exanthematic typhus
Other diseases	
Childhood lead poisoning	

Source: Decree No. 99–363 of 6 May 1999 prescribing the list of diseases for which individual data must be notified to the health authority and amending the Public Health Code (Official Gazette of 13 May 1999) and Decree No. 2001-910 of 5 October 2001, amending the list (Official Gazette of 6 October 2001).

e. Tackling Legal and Illegal Drug Abuse

Drugs are another area of public health protection/enforcement. Narcotics use was seen as a public health issue from quite an early date, and attempts were made to prevent people accessing them by making the manufacture, sale, and even consumption of them illegal. Dealing in narcotics was made illegal in 1916 in both Britain (Defence of the Realm Act, Regulation 40b) and France (Act of 12 July 1916 "on the import, sale, possession and use of noxious substances, in particular opium, morphine and cocaine"), and very strict controls were put in place on their issue on medical grounds (Bachmann and Coppel, 1989). Penalizing users was clearly the softest option, as they are the weakest link in the chain and hence were most accessible to enforcement action. But it also very quickly proved to be the least effective starting point, and trying to stamp out drugs through a crackdown on users alone was an endless task. Most antidrug policies therefore now focus on producers and traffickers: going back up the chain, punishing the middlemen and top men if possible, and destroying production sites. The problem soon transcends the national borders of the country concerned. Some countries, like the United States, feel sufficiently powerful to try and mount enforcement and production site destruction operations alone (or to force the States concerned to do so), while others can only rely on international police cooperation or enabling action by international organizations like the WHO.

One major strategic issue here is whether all substances currently classed as drugs should be banned,

[3] New International Health Regulations (IHR) adopted by the World Health Assembly in 1969, replacing the 1951 regulations, were revised in 1973 and 1981 (WHO, 1983). They are now being reworked to take account of the new international trade situation (OMS, 1999a).

or only the most dangerous ones. There is a growing call for liberalization of so-called soft drugs like cannabis or marijuana and their derivatives like hashish, khat, and so forth (Nadelmann, 1994) on the grounds that they are not lethal, not ruinous to health, and only very rarely lead to physical dependence (Roques, 1999). The argument that they are still dangerous in that they gradually lead users to hard drugs does not seem to be borne out in practice (Jauffret-Roustide and Simmat-Durand, 2004). Some countries have in fact at least partly relaxed their prohibitions (Désesquelles, 1997).[4] By contrast, they remain strictly prohibited wherever the idea prevails that they are harmful, with some authors hypothesizing a "hard use of soft drugs and soft use of hard drugs" (Jauffret-Roustide and Simmat-Durand, 2004; Roques, 1999). Some, although admittedly fewer, voices advocate legalization as the best way to kill off drug trafficking by ruining producers and dealers through the price collapse that would ensue (Nadelmann, 1994). No country to date, however, has ventured to test this theory out.

Contrast this with the case of tobacco. There is a credible argument that, but for its early introduction in Europe, and especially its mass distribution to soldiers in the trenches during the Great War (Ravenholt, 1990),[5] and not least in many cases its state-controlled production and marketing (as in France, with the creation of SEITA),[6] tobacco would have inevitably been banned in the same way as any other drug, and as likely classed as a hard rather than a soft drug (Meslé, 1990). Neither total freedom of movement of tobacco, and probably still less state control of its production and distribution, has stopped smoking becoming a leading cause of death in many countries through the phenomenal increase in cancer of the respiratory system throughout the 20th century, let alone the rise in ischemic heart diseases. Health policies, however, have had to come at it from different angles. It is nevertheless possible to bring within the purview of public health protection/enforcement, such steps as the WHO's political condemnation of the practices of major producers who "use their sophisticated and usually secret research to ensure that just the right dose of nicotine gets delivered to smokers for addiction to occur and be maintained [. . . and who] targeted children whom they need to fill consumer charts as smokers die" (Yach, 2000, p. 3). At the other end of the chain, passing recognition may also be given to those lawyers who claim (and sometimes win) large sums in financial compensation for their sick clients or their families.

Alcohol is a different issue from tobacco, in that the health damage it causes appears only after a certain level of consumption, while below that level, it may even have certain beneficial effects (INSERM, 2001, p. 21). But alcohol has been the target of public health protection/enforcement actions that are often as spectacular as they are ineffective. The Prohibition Era in the United States, the reknowed inspiration for so many police films, springs to mind.[7] More recently, Gorbachev's celebrated anti-alcohol abuse campaign, which ran from 1985 to 1988 and stimulated the then slowly declining Soviet life expectancy, was short-lived, soon giving way to a mortality surge (Meslé *et al.*, 1994; Shkolnikov and Nemtsov, 1997). In France, likewise (Berger *et al.*, 2000), public health protection/enforcement measures were taken against alcohol production, in particular phasing out grower-distiller rights (the French government abolished inheritance of grower-distillers' right on August 30, 1960), and against the consumption of farm-distilled alcohol by such measures as licensing of drinking establishments (Sournia, 1986; Fillaut, 1999). More of the decline in alcohol abuse has been due to economic policies (fixed selling prices and levies) and health education policies rather than to public health protection/enforcement proper, however.

f. Food Safety

After drugs, tobacco, and alcohol naturally comes food. Over time, the food sector has been brought under increasingly detailed, far-reaching and strict regulation, at least in the developed countries, where consumption of homegrown food has become marginal, and even meal preparation is increasingly done outside the home. That it is by no means a side issue is easily exemplified by recalling the acute infant mortality crisis that occurred in France in 1945 as a result of the disruption in the milk distribution chain caused

[4] Even the most liberal countries maintain some restrictions (see Désesquelles, 1997, for a comparative table of legislation in 11 European countries; see also Frydman and Martineau, 1998, for their table comparing legislation in 15 European countries).

[5] Generally speaking, wars have been key factors in tobacco adoption: the American Civil War, Wellington's campaign against Napoleon in Spain, and the Crimean War for the British, but, for Western countries as a whole, the Great War was the most decisive step. Annual average per capita cigarette consumption doubled during World War I, for example (Ravenholt, 1990).

[6] SEITA was actually a cigarette and match production department of central government before becoming a national corporation in 1984, and then merging with the Spanish *Tabacalera* to constitute the European limited company Altadis in 1999.

[7] Prohibition was introduced in 1919 by the 18th Amendment to the Constitution and required a new amendment, the 21st, to bring it to an end in 1933.

by the Liberation (Henry, 1948; Norvez, 1990). Not only are farming and imports closely supervised in developed countries today, but basic foodstuffs are increasingly industrially processed through an entire agri-foodstuffs production process, the health aspects of which are increasingly microregulated, supervised, and controlled, to prevent the risks of biological contamination or to ensure that the increasingly varied range of inputs used in the finished product are safe to eat. Likewise, strict checks are operated on the marketing network (storage, transport, covered and open markets, supermarkets and small shops) and catering (from urban restaurants to school and company canteens). Food safety concerns now approach paranoia levels. France's listeriosis scare in the early 2000s is just one example of the media hype over a handful of deaths (fewer than in previous years) into a scandalous death toll.[8] The mad cow crisis was worse, but the scale of the measures taken on the basis of often misinterpreted if not questionable scientific evidence (Vallin and Meslé, 2001) and ultimately on the basis of the now-sacrosanct precautionary principle, speaks volumes for the demands on safety (and public health protection/enforcement) which our societies now make.

Public health protection/enforcement is also the starting point for another aspect of food safety: dietetics. Policies in this area naturally focus on health information and education campaigns (see below), but notwithstanding the steadfast opposition of powerful lobbies, some countries are also starting to take regulatory control measures. In the United States, for example, the federal Food Drug and Administration made labeling of processed fats in food ingredients compulsory in 2004, while in 2003 alone, 179 state government bills or resolutions were passed to cut consumption of fatty foods (Cérisola and Mistral, 2004). The French government's public health bill tabled in 2004 included proposals to prohibit placing soft drinks dispensers in schools, but the soft drinks industry lobby is still trying to prevent the bill's implementation.[9]

g. Road and Other Transport Safety

As for serious offenses and murder, protecting the public against road and other transport risks is the job of law enforcement in the ordinary sense. The growth in road traffic, especially in the aftermath of World War II, turned road safety into a major public health issue, firstly in the developed countries (Vallin and Chesnais, 1975; Chesnais and Vallin, 1977), but also nowadays in many developing countries (OMS and Banque mondiale, 2004). Granted, regulations and the police are not the only means of tackling this scourge—improved roads, tracks and vehicles, information and education campaigns, organized emergency services for traffic accidents also play their role—but law enforcement action in the ordinary and broader sense, including public health protection/enforcement, are in the first line. The minimum measure is to draw up a highway code, mark out public highways with signs to give it organized, practical application, and to have a compulsory driving license scheme whereby drivers can be required to display an ability to control their vehicle and a minimum knowledge of the rules that they must obey. The basic requirements have slowly been put in place in the different countries (the driving license was established in France in 1893, for example, at least for the Paris region,[10] but became compulsory in Belgium only in 1965). But above all, these provisions have advanced considerably with progress not only in road and vehicle technology, but also that of the means of control (police mobility, radar speed traps, etc.), and a heightened awareness of the danger. The British Road Traffic Act 1930 is probably the first detailed general regulation put in place here (Chesnais, 1985). Road safety measures made a big advance in many countries in the 1970s, partly as a result of the 1973 oil crisis:[11] lowering of speed limits, wearing of seat belts, increased visibility of vehicles (daytime use of headlights for motorcyclists), blood alcohol testing, etc. It also saw a rise in motrobike accidents, against which Japan, for instance, swiftly introduced draconian but effective measures.[12] Claude Levy (1980) reports that Japan banned the use motorcycles with engines over 700 cc (but not their construction for export), and introduced a new driving test for motorbikes from 400 to 700 cc engines that was so difficult that in the first year (1976) that only 4% of those who took it passed.

[8] The so-called soaring toll of 2000 resulted in 9 deaths and one abortion, compared to the average 20 to 40 deaths a year in the 1980s and 1990s (http://www-causfra.ined.fr)

[9] *Le Monde*, 16 February 2005.

[10] The ordinance of August 14, 1893, regulating the movement of "mechanized motor vehicles other than those used to operate licensed railways" stipulated that "driving shall not be permitted [. . .] except by those holding a certificate of aptitude issued by the chief police officer."

[11] Sharp oil price rises in many countries made drivers more aware of the economic as well as the health downsides of speeding (Vallin and Meslé, 2001).

[12] Claude Levy (1980) reports that Japan banned the use motorcycles with engines over 700 cc (but not their construction for export), and introduced a new driving test for motorbikes from 400 to 700 cc engines which was so difficult that in the first year (1976) only 4% of those who took it passed.

It is not only to users that safety measures apply. Vehicle manufacturers, too, are subject to a growing number of increasingly stringent standards, be it on driver vision and vehicle signaling, in-car protection of passengers (seat belts, anchor points for child seats, etc.), shock absorption, or speed (cruise control), not to mention antipollution standards whose objectives clearly go beyond road safety alone.

On a more general note, transport policy clearly has an impact on road mortality. Putting road before railway development (or vice versa), or even (which more or less amounts to the same thing) public before private transport, increases or curbs road traffic and, ceteris paribus, the accident rate. But regulation of the type of vehicles or goods carried offers a range of intermediate measures (no through road for flammable materials, piggyback rail-road transport compulsory under certain tunnels, etc.).

The Scandinavian countries and the United Kingdom took the earliest steps to restrict and check this modern scourge (Chesnais, 1981, 1985). France makes periodic attempts to make up for its late start. Recent new efforts have been made to step up road safety. Paradoxically, it is in the world's least developed countries, where there are fewest vehicles on the roads, that the road death tolls are highest for want of sufficient resources to put in place high quality road safety (WHO and World Bank, 2004).

The first attempts to harmonize traffic safety rules at the international level date back many years. The United Nations and WHO were behind the adoption of two international conventions in 1949 (on road traffic, and on signs, signals, and markings). The Vienna Conventions currently in force date from 1968 (Nations unies/United Nations, 1968a, 1968b). A World Road Safety Day was held in 2004 (WHO and World Bank, 2004).

Other means of transport are also restrained within the confines of regulatory safety measures: the railways, aviation, and waterborne transport (marine or waterway, commercial shipping, or pleasure boating) are very tightly regulated. Enforcement of these regulations is greatly facilitated by the fact that most relate to public transport. For one thing, there is much more public clamor for high safety and surveillance standards (as far as zero-risk level), while for another, there are many fewer transport units to be controlled, and responsibility for their use is much more centralized.

h. Civil Emergency Preparedness: Fire, Floods, Natural Disasters, Terrorism

Another basic function of the modern State is to protect the populace against fire, floods, natural disasters, and the like. This is obviously an age-old concern, at least at the local government level, but the public has been increasingly demanding in this area. So-called civil defense services against fire are long established; for example, in France, the organized fire service was first established during the Revolution (Dalmaz, 1998). In most cases fire-fighting services are part of the armed forces. They are today highly organized and well equipped in the developed countries, where regulations to minimize risks (from the prevention of forest fires to electrical and gas safety standards, etc.) are also well developed. Protection against natural disasters is also largely a matter of regulatory control measures, especially in building standards (earthquake precautions, prohibition on building on floodplains, etc.), let alone the lessons recently learned in France from the consequences of the summer 2003 heat wave, which killed about 15,000 people, provoking a large political debate on the health services' capacity to face this type of event.

i. Tackling Pollution

Regulation and enforcement are also essentially the means by which authorities seek to protect populations against the health-damaging effects of air, water, soil, and other kinds of pollution. The rules are obviously directed first and foremost at the businesses responsible for these problems (from 19th-century factory smoke to modern industrial emissions, pollution by agricultural inputs, and the problems of radioactive waste), but also at the public (domestic sewage disposal, selective sorting of domestic refuse, partial or total driving bans in towns on specific high air pollution days, tackling river and beach pollution, oil spills, etc.). These modern antipollution policies clearly follow the efforts made throughout history (mentioned earlier in Sect. 1 of this chapter), to protect populations from the risks of infection from wastewater or drinking water (sanitation, drinking water supply). While these efforts have now largely paid off in most developed countries, much still remains to be done in many developing countries. It also bears pointing out that the protection of populations from pollution far transcends the sphere of public health protection/enforcement alone and is a major economic issue.

j. Specific Protection of Particular Population Groups

Public health protection/enforcement also includes specific protective measures for particular population groups. A whole area of this policy has gradually formed in Europe in reaction to the damaging effects of the industrial revolution on the health and survival of workers. Under pressure from trade unions and humanitarian organizations, the State has laid down an increasingly complete corpus of protective rules in this area on night work, working hours, health and safety at work, heavy work, and so forth, often making specific provision for children and women, in particular pregnant women. At the same time, special corps of labor inspectors have been established. Such rules often still fall well below these protective standards in developing countries, where child labor is still common practice, to the detriment of both their health and education. In India, for example, the issue is a major talking point, with child laborers themselves increasingly making a vocal stand, and receiving international media coverage in recent years.

On a more general note, specific public health protection/enforcement measures have been taken for mothers and children in most countries, in particular pregnant women, newborns and infants.

k. Pharmaceutical and Medical Safety

Public health protection/enforcement also aims to protect the populace against the various possible ways in which medical activity itself may go awry. Not only does it set out in general terms to contain the dangerous activities of charlatans of all kinds[13] by regulating access to the different professions (doctors, pharmacists, paramedical occupations, midwives, nurses, and health care assistants) and imposing on them, either directly or through likewise regulated professional organizations, appropriate codes of professional conduct, it also sets out to control the validity of procedures and clamp down on fraud. The pharmacovigilance system is particularly complex but clinical procedures are themselves increasingly subject to at least ex post control through the justice system to which discontented patients are increasingly resorting. In the United States in the 1970s, compensation amounts awarded by the courts to the victims of medical negligence (malpractice as much as maltreatment) were so high as to necessitate a substantial increase in insurance premiums (Robin and Nativi, 1987). Disproportionate as court cases may at times be, especially where politics are involved, as happened in the infected blood supplies affair in France in the 1990s (La documentation française, 1993), the issue is a live one. This case clearly underscores the key role that the authorities can and must play in ensuring that medical professionals exercise their medical skills properly. Conversely, by deliberately disregarding the known consequences of traditional commercial blood collection for spreading HIV/AIDS, China's political authorities gave this killer disease an opening that should never have been allowed to happen (Beach, 2001; Shan *et al.*, 2002).[14]

2. Medical Prevention

At the intersection of public health protection/enforcement and medical activity proper lies an entire sector of public health action—that of medical prevention. This can be distinguished between primary prevention, directed toward preventing the occurrence of diseases (vaccination, combating disease-carrying vectors, reducing risk factors) and secondary prevention, directed toward early detection and elimination of diseases before they become full-blown (screening). Both primary and secondary prevention can equally well address infectious and chronic diseases: for example, vaccination against measles, eradication of malaria-carrying mosquitoes, and tackling the risk factors for heart attacks fall within the sphere of primary prevention, while screening for tuberculosis or cancer are secondary prevention concerns.

a. Vaccinations

Vaccination is and always has been a major instrument of health policy ever since the work of Jenner and the discoveries of Pasteur. Most of the diseases that can be prevented by vaccination are under control in the developed countries, but vaccination policies remain a huge issue for the developing countries, where infectious and parasitic diseases remain major causes of death (whether they are vaccinable diseases like measles, or others, like malaria and HIV/AIDS, which cannot yet be immunized against), as well as in developed countries where a fall-off in vaccination uptake could have far-reaching consequences.

Compulsory Vaccinations and Vaccination Campaigns

This is an area where public health protection enforcement strategies (e.g., in countries where vaccination is made compulsory for all or for specific population groups) and enabling policies for medical prevention are inseparable.

Vaccinations against some diseases are compulsory in most countries. In France, for example, this is currently the case for diphtheria, tuberculosis (BCG), tetanus, and poliomyelitis (compulsory vaccination against smallpox was dropped in 1982 after the WHO officially declared the disease to have been eradicated). The list of compulsory vaccinations varies

[13] Or at least those which at a point in time are considered as such, for the lessons of history are that in certain circumstances, the quacks of one period may be recognized as another period's saviors.

[14] See, e.g., an article published in *Le Monde* of 2 December 2003.

from country to country, as do the means of enforcement. In France, failure to vaccinate is a criminal offense, but rarely do the authorities go so far as to prosecute. Compliance is ensured mainly by the fact that vaccination is done in early childhood and is required for enrollment in school. The natural counterpart is that it is offered free of charge in various public and private offices.

But as well as compulsory immunization, vaccination information and promotion campaigns play a very great role everywhere. In the influenza period, for example, vaccination is offered free of charge for the individuals over the age of 65 in many developed countries (especially Britain, Australia, New Zealand, and Canada) (Hannoun, 1999; see also the websites of the different health ministries).

The Eradication of Smallpox

The history of the eradication of smallpox puts the strategic issues of a vaccination policy clearly in context. The pre-Jenner treatment of variolization carried a high risk, but the devastating effects of the disease were such that the individual or collective risk was worth taking. Jenner's vaccine inoculation and its subsequent improvements reduced the risk to almost nothing, gaining full acceptance for the compulsory vaccination strategy. The situation was very different when the WHO decided to launch its eradication campaign in 1966. Except in those very few regions where the disease remained endemic, most countries no longer experienced more than the odd case or small sporadic imported outbreaks, such that in Europe and the United States, for example, even the very low vaccination risk had become less tolerable (i.e., the risk of post-vaccinial encephalitis could be higher than that of contracting smallpox), and public opinion found increasingly less justification for compulsory vaccination whose only remaining purpose was to protect travelers and prevent the recurrence of epidemics (Hannoun, 1999). The WHO therefore sought a new justification for its mass eradication campaign: that of attempting to stamp out all risk of infection for all humankind forever, thereby rendering vaccination superfluous. Whereas there had been an estimated two million-odd cases of smallpox in 1967, highly specific identification of disease areas and the systematic vaccination of all the populations concerned, especially in India and Africa, brought the annual number of cases rapidly down until the very last reported case in 1976. To satisfy itself of the total disappearance of the disease, the WHO offered a $1,000 bounty to anyone reporting a new case. No real case was ever reported, and the WHO declared smallpox officially eradicated in 1980.

The Expanded Program on Immunization

Building on this first great success, the WHO set up the Expanded Program on Immunization (EPI) in 1980 with the aim of immunizing every child in the world against six diseases responsible for most developing country mortality: polio, measles, diphtheria, whooping cough, tetanus, and tuberculosis (Jones *et al.*, 1985). Vaccination of pregnant women against tetanus, to protect their unborn children from neonatal tetanus, was soon added to the list. The aim was to achieve 100% vaccination coverage worldwide by 1990. Unlike smallpox, however, these diseases remain endemic or fiercely epidemic (measles) in large areas of the world, and eradication any time soon remains fairly unlikely, apart from polio. Eradicating this disease, where major gains have already been made, is one of the official goals to be achieved by 2005 (see, in particular Table 107–3). Major resources have been put into this, not just by the WHO itself, but also by UNICEF,[15] the UNDP[16] and the World Bank, as well as through many bilateral cooperation programs and the work of countless non-governmental organizations (NGOs). The outcomes are far from negligible (Desgrées du Loû, 1996; Moulin, 1996), and vaccination policy remains of great strategic importance, not just for the diseases that can be vaccinated against,[17] but also and perhaps especially, for those that cannot.

b. Tackling Vectors

Some nonvaccinable diseases are transmitted to humans by vectors, and action can be taken here to avoid infection. This is particularly so with many tropical infectious or parasitic diseases, foremost among which is malaria.

Malaria—Seemingly Ineradicable

Here again, an attempt can be made to reduce the incidence of, if not eradicate, the disease by drastically reducing the vector population (or, to the same effect, reducing that population's contact with humans). If the parasite cycle can only complete itself by being harbored in the human organism, it will be enough to stop it remaining in situ for a sufficiently long period of time, without having to completely eradicate the vector population. That is more or less what is being done with malaria, even though it seems that one of

[15] United Nations International Children's Emergency Fund, established in 1946 and renamed United Nations Children's Fund in 1953, retaining the same acronym. It is headquartered in Geneva.

[16] The United Nations for Development Fund, set up in 1965 and based in New York.

[17] There is, in particular, renewed interest in BCG to tackle opportunistic diseases in AIDS.

[18] The major marshland reclamation schemes carried out prior to

the main vector species in Africa, mosquitoes of the *Anopheles funestus* genus, attack various animal species as well as humans (IRD, 2000). With no hope of a vaccine, the argument for a WHO-led world eradication strategy was given added weight by the success achieved in the 1940s by European countries where malaria was endemic. These countries moved from basic control of infected areas by marshland reclamation to eliminating the disease through the use of DDT.[18] In fact, the success of the WHO's first attempt in this direction produced hopeful results: in Sri Lanka, after a mass campaign to eradicate mosquitoes by systematic DDT spraying, life expectancy made a spectacular leap from 46 years in 1945–1947 to 60 years in 1954. Notwithstanding that we now know that the decline in malaria was not the only factor in this spectacularly sharp mortality decline[19] the disease had then almost vanished from the island (Molineaux, 1985). But, to an even greater extent than for vaccination, attempts to repeat the operation on anything like a large scale met with much less success, especially in Africa. Not only do the different species of *Anophele* (the vector) or *Plasmodium* (the parasite) not have identical patterns of behavior, but some mosquitoes are becoming DDT-resistant, and some mutant parasites have become insensitive to the preventative action of quinine. Despite the great hopes of the 1980s, there is still no vaccine in sight (Molineaux, 1985).

Other Hopes and Attempts

After malaria, schistosomiasis is surely the second most rife serious parasitic disease in the world. Here, too, WHO-backed systematic campaigns were mounted against the disease vector (a small aquatic snail of the planorb genus). These campaigns obviously went hand in hand with environmental clean-up and treatment for those infected, but also included molluscicide application in the water. The success of such campaigns can have a big impact on the health and mortality of developing world populations, especially in Africa. As for malaria, however, the aim of eradication is still far from being achieved.

Many more examples can be given of attempts to eradicate various tropical diseases in the same basic way as the attack on malaria in Sri Lanka. Few have had any notable success. Aside from the same technological problems as for malaria, one main factor in all the failures is the perennial problem of mounting large-scale operations of this kind in what is not necessarily a conducive economic, social, and cultural context. This strategy of large-scale vertical sectoral programs, indeed, was largely discredited at the WHO Alma Ata conference in the late 1970s.

c. Tackling Risk Factors

There is a fourth important aspect to medical prevention: action on risk factors. The idea is to prevent disease by attacking the factors that contribute to its development. This category obviously includes all road accident prevention measures beyond the public health protection/enforcement mentioned earlier (road quality, vehicle roadworthiness, transport policy, etc.). Here, primary prevention of cancer and cardiovascular diseases is considered.

Cancer

Where cancer is concerned, a distinction must be made between risk factors that derive from the organization of the economy and society and act on groups, and individual lifestyle-related ones (Flamant, 1976: Hatton *et al.*, 1985), even though the two often interact. Occupational risks are an area where policy action is paramount. They are also quite extensively covered by a combination of some of the public health protection/enforcement measures referred to earlier in this chapter and employer liability. But more generally, prevention here is also the focus of ongoing negotiations between employers, the state, social welfare agencies, and trade unions in light of the evolving frontiers of knowledge. Asbestos is a recent example, which also goes beyond the strictly work-related setting, since this versatile substance has found many household (not least in buildings) as well as workplace uses.

The individual factors are directly related to individual lifestyle, especially consumption patterns (of food, alcohol, tobacco, medicines, etc.). Aside from the food safety measures and the regulations on smoking and drinking mentioned earlier, the health strategy here is essentially about educating the public.

Cardiovascular Diseases

Secondary prevention of cardiovascular diseases, sometimes directed toward the same risk factors as cancer (smoking and drinking, e.g.) is traditionally a major plank of developed countries' health policies. Lester Breslow (1985) distinguishes programs directed at isolated factors from multifactorial programs: tack-

1940, such as the Pontine Marshes just outside Rome, had helped reduce the incidence of malaria. It was not really possible to eradicate it until DDT came on the market in 1943. The very last reported case in Europe, however, was in Macedonia in 1976 (retrieved July 20, 2004, from http://www.chez.com/demosolidarites/adiconfindex.html).

[19] In 1960, Harald Frederiksen went so far as to claim that the life expectancy gain achieved in Sri Lanka was due only to rising living standards, an argument easily refuted by Peter Newman (1965).

[20] René Laënnec (1781–1826), French physician, inventor of the

ling smoking, controlling cholesterol levels, and monitoring and controlling high blood pressure. Multifactorial programs seek to reduce all the main risk factors at once (the three just cited as well as others, like obesity). In either case, there are two possible strategies: either using various parameters to identify the most at-risk share of population toward which to gear the entire program (medical approach), or gearing the program toward the population as a whole, wagering on the knock-on effect that universality can produce (community approach), as with the North Karelia program, which is considered more at length below. Another case in point is the program to tackle cerebrovascular diseases launched in Japan in 1969 (Goldman and Takahashi, 1996), focused in particular on a reduction in salt intake.

d. Medical Screening

Alongside vaccines or other means (like tackling vectors) of preventing disease transmission, screening for medical conditions can help prevent a fatal outcome or relatively chronically incapacitating complications. This is often referred to as "secondary prevention." It is another major approach of preventive medicine, and many community health measures are based on this strategy.

Secondary prevention is a strategy that was deployed to particular effect in Europe's recent past in tackling tuberculosis. From Laënnec's stethoscope[20] to the controlled use of x-rays[21] and, finally biological tests (skin test), increasingly early and accurate diagnoses became possible, enabling early treatment of patients and a greater likelihood of recovery with fewer serious after-effects (especially since the discovery of antibiotics). Systematic screening campaigns were organized (in particular through occupational, school, and armed forces health services). It was this strategy much more than the BCG vaccine, which reduced the incidence of tuberculosis to the marginal position it now occupies in developed countries (Vallin and Meslé, 1999).

Screening is now a major weapon in the preventive medicine armory against many medical conditions. Three particularly important areas today are cancer, cardiovascular diseases, and congenital disorders.

Cancer

Anticancer policy is the most important example because, let alone the difficulty of acting on risk factors, there is almost no way of preventing the disease (in the strictest sense). What makes screening particularly beneficial is the close correlation between the success of treatments and how early the diagnosis is made. Also, the importance assumed by cancer in developed country mortality, especially since the huge decline in cardiovascular diseases, has made it a major issue of public health policies in developed countries. All have adopted more or less comprehensive cancer screening programs: screening for cervical cancer through cervical smears, breast cancer through mammography, and prostate cancer through rectal examination and blood PSA (prostate-specific antigen) levels is most commonly found in age- and sex-specific targeted programs. Systematic screening for stomach and colon cancer is still an unresolved issue because of the cost and the more invasive nature of the procedures. Screening for such diseases tends to be restricted to at-risk groups. In Japan, for example, systematic screening campaigns for stomach cancer have been running since the 1960s in certain high-incidence areas (Kitagawa and Hishami, 1970; Oshima *et al*., 1979, cited in Hatton *et al*., 1985).

Cardiovascular Diseases

There is also a varied range of screening programs, some more or less systematic, others targeted to at-risk categories, for cardiovascular diseases, especially those with the highest mortality or invalidity rates. Coronary angiography means that atherosclerosis can be screened for and treated, or a shunt fitted. Still in the field of coronary diseases, ultrasound scans can predict aortic aneurysm, while for cerebrovascular diseases, Doppler ultrasound can detect carotid artery damage.

Perinatal Diseases

The perinatal period also offers wide scope for screening for many disorders, and in all developed countries perinatal screening has been a major contributor to the sharp decline in infant mortality and a reduction in congenital disorders. This is much of what the compulsory antenatal and postnatal visits in many countries are designed to do. In extreme cases, antenatal diagnosis enables therapeutic abortion to be carried out, but also, in the same way as neonatal screening, it allows timely treatment for disorders that otherwise would be fatal or severely incapacitating. In France, for example, screening at birth for phenylketonuria (Guthrie test), introduced in the 1960s, has helped prevent a large number of disabilities simply by the use of a controlled diet. The lineup of means also includes a focus on Rhesus factor incompatibilities (by means of a parental blood test), the risks of

stethoscope and indirect auscultation.

21 Radioscopy and radiography came into large-scale medical use from the first World War (Bordry *et al*., 1992).

22 A reform undertaken as part of the care in the community

German measles, toxoplasmosis or HIV/AIDS in pregnant women, and social security reimbursement of amniocentesis for pregnant women over the age of 38 to detect Down's syndrome.

Medical Check-ups

More generally, age-group-specific check-ups for a comparatively wide range of possible diseases are organized in some countries.

Unfortunately, such a screening policy is much costlier and harder to organize than vaccination and tackling certain infectious disease vectors. In particular, it requires medical and laboratory facilities that most developing countries cannot provide for the entire population, and can only be implemented to the extent permitted by the general economic and social development of each country.

3. From Prevention of Disease to Treatment of Patients

Prevention is better than cure, it is said. And so it is, but when the disease is present, an attempt must be made to find the means to cure it. Should health policies that are closely interlinked—not just in establishing and enforcing health rules, but also in the implementation of medical prevention programs—also be involved in the treatment of diseases (other than by laying down rules of professional conduct)? It is a supremely philosophical and ideological question. Any modern state, however liberal its foundations, can easily accept full responsibility for public health protection/enforcement, and can recognize without too much difficulty that it must be responsible for at least a part of medical prevention, for its foremost duty is to the community, which does not necessarily always coincide with the individual interests of the persons involved. The public authorities have the right to decide on measures of public interest, and they must also bear the cost. Arguably, treatment of disease may be a different matter altogether, being expressly in the interest of the patient (or their family), and for which only the person concerned is competent and responsible: he is free to choose whether or not to seek treatment, and whether or not to resort to medical services, but he must also pay the cost, either directly or indirectly by taking out an insurance policy. But nowhere in the world is there not at least some collective provision to foot part of the bill for the treatment of diseases.

In theory, moreover, that can be done imperceptibly, at no added expense where, for example, the State intervenes only by creating a compulsory insurance system. There is then no need to levy a charge on the public budget. But, where a compulsory insurance system is in place, the premiums paid by the insured persons may not be entirely of the same nature as the taxes levied by the tax authorities, but can be equated to them, and increase the sum total of what are increasingly called compulsory levies. The value and method of funding of the cost of treatment can therefore be said to be a public policy decision. A timely definition is also needed of the risks to be covered, the premiums that can be reasonably charged, and the rates that service providers can charge. The increasing tendency is for the authorities to regulate all these areas in detail, even if in consultation with the social partners.

Beyond protection against collective risks (which is the justification for public health protection/enforcement and medical prevention), authorities have also been drawn into making provision for the treatment of patients to address at least, three different types of objectives: (a) to contain, reduce, or eradicate what are considered priority diseases; (b) to ensure the best possible health for a specific population group; and (c) to reduce inequalities. Multidisciplinary programs exist to address these objectives, covering both patient treatment and disease prevention. A few examples follow.

a. Tackling Priority Diseases

Tackling specific diseases may be seen as a priority for a variety of political, social, ethical, and other reasons. Anything that may reduce the scope of disease, including treatment provision, then becomes a public health issue. Such was the case in the past with infectious diseases like tuberculosis, and AIDS is a more recent, broadly comparable issue. Among degenerative and chronic diseases, some aspects of mental illness and cancer also may have relevance here.

Tuberculosis Then and Now

Tuberculosis emerged as a societal issue fairly early on, in the second half of the 19th century. A social disease, not merely as being chiefly one of poor families living in unsanitary housing and/or enduring poor physical working conditions, but also because these different harmful conditions were closely tied to the social changes wrought by the industrial revolution, urbanization, and free-market capitalism. Also, as tuberculosis was a contagious, stigmatizing disease, all possible means had to be used to minimize its incidence. This is why, in addition to the preventative steps mentioned earlier, national and local authorities in most European countries intervened quite early on in care provision, such as by building sanatoriums that offered free (or almost) care and treatment to sufferers (Faure, 1994, p. 217).

AIDS

More recently, AIDS came similarly onto the official agenda soon after appearing in the 1980s. Some of the reasons were different, not least the shock of forecasts of an unprecedented explosion and doubts about how quickly an effective vaccine could be developed. But others were of the same kind, like the opprobrium attached to a sexually related disease which itself produced a backlash political reaction in favor of people living with HIV/AIDS coupled with the seeming imperative of preventing infection by sufferers belonging mainly to fairly marginal social groups (homosexuals, drug abusers, blood transfusion recipients) spreading to the population at large. There again, the main focus of effort had to be not just prevention but also (if possible) curing sufferers. Huge funding was allocated to research, and once the (very costly) first drugs became available, they were issued in various ways either free of charge or subsidized to sufferers in many developed countries. One tragedy for the developing countries, and especially sub-Saharan Africa, is that these medicines are so costly and the sufferers so numerous that this strategy is not only beyond their reach, but also beyond the reach of many international programs. The other misfortune is that the huge research effort put forth by the rich countries has focused more on medicines than a vaccine, which would have been far more suited to the problem faced by widely infected countries. A glimmer of hope has emerged from the recent legal battle that has enabled some countries like Brazil, India, and Thailand (ONUSIDA, 2004) to start producing antiretroviral drugs without having to pay royalties to the pharmaceutical companies that developed them or others, like South Africa, to import them cheaply. Nevertheless, continuous lifetime treatment of all people with HIV/AIDS remains beyond the financial reach of most of the worst affected countries.

Severe Mental Disturbance

Very early on, the treatment of mental illness was seen largely as a public responsibility—less at the start in the interest of the sufferer (for whom treatment mostly comprised incarceration), than in that of society, which had to be kept safe from the dangerously ill (or simply unwanted). But just as imprisonment gave way to psychiatric hospitals, these gradually evolved into care provision, and this new function eventually came to substantially outweigh the old. In many countries, because of historical and more modern reasons (inability of the psychiatrically disturbed to cope, the unfair burden that their illness places on their families, etc.), psychiatric care has become a more or less full public responsibility. That principle remained intact when in the 1970s and 1980s many countries followed the Italian lead and completely rethought the ways people with psychiatric disorders were treated by switching the focus away from psychiatric hospitals onto treatment in the community (Meslé and Vallin, 1981), or doing away with them entirely, as in Italy, to retain only slimmed-down specialized provision, or ordinary psychiatric wards within general hospitals.[22]

In France, whether treated in the community or in residential care, severe mental disturbances (psychoses, severe personality disorders) form part of the list of chronic and costly illnesses whose treatment is always fully reimbursed by social security, and where prolonged sick leave arrangements are made.[23]

Cancer

Cancer also occupies a special place in modern societies. Most often the cause of prolonged and chronically debilitating diseases, it was long regarded as incurable, or to be treated by painful and costly procedures of uncertain outcome. But the rapid decline in infectious diseases left it as one of the two main causes of death in all high life expectancy countries, second only to cardiovascular diseases. The sharp drop in the latter from the 1970s made it more imperative still to tackle a disease that strikes a chill in contemporary society. Treatment in some countries became a public responsibility to varying degrees. In France, for example, not only do all cancer sufferers qualify for the chronic illness scheme, but new, specialized cancer

movement inspired by Franco Basaglia, culminating in Act 180 of 1978.

[23] More simply called the "chronic illness" scheme, this in fact goes far beyond psychiatric illnesses, in providing free hospitalization and medical care (no self-pay component) for officially prescribed illnesses (currently 30), or "any disorder requiring prolonged and particularly costly treatment," while daily benefits for work incapacity lasting more than six months are maintained (Vallin, 1979b). The 30 prescribed diseases are incapacitating cerebral vascular accident, medullary insufficiency and other cytopenias, chronic arteriopathies, complicated schistosomiasis, severe cardiac insufficiency, active chronic diseases and cirrhosis of the liver, severe primary immunodeficiency and HIV infection, types 1 and 2 diabetes, neurological and muscular disorder and epilepsy, hemoglobinopathies and hemolyses, hemophilia and severe blood-clotting disorders, acute high blood pressure, coronary diseases, acute chronic respiratory disorder, leprosy, Parkinson's disease, hereditary metabolic diseases, cystic fibrosis, chronic renal disease and nephrotic syndrome, paraplegia, polyarteritis nodosa, lupus and scleroderma, severe rheumatoid arthritis, psychosis or acute personality disorder, hemorrhagic rectal colitis, multiple sclerosis, severe ankylosing spondylitis, complications of organ transplant, progressive tuberculosis, malignant tumor or hematopoietic disorder.

[24] "Cancer is a real national tragedy that demands a big effort in

hospitals were built more or less on the tuberculosis sanatorium model, the most renowned of which is surely the Institut Gustave Roussy at Villejuif in the Paris region. Very recently again, the priority focus put on this disease was reaffirmed at the highest level of government in an official statement by the President of the Republic.[24]

b. Guaranteeing the Best Possible Health to Specific Population Groups

For a variety of reasons, it also became seen as a government responsibility to deliver the best possible access to health, including curative treatment provision, to specific population groups. Typical of these groups are workers, pregnant women, children, and the elderly.

Workers

Since the 19th century, the health of workers (essentially manual workers at the time; the preferred present-day term would be *employees*) has been a priority on government agendas, either from concern to preserve the labor force which underpinned the industrial revolution, or from ultimately yielding to workers' demands, especially in regard to the risks run simply by working. In France, for example, the introduction of a right to compensation for a work-related accident or occupational disease brought into being the first instance of comprehensive coverage of certain health care provision. Although it had existed in theory since the Revolution, based on the very general Civil Code provision on personal liability,[25] this right of workers against their employer had to be clarified and strictly regulated by an entire corpus of specific legislation to be really exercisable, and became universal only with the development of compulsory insurance systems. At the end of the day, therefore, it is because of a strong and continual public policy commitment that employees in many countries have full coverage of all work accident and occupational disease treatment costs, plus specific benefits for disruption of employment, and temporary or permanent work incapacity. Alongside the development of this special legislation, the State, local authorities, and mutual insurance organizations also established different occupational health services that play an important preventive role, but that may also be involved in actual care provision.

Pregnant Women

Pregnant women are another population group that benefits in many countries from specific legislation creating an entitlement not just to preventive measures for them and their unborn children (the key preventive role played not just by maternity leave but also special labor law rules merits a passing mention), but also to certain care and treatment provision. Even before pregnancy occurs, medical care (e.g., infertility treatment, in particular medically assisted reproduction) is provided free by the health system in many countries; likewise treatment to bring a high-risk pregnancy to term, or the treatment of certain women's diseases that may affect the child. Finally, specific provision has been made for childbirth and the postpartum period in many countries. This special policy on pregnancy bears a clear relation to policies to support fertility in countries where it is felt to be too low, France being a textbook example. But, in developing countries especially, it is also closely connected with the recent rise in reproductive health programs under the impetus given to this sector by the UNFPA[26] since the Cairo conference. The Cairo conference referred to here is the International Conference on Population and Development (ICPD).[27]

Children

Special provision also exists for children in many developed and developing countries, going well beyond prevention alone. In developed countries, a range of specific policies have been and still are being pursued, including the provision of free medical care or dietary supplements to combat malnutrition (especially through free or subsidized school meals). Most typical of the recent period, however, are the perinatal programs, to which most of the measures referred to in the previous paragraph could have been tied in. These programs were largely instrumental in bringing infant mortality down to levels that were unthinkably low, even a few short decades ago, through an unprecedented reduction in neonatal mortality. They rely heavily on the preventive measures mentioned earlier, but also most often include free treatment of the diseases, disorders, and abnormalities detected by

terms of research, prevention, screening, and treatment, including psychological counselling" (Jacques Chirac, statement of 14 July 2002).

[25] "Any act whatever of man, which causes damage to another, obliges the one by whose fault it occurred, to compensate it" (*Civil Code*, article 1382).

[26] The United Nations Fund for Population Activities, UNFPA, headquartered in New York, was set up in 1969. It is now called the United Nations Population Fund.

[27] International Conference on Population and Development (ICPD) Cairo, 1994 (see, in particular, United Nations, 1998/United Nations, 1995).

[28] Finding that the Ministry for Public Health was working only

screening. This is more easily achieved since this type of treatment is often required as a matter of course in the immediate postnatal period, when the newborn is still in a hospital environment (maternity clinic/ward) and in many developed countries, the period of hospitalization for childbirth is fully paid for by the health service, albeit increasingly foreshortened.

In the least-developed countries, childbirth is seldom so medicalized, and the most urgent infant mortality problem remains post-neonatal mortality, where infection and malnutrition play a bigger role. It is on these aspects of child health that governments, as well as international bilateral and multilateral cooperation have focused. The major WHO and UNICEF campaigns on prevention of early childhood infectious diseases have already been mentioned. The early childhood programs developed by these agencies, along with others like the UNDP (United Nations for Development Fund), the FAO (Food and Agriculture Organization, a United Nations agency, set up in 1945 and headquartered in Rome), and the WFP (World Food Program, set up in 1963), also include many curative aspects, like treating diarrhea by administration of oral rehydration salts (Victora *et al*., 2000), and combating malnutrition (Taylor *et al*., 1968; Kielmann and Taylor, 1969; Beghin and Vanderveken, 1985).

The Elderly

The health of the elderly is another area where policy action in some countries has gone well beyond prevention. In developing countries, where this age bracket still makes up only a very small share of the population, and where traditional intergenerational ties remain very strong, governments tend not to step in, leaving most elder care provision to families. In developed countries with older populations, by contrast, the matter has become a far-reaching societal issue. One point of interest in this connection is the exception made for the elderly in the United States, in an otherwise advanced general free-market approach to payment for health care. As a general rule, this is a cost to individuals and families, who are clearly free to insure against it or negotiate insurance with their employers. But, in an exception to this sacrosanct principle, Medicare was introduced in 1965 for individuals over the age of 65 and, in some cases, people under 65 with disabilities, and those on kidney dialysis (Card *et al*., 2004). Care provision under Medicare is neither complete (only hospital expenses are automatically covered, and Medicare offers only the possibility to insure the costs of medical care on a voluntary basis), nor reciprocity-free (it is available only to individuals with at least 40 quarters' worth of paid-up contributions, and their family members), but it is the only large-scale case in which the United States has created a compulsory insurance system and set the rules and rates. It illustrates how high the health of its older population is on the country's agenda.

Assistance to Victims

Finally, there is the issue of assistance to victims of accidents or attacks. First aid is generally provided by increasingly well-equipped emergency preparedness services. The consequences of road traffic accidents are generally provided for by insurance, broadly within the framework of compulsory insurance. Public help for the victims of natural disasters and attacks has recently developed considerably, even extending with growing frequency to the provision of psychological counseling.

c. Reducing Inequalities

The third big reason for increased policy involvement beyond prevention and into the sphere of actual treatment is the desire to reduce inequalities, be it international inequalities between populations in different countries of the world, or internal disparities within each country. Domestic efforts have mainly been made in two directions: geographical disparities and social disparities.

Reducing Internal Disparities

Geographical disparities in mortality have narrowed significantly in developed countries (see Chapter 55), basically as the result of policy action across all spheres with no overt health objective in many cases. This is because the State, whether centralized or not, generally seeks to extend its economic, social, and cultural development action in as harmonious a way as possible territorywide, thereby laying the foundations for a reduction of all kinds of geographical inequalities that contribute in some way to inequalities in health. Countrywide networks of medical provision more explicitly directed toward, and coupled with, public health protection/enforcement and preventive policy action that are likewise deemed to benefit the population as a whole, clearly contribute to deliver that aim. But some countries have gone further. Finding that some regions were still suffering from specific problems resulting in what was judged to be abnormally high excess mortality, some governments pursued a specific policy to bring the levels down. So, in 1956, the French Ministry for Public Health and Population commissioned INED to survey the causes of the abnormally high infant mortality rate recorded in the Nord and Pas-de-Calais departments (Girard *et al*., 1960), and then mounted a campaign toward local communities, business, and local authorities to try and stem the rise. A more defining case still is that of North Karelia in Finland (Puska *et al*., 1981, cited by Breslow, 1985). Toward the end of the 1960s, this 180,000-strong community had what may have been the highest coronary heart disease mortality in the world (Breslow, 1985). In the early 1970s, a wide-ranging program was launched to reduce blood pressure, cholesterol, and smoking, and to encourage early treatment of people with cardiovascular diseases, involving the entire organized voluntary social service movement and the network of health agencies. Five years later, in 1977, coronary heart disease mortality in the 30–64 age bracket had dropped by 13% among men and 31% among women (Breslow, 1985).

Social inequalities in mortality are also a focus of concern leading to specific public policy action on health. Having moved on from the time when the poor, like the sick, were perceived and treated more as a threat to society than a group deserving care and attention, they were offered first assistance, then specific health programs. France, for example, brought in statutory free medical assistance for the poor in 1893. The establishment of social security systems after World War II did not render these provisions obsolete, because many of the poor fell outside the scheme. They were simply reworked in 1953 into free medical help (AMG) providing free care to anyone living in France who could not afford to pay for it. But even when the universal health coverage (CMU) scheme was created in 1999, benefiting some 150,000 to 200,000 people living in France without social security entitlements, plus the 550,000 previously voluntarily insured, a significant number still fell through the net, as the entitlements were only for persons lawfully resident in France for more than 3 months. A state medical assistance scheme (AME) was therefore kept, and is the only means by which undocumented migrants and their families can access the health care they need. In 2003, 180,000 people were covered by AME.

Obviously, extreme poverty is not the only social inequality in health and mortality, and in the latter half of the 20th century, it was the rest of these inequalities that policy sought to address in many developed countries, by setting up near-universal social security systems. These will be considered further below.

Closing the Gap between Rich and Poor Countries

Policies to reduce international inequalities are of more recent date. They were mostly brought in after World War II, with the creation of the WHO, the rise of the Third World movements, and the establishment of international programs to reduce excess mortality in developing countries. Notwithstanding undeniable spot successes, however, the first tentative efforts based either on the roll-out of large-scale "vertical" programs to tackle specific high-incidence diseases (one of the WHO's main self-appointed missions), or the construction of major referral hospitals intended to energize the country's entire health delivery system (a key, but not always disinterested, strategy in bilateral cooperation measures), soon exhausted the possibilities. Generally, the efforts benefited only a small, privileged, mainly urban share of the population, leaving the bulk of the rural masses by the wayside. At the 1978 Alma Ata conference, drawing on the impressive Chinese experiment with "barefoot doctors," introduced during the Cultural Revolution,[28] the WHO took a radically different tack toward the primary health care strategy (WHO, 1978).

This new strategy was less about trying to eradicate a specific disease more or less completely than attaining decisive all-around health improvements for populations that had the least access to them. The aim was to "address the main health problems in the community, providing promotive, preventive, curative and rehabilitative services accordingly," while the Declaration of Alma Ata specifies that this includes, at the very least, health education, food supply and proper nutrition, supply of safe water and basic sanitation, and maternal and child health care that included family planning, immunization against major diseases, control of locally endemic diseases, treatment of common diseases and injuries, and provision of essential drugs.

Governments are responsible for refocusing their health policies on this new strategy, while international organizations and others in the cooperation community must provide technical and financial support in redeploying the assistance they provide to the health policies of poor countries toward these new objectives.

As obvious and essential as it may seem, this new strategy has encountered a series of obstacles on the ground. However "primary" they may be, these forms of health care are many and various, and costly when

for 15% of the country's population, Mao Tse Tung called in 1965 for a focus on medical work in rural society, as a result of which 150,000 medical workers were given basic training, and left the towns to exercise their skills in rural communities. These "barefoot doctors" were healthcare personnel who had received a few months of basic medical training, followed by advanced training courses. They were to provide stop-gap services to the maximum number of people, including prevention, basic treatment, screening, and referral (of difficult cases) to doctors or hospitals. They were either assigned to villages or formed part of mobile outreach units covering more sparsely populated areas (Selden, 1972).

[29] Except in three countries (Germany, the Netherlands and Ireland) where those on the highest wages were kept outside the

the target group concerned is in fact the bulk of the population. But also, both the main beneficiaries and the actors in the previous system were fiercely—if only passively—opposed to any major redeployment of existing resources. Finally, the rich countries gave no substantial new financial pledges at Alma Ata. Most governments naturally brought in (often through legislation) health policies that endorsed the primary health care strategy, but any attempts to really implement them were few and far between, and almost never produced a real shift in priorities, which might have produced the looked-for results. And yet it was this strategy (whether framed before or after Alma Ata) that has enabled countries such as Costa Rica (Rosero-Bixby, 1985), Kenya (Mosley, 1985), and the State of Kerala in India (Nayar, 1985), not to mention China, referred to earlier, to increase their life expectancies well beyond what their economic development might suggest.

A slew of initiatives have been taken in a bid to give fresh impetus to this strategy, one of the main ones being the Bamako initiative (Brunet-Jailly, 1997; Soucat *et al*., 1997).

4. All for All

In fact, the WHO's adoption of the primary health care strategy can be seen as the international reflection of a growing idea at the time that public policy at all levels should be directed toward delivering access to health to all. The priority focus on primary health care was essential only because the rural masses who made up most of the Third World populations had no access to standard health care provision. The basic aim was to offer a minimum access to health to everyone, without waiting on economic development to maximize access to traditional services. It was a first step toward "health for all by the year 2000," soon to be adopted as a WHO slogan.

From an entirely different angle, this same concern to see public policy guarantee health for all by all possible means was what prompted many industrial countries (especially the European ones) to shift away from leveling the playing field by helping the poorest social groups to access health care toward a collective assumption of responsibility for the health of all within a welfare state, where public health is only one of many elements.

a. Developed Countries: the Welfare State

The welfare state is a concept that extends well beyond health matters to the collectivist assumption of all major social risks (unemployment, cost of family obligations, old age) and needs (education, leave, etc.). We are concerned here, of course, only with health, which is nevertheless exemplary. Disregarding the Soviet system, which no longer prevails in any developed country, health expenditure is by and large paid for in three different ways, ranging from the "social contractual" protection (Dumont, 1998) applied in the United States, via the French-style social security system, to the State-funded system established in Britain after the adoption of the Beveridge Plan (1943).

The "Social Contractual" System

No further consideration needs be given to the American social contractual system, of which Medicare was cited above as the only exception to its free-market principles, other than to say that it is based on the freedom of individuals to insure themselves with private insurers against the risks of disease and accident, either through company-established or mutual programs operated by employers or mutual insurance organizations. It is a model very far-removed from that of the welfare state.

Social Security

The French-style social security system evolved as an extension of the scope of the social insurance plan devised in Bismarck's Germany in the 1880s, rapidly taken up in Austria (1882), Denmark (1891–1892), Belgium (1894), Luxembourg (1901), and finally France (1930). The big difference from the American free-market system is that social insurance is compulsory, although it was initially limited to employees on low incomes (below a statutory maximum). The big change made in the aftermath of World War II in most European countries that had the system was to extend its benefits to all employed workers.[29] In almost all countries, too, it was then progressively extended to farmers, shopkeepers, craft workers, and others. The system is thus based on across-the-board coverage by state-ordained compulsory social insurance, funded out of earnings-related contributions (the cost burden being shared by employer and employee), and jointly run by the social partners (employers' organizations and trade unions) under State superintendence.

Different specific social insurance systems may often be layered onto a so-called general scheme. In France, for example, the general scheme coexists with

system. In Germany, however, since 1970, high wage-earners can opt-into the system, which now therefore covers 92% of employees compared to 70% in 1969, while Ireland has recently moved onto a UK-style universal protection system (Dumont, 1998).

[30] WHO document WHA30.43, available at the item "Resolutions and Decisions" of http://www.who.int/governance/en.

[31] On which, for example, see "Health for all in the 21st century"

a civil service scheme and other category-specific schemes (agricultural, in particular). The health insurance funds contract with public or private care delivery partners (hospitals, fee-for-service practitioners, pharmaceutical companies, etc.), and, in consultation with the State, set the methods of remuneration and cost of medical treatment rates that patients must pay, as well as full or partial cost reimbursement procedures. The vast majority of citizens thus have a recognized right to health in the form of a right of access to medical care, leaving patients free to use the health care providers of their choice (Letourmy, 2000). "Vast majority" does not mean all, however. A share of the population still remains excluded. In France, for example, with one of the highest coverage rates, nearly 1% of the population remains outside the system (Dumont, 1998, p. 2). However, as mentioned earlier, safety nets marginally attached to the social security scheme exist for excluded groups (AME, CMU).

Universal Protection

The most radical change occurred in the United Kingdom in the aftermath of World War II, with the introduction of a universal protection system covering the entire population from the very outset, following the adoption of the Beveridge Plan and the setting-up of the National Health System (NHS) in 1946–1948. All citizens were automatically covered, without having to prove employment or a contribution record. Another feature of this system, which also covers the other fundamental social risks or needs, is that pension, unemployment, and other benefit amounts are in no way earnings related. The British National Health Service provided a template for the systems subsequently adopted in Denmark (1960), Sweden (1962) and, more recently, many others, including Ireland, Spain, Italy, and Greece. It is based on an essentially hypothecated tax-funded, predominantly public, care sector (but with a private sector component for those who can pay). It is free (or almost) to all citizens, but there is restricted choice of points of entry. In the United Kingdom, for example, patients must register on the list of a referring doctor, and can only change doctors in certain conditions. The referring doctor decides on the need for referral to a specialist or hospital treatment. The public authorities have direct control over funding, through budgets allocated to hospitals and fixed fees paid to doctors according to the number of patients on their lists. They also control the medical services provided in public hospitals.

Scheme Coverage May Be Deceptive

A compact publication by Ariel Béresniak and Gérard Duru (1997) gives detailed descriptions of the schemes in force in each of the 15 European Union countries, with a flow chart for each to clarify their maze of complexities. Figure 107–1 shows the comparative systems for the United Kingdom and France.

Notwithstanding the wide differences in the ways they work, these two major systems now provide near-universal coverage of the population for the main health care requirements (especially in-patient care), as Table 107–2 shows. This is the result of major progress made by countries that initially established only limited social insurance schemes toward either extending coverage to almost all the population, or becoming a universal state system. Only the United States stands out for the wrong reasons among OECD countries.

Universal (or near-universal) coverage of the population is not, however, necessarily the same as universal coverage of needs. Not all expenditures are fully noncontributory. Hospital expenses are best catered for, with more than 90% of the costs being paid for in European countries in 1998, barring the odd exception; out-patient care is less so, with rates often between 80% and 90%, and the cost of medicines still less, ranging in many countries from 50% to 75% (Dumont, 1998). Nor do recent trends show any improvement, as problems of funding the social protection system as a whole, and especially disease protection, have recently begun to throw the canons of the welfare state itself into question. The theoretically total coverage offered by the NHS in the United Kingdom should not be taken at face value. Government spending on the NHS is obviously not limitless, and the system's drawbacks—not least long waiting lists for treatment—are enough to drive many toward a very costly, but flourishing private sector.

b. Developing Countries: "Health for All"?

To take WHO founders at their word, it could be reasonably argued that the WHO was set up in 1946 with the task of delivering health to all, since the preamble to its Constitution states, "The enjoyment of the highest attainable standard of health is one of the fundamental human rights of every human being without distinction for race, religion, political belief, economic or social condition" and "The health of all peoples is fundamental in the attainment of peace and security and is dependent upon the fullest cooperation of individuals and states" (WHO, [1946] 1989). There could be no clearer affirmation that access to health for all was a matter of urgency and that this engaged the responsibility of States, and hence international organizations.

Health for All by the Year 2000?

But the noblest intentions of this kind officially proclaimed at the highest level of the world's governing bodies are mere words until the practical programs needed have been decided and the means to carry them out allocated. In its earliest days, the WHO thought to take a "fire-fighting" approach through programs to stamp out major eradicable diseases with basic means, far from being able to deliver "the highest attainable standard of health" for all! For that reason, 30 years later, at the Alma Ata conference, the WHO sought to move closer to its aim with a more direct assault on the problem of poor rural communities denied access to existing health care provision, but also realistically by repositioning health in the more general context of the basic needs of life, and the more modest one of basic health needs. The decision of the 30th World Health Assembly, which was behind the Conference, set the aim of "the attainment by all the citizens of the world by the year 2000 of a level of health that would permit them to lead a socially and economically productive life."[30] This aim was a much less lofty ambition than the highest attainable state of health and indeed failed to deliver all the hopes it had

by the WHO Director General in the "History" section of the "Health for all" page on the WHO website (consulted on 23 July 2004).

raised. Even so, a very ambitious slogan gained popular currency from the 1980s in an attempt to move matters forward—"health for all by the year 2000" (OMS, 1981)—from which time all the WHO's activities would be carried on under that banner.

Or Health for All in the 21st Century?

By the late 1990s, however, the inescapable fact was that health for all would be nowhere near achieved by the end of the millennium. The idea was taken up again in more realistic terms through wide-ranging consensus between the WHO, the United Nations, the IMF (International Monetary Fund, established in 1945), the World Bank, the WTO (World Trade Organization, created in 1995 and based in Geneva), and others. Health for all was still a central concern, but the call was now "health for all in the 21st century," which left plenty of time. It is now a long-term strategic process intended to result in incremental improvements in the health of populations, without being an endpoint. Health for all by the year 2000 was only the start of that process.[31]

The gap between the goal initially set and the resources allocated was too wide. If even in rich countries, whose most comprehensive systems of health care free at the point of delivery had still failed to even up survival probabilities, let alone the span of healthy life, it is hardly surprising that the WHO should never have really been able to implement a strategy that lived up to its noble ambition of equalizing opportunities on a world scale. Too many opposing interests—political, obviously (national self-interest, ideological liberalism), but also economic, technical, and human—were in play. Not to mention that, fundamentally, the WHO lacked the financial resources for such an undertaking, and could only appeal to public or private good will.

As part of its strategy on health for all in the 21st century, the WHO Ninth General Programme of Work, covering the period 1996–2001, lays down 11 public health goals for countries, setting one or more specific targets for each goal to be achieved before the end of the period, mostly in the form of quantified indicators (Table 107–3). For example, the goal of "increasing the span of healthy life" is to be delivered by meeting two targets: life expectancy at birth must not be less than 60 years in any country in 2001, and life expectancy at birth differentials within all countries must be reduced by 50% compared to 1990 (OMS, 1994).

[32] The World Bank is a group of financial institutions in the United Nations system, most centrally the International Bank for Reconstruction and Development (IBRD), set up in 1945. Others in

Naturally, while their representatives at the World Health Assembly may have adopted the program in principle, countries still have the final say on whether or not to implement it and are also responsible for resourcing it on top of international assistance that always falls short of the needs.

More recently, however, all 191 United Nations member countries reaffirmed their commitment to hard economic and social development targets, several of them expressly health related, in the MDGs (Millennium Development Goals) (Annan, 2000; United Nations, 2000). These included reducing the under age 5 mortality rate by two-thirds and the maternal mortality ratio by three-quarters, and halting the spread and beginning to reverse the incidence of HIV/AIDS by 2015.

II. ACTORS AND RESOURCES

Health policy in the broad sense addressed here clearly involves a wide range of actors. It also involves deploying resources, the main problem being that these are usually woefully lacking. A tentative short outline of actors and resources follows.

1. A Wide Range of Actors

Policymaking is clearly the purview of those in power, but few policies can be successfully conducted without the active support of both those responsible for executing them and those on the receiving end. That is obviously true in democratic countries, but equally so in less-democratic ones. A distinction must be drawn between public and private actors, therefore.

a. Public Actors

The State

The State is the fundamental entity of the modern organization of human societies. It is still today and will doubtless remain for some considerable time the main center of decision-making and policy action, notwithstanding the present trend toward the development of supranational entities and decentralization to the regions.

Governments everywhere have a ministry/central department for health, although in many cases its jurisdiction will extend well beyond health strictly speaking (e.g., a social affairs ministry). Clearly, the definition and implementation of health policies will be primarily that ministry's responsibility, but most of the decisions required go beyond its strict remit. As formulated, for one thing, they may impinge on other

TABLE 107–3 Goals and Targets of the WHO Ninth General Program of Work for the Period 1996–2001

Goal	Targets
1. To increase the span of healthy life	Life expectancy at birth not less than 60 years Reduce disparities by 50%
2. To ensure universal access to essential health care	85% of the population must have access within an hour's walk to treatment of common diseases, essential drugs and vaccines, basic biological products and blood products 70% of people with STDs to be examined and treated All countries to launch initiatives for the elderly
3. To ensure survival and healthy development of children	Infant mortality rate not to exceed 50 per 1000 Under-five mortality rate not to exceed 70 per 1000 90% of children immunized against 6 diseases Proportion of low birth weight reduced to less than 10%
4. To improve the health and well-being of women	Maternal mortality rate reduced to 50 per 1000 All pregnant women to have access to prenatal care and trained attendants during childbirth Disability-free life expectancy for women to increase by 15%
5. To ensure healthy population development	Everyone to have access to family planning services
6. To eradicate, eliminate or control major diseases	Eradicate poliomyelitis and dracunculiasis Eliminate leprosy (reduce prevalence rate to less than 1 per 10 000), neonatal tetanus (less than 1 per 1000), and measles (reduce mortality rate by 95% and the incidence rate by 90%) Control malaria, TB and hepatitis B Reduce coronary heart disease mortality among the under-65s by 15% Reduce cancer mortality among the under-65s by 15%
7. Reduce the risk of HIV transmission	Achieve a rate of 50% of people having casual sexual contact using a condom
8. To reduce avoidable disabilities	Significantly reduce disabilities from sensory, locomotor and mental impairment among underserved population groups
9. Improve nutritional status	Reduce the prevalence rate for severe malnutrition by 50% Eliminate vitamin A and iodine deficiencies Reduce the prevalence of iron deficiency anemia in women by 33%
10. To enable universal access to safe and healthy environments and living conditions	Ensure access to drinking water for at least 85% of the population Provide at least 70% of the population with access to sanitary excreta disposal facilities or services Substantially reduce the risks of violence
11. To give all people access to healthy lifestyles and healthy behavior	All people to have access to information

Source: OMS, 1994.

ministries' areas of responsibility. For example, no public health protection/enforcement action can be taken without involving the central authorities responsible for public order (police, army). Health ministries may not even be involved in enacting some of these provisions (road traffic regulations, tackling crime, etc.), while other ministries may also take protective measures for specific population groups under their responsibility (concerning education, housing, work, the environment, etc.) which have far-reaching direct or indirect consequences for health. More often still, the resources to be deployed go beyond what the health ministry alone can allocate, be it financial resources (direct or indirect) or legal measures. In short, most health policy decisions are multidisciplinary in nature and require consultation across departments, not to mention, in many cases, the enacting of new legislation requiring the intervention of parliament and the deployment of democratic debate.

Implementing decisions is a matter for the different administrative authorities concerned. Their remit, and especially that of the ministry responsible for health, is very much a function of the collective health care funding system in each country. It is clearly much greater in the United Kingdom than in the United States. Between these two extremes, in countries with systems based on compulsory social insurance, State policy measures are put into action by semi-public organizations jointly managed by the social partners. In France, for example, the general social security scheme is run by the national health insurance fund (CNAM), a tripartite body of the State, employers' organizations, and trade unions. Finally, to ensure nationwide coverage, these government authorities or organizations have local offshoots. France's health ministry has a district health and welfare authority (DDASS) in each department, while the CNAM acts through a dense network of local social security funds.

Specific governmental authorities are often set up to handle specific areas of health policy implementation. In the United States, for example, the all-powerful Food and Drug Administration (especially its Center for Drug Evaluation and Research) not only enforces compliance with food health regulations, but also licenses the marketing of medication. This agency's influence stretches well beyond its national borders, being a quite proper compulsory vetting point for any foreign-manufactured foodstuffs or medications imported into U.S. territory. In France, the *Agence française de sécurité sanitaire des produits de santé* has jurisdiction only over medication, while foodstuffs are under the control of the *Agence française de sécurité sanitaire des aliments* (Bonnici, 2003). Similar kinds of official agency exist in other areas, like the French *Agence française du sang*, set up in 1992 after the contaminated blood supplies scandal, or the *Service central de protection contre les rayonnements ionisants* (SCPRI) for ionizing radiation (Ceccaldi, 1997).

Local Government

Existing supra- and subnational political structures are often involved in the health sphere. Care must be taken not to confuse the local outposts of central government with decentralized local authorities. In federal states like the United States of America, Canada, India, Brazil, Germany, and others, it is clear that the individual states act independently of the federal State within the limits of their constitutional responsibilities, which tend to be quite wide-ranging in health matters (especially care provision). But even such a highly centralized country as France has several tiers of decentralized local authorities (regions, departments, municipalities) run by elected councils with decision-making powers independent of the State in a wide range of spheres. All have health-related activities.

Not all measures pursued by States and local authorities are purely domestic. They also play a significant role in assisting health improvement in poor countries. This was and largely remains a mainly central government concern, but is increasingly diversifying in many directions. At the macro level, bilateral cooperation is increasingly carried out through multipartnership projects involving either a number of national organizations or a combination of national and international organizations (so-called multi- or bilateral cooperation). At the micro level, transnational cooperation between local authorities has also developed in recent decades. So, French regions and departments have recently struck up agreements with, especially African, partners for health development projects. Individual municipalities are even increasingly involved in this kind of activity, both through traditional twinning and in other ways. Finally, the last 10 years have seen the emergence of what is known as South-South cooperation, where a developing country that has acquired a level of expertise sets up cooperation arrangements with other less-advanced developing country partners. Tunisia is a case in point for reproductive health. Countries such as Brazil, India, and Thailand are others; having developed the means of producing antiretroviral drugs, they entered agreements with other AIDS-hit countries like Mozambique to help them do likewise (ONUSIDA, 2004).

International Organizations

Finally, above nation-state level stand the international organizations. At the world level, within the United Nations system, the main role obviously lies with the WHO. That was the reason for setting it up in 1948; it succeeded the Health Organization set up in 1920 within the League of Nations, which, after World War I, had itself replaced the Office International d'Hygiène Publique (OIHP), created in Paris in 1907.

WHO is tasked with implementing the policies laid down by the World Health Assembly, which is to the WHO what the United Nations General Assembly is to the United Nations. As reaffirmed in its General Programme of Work 2002–2005 (WHO, 2001), its four strategic goals are to (1) reduce excess mortality, morbidity, and disability, especially in poor and marginalized populations; (2) promote healthy lifestyles and reduce risk factors to human health that arise from environmental, economic, social, and behavioral causes; (3) develop health systems that equitably improve health outcomes; and (4) enable the creation of an institutional environment for health and promote an effective health dimension to social, economic, environmental, and development policies. It plans to deliver these goals by focusing on (a) increasing awareness among the different actors in health; (b) managing information, assessing trends, comparing performance, and stimulating research and development; (c) giving technical and policy support to national action on health and international cooperation; (d) negotiating national and global partnerships; (e) setting, validating, and monitoring the implementation of standards; and (f) stimulating the testing of new technologies. Its action is carried on in various major world regions either by the organization's own WHO regional centers (Africa, Europe), or in cooperation with independent regional institutions (e.g., Pan-American Health Organization [PAHO] in America). The WHO also has local representative offices in most countries.

In addition to the WHO, other big international institutions, with which the WHO also has strategic agreements, also intervene in the health policy sphere: FAO, ILO (International Labor Organization, set up in 1919 as part of the League of Nations, which it outlived to become a United Nations agency in 1946; its Permanent Secretariat is the Geneva-based ILO), UNESCO (United Nations Educational Scientific and Cultural Organization, set up in 1945 in Paris), IAEA (International Atomic Energy Agency, set up in 1957 in Vienna), UNIDO (United Nations Industrial Development Organization, set up in 1966, with headquarters in New York and Geneva), and the World Bank.[32] Other institutions with which the WHO has agreements are UNFPA and UNICEF (referred to earlier for their key roles in reproductive health, and maternal and child health) and specialized agencies such as UNAIDS (Joint United Nations Program on HIV/AIDS, Geneva), HCR (United Nations High Commissioner for Refugees, Geneva), and the WFP. Other regional organizations also play a key role in framing concerted programs on health: the OECD (Organization for Economic Cooperation and Development)[33] for Western countries, and the OAU (Organization of African Unity, set up in 1963 in Addis Ababa), which became the African Union in 2002. It is difficult to say exactly where the European Union fits in this lineup, for while it is not yet entirely a State, it is already much more than a simple international organization, exerting a growing influence on the health policies of its 6, then 9, 12, 15, and now 25 member countries.

the group are the International Development Association (IDA), founded in 1960; the International Finance Corporation (IFC), set up in 1956; the Multilateral Investment Guarantee Agency (MIGA), established in 1988; and the International Centre for Settlement of Investment Disputes (ICSID), created in 1966.

[33] Originally set up in 1948 as the Organization for European Economic Cooperation (OEEC) under the Marshall Plan, it reinvented itself as the OECD in 1961; it is based in Paris.

[34] Set up in New York in 1987, Act Up rapidly spread elsewhere, particularly to major cities such as San Francisco, Philadelphia, and Paris.

b. Private Actors

Many private actors are involved in the framing and implementation of health policies. At the base of the pyramid, obviously, are health professionals and patients. But a brief word must also be said about the other societal shapers most involved in health issues—business, the trade unions, and mutual insurance organizations. Add to these the general public itself, and the various NGOs working in the health sphere.

Doctors and Patients

Micro health decisions are taken in the private consultation between doctors and their patients. This is a necessary stage in any modern health policy, at least as far as curative medicine goes. But it is not the only one. From it arise fundamental problems concerning issues of responsibility and freedom of choice which may be addressed in different ways from country to country. Doctors have a responsibility to treat their patients to the best of their abilities, but do they have total freedom of choice in the treatment? Should it be circumscribed by public interest constraints, like the balance between national spending on health and other matters? Likewise, the patient's main concern is to secure the best treatment from his doctor, but is his freedom of choice (of doctor, how the proposed treatment is carried out, etc.) itself circumscribed by limits imposed by the public interest? These questions are high on the agenda today, with the problems of funding total health spending. But they also include philosophical, ethical, and ideological aspects that sporadically come to the foreground of public debate. Proof of that, if it were needed, is given by the fierce controversies around reproductive health issues that flared up in the 1990s around the Cairo conference, setting religious and sectarian groups at odds with the proponents of individual liberties. The attitudes and behaviors of doctors and patients themselves obviously very largely inform policymaking. Indeed, the word *doctor* is too restrictive here. More broadly, it is all health professionals that are involved: specialists in the different branches of medical and pharmaceutical practice, and the paramedical professions (physiotherapists, nurses, midwives, etc.) alike. One of the most pressing issues in the doctor-patient dialogue is that of patients accessing information on their illness and its treatment, and having a say in the decisions. One of the practical repercussions of the developing trend in this area is, for example, the laying-down of legal conditions on which individuals can access their medical records.

But health professionals and patients do not step into this debate only through their individual actions, but also through collective voluntary or even semi-public institutions. Two types of professional organizations are found: (a) purely private trade unions and associations and (b) professional regulatory bodies. The latter have certain official powers to regulate the activities of the profession that they represent. Recent decades have also seen the development of what can be a highly active patients' self-advocacy movement. The highest-profile example must surely be the AIDS support organizations that have been set up since the disease burst onto the scene. This new development reflects a quite radical shift in the patient-doctor relationship. Individually and collectively, patients want more of a say in how their illness is managed by the health system. The activity of an association like Act Up is wholly indicative of this new mindset.[34] Other patient and family support groups for other diseases and disabilities (e.g., paralysis, epilepsy, cancer) are also highly vocal self-advocates for their rights and a say in the decisions that affect them.

Companies

The companies most active in the health field are obviously those engaged in the production of medical resources: pharmaceutical firms, medical equipment manufacturers, hospital builders and developers, and the like. Little would be gained from a lengthy description of their often-considerable influence over health policymaking. Their function may be fundamental to the improvement of health, but their strictly economic interests may also on occasion distort the policy approach. They are not, for example, completely free of implication in the relative failure of the primary health care strategy, or in the eternally protracted delay in developing a vaccine against AIDS or malaria, as neither primary health care nor AIDS in Africa are particular money-making propositions at this time. Other kinds of company, moreover, may play an outright negative role when they form lobbies to thwart the introduction of policies to tackle alcohol abuse, smoking, road transport hazards, for example. Conversely, firms of all kinds who see the health of their employees as a valuable asset to be preserved have and still do positively inform the approach and implementation of health policies. The likely success or failure of any occupational health policy will obviously be shaped by their attitude. Finally, business, or more precisely, employers' organizations, directly inform the framing and implementation of health policies in countries with a compulsory insurance-based social security system.

There is also a very singular type of undertaking, set up to provide development assistance generally, which often includes health development assistance. These are the foundations, usually Anglo-American in origin. Whether big, long-established foundations like the Rockefeller Foundation (founded in the United States in 1913), the Ford Foundation (founded in the United States by Henry Ford in 1936), the Wellcome Trust (founded in Britain in 1936), or more recent ones like the Bill & Melinda Gates Foundation (set up in January 2000), they have all at some point funded large-scale health projects, especially in the developing countries.

Trade Unions and Mutual Insurance Organizations

The same can be said of trade unions, but they may also play a stand-alone health role. In fact, this function has been inseparably linked to the creation of the mutual health insurance organizations, which now mostly operate independently of the unions. In countries where most basic health costs are free at the point of delivery, mutual insurance organizations remain of varying importance in funding health costs that are not free (e.g., the co-payment charge, or patient's fixed contribution per day of hospitalization,) or non-reimbursable treatments. Their role is clearly more important still in countries dominated by the free-market philosophy, in competition, of course, with private insurance companies.

The Public

The public itself is a major actor in health policies, be it simply through the sum total of individual behaviors, or via organized voluntary movements. We are concerned here less with the behavior of patients, already referred to, than of healthy individuals, which will clearly inform prevention (lifestyle, hygiene, risk behavior, etc.), but also screening (attention to symptoms and use of health services). The importance of these factors to health policies has been highlighted in particular by the analysis of certain mortality differentials, like the sex-specific differential (see Chapter 54), social inequalities in mortality (Vallin, 1979a), and the health crisis in the communist regimes (Meslé *et al*., 1998; Meslé and Vallin, 2003). In each of these three examples, one factor of differentiation is the different capability to change individual attitudes, thereby optimizing new ways forward to improvements in health. This is particularly important in bringing about changes to existing behaviors in order to tackle cardiovascular diseases (Meslé and Vallin, 1993). Be it in changing individual behaviors or public pressure brought to bear on governments or local authorities to achieve a specific public health measure, health poli-

[35] *Médecins sans Frontières*, or Doctors without Borders, was set up in 1971 during the Biafra war, and has since been a seminal influence in France and many other countries.

cies are also shaped by voluntary organizations working proactively in this area. It is an area of rapid growth in the number of local voluntary organizations with a wide range of aims, especially in developed countries where public demands are increasingly exacting in this particular sector, as in consumer matters generally.

NGOs

Charities have a long and venerable history. Historically in Europe, they played a key role in health, especially through church activity. Today, what we now call NGOs play a major role in many developing countries, and some have a national, international, or even global reach. The main and also the oldest must surely be the International Committee of the Red Cross with its extensive network of national Red Cross organizations, and its counterpart in the Muslim countries, the Red Crescent. It was established in 1863, initially to see to the war wounded, the conditions of treatment of prisoners of war, and prevention of the risks incurred by civilian populations as a result of wars. One of its first achievements was to secure the signature of the International Convention of 1864 in Geneva after the Crimea War for "the amelioration of the condition of the wounded and sick in armed forces in the field" (see the Red Cross website).

Revised and expanded many times since, this is the root document of current international humanitarian law. It rapidly expanded its peacetime functions and its interventions. It is particularly proactive in prevention and relief in violent situations of all kinds from ordinary road traffic accidents to emergency situations and major disaster prevention and management. More recently, a number of charities specializing in health development assistance to the developing world have been set up and expanded. Prominent in the specific field of health are, for example, *Médecins sans Frontières*,[35] *Médecins du Monde*, and *Pharmaciens sans Frontières*.

But health is not about medicine alone, and the contributions of activist groups working against hunger and for development (OXFAM,[36] CARE,[37] ATD Quart Monde[38]), for children (Save the Children[39]), or for human rights observance (Amnesty International, established in England in 1961, Human Rights Watch,[40] etc.) are no less important. These large or small voluntary organizations—which allow themselves less and less to be co-opted without insisting on certain ethical criteria—have awoken the national and international public authorities to an awareness of the utility of a new concept, humanitarian intervention, which allows them easier access to populations at risk of famine or violence and the resulting health consequences, notwithstanding the principles of national sovereignty. A right to take action, albeit still very restricted, is starting to develop in this sense, especially since the Yugoslav and Rwandan conflicts.

2. Resources

From people to budgets, via provider organizations, instruments, and other specific goods, the resources needed to implement a health policy are many and various and clearly cannot be exhaustively treated in a chapter such as this. The human resources have already been touched on in the section on actors, moreover. Suffice it here, then, to expand on that aspect with a review of some data on the diverse situations of those human resources. Other than that, the focus will be on four other aspects, which arguably cannot go ignored: health care facilities, scientific research and training for health professionals, public information and health education, and health budgets.

a. Practitioners

The number of doctors per capita is a traditional indicator of a population's health care coverage. International comparisons must be approached with caution, as the definition of "doctor" varies between countries, in particular with respect to the level of qualification. China's barefoot doctors, in particular, do not meet current Western criteria, and a legacy of lower qualifications remains in the medical profession in ex-Soviet European countries. Even so, the statistics

[36] The Oxford Committee for Famine Relief was set up in 1942 to deal with the consequences of World War II, especially famine. It now pursues a wide range of development-related activities, including in the health sphere.

[37] Founded in the United States in 1945 to provide relief to populations who suffered in World War II, CARE has developed into an international confederation of voluntary organizations focused on tackling hunger.

[38] Set up in France in 1964 from a concern about entrenched extreme poverty in the industrial countries, *Aide à toutes détresses-Quart-Monde* has since expanded its work to include the developing world.

[39] Save the Children (UK) was established in England in 1919 to provide aid to young survivors in post-WWI war-ravaged Vienna. Save the Children (US) was founded in New York in 1932 to help Appalachian children reduced to poverty by the recession. Save the Children now focuses mainly on Third World countries.

[40] Founded in the United States in 1978, initially with the name Helsinki Watch, to monitor the application of the Helsinki Agreement. HRW now deals with human rights violations generally.

[41] Obstetrics was one of the final areas of traditional medical activity to be nearly entirely hospitalized. In France, for example, it is only since the late 1950s that most births have been hospital births (in maternity clinics).

compiled by the WHO are revealing as to the differences currently found in terms of human resources allocated to health. The number of doctors per 100,000 of the population varies from less than 4 in some sub-Saharan African countries (Burkina Faso, Eritrea, Gambia, Liberia, Niger, Somalia, Chad) and in Nepal, to more than 400 in Spain and Norway, as well as Belarus, Georgia and Russia, and even more than 500 in Italy and Cuba. It is 300 in France, 350 in Germany, but less than 170 in the United Kingdom and 190 in Japan, as shown in Table 107–4.

It might be assumed that the developing country deficit might be at least partly offset by a greater number of nurses. Not so. While the number of nurses per 100,000 of population is above 1,000 in Belgium, and even 2,000 in Finland, it is below 100 in more than 60 developing countries (including China), and even less than 10 in such countries as Nepal, the Central African Republic, Liberia, and Haiti. Figure 107–2 clearly shows, for countries with populations over 15 million, that higher medical practitioner density in the industrial countries is associated with an equally higher density of the nursing profession. This is clearly one explanatory factor of the relative failure of the primary health care strategy.

If the nurse-to-doctor ratio can be seen as a crucial issue in primary health care strategies in developing countries, the general practitioner-to-specialist ratio within the medical profession itself is equally so for any health policy. The development of specialties is

undoubtedly a big contributor to health improvement, but in managing existing resources, health policies cannot disregard the way in which patients access specialists. Should they have unrestricted direct access, or should there be compulsory referral by the general practitioner? The answer to this question has clear social, medical, and budgetary implications.

b. Health Care Facilities

Chapter 106 referred to the importance of the role played by hospitals in the history of medicine and health policies, in particular the turning point in Europe when the paupers' hospital became a care and treatment hospital. From that point, medicine in all industrial countries refocused itself entirely on the hospital, turning it into a linchpin of health policies. Not only were all major care and treatment activities gradually integrated into hospitals,[41] up to death itself (with the recent development of free palliative care provision), but the hospital has also become the referral point for all practitioners, both non-hospital and hospital doctors, as well as for medical research and training, as will be seen in the following point, and also actively informs prevention policies.

But "hospital" is a general concept. In concrete terms, organized hospital provision is a complex network ranging from big hospitals (general or specialized) capable of treating a variety of conditions and having the most advanced facilities available, to the local health clinic carrying out basic procedures. This provision is also underpinned to varying degrees according to country and health policy by a linkage between a public sector and a private sector, the dividing line between which may not be clear, especially in countries where compulsory health insurance predominates.

In France, for example, public hospitals have certain public service obligations (be it in teaching or care) that set them apart from private hospitals, normally called clinics, and for which they receive specific public funding. But the State can also place such obligations on private hospitals, which then fulfill a public hospital role. In any event, both are almost wholly funded from semi-public funds through the health insurance funds that reimburse patients for the cost of treatment or pay hospitals directly under agreements made with them. For patients, finally, the main difference between public hospitals and private hospitals derives from the regionalization to which the

[42] The first telethon, organized in New York by Jerry Lewis for the Muscular Dystrophy Association in 1966, was the first time that a million dollars was received in pledges during a television broadcast. The idea has since been taken up in many countries.

former but not the latter are constrained. This means that the public hospital must treat any presenting patient in its area, whereas the private hospital may but need not do so.

In developed countries, this hospital network structures all medical activity and works relatively well because of the scale of resources allocated. Large referral hospitals are established for all large geographical areas as the hub for many second-rank satellite hospitals or clinics of varying sizes and functions, as well as extensive non-hospital medical provision supported by a network of pharmacies, analysis and medical imaging laboratories, and other local diagnostic support provision, let alone nurses, physiotherapists, and other non-hospital paramedical professions. In other words, patients wherever they live are never far from appropriate medical provision and can always be referred to more specialized providers if need be. Nor must we overlook the extensive, highly specialized adjunct services to this basic general provision, like occupational health services, school health services, maternal and child welfare centers, mobile accident units, or home medical care services, to cite only a few key examples.

Imported on a large scale into developing countries, although less during the colonial period than post-independence, this model could not deliver the same instant benefits. How many ultra-modern hospitals have been built, whether more as a result of prestige- than health-for-all-conscious national policies, or rich countries or private foundations focused mainly on giving a high profile to their humanitarian investments, with no consideration either of the real use of the services they would provide or the inordinate operating resources they would demand? Most of these financial black holes, indeed, have fallen rapidly into decay for lack of upkeep before even being shunned by patients when they have become fee-for-service providers under structural adjustment programs. This grossly exaggerated picture may not be true in every case, but the misgivings are there, and they are not new: it was largely in reaction to this confusion that the WHO launched its primary health care strategy in the late 1970s. This is not to deny the value of hospitals nor the ultimate need for developing countries to develop similar provision to that which prevails in developed countries. Even the Chinese barefoot doctors were in touch with hospitals (either for continuing vocational training or for referring cases beyond their skills). But, in a context of finite resources, the construction of large modern hospitals was arguably not the top priority, since the vast majority of the population would never access them, and overwhelmingly suffered from problems that could have been addressed simply and cheaply in the community. This clash between European-style hospital systems and the WHO's primary health care strategy has surely been among the big health policy issues of recent decades in terms of resource allocation trade-offs, and the debate is far from over.

Capital funding trade-offs for medical facilities are crucial in developing countries, but are also an issue in developed countries. Whenever a major technological advance is based on the use of sophisticated and costly equipment, decisions are required on priorities as to where, when, and for whose benefit it should be installed. Even in countries where the decision is theoretically left to private initiative, the government may have to bring a series of assessments into play (external trade balance, special authorizations for medical facilities, etc.), but in those countries where social security systems and state-run health care predominate, the authorities also have to make substantive trade-offs. The issues around the first scanners in the 1980s, then that of MRI (magnetic resonance imaging), are cases in point.

c. Research and Vocational Training

In health no less than other sectors, two kinds of investment are particularly decisive for continued progress: scientific research and training for professionals.

Research

Who pays for research? Where is it done? The answers vary widely according to the country. Most is done in developed countries, which means that in many cases its broad thrust only very imperfectly addresses the needs of developing countries. The delay in developing an AIDS vaccine because of the priority focus on treatment is only one of many examples. Increasingly, however, developing countries are themselves investing significantly in research, and to that extent, improvements are beginning to filter through.

Also, research within each country may be done in universities or specialized research bodies like INSERM (*Institut national de la santé et de la recherche médicale* [National Institute of Health and Medical Research]) in France, or commercially, especially in pharmaceutical laboratories. The former are mainly engaged in basic research, the latter in applied research, although there is no hard-and-fast rule about it, because some aspects of basic research offer more practical spin-off opportunities than others, and much also depends on who first patents the results, which is the main income-generating outcome of the research effort. That in turn is closely tied to the answer to the question: where does the money come from?

In fact, research draws on three main sources of funding: the public coffers, private finance, and public donations. Governments and local authorities in all countries contribute to the research effort, probably but not always somewhat more in countries less prey to free-market ideology. A large amount of public funding is allocated to medical research in the United States, for example, especially from that powerful funding provider the National Institute of Health (NIH) within the U.S. Department of Health and Human Services. The main difference between France and the United States from this angle is due less to the importance of public financing in France than that the NIH allocates its budget on invitations to tender to a wide range of small and medium-sized research centers, especially universities, whereas INSERM itself conducts a key share of medical research (often, admittedly, in cooperation with universities and hospitals) out of its own budget. In all countries, most drug research, and more generally research that leads fairly directly to the design of saleable medical products, is private sector funded. Finally, charities attract levels of donations for research that are increasingly significant for the sectors that benefit from them. In developed countries especially, there is increasing public interest in research advances. A growing number of single-issue voluntary organizations focused on specific diseases manage to raise substantial research funding. Cancer organizations in many developed countries, and more recently, AIDS groups, are cases in point. The latter case is accompanied by a new trend, referred to earlier, where patients and their families are a driving force. Telethons,[42] for example, are most often staged in France by muscular dystrophy support groups like the *Association française contre les myopathies*.

As well as public, business, and voluntary funding, it must also be borne in mind that foundations can also be major sources of research funding. This includes both general-purpose foundations, as well as those with a more specific health research focus, like cancer research.

Training

Since the rediscovery of the tradition of antiquity and the Arab-Muslim contribution to European medicine in the 19th century, medical training in the industrial countries, not to say the world over, has followed approximately the same model, combining university-based theoretical training with hospital-based experiential learning. Almost all faculties of medicine throughout the world have relatively close links to a so-called teaching hospital, which is itself in most cases involved in research activities (Puzin, 1996). Not only do students learn their future profession in the hospital, but their teachers are also attending physicians or researchers in that hospital. Here again, however, it is not just doctors as such that are concerned by this dual theory/practice training, but all medical professions, regardless of level or specialism. This symbiosis between training and clinical practice has been a decisive factor in progress. But it still has its downsides. The functions and conditions of the exercise of hospital medicine are clearly not all-points identical to those of non-hospital medicine, such that medical training in its current form may not necessarily be adequate preparation for the latter's particular requirements.

In this area, however, funding policies are as chalk and cheese. In some countries, like France, where education, including at the university level, is generally paid for by the State or local authorities, medical training is free (or nearly so). In many others, the reverse is true—it is paid for by students themselves or their families, although the cost burden may be partly alleviated by study grants for needy students offered by specialized organizations (including public bodies) or universities themselves.

In free education systems, the mass democratization of access to university education generally, and students' particular attraction to medical career opportunities, has sometimes prompted the public authorities to question the value to the community of training a surplus of doctors. Medical professional bodies themselves have seen in this a danger of impoverishing their profession by fuelling fiercer competition on the market, which they see as incompatible with the dispassionate and stable practice of medicine. In France, for example, faculties of medicine were the first to be authorized to apply selective entry to their students (whereas previously, any secondary school completer could theoretically enroll in the university course of their choice). This measure itself proved insufficient, and an admission quota was introduced to limit the number of students allowed to enter medical training each year, with specific quotas for each discipline. So strictly and indiscriminately was this policy applied that there are now shortages in certain fields, a fact recently aggravated by the growing fear among potential candidates of finding themselves sued for medical malpractice.

[43] French readers may recall Pierre Mendès France's celebrated and widely reported gesture of drinking a glass of milk in public in 1954 to symbolize the importance of changing behavior and finding alternatives to drinking wine and spirits (Collovald, 2000). It was the

Another important aspect of medical training is keeping theoretical knowledge updated during working life. While there is no lack of continuing medical training resources in teaching hospitals, the same is not true of non-hospital medicine. There are two significant resources here: for theoretical knowledge, professional regulatory bodies stage regular symposiums or specialized professional training courses; while on the material and financial front, pharmaceutical laboratories and medical equipment and instrument manufacturers often support this kind of activity. The leverage this gives them over medical practice and health policies should not be underestimated.

d. Health Education

Without delving into the health grounds sometimes adduced to explain various dietary prohibitions or taboos and the ritual ablutions found in nearly all religions, it must be conceded that all cultures contain various health-related dictates. Most of these tend to relate to hygiene and food. In traditional societies, these norms are learned primarily within the family. With the spread of public education, they are increasingly transmitted in the classroom. And schooling has played and still plays a major role in the improvement and maintaining of health—not only through the specific health education that may form part of the curriculum, but also quite simply by raising general educational levels. In France, for example, the debate as to whether Pasteur, with his discovery of the role of bacteria, or Jules Ferry, with compulsory free education, did most to improve the health of the population is meat for endless discussion; the one certainty is that both were major contributors. Likewise, in developing countries, the role of rising female educational levels in infant mortality decline has been abundantly emphasized (J. Caldwell, 1979, 1986). Not only does education make mothers more apt to seek information on optimum dietary requirements, preventive health, and treatment for their children, but it also gives them access to more independence and decision-making power within the family, assets that they can leverage to obtain the means to do the best by their children.

But the development of modern medicine and the accelerating pace of advances in knowledge and techniques mean that early learning is no longer sufficient to permanently imprint the healthiest behaviors and attitudes. Health education campaigns directed at both adults and children have become a major instrument of health policies (J. Caldwell, 1999). They tend to be targeted directly on health-related behavior or to popularize new health instruments whose collective effectiveness depends on their mass uptake.

The idea of health education campaigns may be either to discourage health-damaging behavior or to encourage healthy behavior. The "discouragement" side can be illustrated by one of the biggest mass education campaigns in developing countries with very high diarrhea-induced child mortality rates, where mothers were taught that children were at risk from dehydration and that the widespread practice of withholding fluids from the child was a recipe for disaster. Coupled with campaigns to promote oral rehydration salts, education was a big contributory factor in bringing down child mortality levels. Similar examples abound in the developed countries as well, such as campaigns on the ingrained belief in the mythical benefits of alcohol among the French,[43] Russians, and Poles, or against the health traps of drug abuse or the hyped-up "macho man" culture of speeding and other risk-taking behavior. On the health-promoting side, countless campaigns on hygiene—the point of which was already grasped by 19th century-hygienists (see Chap. 106)—have often drawn heavily on the discovery of the germ theory of disease (the basis of which is now clearly understood) to strengthen or refocus age-old practices.

In all these areas, health education campaigns have been a potent means of action for health policies. In one renowned example, it may even be said that knowledge was advanced by the campaign. This was the celebrated survey of British doctors on smoking and the incidence of respiratory tract cancer symptoms among their patients, the first result of which was to raise awareness and reduce smoking among doctors themselves even before the survey findings could be used to persuade the authorities of the value of an anti-smoking campaign (Royal College, 1962). This was the springboard for the preventive health drive that brought down tobacco consumption in Britain and led to a decisive decline in respiratory system cancer-related mortality in the United Kingdom (Vallin and Meslé, 2001). Health education campaigns are also behind the attempts to reduce or control cholesterol

starting point of a long campaign that began to deliver results in a falling alcohol-related death rate from the mid-1960s. Conversely, while Mikhail Gorbachev's draconian ban on alcohol sales to the public gave an immediate surge in Russian life expectancy in 1985, a pattern of decreasing life expectancy soon reasserted itself when the measures were relaxed (Meslé *et al.*, 1994), largely due to a failure in having prepared and supported the measures by a mass information and education campaign.

levels following the discovery of its connection with ischemic heart diseases.

Health education campaigns are also a key way to promote the use of new health instruments developed for prevention or treatment. Vaccination is surely the prime example, where robust mass information and education campaigns were behind the large-scale dissemination of vaccines and gaining public acceptance for making some compulsory. The WHO Expanded Program on Immunization (EPI) in particular was, and still largely is, based on this means of spreading vaccination coverage levels among children worldwide. And little persuasion is needed about the vital importance of information and education in the behavioral changes needed to stop the spread of HIV/AIDS, given what is known of its means of transmission, nor the role that both these forces for action play in road accident prevention campaigns. The antispeeding campaign recently launched in France, for example, marks a turning point in the use of driver education and acceptance of responsibility. Instead of hiding the new radar speed traps to catch offenders, advance warning is given of their presence, and the campaign relies on this openness to persuade drivers to watch their own speed, using this system as an aid to self-control rather than trying to find ways of beating a new form of clampdown.

e. Health Funding

Detailed consideration of the complex relationships between health economics and health policies is clearly beyond the scope of this chapter. But this review cannot be brought to an end without a brief look at the varied ways in which financial resources are allocated to health in the different countries of the world. The data for 2001 collected by the WHO (2004) are used here, but limited to countries with populations over 15 million for comprehensible comparisons that nevertheless encompass most of the range of situations covering the overwhelming majority of the world population. These figures obviously must be approached with caution, as the data collected are those supplied by each country to the WHO, and consistency issues may arise between the estimates produced. Nevertheless, the WHO provides two sets of estimates, one presented in U.S. dollars at official exchange rates, the other in dollars converted at purchasing power parities or "international dollars." The data analyzed here are based on the estimates in international dollars. Arguably, however, the broad traits they reveal are sufficiently pronounced to reflect an undoubted measure of the reality.

To Each According to Its Own Means

The most striking thing about the WHO figures is that when it comes to translating the rhetoric and political spin about reducing world inequalities in health into money terms, the limits are soon reached. As Figure 107–3 shows, there is an almost perfect fit between per capita health expenditure and gross domestic product (GDP). Among the 60 countries with populations over 15 million for which data are available, the income scale range from under 400 (Democratic Republic of Congo and Ethiopia) to over 35,000 (United States) international dollars per capita, and the self-same countries are found at the extremes of the total per capita health expenditure distribution, which itself ranges from under 15 in Congo and Ethiopia to nearly 5,000 in the United States. There is a very high correlation coefficient of 0.960, although the best fit of the clusters would clearly be more a slightly concave curve than a straight line. All the wealthy countries naturally fall into the upper right quadrant of the scattergram, with the poor countries in the lower left quadrant, while a handful of emerging countries, already well on the way to economic development (South Korea, Argentina, Chile, Saudi Arabia) occupy the hesitant middle ground between the two extreme clusters. Wherever "health for all" would dictate that the distribution of health funding should maximally reflect needs, the stark fact appears to be that they are allocated by reference to each country's own means.

The trend is even more pronounced than shown on Figure 107–3, because not only do the rich countries spend more on health than poor countries, but they also allocate a bigger share of GDP to it (Figure 107–4). At $35,000 per capita, the United States spends nearly 14% of its national income on health, whereas Congo and Ethiopia spend under $400 per capita, or 3.5%, on health.

Differential Health Efforts

Notwithstanding the very strong linkage of health budgets to national wealth, there is a clear differential to be seen in the effort made by each country for its population's health. With a correlation coefficient of 0.80, the Figure 107–4 clusters are significantly less well aligned than those of Figure 107–3. For the same level of per capita GDP, the health expenditure share of GDP can vary widely, especially in poor countries. For the same very low per capita income (under $1,500), Madagascar and Myanmar spend just 2% on health, compared to Kenya's 8%—four times more. A gap, admittedly less significant, is also seen between very rich countries on broadly the same level: with a

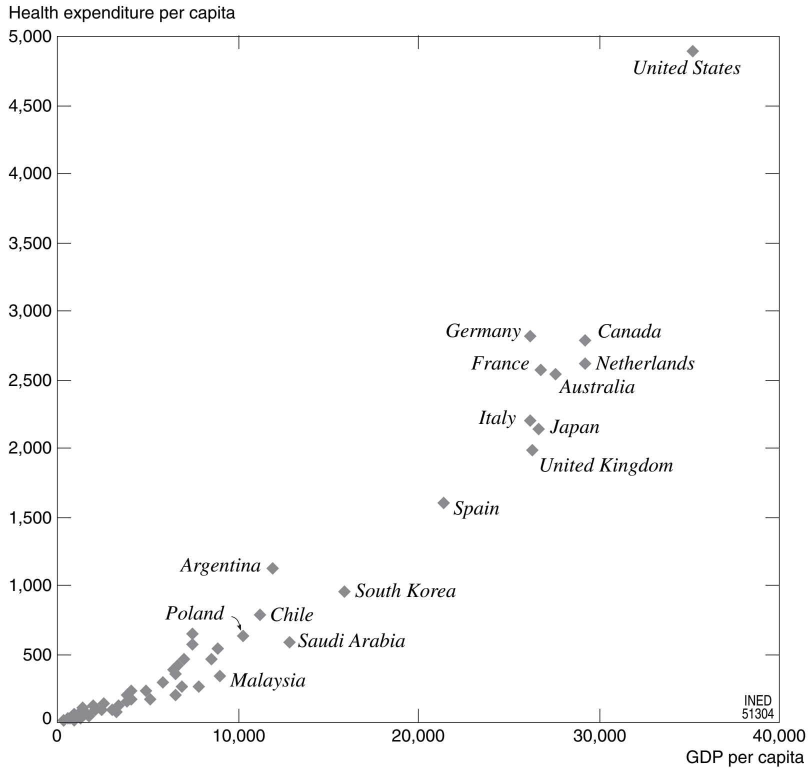

FIGURE 107–3 Total per capita health expenditure relative to per capita gross domestic product in 2001, in countries with populations over 15 million. (Source: WHO, 2004.)

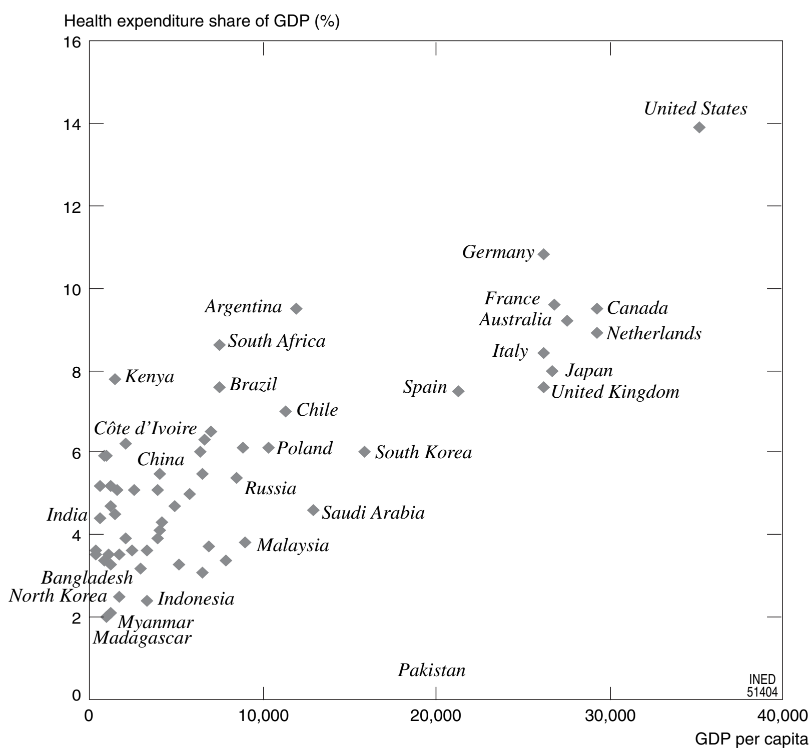

FIGURE 107–4 Total health expenditure share of GDP relative to per capita GDP in 2001, in countries with populations over 15 million. (Source: WHO, 2004.)

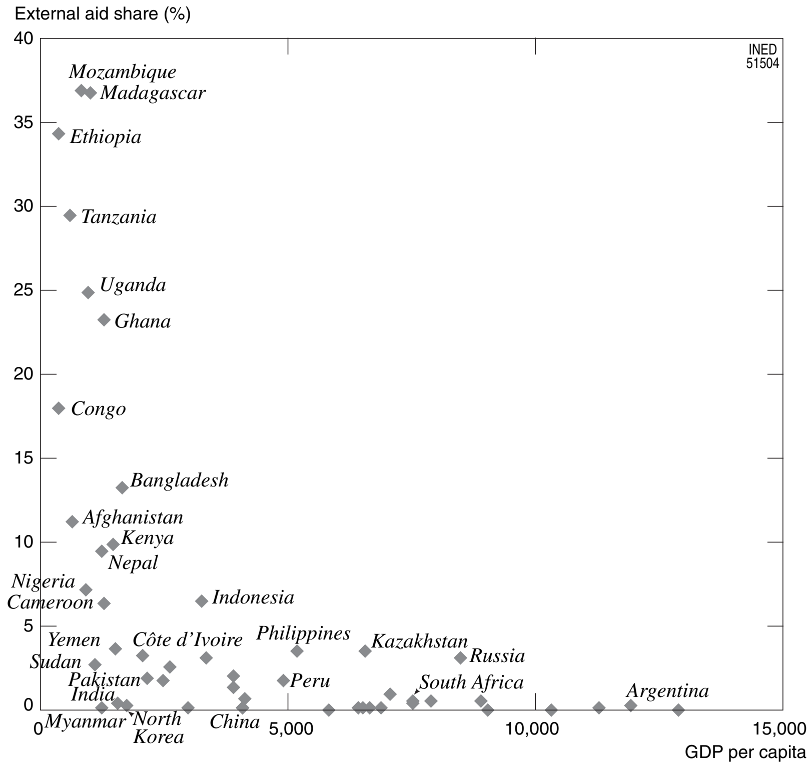

FIGURE 107–5 External aid share of total health expenditure relative to per capita GDP in 2001, in countries with populations over 15 million. (Source: WHO, 2004.)

per capita income of $26,200, Germany spends 10.8% of its GDP on health, and the United Kingdom just 7.6%. Conversely, markedly lower-income countries like Argentina ($12,000 per capita) and even South Africa ($7,500) spend as big a share of their GDP on health as does France or Italy.

The Confusing Role of External Aid

It might be thought for the poorer developing countries at least, that external aid for health (included in the WHO computation of total health expenditure) lies behind this diversity. Figure 107–5 shows that this share is highest in the poorest developing countries. But it also shows the extreme inequality in treatment of countries on the same level, especially the poorest ones. For a per capita income under $2,000, the external aid share of health expenditure varies from over 35% (Mozambique, Madagascar) to close to 0 (Myanmar, India, North Korea). Nor is there any evident link with the previous observation; quite the contrary since, among these countries, Kenya's 8% of GDP spent on health is less than 10% funded for the purpose by external aid, while the maximum level of external funding is received by the two countries which spend only a total of 2% of their GDP on health. In other words, it is not the poorest countries making the most effort that get most assistance.

Figure 107–5 also clearly shows how middle-income countries are affected by unequal treatment from international aid. So, albeit hard hit by AIDS, South Africa's health expenditure is less than 0.5% funded from external aid, while higher per capita GDP Russia's health spending is over 3% covered by external aid—more than 6 times more.

The Publicly Funded Share

On a different note, a comparison of the share of public funding from all sources (state, local authorities, compulsory insurance schemes) in health expenditure reveals two completely different worlds (Figure 107–6). In poor countries, there is almost no connection between total health expenditure and the publicly funded share of spending. The bracket of under $50 per capita spent on health includes, for example, North Korea (nearly 75% publicly funded) and Myanmar and Sudan (under 20% publicly funded). In this bracket—between $100 and $200 per capita on health—exactly the same gap between public contributions recurs, widest in Uzbekistan and Algeria, narrowest in India and Côte d'Ivoire. Ostensibly, indeed, the extent of the

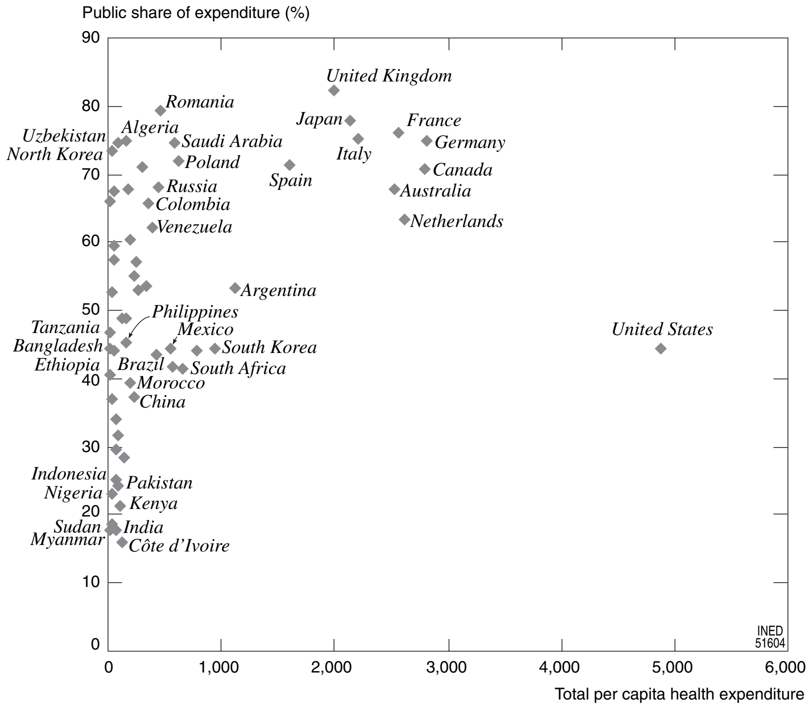

FIGURE 107–6 Public share of health expenditure relative to total per capita health expenditure in 2001, in countries with populations over 15 million. (Source: WHO, 2004.)

public effort in poor countries, which still falls far short of the needs, has little effect on total expenditure and varies more with the political regime than any real health agenda.

The situation is very different in wealthy countries, where there is a close correlation between total health spending and the public share of expenditure. It is highest in the United Kingdom (over 80%) where total per capita expenditure is lowest of all the rich countries included in Figure 107–6 (only Spain is lower, but it is also appreciably less wealthy than the United Kingdom). Conversely, the public share is lowest in the United States, where total health expenditure is well above the rest.

When looking at Figure 107–6, it is difficult to understand why collective health care funding systems have been so hard hit in the developed countries in recent decades. The free-market ideology, which has held the world economy in almost unchallenged sway since the fall of the Berlin Wall, operates in health matters on the twofold principle that the public management of economic affairs is nonsense because the squandering of resources can only be avoided by private enterprise operating in response to market constraints, and that health is a good like any other and no exception to the rule. The conclusion is then obvious: to halt the recent staggering increases in health expenditure, no time must be lost in returning more of health provision to private hands. The very opposite is what we are seeing here: the higher the public share of health spending, the lower total expenditure. The case of the United States is extreme to the point of distortion: while the public share of total spending is barely over 40%, not only does it have by far the highest per capita spending in the world (approaching $5,000), but also its spending accounts for the biggest share of national income (nearly 15%). For all that, it cannot be said that it has a higher life expectancy or quality-adjusted life years than anywhere else. By contrast, it is reasonable to wonder whether inequalities in health and mortality may not be higher than might be expected from such a level of expenditure. But that would be to beg the question of one of the issues in the following chapter, which analyzes health policy outcomes.

APPENDIX Acronyms

English Names		French Names	
[AFM]		AFM	Association française contre les myopathies
AIDS	Acquired Immunodeficiency Syndrome	SIDA	Syndrome d'immunodéficience acquise
[AME]		AME	Aide médicale d'État
[AMG]		AMG	Aide médicale gratuite
[ATD-QM]	ATD Fourth World	ATD-QM	Aide à toutes détresses—Quart-Monde
[BCG]		BCG	Bacille de Calmette et Guérin
[CEPED]		CEPED	Centre français sur la population et le développement
[CHU]		CHU	Centre hospitalier universitaire
[CMU]		CMU	Couverture médicale universelle
[CNAM]		CNAM	Caisse nationale d'assurance maladie
[DDASS]		DDASS	Direction départementale de l'action sanitaire et sociale
DDT	Dichloro-diphenyl-trichloroethane	DDT	Di (para-chloro-phenyl)-trichloroethane
EPI	Expanded Program on Immunization	PEV	Programme élargi de vaccinations
FAO	Food and Agriculture Organization	[FAO]	Organisation pour l'agriculture et l'alimentation (OAA est inusité)
GDP	Gross Domestic Product	PIB	Produit intérieur brut
HBV	Hepatitis B virus	VHB	Virus de l'hépatite B
HIV	Human immunodeficiency virus	VIH	Virus de l'immunodéficience humaine
HRW	Human Rights Watch	[HRW]	
IAEA	International Atomic Energy Agency	AIEA	Agence internationale pour l'énergie atomique
IBRD	International Bank for Reconstruction and Development	BIRD	Banque internationale pour la reconstruction et le développement
ICPD	International Conference on Population and Development	CIPD	Conférence internationale sur la population et le développement
ICSID	International Centre for Settlement of Investment Disputes	CIRDI	Centre international de réglement des différends internationaux
IDA	International Development Association	AID	Association internationale de développement
IFC	International Finance Corporation	SFI	Société financière internationale
IHR	International Health Regulations	RSI	Règlement sanitaire international
ILO	International Labour Office	BIT	Bureau international du travail
ILO	International Labour Organization	OIT	Organisation internationale du travail
IMF	International Monetary Fund	FMI	Fonds monétaire international
[INED]		INED	Institut national d'études démographiques
[INSERM]		INSERM	Institut national de la santé et de la recherche médicale
[IRD]		IRD	Institut de recherche pour le développement
IUSSP	International Union for the Scientific Study of Population	UIESP	Union internationale pour l'étude scientifique de la population
[IVS]		IVS	Institut de veille sanitaire
JAMA	Journal of the Medical Association of America	[JAMA]	
LN	League of Nations	SDN	Société des nations
MDG	Millennium Development Goal	[MDG]	Objectif de développement pour le millénaire
MGA	Muscular Dysmorphy Association	[MGA]	
MIGA	Multilateral Investment Guarantee Agency	AMGI	Agence multilatérale de garantie des investissements
MRI	Magnetic Resonance Imaging	IRM	Imagerie par résonance magnétique
NGO	Nongovernmental Organization	ONG	Organisation non gouvernementale

CHAPTER

108

Health Policies: Can the Results Be Evaluated?

JACQUES VALLIN AND FRANCE MESLÉ

Institut national d'études démographiques (INED), Paris, France

Can the results of health policies be evaluated? There is no simple answer to this question. First of all, it is possible to accept several notions concerning health policies according to whether one considers a health policy, in the strict sense, as being a policy defined by a health authority with the precise objective of improving health, or whether one refers, on the contrary, to all public measures by whatever public body concerned which render it possible, knowingly or unknowingly, to improve health. Moreover, whatever limits are set, the evaluation of the global effect of the policy implemented must be distinguished from that of the specific effects obtained from a given measure taken to attain a given objective. Between the two, one might focus on either the action of a given collective body and attempt to evaluate the global result of the measures it has taken or, in another register, consider a given objective and measure the results obtained in this precise area thanks to a raft of measures taken by the different organizations concerned. One might also vary this almost infinitely by multiplying the different possible combinations of actors/objectives/measures taken. We will of course not be able to review all the possible subjects of evaluation, but we will attempt to give a few examples at different possible levels of evaluation.

However, the complexity of the subject is far from being the only obstacle to obtaining an answer. We will only refer to two obstacles, which are sometimes insurmountable given the current state of knowledge. On the one hand, if one may truly speak of a result, can any such result really be attributed to a public measure? Or may it not be linked to other factors? The question is already a very tricky one when it comes to measuring the effect of a specific measure. It is true that we have in this case a certain number of theoretical methods, but often the data from observations are missing in order to apply such methods unless a research-action program is designed beforehand with the measuring of the result as an inherent aspect. However, the situation becomes practically insoluble when looking at the global results of policies. In most cases, it will be necessary to resort to explanations that are practically unverifiable, unless one day, observation systems should become available, such as those that will be evoked in the following chapter by Viviana Egidi and Vittoria Buratta, possibly blazing the trail for a complete monitoring of operations.

On the other hand, measures taken to improve health may require varying lengths of time before producing an effect. Therefore, there are even fewer cases in which perfectly adequate data for measuring results are available. Moreover, the effect of a measure taken may be spread over time. A sudden reduction in alcohol consumption may, for example, have immediate effects on the mortality of alcoholics whose death was only awaiting the absorption of the last, lethal dose, but it will also have effects in the longer term on the evolution of different ailments linked to alcohol. There are even cases where one measure taken may have positive effects in the short term and negative effects in the long term. For example, a campaign for the eradication of malaria based on the destruction of mosquitoes using an insecticide may result in a rapid decline in the endemic disease in the short term, but if this also leads to the development of the resistance of mosquitoes to insecticides, the long-term consequence may be a strengthening of the disease.

Therefore, we cannot assure the reader that after reading this chapter he or she will have complete and final answers to the question. However, we do hope to provide a few ideas as to how to approach the problem by preparing the terrain on three levels: the appraisal of the global results of a health policy, the measuring of the specific effects obtained by a program targeting a specific pathology, and, finally, the evaluation of the impact of specific measures taken in favor of target groups. On the other hand, in each case, we will also try to do more than answer the question, "Is it possible to measure?" since, whether the answer is positive or negative, we will at least try to discuss, each time, the most plausible hypotheses concerning the reality of the effects obtained.

I. GLOBAL RESULTS: HEALTH POLICIES AND INCREASED LIFE EXPECTANCY?

There are two potential pitfalls in trying to globally assess the results of a health policy. The first, already mentioned, is that of not being able to decide between a stricter or wider definition of the health policy. Should it be limited exclusively to the actions of organizations specifically in charge of the question, as for example, a ministry of health? Certainly not, if we wish to remain consistent with the position adopted in the previous chapter. But should all collective actions aimed at improving health, even if not acknowledged as such, be included? Here again, we would adopt a wider view. After all, has not the World Health Organization (WHO) itself explicitly included in its strategy of primary health care the development of basic agricultural production? And it is a known fact that education has an impact on mortality decline. Therefore, all policies having an effect on health must be evaluated. Furthermore, a health policy is decided not only at the government level, but many other collective bodies, whether infranational or supranational, public or private, play a part, including the populations concerned, whether through a juxtaposition of converging individual behaviors or through associations. However, is there not another pitfall, that is, the risk of confusing the results of the policies (in the wider sense of the term) that have an effect on health and life expectancy and those of the simple development "of the progress of the human mind" in the way Marie-Jean-Antoine de Condorcet ([1795]) understood it? There are two pitfalls therefore, but also two ways of considering things globally, which may combine, since if one considers that man is a "political animal" according to Aristotle[1] and that all human progress is fundamentally political in nature, why not extend our ambition so far as to evaluate the effect of this human progress on human health and life expectancy? But what progress and in what field? In the medical domain? Or in the economic and social domains? We have come full circle. Finally, are not all attempts at global evaluation in vain? Let us at least briefly evoke what such an evaluation might be before admitting that the context must undoubtedly be taken into account, simply for reasoning in terms of comparable economic development or better maybe, at a comparable stage in the health transition.

1. Can a Global Approach Be Attempted?

Can it be said, that in a given country, life expectancy is higher because, globally, all of the policies that have an influence on it are better? In wanting to encompass everything, is there not a risk of being reduced to expressing such banalities as "The best health policy is that of the country that has the highest life expectancy"? In that case, it would obviously be easy to claim without even having to check the figures that the policy of the United States is better for health than that of Nigeria! Would it be more credible to base the comparison no longer on the level of life expectancy attained but on its progression observed over a given period? This is far from certain. Can it be said, for example, that policies implemented in the second half of the 20th century were better for health in Tunisia than in France, since from 1946–1951 to 1997 life expectancy in the former country improved by almost 40 years, increasing from 33.3 years to 71.9 years (Waltisperger *et al*., 2001), whereas it only increased by 12 years in France, from 65.8 years in 1948 to 78.5 years in 1997 (Vallin and Meslé, 2001a)? Obviously the comparison is not justified, as the effort concerning health (in the wider sense) to be deployed to gain years of life expectancy starting from the age of 33

[1] In his "Politika" Aristotle (384–322 BC) insists on the high degree of social organization of man as crowned by the organization of the state (Aristotle, [1874]. As Marcel Prélot wrote (1961, p. 6): "Ancient man, as defined by Aristotle thus appears as a "civic animal." The scope of the definition is greatly reduced when "zoon politikon" is translated as "social animal." The animal is also social, but only man is political. Instead of living in herds or hordes, his specific characteristic is to live integrated within the social organism constituted by the Polis, the City; and this is for him, both a natural and ideal necessity."

is not at all the same as that which would enable an improvement of the same magnitude over the age of 65. Would it be more justifiable to say that Tunisia has nonetheless implemented a better health policy than France because France took 160 years to go from a life expectancy of 34.9 years in 1806 to 71.5 years in 1967 (Vallin and Meslé, 2001a)? Even less so, it is the historical context that is not comparable, the medical means (to mention only the most obvious) having changed radically in the meantime. A better question would undoubtedly be to ask whether, in a given country, a change in policy produced a result in terms of health. But what kind of change? It is possible to imagine what a study of a specific change of direction concerning health practices, food production, or education might be: we will deal with the evaluation of the results of such changes in Section 2. But does the question lend itself to a global approach? This is doubtful. It would be necessary to refer to a strong policy change, globally revolutionizing policies followed in all areas. Let us explore two possibilities: comparing the evolution in the life expectancy of a country before and after a revolution or comparing two countries according to whether or not they have experienced the revolution in question.

a. Before and After a Revolution?

There have been plenty of revolutions during the last three centuries; what are lacking, however, are the data to explore this first approach. With the instruments for historical reconstructions available to us today (see Chapter 126), it would be conceivable to launch a vast research project on this question, but for now we will have to be content with answering it with just a few rudimentary elements.

According to the answers of the major historical demographic survey conducted in France by Louis Henry (1980; see also Fleury and Henry, 1958; Séguy *et al.*, 2001), the French Revolution seems to have brought about new policies that resulted in a leap forward in life expectancy, especially through a decline in infant mortality. According to this survey, life expectancy stagnated between ages 27.7 and 28.9 during the three decades of the 1760s, 1770s, and 1780s (Blayo, 1975) but increased by 10 years in the four following decades, reaching 38.8 years in 1820–1829.[2] It is a fact that important economic and social reforms were in preparation under the Ancien Régime and they might have also resulted in a marked improvement in life expectancy, but it is still possible that the Revolution, in spite of the negative effects of the violence, which undoubtedly would not have occurred without it, amplified the increase in life expectancy.

Can the same be said of the October 1917 Revolution in Russia? There is unfortunately too few data to risk such an assumption. But what can be said, for instance, of the advent of the Communist regime in a country such as Czechoslovakia? The fact that it occurred among the ruins caused by World War II obviously poses a problem. However, comparing only two periods of peace from 1921 to 1937, life expectancy in Czechoslovakia increased for men by 8.5 years in 16 years, progressing from 46.4 years to 54.9 years (OFS, 1974), whereas in the same lapse of time (1950–1966), it only gained 6.3 years under the Communist regime, from 60.9 to 67.3 years (OFS, 1980). The value of such a comparison may seriously be called into question. On the one hand, increasing life expectancy beyond the age of 61 years in the 1950s was perhaps more difficult than increasing it beyond the age of 46 in the 1920s. But above all, due to a lack of reliable data between 1937 and 1950, to what should the 6-year increase be attributed? To the last years of the Czechoslovakian democracy? To the German occupation? Or to the first years of the Communist regime? Unless it was simply due to the effect of the arrival of antibiotics, an effect independent of the political regime in place.

It would be interesting to discuss the case of China which, according to United Nations estimates (United Nations, 2003), had an increase in life expectancy of close to 18 years in the 15 years after Mao Tse-tung took power, increasing from 42.9 years in 1950–1955 to 60.6 in 1965–1970. Although we lack any solid point of comparison for the period before that, it is hard to deny the fact that this period marked a break in the evolution of the health status of the Chinese population (in the third part of this chapter we will come back to this issue). However, in Cuba, a country often cited as an example for its improvements in terms of health compared with other poor countries, when Fidel Castro came to power in 1959–1960, there was no break in the evolution of life expectancy estimated by the United Nations. Another interesting point to discuss would be that of the effects of decolonization, namely in Africa. In the case of Tunisia, for example, it may be assumed that the policy implemented during the first decade of Independence was better for improving the health of the population than the policy implemented by France during the last decade of the colonial era

[2] The survey conducted by Louis Henry does not provide results on all of the intermediary decades, but for females it gives the following progression: 28.1 in 1780–89, 32.1 in 1790–99, 34.9 in 1800–09, 37.5 in 1810–19 and 39.3 in 1820–29 (Blayo, 1975). According to our own reconstruction for the 19th century it seems that life expectancy for the two sexes reached close to 35 years from 1806 and 40 years in 1823 (Vallin and Meslé, 2001a).

because from 1956–1961 to 1968–1969 life expectancy leapt forward by 10.6 years, whereas from 1946–1951 to 1956–1961 it had only increased by 6.7 years (Waltisperger *et al*., 2001). But in a country like Niger, United Nations estimates tend to indicate the opposite, with an increase of only 4.0 years in life expectancy in the 15 years following Independence compared with 4.5 years in the previous 15 years.

Another possible field of study for this approach is the fall of Communism in Europe. The case is all the more interesting because it concerns countries that had experienced, since the middle of 1960s, a long period of stagnation, of regression even, in life expectancy before abandoning the Communist regime. But here again, the same event, this time occurring at exactly the same moment and in countries with highly comparable standards of living and health statuses, shows rather different results. Whereas countries such as Russia or the Ukraine plunged deeper into crisis (Meslé and Vallin, 2003b), others, such as Poland, the Czech Republic, and Hungary, started to experience an increase in life expectancy just after the fall of the Berlin Wall (Meslé, 2004b).

This global historical approach is not yet conclusive. It is true that major political changes rarely have a neutral impact on changes in health, but, assuming that the data exist to conduct a highly global analysis, such an analysis would be of little interest if it were not completed by an in-depth study of the aspect of the change that had a real effect on the health situation.

b. With or without a Revolution?

It would be possible to enhance the analysis by comparing, for a given event, two countries in other respects rather similar, one of which would have experienced the event and the other not. For example, a comparison may be attempted between the French Revolution and the case of England or Sweden. We saw that France had gained 11 years in life expectancy between 1780–1789 and 1820–1829. According to the estimates of Wrigley and Schofield (1981), between 1791 and 1826 England only gained 2.6 years (passing from 37.3 years to 39.9) and, according to estimates of Ingvar Holmberg (1970), Sweden only gained 1.6 years (from 37.9 years to 39.5). However, we hesitate to attribute this increase in life expectancy in France to the Revolution alone. One may well be intrigued by the fact that in all three cases, the point of arrival is the same (approximately 40 years life expectancy around 1826), which means that France in 1789 was very far behind Sweden and England. The success of revolutionary policies did no more than enable France to catch up. It seems that it was not so much due to the fact that the policies were better than those implemented in England and Sweden but that those of the French Ancien Régime were worse. There again, an in-depth analysis of the effects of the different changes brought about by the Revolution would be indispensable in order to reach a conclusion.[3]

Closer to home, one of the most interesting comparisons is the one of the changes observed between the two Germanys after the creation of the Federal Republic (FRG) and the Democratic Republic (GDR), in 1949. Starting with very similar levels (even though very precise data are missing), life expectancy in the two Germanys evolved rather differently after their separation (Figure 108–1). Initially, after a few years of Communist rule, the life expectancy of East Germans caught up with, and even overtook, that of West Germans, the progression of which started to flag at the beginning of the 1960s. Therefore, in the period between 1970 and 1974, life expectancy in the GDR maintained a half-year advance on that of the FRG. Milton Roemer (1985) attributed this phenomenon to the fact that while West Germany had just kept the health insurance system implemented by the Bismarkian reforms of the 19th century, East Germany had developed a health system entirely run by the State and which focused on prevention and universal access to comprehensive health services free of charge. This explanation was all the more plausible as the difference in life expectancy, to the advantage of the GDR, was accompanied with an even greater difference in the standard of living to the benefit of the FRG. However, a short time afterward, whereas the differences between policies remained, life expectancy in the FRG resumed a rapid increase while that of the GDR stopped growing. On the eve of reunification, the difference was much greater, but this time it was to the advantage of the FRG: 2.5 years in 1989 and even 3.1 in 1990.

This reversal of the situation can only be explained if one places oneself in the more general context of the health crisis that hit all of the European countries in the Communist block from the mid-1960s. In all the industrialized countries, when the decline in infectious mortality was such that to obtain new substantial increases in life expectancy it was necessary to counter the growing negative effects of industrialization and to fight mortality in new areas, Western countries managed to control manmade diseases and found

[3] Whilst bearing in mind the fact that the differences in life expectancy observed for the 18th century may have been partly due to differences in the methods of estimation employed (see Chapter 68).

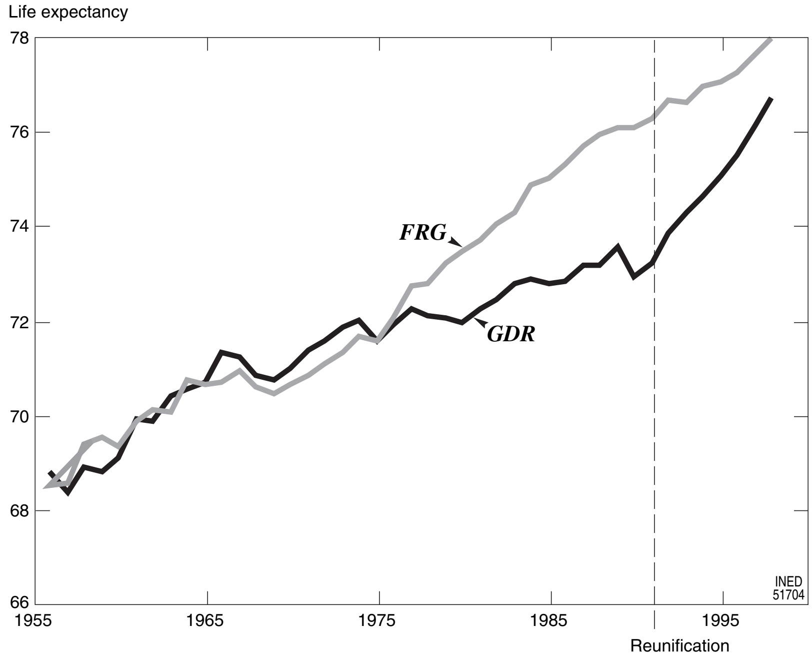

FIGURE 108–1 Compared changes in life expectancy at birth in East Germany and West Germany (both sexes). (Source: Human Mortality Database: http://www.humanmortality.org; Scholz and Maier, 2003.)

means of rapidly reducing cardiovascular mortality that Eastern block countries were unable to adopt, while the burden of manmade diseases was developing (Meslé and Vallin, 2002). However, in a third phase, with the reunification and the extension within the GDR of the West-German political system, the increase in life expectancy of East Germans accelerated, making up for a great deal of the difference in a few years. This difference was of only one year in 1999.

Two major conclusions stem from these examples and especially from the latter. On the one hand, if one wishes to build a remotely intelligible reasoning based on international comparisons, one must absolutely be able to distinguish between the main factors behind improved health, and if one wishes to confine oneself to a global comparison the minimum requirement is undoubtedly to make sure that standards of living are relatively similar from the outset. Moreover and, maybe, above all, it should be noted that the same global political system may be advantageous for health at a given stage of the health transition and a disadvantage at another stage. It is therefore necessary to reason in terms of equal stages in the health transition.

2. At an Equal Level of Economic Development

In the study he carried out in 1985, Milton Roemer sought to compare, two by two, developed countries (with the exception of the two Germanys) having not only comparable per-capita incomes but also, and more generally, major sociocultural similarities. He thus compared the United States and Canada, Belgium and the Netherlands, Austria and the United Kingdom, and New Zealand and Australia.

As he observes, in spite of a slightly lower rate of income per capita, a clearly less hospitable climate, and a substantially smaller share of national income dedicated to health expenditure, Canada benefited from a life expectancy greater—by one year—than that of the United States.[4] He attributed this difference to the fact that the United States is one of the few Western industrial nations that has not adopted a collective system of health care coverage, whereas since 1962 Canada has had a provincial-federal program for medical and hospital insurance covering practically the whole population (Roemer and Roemer, 1981). Even better, according to Milton Roemer, other countries, where income per capita is substantially lower than in the United States, such as Japan, Sweden, and the Netherlands, also have higher life expectancies, thanks to their collective coverage of health care expenditure. Roemer goes on to say that the argument

[4] Milton Roemer quoted the latest result available at the time which were life expectancies for 1977: 74.3 in Canada and 73.3 in the United States. In 2000, the difference, in the same direction, was of 2.2 years for women (with 81.9 years compared with 79.7) and 2.4 for men (76.7 compared with 74.3).

often put forward to challenge the assumption of a greater heterogeneity of the American population, which includes large African-American and Latin-American minorities whose health is apparently weaker, is not valid because even when only the white American population is considered, life expectancy in the United States remains lower than that of the overall population of Canada and of those of the other countries quoted.

In the same way, even between countries with advanced social welfare systems, Milton Roemer showed that the result in terms of life expectancy is better when the social welfare coverage is complete. He thus attributed the difference in life expectancy observed between Belgium and the Netherlands at the end of the 1970s to the fact that, in the Belgian system, health insurance was much more imbued with liberalism (imposing on patients a large financial participation, which penalized the poor) than the Dutch system in which almost everyone could consult doctors without paying anything. And it is for the same reason that the life expectancy of Austrians at the time was lower than that of the British who apparently had a lower standard of living or of that of the Australians which was no higher than life expectancy among New Zealanders, although their income per capita was almost twice as high.

In the developing world there are also many examples of countries that are culturally similar and which had, at the outset, comparable living standards but where life expectancy has evolved differently. Figure 108–2 presents several cases based on life expectancy estimates provided by the United Nations for the period 1950–2000 (United Nations, 2003). In East Africa, for example, it is possible to contrast, at least in a first instance, the high increase in life expectancy observed in Kenya and Zambia to the slow progress of Uganda and Malawi. It probably is due to the substantial efforts made by Kenya and Zambia in favor of economic and social development in general, but also of primary health care. Subsequently, however, AIDS has hit these countries more violently, eating away at a large proportion of the progress made. Is this to say that their mode of development has made them more fragile in the face of the AIDS epidemic? It may also be that Uganda, which has resisted the epidemic better than the other countries in spite of being hit first, has adopted a better strategy in the fight against AIDS.

In Western Africa, before the advent of AIDS, Côte d'Ivoire (Ivory Coast) or Benin apparently implemented policies for development and for health that were much more efficient than those implemented in Niger. It may of course be said that Côte d'Ivoire was able to bolster such policies thanks to much more favorable economic prospects, but this was not so true for Benin. On the other hand, as in the case of Benin, Côte d'Ivoire was harshly hit by AIDS while Niger was spared, which reduced the difference in life expectancy to nothing. In West Africa again, two English-speaking countries belonging to the same subregion, Sierra Leone and Gambia, had life expectancies that diverged greatly. Whereas Gambia, a small country quietly implementing a development policy that also addressed the issue of health, had a much faster-than-average increase in life expectancy for sub-

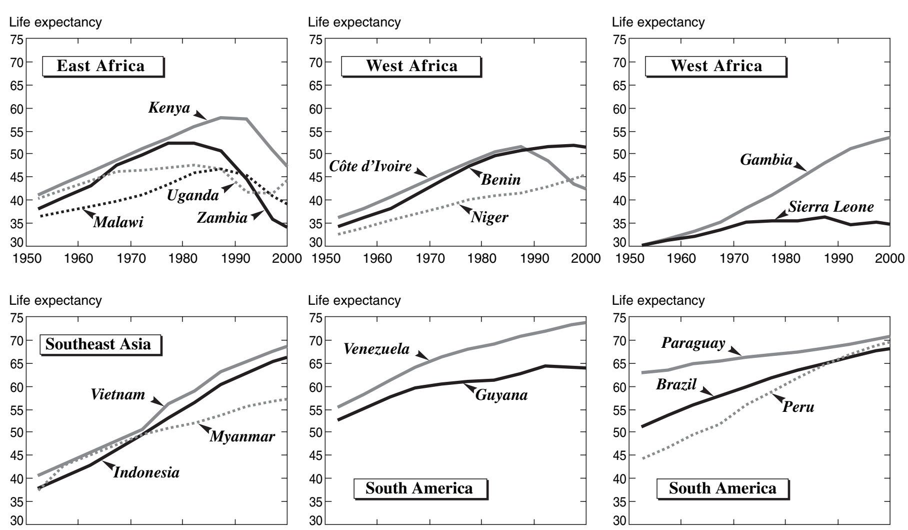

FIGURE 108–2 Compared changes in life expectancy in several countries belonging to the same cultural area and with comparable baselines for standards of living. (Source: United Nations, 2003.)

Saharan Africa, life expectancy stagnated in Sierra Leone without it being possible to attribute this to the recent political-military events only, however dramatic these may have been.

In Southeast Asia, in Indonesia and to an even greater extent in Vietnam, in spite of 30 years of war out of the 50 years observed here, life expectancies increased much faster than in Myanmar, a country which, in spite of its potential wealth, is far from being a star in terms of economic and social-sanitary development.

Figure 108–2 also illustrates two types of contrasts in South America. Starting with comparable levels of life expectancy in 1950, two countries of the Guyana Plateau, Venezuela and Guyana, have diverged a great deal. Due in large part to its exploitation of oil resources, Venezuela has benefited from a strong increase in life expectancy. In Guyana, on the contrary, life expectancy has only increased slightly, especially since Independence, which did not produce policies equal to the hopes it had fostered.

Inversely, Peru, Brazil and Paraguay, starting with very different levels of life expectancy in 1950 have converged greatly. Peru, an Andean country with difficult living conditions, has made spectacular progress nonetheless, whereas Paraguay has progressed only very slowly. Here again, differences in the approach to economic, social, and health development undoubtedly have something to do with this.

3. At a Given Stage of the Health Transition

There are two different angles from which it is possible to try to evaluate the effects of policies on changes in life expectancy, according to whether one considers countries with similar conditions at the outset and for which a divergence in mortality changes are observed or whether, on the contrary, one compares countries with relatively low levels of life expectancy with more advanced countries that the former are catching up with. In a recent study (Vallin and Meslé, 2004), we showed that, at the level of the general history of health improvements, these phenomena of divergence and convergence could be related to an explanatory model that should help provide a better understanding of the relations between these movements of life expectancy and the overall effectiveness of policies. The idea is that when a major health innovation emerges, such as vaccines and antibiotics in the past or, more recently, new strategies in the fight against cardiovascular diseases, a certain number of pioneering countries are able to develop policies to ensure that the entire population benefits from these innovations. In these countries life expectancy increases rapidly, whereas in the others it stagnates (unless they have not yet fully exploited all the resources of the previous innovation and continue to do so). Subsequently, however, countries lagging behind re-orient their policies to acquire the means to benefit from the new technologies, and they do so all the more easily when these technologies become increasingly accessible, whereas the pioneers tend to reach their upper limit because they have almost exhausted their resources. The countries lagging behind are then able to catch up with the pioneers, thanks to a more rapid increase in their life expectancy.

If one reasons in terms of a group of countries studied at a comparable stage of economic development, for example, industrialized countries, and if following an innovation in health care some of these countries progress rapidly whereas others stagnate, it would be normal to attribute the advantage gained by the leaders to a better overall policy. On the contrary if situations converge, it would not be possible to claim that the countries where life expectancy is increasing fastest, to the point of catching up with those that were in advance, practice a better policy than the pioneers because the latter find themselves blocked by the absence of another innovation. These countries are not at the same stage of the health transition. However, it is possible to compare countries that are lagging behind according to their capacity to catch up.

We have shown that in two or three centuries of health transition, there have been at least two major divergence-convergence movements of this type and that a third may have started. The first is related to the discovery of modern means of fighting against infection. It initially caused profound divergences between several pioneering industrialized countries and the others, and then the divergences developed between developed countries and developing countries until there emerged, especially right after World War II, a global movement of convergence. The second, linked to the implementation of policies able to check man-made diseases and of efficient means to fight against cardiovascular diseases, concerns countries which in the 1960s had reached a stage at which possible gains from fighting against infectious diseases had become negligible, basically, the industrialized countries. The third may have already begun due to the major successes of some countries, which are leaders in the fight against aging and in mortality decline at advanced ages.

The most tangible example of divergence-convergence and of the global role of policies in the explanation is certainly the one that has, in the last 40 years, opposed industrial countries in the East and the West (in the very political sense of these two cardinal

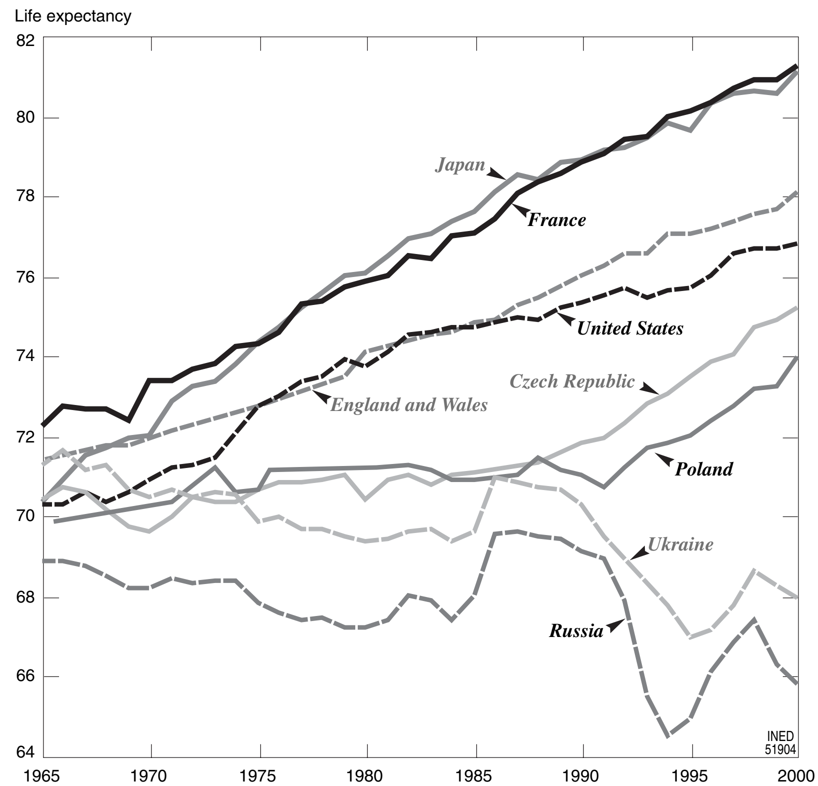

FIGURE 108–3 Compared changes in life expectancy in four Western countries and four Eastern countries since 1965 (sexes combined). (Source: Vallin and Meslé, 2004.)

points). Figure 108–3 illustrates the evolution in life expectancy among the most significant countries, four in the West and four in the East (Vallin and Meslé, 2004).

At the time these eight countries, all major industrial countries in the developed world in the beginning of the 1960s, had very similar life expectancies (between 69 and 71 years) and had reached levels of economic development, which even though dissimilar (it is impossible to deny the fact that Eastern countries were at a disadvantage) were very much in advance of the Third World. Everywhere, infectious mortality was reduced to such a degree that subsequent improvements could no longer have a substantial impact on life expectancy, whereas increases in life expectancy were slowed down or even stopped because it was impossible to make any substantial gains on other fronts and because of the growing threat of man-made diseases (traffic accidents, smoking, alcoholism, etc.). From the second half of the 1960s, however, Western countries simultaneously managed to curb man-made diseases and reduce cardiovascular diseases, whereas Eastern countries were unable to do so. In the West, increasingly well-targeted policies concerning the consumption of tobacco, road safety, work accidents, alcoholism, and so forth bore fruit while new means were used in the fight against cardiovascular diseases: technological means, of course, but also changes in behaviors, namely in eating habits. In Eastern countries, on the contrary, the mode of industrial development made the fight against pollution and accidents more difficult, whereas the decline in the value of individual initiatives created mentalities that were not very conducive to adapting new behaviors in the prevention of cardiovascular diseases (which require the participation of each individual) in countries where people were used to everything being done by the State. Hyper-centralized policy strategies that had proved very efficient in making available all the simple means for fighting against infectious diseases turned out to be inoperative for the much more subtle and complex fight against cardiovascular diseases. Of course, to these reasons must be added the fact that the arms race and space exploration led the Soviet regimes to economic and budgetary choices that had negative on the development of other sectors, namely that of health, depriving these countries of the means of deploying new technologies in the fight against cardiovascular diseases for the benefit of the greater number. The divergence of life expectancies observed from 1965 to 1980 also directly results from the global political divergence between the two groups of countries.

From the end of the 1980s, however, this situation evolved even before the fall of the Berlin Wall. In the USSR (in Russia and Ukraine; see Figure 108–3), in 1985, the campaign against alcoholism conducted by Gorbachev resulted in a leap forward in life expectancy. This operation has since fizzled out, and the tendency is toward deterioration in spite of substantial fluctuations. On the contrary, in the Czech Republic, where the policy started to change even before the country abandoned Communism, growth in life expectancy resumed from 1988–1989, and Poland followed suit two or three years later. These two countries are now on the verge of catching up with the countries of the West, at least concerning cardiovascular diseases, since in the West, Japan, France, and a few other countries may have already begun a new stage (Vallin and Meslé, 2004), leaving behind other countries such as the United States.

However, even making comparisons at comparable stages of health development, the benefit of such a highly global approach to the effectiveness of policies soon reaches its limit. It is not possible to determine what, within a general policy orientation, is truly responsible for success or failure in terms of improved health. It is not known, except if one takes information from other sources, which implemented measures actually have had which effects.

It is therefore necessary to examine the different measures or groups of measures (programs of action) implemented to attain the objective. This is what we will attempt to do now from two different angles: that of (a) programs aimed at reducing and even eradicating a disease or a cause of death and that of (b) policies aimed at globally improving health or the survival of a specific group within the population.

II. REACHING TARGETS IN PATHOLOGICAL TERMS

Concerning programs of action targeting specific pathologies, it is necessary to distinguish between several types of evaluations and to identify what we are truly interested in.

There are two very different fields of investigation in this area (Khlat, 1997b): (a) clinical trials, which make it possible to test a procedure from the point of view of its medical effectiveness as well as of its feasibility (acceptability, practicability, etc.); and (b) large scale programs of action, within the framework of a health policy for the benefit of the entire population. The first level is obviously fundamental; it is on the basis of its results that the political authorities may decide, in full possession of the facts, on such or such a health policy orientation aimed at making best use of scientific knowledge. For example, thanks to clinical trials it is possible to know whether one vaccine is more effective than another, whether a given antibiotic is more adapted in certain circumstances or if a procedure for the early screening of cancer may help in improving the survival of patients. In addition, many clinical trials are run, they are conducted according to strict scientific rules, and they provide proof of the effectiveness or ineffectiveness of a given procedure.

But it is obviously not this type of evaluation that we are interested in here. We have to judge, not the theoretical results of a procedure for the fight against a disease, but the actual consequences on the population of a program of action aimed at reducing, or even eliminating, a disease or a cause of death. However, there may be a great difference between theoretical efficacy of a procedure and its practical effectiveness when it is employed on a large scale in the field. For example, within the framework of a clinical trial, the protocol for the prevention or the treatment is administered under the direct and permanent control of specialized medical staff, whereas in the case of a large-scale program the application of the protocol depends largely on the willingness to participate and attention on the part of the public or the patients. Inversely, especially concerning contagious diseases, action on a massive scale may change epidemiological conditions and benefit the health of those who are outside the scope of the program. In other words, the same protocol may have more or less effectiveness in the field than efficacy in a clinical trial.

Between the two, there are what might be called epidemiological tests in which an attempt is made to test the effect in the field by applying the protocol in the same conditions as in a global policy but on a small sample of the population of which the changes in morbidity and mortality are followed as the program is implemented. At the same time the changes in the same indicators in another control sample not subjected to the program are followed (Khlat, 1997a). This type of test is not in itself quite what we are aiming for here since whatever is done there generally remains a substantial difference between the test and the real-life program itself. What is more, it is often difficult to make a comparison with the control sample since, apart from the ethical problems the method poses, the latter may indirectly benefit from spin-offs of the action conducted in the test area, as in the case of several studies in Bangladesh for example (Mostafa and Rahman, 1997; van Ginneken *et al.*, 1998). What we would like to discuss here, inasmuch as possible, is the real demographic effect of a large-scale program of action aimed at fighting a given disease or cause of death. It is in this area unfortunately that it is most difficult to obtain proof and where useful data are least abundant. We will reason here in terms of mortality given that morbidity data are even more incomplete.

A last preliminary precaution concerning language, given that a large-scale intervention is involved, has to be mentioned. As Myriam Khlat (1997b) points out, at this level, there are two types of evaluation that must be differentiated: that of the program and that of the program results. It is the second type—the program results—that interests us more.

1. Infectious Diseases

It was essentially the widespread use of vaccines and antibiotics that made the spectacular decline of infectious mortality possible in all of the developed countries initially and subsequently now in most developing countries, even though in the old Europe their decline had already begun thanks to improved diets and hygiene. Although in many developing countries, infection diseases remain major public health issues, this is also greatly due to the fact that the policies implemented have not yet made it possible for all populations to systematically benefit from them. Beyond this obvious fact we will, however, try to take stock of the progress of some of the major programs of action.

a. The Eradication of Smallpox

In Chapter 106 we evoked the long history of the fight against smallpox from the ancient Chinese practice of variolization until its near disappearance in developed countries thanks to the widespread use of the vaccine developed by William Jenner at the end of the 18th century and finally its total eradication all over the world. Thanks to political action, the large-scale use of Jenner's technique was made possible in Europe and North America, and it was political action orchestrated on a global scale by WHO that made its total elimination possible (see Chapter 107). This is the greatest historical example of a concerted and sustained fight against a disease, and it is the only case to date of the global eradication of a human disease through the implementation of policies voluntarily directed against it.

b. The Case of Measles

The case of measles is rather different. This disease had disappeared in developed countries as the main cause of infant deaths well before the first effective vaccine was developed in 1969 (Vallin, 1992; Vallin and Meslé, 1999). However, it continued, and still continues to be a serious disease and a major cause of infant and child mortality in a number of developing countries, namely in sub-Saharan Africa. Is the vaccine the tool on which the health policies of these countries should be based? Measles is undoubtedly the most interesting example for a discussion on the role of vaccination in the reduction of mortality. Since the end of the 1980s, there have been two opposing theses on this subject.

The first is based on the idea that measles is not a serious disease in itself but only becomes so through its possible complications, which only manifest themselves and turn to disaster if the child is badly fed (Morley, 1973; Walsh, 1983). Therefore, any policy based on seeking to provide good vaccination coverage against measles is pointless because the only children who risk dying from the disease are malnourished children who would die in the short term anyway even if not from measles (Mosley, 1985b). At the end of 1980s, however, the Danish anthropologist Peter Aaby (1988, 1989, 1992) conceived of a completely different explanation for the high lethality of measles in Africa, thus reaffirming the importance of anti-measles vaccination. According to him, the lethality of measles is not linked to a characteristic of the host (malnutrition) but to the mode of transmission, as children who receive a strong dose of the virus die more frequently, whatever their nutritional state, than those who receive only a small dose.

Until the middle of the 1990s, there were few studies that allowed valid comparisons between the all-cause death rate of children vaccinated against measles with that of non-vaccinated children, even though a number of limited studies supported Aaby's thesis (Hartfield and Morley, 1963; Kasongo, 1981; Aaby *et al.*, 1984), and, in a rather general manner in sub-Saharan Africa, the results of vaccination campaigns were rarely as effective as hoped. In 1996, however, Annabel Desgrées du Loû wrote a book on the subject based on the experience of Senegal. Her main conclusion was that, although the results obtained during the vaccination campaigns often seem disappointing, it is probably because they are limited to spectacular operations involving the massive distribution of vaccines at a given moment and without a permanent structure able to maintain the vaccination coverage thus obtained. On the contrary, in the rarer cases when such a follow-up is properly provided, measles disappears, which in turn results in a substantial decline in total mortality. But Annabel Desgrées du Loû also shows that, even in the case of a vaccination campaign that is not followed up, it is possible to observe a marked decline in total mortality, as long as the "crackdown" operation in question is sufficiently massive. The difference is that once the immediate benefit of the vaccination has passed measles returns and mortality increases again because the new cohorts of children are not vaccinated. It should also be noted, that for quite a long time afterward, the elder children are protected and the new measles epidemics are less violent.

More generally, recent studies prove that the progress made by the Expanded Program on Immunization (EPI) makes it possible to obtain substantial declines in infant mortality in Africa (see Chapter 107). Such is the case, for example, of a study in Sierra Leone (Amin, 1996). However, in Africa, at the national level, mortality is only measured approximately and occasionally, within the context of household surveys. No African country is able to measure annual changes in mortality and to link them, at this level, with that of vaccination coverage. It is, of course, even less realistic to hope to make a comparison at a national level between total mortality and mortality from measles, as the large-scale gathering of causes of death poses a huge problem.

However, there is much hope today that measles will soon be eradicated as was smallpox. In 1994, the 24th pan-American Health Conference set the objective of eradicating measles on both North and South America. The results have been remarkable due to systematic vaccination. Measles has ceased to be endemic in the Americas, most of the countries having proved that the transmission has been interrupted. The last case of indigenous transmission, detected in Venezuela, dates back to 2002 (de Quadros, 2004). It is true, that as long as eradication is not worldwide, vaccination remains necessary to maintain this situation in the Americas, but if a single concerted policy could be conducted with as much firmness on a global scale, total eradication could be possible: "A world free of measles by 2015 is not a dream" (de Quadros, 2004; p. 138).

c. Influenza

Influenza, which 40 years ago was still very deadly, is another story. After smallpox, influenza is perhaps the only major cause of mortality for which vaccination has played a decisive role in Europe. In France, for example (Figure 108–4), until toward the end of the 1960s, this very infectious disease was responsible for a mortality that varied between 5 and 50 per 100,000. The development of the first vaccine (1945) had no visible effect. For each flu epidemic, it was necessary to have a vaccine capable of anticipating the mutations of the virus. As soon as the polyvalent vaccine was put into service and introduced in France in 1970, mortality caused by flu collapsed. The disease is still an epidemic but it kills fewer and fewer people as the vaccination coverage progresses, namely among elderly people. From this point of view, the availability (free of charge in France) of this vaccine from the age of 65 and the campaigns to promote it have played a very important role in the decline in mortality at advanced ages. Flu epidemics were accompanied by high excess mortality due to associated diseases (pneumonia, bronchial pneumonia, etc.). At the same time their decline eliminated in France the last cause for annual fluctuations in total mortality and substantially contributed to the increases in life expectancy obtained during the 1970s and 1980s.

d. Malaria

Malaria, caused by a parasite (*Plasmodium*) transmitted to humans by a mosquito (the anopheles), is still responsible for high mortality in many tropical countries, namely in Africa. Although it is one of the first tropical diseases that modern medicine has tackled, namely for the benefit of the colonizers whom it hit hardest, there still is no vaccine against it, in spite of periodic announcements. Two types of actions are implemented: (a) action against the parasite, through the administration of quinine, known about since the 18th century, or synthesized products developed after World War II, both preventively and curatively; and (b) action against the vector, either through destroying its favorable environment (draining of wetlands), through the setting-up of a barrier again the host vector (mosquito nets, protective clothing, etc. impregnated with repulsive products) or by the destruction of the mosquitoes themselves, through the pulverization of insecticides, the most famous being DTT, which was developed during World War II.

It is against this highly endemic disease in many developing countries that the World Health Organization directed one of its first major vertical health programs.This strategy was very successful in Sri Lanka at the end of the 1940s. Following a massive campaign in 1945–1946 to destroy the mosquitoes by systematically spraying DDT all over the island (70 000 km^2), malaria disappeared (only to return two decades later) and life expectancy made a spectacular leap forward from 46 years in 1945–1947 to 60 years in 1954. The relation between these two latter phenomena was indeed questioned (e.g., by Frederiksen, 1960, 1961, 1966) on the grounds that the mortality decline had already begun before and that the causes of the decline following the eradication campaign had no more to do with the results of this campaign than before. However, several meticulous studies have since confirmed the major role played by the eradication of malaria in the mortality decline (Newman, 1965, 1977; Gray, 1974; Molineaux, 1985). By analyzing mortality change by district, it is possible to compare the results obtained according to the highly variable degree of malaria infection in each district. Districts never having been infected can serve as control areas, as in a real-life test-case study (Figure 108–5). It is also possible to establish a model according to the degree of malaria infection of the districts. Assuming that without eradication of malaria, mortality decline would be the same in absolute value in all the districts, Paul Newman demonstrated that 43% of the decline of the crude death rate observed on the scale of the island between 1946 and 1960 (representing a reduction of 20% of the rate of 22 per 1,000 observed in 1946) was due to the eradication of malaria. However, Ronald Gray, believing this hypothesis underestimated the reduction of possible mortality without the eradication of malaria, considered it more appropriate to assume the decline in the absence of eradication to be proportional to the initial death rate. He thus showed that eradication had nonetheless caused a 27% decline in total mortality. Therefore neither the (temporary) success of the eradication campaign nor its major impact on total mortality may be denied.

Unfortunately eradication was not definitive, as malaria reappeared in Sri Lanka in the 1970s. As long as eradication is not obtained at a global level, the disease can reinfest a country and become endemic once again. Sri Lanka is the only example of the successful eradication of malaria at the level of an entire country. Malaria was indeed eradicated in Mediterranean areas, but the endemia had never been as strong and as generalized as in tropical regions. There is of course the experience of Guyana where malaria was also eradicated from the most populated part of the country, at the same time and with the same

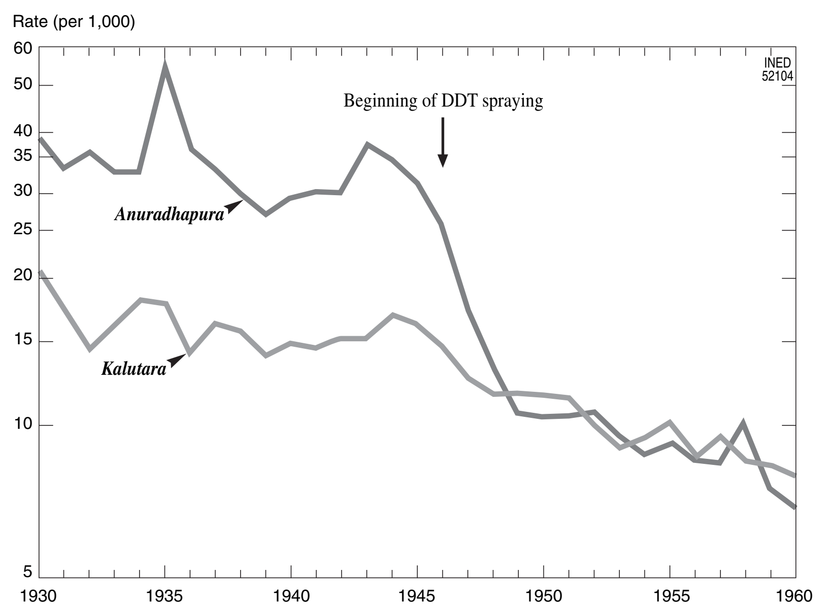

FIGURE 108–5 Sri Lanka: Evolution (before and after eradication of malaria) in the crude death rate in the district most infected with malaria (Anuradhapura) and in the district least infected with malaria (Kalutara). (Source: Newman, 1965.)

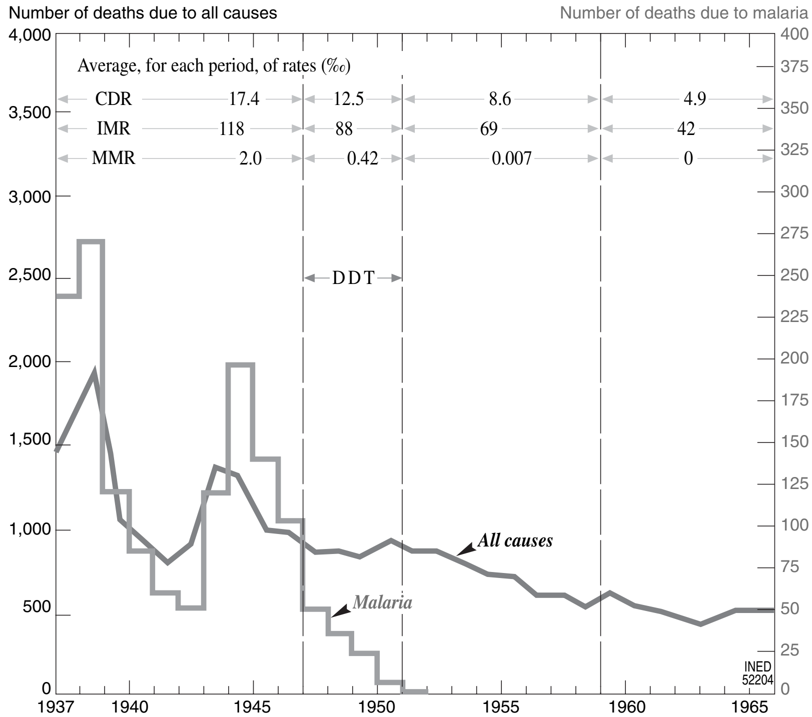

FIGURE 108–6 Sugar plantations in Guyana: Evolution in all-cause and malaria death numbers (the average crude death (CDR), infant mortality (IMR), and malaria mortality (MMR) rates are noted for each period above the graph). (Source: Giglioli *et al.*, 1976.)

methods used in Sri Lanka (Molineaux, 1985), with comparable results (Newman, 1965; Giglioli *et al.*, 1976) (Figure 108–6). But this did not concern a whole country. The operation was conducted only along the narrow coastal stretch where the sugar cane plantations are situated (and 90% of the population), and it was not very difficult to systematically spray the DDT. For the rest, only very localized operations were done, more for experimental reasons than with the aim of eliminating the disease from the country, as for example in Kisumu in Kenya (Payne *et al.*, 1976) or in Garki in Nigeria (Molineaux and Gramiccia, 1980; Cohen, 1988). Even though these trials generally produced rather convincing results, the means needed to extend them over the whole country were never made available. It should be said that to do in a country like Nigeria or the Democratic Republic of Congo what was done on the Island of Ceylon or in the coastal region of Guyana would have required investing considerable financial and human resources to which priority has never really been given. Lastly, it should be added that when one considers the experience of Sri Lanka, which also proves that even on an island malaria can return after 20 years, without strong international concerted action, reluctance to do anything at the level of a single country is understandable. Rightly or wrongly, there has never been, in the case of malaria, anything done on the same scale as the vast global operations for the eradication of smallpox or as the EPI. However, in the meantime the mosquitoes have acquired a certain resistance to insecticides whereas the parasites have mutated toward forms that are increasingly resistant to quinine and its derivatives. New products are constantly being developed, but the disease always ends up adapting itself.

e. AIDS

AIDS, a disease that appeared in the early 1980s, occupies an exceptional place in medical history and represents a major challenge to present-day health policies. It has even cast some doubt over the celebrated triumph of modern medicine over infectious diseases. In fact, it has not totally called into question the first phase of the health transition, that is, the phase in which infectious diseases are eradicated or largely controlled (Caselli *et al.*, 2002; Vallin and Meslé, 2004), which is nothing more than what Abdel Omran (1971) referred to as epidemiologic transition (see also Chapter 57). Rather, it has only delayed, sometimes very seriously, its completion in a certain number of countries with very vulnerable economic and sociocultural contexts. It is particularly interesting to examine here, at different levels, some of the aspects of the health policies implemented in response to the epidemic.

Even if it is almost certain that its origin is African (Grmek, 1989), the epidemic was first observed in developed countries, namely in North America where it severely hit homosexual populations. In San Francisco, for example, which was at the epicenter of the beginning of the epidemic, the homosexual community was rapidly decimated (Hessol *et al*., 1992). As soon as the syndrome was described, the cases multiplied very quickly and all the patients seemed fated to die. At the beginning of the 1980s in the United States, the number of AIDS cases doubled every six months (Allen, 1984, Grmek, 1989). From 200 cases identified at the end of 1981, the number of affected people increased to 450 in mid-1982, to 750 at the end of 1982, to 1,800 in mid-1983, to 3,000 at the end of 1983 (Grmek, 1989, p. 72). This rapid growth provoked a great deal of emotion within the scientific community and led very early on to nightmare scenarios since no treatment seemed to have an effect. The fact that this sudden eruption first appeared to threaten developed countries had important consequences for the orientation of the policies implemented, some of which were very positive, others much less so.

On the positive side it should be stressed that a considerable effort was immediately deployed in the area of research. In the field of biology, but also in epidemiology, demography, and sociology, impressive and unprecedented means were mobilized for research on this infectious disease, inciting lively competition between researchers on each side of the Atlantic. Very soon, as early as 1983, the pathogenic agent was identified by the team of Luc Montagnier at the Institut Pasteur (Barré-Sinoussi *et al*., 1983), opening the way to more targeted research toward finding potential ways of fighting the disease. But the less positive side, residing in the fact that the alert was first triggered off in developed countries and in a specific context of the mode of transmission of the disease is that, very quickly too, the race to find an effective and lucrative treatment prevailed over research into finding a vaccine. A first step toward treatment was made in 1984 with the discovery of the anti-retroviral properties of AZT, which made it possible to increase patients' life expectancy, which had hitherto been very short (Fischl *et al*., 1987). Then in 1996, much more effective tri-therapies were developed, even though they presented considerable disadvantages and do not yet provide a total cure (Amoroso *et al*., 2002). A vaccine still has not been found.

The way the epidemic has evolved in the developing countries and especially in sub-Saharan Africa shows to what extent such a vaccine is needed. In the developed countries, the epidemic never really spread beyond three specific categories of population at risk: homosexuals, drug users, and persons having received blood transfusions. In particular, heterosexual transmission, the means for the virus to access the population as a whole, has always remained very limited in the North.[5]

For each of these three populations (homosexuals, drug users, and receivers of blood transfusions), specific policies have been conducted, based on the mode of transmission. Concerning persons receiving blood transfusions, the epidemic was almost immediately stopped thanks to a reorganization of blood collection procedures, making it possible to exclude contaminated blood. Concerning drug users, the channel of infection is the shared syringe. Policy targeting drug users consisted of convincing the people concerned not to use the same syringe twice, either through information campaigns or through needle exchange programs that provided for the exchange of syringes free of charge (Stine, 1998, Chap. 9). The results were radical in the countries of the West. Since the end of the 1990s, drug users have only represented a small proportion of the new cases of contamination (see, e.g., for France: Lert *et al*., 2004). Concerning homosexuals, the most urgent messages were prevention and avoiding unprotected sex. It was also just as important to understand why in the countries of the North sexual transmission was essentially homosexual. When it became clear that the main factor for the difference was due to the greater frequency in changes of partners or to the fact of having multiple partners (Brouard, 1994), greater insistence was also made on the importance of changes in behaviors and on the absolute necessity of practicing safe sex in unstable relationships. Targeted information campaigns also played an important role. Lastly, even though heterosexual transmission has not developed much, it is nevertheless important to avoid it happening and, here again, since prevention depends essentially on the use of condoms in casual sexual relations, general campaigns for the promotion of new behaviors have been directed toward the young, for example, whereas easier access to condoms has been provided.

As for those who have HIV/AIDS, the number of which has never been huge compared to the other causes of morbidity, in addition to looking for treatments the main effort has been making such treatments available to them as much as possible as soon as they are developed. This has been especially important because these treatments are very expensive.

[5] It should be noted, however, that one factor contributing to the continued prevalence of AIDS in certain European countries is the arrival of immigrants carrying the virus, especially from sub-Saharan Africa. In France, for example, this is the main component in female prevalence (Lert *et al*., 2004).

However, given that the number of infected persons has been contained, it has been relatively easy to ensure the collective funding of these treatments in rich countries.[6]

As a result in the developed countries, the initial dizzying increase in the number of new AIDS cases was very quickly reduced. In Europe (except for the countries of the former USSR), progression of HIV prevalence seemed to stop at the end of the 1980s, and if since the beginning of the 1990s it has remained at an almost constant level of 50 per 1 million inhabitants (EuroHIV, 2003, p. 40), it is essentially because of improved screening. But above all, the arrival of tri-therapies made it possible, in the second half of the 1990s, to reduce the prevalence of the AIDS disease faster than it increased. From over 60 per 1 million inhabitants in 1994 it has declined to 25 in 1998 and 20 in 2002, whereas mortality from AIDS dropped to under 10 per million after having culminated at close to 50 in 1995 (EuroHIV, 2003, p. 40).

The situation has been almost the same in North America. In the United States, after having reached a peak of close to 80,000 in 1993, the annual figure of new AIDS cases dropped to under 50,000 in 1997 and has stabilized at approximately 40,000 since then. The number of deaths due to AIDS peaked at 51,000 in 1994 before declining quickly and leveling off at 20,000 in 2000–02 (CDC, 1995, 2002).

Although the disease has not been eradicated, it has ceased to be epidemic. On the negative side is the situation in the former USSR (especially Russia) where HIV prevalence has recently soared, burdening these countries with what the OMS refers to as "the seeds of potential massive epidemics" (WHO-BRE, 2002, p. 22).

The situation is completely different in developing countries and especially in sub-Saharan Africa. In this region, by far the most affected in the world, the transmission of AIDS, which is essentially heterosexual, presents a grave threat to the whole population. This is due to the same reasons as the high degree of homosexual transmission in Europe and North America: frequent changing of partners and multiple partners (Brouard, 1994). Even if these phenomena are less developed as they were among homosexuals,[7] they have led to the whole of the population being affected by the epidemic which in certain countries, especially in Southern Africa, has reached frightening proportions, the prevalence of HIV infection reaching as much as 15% or 20% of the total adult population. In some countries, life expectancy has declined by between 15 and 20 years or even more. According to the United Nations, in 15 years, South Africa has lost 15 years in life expectancy, Zambia 20 years, Botswana 25 years, and Zimbabwe almost 30 years (United Nations, 2003).

These countries are almost completely powerless in the face of this disaster. Those worst hit are not, however, those lagging furthest behind in Africa in terms of health development. The four countries mentioned earlier were even those where life expectancy, in sub-Saharan Africa, had progressed most since World War II. Yet, their health systems were completely overwhelmed by the scale of the disaster and their economic and social structures badly affected by a sudden mortality crisis in the age groups of the economically active. And the result was just as disastrous in countries slightly less affected but much less provided for before the epidemic. Of course, no African economy was able to cover the cost of caring for AIDS victims and this remains largely the case, even with access to cheaper generic drugs. Patients continue to die in a short time. The only policy that is realistically possible is prevention through information campaigns and the promotion of changes in behaviors in favor of more stable unions and the use of condoms in casual sexual relations. Substantial efforts have been made in this direction by the countries themselves and by the international community. But here again the task is huge since not only well-defined categories of the population need to be contacted, as in northern countries, but the population as a whole, in the most remote rural areas as well as in the big cities. Until now, in spite of the already very high prevalence rates reached, the epidemic is far from having been brought under control in Africa and is becoming an even greater threat in other regions of the South.

In Asia, Thailand was the first country to be hit by AIDS and has suffered hardest with approximately one million persons infected since the beginning of the epidemic for a total population of 61 million inhabitants. Government response to AIDS in Thailand was rapid with the implementation from 1987 of a multisector program to fight the epidemic. This program, which associated all the ministries, nongovernmental organizations, and different private donors and companies, set five priorities: informing and educating the public (prevention); human rights and social assistance; promoting research; providing patients with treatment; and covering its cost. These efforts soon

[6] It should be noted, however, that although AIDS treatment benefits from collective coverage, either totally or for the most part, in most European countries and in Canada, this is much less the case in the United States where Medicare and Medicaid now cover only 20% of patients.

[7] According to Nicolas Brouard (1994), whereas the rate of partner change (average number of new partners per year) was 7 in the cohort of homosexuals in San Francisco, among heterosexuals it is approximately 3 in sub-Saharan Africa compared with hardly more than 1 in Europe or in North America.

bore fruit as shown by the remarkable decline in HIV prevalence among young army recruits, which dropped from 12% to 8% between 1991 and 1995 due to changes in their behaviors (reduced frequentation of prostitutes, increased use of condoms) (Nelson *et al.*, 1996). It is striking to note in this instance the importance of experience acquired previously in the area of family planning. The fact that Senator Meechai Viravaidhaya, often nicknamed "Mr Condom" who heads the Association for Population and Community Development, was the national leader for the family planning campaign before being in charge of the fight against AIDS certainly played a major role.

In Uganda, the prevalence rate peaked at 12% in the mid-1980s and even declined slightly after that (Mulder *et al.*, 1994), much less than the level reached in South Africa, where the epidemic only really took off in the mid-1990s. But even if the remarkable prevention policy implemented in Uganda may be evoked, the reasons for this difference remain uncertain (Caraël and Holmes, 2001).

For the African countries most affected, as well as for other developing countries where the epidemic remains a serious threat, only a vaccine could provide tangible hope to gain real control over the disease. But the development of such a vaccine has turned out to be a long and costly process and for the pharmaceutical laboratories, the drug market is financially much more interesting. The African AIDS epidemic is one of the most serious international health policy failures in recent decades.

2. The Fight against Man-made Diseases

It is a known fact that during the 1960s growth in life expectancy was curbed, even blocked for a time, in most industrial countries (apart from the notable but almost unique exception of Japan). Apart from the fact that infectious mortality had become so low that subsequent successes in this area had no more effect on life expectancy, the latter increasingly came under the attack of what Abdel Omran (1971) called "man made diseases." How have health policies contributed to reversing this trend? We will evoke three cases: alcoholism, smoking, and road accidents.

a. Alcoholism

Even if the (very moderate) consumption of alcohol is becoming increasingly acknowledged as having some positive effect on health (Poikolainen, 1995; Holman *et al.*, 1996), it is obvious that an abusive consumption of alcohol is deadly. It is deadly either directly and brutally (acute alcoholism, sudden aggravation of cerebrovascular diseases) or more slowly (cirrhosis of the liver, cancer of the oesophagus, alcoholic psychosis, etc.), or indirectly (accidents at work or road accidents, homicide, suicide). In certain countries, such as France, Russia, and other Eastern European countries, mortality due to alcoholism, which grew rapidly at the end of the 19th century, became exceptionally high after World War II. In the mid-1960s there was a reversal of this trend in France, whereas it increased in Russia.

In the case of alcohol-related mortality a simple policy, not even necessarily intended principally to that end, can have a considerable impact. For example in France the 1957 *Loi d'assainissement économique et financier* (Law for Economic and Financial Stabilization) resulted in a sudden increase of one year in life expectancy, essentially due to the immediate decline in mortality caused by acute alcoholism and alcoholic psychosis, but also by alcoholic cirrhosis of the liver (Figure 108–7). Not only did this law considerably restrain the capacity for consumption of the French, but it was also accompanied by an increase in taxes per liter of red wine which raised the price from 0.92 francs to 1.40 francs per liter (Meslé and Vallin, 1993). This type of effect, however, is short-lived because in the absence of a sustained campaign against alcohol abuse, consumption and mortality return as soon as the standard of living rises again. In fact, in France, this measure was only a sort of accident in a panorama that included many other, more precisely targeted measures,[8] the cumulated effects of which finally resulted in a lasting change in the trend of alcohol-related mortality after 1965 (Vallin and Meslé, 1988, Nizard and Munoz-Perez, 1993).

[8] Measures reducing access (e.g., the gradual closing down of drinking establishments, the number of which continually declined between 1954 and 1991; regulation of sales outlets, especially at the workplace; and the gradual disappearance of the privilege of home distillers in 1960), development of preventive measures against road accidents (creation of the offense of driving under the influence of alcohol in 1958) and in schools (screening of early alcoholism in schools, and from 1955, education programs on alcoholism), organization of anti-alcohol advertising campaigns (the slogans of some of which have remained very popular, such as the one of 1956, "les parents boivent les enfants trinquent" [The parents drink and the children suffer] or "boire ou conduire, il faut choisir" [Drink or drive, you have to choose], "boire un petit coup, casse cou" [To have a drop is reckless], "un verre ça va, trois verres bonjour les dégâts" [One drink's fine, three are trouble]) etc., the regulation of advertising in 1960 (forbidding the association of alcohol with sports or with automobiles, or forbidding claims of stimulating or aphrodisiac properties, etc.), control of the quality of wine (with the obligation, in 1964, of distilling or converting into vinegar low-quality wines and the creation, in 1965, of a VDQS label) (Berger *et al.*, 2000).

(Source: Nizard and Munoz-Perez, 1993.)

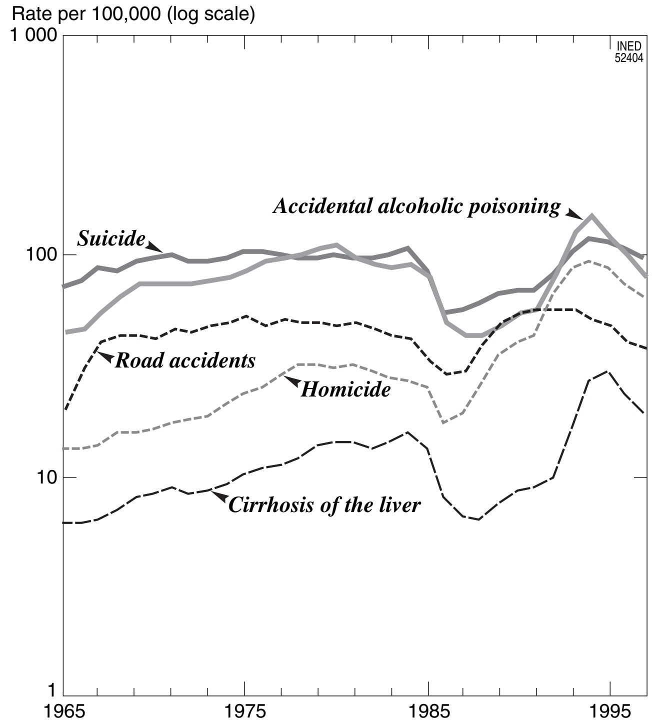

FIGURE 108–8 Changes in age-standardized death rates according to different alcohol-related causes of death in Russia. (Source: Meslé *et al.*, 1998.)

The anti-alcohol campaign conducted by Mikhail Gorbachev in 1985 in the USSR under Perestroika was different and involved a reduction in production, reduction in sales (controlled by the State), increase in prices, and restrictive measures against home distilling (Shkolnikov and Nemtsov, 1997). The effect on life expectancy was immediate: whereas it had been declining for 20 years, from 1984 to 1987, it suddenly increased by 3.2 years for men and 1.4 years for women (Meslé *et al.*, 1994; Shkolnikov *et al.*, 1995). It has been demonstrated that this sudden improvement was entirely due to a sudden decline in alcohol-related mortality, either directly under the form of accidental alcohol poisoning (under which heading acute alcoholism and alcoholic psychoses were included) or of cirrhosis, or indirectly through a decline in the number of homicides, suicides, and accidents in the workplace and on the roads (Figure 108–8) (Meslé *et al.*, 1998).

The decline in violent deaths alone explains 53% of the increased life expectancy among males and 33% among females (Meslé and Vallin, 2003a), and the rest is in all likelihood due to a slight reduction in deaths from other causes (namely cardiovascular diseases) greatly influenced by alcohol. Lastly, even if these improvements had begun slightly before the official launch of Gorbachev's anti-alcohol campaign, it was also clearly demonstrated that most of the decline in alcohol-related mortality and the increases in life expectancy were directly linked to a reduction in the consumption of alcohol following the campaign itself (Figure 108–9) (Meslé *et al.*, 1994; Shkolnikov and Nemtsov, 1997). In that sense, it can indeed be said that this energetic anti-alcohol campaign had a major impact. However, the effect was short-lived. The Gorbachev government soon had other urgent matters to deal with, and the anti-alcohol restrictions soon fell into abeyance. From 1989 life expectancy started to decline once again and this decline accelerated further in 1993–1994, after the collapse of the USSR because of the serious economic and social crisis set off in Russia by the sudden and ill-controlled transition to a market economy. Before this crisis, the relapse was entirely attributable to a resumption in the consumption of alcohol; with the crisis, of course, many other causes came into the equation, but alcohol continued to play an important role (Meslé *et al.*, 1998).

However effective at the time, a crackdown such as the one in 1985 in the USSR can only have very temporary effects. The fight against alcoholism requires a real cultural revolution and only a long-term policy focusing on information and education rather than on repression can have a sustained impact. In the countries most affected, strong belief in the virtues of alcohol is the main obstacle that needs to be overcome.

b. Smoking

Tobacco is harmful to health in several ways. It especially affects the aerodigestive tracts (oral cavity, pharynx) and the rest of the respiratory system (larynx, trachea, lungs), by provoking cancers of these tissues but also by causing other respiratory diseases (emphysema, chronic bronchitis, etc.). Moreover, some of its components, passing through the blood, are also aggravating factors for a number of diseases, of which the following are at the top of the list: ischemic heart diseases, aortic aneurism, and cancers of the bladder and the pancreas. A number of studies have revealed the impressive evidence of excess mortality provoked by smoking. Cuyler Hammond (1966) demonstrated that out of a sample of one million Americans, for example, men aged 45–54 smoking 40 cigarettes a day or more had an all-cause death rate nearly three times higher than that of nonsmokers, whereas, for France, Michel Blanc (1985) calculated that the elimination of smoking as it prevailed in 1968 would enable males to increase their life expectancy by 3 years.

As in the case of alcoholism, the situation cannot be improved simply by waving a magic wand. It requires a sustained policy in which health information and education of the masses play as much of a role as regulating the production and distribution of tobacco as well as protecting living environments. In the case of tobacco the problems are even greater than with alcohol because its addictive power operates even faster.

It is in the United Kingdom that the first benefits were reaped from a policy of information and prevention. However, paradoxically, actual government action was relatively limited (an information campaign against the dangers of smoking and the setting-up of health centers to help people who wish to stop smoking, and then, in 1964, the banning of advertising of tobacco on television), but it was greatly backed up by private initiatives and strong public awareness, namely thanks to follow-up work by doctors (RCP and ASH, 2002; Doll *et al*., 2004).

A study by The Royal College of Physicians (RCP, 2000) shows that smoking, which had taken unprecedented proportions after World War II (as much as 60% of smokers among men and more than 40% among women), had declined slightly at the beginning of the 1960s, at the time when a major survey among British doctors was being conducted, but it took until the second half of the 1970s for a continued decline to occur, first among men, then very soon after, among women (Figure 108–10). In 1997, the last year for which data were available for the drafting of the report, the proportion of smokers had dropped to an equal 25% level among both sexes.

The example of the United Kingdom was soon followed by other English-speaking countries (namely the United States) and Northern European countries, and later by the other European countries.

In terms of mortality, it is easy to identify the consequences of these changes on the evolution of mortality caused by lung cancer, presented in Figure 108–11 for six European countries and by sex. The effect of the decline in smoking was obviously not direct. One sees, for example, that in the United Kingdom the first decline in the 1960s only slowed down the increase in male mortality by respiratory

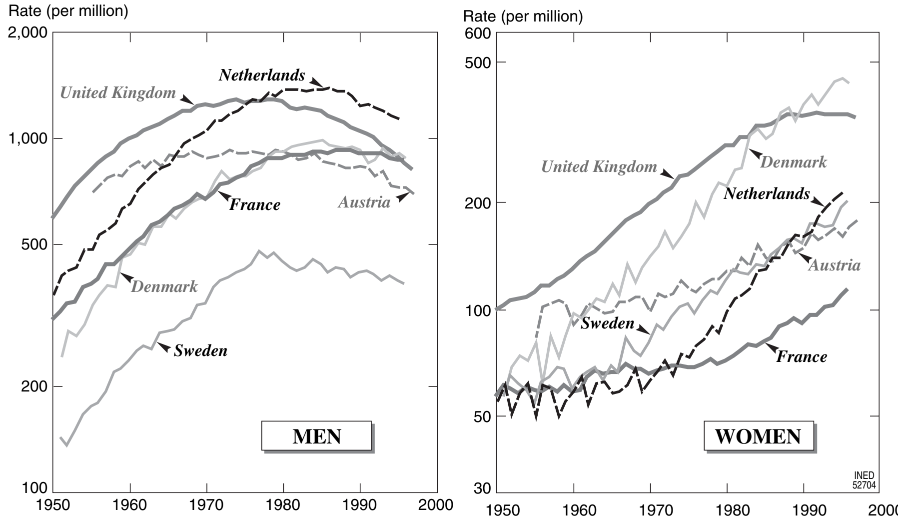

FIGURE 108–11 Evolution since 1950 of age-standardized death rates for cancer of the lungs, the bronchus and larynx in various European countries (logarithmic scale). (Source: Vallin and Meslé, 2001b.)

cancer and the reason why the strong decline begun in 1976–1977 coincides with a complete halt in the increase of this mortality is especially because male smoking ceased to grow from the end of the 1940s. Mortality among women, whose consumption of tobacco only really ceased increasing at the beginning of the 1970s, continued to get worse. However, it is the decline in smoking among both sexes from the end of the 1970s which also finally resulted in a decline in male lung cancer mortality and halted the increase in female lung cancer mortality. At the end of the 1990s, the decline obtained among men was substantial (close to 40%), and it seemed that the decline was beginning among women.

Concerning men, rather similar results were obtained at about the same time in Sweden, a country where respiratory cancer mortality has never been as high as in the United Kingdom. But this was also the case, a little later, in the Netherlands, where male lung cancer mortality reached a level at the beginning of the 1990s that was even higher than the maximum ever observed in the United Kingdom. On the other hand, in France, although the increase in male lung cancer mortality was curbed from the end of the 1970s, the real turnaround was still hardly noticeable at the end of the 1990s. This is because the anti-smoking campaigns there were started later and have only been raised to a higher pitch in recent years.

Concerning women, the situation is even more problematic. Indeed, everywhere traditionally women have always smoked much less than men, but this difference has greatly reduced until it has sometimes completely disappeared and, except in the United Kingdom, female consumption has constantly increased in each of the countries represented in Figure 108–11, which explains the reason why the increase in lung cancer mortality continues there. Why do anti-smoking policies have less influence on women than men? Women, notably young women, undoubtedly have more reasons than men to resist the new social pressure from anti-smoking campaigns. For many of them smoking was and still is a symbol of emancipation to which they attach more importance than to the need to stop smoking in order to prevent hypothetical lung cancer.

c. Road Accidents

Road accidents did not start with the advent of the automobile but the latter increased their impact very much. The development of road traffic with the invention of mechanical horsepower made road accidents one of the leading causes of violent death. At the end of the 1960s, more than 15,000 people died each year on the roads in France each year, representing a crude death rate of more than 30 per 100,000 inhabitants, comparable to figures in the United States (26) and Germany (30). In fact, the number of road deaths in France exceeded 15,000 in 1967 and reached its maximum of 18,630 in 1972 (Vallin and Chesnais, 1975). Policies were relatively quickly implemented to deal with this problem at different levels (see Chapter 107), but it was only starting in the 1970s that this modern-day problem was curbed in most European countries (Figure 108–12). It was also at this time that road accident mortality declined noticeably in Japan,

FIGURE 108–12 Evolution since 1950 in age-standardized road accident male death rates in European countries (logarithmic scale). (Source: Vallin and Meslé, 2001b.)

North America, and Australia. However, it is continuing to grow in many developing countries.

One of the major ways of preventing road accidents has been and still is to improve the road network and the vehicles. However, the results of these improvements are ambiguous to say the least. Let us take, for example, the construction of motorways. There is no doubt that motorways are much less dangerous than ordinary roads. In France, for example, the number of deaths per kilometer traveled is 3.5 times less on motorways than on primary or secondary roads (DSCR, 2004). The increasing importance of motorways in road transport has therefore saved many human lives. However, the development of motorways has enabled a much greater number of vehicles to get onto the roads and has subjected a growing proportion of the population to the risk of accidents. It is true that the development of transport is an essential factor for economic development, but, at this level, it is transport policy as a whole that is called into question. A considerable investment into road transport has obviously been made to the detriment of other much less dangerous means of transport, such as air travel or railway. The development of roads and automobiles has also created the conditions of a cultural preference among the public for the most dangerous means of transport, whereas the lack of investment into railways or fluvial navigation has diverted goods traffic to the roads, making them even more dangerous. This choice concerning the society we live in was made in all the industrial countries at the turn of the 1950s–1960s and is something that is difficult to reverse today.

Nevertheless, road safety policies have been reinforced everywhere (see Chapter 107), and in almost all the industrial countries, a significant change occurred in the mid-1970s. The movement was particularly synchronous in Europe, as shown in Figure 108–12. It was the consequences of two factors combined. The accumulation of preventive measures (improvement of the road network and of the safety of the vehicles, speed limits, wearing of safety belts, etc.) finally yielded its dividends, but at the same time the shock of the oil crisis in 1973 provoked among drivers a change in attitude toward speed, a great consumer of fuel.

Thus, thanks to an accumulation of complementary measures, road safety policy has made it possible to reverse the trends in most developed countries. Nevertheless, something that should not be ignored is the importance of the influence of temporary phenomena which may act either positively or negatively, nor, above all, should it be forgotten that this question remains far from resolved in developing countries where road accidents are increasingly becoming a major public health issue.

3. The Fight against Cardiovascular Diseases

Beyond curbing man-made diseases, the success won over cardiovascular diseases was a crucial factor in the return of a sustained increase in life expectancy in industrialized countries from the beginning of the 1970s. This event even occupies such an important place in changes in health in the last three decades of the 20th century that we have already substantially covered it in our first section on the global evaluation of health policies. We have, in particular, already stressed the profound difference between East and West engendered by the opposition between the success of the policies conducted in the West in this area and the incapacity of Communist countries to implement adequate strategies.

We shall therefore simply complete it here with a few points of detail based on the example of France, the country for which we have reconstructed death series by constant cause definition since 1925 (Vallin and Meslé, 1988, 1998; Meslé and Vallin, 1996), an absolute prerequisite for following over time the dif-

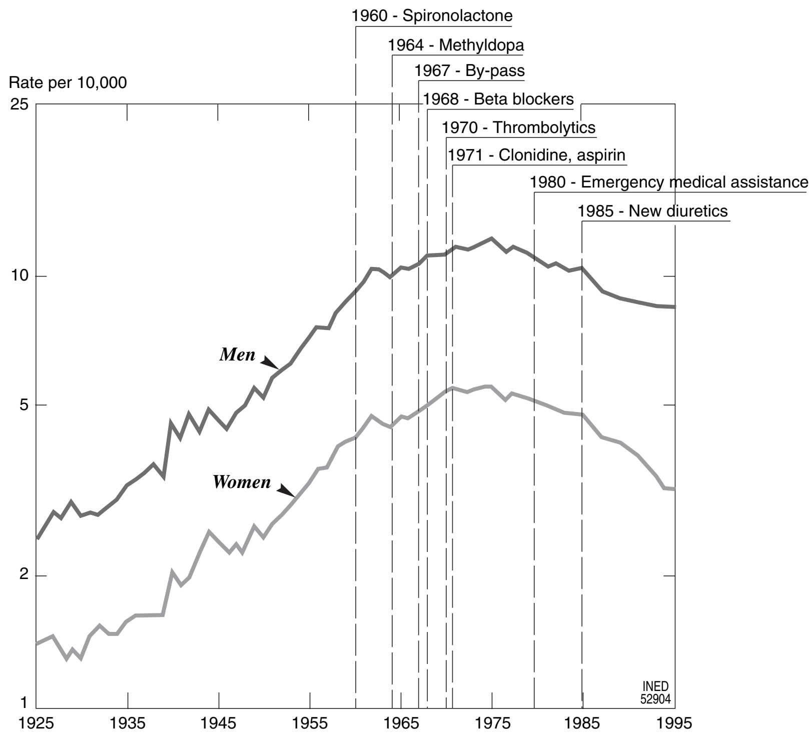

FIGURE 108–13 Evolution of age-standardized myocardial infarction death rates in France since 1925 and dates of introduction of the main medical innovations. (Source: Caselli *et al.*, 1999.)

ferent components of cardiovascular mortality. In fact, in France, total cardiovascular mortality had started to decline long before the 1970s, but this slow global decline was the result of contrary movements of causes toward decline (heart failure, pulmonary heart diseases), stagnation (cerebrovascular diseases), or increase (acute myocardial infarction), and it was when cerebrovascular mortality started to decline and, above all, when the trend concerning myocardial infarction was reversed, that the global decline in cardiovascular mortality took off decisively.

Two major factors have played a part in ensuring the success of the policies conducted in this area: the dissemination of new technologies and changes in behavior. Figure 108–13 clearly shows how the accumulated positive effects of new technologies have weighed in the balance toward a reversal of the unfavorable trend of myocardial infarction mortality:[9] monitoring and control of hypertension (with the distribution of spironolactone from 1960, of methyldopa from 1964, of beta blockers from 1968, and of clodinine since 1971), prevention of angina pectoris (beta blockers), treatments against thrombosis (a second generation of thrombolytics effective against atheromatus coronaries and brought out from 1970), coronary by-passes (performed for the first time in 1967), the organization of emergency procedures that became very effective from the 1980s with the setting-up of *Service d'assistance médicale d'urgence* (Emergency Medical Assistance Service), and so forth (Biraben, 1988).

But the second factor behind the reversal in the trend is no less important. The increase in mortality was due to that of the risk factors. We have already mentioned the role played by smoking and alcoholism. The period of the 1950s and 1960s was also marked by a change in diet under the effect of a higher standard of living (with the increase in the consumption of animal fats), the transformation toward a sedentary lifestyle (with work evolving, less manual and more office work), not to mention pollution of the environment, all of which contribute to high cholesterol and hypertension. The reversal of the trend toward an increase in infarction mortality observed at the turn of the 1970s reflects not only the distribution of new medical technologies enabling early diagnoses and treatment, but also a change in behaviors toward risk factors.

[9] However, one should be cautious about the extent of the increase in myocardial infarction mortality as about the decline due to certain ill-defined causes such as, namely heart failures and, especially, ill-defined heart diseases. Even after reconstruction of death series by constant cause definitions, the real content of the different sections remains subject to changes due to improved diagnostic techniques. It is almost certain that the increase in infarction mortality during the 1950s and 1960s is lower than Figure 108–12 suggests. This bias does not, however, call into question the reasoning.

In both cases the precise role played by health policies, in the strictest sense of the term, is rather difficult to determine. It is obvious that in a country like France where costs are essentially covered collectively, this greatly facilitated quick access for the majority of the population to often very costly new technologies. In the same way efforts to provide information and education concerning a healthy diet and attention to early symptoms and screening for cholesterol and hypertension also have played an important role. But more generally, success has come in the form of awareness on the part of the public and the patients themselves of the fact that improved health in general and in the area of cardiovascular diseases in particular requires that everyone should play their part.

Figure 108–13 shows rather clearly that, at least until 1996, the year at which the graph stops, the decline in myocardial infarction mortality was more rapid among women than men in spite of the latter having higher rates. The reason is that women, because of the greater attention they pay to their bodies, were more willing than men to adopt the necessary changes in behavior and to benefit from technological progress (see Chapter 53). Since then, however, we know that men have made up for most of their disadvantage by adopting behaviors more favorable to their health (Meslé, 2004a). Success in this case results therefore more from a global social change than from the implementation of precise health measures.

III. FULFILLING OBJECTIVES TARGETED IN TERMS OF GROUPS

A third way of evaluating health policies consists of examining whether or not and to what extent specific programs aimed at reducing the morbidity or mortality of certain target groups are crowned with success. At a given stage in socio-sanitary development it is indeed in the collective interest for certain groups, considered as disadvantaged or exposed to specific risks, to be the object of specific measures. Here again examples abound. Let us examine two types of concerns among others: protection at certain stages in life and the reduction of inequalities.

1. The Protection of Certain Stages in Life

At certain times in life the human being is exposed to specific health risks that most societies have more or less tried to contain. In modern societies, specific policies are developed to protect the newborn, children, schoolchildren, workers, pregnant women or women just out of childbirth, and the elderly. Let us take three examples: infancy, maternity, and old age.

a. Infancy

Developed Countries

In developed countries, after a brilliant victory over infectious infant mortality, greatly due to traditional policies of maternal and child protection, the main objective of recent decades has been to obtain a decline in neonatal mortality. Many countries have set up special programs in this area. Such was the case in France with the launch in 1971 of an incentive program aimed at prevention and care and benefiting from major budget contributions for several years.[10] This program (MSPSS, 1971; Chapalain, 1975) included seven measures: training and advanced training of health care workers, vaccination against German measles, reinforcement of the medical supervision of pregnancies, improvement in the supervision of deliveries, the resuscitation of newborn babies in the delivery room, and the equipment of obstetric wards and neonatal intensive care units. A series of three surveys (1972, 1976, and 1981) was organized to monitor the development of the program and its results (Rumeau-Rouquette, 1979).

The results were not long in coming. It is possible to follow the program with a simple but significant indicator: the proportion of women in childbirth having had 4 prenatal consultations or more, which was only 49% according to the survey of 1972, rose to 60% in 1976 and 80% in 1980 (Rumeau-Rouquette and Blondel, 1985). Moreover, the state of health of newborn babies considerably improved, with reductions in the proportion of both premature births and late births.[11] But neonatal mortality especially fell sharply. Indeed, like all the other components of child mortality, neonatal mortality had been declining since World War II, but at a much slower rate than post-neonatal mortality and, since the latter had dropped to a very low level, the resistance to the decline in neonatal mortality started to curb the decline in total infant mortality (Figure 108–14). With the launch of the peri-

[10] With the finance act of 1971, a budget of 9.5 million francs had been earmarked for new measures and for the duration of the sixth four-year plan this program was a part of, a total of 257 million francs (in constant francs) was provided (Rumeau-Rouquette and Blondel, 1985).

[11] The proportion of births at under 37 weeks of pregnancy fell from 8.2% in 1972 to 5.6 in 1981, and the proportion of births after 43 weeks of pregnancy or more fell from 4.0% in 1972 to 3.4 in 1981 (Rumeau-Rouquette and Blondel, 1985).

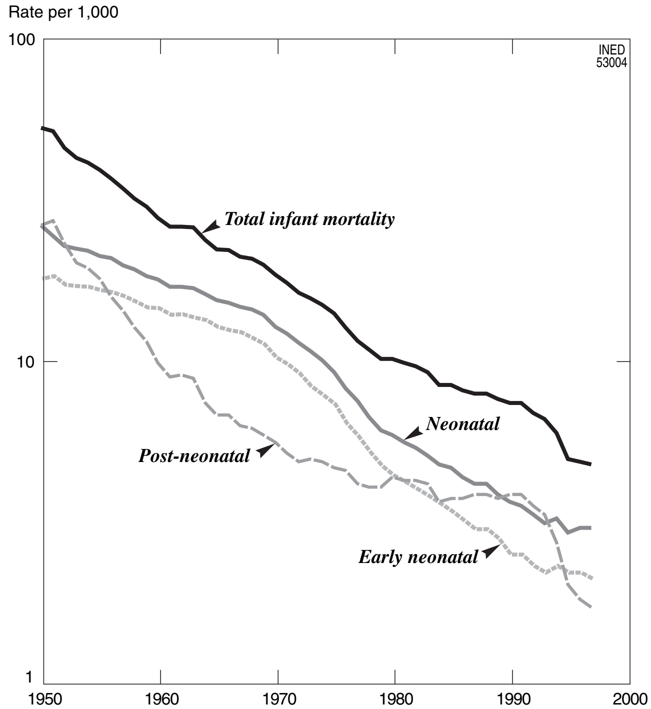

FIGURE 108–14 Evolution between 1950 and 1997 of the different components of infant mortality in France. (Source: INSEE, statistical yearbooks.)

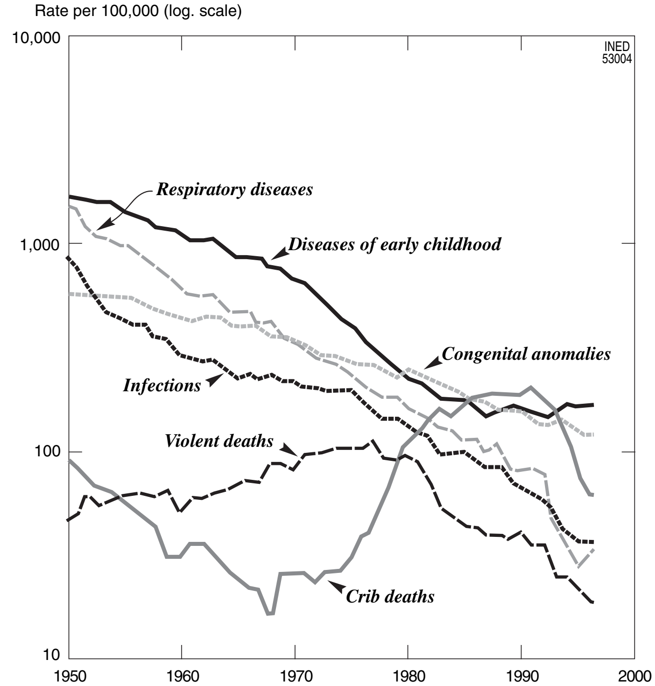

FIGURE 108–15 Evolution of crib death mortality among other causes of infant death. (Source: Meslé, 2000.)

natology program of 1971, these trends suddenly reversed. Whereas the decline in post-neonatal mortality slowed down because of the very low level it had reached, neonatal mortality collapsed. And this success concerned both total neonatal mortality (0–27 days) and early neonatal mortality (0–6 days).

From the 1980s, infant mortality continued to decline thanks to the continued and very rapid decline in neonatal mortality. However, post-neonatal mortality stopped declining and at the end of the 1980s, it rose once again above neonatal mortality, calling into question the decline in infant mortality. In fact, this unfavorable evolution of post-neonatal mortality was to a great extent due to an error in medical policy which was the cause of a sudden increase in crib deaths. The extraordinary increase of this cause of death between 1975 and 1985 is due to the generalized placing of babies on their stomachs in their cribs. It is true that this practice initially saved lives of children by substantially reducing mortality due to anoxia and hypoxemia (Meslé, 1995), but it later became apparent that it caused a surprising increase in crib deaths (Sénécal *et al*., 1998). It was enough for the medical establishment to agree and to change policy by imposing on maternity wards that babies should be placed on their side and by advising mothers to do the same for the increase in crib deaths to stop, then suddenly to collapse when the new practice was generalized (Figure 108–15).

Developing Countries

In the case of developing countries everything said above concerning vaccines constitutes in itself an effort almost entirely focused on improving the health of children and reducing their mortality. Nonetheless, it is not the only effort made in this direction. We believe it is particularly important to complete the picture here by evoking two other major health policy actions in favor of children: the fight against diarrhea with oral rehydration procedures and the fight against malnutrition with food supplement programs.

i. Programs against Diarrhea Toward 1980, diarrhea was the first cause of death among children in developing countries (and in the whole world, given the very low infant-child mortality of developed countries). Efforts made since then to counter this cause of death have essentially relied on oral rehydration therapy (ORT), a technique developed in Bangladesh at the end of the 1960s, the dissemination of which was greatly encouraged by the WHO from 1979, following the Alma Ata Conference.[12]

[12] In fact, this expression often covers complementary actions such as administration of oral rehydration salts, rehydration using domestic fluids, overhydration, and sometimes even medical treatment.

Although many National Control of Diarrhea Diseases Programs (NCDDP) have been established, few have been evaluated at a national level. In an exception to this, Cesar Victora *et al*. (2000) list four cases in which global evaluation elements are available: in Brazil, the Philippines, Egypt, and Mexico. In Brazil, the proportion of hospital admissions for diarrhea out of the total number of admissions of children (in the major pediatric hospitals in the nine northern states) fell from 57% in 1980 to 30% in 1990. At the same time, whereas the campaign for the use of rehydration salts had been launched in 1980, a survey showed that in 1991 mothers had used the therapy in 35% of all the diarrhea cases and in 62% of the cases they judged to be severe. Lastly, the study of a simulation showed that this therapy accounted for three-quarters of the decline in diarrhea disease mortality. In the Philippines, with the development of NCDDP, diarrhea disease mortality declined by 5% per year during 20 years, whereas infant-child mortality for other causes declined much more slowly. In Egypt, decline in diarrhea mortality was even faster, with reductions of 4.2% per year in 1970–1977, 7.8% in 1978–1983, and 15.9% in 1984–1990, greatly accelerated by the introduction of ORT. In Mexico, lastly, the proportion of infant-child diarrhea mortality (0–5 years) fell from 26% in 1983 to 11% in 1993.

On a global scale, it is estimated that the number of deaths caused by diarrhea fell by 4.6 million in 1980 to 3.3 million in 1990 and to 1.5 million in 1999. The NCDDPs and especially the oral rehydration programs seemed to have been the reason for this massive decline (Victora *et al*., 2000).

ii. Food Supplement Programs Nutritional deficiencies among children are frequent in poor countries. Different studies have shown that in the 1970s, two-thirds of children's deaths could be attributed to nutritional deficiencies (Puffer and Serrano, 1973; Kielman and McCord, 1978; Chen *et al*., 1980). Several approaches to the infant nutritional problem have been the object of programs, with varying degrees of success. The simplest in its concept is obviously the one that advises maintaining or reinforcing prolonged breastfeeding traditions. With modernization, breastfeeding practices have declined without mothers having access to healthy, balanced artificial milk for their children. This problem was revealed as early as the 18th century in Europe and already at the time was the object of campaigns promoting breastfeeding. The promotion of breastfeeding has also been, in the last 20 years, one of the five mainstays of the GOBI-FFF (growth monitoring, oral rehydration, breastfeeding, immunization–food, female education, and family planning) launched by UNICEF in the 1980s. According to UNICEF (Chen *et al*., 1997), 57 out of 102 countries launched campaigns promoting breastfeeding, but have not, unfortunately, provided evaluations of the results.

Other programs focus on vitamin A supplementation. Vitamin A deficiency is associated with high child mortality because of the different diseases it provokes, for example, xerophtalmia. An Indonesian study on 26,000 children of preschool age showed that the group having received vitamin A tablets twice, at six-month intervals, had a death rate at 12 to 71 months, 33% lower than that of the control group in the year that followed the vitamin supplementation (Sommer *et al*., 1986). Similar results were obtained in southern India (Rahmathullah *et al*., 1990) and in Nepal (West *et al*., 1991) but neither in Sudan (Herrera *et al*., 1992) nor in Ghana (Ross *et al*., 1995) where the vitamin A supplementation had practically no effect on mortality. Out of the 67 countries involved in this action through the GOBI-FFF program, 35 "will come close to eliminating the problem" (Chen *et al*., 1997).

More generally, food supplement programs have been implemented, the first of which, in the 1950s, were intended to fight against malnutrition in young children. In centers for nutritional rehabilitation, undernourished children received a balanced diet made up of food available on site and prepared according to local recipes, with the participation of the mother in the choice and preparation of the ingredients. The dual objective was for the children to recuperate and for the mothers to become informed. These programs are effective in the short term: Beghin and Viteri (1973) found that approximately 70% to 80% of malnourished children recuperated during their stay if the center was well run. Although this type of action was in vogue in the 1960s, it was soon abandoned. Resources needed to ensure coverage for all malnourished children mobilized were never mobilized, and the real impact of these centers has always been marginal (Beghin and Vanderveken, 1985). Much less costly per day than hospital care, these programs nevertheless stretched public health budgets of developing countries.

Programs for the noncommercial distribution of food to selected children with the aim of improving or protecting their nutritional state took over in the 1970s and 1980s and constituted, in the mid-1980s, the most widespread form of intervention in this area. Although substantial funds were dedicated to them (Beghin and Vanderveken, 1985), the results were disappointing (Beaton and Ghamessi, 1979). There were several reasons for this. On the one hand, the management of these programs turned out to be complex in that it proved to be extremely difficult to avoid both high dropout rates and diversion of food. In addition, the cost of extending the programs to all children at risk is very high.

Except for periods of serious crisis, complementary food programs have proved to be costly and difficult to implement. Two approaches seemed, for a time, more promising: supplementary diets for pregnant women, which make it possible to reduce the proportion of newborn children with low weight (Mora, 1979; Cole *et al*., 1995), and the nutritional parts of programs integrating health care and nutrition. In both cases, due to the fact that food programs are associated with other actions, their cost is diminished. On the other hand, it is more difficult to measure actual performances. In a few cases, it has been proved that nutritional supplements had a direct impact on the survival of children, as, for example, in the Narangwal study (Taylor *et al*., [1968] 1983). However, here again, pilot studies should not be confused with actions on a national scale. Such programs have never been generalized anywhere. Some authors have even suggested that this cannot be done efficiently (Gwatkin *et al*., 1980).

b. Maternal Risk

Decline to an almost imperceptible level of maternal mortality in the most developed countries has been one of the major successes of health policies. Specific policies were implemented in this area from the second half of the 19th century, and in most cases, in fact, these were associated with those aimed at the health of the children (namely in the framework of maternal and infant protection). It is true, maternal mortality greatly declined—in part due to improved general hygiene and diet conditions but also, in countries like France and Sweden, due to the early decline in fertility—before these policies were explicitly aimed at making medical progress available to the majority of the population; however, they did play a major role in the final result.

It is possible to measure maternal mortality by relating the number of deaths of pregnant women or women in childbirth either to the number of births (maternal mortality ratio) or to the number of women of reproductive age (maternal mortality rate) (see Chapter 45). In this case we are using what is most common: the maternal mortality ratio. In most cases, maternal mortality is due to five main causes: infection, hemorrhaging, eclampsia, obstetrical accident, and abortion.

The first major breakthrough was the discovery, well before Pasteur, of the contagious nature of puerperal fever, perhaps as early as 1790 by the Scotsman Alexander Gordon, but in any case in 1840, simultaneously in the United States by Olivier Webdell Holmes and in Austria by Ignaz Semmelweis. This discovery met with resistance on the part of some obstetricians until the 1930s (Loudon, 1992), but it was rapidly adopted by many others. In Sweden, for example, the generalization of precautions to prevent contagion greatly contributed to reducing the incidence of puerperal infection from 5,300 per 100,000 in 1881 to 220 in 1900 (Högberg and Broström, 1985).

At the same time, surgery progressed, encouraged by the introduction of the first methods of anesthesia, which made it possible to reduce the number of obstetrical accidents. Later, of course, came sulphonamides, then antibiotics, for the efficient treatment of infections, new progresses in surgery and anesthesia facilitating caesarean births, modern methods of transfusion, and other means of fighting against hemorrhages. Recently, it has been possible to follow the impact of all these technological advances on the evolution of maternal mortality ratio, as Judith Fortney does in Chapter 45 (see Figure 45–1). However, it is thanks to maternal health policies that it has been possible for these advances to be adopted for the benefit of all mothers. These policies were fully implemented in 1950s with the generalization of childbirth in hospital and more recently by increased medical supervision of pregnant women. From a maternal mortality ratio of the order of 1,500 to 2,000 per 100,000 in the 18th century, ratios fell to between 500 and 800 at the beginning of the 20th century and have since fallen to ratios of less than 10 today (sometimes even less than 5) (Chapter 45).

Unfortunately, the best proof that technical progress is not enough and that the final victory in this area as in many others concerning health depends, above all, on the policies implemented is the diversity of situations in developing countries today. The financial cost of the basic elements for a very strong reduction in maternal mortality (prevention, antibiotics, conditions of delivery) is very low. Yet, in 2000, the maternal mortality ratio still varied, in developing countries, from 92 per 100,000 (Sri Lanka) or even 43 (Costa Rica) to more than 1,000 (Kenya, Burkina Faso) or even 1,500 (Tanzania) or close to 2000 (Afghanistan, Sierra Leone, Malawai) (WHO *et al*., 2004). Not only have countries like Costa Rica or Sri Lanka done a great deal to enable the majority of the population to benefit from the elementary means available today in the fight against maternal mortality, but they have done so in context of general policies for the promotion of women's rights placed at the very heart of their economic and social development policies. From the 1980s and 1990s and, even more so, since the last Conference on Population and Development (held in Cairo in 1994), WHO and UNICEF have coordinated their efforts to eliminate most of maternal mortality, an objective which should be easily attained, and even to go as far beyond this as possible by attempting to have all countries adopt the concept of "safe motherhood" (see www.safemother hood.org).

c. Old Age

Many developed countries have conceived health policies directed especially toward elderly persons. In countries where general coverage of health costs is extensive, these programs only play a subsidiary role, that is, dealing with problems not sufficiently covered by the general health plan. An interesting case is that of the United States, where the collective coverage of health costs is not the general rule but where a special program for elderly people was set up about 40 years ago.

Medicare, created in 1965, is a government program that covers all Americans aged 65 and over (see Chapters 107 and 117 on the United States). The law was adopted as a reaction to the fact that medical costs were increasing much faster than was the cost of living. Toward 1960 it became evident that private insurance could no longer provide sufficient coverage for elderly citizens, whether or not they benefited from a retirement pension. It was estimated at the time that only one out of four Americans aged 65 and over benefited from insurance covering 75% of a hospital bill.

Given that Medicare is, as Carl Haub writes in Chapter 117, "the largest government health programme in history [of the United States]," it is important to know if it has had any positive effects in an area where some are to be expected: life expectancy at age 65. Among men, the pace of increase in life expectancy at 65 was faster from 1965 than between 1950 and 1965. Whereas in 15 years, Americans aged 65 had only gained 0.1 years of life expectancy between 1950 and 1965, they gained 1.3 years between 1965 and 1980, more than 10 times more. And they gained another 2.3 years from 1980 to 2001 (Figure 108–16). However, it is not certain that this leap forward is really attributable to the Medicare program (Card *et al*., 2004). First the situation is much poorer for women. Whereas they

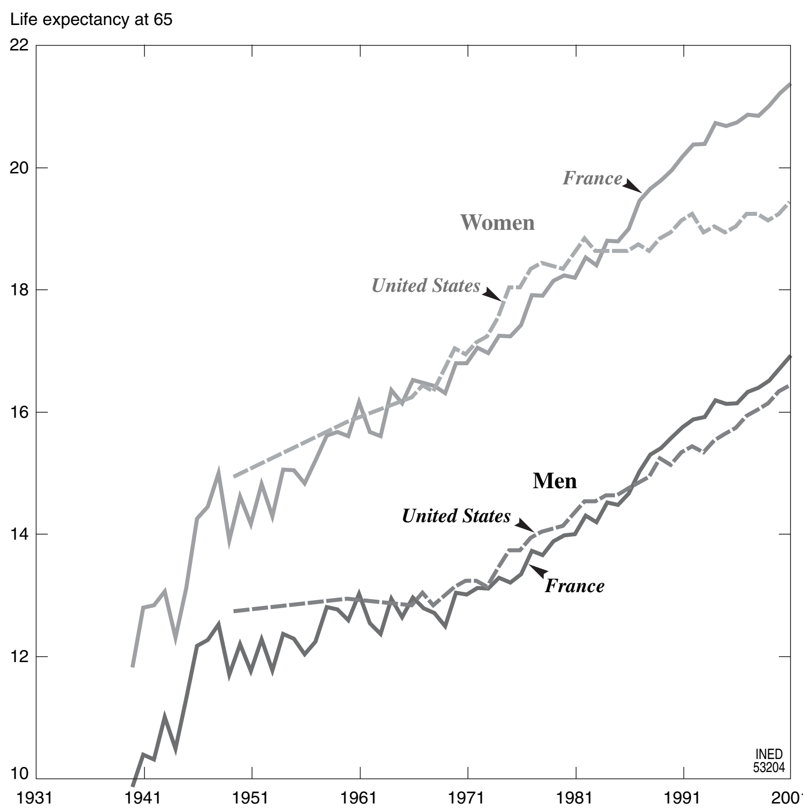

FIGURE 108–16 Evolution of life expectancy at 65 according to sex in the United States and in France, since 1940. (Sources: United States: life tables published annually in *Vital Statistics of the United States, Volume II*; France: Vallin and Meslé 2001a.)

had gained 1.3 years in the 15 years preceding Medicare and had gained another 2.1 years during the 15 following years, they have only gained another 1.1 years in the last 21 years.

But above all, the creation of Medicare coincided with the beginning of the cardiovascular revolution which has opened in all the Western industrial countries a new area for an increase in life expectancy, especially at advanced ages. If one compares the evolution in American life expectancy at 65 to that of the French, for example, we see that the acceleration of the 1970s probably has little to do with Medicare, except if one assumes that without Medicare life expectancy would have continued to stagnate among Americans and that the slowdown observed among American women from the 1980s would have occurred earlier.

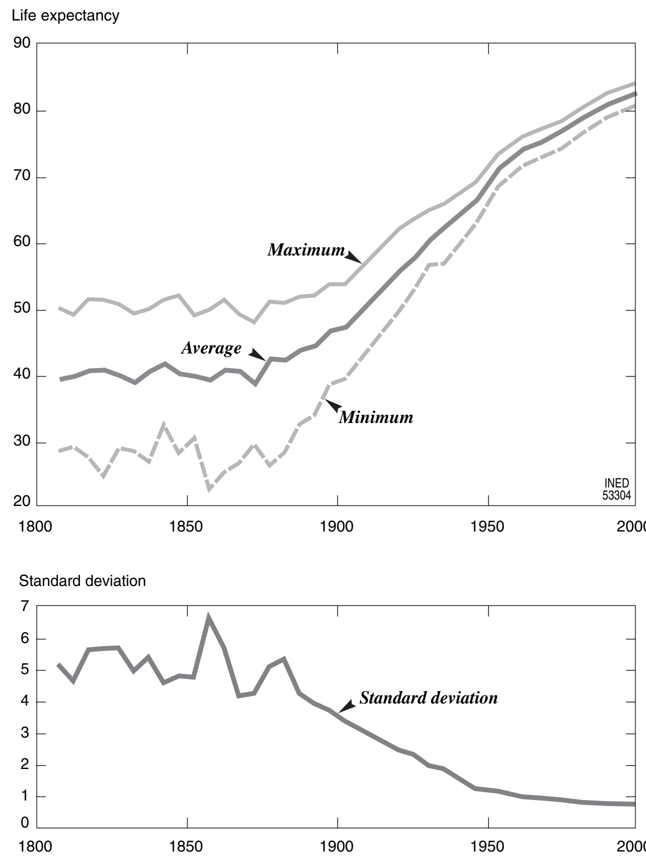

FIGURE 108–17 Evolution in two centuries of geographical variations in female life expectancy in France by department. (Source: Chap. 55, Fig. 14.)

2. The Reduction in Inequalities

Inequality in health is multiform: inequalities between sexes, differences between urban and rural areas, geographical variations, differences in social or ethnic groups, differences between developed and developing countries, and so on. It is also multifactorial: biological differences, selection factors, environmental constraints and nuisances (domestic, professional, residential, etc.), cultural and behavioral differences, and influences due to social (positive or negative) and economic policies. It has also in a diverse number of cases been the object of specific policies aimed at reducing these inequalities. Since it is not possible to deal with all of these in this chapter we shall limit ourselves to three types of disparities: geographical disparities, social inequality in relation to death, and finally North-South inequalities.

a. Geographical Disparities

The role of health policies in reducing geographical variations in mortality was discussed in Chapter 107. In this area, the policy objective is rarely specifically aimed at health but more generally at addressing inequalities in living conditions throughout the whole territory, the idea being that all the regions of a given country should have access to the same development opportunities and that measures implemented by the State should correct the disparities that may be caused by natural conditions in a free market context. France is a good example of the extraordinary change from a health point of view through the somewhat equal distribution throughout the whole of the country of the benefits of medical progress (Figure 108–17).

Whereas during the first half of the 19th century female life expectancy at birth was approximately 40 years nationally, it varied according to the *département* from less than 30 years to more than 50 years. In other words, the difference between the extremes was more than 20 years, more than half the average life expectancy. The standard deviation itself was about 5 years, approximately 13% of the average. This huge gap started to close during the second half of the 19th century, and the phenomenon accelerated from the 1890s, after the coming of the Third Republic, the discoveries made by Pasteur, and the creation of obligatory school attendance and free public, nonreligious schools. From the beginning of the 1950s, for a mean age of 71 years, the deviation between the extremes was no more than 5 years (7.5%) and the standard deviation of 1.1 (1.5%). Since then, geographical differences have lessened but more slowly. At the turn of the century, with a life expectancy of 82 years, the maximum deviation was only 3.3 years (4%) and the standard deviation was 0.7 (0.8%). It would be interesting to know to what extent this massive long-term reduction in geographic inequalities observed in France occurred elsewhere and if it differs according to the degree of national solidarity deployed as a result of the economic, social, and/or health policies. Unfortunately, we are far from having the required historical data.[13]

b. Social Inequalities

Reducing social inequalities in death is at the heart of health policies, namely in industrial countries which just after World War II developed collective systems for the coverage of health expenditure. These systems attempted to combine the philosophy of insurance (the healthy individual pays contributions for the sick person he may one day become) with that of social solidarity (the rich pay for the poor). If one judges by recent changes in mortality according to social category, the least one can say is that the result is not very good. In all European countries where it has been possible to measure them, social differences in mortality have tended to worsen in recent decades.

This evolution is clearly discernible in a country such as Finland, where it has been possible to follow it thanks to a systematic coupling of census data and civil registry information (Valkonen and Martelin, 1999). It is true that the trend for life expectancy at 35 (Figure 108–18) is toward an increase for all social categories, but the difference between workers and managers has greatly increased in 30 years, going from 4.5 years in 1972–1974 to 6.1 years in 1993–1995, among men. Among women, the phenomenon is less acute but just as real, the difference increasing from 2.3 to 3.0.

In Britain also, differences have increased (Figure 108–19). For men, the life expectancy differential at birth between category V (unskilled blue collar workers) and category I (managers) has gone from 5.5 years in 1972–1976 to 9.5 years in 1992–1996.

In France too, an unfavorable evolution in social mortality has been observed for the years from 1950 to 1980 (Desplanques, 1984, 1985), but more recent data do not give any clear indication as to this trend continuing.

Anton Kunst (1997) compared the evolution of social mortality in six European countries from the 1970s until the 1980s. Everywhere, the difference between manual and nonmanual occupations (Table 108–1) increased. And given what is revealed by more

[13] An attempt made by Tapani Valkonen (2001) at summarizing regional deviations in life expectancy in Europe shows to what extent this remains elusive. On the one hand, this study describes changes since the end of the 1960s and therefore begins at a time when the phenomenon was practically over in France. On the other hand, Valkonen was only able to gather data for fewer than half a dozen countries.

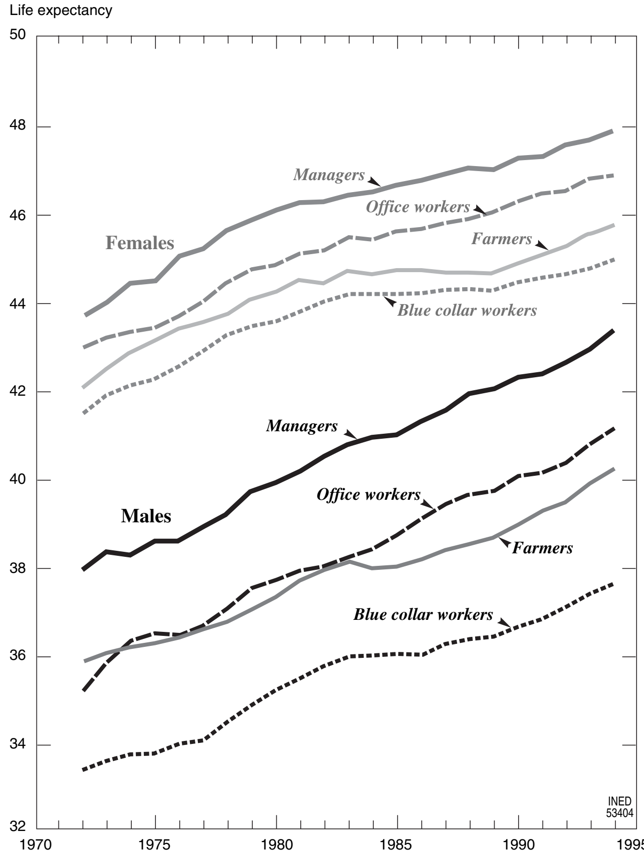

FIGURE 108–18 Evolution in life expectancy at 35 in Finland, by social category and sex, since 1970. (Source: Valkonen and Martelin, 1999; Valkonen, 2001.)

recent data for Finland and Britain, it is clearly apparent that differences will continue to widen.

This widening of social mortality differentials is obviously a failure in relation to the objective defined in 1985 by the WHO Regional Bureau for Europe: "By the year 2000, the actual differences in health status between and within countries should be reduced by at least 25%" (WHO, 1985).

This failure, however, is not necessarily that of the collective health coverage systems prevailing in Europe. It is not possible to know what the situation would have been in the absence of such systems which, it is assumed have made it possible to contain the adverse effects of strong factors. Featuring among these factors are indeed, for certain countries, increasing social inequalities and income differentials (Carrol and Davey Smith, 1997). But this explanation is not adequate since although it certainly applies for countries such as the United Kingdom, it has not played a role in countries, such as Finland, where differences in income have tended to decrease. The main factor in the recent aggravation in social mortality comes from the decline in cardiovascular mortality. The most privileged social groups benefited faster and earlier from this decline. This follows the same principle as the one evoked in the first part of this chapter concerning global evaluation: each major breakthrough in health introduces a phase of divergence because the countries with the greatest capacity to benefit from the progress do so before the others. The same thing applies, within a country, to social groups, the most privileged having a greater capacity to immediately benefit from the progress (Vallin and Meslé, 2004). An eloquent example is that of the role played in Britain by the decline in smoking. The change in attitude which contributed to reversing the trend of increasing lung cancer mortality first occurred among white-collar workers, greatly contributing to the increase in life expectancy differential between social groups (Harding *et al*., 1997).

It would be interesting to compare the European results with those of the United States where there is much less welfare coverage. Unfortunately, we do not have data for the United States that are comparable to the data concerning Europe because of the lack of a strict match between census and civil registry data. On the other hand, the United States has produced a great deal of statistics concerning what is referred to as "race."[14] Because black Americans have on average a socioeconomic status inferior to that of white Americans, this provides another angle from which to view social differentials in mortality.

We already mentioned in the previous section the rather disappointing results produced by the Medicare program on the evolution of life expectancy at 65. If the evolution of life expectancy among black Americans[15] is compared with that of white Americans, one notes, among other things, that not only has the differential not declined, but it has increased considerably (Figure 108–20).

Whereas life expectancy at 65 of whites increased by close to 2 years from 1959–1961 to 1985–1990 (13.0 to 14.9 years), that of blacks increased by hardly more than 1 years (11.9 to 13.1), and the absolute mean deviation almost doubled from 1.0 to 1.8 years. For women, the deviation—which was already greater than that for men at the beginning of the 1960s (1.3 years)—also increased in the same proportions, reaching 2 years in 1985–1990. Yet, the creation of Medicare was accompanied by that of Medicaid, intended to facilitate access to health care for the poor (see Chapter 117), and the elderly black population should therefore have largely benefited from these two programs. Here again, failure may not necessarily be attributable to the programs themselves, which probably lessened what would have occurred otherwise, but to the dual influence of the widening social gap in the United States and the cardiovascular revolution white Americans benefited from earlier.

[14] The notion of race is ambiguous because of its biological connotation. But what Americans refer to as "race" is more of an ethnic and cultural characteristic associated with a skin color with very ill-defined biological criteria (for more details, see Chapter 95).

[15] Mortality among black Americans is greatly underestimated at advanced ages by official statistics because of the exaggeration of the ages declared. However, in a recent article, Irma Elo and Samuel Preston (2004) published life expectancies at 65 since the 1940s, reestimated to correct this bias.

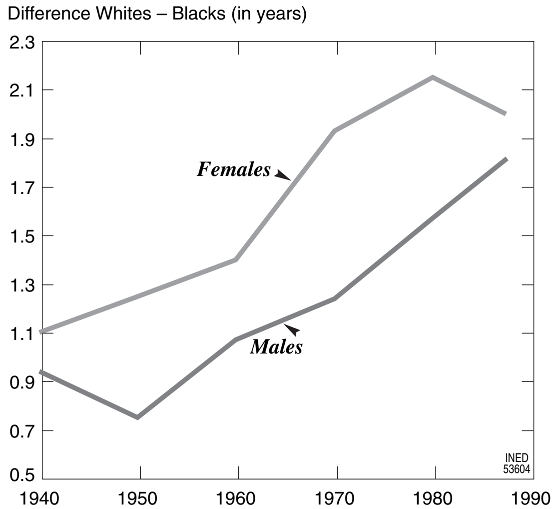

FIGURE 108–20 Difference in life expectancy at 65 between whites and blacks in the United States, by sex, 1940–1990. (Data for blacks from Elo and Preston, 2004; data for whites from life tables published annually in *Vital Statistics of the United States, Volume II*.)

c. North-South Inequalities

One of the major challenges in the reduction of differences in health statuses between developed and developing countries, to which WHO has been committed since its creation, has been to provide rural populations, which constitute the great majority of the population of developing countries, access to medical advances that are already available to most urban populations in the Third World. Such was the objective promoted by the primary health care strategy. And it is a fact that developing countries that have applied this strategy the most effectively have also been the most successful in rapidly reducing excess mortality in rural areas and in generally getting closer to the life expectancy of developed countries. However, this is on condition that it is done within the context of a development policy in which social issues weigh as much, if not more, than economic issues.

China, which inspired this strategy, has been one of the best examples of success, at least up until a certain stage, in spite of all the reservations that one might have concerning the political regime of this country. Unfortunately, there are very few data on rural mortality rates in China in the 1950s. Judith Banister (1987) quotes, with much precaution, a few results of recorded infant mortality, according to which the latter apparently declined from 73 to 20 per 1,000 between 1957 and 1974 in rural areas and from 35 to 10 in urban areas. Even though these figures are certainly underestimated, notably at the beginning of the period and in rural areas, the reduction in the difference between the city and the country is beyond doubt, indicating

that the key to global success resides in a wide dissemination of improved health standards, the main assets of which undoubtedly have been the administrative organization of the territory, the mobilization of the masses, health education, and, above all, a definite will to satisfy the elementary needs of the great majority of the population (Mosley, 1985a, 1985b; see also Chapter 112). However, after the death of Mao Tse-tung, the liberalization of the economy benefited the urban minorities on the coast and considerably slowed down national health improvements. Thus, Chinese life expectancy, which had increased by close to 30 years from the beginning of the 1950s to the end of the 1970s—closing most of the gap with developed countries—reached a ceiling in the 1980s at just under 70 years (Table 108–2). Likewise, infant mortality, after having rapidly fallen from 140 to 38 per 1,000, has not declined any further in the last two decades.

In fact, since the beginning of the 1980s, it was clear that the strategy of primary health care could not succeed independently from the general context defined by the economic and social mode of development. Henry Mosley (1985b) cited, for example, the ambitious health operation of the province of Lampang in northern Thailand, where the recruiting and training of 6,000 primary health care assistants (for 600,000 inhabitants) and substantial financial support were not efficient in that the system did not focus enough on the basic needs of the population (food, infant health, drinking water, and public health) but on the contrary tended to insist on medical care, which had less of an effect on the health status of the population.

It is also at this time that in India, a vast politically heterogeneous federation, the success of the health policy of a state such as Kerala (Nayar, 1985) contrasted with the stagnant situation in Western Bengal (Nag, 1982). If, according to classic indicators, these two states had comparable medical resources, the different use made of them resulted in a wide difference in life expectancy. Having focused more on social development (social services, training, health services, public transport, etc.) and having encouraged greater awareness of the need and the right to use these services, Kerala made it possible to make the most of what was already—ahead of its time—a primary health strategy. In contrast to Kerala, Western Bengal, concerned about giving the priority to economic development, failed. Succeeding in considerably reducing social inequalities in death and in reducing the gap between urban and rural populations, Kerala attained one of the highest life expectancies in the developing world, whereas Western Bengal remained far behind.

Also very early on is the case of Costa Rica, which in 1970 implemented a model policy in primary health care for poor social groups in rural areas. Whereas in 1960–1964, the national infant death rate was more than twice that of the capital, San José, in 1978–1980 the relative deviation was no more than 5% (Rosero-Bixby, 1985). Thanks to this improvement, with a national rate of 20 per 1,000, the health status of Costa Rica caught up with that of industrial countries while in terms of economic performance it remained well below these countries.

But beyond examples of marked differences of this type, that one could list almost endlessly, what is the situation regarding the global reduction in North-South inequalities? To take into account the numbers of people concerned, Figure 108–21 represents the distribution of accumulated populations from different countries in the world according to life expectancy at three successive periods (1950–1955, 1975–1980, and 1995–2000). Developed countries are assembled under the continuous blue line and developing countries under the continuous pink line. At the beginning of the 1950s, life expectancies ranged between 30 and 75 years. The Third World, with life expectancies ranging for the most part between 30 and 55 years (only a few countries with low population rates did better), differed greatly from industrial countries whose life expectancy rates varied essentially between 60 and 70 years. This considerable dichotomy was characteristic of the huge difference that separated those whom Frantz Fanon (1961) called "the damned of the Earth" from the rich.

At the end of the 1970s, the global spectrum of life expectancies slightly narrowed to come closer to the maximum observed in 1950: there are no more countries with a life expectancy below 35 years and the 35–40 group is only composed of a few rare countries with low population rates, whereas no country has gone beyond the maximum bracket of 70–74 already present in 1950–1955. What is more, although the great majority of developed countries have got closer to this peak of the 1950s, a good many developing countries, including China, have closed most of the gap that separated them from developed countries whereas most, including India, had exceeded the threshold of 50 years life expectancy. At this time, however, developed and developing countries still remained far apart, the 65–69 years life expectancy bracket being only very weakly represented.

In 1995–2000, the panorama was upset once again, but under the effect of two different phenomena. On the one hand, the larger populations of developing countries continued to catch up with the top of their distribution, even exceeding the absolute maximum observed in 1975–1980, as certain countries in the group exceeded 75 years of life expectancy. On the other hand, because of phenomena of divergence, within both developed countries and developing countries, a rear guard emerged. As a consequence, the overall range widened, now going from 35 to 85 years. On the one hand indeed, sub-Saharan African countries (under the darker, dashed line) were practically

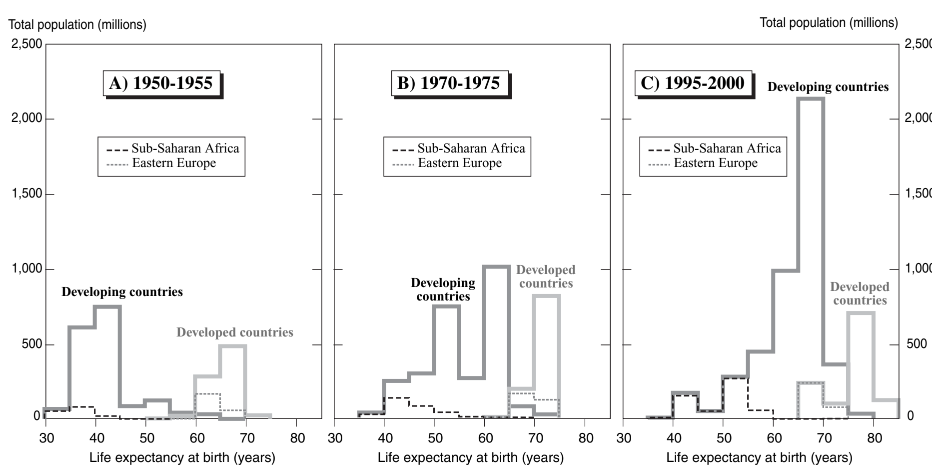

FIGURE 108–21 Total populations according to life expectancy level (Source: Meslé and Vallin, 2003a.) (Figure 108–21 also reproduced in color plate section.)

alone in having life expectancies below 55 years and some of them, namely those hardest hit by AIDS, significantly increased the number in the 40–44 life expectancy bracket. On the other hand, the cardiovascular revolution made it possible for Western industrial countries to take another leap forward, and they are clearly separate from East European countries (represented under the dotted blue line) which now find themselves at the same level as the larger populations of former Third World countries.

In other words, overall, the policies conducted, whether they concern health directly or more global actions and whether they have been conducted locally or are part of international collaborations, have for the majority of them definitely been part the driving force behind a decline in the North-South gap concerning the larger populations. But this result can only leave a bitter taste in the mouths of populations in the North and the South, which have for different reasons and in different ways been abandoned by the wayside.

CONCLUSION

Evaluating the results of health policies, especially when this expression is used to cover all collective measures directly or indirectly aimed at improving health, is usually a great challenge. However, the difficulty resides in the difference in degree according to the angle of observation chosen. It is at a maximum when one seeks to evaluate the results of a political system globally. It is less difficult and sometimes relatively easy to measure the success or the failure of a specific program aimed at obtaining a clearly defined objective. We have seen this, for example, in the case of the global eradication of smallpox, of the anti-malaria campaign of the end of the 1940s in Sri Lanka, of anti-alcohol campaigns, and with certain actions aimed at reducing infant mortality. It is then possible to evaluate the success or failure as well as the scale and sustainability of the results. Concerning policies aimed at reducing inequalities, there again, situations vary, but in most cases problems of interpretation of the same order of complexity are to be found as those concerning global evaluations. This is especially true concerning social inequalities or recent evolutions that appear to present a failure in systems for the collective coverage of health expenditures, but where in fact the aggravation of social inequalities is undoubtedly less than it would have been in the absence of such systems, because of the powerful divergence factors affecting the societies concerned.

More than in any other area, health policies are confronted here with a reality that is becoming increasingly obvious: it would be pointless to assume a health policy can reduce social inequality in death independently from a reduction in inequalities in living conditions in all domains, from the economic to the cultural. More generally, it seems that the main conclusion of this chapter is that it is impossible to dissociate the global results of a health policy from all of the effects produced by economic, social, and cultural policies with which it forms a whole, even though this whole is made up of contradictions. In addition, our analytical instruments are for the time being far too crude and inaccurate to be able to evaluate global results with precision. We may be better equipped to do so if one day we are able to have statistical series allowing long-term comparisons based on more precise indicators such as those suggested in Chapter 109 by Viviana Egidi and Vittoria Buratta.

Information Systems for Health Policies

VIVIANA EGIDI AND VITTORIA BURATTA

Dipartimento di Scienze Demografiche, Università degli Studi di Roma "La Sapienza," Rome, Italy

Instituto Nationale di Statstica (ISTAT), Rome, Italy

INTRODUCTION

Over the recent decades, numerous countries have reorganized their health systems considerably in order to increase effectiveness, improve the quality of service, improve the ability to respond positively to the population's needs, and assess and improve the system's fairness. This revision had become all the more urgent in the need to curb the generalized trend of rapid increase in the cost of health services brought about by both technological progress and the aging of the population (Moise and Jacobzone, 2003). This trend was all the more worrying as it coincided with a stagnating economy and increasingly limited resources.

The solutions adopted, whether at an institutional level or at a management level, are as varied (Docteur and Oxley, 2003) as the historical and cultural contexts of the different countries, but they have all led to health policies becoming increasingly dependent on empirical information which enables them to be evidence based. Whether it is a question of defining a public health policy or of assessing its results, information has become a major tool of this strategy. In a field as complex as health, where economic objectives of efficiency and profitability must obviously be reconciled with objectives of fairness and social justice in access to health care, the availability of information that makes it possible to describe the numerous aspects of the system, and to understand the overall dynamic as well as the underlying interrelations, is an increasingly decisive factor in the success of actions undertaken and in the continuity of the system itself. Political leaders at various levels (government, health workers, citizens) continually require information to enable them to make decisions, establish priorities, evaluate the costs and the benefits, as well as the effects and results of their actions. At the same time, a high demand for information comes from the public which increasingly demands to be able to check that requirements for rationalizing the system and managing costs do not go against individual and collective rights to health or to the fairness of the system.

As attentive observers have often pointed out (Zurkowski, 1974; Shenk, 1997; Stanley and Cripsham, 1997; Hill, 1999), in our modern societies largely based on statistical information, the anarchistic multiplication of all types of information, sometimes apparently or truly contradictory, can lead to a lack of effectiveness in information tools, at the very time when they have become essential; public opinion can therefore be diverted and the decision makers deprived of an essential tool. The extraordinary progress made over recent years in information technology has reinforced this risk by substantiating the false idea that intensive use of advanced technological tools necessarily improves information and makes its use by public authorities, institutions, health workers, and citizens more effective. The thaumaturgic capacity too frequently attributed to new information technologies, which provide access to all types of data, and which are supposed to make it possible to extract the best information at a lesser cost, is confirmed by the recent proliferation of survey results and administrative statistics made available to the general public. This is undoubtedly a case of "rich data, poor information" (Chen and Frolick, 2000).

In reality, in order to obtain real information from basic quantitative or qualitative data, it is necessary to go through a process of selection, which can only be carried out in the context of an initial conceptual framework, which alone can give meaning and informative power to the data available. The best database, even with the most modern and effective analysis, can never alone satisfy the need for interpretation hypotheses. It is the hypotheses themselves which, throughout the process from basic data collection to the development of useful information, determine the quality and the explanatory capacity of this information.

There is an additional crucial aspect to these problems when the user of statistical information is required to stimulate or monitor policies at the supranational level. Beyond the usual requirements of relevance, exactitude, and opportunity, statistical information should also satisfy the overriding necessity of comparability, despite social, cultural, or normative differences which separate countries and which frequently make it very difficult to make a simple comparison of phenomena which are apparently of the same nature.

Thus, in recent decades, new requirements for rationalization have brought new information needs to the forefront of the health policy scene. In the next seven sections we will briefly discuss the necessity of the following actions:

1. Creating information systems
2. Identifying the objectives
3. Identifying the stakeholders
4. Defining a conceptual framework
5. Building information bases
6. Taking into account a complex reality
7. Ensuring comparability

An eighth section will illustrate these subjects with some examples of information systems.

I. CREATING INFORMATION SYSTEMS FOR HEALTH POLICIES

To implement a public intervention within the context of a health policy, or, more generally, a social policy, requires at least four basic stages to be carried out:

1. The precise identification of the *objectives* to be reached

2. The development of a *conceptual framework* highlighting the aspects of the phenomenon that need to be explored or that should be focused on as they condition the achievement of the objective, as well as the relationships that may exist between these different aspects

3. The creation of an *information base* on these different aspects and the organization of its update from administrative sources and surveys

4. The definition and implementation of a *system of statistical indicators*, making it possible to monitor the evolution of the targeted phenomenon and its differentials, to regularly check that the direction followed is the one that will lead to the objective, and to evaluate the effect of the results obtained

The explicit or implicit reference to a conceptual framework is the key criterion to any element of statistical information, which otherwise would only be simple quantitative data of little interest beyond that of the process that generated them. Furthermore, in order to convert statistical information into indicators, it is necessary to be very sure of its adequacy to the targeted objective, in knowledge or in action, as well as the basic hypotheses on which the indicators were built or chosen within the wide panoply of existing statistical information. The traditional chain of knowledge (data-information-knowledge-wisdom) is thus enriched by an additional link, the indicator, where the selection is made, among the available information, of the elements necessary to identify the needs, to orient the choices in the different policy actions possible, to evaluate the costs and benefits, to evaluate the effects of the actions taken and their relevance with regard to the targeted objectives (Laaser, 1996). Recognizing this additional link should make it possible to break out of the vicious circle which seems to have seized information from modern societies and resulted in the availability of an enormous amount of data, notably statistical, and which runs the risk of obscuring rather than facilitating real knowledge of these phenomena.

But what is an indicator? There are numerous definitions of this concept, which are frequently inconsistent with one another in the literature. According to a classic World Health Organization (WHO) definition, indicators are "pieces of crucial, selected information that help to measure changes in relation to priority needs and allow for monitoring of specific aspects of health policy or of factors relevant to the determination of health care and related policies" (WHO 1981c). Other definitions place the emphasis on the function of indirect measurement of the indicators in relation to the studied phenomenon. In any case, the indicator never has a value in itself, apart from that which it could have with regard to the frame of reference that makes it possible to provide an interpretation. The majority of the definitions are consistent on this point.

The debate regarding the requirement in terms of social indicators and their use is certainly not new. Before the 1960s what is known as the "social indicator movement" (UNSO, 1975; Bauer, 1996) attracted the public's attention on the necessity of equipping society with measurement tools that would make it possible to take into account not only economic progress but also social and human development. This enthusiastic phase, which lasted up to the end of the 1970s, was followed by a period of disenchantment and loss of interest in social indicators, the idea being that too many expectations had been placed on the tools themselves, which could obviously never be a substitute for the political process of decision making or the definition of priorities by decision makers and managers (OECD, 1996).

Nevertheless, the indicators have continued to play a limited but important role in some social areas such as education and health. For example, the strategy of the "Health for All by 2000" program launched by WHO at the beginning of the 1980s, made substantial use of a set of indicators, aiming at the measurement of the process followed by the different countries in Europe to achieve the 38 targets laid down in the regional strategy for the continent (WHO ROE, 1993). It can be said that in the field of health, reference to sets of indicators has never been missing from national (van de Water and van de Herten, 1996) or international organizations, even though their greatest advantage has always been on the provision of service rather than on demand, and, even less, on the evaluation of quality of life or the level of user satisfaction. It is only very recently that these aspects have entered on an equal footing into the field of analysis and have led to the development of new indicators.

II. IDENTIFYING THE OBJECTIVES OF HEALTH POLICY

To build an information system, a first fundamental distinction must be made between the objectives of knowledge and decision making and the objectives of policy action and evaluation. These two types of objectives do not necessarily alternate, as the first type is frequently a premise to identifying specific actions from which the aims of the second type could be defined. In practice, they frequently result from distinct subsystems within the same information system. This distinction makes it possible to clarify the nature of the objective and to know how to build the indicators. The objective of the first type is general, such as the evaluation of a population or a group's good or bad health, the evaluation of differences in health in order to promote greater equity in the matter, the identification of groups or geographical zones suffering from specific problems, monitoring specific illnesses that have a high social or health impact, and so forth. In all these cases, the system of indicators is built a priori and can lead, or not, to identifying particular objectives for health policy initiatives, according to the use that is made of them.

The case of evaluating policy actions is different. Here, the system of indicators is closely linked to the targeted objectives and is generally built as an integral part of the policy activity whose effectiveness must be evaluated. Thus, for example, an initiative aiming to improve the effectiveness of a health structure must indicate in advance the evaluation tools that should be used for measuring the manner in which the program attains its objectives. It is a well-known fact that certain evaluation criteria can enter into conflict. More intense use of the structures, measured by a higher rate of use does not necessarily correspond to better effectiveness but can result in unduly prolonged stays in hospital.

Evaluating the overall performance of a health system, which has retained the attention of WHO and national governments in the past few years (Murray *et al.*, 2003), is a different objective again, which requires elements that are relevant to both the first and the second types of objective. Indeed, it requires, at the same time as a general and multidimensional vision essential to evidence-based decision making, care in the evaluation of a comparable nature to monitoring interventions. The debate on the sets of indicators to implement and regularly update is currently ongoing and several initiatives have been undertaken to create a consensual conceptual framework.

Regarding the characteristics of these types of tools, we must emphasize the problems caused by the frequent confusion between the objectives of strategic evaluation and the objectives of monitoring specific actions and how these can skew the evaluation. Indeed, particularly at a national level, the recent debate has focused on short-term objectives (moderation of costs, contribution of individuals and families to health expenditure, patient satisfaction, etc.), often losing sight of the main objective of any health system, which should be to improve the population's health while combating inequality (Murray and Evans, 2003). It is absolutely necessary to revert to a more correct use of the various available tools and to a more long-term view of evaluation. A set of indicators that only fulfill sectoral objectives, and are frequently limited to certain specific functions of the health system when they are not limited to one particular process, is only significant with regard to these objectives. It is not rare that a short-term success in achieving these objectives coexists with a mid-term and long-term failure in the general improvement of a population's health and in the fairness of the health system.

III. IDENTIFYING THE STAKEHOLDERS OF HEALTH POLICY

The objectives of health policies can also vary according to the stakeholders: from local, to national, to supranational, each player is situated at a different level of general knowledge, has different abilities, and needs different anchorage points for his or her activities and decisions. Thus, for example, the role of the European Union with regard to the health policies explicitly specified by the Maastricht Treaty is to formulate a common policy at the European level for general problems of major social importance (cancer, drugs, AIDS, health promotion and education, accidents, pathologies related to pollution). This obviously requires the availability of comparable statistical information in each member state. Regarding the objectives targeted by the national and local governments, these can vary considerably from one country to another according to the type of internal organization and the system of delegation that exists in the field of health policies and health management.

Moreover, stakeholders can distinguish themselves according to how the health system is defined, for example, according to what is understood in the strict sense, that is, all the structures and resources intended to intervene directly on health, or in the broader sense, that is, all the institutions and resources that carry out activities and make decisions which, directly or indirectly, affect public health (quality of the environment, food production, control of risk factors associated with behavior, safety in the workplace, etc.). In this latter case, which is certainly more effective for reaching the ultimate objective of improving the health of the population, management of responsibilities, as well as the information medium necessary to direct the various actions, can become extremely complex. This vision, despite its complexity, has the advantage of highlighting the articulated system of interrelations that exists between health and the other aspects of economic and social life, and favors improvement in the coherence of policy actions in the various fields.

Finally, identifying the objectives targeted through public health intervention pre-supposes that choices have been made on the basis of a list of priorities. The objectives should therefore be chosen on the basis of a cost-benefit analysis and should be measurable. From this point of view, a circular process is set up that encompasses, on the one hand, the requirements in statistical information to direct the definition of the policy goals and to establish priorities, and on the other hand, the need for objectives to direct the collection and analysis of statistical material. The solution to this contradiction can only be found through an iterative procedure of progressive reciprocal adjustments.

IV. DEFINING A CONCEPTUAL FRAMEWORK

Creating a conceptual framework from which the system of indicators will obtain its justification and its direction presupposes that it either refers to a health theory or, at least, to a system of relations between individual and collective health and different factors and phenomena that could influence it. Without an explicit explanatory framework, it is difficult for researchers and policymakers to reach a consensus. In our pluralist societies, researchers and policymakers should be involved in making policy decisions and in choosing objectives and therefore also in collecting information on which they can rely.

There is currently no general framework for describing and analyzing the health of individuals and the population, or the relations that link health to different living conditions. However, there is already a general consensus on the numerous elements that should be taken into consideration in such a plan. A brief description of the logic followed by the creation of a system of relations concerned with health objectives can help in understanding the choices made. Individuals, with their own biodemographic characteristics (sex, age, genetic inheritance, and biological heritage) are presumed to live their lives exposed to the influences of the different environments that surround them (Caselli *et al*., 1990): the *physical environment*, made up of a system of natural resources and external manmade conditions, the *vital environment*, made up of elements indispensable to life (water, air, food); the *social environment*, that is, the system of social relations to which individuals belong: family, network of relatives and friends, school, work, and the cultural system and dominant values in the society and in individuals' reference groups; the *medical environment*, from which individuals obtain their information on behavior that is beneficial or harmful to health and to which they turn when they have a health problem or they become aware of worrisome symptoms, to obtain a diagnosis on their health and the necessary treatment to reestablish their psychophysical balance or to restore their well-being. Numerous tools with which individuals are equipped during their lives (starting with their level of education) influence their ability to construct positive relations with these different environments by understanding the possible negative effects and by establishing more effective relations with them to satisfy their needs. Naturally, the relationship established between the different environments, and between these and an individual's medical history is not a one-way street. On the contrary, in the case of some nonformalized environments, such as the family or the network of relatives and friends, individuals and their history considerably condition the type and quality of the relationships that they establish with these external contexts and the sequences of action-reaction put in place.

Individual medical history is developed in close connection with an individual's life history of which it is part. This is marked by various important morbid events: the occurrence of an illness, the shock of a trauma, or an anomaly in the psychological, physiological, or anatomical structure or functions, according to the type of health process that is under analysis. In particular, in the case of illness, such facts may not be immediately noticed by the individual, thereby often considerably delaying diagnosis and the onset of treatment. The diagnosis of the problem or the transition of a latent condition, structural or functional, physical or mental (a deficiency), the intermediate result (a disability), and the final result of the process, positive (cure, rehabilitation), or negative (chronic illness, permanent disability, death) are all affected. Individuals live and interpret their life history, including their medical history, through the prism of their own perception (Bowling, 1991). This prism substantially conditions their ability to interact with their different environments and has important consequences on the development and the results of their medical history.

From a demographic point of view, collective phenomena and processes correspond to each of these individual events and phases. These phenomena and processes are the targets of a health policy's interventions. In this plan, the traditional morbidity indicators such as incidence, prevalence, lethality, mortality, and the duration of the illness, or the health indicators, such as the different measurements of disability, are all at the same level as the indicators based on the perception that individuals have of their own health.

The various contexts considered as favorable to health can also result in specific sub-systems of indicators. Different typologies of indicators are used in association with the characteristics of the sector and the type of presumed relation to health: morbidity indicators, service indicators, resource indicators, indicators of the demand for health care, and so on.

Other subsystems are then developed to complete the framework necessary for managing the system, especially at the macro level (i.e., funding and expenditure).

V. THE INFORMATION BASE: A COMPROMISE BETWEEN CONTENT AND TECHNOLOGY

As we mentioned earlier, a number of illusions have been generated by the extraordinary technological progress of the last few years. It is almost as if we hoped that the speed and effectiveness of calculation of computers could make up for theoretical weakness and lack of relevance in the interpretation hypotheses.

Today, while it is no doubt essential to maintain elementary information bases that are useable for developing solid and reliable measurements of the phenomena to be studied, it is also true that direct use of elementary statistics (micro-data) is only required for a small number of specific objectives, such as those for research into the relation between the various behaviors of the same individual, and the effect of some of these characteristics and behaviors on his or her health.

Information systems based on indicators are all the more useful, as a support for evaluating decisions and policies, when they are created in such a way that they can be continually updated and gradually adapted to the knowledge requirements that may become apparent over time. Their usefulness is even greater if they have been created in such a way that they can answer questions at different levels, in other words, when they make it possible to reconcile the information needs of decision makers who plan health interventions, each at his or her level of responsibility (local, national, supra-national) in the context of compatible objectives.

VI. CREATING SYSTEMS OF INDICATORS REPRESENTATIVE OF A COMPLEX REALITY

No unidimensional indicator can alone represent the diversity of phenomena or the multiplicity of the dimensions that should be taken into consideration in order to evaluate a population's health or to implement policies aimed at all of the health problems in the complex world in which we live today. It is therefore necessary to develop systems of indicators which, as a whole, can take into account the different dimensions that are useful in the description and analysis of the health of populations, and which are thus capable of providing an integrated view of the different contexts that, directly or indirectly, influence the health of populations.

The definition of the objectives provides a guide for selecting the indicators by making it possible to monitor the variables whose evolution must be evaluated or which are targeted by the health policies (e.g., the incidence of AIDS, the mortality rate by cancer, changes in lifestyles that are dangerous to health, etc.). The available statistics or those which can be obtained through surveys rarely satisfactorily explain the real determinants of a population's health or the risky etiological factors, even when a precise definition of the risk has been provided. What is generally available is information on variables that, at best, can be considered as proxies for the real determinants or risk factors. Most frequently the information available only enables the population to be listed according to the various characteristics linked to health, without the possibility of interpreting these relations as cause-effect relations. We can therefore only identify groups of individuals that form potential targets for various specific interventions.

A set of indicators developed to take into account different contexts that influence health or different aspects of its condition does not necessarily create a system. Collecting and analyzing basic information, even guided by an explicit conceptual framework, needs to be improved through the evaluation of the characteristics of each element of the system (the indicators) and of their interrelations.

The relevance, credibility, exactitude, topicality, and sensitivity of each indicator must be evaluated. Particular attention must be paid to the purity of the indicator, in other words, to its capacity to quantify a phenomenon in the absence of spurious effects of other phenomena (for demand indicators, the population's age and sex structure, for example). Furthermore, the indicators should be comparable, especially when the objectives pre-suppose the need to compare different situations within the same country or between different countries. From this point of view, it is necessary to be aware that researching comparability can reduce the quality of the indicators in terms of relevance and reliability. In some cases, taking the quest for comparability too far can result in empiricism such that the indicators not only lose all interest for the public and for decision makers, but can even cause errors. For international comparison, for example, indicators of results are preferable to data on implementation methods insofar as health care systems can vary considerably from one country to another, and it is therefore practically impossible to obtain measurements of comparable methods. Without knowledge of specific legislation regulating the provision of health care and its funding in each country, the international comparison of method indicators can lead to an erroneous vision.

Once the elements that can be used to create a system of indicators have been identified, the selection then needs to be carried out followed by the clarification of the linkages between the various elements selected. The system should not be redundant, in the sense that it should not only contain relevant indicators or only the most important, but should also contain elements concerning the availability of medical resources and elements relating to needs. Furthermore, the system should be flexible enough to guarantee its usefulness for different types of users, the possibility of reproducing it, and that of regularly updating it.

In fact, when a system of indicators is set up, it is important to consider the different categories of potential users. As stated previously, from the implementation phase the different levels of decision making in force in the area of health policies must be considered. The system of indicators should provide these different levels of decision making with elements of direction, decision, allocation of resources, and the monitoring and evaluation of the actions undertaken. However, it should not be forgotten that important users of the system are the public in their dual role of decision maker for their own families' health strategies, and as censors of the government's activities. Certain organizations of civil society devote their activities to the evaluation and control of specific aspects of the relation between public demand and the service provision of health structures. These organizations are interested in monitoring the results of health actions and are therefore potential users of the information systems; their specific needs also should be taken into consideration.

Another specific type of users are health workers who, in their daily routine, need elements of information that enable them to evaluate their work and apply it to other realities. These requirements assume a very specific level of detail, which could be difficult to ensure with an information system directed toward strategic decisions. In the context of this purpose, particularly in the clinical field, systems for communicating and sharing information on medical practices have been developed, which have contributed significantly to the spread of improved approaches and reduced the considerable differences that existed previously (OECD, 2003a). Evidence-based medical practice set up on this basis and with these tools has affirmed itself over recent decades and has opened the way to considerable progress in the treatment of the most important pathologies. The problem now is to create connections between these specific information systems and the higher level information systems, which due to satellite systems, for example, make it possible to supply the higher level with composite indicators without losing the specificity required by the daily activity.

It is not necessary to expand further on the various stages for a successful implementation of a perfect system of indicators that includes all these characteristics and properties to understand that such a system is more an aspiration toward an ideal situation than feasible instructions. It is improbable that real conditions will make it possible to conform to this theoretical framework in the near future. In practice, numerous compromises are necessary.

VII. ENSURING COMPARABILITY THROUGH HARMONIZATION

In Europe, comparability became a crucial requirement during the 1980s and 1990s, following the publication of WHO's Regional Office for Europe of the *Targets for Health for All by 2000* (WHO, 1985), which established a vast panoply of indicators for measuring progress toward the objective of "Health for All by 2000." Indeed, the strategy of "Health for All by 2000," launched by the World Assembly of WHO in 1977, made the countries increasingly aware of the need to have adequate and comparable information for the formulation, monitoring, and evaluation of policies. Indeed, this strategy stresses the need for quantitative objectives, which are translatable in the form of statistical indicators, which facilitate the monitoring, evaluation, and transparency of health policy decisions (WHO, 1981b). WHO Regional Office for Europe, in adapting the world strategy to the European context, has adopted a set of objectives (38 in total), which include the need to implement a health information system based on a core of internationally comparable indicators in each country (WHO ROE, 1980, 1993). Consequently, the need to develop common methods and tools to carry out comparative analyses of the population's health has increased. The main problem was that the majority of the indicators selected posed enormous problems of comparability between countries. Despite the progress made regarding the definitions to adopt and the measuring tools to employ, these issues are far from being completely resolved.

Fifteen years have gone by since the first *Consultation to develop common methods and instruments for health interview surveys*, held under the aegis of the WHO Regional Office for Europe, and the Central Bureau of Statistics of the Netherlands in 1989. Two other consultations followed in 1990 and in 1992, which were also devoted to household health surveys. Both meetings made considerable progress toward improved comparability between countries, especially in the field of measuring disability. However, much remains to be done before we can conclude that enough headway has been made in harmonizing health indicators (a process which, in fact, has only just begun), or even sufficiently explored the perspectives. Different measurements based on household health surveys must be analyzed, as must other sources (registers, hospital statistics, etc.). When the problems that impede the comparability of data from these sources are resolved, they will become information sources of great value.

The first cycle of consultations started a process which has since then resulted in numerous confrontations. As an example, let us quote two significant cases. The first is that of the Eurohis project (*Common methods and instruments for health interview surveys in Europe*) directed by WHO Regional Office for Europe.

The overall objectives of the project were as follows:

- The development of Health Interview Survey (HIS) tools
- Common methods and tools (a guide) for use in household health surveys, as an integral part of national health information systems
- The promotion of their use in national surveys on household health
- The adaptation of national data for international comparison
- The development of analytical methods to improve the comparability of health survey data already available
- The adaptation of national HIS for international comparison, to demonstrate, as far as possible, their potential with regard to international comparisons

The project aimed to establish indicators in the following fields:

Chronic physical illnesses
Mental illnesses
Alcoholism
Physical exercise
Medical consumption: recourse to health services
Medical consumption: recourse to medication
Preventative action: vaccination, check-ups, etc.
Quality of health

The Eurohis project came to an end in 2002 and resulted in a set of recommendations, which appeared in a WHO publication (Nosikov and Gudex, 2003).

The second example concerns a project for harmonizing data pertaining to disability. It was generated by the Washington City Group on Disability Statistics whose main objective is "to guide the development of a small set(s) of general disability measures, suitable for use in censuses, sample-based national surveys, or other statistical formats, which will provide basic necessary information on disability throughout the world" (http://unstats.un.org/unsd/methods/citygroup/washington.htm). The project is still in the development phase and should conclude in 2005.

The aim is now to follow this path and widen the field to include other tools and indicators, to analyze their characteristics and effectiveness under different conditions, as well as to eliminate the factors that prevent or impede access to a satisfactory level of international comparison, beginning with numerous differences in the quality of statistical data on methods. The identification and eradication (or at least control) of these problems would improve the comparability of the indicators without sacrificing the specificity of the information. This is obviously a difficult task (as can be seen in the scale of efforts made that have not always met with success), but it is a task which must be carried out if we wish to build a system that allows for international comparison of the population's health, as well as a basis for formulating recommendations for the health and social policies of each country and the monitoring of the actions undertaken by each country to achieve "Health for All."

VIII. SOME EXAMPLES OF INFORMATION SYSTEMS

At the international level there have been numerous attempts to build systems of indicators, for the purposes of description and perspective, as well as for policy purposes. Among the most visible is the OECD (Organization for Economic Cooperation and Development) Health Data system, the most recent edition (annual) of which dates back to 2003, and WHO's "Health for All for the 21st Century" system of indicators.

OECD's system is one of the historical systems of reference in the area of health. It is a typical cognitive system, that is, a very large collection of indicators, updated annually, which relates to multiple fields: from the health of the population to the operation of health systems and to the environmental and social frame of reference (Table 109–1). The data are presented at a national level for the various countries and in historical series (since 1960). Since 1991, the system has been available in electronic form as a CD-Rom containing the whole consultable database, supplemented by meta-data.

As is recalled in the brief history on WHO's website,

> Health for All was adopted in 1977 and launched at the Alma Ata Conference in 1978 to underline the fact that despite the ambitious proclamations enshrined in the WHO Constitution,[1] large numbers of people and even whole countries, were not enjoying an acceptable standard of health. By the late 1970s nearly 1 billion people were living in poverty. The HFA renewal process was launched in 1995 in response to accelerated global change and to ensure that individuals, countries and organizations are prepared to meet the challenges of the 21st Century.
> (http://www.who.int/archives/hfa/history.htm)

This strategy was accompanied very early by the implementation of a system of indicators intended to ensure monitoring, in order to periodically verify its progress and to evaluate the national initiatives of adaptation to the strategy. In fact, while on the one hand, this strategy is aimed at all WHO's member states in the same way, its adaptation to national realities is left to each country in the context of each country's own health policies. The year 2020 is the target date for completion. It can be viewed online at http://hfadb.who.dk/hfa/.

The available indicators relate to many aspects of the health of populations and its determinants. Definitions are provided for each indicator, as well as a classification. The principal fields selected are as follows:

Demography and socioeconomic situation
Mortality
Morbidity, disability, and hospital discharges
Lifestyles
Environment
Health care resources
Health care utilization and expenditure
Maternal and child health

FINAL REMARKS AND CONCLUSION

As we emphasized at the beginning, in recent years a number of the world's large countries have been faced with problems caused by increasing constraints

[1] In its preamble, WHO's Constitution proclaims, inter alia, "The enjoyment of the highest attainable standard of health is one of the fundamental human rights of every human being without distinction for race, religion, political belief, economic or social condition." The Constitution also stipulates that "the health of all peoples is fundamental in the attainment of peace and security and is dependent upon the fullest cooperation of individuals and states."

TABLE 109–1 List of the Variables Included in the OECD's 2003 Health Database

Part 1. Health status
Mortality
- *Life expectancy*
- *Causes of mortality*
- *Maternal and infant mortality*
- *Potential years of life lost*

Morbidity
- *Perceived health status*
- *Healthy life expectancy/Disability-free life expectancy*
- *Infant health*
- *Congenital anomalies*
- *Dental health*
- *Communicable diseases (HIV/AIDS)*
- *Cancer*
- *Injuries*
- *Absence from work due to illness*

Part 2. Health care resources
Health employment
In-patient beds
Employment-to-beds ratio
Medical technology
Education in health and welfare

Part 3. Health care utilization
Prevention (immunization)
Consultations
In-patient utilization
Average length of stay
- *Average length of stay for in-patients and acute care*
- *Average length of stay by diagnostic categories*

Discharges
- *Discharge rates by diagnostic categories*

Surgical procedures
- *Total surgical procedures*
- *Surgical procedures by ICD-CM*
- *Transplantation and dialyses*

Part 4. Expenditure on health
National expenditure on health
- *Total expenditure on health*
- *Expenditure on personal health care*
- *Expenditure on collective health care*
- *Prevention and public health*
- *Expenditure on health administration and insurance*
- *Expenditure on health-related functions*
- *Expenditure on medical services*

Total expenditure on medical services by functions
- *Expenditure on in-patient care*
- *Expenditure on out-patient care*
- *Expenditure on home care*
- *Expenditure on ancillary services*

Medical goods, dispensed to out-patients
- *Total expenditure on medical goods*
- *Pharmaceutical and other medical non-durables*
- *Therapeutic appliances and other medical durables*

Part 5. Financing and remuneration
Health expenditure by source of funds

Part 6. Social protection
Social expenditure
Health care coverage

Part 7. Pharmaceutical market
Pharmaceutical industry activity
Pharmaceutical consumption
Pharmaceutical sales

Part 8. Nonmedical determinants of health
Life styles and behavior
- *Food consumption*
- *Alcohol consumption*
- *Tobacco consumption*
- *Body weight and composition*

Environment: air quality

Part 9. Demographic references
General demographic
Population age structure
Labor force
Education and training

Part 10. Economic references
Macroeconomic references
Monetary conversion rates

on health resources while an increase in demand has been reinforced by technological progress and population aging. The case of the United States, the United Kingdom, Germany, and the Netherlands are emblematic. Even though they involve national systems that are completely different from one another (from the private model of the United States to the universal public system of the United Kingdom, from the social insurance model of Germany to the combined system of the Netherlands), since the end of the 1980s, they have all experienced a period of crisis and reorganization (Docteur and Oxley, 2003). The curbing of costs has, as noted by some, become the "war cry" of decision makers, of managers, and, sometimes even, of practitioners (Patrick and Guttmacher, 1983).

In this general context of the desire to rationalize health systems, the role played by indicators has become a fundamental one, as we have already mentioned. Just as fundamental is creating a link between the system of indicators and the decision making system. However, too frequently when discussing indicators, we run the risk of becoming immersed in the swirl of an operationalization logic, by imagining that indicators should only be used for specific objectives. Vice versa, the current situation obviously requires systems of overall cognitive indicators as well as systems of indicators directed toward specific problems.

As is the case for the system that Eurostat is currently setting up in cooperation with all the countries of Europe, and as is the case for national systems (Italian, German, British, and Dutch, e.g.), the first type of system should supply a framework of information constituting the base from which institutions and governments should steer, to decide on which phenomena to take into consideration, the actions to carry out, and the methods of health surveillance (Egidi, 2003). At certain stages of activity and programming, compartmentalized reasoning is impossible; an overall vision is absolutely necessary in order to identify the effects, desired or undesirable, of the interrelations between health and the health system and other economic and social sectors. The availability of systems of this type should make it possible to combat the tendency to promote actions in the absence of a wide view and perspective. Furthermore, these systems are also systems of democratic information accessible to all, that enable the public as well as experts to become aware of the stakes of a situation, which concerns the general public as much as it does public and private decision makers.

The objective of the second type of system is to provide information on which operators and decision makers can base their decisions or commitments. A small number of general indicators are no longer satisfactory. Information at the level of specific needs is required. The increasing complexity of problems consequently leads to an equivalent complexity in the required information systems, which must respond to personalized choices through their diversification.

In short, health information systems should become everyday tools in both the programming and evaluation process as well as in access to understanding public health issues. However, the measures taken should be integrated in a conceptual framework that reflects the interpretative plan of the phenomena and processes concerned. A model that should be based on the debate involves not only the decision makers but also researchers and experts because information alone is never neutral and should be explicitly positioned in an explanatory framework.

Let us emphasize two aspects. First, the need to persevere in this sometimes very difficult path toward the harmonization of indicators and systems of indicators for analyzing the health of the population and the effectiveness of health systems, as well as for monitoring health policies and actions recommended at the international level. In these fields, supranational organizations play a crucial role; they should promote systems that are coherent with one other. Unfortunately, there is no shortcut to this goal. The illusion of the effectiveness of standardized tools that are incapable of taking into account the specific health systems and the social organization of each country, requires that problems of interpreting differences in level or evolution be overcome, and that we become aware of the continuing impossibility of carrying out direct comparisons between countries, even with data that have apparently been collected on the basis of identical definitions and methods (Egidi and Buratta, 1997).

Secondly, the differences and the evolution of the mechanisms that are the basis of demographic phenomena must be evaluated. It is perhaps superfluous to draw attention to the fact that, over time, natural changes occur in the population and the groups comprising it, caused by the aging of individuals and the passing of successive cohorts. Too frequently a cross-sectional approach to analyses and to monitoring progress toward the chosen goals does not permit the correct evaluation of real developments. Thus, for example, the variation in the prevalence of a given disease at a given age between two successive periods can occur without any specific public health initiative. This could be a simple consequence of certain individuals being progressively substituted for others whose life histories cause a change in the incidence of the same disease. The diffusion of attitudes with regard to prevention can be favored by the arrival of better educated cohorts of individuals. The reduction of disability among elderly people can be a result of the aging of individuals who have been better protected during their working lives against risks specific to certain particularly dangerous jobs. It is rare to have the information necessary for the adequate development of a longitudinal approach which makes it possible to evaluate the relations between the life histories of different cohorts. Nor is it common to have access to information that makes a longitudinal evaluation of consequences in terms of health possible, or the calculation of indicators capable of measuring the effect. More often we must be satisfied with cross-sectional or period data and it is necessary to rely on the good judgment of users to at least indirectly take into consideration the effects of such mechanisms.

IV

MIGRATION POLICIES AND MANAGEMENT OF THE POPULATION PYRAMID

GRAZIELLA CASELLI, JACQUES VALLIN AND GUILLAUME WUNSCH

Along with fertility and health, two other major spheres of population policy action relate to the third big factor of population dynamics—external migration—and changes in population structure. Strictly, this latter sphere is another way of coming at the first three, as whatever influences fertility, mortality or migration may feed into the population structure. Combining migration policies and those for the management of the population pyramid in the same part when a whole part has been given to each of the first two factors of dynamics—fertility and health—therefore, smacks of the arbitrary. We take full responsibility for that. It is partly due to the fact that this Treatise has from the outset focused consistently on the natural forces of population development, because we are mainly concerned with large-scale populations (countries, groups of countries, world), where fertility and mortality are much bigger shaping factors than migration. A single chapter on migration policies—chiefly international migration—was thought to suffice here, therefore, given that internal migration has little effect on total population dynamics, and chiefly affects composition. As to the latter, it was also decided not to attempt exhaustive coverage. Many aspects of population structure are of government concern and may be the subject of policies. Our chosen aspect—age structure—is far from the only one. Many countries have strict policies on geographical distribution, where internal migration is a powerful factor, whether in respect of urbanization or broader area planning and development. However, a separate chapter on this was not thought to be required; instead the authors of the country case studies were asked to cover it if necessary, as the analysis of national policies is where an issue so tied to the geographical context of each country can best be understood. Other key aspects of a population structure may also be policy concerns: the social structure, for example, is highly susceptible over the long-term to economic and social policy options;

the sex structure, a growing focus of concern to the governments of some countries where large-scale sex preselection is beginning to be practiced; etc. But limits must be drawn, and so again, the choice has been to focus on the aspect of population structure that has most influence on its development: age structure, which is entwined with cohort replacement.

This fourth part is therefore divided into two chapters: Chapter 110, by Stefano Baldi and Raimondo Cagiano, on migration policies, and Chapter 111, by Michel Loriaux, on the economic and social management of the population pyramid.

Migration Policies

STEFANO BALDI AND RAIMONDO CAGIANO DE AZAVEDO

Facoltà d'Economia, Università degli Studi di Roma "La Sapienza," Rome, Italy

Broadly speaking, most political decisions have an impact on migrants and can therefore be considered as including, whether in an explicit way or not, some migration policy elements. For example, everything that directly or indirectly affects the social sector necessarily influences migration behaviors. However, for reasons of simplicity, the following discussion will only deal, except occasionally, with those policies that are explicitly related to migration; it will also be about labor migration only, without taking into account such movements as those of refugees, displaced persons or asylum seekers (concerning those points, see Chapter 62).

The major reason why workers emigrate to a foreign country is that they are seeking for better living standards, and even for better chances of survival sometimes. The present economic situation in the world, particularly in the poorer countries, is likely to intensify international migration. The growing demographic imbalance between the different countries or regions in the world, particularly in those places where it is combined with wide disparities in terms of wealth distribution, is bound to increase the pressure for migration.

As a matter of fact, international labor flows are a source of immense potentialities, both for the countries of departure and those of reception; however, they have also necessarily become a major political problem.

According to the Program of Action of the International Conference on Population and Development (ICPD) organized by the United Nations in Cairo in 1994 (United Nations, 1995b, item 10.15), "it is the right of every nation State to decide who can enter and stay in its territory and under what condition. Such right, however, should be exercised taking care to avoid racist or xenophobic actions and policies." In fact, governments and bureaucracies have paid little heed to the problems caused by immigration, which has often resulted in negative attitudes developing among local populations toward immigrants, making it easier for xenophobic rhetoric to emerge, as well as opinion campaigns aimed at limiting the admission of foreign workers.

The analysis of migration policies can be divided into four points:

1. The migration policies of the receiving countries
2. The migration policies of the countries of emigration
3. International organizations and migration policy agreements
4. New elements in migration policies

I. THE POLICIES OF THE RECEIVING COUNTRIES

Although any classification of social phenomena is necessarily arbitrary and questionable, still the various areas for migration policies intervention must be distinguished so as to make the discussion as clear as possible. Only, it must be emphasized that such distinctions should not be understood as drawing impassable borders. There are necessarily blurred areas and discrepancies between the different spheres, whatever classifying system is adopted.

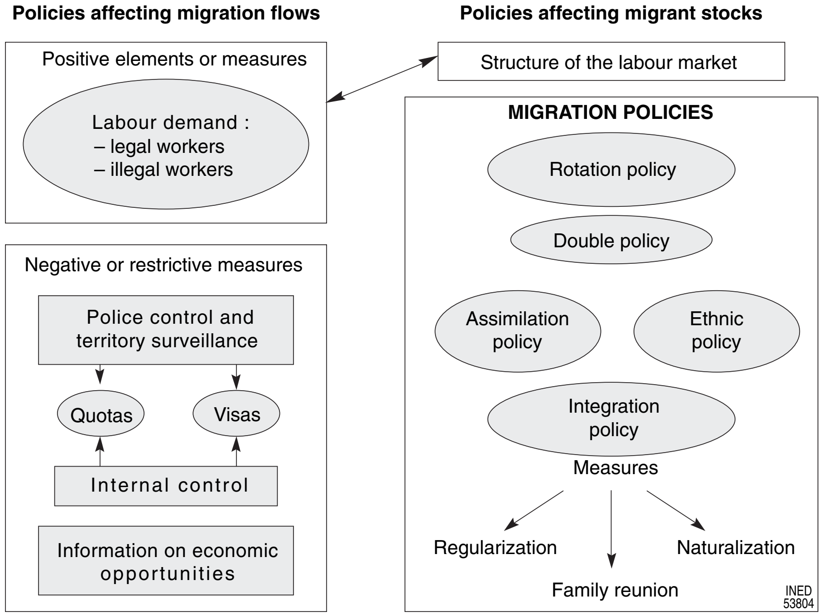

FIGURE 110–1 A schematic comparison between the logistics and methods of flow policies and stock policies as determined by labor demand in the countries of reception.

The simplest, and probably most efficient, approach consists in distinguishing between policies that aim at affecting flows and those that influence stocks. We will proceed along such distinction, first concerning the policies of the countries of reception, and again in Section 2 of this chapter, concerning the countries of departure.

Policies concerning flows and those affecting stocks are obviously closely interdependent, but the methods used by those two types of policies are different, and they each have their own characteristics, as summarized in Figure 110–1.

1. Policies Affecting Immigration Flow in Receiving Countries

Those policies that aim at influencing migration flow may clearly work several ways. Measures can be adopted to increase (positive measures), reduce (negative measures), or keep stable the net number of admissions.

The most significant positive element that affects migration flows is demand for employment. The volume, composition, and schedule of migration flows are, more often than expected, determined by employment demand rather than by supply.

Moreover, the labor market is segmented in such a way that in certain developed countries, substantial unemployment (among the natives) coexists with quite sizeable immigration. This is because immigrants usually accept work in sectors that imply risks or even danger (e.g., in mining or industry), or in illegal activities (such as prostitution, drug trafficking), particularly where the natives are not inclined to do so.

On the other hand, the richer countries, where the populations are aging, may also need to use immigration to compensate for the lack of native labor in some particular sectors, including services (domestic services, catering), the building industry, and public works.

Several reasons account for immigrant workers accepting low-skilled, or unskilled, underpaid jobs from the start. Firstly, most immigrants from the South come from rural areas, have low educational levels or are even illiterate, and have no experience working in industry. They also have language challenges. But above all, because of their status—due to precarious work permits, and sometimes to their being illegal immigrants—they are in a weak position when it comes to negotiating salaries, all the more so because to them survival is a matter of emergency.

As a matter of fact, many immigrant workers are in breach of immigration regulations. Such a situation has been termed *illegal* or *clandestine immigration*, and the migrants themselves *illegal* or *undocumented immigrants*. As the presence of an illegal worker implies the existence of an illegal employer, the size of the phenomenon is closely related to tolerance—or need—of illegal labor.

Migration flows may have substantial consequences over the structure of the population, in the country of reception as well as that of departure. Employment-related migration usually concerns groups of male young people of working ages (25–45 years old). Migration policies that aim at family entry and settlement may correct the imbalance characteristic of populations of migrant workers. Differences are often to be observed in the fertility—and sometimes the mortality—between the migrants and the natives. Fertility rates are usually higher among the former than the latter. The situation is not quite so clear as far as mortality is concerned, because of the effects of selection as the migrants enter a country or leave another, but the fact is that immigrants are usually provided with health facilities that are not quite as good as those provided to the natives. However, those differences, which have a direct effect over growth rates, tend to fade as time goes by and the migrants integrate or assimilate.

Volume II, Section II in this book is on the determinants of migration; those clearly have direct and indirect implications for migration policies, which vary in time as well as from one country to another. Those policies may be either positive, in favor of immigration, or negative, aimed at restricting it or even at encouraging emigration.

Positive measures aimed at encouraging immigration may result from different objectives and make more or less intensive use of various instruments with a view to reaching the implicit or explicit targets of the government in the country of reception.

It is usually a question of meeting internal needs, mostly economic ones. It may be a matter of general need for reconstruction or economic growth, such as experienced by many European countries after each of the two world wars or during the Thirty Glorious Years (1945–1975), but there may also be more specific needs in certain sectors of the economic system that suffer from lack of one type of labor or another. For example, immigration was encouraged in the last century in Europe for the specific needs of the mining sector and the steel industry. In more recent times, the sector of personal services (domestic, medical, and assistance services) has been making much use of immigrants from Central and Eastern Europe, and even from Asia. Apart from Europe, the Gulf countries, and before them North America, Australia, and New Zealand have always used immigration to serve their economic development.

In the latter cases, what was at stake in those policies was even, in a more general way, to get colonists to settle on uninhabited lands, as is still the case nowadays as Israel actively implements its policy of drawing the Jewish diaspora together. Likewise it is mainly for political and cultural reasons that West Germany has always claimed willingness to take in any person of German descent who would like to come and settle there; the ultimate point of such a policy was reunification.

Specific migration flows were also encouraged, or even planned, with a view to settling conflicts (e.g., in the aftermath of colonial relations) or to organizing cooperation for development. There are many recent agreements in which extraordinary quotas for agreed immigration were set between the countries of destination and those of departure, just as such cooperation agreements include all kinds of interventions for development—loans at favorable rates, investment flows, letting the partners off their debts, and other supporting measures for underdeveloped economies. Such agreements have been concluded between Germany and Turkey, Italy and Albania, Tunisia and Morocco, and others.

Besides such economic and political objectives, there are also humanitarian ones contained in the measures concerning the admission of refugees, whether as part of international agreements on the right of asylum or of specific policies such as those on territorial asylum in France, which makes it possible for persons who are threatened by war or persecution to get asylum in a receiving country. In the last few decades, the restrictive policies enforced in the richer countries with a view to slowing immigration down have badly impaired the existing system (particularly since the Geneva agreements). However, there are a few remnants of it, which could be reactivated. An example is provided by the recent history of the Balkans.

In more recent times a specific need for support has emerged in the countries of the North of the World, where very low fertility rates, combined with high levels of life expectancy, have caused unprecedented demographic aging of the population. True, no country has explicitly adopted an immigration policy aimed at meeting that need yet; still, it is not impossible that such types of measures be taken in the near future. In fact, a recent UN report strongly recommends that the countries concerned begin to do so (United Nations, 2000).

In any case, in all those different areas, the trend is in favor of negotiated and international agreements. Most of the time such agreements are developed and implemented due to the pressure of growing needs. As a consequence migration flows are taking extremely varied forms, and can be defined in very different ways depending on which questions are asked—Who? How many? How? Where from? Where to? Under what legal conditions? In what political contexts? (Golini, 2003).

Negative measures, still more than positive ones, are also intended to meet national concerns in the countries of destination. The latter are clearly bent on controlling the flows, and when immigration seems undesirable to them, they enforce drastic policies so as to limit the flows, or even to stop them altogether, or again to turn the immigrants out of the country.

Such policies may be related to chauvinism, as was the case under the fascist regime in Italy, or to a situation of conflict, such as prevails between Israel and the occupied Palestinian territories. More often yet they express a more general concern with regulating immigration flows for economic or socio-cultural reasons, which often merge in a more or less confused, or even demagogical way, particularly in times of elections.

In several European countries, including those where immigration is recent, such as Spain, Italy, or Greece, measures setting a limit on admission flows are combined with regularization action through which the situation of immigrants who previously entered the country in a disorderly, or even illegal way, can be resolved.

In the countries where there has been long-standing immigration (France, Germany, the United Kingdom, Canada, the United States, Australia), regularization and control measures are also usually combined with integration policies in which the provisions for naturalization or access to citizenship play an important part, with wide differences from one country to another. For example, in Europe, France, where the right to citizenship by virtue of birth in the country prevails, can be considered favorable to naturalization, as opposed to Germany, where the right to citizenship by virtue of kinship prevails, making naturalization more difficult to get; on the other hand, American and Canadian legislations are far more favorable to naturalization than the French legislation.

In any case the economic situation, particularly that of the labor market, plays an extremely important part; however, internal and international rules in favor of basic human rights, of which the different countries are more or less observant, are also important. It is in that view that family entry and settlement is one of the most widely accepted exceptions to restrictive policies.

In spite of controls, a number of migrants manage to get across most borders. The United States is the country with the largest number of illegal migrants (7 million of them in 2000, by Immigration and Naturalization Service estimates) because they have such a long border with Mexico. According to the Organization for Migration (IOM, 2003), illegal entries into the European Union may well be as many as 500,000 a year.

Controlling immigration may eventually lead to militarization of borders, which may have an impact on the political system in the country of destination.

> There is a fear that militarizing external borders may eventually lead to the militarization also of society. [. . .] A complete control is nearly impossible in the Western democracies today, considering the political costs of militarizing/policing borders and internal structures. Neither does it seem possible due to the fact that the labor market in itself represents a "pull" factor in many of the countries, indicating that (sometimes powerful) groups are having vested interests in a continued flow. Besides, it seems difficult to stem immigration without discouraging tourism, as a significant number of illegal immigrants today legally entry as tourists in the first place. (Brochmann, 1993)

The *quota* system, in which the number of immigrants is set based on their initial nationality or other such criteria (IUSSP, 1982), is used with a view to limiting the number of newcomers and stabilizing immigration. Switzerland provides an example of countries that offer different quotas to immigrants depending on the type of work permit (on a year, season, or short visit basis) that they apply for.

Visas and border controls can be more efficient if they are buttressed with computerized databases on undesirable persons (as stipulated in the *Schengen* agreement, e.g.). The criteria used by host countries for work visas (and hence for immigrant selection) are widely varied—family entry and settlement, skills, random methods (such as lotteries), and so on. The efficiency of visas as a means to control entries is closely related to the internal controls to which foreigners are subject.

The authorities in charge of immigration policies can establish several types of internal control. These range from internal surveillance to access to a resident's permit or an identity card, access to lodging and social benefits, measures taken against employers, etc.

Theoretically, potential migrants will ground their decision to migrate on assessment of several elements. Salaries in real terms in the country of destination rank among the most important elements. The level of employment, the possibilities of getting accommodation, and last but not least, the financial and moral or psychological cost of migration, are also important. Last, specific information, focused on the economic opportunities offered by the host countries, may help potential migrants to make correct assessments.

2. The Stock Policies of the Host Countries

A stock policy is any measure or regulation that either encourages migrants to settle in the host country for long periods of time, or even for their entire lives,

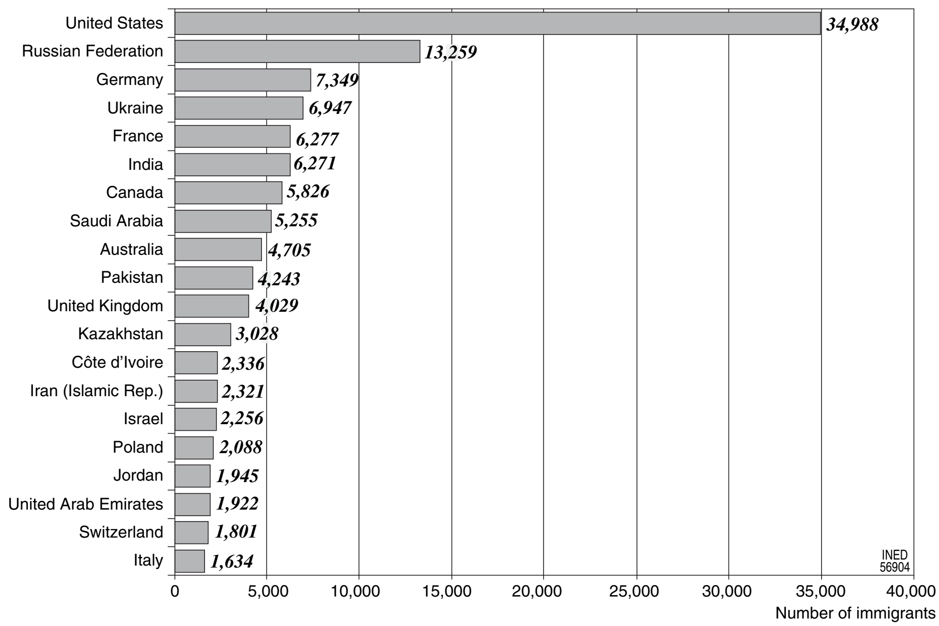

FIGURE 110–2 Numbers of immigrants (in thousands) in those countries where stocks were largest in 2000. (Source: United Nations, 2002.)

or to stay there for a very limited period only. Considering equal flows, such policies will determine the size of the stock, but also the rotation pace and hence the characteristics of the stock.

Figure 110–2 is an illustration of the comparison between the sizes of the largest immigrant stocks in the world.

Immigrants from the same country or region who have been living in a country for a long time eventually form a community. The latter may be more or less attached to their origins, depending on both the policies enforced by the host country and the immigrants' attitude.

Before studying the various degrees of immigrant integration into host societies, we must mention the part played by labor market structures as a determining factor in the formation and composition of migrant communities.

Immigrants, as mentioned earlier, usually find jobs among the lowest segments of the labor market. Supply of cheap labor from immigrants makes it easier for the host country to keep up its social system, particularly in times of economic recession. Besides, as far as illegal workers are concerned, the cost of labor is further brought down through nonpayment of welfare costs (health insurance, pension funds, etc.).

Despite the economic benefits derived from it, immigration is often described as a threat to the host country's economy. It is considered one of the factors in rising unemployment (particularly for unskilled workers) and is sometimes perceived as a danger to social stability. Such a biased image fails to take into account the fact that the labor markets, in most developed countries, are characterized by segmentation. It also ignores the fact that certain chores are economically and socially unattractive in the eyes of native workers. It thus appears that immigration has no effect either on the nationals' income or their employment (OECD, 1993).

One of the most obvious effects of immigration for the host country is that it reduces the cost of labor. In the short and the middle term, immigrant workers are underpaid and overexploited, as compared with native workers, because of their weak, marginal position in the labor market; they are also usually employed in particularly difficult sectors (the steel industry, mining, fisheries, etc.), in services that do not pay well (as domestic servants, in the food industry, etc.), or in seasonal work (agriculture) that nationals, even when they are unemployed, find unattractive. Small and medium-sized enterprises are particularly in need of cheap foreign labor, which makes it possible for them to remain flexible and keep their production costs down. Immigration thus generates immediate profit for many different groups (heads of companies, middle-class households, etc.), while the cost for society (in terms of welfare, educational, and health services) is deferred.

In most cases, foreign immigration has proved not to be a temporary phenomenon. Most immigrant workers who entered the host country in periods of economic growth subsequently decided to stay longer than might have been expected.

However, there are exceptions. Switzerland provides a famous example of workers' rotating immigration. The system is characterized by short-term work permits and seasonal authorizations. Workers then have to make frequent moves between their native country and the host country. To make sure that temporary workers actually remain so, rotation must be fast. Naturalization and family entry and settlement are very rare. Egyptians migrating to the oil-producing Arab countries where there is regular rotation of foreign labor is another example of temporary migration.

There is still a lot of seasonal work in many European countries, such as Germany (particularly from East European countries) or Italy (from North Africa).

The various degrees of integration in the host society can be classified as (a) assimilation, (b) the ethnic approach, or (c) integration. *Assimilation* can be considered as full acceptance of immigrants by the host society, until they are completely absorbed into it. Immigrants are scattered within the national community, with which they identify, and from which they eventually stop thinking of themselves as different. The much-used "melting pot" image gives an idea of ethnic identities mixing into a new homogeneous identity that emerges from the mixing. Any form of assimilation makes integration easier, because it accelerates the learning process and the use of public and private services in the host country.

Conversely there are cases (as Asians do in Britain) when immigrants do not really wish to get assimilated into the host society. In such cases they tend to establish close collaboration within the immigrant community that they form and to keep up close links with their native country.

The *ethnic approach* has negative aspects, such as the emergence of rivalry between the different groups, but also positive ones, such as cultural enhancement. The United Kingdom provides a typical example of that form of approach. The government guarantees all individuals the right to participate in the country's social, economic, and public life, while fully preserving their freedom to practice their own faith and keep their cultural identity. "Ethnic minorities" are thus recognized and classified. Even in censuses, the population is classified in different ethnic categories—White, Caribbean Black, African Black, other Black, Indian, Pakistani, Bangladeshi, Chinese, other. One side effect of such an approach is that it may heighten the risk of discrimination in terms of housing, schooling, and so forth.

Multiculturalism is a slightly different approach, in which ethnic and other differences are not only tolerated but even encouraged sometimes. In that way, identifiable groups coexist and interact so as to create a heterogeneous, stable society. In the near future, a new ethnic model may possibly emerge and develop in the East European countries where immigration is now a serious problem.

The *integration* of immigrants can be considered from two points of view—the integration of immigrants into the native society (which is the concept most in use), but also the integration of the natives into the immigrant community (in terms of acceptance of their traditions, religions, etc.). In both cases, integration is made complicated by interaction between the policies and societies of the host countries and those of departure.

Integration is not always the result of a deliberate decision; it sometimes happens through necessity rather than by choice. The legislation or the practices of the administration on the labor market may prove to be means to force migrants to seek to be integrated into the host country.

Within the European Union, the aim of integration is to gradually eliminate legal, cultural, linguistic and other obstacles, so that immigrants can have the same way of life as the nationals of the host country. Along that line, the European Council stated at the Tampere meeting (October 15–16, 1999) that

> The legal status of third-country nationals should be approximated to that of Member States' nationals. A person, who has resided legally in a Member State for a period of time to be determined and who holds a long-term residence permit, should be granted in that Member State a set of uniform rights which are as near as possible to those enjoyed by EU citizens: e.g. the right to reside, receive education, and work as an employee or self-employed person, as well as the principle of non-discrimination vis-à-vis the citizens of the State of residence. The European Council endorses the objective that long-term legally resident third-country nationals be offered the opportunity to obtain the nationality of the Member State in which they are resident. (European Union, Conclusions of the Presidency, para. 21)

Assessing integration possibilities requires taking immigrants' attitude into account. In many cases, particularly soon after they have arrived, immigrants will clearly express a wish that they be recognized in their minority groups, an attitude that could be interpreted as a wish not to get integrated into the host society and remain an ethnic minority. High concentration of immigrant populations may delay the integration process, because it encourages keeping up the traditions of the native country, traditional ways of life, and preferential marriages.

However, keeping up the original culture does not necessarily mean a loss in terms of integration. People can well be integrated through their job and daily life, while continuing to practice their religion and preserve their beliefs and customs. The United States and Canada provide good examples of multiethnic integration: the Greeks, the Spaniards, the Italians, the Irish, and the Poles live together, and are integrated into American society in many ways, but to a large degree they continue to preserve their individual ethnic identities and spend their leisure time with their own ethnic communities.

Integration is a psychosocial, long-term process. It takes both time and willingness (or alternatively, necessity). Temporary immigrants are seldom interested in becoming integrated simply because they think they will be staying a short time. Later they may try to get a little more integrated, just enough for them to live quietly.

Integration policies are very slow in producing effects. Also, they are not really compatible with political situations in which governments are expected to find rapid solutions to the social pressure problems that are derived from immigration. Not only the central authorities, but also the local ones, play a crucial part in implementing integration policies that usually target minorities whose demands are very heterogeneous.

The problems related to immigrant integration concern housing, health, education, employment, as well as the social and cultural dimensions. Each of those issues is important and can provide indicators as to the degree of integration among immigrant communities. However, the problems of housing, welfare, employment, and education do not concern only immigrants, and hence cannot be considered as solely related to such or such an integration policy. Local administrations are faced with those problems at a general level.

Immigrants only put in an additional dimension, which the authorities must take into account as they seek for such solutions as may promote local development within society. This applies at a local as well as a national level. In other words, certain policies aim at overall improvement of living conditions (housing, health, employment, services, etc.) with a view to securing social stability, economic growth, and welfare; other policies are more specifically intended to promote the integration of the foreign part of the population; but all have an influence over the degree to which immigrants are integrated.

Accommodation is usually the very first problem that newcomers have to face. Immigrants are subject to accommodation conditions that are inferior to those of the nationals. They often suffer discrimination on the part of landlords, and eventually go and live in areas where they are tolerated because such areas are spurned by the natives. As a result, they are concentrated in specific residential areas, where the quality of accommodation is bad and living conditions are far below standards.

"Education is of vital importance to the integration of immigrants' children. Both the level of schooling achieved and the diplomas obtained are determining factors in their success in the labor market and their integration into the society of the host country" (OECD, 1995). The concentration of immigrants in specific areas has consequences for education, because the normal implementation of school curricula may be disturbed by the fact that so many children speak different languages and have such different cultural backgrounds. Some countries, such as the United Kingdom, have been trying to distribute immigrants' children among different schools, so that they are not concentrated in some schools only. As education is the main means for young people to make their way into society, immigrant parents usually wish their children not to lose their cultural and religious heritage. Integration policies at school must then guarantee both that cultural identities are preserved and that there is no discrepancy between the education provided to immigrant and to native students.

The issue of immigrants' access to health insurance and old-age pension is closely linked to that of illegal employment. Clearly there is discrimination in the labor market, though it is so complex that it would be difficult to assess. Employers are usually less interested in their employees' integration than in the quality and quantity of the work they provide, whatever their nationality. Immigrants' position on the labor market is one of the basic indicators of their integration.

The level and quality of the education of immigrants' children play a crucial role in their access to vocational training. In this respect, there are two possible approaches: supporting them through the development of specialized training, or implementing antidiscrimination policies at recruitment level.

The idea of the cultural and social dimension of integration includes all the activities of volunteer associations that work toward the benefit of immigrants. Among such associations are those created and run by natives (religious associations, trade unions) and those set up and managed on an ethnic or interethnic basis. The latter are particularly involved in political, social, and cultural activities, either within or outside their communities. Some associations are created with a view to securing well-being and support for their members; if, as sometimes happen, the necessity for such associations is felt to decline, then they either die out or change their activities. For example, some regional ethnic associations are now no more than meeting places for elderly immigrants.

Integration should not necessarily be considered in a positive sense. Immigrants also may be integrated into corrupt groups, with criminal or antidemocratic activities. Paradoxically a high rate of crime among immigrants may be an obvious sign of their capacity to get integrated in the host country. One significant example is the trafficking of women from developing countries, or in more recent times, from Central and Eastern Europe to Western Europe.

> Trafficking in women occurs when a woman in a country other then her own is exploited by another against her will and for financial gain. The trafficking element may—cumulatively or separately—consist of: arranging legal or illegal migration from the country of origin to the country of destination; deceiving victims into prostitution once in the country of destination; or enforcing victims' exploitation through violence, threat of violence or other forms of coercion. (IOM, 1995b)

Sweden and Germany provide two interesting cases for an understanding of the various degrees and methods of integration.

Sweden has been gradually reinforcing its integration policy since the 1970s. Now, every foreign-born resident who has decided to live in the country must demonstrate a degree of integration. The Swedish immigration policy is based on a tolerant kind of multiculturalism. Immigrants are regrouped in parallel organizations by nationality. In that integration process, Sweden, along with the other Scandinavian countries, forms the most advanced region, as it guarantees the right to vote in local elections to those immigrants who have permanently settled on Scandinavian territory.

Germany is totally different, in that the country does not officially consider itself an immigration country. In the past, Germany firmly supported rotation policies and was harshly critical of integration policies. Now, they have changed their approach, and the integration of foreigners and their families who are legal residents on their territory (particularly the "invited workers," who immigrated in the 1960s and 1970s) is one of the principles of the government's "foreigner policy". In Germany's explicitly expressed position, migration has always been reduced to the needs of the country's economic development. As a consequence, even the very limited forms of integration offered to the invited workers who had been living for many years in Germany were never intended to make the immigrants more German-like.

The success of an integration policy depends, to a degree, on the measures intended to limit future immigration. The most significant legislative instruments to control and stabilize immigrant communities are regularization, naturalization, and family entry and settlement. Policies in this respect are extremely varied, even within the European Union (Table 110–1).

TABLE 110–1 The Degree of Integration and the Migration Policies Adopted in Some European Union Countries (as of 1994)

Easy naturalization	**Difficult naturalization**
Sweden, France	Germany
Recognition of "ethnic minorities"	**"Immigrants" or "Foreigners"**
United Kingdom, the Netherlands	All other countries
Formal "multiculturalism"	**Assimilation or departure**
Sweden, the Netherlands	Germany
No residence restriction	**Local residence restrictions**
United Kingdom	Belgium

Source: Macura and Coleman, 1994, p. 60.

Regularization is a means to reduce the number of illegal immigrants. That type of measure is usually used before tightening immigration restriction measures. It has not been proved that regularization measures affect future immigration flows. The regularization of illegal migrants is always combined with sterner measures of immigration limitation. It does ensure that immigrants are better protected, but past experience has shown that it does not prevent new illegal immigrants from coming.

Naturalization can be used as a means to accelerate the integration process. It is easier to secure for those immigrants (or their offspring) who grew up in the host country.

The host countries have widely different policies as far as naturalization is concerned: some countries, such as Canada or Sweden, encourage immigrants to get naturalized as soon as possible so as to make their integration easier. On the contrary, other countries, such as Switzerland or Germany, are very restrictive and consider naturalization to be a reward for immigrants. The issue has also been discussed in world conferences such as the World Summit for Social Development that was held in Copenhagen in 1995, when the final declaration mentioned that "governments of receiving countries are urged to consider giving to documented migrants having the right to long-term residence, civil and political rights and responsibilities, as appropriate, and facilitating their naturalization" (United Nations, 1995b, point 77).

Family entry and settlement is one of the most important means used by the host countries to promote or reduce the integration of legal immigrants. According to the Programme of Action of the Cairo Conference:

"All Governments, particularly those of receiving countries, must recognize the vital importance of family reunification and promote its integration into their national legislation in order to ensure the protection of the unity of the families of documented migrants" (United Nations, 1995e, point 10.12). It is important to note that the Conference, after lengthy discussions, could not come to an agreement on recognizing reunification as a basic right. The right to immigrate may be granted to spouses who are separated, or extended to other family members of those immigrants who have a long-term resident's permit. Family reunification is particularly important for migrant women who are admitted into a country mostly on the grounds that they have family ties with nationals of the host country or with other immigrants. Therefore, they are dependent on the migration and status of other persons. The women who are admitted as workers are usually confined to traditionally feminine jobs (as domestic workers, in services, care, etc.). In fact family reunification policies have made family flows possible. Due to drastic reduction of workers' flows, the latter are now the very first source of residence permits in some countries, such as Italy.

Mixed marriages (between nationals and immigrants) may be considered an indicator of integration. However, it must be kept in mind that marriage is sometimes used as a means to get a resident's permit or the nationality of the host country. A few recent surveys (Tribalat, 1996) have shown that mixed marriages are comparatively unstable, which suggests that they do not necessarily entail reinforcement of the assimilation or integration of immigrants into the host society.

Many different attempts have been made to measure the integration of immigrants (Cagiano de Azevedo *et al.*, 1992; also see Chapter 84). The most useful sources in developing integration indicators include basic demographic data, position within the labor market, household and family structures, the length of the stay, economic activity, education, income, accommodation conditions, naturalization, personal attitudes, and legal status. Two basic aspects must be taken into consideration in measuring migration. On the one hand, there are problems related to the diversity of sources, as a result of data on international movements being probably incomplete; and on the other hand, there are conceptual problems:

> While births and deaths can be defined biologically and marriages and divorces legally, migration is more difficult to define. Migration entails not only the crossing of international borders but also entails the intention of staying in the country or area of arrival. Although international migration may well in many cases entail legal procedures, it remains the most difficult of demographic phenomena to define correctly. (United Nations, 1991, p. 95)

II. THE POLICIES IN THE COUNTRIES OF EMIGRATION

The distinction previously adopted for immigration countries between those policies that impact on flows and those that affect stocks also applies to the countries of origin (Figure 110–3).

1. The Flow Policies of Emigration Countries

Before we study the political measures that affect the flows in the countries of emigration, we will mention the main basic factors that determine those flows: the demographic situation, the labor market, the migrants' networks, and educational level and profile. Next we will discuss how policies can be implemented through border controls, administrative structure, and information on receiving countries.

The demographic situation in the emigration countries is obviously a key factor in migration. The most important variables include growth pace, fertility, birth and mortality rates, and population distribution by age and sex. When fertility is high and mortality is low, the number of people of working age who enter the labor market grows very fast, and the phenomenon continues for some time after fertility has begun to decline. The pace of job creation then can hardly keep up with that of the growth of manpower. In many developing countries, the emigration of part of the population of working age has been a means to solve this demographic problem, at least in part; simultaneously it has also been a source of additional income for development, through foreign currency transfers.

In Western countries population growth is under 0.5% a year, as opposed to over 2% in the developing countries. When the resources of a region prove not to be enough to meet the basic needs of its population, migration appears to be a safety valve. The current demographic situation in the North African countries, for example, despite the very fast decline in fertility that they have experienced in recent times, still implies substantial growth of the population of working age in the next 20 years. Those countries will thus remain a source of migration pressure for another two decades, particularly on the countries in the South of the European Union, unless their economic development is fast enough to absorb that potential excess of labor.

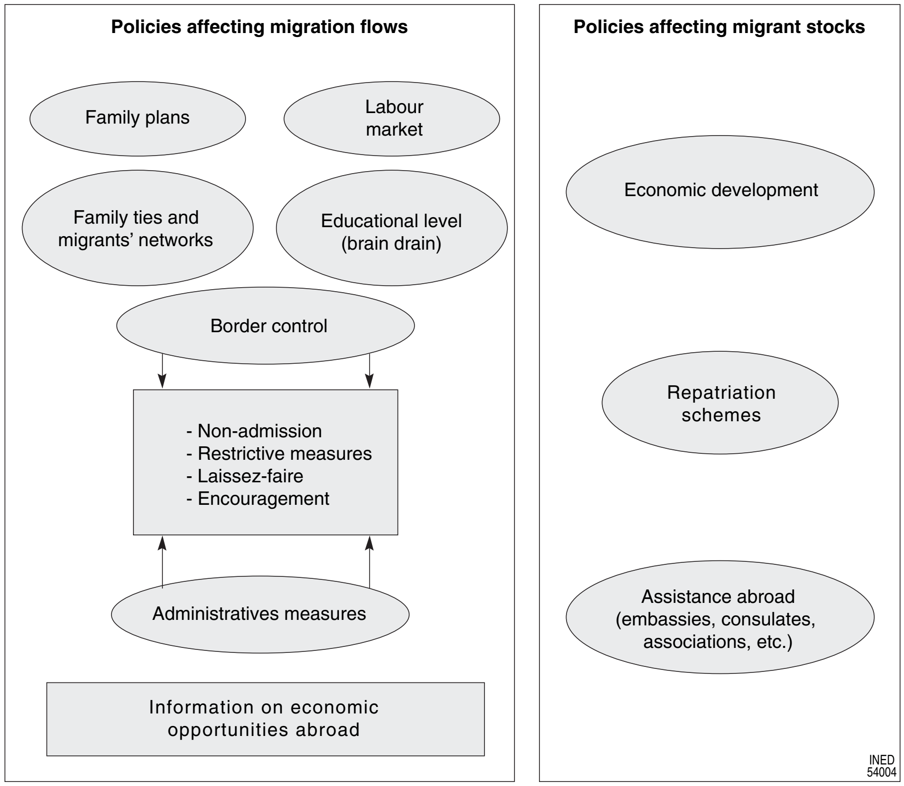

FIGURE 110–3 A schematic comparison between the logistics and means used in flow policies and stock policies in the emigration countries.

> Development and demographic balance are no longer considered the sole concern of the individual states involved but rather as problems facing a wider human community comprising all of the countries affected by these issues, which, in accordance with the subsidiarity principle, may be dealt with as appropriate by local, regional, national or international institutions. (Council of Europe, 1995)

A distinction must be drawn if the effects of emigration on the labor market of the countries of departure are to be assessed. In the case of unskilled or low-skilled workers, emigration can be considered a cheap, fast means of alleviating unemployment. In the cases of highly skilled persons, emigration (which is then referred to as "brain drain") may have long-term negative consequences over the development of the country of departure. Brain drain can be viewed as resulting from an understandable wish among highly skilled workers to make maximum use of their investment in education. In the available literature, brain drain is often considered as a loss for the emigration country, though it is not always the case. Nowadays, the mobility of skilled persons is usually related to the training process (e.g., doctorates) or to progress in their careers (in international research laboratories). The negative aspect of brain drain is in the lack of skilled labor in the countries of origin (e.g., the lack of doctors in developing countries). Their departure is a problem for the countries of emigration. However, if the inactivity or unemployment rates are high among the skilled workers of the country of origin, the emigration of skilled workers may have positive effects on employment for the skilled persons who stay in the country, and in the long term, the consequences are not necessarily negative for the population as a whole, because foreign currency transfers may then play a major part in the development of the country of emigration. Besides, cultural (scientific or vocational) transfers, in the long term, are important stimuli for an improvement of the internal situation. Some countries are in favor of the emigration of their skilled nationals for that very reason.

Migration networks are generally a means to disseminate information on employment opportunities and administrative procedures in the receiving countries. The existence and efficiency of such networks have been proved through many surveys conducted among migrants. The rapid development of Turkish emigration to Germany can largely be accounted for through the efficient network established in the 1960s. The same applies to Filipinos who emigrate to the

United States. On the one hand, such networks may help emigrants at the time of departure, and later protect them in their new environment; on the other hand, they may slow down the integration process.

The brain drain issue is related not just to the distortions of the labor market, but also to the educational system. The lack of demand for skilled workers or lecturers and researchers encourages such highly skilled persons to emigrate, because they must have a more favorable environment if they are to progress in their careers. Emigration may also result from lack of infrastructure or junior technical staff, as the organization of their research or specialized work is dependent on those. Such emigrants are unlikely to return to their country of origin.

A wide variety of border controls and other such administrative measures, ranging from prohibition to encouragement, can be enforced by the governments of the countries of emigration with a view to adjusting the flows (Appleyard, 1989). Stark prohibition of emigration is seldom efficient (the case of Algeria in 1973, though, is a success story). Better results can be reached through selective control in which limits are set to the emigration of persons with certain qualifications. In the case of laissez-faire policies, governments try to remain neutral, only establishing minimal or no control. On the contrary, some countries actively encourage workers to emigrate and do their best to increase the number of their nationals abroad (as was the case for the Philippines in the 1980s). It must be kept in mind that migration policies also reflect the internal political regimes. In totalitarian countries, emigration, far from being an objective of the government, is usually strictly forbidden.

Other measures have also been taken to regulate emigration flow as deemed desirable—instituting authorizations prior to emigration, defining the standards required of private recruiting agents, setting maximum recruiting fees to be paid by workers, requiring minimum guarantees in contracts of employment, and so forth.

It is very important for the country of emigration to provide potential emigrants with data and information on the economy and labor market of the possible receiving countries. Potential emigrants have very poor and superficial knowledge on the laws in those countries. In that respect, the media have great influence, though they may mislead potential emigrants by disseminating false information, particularly by giving the public an overly positive image of the economic situation and employment opportunities in those countries that are perceived as potential receiving countries. This is probably what happened to many Albanians who emigrated to Italy in the early 1990s, grounding their decision on the attractive image of Italy disseminated by Italian radio and television stations.

Information on the receiving countries would empower migrants in several respectsby explaining how to select recruiting sources, examine and accept a contract of employment, organize money transfers, and set up adequate saving and investment plans (Gunatilleke, 1992). In fact, all of these activities require full collaboration between the countries of departure and those of destination.

2. The Stock Policies of the Countries of Emigration

The economic situation and its prospects in the country of emigration are very important in the decision to emigrate. As long as the country remains in an underdeveloped situation, with no signs of economic take-off or will to achieve development, and gaps widen between salaries in the countries of the North and those of the South, not only will the number of people who wish to emigrate increase, but those who wish to come back to their native country are also deterred from doing so.

The economic effects of migration over the country of emigration are also to be felt through transfers of foreign currency and goods. Foreign currency transfers may have several kinds of positive consequences on the economy of the emigration country. They provide a source of foreign currency and are a factor of national income growth by means of the additional yields of savings and investment they generate. The level of those profits depends not only on the number of emigrants but also on their average incomes (salaries and other earnings), their propensity for saving, and the portion of their savings that they decide to transfer and invest in the country.

Here again, the case of Albania is interesting. According to an IOM study (IOM 1995a), 43% of Albanians have relatives who emigrated between 1992 and 1995. Most left the country illegally; the emigrants usually had good education and qualifications. In return, the transfers received by Albanians who stayed behind involve large sums, which often are their main means of subsistence.

For most countries of emigration, transfers are a major source of foreign currency, and this is reflected, in a way, in the set of policies devised to encourage emigrants to transfer their savings. For example, in some countries preferential conditions are granted in terms of exchange rates for such transfers and interest rates for their investment. Transfers are supposed to be individual and family actions, and consequently cannot be directly oriented by governmental policies. Theoretically when emigrants send money to their family, the country of origin should not interfere in the way the funds are used. In practice, however, the government can enforce financial and investment policies through the banking system; in developing countries, however, banking systems are usually unsatisfactory and sometimes corrupt. As a consequence, emigrants had rather send their money through informal channels (through relatives or friends, etc.) or use such safe, fast channels as the famed Western Union. Often, their funds are not sent home and are instead used to pay debts or contribute to the ethnic mutual assistance networks in the receiving country.

The debate on whether international migration promotes or delays development prospects, in both the countries of emigration and of immigration, will continue. The question is related to such various issues as poverty alleviation, improvement of living standards, and job seeking or creating, conflict prevention, reinforcement of democracy, and observance of human rights. Bilateral agreements between developed and developing countries increasingly tend to include a significant migration component, just like those on economic cooperation, external debt settlement, reduction of obstacles to commercial exchange, and other initiatives intended to promote the economic development of the labor-exporting countries. Personal mobility (emigration and repatriation) has thus come to play a crucial part in international relations.

The countries of emigration may develop repatriation plans so as to provide emigrated workers with economic opportunities in their native country and facilitate their reinsertion into their original society. Due to continued economic constraints in developing countries, the promotion of return migration has proved difficult hitherto. The countries of emigration usually contend that the issue of return migration must be considered within the context of economic development.

To a certain extent, the countries of emigration may provide assistance to their emigrated nationals. The existence of an embassy or consulate in the receiving country may play a major part in implementing migration policies. In fact, not only can they be used as a point of reference for emigrants, but they can also help maintain links with the native country. At least, consular issues (bilateral agreements, repatriation, money transfers, administrative affairs, etc.) can be solved more easily thanks to the presence of an official representation. However, many countries of emigration, as they are developing countries, cannot afford to have permanent diplomatic missions in every country.

International Organizations and International Agreements in the Area of Migration

Many different international organizations deal with issues related to migration policies at various levels. The main ones are the Population Division of the United Nations in New York, the United Nations Office of the High Commissioner for Refugees (UNHCR) in Geneva, the United Nations Population Fund (UNFPA) in New York, the International Labour Organization (ILO) in Geneva, the International Organization for Migration (IOM) in Geneva, the Organization for Economic Cooperation and Development (OECD) in Paris, the Council of Europe in Strasbourg, the European Union (EU) in Brussels. As mentioned in the *Action Plan* of the Cairo Conference:

> The role of international organizations with mandates in the area of migration should be strengthened so that they can deliver adequate technical support to developing countries, advice in the management of international migration flows and promote intergovernmental cooperation through, inter alia, bilateral and multilateral negotiations. (United Nations, 1995e, point 10.8)

The world conferences that have dealt with the issue have played, and may further play, a very important role in devising policies for the future. In recent times, the three most important ones were the International Conference on Population and Development (ICPD, Cairo, 1994), which issued a *Programme of Action*, the World Summit on Social Development (Copenhagen, 1995), which issued a *Declaration* and a *Programme of Action*, and the 1999 meeting of the General Assembly of the United Nations, when the efforts made to reach the ICPD objectives were reviewed.

Bilateral and multilateral agreements may also play a very significant part in the evolution of migration policies. As mentioned in the Cairo *Programme of Action*, the governments of the countries of destination are invited to

> consider the use of certain forms of temporary migration, such as short-term migration or migration related to a specific project, as a means of improving the skills of the nationals in their countries of origin [. . .]. To that end they should consider, as appropriate, entering into bilateral or multilateral agreements. (United Nations, 1995c, point 10.5)

Two major recent examples of regional integration agreements related to migration policies should be mentioned at this point—the North American Free Trade Agreement (NAFTA) and the Schengen Treaty, the latter of which was concluded between some of the member countries within the European Union. Both agreements also were intended to limit illegal immigration.

NAFTA, the most extensive area for international free trade in the world, is mainly intended to support Mexican economy with a view to reducing illegal immigration to the United States. However,

> because of the differences between the Mexican and the US productive structures and the size of their respective economies, rapid convergence of their standards of living is inconceivable, and, irrespective of signs that the gap is beginning to close, migration flows over the next few years will remain high. A reduction in the propensity to emigrate as a result of greater economic integration can only be a long-term objective; to recognize it as such is to avoid making the mistake concerning the nature of migration and development processes that characterized European policies after the frontiers were closed in the 1970s. (Tapinos, 1994)

Border control is abolished among the countries that signed the Schengen Treaty. However, identity control remains possible, for the prevention of international crime. The agreement also deals with police and judicial cooperation as well as coordination of control on the external borders of the Schengen space, through a common approach to the visa and asylum procedure policies. Even though the unification process has begun in the area of immigration, there are still countries in the European Union that are unwilling to give up control on their own borders for non-Union nationals.

The European Union has taken a somewhat tortuous path before it could come to a common approach to migration. The initial objective of the common policy had been zero immigration, before it took a new turn with the Barcelona Declaration in 1995, which was both a point of achievement and a new start, as soon afterward the European Council, meeting in Tampere in 1999, announced for the first time that the objective was to develop a common immigration and asylum policy. The declaration of the European Commission (the *Community Immigration Policy*, 2000) followed immediately, putting an end to the zero immigration policy and recognizing the European Union as a zone for immigration. (Zero immigration was referred to as part of a policy in which borders are controlled, or even closed, effectively barring new immigrants out. Despite such a policy, no decrease was observed in the flows, due to the demand for immigrant labor from the market.) The Laeken European Council meeting (2001) then emphasized the necessity to define a migration flow policy as an essential component of any common external policy. The next year, however, in Seville (2002), the Council somewhat left aside its overall view of migration flows, paying more attention to short-term initiatives aimed at reinforcing control over illegal immigration and terrorism, thus pushing the principle of a common security and justice space adopted in Tampere into the background. Eventually, the draft Constitutional Treaty was signed at the European Council held in Salonica (2003). It included a specific section on security and justice and placed immigration issues among decisions to be made by a qualified majority. The draft treaty was thus giving a mandate to the European institutions for them to develop a common immigration policy such as could facilitate efficient management of migration flows. Henceforth it was impossible for member states to fail individually to enforce the relevant rules that had been decided on by a qualified majority. This gives full measure of how much progress has been achieved, if the Constitutional Treaty is ratified.

III. NEW ELEMENTS IN MIGRATION POLICIES

1. Cooperation in Migration Matters

However strict they could be (with actual, rigorous control at the time of admission as well as subsequently), the policies adopted by developed countries clearly never had any direct effect over the basic factors that cause emigration from developing countries. On the contrary, cooperation and development program do have an impact on the source of international migration movements; at the same time, they are a way of refusing to accept economic and political underdevelopment as the result of fate (OECD, 1994).

Immigration is becoming a major issue for the main developed countries, particularly European ones, who are trying to establish new laws and regulations so as to reduce the access of immigrant workers to the labor market. The very fact that their legislative activity is intensifying is a token of the political importance of the issue. The measures taken to fight illegal immigration are more or less the same everywhere (border control, territory surveillance, prison or expulsion sentences against workers who have no employment permit).

However, it is recognized that the

> governments of countries of origin and destination should seek to redress the causes of emigration in order to alleviate the massive and uncontrolled international migration flows. The redressing of these causes would require increased effort to achieve sustainable economic and social development, avoid international and internal conflicts, respect the rule of law, promote good governance, strengthen democracy, promote human rights, support education, nutrition, health and population-relevant programs, and ensure effective environmental protection. (UN-ECE, Council of Europe and UNFPA, 1994, *Recommendation 31*)

A new form of cooperation is necessary. Developing countries, with the assistance and cooperation of developed ones, must ensure that economic growth is ever concomitant with job creation. Concurrently they must establish such social and institutional structures as are likely to slow down their demographic growth.

As recently emphasized by the United Nations,

> international migration, with its intricate web of demographic, social, economic and political determinants and consequences, is a topic that has moved to the forefront of national and international agenda. In the last few years, immigration has become a major issue of concern in an increasing number of countries. More recently, in the aftermath of the events of 11 September 2001, some countries have further tightened their policies towards immigrants, refugees and asylum seekers. (United Nations, 2002)

Through international cooperation, it is probably possible to limit migration flows so as to adjust them to the receiving capacity of the host countries. Many governments in the receiving countries have realized that it is not possible to reduce immigrant flows without taking the economic and social situation in the countries of origin into consideration. In such a view, many options have been examined (and experimented in some cases), such as opening up international trade, increasing direct investment, rescheduling external debts, or targeting public development aid in the emigration countries.

Many receiving countries now have to find a compromise between investing in integrated development plans in the emigration countries and investing at home in social infrastructure and services for immigrants. In fact, short of militarizing societies and fuelling the kind of tension on which fundamentalist movements feed, migration flows cannot be controlled without achieving development, or at least without development actually beginning to be visible in the countries of origin. If no action is taken in that respect, the level of social tension between the nationals and the immigrants, or between the receiving countries and those of origin, can only go on deteriorating.

It is necessary to develop joint (multilateral or bilateral) agreements on migration flow control. Such agreements must ensure that development aid is efficiently used, particularly in the areas from which migration flows start, on the one hand, and take into account the needs of intensive labor sectors, on the other hand.

Political stability is essential to developing long-term economic and social reforms in the countries of emigration. Regional integration, with all the efforts made to achieve it, might be one means of reducing tension in some regions where governments have difficulties establishing stability by themselves.

Immigration measures have been viewed as part of those on international cooperation, particularly those on cooperation with the countries of origin. Such cooperation measures include not only financial aid, investment in the countries of origin, vocational training, and economic and technical cooperation, but also admission of a limited number of immigrants. The number must be discussed with the countries of origin so as to secure their cooperation, which is indispensable in controlling the migration flows that exceed the levels set in the cooperation programs. The very existence of economic cooperation provides good motivation for the governments of countries of origin to actively and efficiently exert preventive control over migration flows: otherwise, they would see little point in doing so (Council of Europe, 1995).

2. Possible Future Developments in Migration Policies

The measures to be taken in immigration must be planned in close coordination with those relating to international cooperation, particularly with the migrants' countries of origin. Agreements must be secured with emigration countries on the circumstances under which they would be willing to help in controlling the migration flows that are in excess of the levels agreed in cooperation programs.

Cooperation between receiving countries and those of origin, which is essential in controlling migration flows, also requires that great attention be paid to the actual use of aid in the regions and villages from which migrants come, where the decisions to emigrate are taken. Although such decisions are prompted by national and international considerations, they are eventually determined by local pressure emergency.

South–South cooperation still remains a largely theoretical plan. Developing countries have not really managed to increase collaboration between neighbors. Future effective South–South cooperation is likely to have positive effects over migration. In fact migration policies are one of the major potential areas for cooperation between developing countries. Operating collaboration agreements between economic systems in the Third World (or South) countries may well solve the development problem, at least partly. The North could find enough resources to support such cooperation, so as to decisively contribute to launching a development process. South to South relations do not necessarily have to involve all the countries simultaneously; on the contrary, it would be best to bring together those countries that belong to the same geographical area and have similar problems, or comparatively homogeneous characteristics (Arab countries, the Sahel region, Latin America). Moreover, those countries should decide by themselves which countries should associate with which others.

As Claudio Grua (1991) wrote, the fundamental functions of such regrouping could include:

Creating sound structures for cooperation between countries

- Liberalizing trade within the zone and defining a common trade policy (customs duty, tariffs, negotiation on the location of international headquarters)
- Defining some common development programs in major areas of common interest
- Creating supranational agencies for the management of strategic resources
- Establishing a regional union for payment purposes so as to reduce both needs in hard currency and debts with the international monetary system

Besides stimulating synergies in the zone, such a policy would offer the possibility of speaking with one voice in international institutions, at least on subjects on which general agreement can be reached—which would promote the emergence of a political group on an international scale.

In such a context, what the developed countries can do is quite clear: aid must not only be part of a program of organic transfer of resources, as mentioned earlier, but also be granted under specific conditions and organized so as to ensure that it is successfully used. Reference to the Marshall Plan could be a source for useful suggestions.

3. Co-development Processes and Decentralized Cooperation

Among host countries as well as those of origin, many belong to the same region, though located on different continents (e.g., the Mediterranean region). A new approach to the migration issue could be devised as a kind of co-development process, in which countries (or certain regions) of origin would be considered as internal underdeveloped regions within the host countries. Such zones would then receive all the aid and facilities that migrant-receiving countries provide to their own regions.

Usually, at the time when cooperation programs are developed, no study is conducted on the current demographic situation, nor on the possible effects of such programs over the situation; and no follow-up system has ever been set up so as to assess the expected or the final results from a demographic point of view. In fact, the criteria for selecting cooperation activities should be changed so that they are better suited to the political and economic context; priority sectors should be defined and appropriate strategies established.

Prospective demographic growth is expected to remain high in developing countries. This is an obstacle to absorption of the expanding manpower through local economic development alone (not to mention the needs in improved public services, particularly in the social sector); consequently, it is a strong incentive to emigration, particularly from Africa to Europe. Whereas in the past, emigration was a possible means of overcoming the obstacle, it is now drastically limited by the strict policies enforced in the host countries, which are also favorite destinations for migrants from Eastern Europe—hence the necessity to establish close cooperation between developing and industrialized countries, such as make it possible for every party to work complementarily to one another.

Developing countries will have to examine how to reorganize and expand their social sector and implement population policies in which the most isolated categories of the population are included. They must also campaign at all levels to improve the situation of women, whose social condition is still often precarious and who suffer from discrimination in education and employment. In many countries, the law and the customs even grant them rights that are inferior to those of men, and women find it difficult to assert their role and personality in societies that still force them to have large families so as to ensure that they get minimum support in old age.

There is a risk to using temporary emigration to promote vocational training and to profit from migrants' financial transfers: emigrants may be unwilling to return to their native countries at the end of the agreed period. This, however, is not sufficient reason for host countries to put an end to the experiments conducted here and there on controlled temporary immigration, in which promise of return to their native country is secured from the workers. Certain trials made in European regional or local institutions provide promising examples.

On the other hand, new forms of migration are emerging, such as transit migration, in which migrants go to one country with a view to trying to go to another later. This is usually a type of illegal migration that takes advantage of certain flaws in the system. A typical example is when people migrated by stages from East European countries to Western Europe, in the wake of the 1989–1991 political upheavals (OECD, 2000).

The issue of differences in the cultures and value systems of emigration societies and host ones must also be taken into consideration. It is a long way still to harmonious cohabitation. Cultural cooperation must be firmly planned and developed, giving high priority to improving mutual understanding. Some programs have been initiated along that line, but they are still too timid, with respect to their priorities as well as to the resources that are granted to them.

4. Migration as a Move Planned at the Micro Level

It would be profitable to examine and develop new concepts with a view to better understanding and dealing with migration phenomena. An interesting approach consists in considering migration as an individual plan. The new migration flows from the Third World cannot be considered as though they were the same as the traditional migration of workers. The latter is usually regulated by international agreements between the country of origin and the host one, so as to benefit both countries. A large proportion of recent flows could be better accounted for if the decision to migrate is taken into account at the micro level.

In that prospect, an individual decision to migrate can be considered part of a rational plan developed on the basis of an economic and social assessment of costs and profits. In fact the decision to emigrate is usually made at the family level. In the distribution of individual roles and tasks, certain members of the family are selected to stay at home and participate in farming, while others are entrusted with small trading or transport activities, and yet others must go and earn money elsewhere by migrating, particularly abroad, and transfer as much of it as possible to the family, so as to keep the latter supplied with consumer goods or capital.

In such circumstances migration tends to strengthen family ties within the extended family in the most traditional sense, in the migrant's native village and region. As a rational plan based on integrated economic decisions, individual migration then contributes to family development from an economic and other points of view. Decisions concerning marriage, the question of how many children to have and when, and sometimes the decision to return to the native country, thus become stages in a well-planned process. This partly contributes to high demographic growth continuing through the stages of demographic transition among some populations. Migrants' plans thus appear to be fully part of a process of family building that may influence the plans of their future children later. This type of migration planned at micro level usually is a condition for the survival of village and regional economies.

The male or female members of a family who emigrate as a result of such rational plans are bound to supply the family with additional resources as soon as possible, not only in financial terms (transfers) but also in terms of consumer and capital goods, such as cars and other means of transport, goods for small traders, and consumer durables.

Once the decision to emigrate has been made, the persons involved have to face the many difficulties of migration, and accept the ups and downs of it. The first shock for migrants is usually at the macro level: they have to face borders and a State, away from the possibility of assistance from their family, whom they cannot get in touch with. This is not in conformity with their initial plan, particularly with their ambition to start making financial transfers soon after their departure. As for host countries, they have to choose between forbidding long periods of stay and integrating immigrants. These are two approaches that used to cause division among politicians in some European countries in the 1960s and 1970s.

The macro effects of this type of migration remain to be studied, though some of the consequences have been clearly identified already. In Morocco, for example, according to the National Trade Agency, the financial transfers made by emigrants (exchanges in kind not included) amounted to 20 billion dirham in 1994. This in value is half the amount of the country's exports, 30% of imports, 150% of the profits from tourism, and 250% of the payments for the external debt. The savings from emigrated Moroccan workers not only make it possible for the country to pay the bills for its external debt, but they also have consequences for local economies in the migrants' native regions.

The levels of resources transferred in foreign currency or in kind by emigrants are such that they are enough to create an actual transnational economic zone. Such transfers, though, may be partly derived from illegal, or even criminal, activities. The zone thus created by migrants also requires new regulations and new forms of cooperation. The part played by migrant communities in cooperation is no longer just rhetorical or abstract; it is a basic element in the current economies and has many political and cultural implications.

APPENDIX Definitions Adopted by the International Convention on the Protection of the Rights of All Migrant Workers and Members of Their Families (United Nations General Assembly, 69th Plenary Session, 18 December 1990)

Migrant worker refers to a person who is to be engaged, is engaged or has been engaged in a remunerated activity in a State of which he or she is not a national.

Frontier worker refers to a migrant worker who retains his or her habitual residence in a neighboring State to which he or she normally returns every day or at least once a week.

Seasonal worker refers to a migrant worker whose work by its character is dependent on seasonal conditions and is performed only during part of the year.

Seafarer, which includes a fisherman, refers to a migrant worker employed on board a vessel registered in a State of which he or she is not a national.

Worker on an offshore installation refers to a migrant worker employed on an offshore installation that is under the jurisdiction of a State of which he or she is not a national.

Itinerant worker refers to a migrant worker who, having his or her habitual residence in one State, has to travel to another State or States for short periods, owing to the nature of his or her occupation.

Project-tied worker refers to a migrant worker admitted to a State of employment for a defined period to work solely on a specific project being carried out in that State by his or her employer.

Specified-employment worker refers to a migrant worker:
(i) Who has been sent by his or her employer for a restricted and defined period of time to a State of employment to undertake a specific assignment or duty; or
(ii) Who engages for a restricted and defined period of time in work that requires professional, commercial, technical or other highly specialized skill; or
(iii) Who, upon the request of his or her employer in the State of employment, engages for a restricted and defined period of time in work whose nature is transitory or brief; and who is required to depart from the State of employment either at the expiration of his or her authorized period of stay, or earlier if he or she no longer undertakes that specific assignment or duty or engages in that work.

Self-employed worker refers to a migrant worker who is engaged in a remunerated activity otherwise than under a contract of employment and who earns his or her living through this activity normally working alone or together with members of his or her family, and to any other migrant worker recognized as self-employed by applicable legislation of the State of employment or bilateral or multilateral agreements.

CHAPTER

111

Economic and Social Management of the Population Pyramid

MICHEL LORIAUX

Institut de démographie, Université catholique de Louvain, Louvain-la-Neuve, Belgium

I. POPULATION POLICIES OR MANAGEMENT OF POPULATION STRUCTURES?

Our era has become the era of management in all directions: business management, personnel management, management of inheritances, natural resource management, time management, and why not, in this context, management of the population and more specifically management of the population pyramid?

It is true that the idea isn't new; a desire to influence population size and growth may be found in diverse epochs and in very different civilizations. Demographic interventionism on the part of States has often been justified by the need to combat demographic decline, real or anticipated, in acting on childbearing, marriage or migration.

On the other hand, while population policies, whether they be pronatalist in the North or antinatalist in the South, have been put into effect almost everywhere in the world beginning several decades ago, it is more uncommon for them to be explicitly oriented toward managing the population pyramid, that is, the distribution of the population by age and sex.

One could, however, think, a priori, that this distribution is more important than the absolute size of the population, in that it directly conditions the relationships among citizens, whereas the size of populations seems to come into play in a more indirect manner, and often as a function of exogenously defined objectives (e.g., to support a comparison with regard to a neighboring country, or satisfy expansionist visions) or internally defined objectives, but without marked differentiation between the different members of the community (increase collective well-being, improve the educational or health level of residents, etc.).

Between the praise of numbers or the fear of depopulation on the one hand, and the dread of numbers or apprehension about overpopulation on the other hand, history provides us with a complete and varied catalogue of attitudes regarding the pace of demographic growth.

> Demographic causality is invoked both by those whose understanding of the slowing of demographic growth of developed countries leads them, for example, to worry about the consequences of population ageing on health expenditures, and by those who attribute to demographic growth all of the planet's ills, from poverty to environmental degradation. (Tapinos, 1996).[1]

However, as the majority of Western countries seem to have settled into a situation of quasi-stationarity (with more or less no growth) and practically all of the countries described as developing have initiated their

[1] "La causalité démographique est invoquée aussi bien par ceux qui appréhendent le ralentissement de la croissance démographique des pays développés et s'inquiètent par exemple de l'incidence du vieillissement sur les dépenses de santé, que par ceux qui imputent à la croissance démographique tous les maux de la planète, de la pauvreté à la dégradation de l'environnement."

demographic transition and are taking great strides toward levels of fertility close to the replacement level, the obsession with world overpopulation has regressed and a more sustained attention is being given to age groups and to the relationships among generations.

For example, since the end of the 1990s, UNFPA reports on the state of world population have above all emphasized the "new generations," even if, both for reasons of prudence and for continuity regarding demographic policies previously extolled quite vigorously, the UN organization still greatly emphasizes the fact that "the era of rapid population growth has not yet come to an end" (UNFPA, 1998) and that it is desirable to remain vigilant.

Of course, there have always been young, adult, and elderly generations in a population, but the new twist is that "more young people than ever are entering their childbearing and working years. [. . .] At the same time, the number and proportion of people over age 65 are increasing at an unprecedented rate" (UNFPA, 1998). At least that is the case in the South; the situation that has already prevailed in the North for a long time, without having the same intensity or exactly the same characteristics, likewise poses new problems in terms of relationships among different age groups.

In sum, we are discovering (or rediscovering) that a population is not a monolithic entity that can be fully described by its size and rate of growth and that behind the placid and anonymous appearance of an age and sex structure, there are extremely complex problems of relationships among generations, and beyond, relationships between men and women who interact not only in households and families, but also in schools, enterprises, institutions, and associations.

II. DEMOGRAPHIC STRUCTURES CHANGE BECAUSE EVERYTHING CHANGES, AND VICE VERSA

But if these demographic structures were stable or relatively invariant over time, they wouldn't be at the heart of the passionate debates about the future of our societies that they presently stimulate. And the modes of social, economic, and political organization that would have been deemed satisfactory in the past wouldn't be called into question for the present or the future.

If it is otherwise, it is, of course, because population dynamics have a direct influence on population structure and any action seeking to modify the number or alter the pace of growth ends up, in reality, acting simultaneously on the composition of the population (see Chapter 4, Volume I). This is obvious for demographers, who are familiar with the interrelationships between demographic movement and population structure, even if they do not always perceive well the important implications of these interrelationships outside of the limited field of their discipline. But failure to recognize this is a big mistake for those who are ignorant of demographic analysis.

In past centuries, this condition of invariance, without being fully satisfied, was reasonably approached due to maintenance of fertility and mortality at high thresholds, which were only periodically disturbed by the random events of history (wars, epidemics, famines, etc.). In contrast, from the time when the demographic transition leading from regimes with high fertility and mortality to new regimes with low values of these parameters was set in motion in a sustainable manner, its effects on the age composition began to be felt, following a well-known process, which began with a distinct reduction in the young age groups as a consequence of the fall in birthrates, and which was followed by an increase in the importance of adult and elderly age groups, both in absolute and relative numbers, and described as population aging (see Chapters 68, 69, and 77).

The advantage, in the European countries that were the first to be affected by this process, was that the process extended over a relatively long period on the order of 150 to 200 years, and that all of the institutions destined to favor the maintenance of high fertility necessary to compensate for the ravages of very high mortality had the time to adapt progressively to the demographic change. Marriage practices, family structures, moral and religious codes, laws, types of education, inheritance rules, forms of labor organization, and systems of health and welfare were revised, often fundamentally, so that technological, economic, social, cultural, and political structures would be in more or less substantial conformity with the demographic structures.

Did the demographic change initiate the other changes, or was it the reverse? The question is relatively subordinate because, rather than a strictly causal approach which quickly gets lost in the sinuous meanderings of causes and consequences, it is preferable here to resort to a global and systemic approach. In effect, the main point is above all to understand that most of the changes that took place were not contingent, but constituted heavy currents strongly integrated among themselves. For example, we know that the progress in life expectancy was not simply the consequence of more effective medicine, but also and especially of better hygiene and training of mothers in infant welfare and child care as well as the general life conditions which were less demanding for all workers, and were only made possible thanks to progress in productivity, in the reduction of work time, and in the increasing of salaries.

In a parallel fashion, the passage from the traditional family to the modern family[2] was possible only because mortality declined, especially infant mortality, because solidarity of proximity was less solicited, and because the State and collective social institutions were able to substitute for the family to ensure schooling of children and the care of the elderly. The increase in the level of schooling as well as the improvements in health and in the standard of living of the elderly thus considerably modified the social and health structures. This resulted in turn in new progress in life expectancy at all ages and contributed, in the process, to the new and continually growing category of retirees, who pose today the problem of financing social security in a context of budgetary restrictions and reductions in the size of the potential labor force. That these changes weren't often necessarily perfectly synchronized or even entirely coherent does not call into question the principle of the existence of an overall outline that has been progressively put into place via linking of phases of order and disorder, of disorganization and reorganization.

[2] The forms of the family are very diversified and most typologies proposed to account for this diversity are incomplete or unsatisfactory. The classification adopted in the 19th century by Frédéric Le Play (1871) distinguished three models for France: the nuclear model (where children marry "outside of the parental home with an egalitarian inheritance sharing"); the model of the founding family (where only one of the children is chosen as the privileged heir and "once married, remains in the home of the parents"); and a community or patriarchal model (where "all the children who marry establish themselves in the paternal home"). But for Alain Collomp (1992), the theory developed by Le Play to support his conservative plea, according to which "the nuclear family would be a recent decomposition of the 'stable' forms of the family group, founding family and patriarchal family," is incorrect and should have been contradicted by the most recent work in historical demography that shows that

> the predominance of the egalitarian nuclear model, this modern form of the family, has been solidly implanted in Great Britain, in the Netherlands and in northern and western France since at least the end of the Middle Ages. On the other hand, under the effect of economic and demographic difficulties, the family group was able to evolve from the simple, nuclear structure to more complex forms, founding family, "*frérêches*" (cohabitation of multiple couples of the same generation) or big communities. This phenomenon appeared in certain provinces in the centre and south of France in the 15th and 16th centuries. In Ireland, the founding family only developed from nuclear structures in the second half of the 19th century, following the subsistence crises and the massive emigration of the young to Great Britain and the United States. (p. 16)

However, these important observations on the periods prior to the onset of the industrial and demographic revolutions do not constitute, in themselves, a denial of the idea that the passage from a traditional society to a so-called modern society has greatly upset the majority of societal structures, including family structures, at the same time with respect to the type of regulation of the relationships among generations and regarding the size of families. What is important to note here is that from the time that the strong constraints of high mortality that weighed on the family were attenuated and economic growth took off, the conditions emerged to encourage the establishment of public welfare systems (solidarity) among generations as a substitute for (or complementary with) the private solidarity that characterized rural societies.

III. TO ACT ON THE AGE AND SEX COMPOSITION DESPITE THE INERTIA AND RESISTANCE?

To recall these elementary principles of the dynamics of population change is useful for seeing not only that the age and sex composition of the population are at the heart of societal change, but also that these population structures are part of a complex, interdependent network. It is difficult, even dangerous, to try to intervene in these processes, under the different pretexts of ethics, justice, economic efficiency, political manipulations, and so forth, because societal systems, governed by a principle of homeostasis,[3] strongly

[3] The concept of homeostasis was introduced in 1932 by the American physiologist Walter B. Cannon, and it constitutes one of the cornerstones of the systemic approach. It literally means "remain constant," and designates a property of complex systems (living cell, human body, business, army, nation, etc.) to maintain their structure and functions by a series of regulatory mechanisms that seek to assure a dynamic equilibrium. When one of these systems is subject to disturbing influences, it reacts by corrective actions that seek to maintain its general internal equilibrium. If it does not succeed in doing this, it is obliged to change and to adopt a new way of functioning, or worse, to disappear. "Homeostasis in this way appears as an essential condition of stability and thus of survival of complex systems" (de Rosnay, 1975). A biological example is that of the human body, which, when it is attacked by a microbe or a virus, initiates diverse defense mechanisms such as a fever or certain biochemical reactions. If the response is sufficient to counter the attacker, the result is healing; otherwise, it is the destruction of the system, death. In the social arena, when the existence of a revolution is invoked, it is in principle the indication that the society in question has not successfully overcome the internal and/or external aggressions nor has it been able to maintain its previous social equilibrium. The case of the French Revolution is illustrative of such a situation, where the monarchy and the regime of social classes that supported it did not succeed via their instruments of control and repression in containing the rise of new ideas about liberty and equality and in limiting popular discontentment. Many policies (economic, social, or demographic) can be analyzed in the same way; generally, they only have a serious chance of success if they are implemented in a favorable context, without clashing with any strong resistance from the population or from influence groups. A typical example of homeostatic resistance is that which opposes

(continued)

resist these stimulations or aggressions and tend to maintain their equilibria by activating all of the regulatory mechanisms available. But these mechanisms are all the more numerous and complex as the systems that they regulate are themselves complex. Anyone who seeks to act on populations or their structures should contemplate these principles of the systemic approach, because they will often discover the reasons for the numerous failures of actions taken in this domain. These failures are generally perceived a posteriori as not understandable or foreseeable, but this is probably the case less than is supposed, so as to justify them or absolve those responsible for the actions.

In reality, what is true about demographic structures is also true about other structures (social, economic, technological, etc.), but it is reasonable to think that the demographic structures have some specificities such that they are probably more resistant to voluntary manipulations. The inertia of demographic phenomena is certainly there for a reason, even if it is noticeably weaker in periods of rapid change like our own than was the case in preceding periods, when changes were much slower.

The fundamental modifications of demographic variables and structures are operative in the medium or long terms, whereas short-term economic variations, while sometimes brutal, do not generally entail lasting consequences. These fundamental changes are often only visible if the behaviors of two successive generations are compared, that is, at intervals of around 25 to 30 years. Of course, sometimes, via the effect of natural chances or policy actions, we see events or circumstances that can have immediate and profound impacts on the population. For example, this may occur with a massive deportation of residents, a sharp diffusion of a deadly epidemic, the implementation of a highly coercive antinatalist policy, or a forced international migration resulting from an ecological catastrophe. In these cases, not only may the total numbers and the spatial distribution of the population be strongly affected in the short term, but also the gender composition (case of China's one-child policy) and the age composition (migration of workers, ethnic extermination of women and children to prevent reproduction of a group, etc.). Even if it is the outcome of deliberate strategies, the elimination or purification of a class, an age group, an ethnic group, or race does not constitute, in a democratic context, an acceptable policy for managing the population and its distribution by sex and age. We thus limit ourselves here to means and instruments more classically respectful of the founding principles of democratic societies.

The idea of taking action to influence the age and sex composition of a population in order to transform them in a sense deemed to be desirable a priori can, nevertheless, seem seductive. But such action immediately runs into numerous difficulties regarding choices of objectives; of institutional, policy, financial and other means of achieving them; of assessing their effectiveness; and, finally, of evaluating their moral legitimacy and their acceptability in a democratic context.

Different questions must be addressed or evoked. Is it possible to implement policies that seek to manage the population pyramid? What may their objectives be? Can they be effective? Are they scientifically based? Are they morally ethical and legitimate? It is preferable to deal with such questions in as concrete a manner as possible, based on reflection concerning a number of societal aspects.

IV. AGE POLICY: WATCH OUT FOR UNEXPECTED EFFECTS!

The intention to influence the evolution of the age and sex composition of the population assumes that the composition has been deemed to be inadequate or that it may evolve in the long term in an undesirable way. This implies right from the start that what is adequate or desirable is known, and implicitly that reference is made to a sort of theoretical norm of an ideal population, in the same way that Adolphe Quetelet (1869) considered the average man as a divine ideal from which human beings would deviate only due to the capriciousness of nature or the random effects of reproduction. But the existence of such an ideal is eminently debatable, for populations as much, if not more, than for individuals.

It is not a hindrance that a lot of demographers or politicians and experts continue to refer to this notion, explicitly or implicitly. The ideal most often evoked is that of a stationary population or, sometimes, one that is growing slightly, with an age structure such that the

demographic policies, pro- or antinatalist, when they are contrary to dominant cultural values and norms, often reducing their effectiveness to very little, or even nothing. There have been violent illustrations of this in developing countries (India, notably) when family planning programs were forced on the population (Verrière, 1978). In the other direction, in the European countries where government authorities and international agencies generally consider fertility to be too low, most efforts to stimulate the fertility of couples have turned out to be unfruitful (birth premiums, family allowances, parental leaves, tax deductions, etc.) because they did not offer a sufficient counterpart to stem the propensity of parents to limit their childbearing to less than two children because of their high cost, and also the competition from other opportunities (leisure, women's work, self-fulfillment, etc.).

burden of persons described as inactive (the elderly and the young) does not weigh too heavily on those in the labor force and that the products of economic growth (the *surplus* or the *rent*) can be devoted to productive investments, rather than to demographic investments that just allow maintenance of the same standard of living to additional individuals or to the too many who are inactive. From this perspective, a shrinking or aging population is considered to be a catastrophe that must, if not be avoided at all costs, at least be limited as much as possible, by actions seeking to repopulate the "empty cradles"[4] or to replenish the age pyramid in its central portion by the massive contributions of foreign populations of labor force age that can fill the holes or the depressions brought about by previous changes.

Such policies had their moment of glory and their fervent defenders, and they have sometimes had a certain efficaciousness. This is especially clear regarding controlled immigration, where the massive transfers of foreign labor have on occasion permitted sustaining economic activity in strategic sectors such as coal mines or the iron and steel industry, deserted by native populations in search of better-paying or less difficult work. Unfortunately, what pays off during several years or decades is not necessarily going to be profitable in the long term. And the problems of integration of migrant populations, which most European countries are confronting, are often the delayed consequences of migration policies and procedures put into effect previously (for economic, demographic and sometimes political reasons, such as welcoming those from former colonies). Today, those who were seduced by the sirens of prosperity and who thought they would be able to avoid their miserable conditions sometimes reproach their countries of origin for having sold their health or their cultural tradition "for a sack of coal" (Franciosi *et al.*, 1996). And their descendants live their dual national affiliation with difficulty, feeling rejected at the same time by both their countries of origin and adoption; they constitute, according to the media, the hotbed of urban violence and of suburban insecurity.

In addition to these delayed perverse effects, it can even be asked if the solutions to the sectoral shortages of labor that were provided by this migration, with apparent success initially, didn't in reality contribute to delaying clean-up and restructuring measures for certain sectors that subsequently rather rapidly showed themselves to be in a deficit position or insufficiently competitive.

These questions are even more pressing with regard to the measures taken to counter the fall of fertility and aging, to the extent that they often have seemed adapted to the current demographic context and to the perspectives of emphasizing in the future observed past trends, but without taking account of the changes that were under way in other social sectors. In other words, too many experts and demographers,[5] obsessed by the risks of weakening of all kinds (of military might, of productive power, of the capacity to colonize, of evangelization, etc.) that the decline in fertility and the aging had previously prompted, continued to talk about the future, all other things being equal, in amplifying the consequences linked to the following or even the acceleration of these trends, without taking into account the fact, rather evident, that if the demographic structures were changing, it was probably because the other basic structures of the society (technological, economic, social, cultural) were also changing profoundly.[6]

[4] The expression "empty cradle" was frequently used during the 20th century to criticize a level of fertility deemed to be too low. There is even a theatrical play from Quebec written right after World War II with this title (Vekeman, 1945). Moreover, it is also in Quebec, in the 1960s, that the expression "revenge of the cradles" appeared, curiously, as Jacques Dupâquier (2000) writes: "At the same time when this was ending, the Francophone minority being abruptly less fertile than the Anglophone majority." In France, it is also common to refer to "the empty cradles of Marianne" (Dûpaquier and Biraben, 1981).

[5] The notoriety of Alfred Sauvy undoubtedly explains why he is frequently cited as one of the principal individuals contemptuous of population aging, but in fact he belongs to a diverse line of French scientists and politicians which began before him and which still continues presently, even if we sometimes see certain changes in who is setting forth the argument: Pierre Chaunu and Jean Legrand (1979), Jean-Claude Chesnais (1995), Evelyne Sullerot (2000), Gérard-François Dumont (2002), Michel Godet (2003). In this regard, see the works of Patrice Bourdelais (1993) and Paul-André Rosental (2002), who have written about the history of French demography and especially of pronatalist sentiments.

[6] The following observation is at the base of this theory: a complex system can only assure its durability, its stability over time, if its principal elements are themselves in relative harmony or complementarity. When an important element undergoes a significant change, the set of interdependencies among the elements means that the other elements must adapt in turn, under the penalty of creating tensions and compromising the good functioning of the system. In our Western societies it is often technological innovations that initiate the processes of transformation of the other structures. For example, the mechanization of agriculture was responsible for an increase in productivity and a reduction in prices that forced the closure of less profitable enterprises and resulted in rural out-migration, with a long-term consequence being a total remaking of the social landscape and of the societal system. Closer to us, when the religious fundamentalists took power in a country with a secular government, this resulted in a change in the status of women and in relationships between the sexes, and also of lifestyles and cultural behaviors (rejection of Westernization, etc.).

V. THE BABY BOOM: GOOD LUCK OR BAD LUCK OF HISTORY?

Without a broad convergence of the great societal currents, the risks of destabilization of societies due to the demographic changes evoked above would be real, but a greater fear is that the demographic conditions will not change, rather than the contrary, when revolutions are at work in other sectors of societal activity. What these demographers have not perceived or understood is the fact that Western demographic aging was no longer simply the consequence of the reduction in fertility, that this first cause was increasingly being supported by a second cause linked to the prolongation of life, and that classical aging, from the bottom of the population pyramid, was being accentuated by aging from the top. But they also didn't understand that the quantity of labor was no longer the decisive criterion for economic development and that its quality was much more important, due to technological progress and the complete revision of the production function combining capital and labor. To produce more children in this perspective results in being exposed later to a swelling of the reserve army of the unemployed. All things considered, it may even be said that couples were more realistic and farsighted, in reducing their fertility, than the scientists who were advising politicians, often moreover condemning the selfishness and the lack of civic sense of their fellow citizens.

One can even ask, with the passage of time, if the rise in fertility after World War II, this "baby boom" that was welcomed by so many observers as an unexpected opportunity to make up for the damages caused previously by the secular trend toward declining fertility, wasn't in reality an unfortunate accident of history that would have been better to try and check rather than to encourage.[7] Indeed, the large number of births that persisted for 20 years, until 1965, and which seemed to compensate for the births lost in the interwar period, was a destabilizing factor of demographic structures, because after the baby boom came a baby bust, and these fluctuations in the size of successive cohorts will have economic and social consequences until at least halfway through the 21st century. Current and prospective problems of financing social security are in large part linked to the fact that the baby boomers, who presently constitute a large share of the labor force, will reach retirement ages when the small cohorts born after 1965 will themselves be in the labor force, accentuating the dependency ratios of those not in the labor force relative to those who are, and risking creation of strong tensions between those working and retirees.

If we were to realize a renewed growth of childbearing, as some call for (Chesnais, 1995; Godet, 2003), we would then run the risk of repeating the cycle of successive peaks and troughs impacting different sectors, beginning with schooling and going all the way to retirement, and including along the way marriage and occupational activity. The presence of more numerous youths would first necessitate greater efforts in the areas of infant and child care and schooling, and this would be followed by growth in the supply of labor, which, however, will be satisfied only if there is a corresponding growth in demand. For a while, the dependency ratio would improve and the tension between taxpayers and beneficiaries of social security payments would be reduced, but the opposite would occur without fail afterward if fertility did not remain indefinitely at its new higher level.

A certain degree of cyclical behavior of the phenomena responsible for demographic change is undoubtedly difficult to avoid. This is, for example, suggested by Richard Easterlin (1975). But to encourage it by a policy supporting fertility that does not take into consideration the long-term consequences of the expected immediate results would be a very inconsistent position.

[7] This thesis contradicts the most current theory, alluded to by many authors (Godet and Monti, 2000), Alfred Sauvy first among them, who think that there is a positive relationship between demographic growth and economic growth. The proof for them is given most notably by the fact that the baby boom apparently stimulated household consumption as a consequence of the growth in the number of children, and it isn't simply by chance that this period corresponds for the most part to the *Trente glorieuses* (Thirty Glorious Years) of Jean Fourastié (1979), whereas the drop in childbearing and the demographic aging that have followed have been accompanied by a recessionary phase whose effects are still being felt. As Alain Minc (1987) has written, in a phrase as brutal as it is short, "Expansion and youth always go together, as do recession and ageing." But in reality, things are probably a lot more complex, and there may not be any mechanical relationship between population growth and economic growth. For Jean-Claude Chesnais (1987), who does not at all conceal his pronatalist leanings, to reduce the question of development to a competition between two growth rates constitutes an abusive simplification. And even if we acknowledge that, in certain contexts, demographic pressure can constitute a factor speeding up technological progress and changes in political and social structures (the thesis of Boserupian adaptation), nothing proves that it is a necessary and sufficient condition. In the absence of which, one would have to accept that all of humanity is condemned to live eternally in recession and in crisis, to the extent that it has entered a long-lasting period of slowing of its demographic growth and even, in the long term, of reduction in its absolute numbers. At present, nothing proves that technological progress is slowing down, even in those regions of the world where the demographic decline is already observable or potentially under way.

VI. A POPULATION ISN'T A BUSINESS

In speaking of the management of population structures, it is tempting to make the analogy with management of business personnel. In both cases there are populations, even if one is a macro type while the other is micro, for which they have their own dynamics depending on the flows of entries and exits, and to which the principles of demographic analysis can be applied.

However, the comparison runs up against some major differences.[8] In a business organization, the new entrants are based on hiring, which is closely linked to the firm's policy as a function of its business activity and prospective profits. Exits, apart from a few cases of death among the employees, are essentially dependent on retirement and termination. Those in charge have numerous possibilities available to them for influencing the volume of employment, and the decisions made are most often directly operational. The firm can also makes its work force more youthful, by hiring younger workers and encouraging older workers to take their anticipated retirement, which can effectively be a means of reducing costs or following technological change. On the contrary, the firm may wish to avoid too rapid a reduction in the age of the work force following a large expansion, so as not to lose the know-how and the institutional memory of the enterprise. In brief, targeted policies can be used to address clearly defined objectives, because there are well-identified means to put them into action.

In contrast, at the macro level, for the population of a country or a region, the objectives are hardly ever clearly defined, and the means are at once poorly identified, of uncertain effectiveness, and often ambiguous with regard to their congruence with fuzzy objectives. For example, to not want to act against mortality seems immoral and humanly intolerable, even if official policy was to slow population aging and it is well known that progress in life expectancy at older ages accelerates the aging process. In the same manner, encouraging foreign immigration so as to make the age structure younger can conflict with the imperatives of an employment policy during a period of economic crisis and high unemployment. Or again, a lot of pronatalist policies, not daring to describe themselves as such for fear of shocking public opinion or of giving the impression of limiting the range of choices offered to couples, have failed, dissolving into a confused mix of measures seeking to influence behaviors, measures that were neither coherent nor capable of modifying reproductive behaviors.[9]

It is clear that at the outset demographic change and family policy were strongly associated and that family policies adopted by countries such as France had explicit demographic objectives. But the opportunity of pursuing this coupling today raises great doubts.

Didier Blanchet (2000) immediately eliminates the pronatalist scenario, deemed to be too "offensive and unrealistic," considering that "ageing from above, due to the prolongation of life [. . .] will subsist, even with fertility maintained at the replacement threshold," and that only a quite unlikely return to fertility levels comparable to those reached during the baby boom, on the order of 2.7 to 3 children per couple, would allow a stabilization of the dependency ratio (out of the labor force/in the labor force) at a level close to that reached in 2000, which

> would imply permanent demographic growth on the order of 1 to 2%, representing a doubling of the population every 50 years. It is on one hand an objective that is almost surely beyond the reach of the instruments of family policy, and on the other hand even if it can be envisaged, it hardly seems desirable. At best it would be desirable temporarily: it is

[8] Despite the similarity, it would not be realistic to claim to be able to manage the characteristics of a global population as can be envisioned doing for a very specific population, such as that of a firm or an occupational group. The issue would not be limited to simply borrowing of demographic techniques in order to attain human resources management objectives, according to a practice that has become common in large organizations: multinational firms, armies, and so on, as Régine Monti (2003) shows in her doctoral thesis on *La gestion prospective des âges des populations larges.* The dreaded and denounced danger would be that the sorcerer's apprentices of population policies are inspired by these experiences to export them in a context of global populations, believing to be able to demonstrate high operational efficiency.

[9] In many European countries, the measures adopted to stimulate births were limited to financial incentives (diverse payments, tax advantages, etc.), which did not necessarily produce the desired effect, probably because they were insufficient to bring about a radical change in the fertility behaviors of couples. In some of these countries debates even took place concerning granting a salary to stay-at-home mothers, a measure which would have undoubtedly resulted in greater success but which has never been put into effect, to our knowledge, for lack of adequate means to make the project operational. In addition, the policy encountered fierce opposition from feminist groups, who saw it as a way to reinforce sex role differentiation and to keep women in domestic and reproductive functions. Conversely, the Scandinavian countries have often shown greater imagination, with emphasis on measures designed to more easily reconcile the occupational and family roles of women (day care centers, parental leaves, etc.) and to better share the distribution of domestic and educational tasks between the partners (Monnier and Prioux, 2000).

indeed necessary, one of these days, to adjust to the prolongation of life other than by a risky acceleration of demographic growth. (p. 892)[10]

VII. GOOD OR BAD STRUCTURES: SOME PROPOSITIONS

Can we, nonetheless, identify some general principles that can guide action relating to the management of age structures, and make some propositions?[11]

There are not, in and of themselves, good or bad population age and sex structures. There are only populations that are well or poorly adapted to the societal contexts with which they are associated, as well as to the social ends pursued by the community or the nation.

Inertia, stupidity, or the apparently unavoidable character of certain demographic trends should not lead us to deal separately with population phenomena, without taking into account other societal phenomena. These other phenomena are at least as important as demographic phenomena, if not more so, but their changes are much harder to predict, and these changes can upset the relationships of the demographic system with the other basic systems of society (economic, sociological, ecological, etc.).

To fix population policy objectives with reference to intrinsic thresholds (threshold of zero growth, replacement level, dependency ratio of inactives to actives, etc.) stems from a dangerous belief that can focus all worries around parameters whose social significance is only relative and whose interest for the future of the community is limited and conditional.

The idea, apparently tempting, to limit the adverse consequences of temporal variations of the principal demographic variables (fertility, mortality, migration) should be received with prudence. Imagined corrective measures, generally uncertain, cannot only fail but they may also cause a delay in relation to the phenomena to be corrected, or they may cause an excess in the degree of correction envisaged, and thus result in bigger problems than those they were meant to resolve.

To the extent that demographic phenomena have a certain degree of inertia and rather important reaction lags, a population policy (including management of the population pyramid) must be designed from a medium- or long-term perspective. But political decision makers often have only a short-term vision of the domains that they must manage, so it is difficult to imagine that they would be able to give priority to long-term societal projects when those projects are, in addition, in conflict with their immediate electoral interests.

Even if it cannot be denied that the age and sex composition of a population can have a considerable impact on major macro-economic equilibria, and beyond, on the way of life of citizens and on the entire functioning of a society, it is also quite evident that scientific knowledge concerning the relationships among these phenomena is still largely in an embryonic stage. Hence, this knowledge alone can only rarely legitimate interventions to these population structures and a fortiori serve as the specific basis for active policies seeking to manage the population pyramid. Thus, the orientations of policies and the choice of measures to adopt come back at least as much to normative and ideological options as to scientific knowledge, and it is imperative first of all to clarify things for citizens by clearly indicating the real reasons that underlie proposed actions. No more than other policies, demographic policies or strategies for managing the age pyramid should not undermine the principles of self-determination and freedom of choice, and it is useful to avoid their resulting in limiting the exercising of certain fundamental rights (to education, to work, to health, to family reunification, etc.) or in creating growing disparities between social classes or generations.[12]

[10] "le vieillissement par le haut, dû à l'allongement de la vie [. . .] subsistera, même avec une fécondité maintenue au seuil de remplacement des générations" et que seul un retour tout à fait improbable à des niveaux de fécondité comparables à ceux atteints durant le baby boom, de l'ordre de 2,7 à 3 enfants par couple, permettrait une stabilisation du rapport de dépendance inactifs/actifs à un niveau proche de celui atteint en 2000, ce qui "impliquerait une croissance démographique permanente de l'ordre de 1 à 2% soit un doublement de la population tous les cinquante ans. C'est d'une part un objectif dont on est quasiment sûr qu'il est hors d'atteinte des instruments de la politique familiale et qui, d'autre part, quand bien même il serait envisageable, n'apparaît guère souhaitable. Il le serait au plus à titre transitoire: il faudra bien, un jour ou l'autre, s'adapter à l'allongement de la durée de vie autrement que par la fuite en avant dans la croissance démographique."

[11] Some of these have been taken, in whole or in part, from a paper presented in Lille (France) at the Sixth National Demography Colloquium (Loriaux, 1986).

[12] The big international conferences that marked the 50th anniversary of the United Nations produced reports that are types of universal charters often proposed to member states as sources of inspiration for putting into place action programs or policies. This is the case for the programmed of the International Conference on Population and Development (ICPD) held in Cairo in 1994, which includes many noble declarations concerning individual liberties, but which is astonishingly silent when it comes to proposing concrete measures in certain sensitive areas, for example, with regard to the right to family reunification for (legal!) immigrants or assistance with transfers of medical technology sought by all the countries of the South but rejected by most of the Western nations (with confirmation at later meetings of the United Nations Economic and Social Commission at New York) (Lassonde, 1996).

VIII. A NECESSARY REVERSAL OF THE PROBLEM

In view of all this, must we give up all hope of interventionism with regard to management of the age and sex composition of the population, and instead prefer a laissez-faire approach? This would leave us at the mercy of natural evolutions, which would at least have the merit of integrating a complexity that our models, mental or mathematical, don't seem to be able to provide. This way would at least have the advantage of avoiding the uncontrolled changes linked to the questionable experiments of sorcerers' apprentices in the management of human resources. But human reason acknowledges, only with difficulty, that leaving these evolutions to chance (or to something that resembles chance) may be an optimal solution. Rather than laissez-faire, wouldn't it be better to reverse the problem and acknowledge that it is not the population structures that one must try to change temporarily to align them with other societal structures, but rather these other structures and our types of organization that it would be better to put into harmony with the population structures?

Given that the age and sex compositions resist limited stimuli rather easily, while their profound changes are practically impossible to counter, it is therefore probably much simpler to transform our institutions, our laws, our rules, our moral codes, and even our cultural models to avoid their coming into conflict with our demographic structures. At least we have the means to do this via the diversity of instruments at the disposition of governments and public authorities. It would suffice if they would show the political will to use them and show that they have the imagination and innovativeness to find solutions adapted to new situations.

The population aging of industrial countries offers us some rather remarkable examples of this. In the absence of being able to prevent the elderly from living longer and longer or to find the magic wand that will make the numbers of young workers increase, that is, to find how to make the collective aging recede on all fronts, can't we find modes of organization that reduce the tensions between generations or that attenuate the adverse consequences of disparities between the sexes? Such modes of organization can be imagined; however, acknowledging them often runs into strong political, economic, or cultural resistance, so that it always seems preferable to try, often in vain, to modify at the margin the former modes of organization that previously demonstrated their worth but which, generally, are no longer at all adapted to the current societal contexts, rather than reforming them radically. It is possible that the democratic mode of functioning makes radical reforms difficult, if not impossible, due to the absence of a sufficiently broad political consensus. If this is the case, however, we will have to wait until our societies become virtually unmanageable in the face of the numerous challenges that will soon be imposed on them by the increasingly profound and rapid changes in the societal environment.

IX. THE FINANCING OF SOCIAL SECURITY: A FALSE DEBATE?

Many demographers (Guillemard, 1986; Euzéby and Euzéby, 1996; Bonnici, 1997), acknowledge that the introduction of social security systems around the second half of the 20th century constituted a great social advance, in allowing society to cover, as never before, two of the greatest risks to which workers were exposed: illness (or accident) and old age. It is, to a great degree, the combination of strong demographic growth (natural increase or via migration) and strong economic growth that created the opportunity without which the great social reforms after World War II would hardly have been conceivable. It is also, in large part, this combination that oriented, in many countries, the choices regarding retirement toward a pay-as-you-go (redistributive) system rather than a system with individual private accounts (system of capitalization). The large number of workers compared to the number of elderly people out of the labor force allowed pensions to be provided to those who had contributed no or very few payments, without compromising the equilibrium of the system. However, several decades later conditions had changed substantially: risks have grown sharply, principally the risk of old age, which has become a near certainty, while receipts have tended to regress in the face of continually expanding expenditures. Is this to say, as is often repeated in the media, that social security systems have become explosive and even, according to some (Minc, 1987), that the fuse of the bomb has already been lit? This is only really the case if nothing else is envisaged to help the systems evolve than to reduce payments, ration health expenditures, put a ceiling on pension amounts, or increase taxes on salaries.

One of the remedies most often recommended, including by international organizations like OECD (1998), is, for example, to increase the legal age of retirement, "which would have as a double consequence to increase the number of those in the labour force while at the same time reducing the number of retirees, thereby contributing to alleviating the financial pressure on the retirement system" (Tapinos, 1996).[13] Increasing the retirement age is certainly not an inconceivable scenario, in view of the lengthening of the average life, but the arguments supporting such measures are nearly always exclusively financial, without any consideration of the counterarguments, by nature more sociological or political (Gaullier, 1988).[14] In addition, the defenders of such policies often lose sight of the fact that such actions, even if they can be easily adopted by administrative order, risk encountering fierce opposition, not only from workers and their unions, but also from employers. Moreover, from a technical point of view, our societies, which are undermined by unemployment, seem to suffer more today from an excess of labor than a shortage, and to claim to take care of the problem by an artificial extension of salaried employment reflects more a mechanistic vision of social relationships than a systemic approach to the complexities of the labor market.

This type of proposition seems more inspired by a projection into the future of past situations and by a recourse to old recipes than by an expanded analysis of current and future trends of demographic structures. Such an analysis could inspire bold prospective scenarios regarding the economic and social roles of the elderly and concerning new relationships between generations, beyond the questions, most certainly important but nonetheless fairly small, of financing of pension funds. The day when the economy will cease to be an end in itself to which the society seems enslaved in all of its other dimensions, to become again what it should have never stopped being, namely, an instrument at the service of the realization of the collective objectives and of the satisfaction of the essential needs of the citizens, all of these questions, today apparently without answers, will perhaps find solutions for which we will ask why they didn't appear sooner.[15]

X. INTERGENERATIONAL EQUITY: A CLEVER DIVERSION FOR OTHER LESS AVOWABLE ENDS?

I am sometimes astonished to observe to what degree currents of thought, considered by many as innovative, seek to call into question earlier social advances in the name of economic efficiency, of political realism, and even of justice or fairness. In particular, the concept of equity among generations has become practically unavoidable, and it is hardly possible anymore to address the question of social policies without evoking it. A priori the idea can seem seductive, because it's about trying to ensure an equitable sharing of resources among generations, so that none of them takes any substantial advantages to the detriment of others. But demographic aging has given this theory a remarkable field of application, in that the number of elderly is increasing while the number of youth is diminishing, at least relatively, and the elderly are often considered not only as a burden to the society that devotes growing resources to them that could be used by other age groups, but also as an obstacle to development, as expenditures in their favor are ordinarily counted as consumption expenditures rather than investment.

Although most authors (Wisensale, 1997; Masson, 1999, 2000) acknowledge that the very notion of equity is difficult to define and even more difficult to render operational, it seems necessary to refer to it to be politically correct, even if the most immediately visible consequence is to exacerbate tensions among generations and to make more difficult the management of multigenerational societies. Preserving justice among generations thus risks creating the conditions for war among generations, whereas certain lucid authors haven't failed to notice that the discussion of intergenerational equity had been for many "a clever diversion" (Wisensale, 1997) to limit the intervention of governmental authorities in social programs and favor reductions in taxes, in particular for the benefit of the rich, in modifying the public image of elderly persons.

From there, in fact, it is no longer unreasonable nor unjust to ask if health care shouldn't be rationed as a function of age, dismantling the systems of protection and privatizing social security, and even, based on principles inspired by the works of a philosopher like John Rawls (1971, 1993), to restrain or suppress the

[13] "ce qui aurait pour double conséquence d'accroître le nombre des actifs tout en réduisant celui des retraités et contribuerait ainsi à relâcher la pression financière sur le système de retraites"

[14] It is relatively easy to acknowledge that if workers remain in their jobs longer there will be additional social security tax payments made and a reduction in the amount of pension payments (more receipts and fewer expenses). On the other hand, frequently neglected, for example, is the fact that if such measures extending the working life are taken (and accepted), they will also have as an indirect consequence delaying when retirees can get involved in diverse benevolent activities or second careers (Gaullier, 1988) and be able to offer their services on the market of the social economy.

[15] Without entering here into a discussion that goes beyond the focus of this chapter, it should be acknowledged that numerous ideas and propositions for restructuring our modes of functioning and of collective organization remain confined to small intellectual circles and have difficulty penetrating political milieus where they could be the subject of expanded democratic discussions. This is, for example, the case for alternative modes of financing social protection, such as universal allocation (van Parijs, 1990; Ferry, 1995) or taxation of capital and/or value added, but also for boldly innovative means of struggling against the early exclusion of older workers from the labor market thanks to the introduction of "multiple activity" contracts (Gaullier, 1999).

right to vote of the elderly (van Parijs, 1999). Have we thus arrived at this incredible paradox where the industrial societies, which are the only ones to have succeeded in mass-producing elderly people, the same as cars, televisions, or cell phones, are now trying to find means to get rid of them surreptitiously, as they would with toxic or nuclear waste? In addition, in the name of equity, an old humanist notion has been transformed for the occasion into a redoubtable ideological arm for confrontation of different age groups, most notably children, parents, and even grandparents.

The debate has, moreover, for several years taken a supplementary dimension with the rise of ecological movements, because the threats to the environment and the risks of running out of natural resources have expanded the search for equity from current generations to future generations, which of course does not simplify the problem. In reality, when it is defined in such a summary fashion, this notion of equity, which is only based on very incomplete criteria, leads us to treat a complex problem in a simplistic manner, with the risk of accentuating the injustices that we claim to be combating in referring to it.

Without a doubt, the efforts made to put in place systems of intergenerational accounting in order to better discern the flows of resources among generations should be encouraged, in particular to demonstrate the bilateral nature of the transfers. But this should be done on the condition that hasty conclusions not be drawn that go beyond the potential of such tools and that would leave obscure some important issues that are extremely difficult to resolve: What value should be given to economic and social investments made by earlier generations? Should we consider the expenditures made for elderly persons as an income from their investment for subsequent generations? Should we consider a part of the sums spent on children as an investment in the future productivity of society? How can we decide on the distribution of investments in research, preservation or protection of the environment and defense among the different age groups? (Wisensale, 1997).[16]

XI. A MORE POSITIVE APPROACH: SOLIDARITY OF THE AGES OF LIFE

With equity being a vague and suspect concept, more divisive than unifying, it seems more interesting to promote another concept, even if it is also relatively fuzzy and carries a heightened ideological charge: *solidarity*. This has the enormous advantage of favoring a positive vision of the social structure and searching for integrating formulas taking better account of the new stakes created by demographic and economic change.[17]

It is, indeed, necessary to acknowledge that aging societies present certain fragile aspects, certainly linked in part to the existence of elderly dependent subpopulations, but also and especially to the fact that the transformations of age and sex structures take place parallel to unprecedented changes in the global economy and make existing modes of organization obsolete. However, to take advantage of these fragile aspects to dismantle the edifice would be suicidal (or criminal) if the new principles founding the reconstruction don't take account of the requirements stemming from the new age structure. Because aging has strengthened the need for linkages among the generations, which were, paradoxically, less important[18] in the former demographic regimes (when generations followed one another practically in a chain, with limited periods of cohabitation), but which have become all the more necessary currently, as the progress of longevity has resulted in a strengthened coexistence in the same times and places of multiple

[16] For more on questions raised by generational accounting and its principles, see Laurence Kotlikoff (1992).

[17] This point of view is fully shared by one of the authors who has greatly contributed to the debate about equity and generational solidarity in France, André Masson (2000):

> [the concept of generational equity] suggests too much that each generation, working only for itself, must "evaluate its accounts" (assets and liabilities) with respect to the other generations if it is possible to do so. We thus lose sight of the unavoidable and fertile character of the generational link assured by the family and by the society, as "systems of co-operation in time among generations" (Rawls, 1993). [. . .] Recourse to solidarity is already justified by the disappointments of the concept of intergenerational equity: the difficulty of establishing a precise accounting for each generation, the inadequacy of the altruism invoked by "libertarians," the omission of specific relationships among family generations. [. . .] In breaking away from the narrow views of equity, generational solidarity allows for generating, within the family as in society, a mutually advantageous cooperation among generations against the inadequacies of markets. (p. 356, 362)

[18] This fact merits emphasis because traditional societies are often presented as being characterized by solidarity, which was probably the case, while contemporary societies are more individualistic, with forms of bureaucratic solidarity, anonymous, and impersonal. However, former solidarities were more justified by the regime of high mortality that prevailed, as well as by the insecurities linked to the physical and human environments. Conversely, in our developed societies, the idea often prevails that basic solidarities are less necessary because of the elevated standard of living and the disappearance or attenuation of certain risks, whereas it is precisely the opposite and the impression of individual freedom of choice is only possible because many forms of institutional solidarity exist, often unknown to us, under multiple expressions of assistance or assurance and diverse mechanisms of redistribution of collective resources.

generations. In other words, the prolongation of life has resulted in growth in the periods of life lived in common among the different age groups and has assured the contemporaneousness of generations all the more heterogeneous vis-à-vis one another as the acceleration of history has given them extraordinarily varied event trajectories.

The principal challenge already being confronted by aging societies is certainly that: to assure a stimulating cohabitation among all generations, young, adult, and elderly, each carrying their own social and cultural peculiarities, their hopes, and their contradictions. That is why future solidarity can only be global and why it must be considered in terms of the totality of the group and not in its separate fragments, or worse, in terms of individuals, who never constituted a group simply by being juxtaposed. That is also why solidarity must turn away from forms derived from assistance or assurance in which it tends to be comprised today (France, 1996) and find again the more organic forms linked to the acknowledgment of the existence of a community in which each member has a useful role to fill and an honorable status to occupy.

"Youth, adults, and elderly, healthy and ill, active and inactive, same fight!" we could say, but also "same founding principle of solidarity!." Nothing is won in advance. The contradictions are often fierce, the interests divergent, and the resistance to change is strong. But success cannot result from negation of the difficulties, nor from refusal to search for original solutions. Probably nothing will be solved via prudent policies and timid compromises, nor from measures without a long-term plan or an innovative spirit. The intelligence of the "gray revolution" (Loriaux *et al.*, 1990) will be to make all generations understand that the future depends on the acknowledgment of others, and that in a war of generations, gaining victory over other age groups would be devastating stupid, resulting in each group losing more than it gains. If it is not reason that will help us find the path to natural solidarities, it will be necessity.

As Henri de France (1996) has written,

> when the social and economic context with which we have been familiar for the past 50 years (the game of private interests corrected by the anonymous 'social safety net') will have shown that its fruitfulness is henceforth exhausted, that will then be, as in 1789, the end of one world. A collective survival reflex may then push men to admit that a social life is possible only when constituted of interdependent cells and solidarity. That of course does not prevent either inequalities or conflicts, these being normal features in an organic society. But it would lead each person to discover that other people's lives are important to him, and that it is not possible for the head to say to the feet, 'I don't need you'. The survival of human groups today depends on this radical change in perspective, and thus spiritual aspects appear to have to be 《the infrastructure》 of the material elements, if it is desired that social reproduction continue.[19] (p. 22)

Let's not make a mistake here: it's not a question of pleading for a return to traditional societies, but of advocating that all collective efforts seek henceforth to give to the social link its forgotten primacy and to reaffirm the dependence of the economy in relation to the society. Contemporary societies have entered a crucial phase of their transition, in which generations will have to declare if they wish to cooperate with one another for a better future or if they choose the path of isolation and confrontation. Examples exist almost everywhere in the world that militate in favor of each of these possibilities, and there is nothing currently that allows us to affirm with certainty that the optimistic outcome will necessarily carry the day over the pessimistic outcome. What does seem rather certain is that solidarity, which attests to the reciprocity of dependence and the necessity of intergenerational exchanges, constitutes, if not the only, then at least probably one of the better possible responses to the changes of demographic structures by age and by sex.

XII. DECLINING BIRTH RATES AND PENSION INSOLVENCY: A VICIOUS CIRCLE?

A young Swiss author, physician by training and banker by profession, David Cosandey (2003), recently published a work with a title as enigmatic as it is provocative, *The Culpable Insolvency of Retirement Pensions. How Our Old-Age Insurance Makes Fertility Decline*,[20] which counters many established ideas about retirement systems while raising strong controversies that are probably not ready to be appeased. And yet

[19] "lorsque le cadre économico-social qui nous est familier depuis 50 ans (le jeu des intérêts privés corrigé par le filet anonyme des 'assurances sociales') aura manifesté que sa fécondité est désormais épuisée, ce sera alors, comme en 1789, la fin d'un monde. Un réflexe collectif de survie peut alors pousser les hommes à admettre qu'il n'y a de vie sociale possible que constituée de cellules interdépendantes et solidaires. Cela n'empêcherait, bien entendu, ni les inégalités ni les conflits, ceux-ci ayant leur place normale au sein d'une société organique; mais cela amènerait chacun à découvrir que la vie de l'autre lui importe, et qu'il n'est pas possible à la tête de dire aux pieds 'je n'ai pas besoin de vous'. La survie des groupes humains dépend aujourd'hui de ce changement radical de perspective, et c'est ainsi que le spirituel apparaît comme devant être 'l'infrastructure》 du matériel, si l'on veut que la reproduction sociale se poursuive.' "

[20] *La faillite coupable des retraites. Comment nos assurances vieillesse font chuter la natalité.*

the author's avowed goal is none other than to reestablish the solidarity among generations that apparently was worsened precisely by the introduction of retirement systems.

The paradox is total: whereas usually the explanation is that it is the reduction in births following the baby boom and the succession of small generations compared to the previous full generations (the baby boomers) that is responsible for the financial difficulties of our retirement systems, Cosandey supports the converse argument, affirming that it is because of the institution of retirement systems that falling birthrates emerged (or were strengthened) because these social protection measures broke the natural linkages of reciprocal solidarity among the generations and caused us to lose sight of the fact that to be able to finance and pay for retirements, there must be a new generation of largely the same size as the preceding one. In the absence of this perspective, childbearing can only diminish, and its drop precipitates the breakdown of retirement systems, which self-destruct via this tragic vicious circle.

To transform this vicious circle into a *virtuous* one, there is only one remedy: stop basing the calculation of retirement pension amounts on the number of years of professional activity spent paying into the system and henceforth take into account the only important parameter, namely the number of children raised or supported by the individual, while putting into place "a structure allowing everyone, even non-parents, to contribute to the new generation, so as to have the right to a pension also." In short, make "clairvoyant" systems that are currently "blind."

And the rule is true, whatever the method of financing pensions, by redistribution (pay-as-you-go) or by capitalization (individual retirement accounts), because both are functions of economic dynamism and thus of demographic vitality. Cosandey considers, moreover, that to reform old-age insurance and make it more equitable and viable for the long term, it will hardly be necessary to upset either the institutions or their means of functioning, but only to modify some parameters and calculation rules. In sum, what is needed is simply to make current retirement systems be more similar to traditional systems of family protection, in which solidarity was expressed by virtue of a relatively simple principle: parents feed, shelter, and educate their children in exchange for which the children, after reaching adulthood, support, care for, and protect in turn their now-elderly parents.

Despite inevitable weaknesses, notably in cases of the premature death of children or family conflicts that may deprive parents of their old-age indemnity, this system functioned relatively well and according to an equitable principle.[21] By contrast, with the making of anonymous intergenerational systems of social protection that were disconnected from family linkages, intergenerational exchanges were perverted to the extent that the contributors (the parents) have to pay for the non-contributors (non-parents). They act so as to give to the oldest the condition of receiving from the youngest, whereas it is to give to the youngest that should condition receipt of a pension by the oldest.

And in such a regime, one can't reproach non-parents for showing themselves to be selfish or not being characterized by solidarity: they simply show the good sense and rationality of taking

> the most gratifying path that the authorities, the law, the society offers them. [. . .] Those without children appear to come out ahead. They can more easily travel, devote themselves to sports or reading, buy clothes, engage in their favourite hobbies. They enjoy tranquillity in their personal affairs and a superior standard of living. They symbolize affluence and success. [. . .] With everyone taking advantage of the investments realized by parents, our systems of old-age insurance encourage what can be called a tactic of "demographic parasitism." (Cosandey, 2003, p. 47, 48)[22]

[21] Several recent works show that private solidarity is far from having disappeared. Even if it has receded in the face of increased public solidarity supported by economic progress, it continues nonetheless, often in a complementary manner with regard to public solidarity. Illustrations of this can be found, notably in the research of André Masson (1995, 2004) and of Claudine Attias-Donfut and Martine Ségalen (1998), who writes:

> Solidarity between the young and the elderly in rural societies was of a private nature; this was disrupted by the effects of industrialization, which made proletarians of several generations, and by migration, which ruptured family linkages, both social and cultural. These linkages re-established themselves when the condition of workers improved, notably thanks to the appearance of retirement pensions. It is after the Second World War that economic growth, in conjunction with the social burst which appeared in the years 1945–1950, favoured the development of strong social protection instituting a national solidarity among generations. [. . .] In brief, in discharging the family from its traditional function of taking care of economic needs in old age, public solidarity has not eliminated the private mutual aid between young and old, but has changed its orientation, while at the same time transforming the respective statuses of the generations, It has also contributed to the emergence of new linkages, established on the basis of the autonomy of generations. (p. 33, 36)

[22] "le chemin le plus gratifiant que les autorités, la loi, la 'société' leur offrent. [. . .] Les inféconds font figure de gagnants. Ils peuvent plus facilement faire des voyages, se consacrer au sport ou à la lecture, s'habiller, se consacrer à leur passe-temps favoris. Ils jouissent de la tranquilité dans leur chez-soi et d'un niveau de vie supérieur. Ils symbolisent l'aisance et le success. [. . .] En faisant profiter tout le monde des investissements réalisés par les parents, nos assurances vieillesses encouragent ce qu'on pourrait appeler une tactique de 'parasitisme démographique.' "

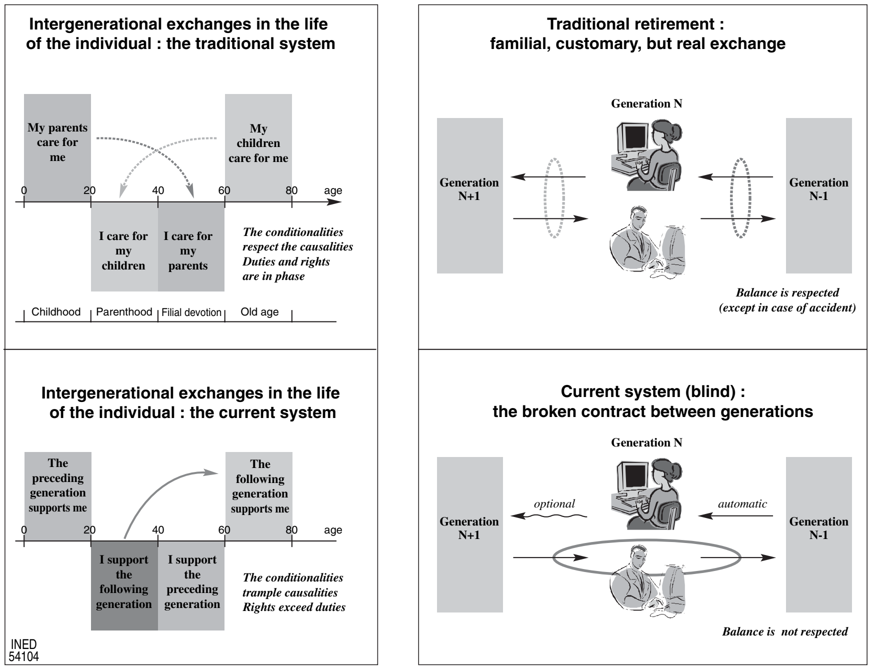

FIGURE 111–1 A vision of intergenerational exchanges, in the traditional system and in the current system, according to David Cosandey (2003). Extract from a presentation by the author of his work at a conference before the Central Council of the Economy, Brussels, June 2004.

Is it really necessary to penalize non-parents and provoke potential opposition between fecund and non-fecund couples or individuals? Not necessarily, because Cosandey imagines in his clairvoyant pension system several means permitting individuals who had no children, or only one (i.e., less than the threshold number established to benefit from a full retirement pension, being in principle two children) to contribute to the following generation and to acquire rights for their retirement (a minimal pension, financial sponsorship, fusion of retirement payments and child allocations, etc.).

As to the remedies currently evoked to confront the financial insolvency of the present systems, Cosandey rejects all of them, one after the other, because of their inefficiency and their injustice or because of the uncertainty of the expected results. This is the case for raising the retirement age, increasing taxes on persons and/or consumption, improving the productivity of work and/or increasing employment rates (most notably, of women), and resorting to immigration and investment in the economic actions and obligations of developing countries that are experiencing strong economic growth.

The solution to "furtively go back to the traditional system where grown-up children personally take care of their elderly parents as thanks for having been looked after in their own childhood" is itself rejected because, in making the role of the State disappear, where the State "offers a guarantee for parents having lost their children, thereby permitting a certain redistribution of income and avoids promiscuity among generations," this would be a step backward for society.

In sum, Cosandey's attempt merits consideration to the extent that he encourages a recasting of intergenerational solidarities on more explicit foundations, and at a time when not only are aging societies facing an imperative need for solidarity (precisely because they are aging and thus more weakened in certain segments of their populations), but also because they have never been so multigenerational as they are today, integrating numerous and strongly differentiated generations in an increasingly broad age interval, going from 0 to 100 and beyond.

The result of all this is that to manage these multigenerational (and in addition, multicultural) societies has become a real policy conundrum, if we are really willing to admit that good governance must seek to satisfy in an optimal way the needs and aspirations of all citizens, whatever their age, sex, social category, or religious or cultural affiliation. Unfortunately, it is at the moment when solidarity among generations should be recognized as one of the essential cornerstones of our societal edifice that it is under attack, disavowed everywhere and denigrated in the name of pretexts that are most often fallacious.

Exacerbated individualism and the winds of economic liberalism that have blown since after World War II in our Western societies have greatly contributed to the establishment of this disastrous climate. They created the sentiment that protection of the group or the community was less necessary from the time when essential needs (and even less essential needs or superfluities) were assured and the great risks (illness, unemployment, accident, old age) covered, leaving to each individual the possibility of managing his life in an autonomous fashion, freeing himself from collective constraints.

The discourse of insurers and bankers being increasingly along this line of thought, all of the current efforts seeking to encourage private insurance formulas or to replace, partially or totally, the systems of redistribution by systems based on capitalization are insidious ways of doing harm to the principle of intergenerational solidarity and encouraging young workers to break the great chain of solidarity among the generations. Only omitted here is a reminder that these supposedly miraculous formulas are subject to the random effects of economic fluctuations and to the risks of financial crises. Above all, young workers will run up against the challenge of the prolongation of the average duration of life of retirees (which could double, from the current 10–20 years to 30–40 years, if the legal ages of retirement are maintained).

Despite its undeniable originality, Cosandey's thesis nonetheless suffers from unavoidable flaws that compromise its chances to ever be adopted by public authorities, even if Cosandey can boast about a reform adopted in Germany in 2002[23] as a modest outline of a clairvoyant retirement system.

Indeed, the empirical analyses on which Cosandey relies to demonstrate that from the time when more or less generous retirement pensions were put into effect or strengthened in several countries (France, Germany, Switzerland, Italy, United States), childbearing declined ("each time that old-age pensions, in their current form, were strengthened, childbearing declined. And vice versa") are not entirely persuasive. They are based on a simplistic concept of causal relationships that does not take account of the transformations of the societal context that make the classic phrase, "all other things being equal," absurd. We must never lose sight of the fact that the demographic behaviors of individuals and couples are, first and foremost, social realities that only take their full and complete meaning if they are situated in the totality of changes of the systems in which they are operating.

Without a doubt, we should acknowledge that it isn't the discovery of the birth control pill or other technical reasons of this type that can explain by themselves the decline of fertility. There existed a set of convergent historical factors that contributed to the modification of reproductive behaviors, and the institution of systems of social protection constituted only one element among many of these societal changes that accompanied the industrial revolution.

Among these other elements, we can certainly allude to the changes in women's status and the increased participation of women in the market economy, the reduction of infant mortality, the preference for quality of children rather than quantity, the transformations regarding conjugal unions with the appearance of free unions and the wave of divorce. In brief, it is the entire family, with the positions occupied by its different members and its ends, that has been subject to profound transformations and which has been reprogrammed as a function of new technological, economic, social, and cultural contexts.

As a consequence, to dream of a new increase in fertility to the levels attained in the 1960s is unrealistic. Many potential parents have understood that it would be better, in the contemporary context, to be parsimonious about childbearing, so as to conserve all of the chances to endow their progeny with the best means of success possible, notably in terms of schooling in an increasingly competitive society.

In the face of persistent youth unemployment, which is not, however, incompatible with an increase in value added and in collective wealth, we might ask why there would be a return to higher fertility and investment to increase the quantity of human capital at a time when it is increasingly in competition with technical capital, despite the improvement in the productivity of labor.

But the most unfavorable argument against Cosandey's model is without doubt that, by the admission of the author himself, the system he advocates could only be operational beginning in 2050, in order to give time to new generations to reconstitute their numbers. That is, about 30 or 40 years after the advertised frontal shock among the generations will have taken place and the dreaded catastrophe (the failure of the retirement systems) has taken place (if at least one follows the forecasts of those predicting apocalypse). On the contrary, it is possible that the worst will be avoided and efficacious regulatory measures will have been taken in a timely fashion (if one adheres rather to the arguments of the optimists).

[23] The Riester reform, from the name of the minister who proposed it.

XIII. THE ULTIMATE QUESTION: RENEGOTIATE A NEW INTERGENERATIONAL CONTRACT

Starting with a question that appeared to be purely technical, highly objective, and of apparent simplicity, How do we manage the population pyramid?, we very quickly were led to ethical, normative, and ideological considerations. The reason for this is not very difficult to understand: a population is not a simple statistical construction and even less just human material, adjustable to the imperatives of the economy or of politics. The question of management of the demographic structures cannot be reduced to a sort of engineering of the human resource without inevitably falling into one or the other of the faults criticized here. Unfortunately, engineers or human resource technicians are listened to today more than philosophers, ethicists, or sociologists, and when these latter speak, they never do so with one voice.

In addition, the social sciences have never been as partitioned as they are at present, when the need for interdisciplinarity is so often expressed. Experts speak to experts, and ideally, only to those of their own discipline, or even their own "scientific chapel," and their relationships with the citizen are at the very least difficult.

> The citizen will have a good deal of difficulty appropriating what the experts tell him about the society in which he lives, either because they propose to him an image in little pieces that are impossible to put together, or because on the contrary they reconstruct it entirely in the image of their own system of thought, erected in Universal and definitive truth. (Supiot, 1996)[24]

These truths are much less neutral than indicated by the formal or informal models on which they depend. But the increase in the circulation of information and knowledge via computer and telecommunication networks has not had a parallel impact on the diversity of perspectives and points of view on objectives to pursue and the means to achieve them. Rather, it has favored concentration around dominant models, principally from the big international institutions or the big research centers that are effectively under their authority.[25]

Instead of being totally unique, thought has become institutionalized and normalized, so that there is no longer a place for an autonomous wild thought. To "preserve prosperity in an aging society," as OECD (1998) proposed in one of its recent and important research programs, is certainly not a goal to be condemned on its own merits. But it is rather disquieting to note that between the OECD, the United Nations, UNDP, the ILO, the Council of Europe, and the European Union, the convergence of solutions recommended is such that they appear to be closely under the influence of a single dominant school of thought.

There is no doubt that we can agree with the idea of encouraging an "active ageing" (Cotis, 2003), in favoring a greater flexibility of life cycles and greater freedom of choice regarding the passage from professional life to retirement. But is it necessary to automatically propose simultaneously to "slow expenditures of public retirement regimes and systems of health insurance"[26] (OCDE, 1998)? Nothing is less evident and, in any case, it would be regrettable if decisions concerning such crucial problems were to be made without a broad public debate being organized, at which the principal social partners and all those in positions of responsibility could participate.

The long-term future of our aging societies is too profoundly linked to these choices to allow them to be made hastily and left to the discretion of a small group of experts guided by political and financial or intellectual elites, who risk forgetting that the real question is not "how to preserve prosperity in an ageing society" (OCDE, 1998), but rather "how to renegotiate a new social contract among generations with solidarity that ensures to each the recognition of a valued role and status, without exclusion or marginalization, whatever his sex and his age" (Loriaux, 2002).

Acknowledgment

This chapter was translated from the French by David Shapiro.

[24] "aura bien du mal de s'approprier ce que les experts lui disent de la société où il vit, soit qu'ils lui en proposent une image en miettes impossibles à recoller, soit qu'ils le reconstruisent au contraire tout entier à l'image de leur propre système de pensée, érigé en Vérité universelle et definitive."

[25] This may be taken account of in observing to what point certain concepts are diffused like a train of powder across the international scientific community, governing powers and to the larger public, often beginning with confidential work of small groups of experts. In the field of demography and development, this was the case for the concept of integration of population and development and, more recently, for those of reproductive health and sustainable development. The criticism formulated here does not deal with their value as such, but with the way that they were diffused, without precaution nor a detailed examination of their implications, with considerable means of publicity and propaganda (worldwide diffusion in real time, translation into multiple languages, etc.) under the auspices of big organizations or powerful pressure groups that left little place for any contesting after the fact or even a simple critical reevaluation.

[26] "Why must spending on public pensions, health and long-term care be contained?" (OCDE, 1998).

COUNTRY CASE STUDIES

GRAZIELLA CASELLI, JACQUES VALLIN, AND GUILLAUME WUNSCH

Family and fertility policies, health policies, migration policies, policies on age distribution, each country and era has its own priorities, and population policies often address one or other of these aspects more than the others as circumstances vary. But regardless of the time or period, policy action tends to have planned or unplanned consequences in all these spheres, and it is important to be aware of these, get a purchase on the totality and interplay of all government measures that can influence population dynamics, intentionally or otherwise. The most appropriate way of doing this seemed to be to analyze the population policies in the broad sense of a selected group of countries.

The choice of countries was relatively straightforward. It was first decided to cover the two most populous countries in the world—China and India. Isabelle Attané studies the former in Chapter 112, Jacques Véron and S. Irudaya Rajan the latter in Chapter 113. To these two big Asian countries were added three other developing countries. First, a large country in Latin America–Mexico—whose population policy is covered in Chapter 114 by Maria-Eugenia Cosio-Zavala, then two countries in sub-Saharan Africa—Kenya and Côte d'Ivoire. Kenya, analyzed in chapter 115 by Valerie Golaz and Carolyne Wanja Njue, was among the first in this region to experience the onset of fertility decline. Côte d'Ivoire, covered in Chapter 116 by Amoakon Anoh, represents the African countries where it had still not occurred at the start of the 1990s.

As a counterpart to these five developing countries, we selected three developed countries: the United States and Russia, the two biggest, represent completely different experiences. The United States, which dominates today's world in all matters from its unassailable superpowerdom, and where free enterprise is the overarching principle in all economic and social matters with obvious consequences for population policy, is covered in Chapter 117 by Carl Haub. Russia, by contrast, represents the former communist bloc, and especially the countries of the former USSR, where the onset of demographic transition was much later than in Western Europe, and in fact only very shortly before their subjugation to communism. It is analyzed by Serguey Ivanov, Anatoly Vichnevsky and Sergei Zakharov in Chapter 118. Finally, France was also chosen as a case apart of demographic transition without population growth, and the acute awareness of low fertility problems it rapidly came to. This case is analyzed in Chapter 119 by Jean-Claude Chesnais.

Increasingly, however, notwithstanding the few supranational powers they actually possess, international organizations are stepping into population issues and having a major, if only indirect, influence on population policies. For that reason, these analyses of national experiences have been supplemented with a general review of international population policies by Jean-Claude Chasteland in Chapter 120.

CHAPTER

112

Fifty Years of Demographic Policies in China:

An Assessment

ISABELLE ATTANÉ

Institut national d'études démographiques (INED), Paris, France

After their victory over the Nationalist armies in 1949, the Chinese Communists found themselves in charge of a country exhausted and ravaged by war, its economy ruined by decades of internal strife and foreign interference. The new leaders had to put China back on its feet, rebuild its identity after a century of humiliation—in short, restore its dignity. The time had come to break with old feudal ways. Society had to be reshaped from top to bottom. The task was colossal.

The key concerns of young Communist China were the economy and society. Two groups were singled out as the prime victims of the social order: the impoverished peasantry and women. Pervasive abuses by the propertied classes had to be stopped. The traditional family became a target of the class struggle. The country set out to eradicate the "three main differences" (towns vs. countryside, manual workers vs. intellectuals, workers vs. peasants) (Attané, 2002c, p. 355). The regime preached equality, balance, a fair distribution of resources and the means of production, and harmonious economic development. Another goal was to improve the quality of the population by a campaign to combat devastating mortality and by raising the consciousness of the masses through education.

Mao Tse-tung's death in 1976 marked a radical break with egalitarian ideology. The reforms launched by Deng Xiaoping in the late 1970s opened the doors wide to individual initiative. The economy was liberalized. The winds were changing, the socialist dogma was buried, and social inequality deepened.

In both its hardline and liberal phases, this half-century of Chinese socialism relied extensively on all manner of authoritarian policies. No area was spared—the economy, the circulation of people, health, reproduction, and so on. In this chapter, we review the main demographic policies—in the broadest sense—implemented since 1950. We then assess the achievements, and their consequences, at the turn of the 21st century.

I. HOUSEHOLD REGISTRATION AND MOBILITY CONTROL

Among the most decisive population policies, the one that had the most visible and lasting impact on Chinese demographics—along with birth-control policies—was the control of personal mobility. As early as 1955, a household registration system was set up under the authority of the Interior Minister. But its implementation remained very partial, most notably because of staff shortages. Control of population movements was not enforced until the Regulations on Household Registration of 1958. One of the main goals was to end illegal migrations to urban areas (Blayo, 1997, p. 28). To justify the introduction of this rigid and restrictive system, the authorities invoked the need to spare China from the informal urbanization typical of other developing countries. Curbing urban growth soon became a major priority. This, it was hoped, would prevent the worsening of urban employment conditions and channel population movements to better serve the regime's interests. At the advent of the People's Republic, urbanization was a marginal trend. One in ten Chinese (10.6%) lived in a town or city, a far smaller proportion than the worldwide average, which had already reached 30%. (The definition of the urban population has changed frequently since the 1950s. For more details, see Blayo, 1997, p. 101–111.) The rate remained modest until after Deng's economic reforms, which led to a gradual easing of restrictions on internal migration. In 1978, urbanites still accounted for only 18% of the total Chinese population. Until the 1980s, therefore, population migration and worker mobility—the keystones of the planned economy—were tightly controlled. The Public Security offices kept a special watch on interprovince migration; except for compulsory transfers, it was nearly impossible to migrate from rural areas to urban areas without official permission (Cai Fang, 2002, p. 169). Even today, despite its steadily declining effectiveness, control is exercised via household registration: the *hukou* system. The *hukou* is a residence booklet that includes, among other information, the holder's date and place of birth, ethnic group, and marital status. A veritable internal passport, it obliges each individual, from cradle to grave, to reside in his or her birthplace, making migration virtually impossible. For many years, legal migration was a one-way ticket, each type of locality being assigned to a specific position in a very rigid hierarchy. A person could leave a large city for a smaller one, a town, a district or township capital, or a village (Figure 112–1). Horizontal migration was tolerated for people wishing to move to a locality of identical rank; so was vertical migration, but only from the larger unit to the smaller unit, not vice versa. A person born in a village could move to another village in the same province, subject to permission by the authorities of both localities. This registration system served for many years as a key instrument in the arsenal deployed by the regime to subjugate society (Trolliet and Béja, 1986, p. 155).

Even marriage did not afford an escape from *hukou* control. If a peasant woman married an urban dweller, the husband could resettle in his wife's native village, as the locality was of lower rank. But there was no hope of transferring the wife's *hukou* to the city. An urban dweller married to a peasant woman could not even look forward to being joined by his children one day, as the urban or rural status enshrined in the *hukou* was transmitted by the mother. Today, a child is free to choose between mother's or father's *hukou.* As a result, the system spawned a Chinese Communist invention that was—to say the least—unusual: couples separated for administrative reasons and saw each other only once a year, usually during the spring festival vacation. The only ways of being freed from this compulsory residence order were to enlist in the People's Liberation Army, to become a Party member, or to obtain a university degree, which entitled the holder to a job in a State-owned company.

FIGURE 112–1 Structure of Chinese territorial administration. (Source: Attané, 2002b, p. xvii.)

The system helped to turn China into a frozen society. Far from closing the gap between urban and rural areas, the system fostered the perception that the right to live in urban areas was a privilege reserved for a minority. This feeling was exacerbated by the rationing system introduced after the Revolution. Ration coupons, for which only urban *hukou* holders were eligible, gave access to grain in the State-run market. Peasants were obviously excluded, and this posed an insuperable obstacle to their settling in cities. (Until 1985, it was illegal to sell grain on the free market.) As the coupons could be exchanged only in the issuing town or city, they were also a means for controlling personal travel and thus complemented the *hukou* system (Trolliet and Béja, 1986, p. 157). Rationing of staple commodities was abolished in the early 1990s.

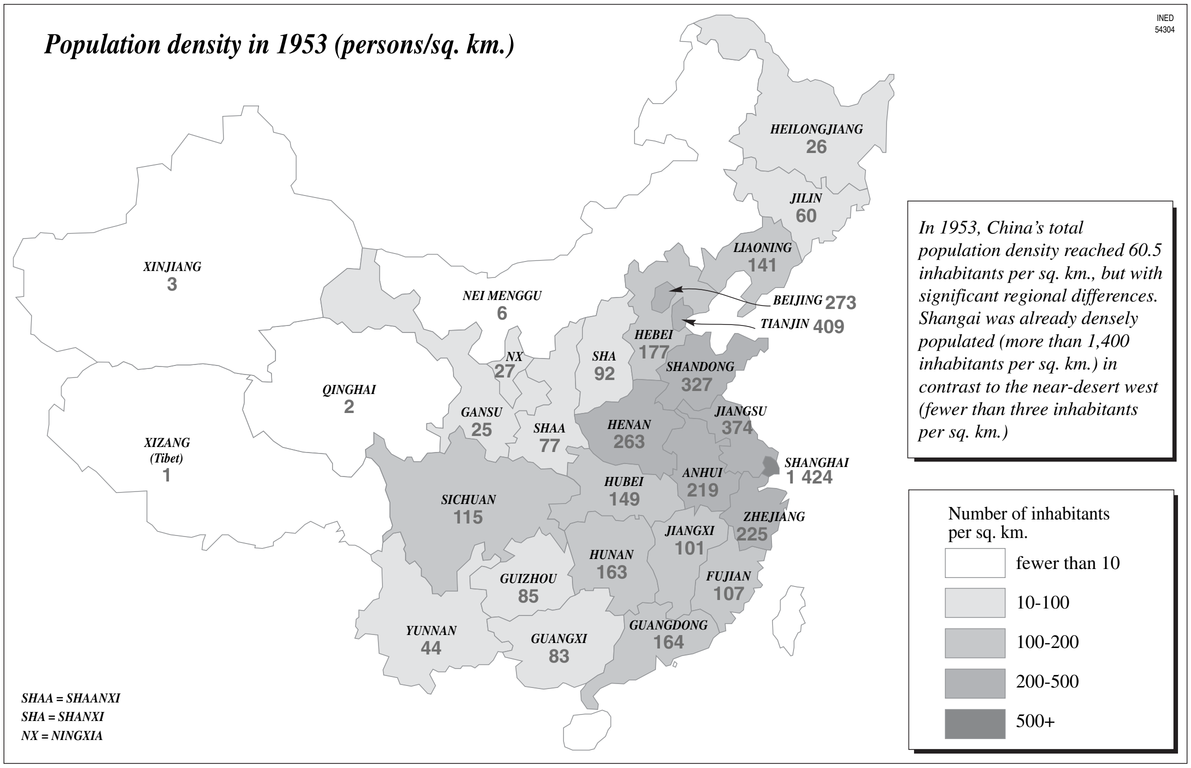
Out of exhaustion rather than because of a political decision, the regime gradually relinquished control over all personal movement. Rural decollectivization—the first step in economic reform—freed an abundant labor supply from the obligation to work on farms. The excess agricultural workforce was forced to turn to nonfarming activities in order to survive. The businesses in cantons and towns (*xiangzhen qiye*) specially created to absorb this glut became increasingly incapable of doing so. Very often, the excess rural labor had other no choice than migration in order to meet the needs of new private-sector urban companies, which required large amounts of cheap labor. Meanwhile, the restructuring of State-owned companies put millions of people out of work. Having failed to reassign these workers itself, the State turned a blind eye to many individual migrations, the only solution for finding new work. The dichotomy generated by the personal registration system thus became less biased against peasants.

The paradox is that the job seekers were forced into illegality solely because of the registration system's inconsistency. The system defines a migrant as anyone who legally transfers his or her *hukou* to a place of residence other than his or her place of birth. Now this legal migration, while ever less restrictive, remains subject to annual quotas well below requirements: 17 to 19 million people are allowed to migrate per year, "une population flottante nécessaire mais exclue" (Attané, 2002b, p. 185).

Migration with transfer of residence to the host locality thus accounts for a minimal share of actual migration. Most flows are generated by illegal migration, that of the "floating population" (*liudong renkou*). This phenomenon, specific to China, denotes temporary or permanent movements of persons in a province or between provinces, very often from rural areas to urban areas, without *hukou* transfer. Even if they relocate at several hundred kilometers' distance, these persons are officially regarded as still residing in their place of origin. In practice, they therefore avoid any form of control, including on the number of births. This illegal migration is, by definition, hard to quantify. Recent estimates give a broad range of 80 to 130 million people—a significant mass of about 10% of the total population. Therein lies one of China's most blatant contradictions in its march toward globalization. The *hukou* system, while totally inappropriate to today's economic requirements, has undergone no substantial change since the late 1950s.

Rural-urban migration remains the strongest driver of urbanization, although the natural increase is still rather brisk in the urban population at 0.7% in 1999, versus 0.9% in the countryside. The loss due to rural exodus has considerably reduced the overall growth of the rural population, which has become negative in the latest intercensal period: there were 783.8 million rural dwellers in 2000 versus 834.4 million in 1990, or an annual average decline of 0.6%. By contrast, the total growth of the urban population (cities and towns) has become truly explosive, averaging 4.4% per annum in the past 10 years. It should be borne in mind, however, that the changes in the definition of urban localities and the incorporation into these localities of some rural areas have increased the urban population in relatively artificial ways in the past two decades (see Blayo, 1997). The tripling of the number of cities since 1982 has also played a decisive role. The urban explosion has therefore not been as strong as the raw figures imply. With an official urban population of 459 million, or more than one in three inhabitants (37%), China lags behind the rest of the world: the urban population stands at 47% on a global average and 76% in what the United Nations classifies as the "most developed countries" (Figure 112–2).

But China will soon catch up. According to official projections, one in two Chinese (47%) will be urban dwellers by 2020, and the proportion will rise to at least 60% by 2040–2045 (Li Jianmin, 2002, p. 283). The number of towns and cities tripled in the past two decades, from 236 in 1982 to 667 in 1999. Three very large cities have more than 7 million inhabitants: Beijing, Tianjin, and Shanghai. For a while, therefore, China will have succeeded in curbing the size of sprawling megalopolises: with 11.5 million and 14.3 million inhabitants respectively in 2000, Beijing and Shanghai remain modest by comparison with such giants as São Paulo, Mexico, and Bombay (18 million) and Tokyo (26 million).



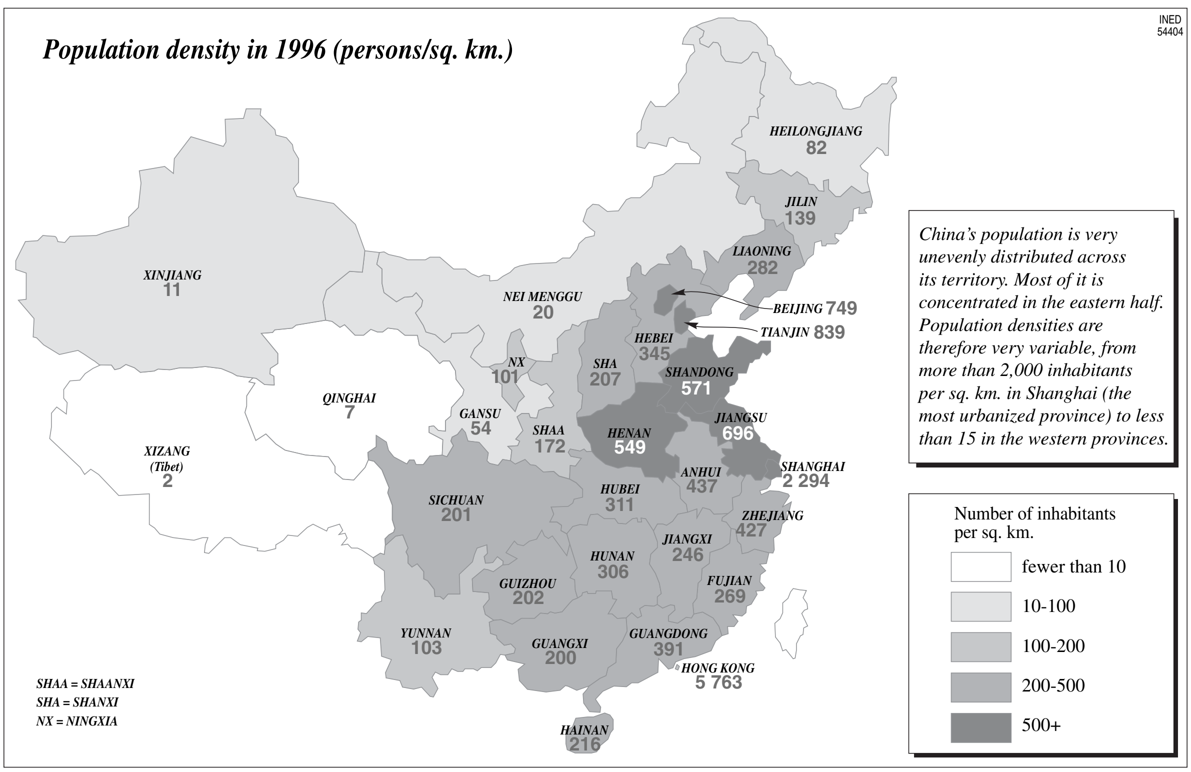


FIGURE 112–2 Population density by province in 1953 and 1996. (Source: Attané, 2002b, p. xviii, xix.)

II. BALANCING REGIONAL DEVELOPMENT AND STRENGTHENING BORDER REGIONS

For all socialist countries, central economic planning implies the planned allocation of all factors of production. Rational reproduction of the population must be ensured, particularly to allow optimal use of labor. By making industrial development the top priority of its first five-year plan (1953–1957), young Communist China forced itself to strictly manage its human resources. To meet the needs of the socialist economy more effectively, migration had to be controlled. As part of a planned process, migration would serve to balance labor requirements among regions. The authorities acted swiftly to curb urbanization and restrict population movements inside China—particularly the spontaneous migration of peasants to towns and cities.

In the early days of the regime, China's rulers saw a large population as a powerful asset. Although it reflected the varying hospitality of the soil, the terrain, and the climate, the population was unevenly distributed across the national territory. The eastern half of the country consists of plains and hills; the western half, with a rigorous climate, consists of plateaus and mountains. The west, which accounts for more than one-half of China's surface area (including Inner Mongolia, Xinjiang, Tibet, Qinghai, Ningxia, Gansu, Shaanxi, Yunnan, Guizhou, Guangxi, and Sichuan) contained only 28% of the population in 1953. These proportions have barely changed. In 2000, the year of the latest census, the west, with 319 million inhabitants, accounted for only 25.7% of the total population. Just after the Revolution, therefore, almost three-quarters of Chinese lived on less than one-third of the territory. The corollary was a highly disparate range of population densities: from over 300 people per square kilometer in Jiangsu and Shandong to fewer than 5 in Xinjiang (3/sq. km.), Qinghai (2/sq. km.), and Tibet (1/sq. km.). Concentrated in the eastern part of the country, the population lived far from the national reserves of natural resources needed by industry. There, infrastructure was lacking and workforce skills were low. Most modern plants were located in the coastal regions; heavy industry—which the Japanese began setting up in 1931 as part of their expansionist policy—was concentrated in southern Manchuria. In the rest of the country, the forces of production were weak and industrial facilities obsolete (Meissner, 1990, p. 9–33). To cancel these imbalances, China acted promptly to redistribute its population. Another goal was to foster the development of remote rural areas by sending managers and skilled labor there. Achieving balanced regional development required better management of human resources and local resources such as raw materials. A senior Chinese official declared in 1964:

> China has enough space . . . We have rich mineral resources and huge tracts of land that are just asking to be cultivated. Let us take the example of the north-west: Xinjiang province. Only 6 million people live there, but Xinjiang could easily provide enough living space and food for 50 million. (qtd. in Tien, 1973, p. 130)

In the very first five-year plan (1953–1957), the government implemented an interregional migration policy. The stated goal was to deconcentrate industry by promoting its expansion in the hinterland and to place new land under cultivation. But there was another purpose as well: to stem the growth of towns and cities, where rural-urban migration, then in full swing, was creating ever greater problems, that is, housing and food shortages coupled with substantial underemployment. The measures adopted accordingly sought to keep the rural population in place (thanks to the *hukou* system) and reduce the urban population. In all, 1.3 million blue-collar workers and skilled white-collar workers were transferred from urban areas to rural areas, of whom 950,000 between 1953 and 1962 and 200,000 between 1963 and 1981 (*China Daily*, April 25, 1982, qtd. in Blayo, 1997, p. 55). Massive projects were launched to build new infrastructure and clear arable land. Between 1950 and 1958, China built 94,000 kilometers of roads and 5,400 kilometers of railroads. In the same period, the surface area under cultivation grew by 11%, with the largest expansions in Xinjiang, Inner Mongolia, and the northeastern regions (Meissner, 1990, p. 31).

The policy of planned migrations thus served two purposes: the first was economic, the second demographic, namely, to correct unbalanced population distribution. The policy relied on the multiple systems for controlling individuals instituted in the early decades of the regime.

The central government supported the development of remote regions, with a special emphasis on border areas. The policy also had an ethnic objective, albeit not always clearly stated: these peripheral areas, sparsely inhabited but rich in natural resources, were also those in which ethnic minorities were concentrated. Because of their crucial strategic importance, the main targets were the north and the west: Inner Mongolia, bordering on the People's Republic of Mongolia and sharing a short border with the USSR; Xinjiang, two-thirds of whose borders touch the Soviet Union and Pakistan; and Tibet, neighbor of China's timeless rival, India. Strengthening the presence of the Han (the majority ethnic group, now representing over

90% of the total population) in these areas was also a way to dilute the indigenous populations and so dampen any separatist aspirations. Thus, to reinforce central authority, guarantee stability on its frontiers, and promote economic development, China set out to strengthen these sensitive regions. A Chinese general declared in 1965: "In recent years, rifle in one hand and shovel in another, officers and men [. . .] have preserved security on the borders of the Motherland and have worked to build socialism by engaging in agriculture," (according to an article published by *New China News Agency*, January 2, 1965, qtd. in Tien, 1973, p. 129).

China very quickly turned Xinjiang into one of its main pioneer lands, most notably because, during the phase of Sino-Soviet friendship, it was the link that was supposed to ensure continuity between economic spaces (Larivière and Sigwalt, 1996, p. 178). Xinjiang (literally "new frontier") was not incorporated into China's sphere until 1759, date of its conquest by the Manchu dynasty of the Qing. In the two centuries that followed, its ties to the central government remained very loose—so much so that, on several occasions, it found itself in a state of near-independence. Since 1949, the year marking the conquest of power by the Communist Party and the inauguration of effective nationwide control, Xinjiang has been ever more firmly anchored to China. Xinjiang is an object of both desire and fear. It is desired for the wealth of its subsoil and its strategic position, but loathed for its indigenous population: the rebellious, untamed Uigurs. As Turkophone Muslims, Uigurs are fixated on the pinnacles of Muslim civilization that are Istanbul, Samarkand, and Bokhara, rather than on Beijing. They possess the rich cultural traditions of Central Asian Muslims, but have nothing in common with the Han. Uigurs also have a strong sense of identity, largely tied to their geographic concentration on a territory of their own, where they form a majority, but of which they are gradually being dispossessed. In 2000, Uigurs, Kazakhs, and Kirghizes accounted for 53% of the total Xinjiang population. Hence ethnic grievances and separatist claims have risen, driven by rejection of Chinese supremacy (Becquelin, 1997, p. 10–21).

With respect to its ethnic minorities, the Communist regime installed in 1949 broke, at least in its rhetoric, from the narrowly homogenizing views of the Nationalists by emphasizing China's multinational character. Nevertheless, the goal of strengthening national unity persisted. In the 1950s, for economic and strategic purposes, the Communists implemented a Sinification policy to be achieved through population transfers. The radio and press appealed to the socialist consciousness, patriotism, and spirit of adventure by encouraging young people to migrate. There were several forms of planned migration: transfers of entire families for a defined period; transfers of married men, young or mature, sent off alone and to be joined later by their families; and transfers of young unmarried men and women for permanent settlement in the region in order to realize long-term projects (Blayo, 1997, p. 47). Migration was encouraged particularly to Xinjiang (Tien, 1973, p. 123), where the construction of irrigation systems and establishment of State-owned farms created a major need for migrant labor. Thousands of soldiers discharged from military duty (by becoming "peasant soldiers") were sent to the peripheral provinces to occupy key positions and disseminate the technical knowledge needed to improve agricultural and industrial production. As an incentive to compensate for their isolation and distance from their native regions, the settlers were offered various benefits, especially financial. These typically consisted of bonuses (Tien, 1973, p. 124–125). By 1959, 220 State-owned farms had been set up on 13 million *mu* (one *mu* is equal to 0.067 hectares) in Xinjiang, accounting for 30% of the province's farmland at the time. Around 1960, between 150,000 and 200,000 peasant soldiers were reportedly stationed in Xinjiang (Tien, 1973, p. 127).

Since 1949, the most sensitive regions have been massively settled. The number of Han in Inner Mongolia doubled between 1953 and 1964 from 5.1 million to 10.7 million. In Xinjiang, it rose sevenfold from 330,000 to 2.3 million in the same period—an annual average growth rate of 18%—and doubled between 1964 and 1982. Planned migrations were curtailed from late 1958 onward. But this did not spell the end of population transfers for economic, hegemonic, and strategic purposes. Today, 18.5 million Han are settled in Inner Mongolia, where they make up 80% of the province's population. Another 7.5 million Han live in Xinjiang, accounting for 40% of the inhabitants of the province—an increase of 34% since 1982 (Attané and Courbage, 2000, p. 257–280). The phenomenon is harder to measure in Tibet, where military personnel, who represent a sizable proportion of the Han presence, are excluded from census statistics. Whatever the validity of the figures, the Han surge is manifest, averaging 5% a year in 1964–1982 and 3% in 1982–2000. This is well above the increase achievable through natural growth, even at a brisk pace. In 2000, 160,000 Han were living in Tibet, twice as many as in 1990. (The Han population in Tibet fell between 1982 and 1990, before the revival of China's political and economic interest in its western provinces.) Officially, therefore, 6% of the Tibetan population is Han (Table 112–1). We should emphasize that, according to inde-

TABLE 112–1 Han Population (in Millions and %) in the Most Sensitive Border Provinces, According to Censuses, 1953–2000

Province	1953	1964	1982	1990	2000
Inner Mongolia	5.120 (83.9%)	10.743 (87.0%)	16.278 (84.5%)	17.290 (80.6%)	18.466 (79.2%)
Xinjiang	0.332 (6.9%)	2.321 (31.9%)	5.284 (40.4%)	5.695 (37.6%)	7.489 (40.6%)
Tibet (Xizang)	—	0.037 (2.9%)	0.091 (4.9%)	0.081 (3.7%)	0.159 (6.1%)

pendent sources, these statistics leave out several hundred thousand military personnel, whose inclusion would raise the proportion of Han in Tibet to about 15%. Better than speeches, these colossal transfers of Han population to buffer zones reflect the strategic fears as well as the hegemonic designs of the central government, in the name of national unification.

Xinjiang—like all the other provinces of China's "Far West," for that matter—has not finished with the Han. After 20 years of economic liberalization, with the eastern coast being recognized as the sole beneficiary of the reforms, the government launched an ambitious program to "develop the West" in 2000. This strategy is not only economic but also political. Its aim is to buttress the power of the Beijing authorities through economic growth driven by the central government. Poverty in the remote regions is to be reduced by encouraging local investment in capital and technological advances. The program priorities are infrastructure, environment, and training. Large-scale projects are under way in transportation and communications, such as airports, rail links, highways, and telephone networks. Their unifying effect is unquestionable. But Xinjiang's value to the Chinese economy is largely due to its oil-production facilities (Domenach, 2002, p. 319–321). Behind this strategy also lies a calculation with regard to Buddhism and Islam, which the Chinese Communist Party (CCP) does not deny: "When the economy develops, the attention of the people will gradually shift from religion to the joys and pleasures of this world" (article in *Far Eastern Economic Review*, August 21, 2001, qtd. in Domenach, 2002, p. 319–321).

III. HEALTH POLICIES

Since 1949, as we have seen, China has gone through two distinct phases: (1) the hardline socialist era, marked by a quest for social equality (1950s to 1970s), and (2) the liberal era, which saw a transition toward the strangely syncretistic system of a socialist-style market economy (1980s and 1990s). The two crucial reforms were the decollectivization of agriculture and the restructuring of State-owned enterprises. Hitherto, collective institutions had taken charge of every Chinese from cradle to grave. By disrupting the overall social organization, the dismantling of those institutions had repercussions well beyond the economic sphere. Previously, each citizen, through his or her work unit, was strictly dependent on the State in all areas of everyday life: employment, housing, health, child education, retirement, social insurance, and so on. By taking down its collective structures, the State has, in effect, partially or totally handed over to the private sector a set of functions that it could no longer perform.

Public service, as developed by Mao Tse-tung in the 1950s and 1960s, was informed by the principles of egalitarianism and massification. The focus was on public health, with three main goals: rapid improvement of access to health care, prevention and mass campaigns, and creation of a comprehensive insurance system. Priority was assigned to training medical workers in charge of dispensing primary care, and to pharmaceutical production. This strategy enabled China to achieve remarkable progress—particularly, as we have seen, in combating infant mortality and improving life expectancy at birth. In less than three decades, rural areas were provided with infrastructure offering access to primary health care for all local residents. By the eve of the reforms, mass vaccination campaigns, most notably against the most lethal child diseases, had eradicated large-scale epidemics and the worst health scourges. Patriotic health campaigns (*aiguo weisheng yundong*), were launched, in particular to eliminate agricultural pests. One of these campaigns was aimed at eradicating the "four pests" (*si hai*): flies, mosquitoes, rats, and grain-eating sparrows. But when the elimination of sparrows turned out to have serious ecological consequences, they were replaced by bugs as targets.

Another example is the campaign against schistosomiasis. Known as "snail fever" in Chinese, this parasitic disease is caught by walking barefoot in contaminated water. The authorities informed the population about the disease's transmission, helped to screen for the disease, and facilitated treatment. A number of community initiatives, such as sewer construction, were taken to improve sanitation standards. Drawing inspiration from the Soviet system, China established centers for disease and epidemic prevention supervised by the Health Ministry in various regions (Liu and Hsiao, 2002, p. 391).

Other initiatives launched in the 1950s and early 1960s were largely modeled on the USSR, which provided a large share of technical assistance at the time. Several schools were opened to offer "university-level" medical training (typically in 6-year programs); some of the older schools were transferred from the cities on the eastern coast to regions with urgent needs, particularly in the west. Schools providing intermediate-level medical education (2- to 3-year programs) opened to train medical assistants, nurses, midwives, pharmacists, technicians, and other categories. In 15 years, these schools reportedly turned out more than 100,000 doctors, about 170,000 medical assistants, and 185,000 nurses—a more than 250% increase in the health care workforce. Between 1949 and 1965, the number of hospital beds rose from 84,000 (1 per 6,500 inhabitants) to 650,000 (1 per 1,200 inhabitants).

As with birth control, the health policies implemented from the 1950s onward owe their success largely to China's administrative organization. After the agrarian reform, collective property and central control by different echelons of government became the predominant type of social and political organization. The three-tier health care system was modeled on the administrative system. In rural areas, clinics were set up in villages, medical centers in towns, and hospitals in district capitals. Village clinics were staffed by low-skilled doctors, who had only 1 year of training after middle school. Town medical centers, which had a capacity of 10 to 20 beds, were supervised by doctors with 3 years of medical training after 6 years of secondary schooling. The practitioner was generally assisted by midwives, nurses specializing in maternal and child care, and village doctors. The district hospitals were far larger facilities (200–300 beds) staffed by fully qualified doctors with 4 to 5 years of medical training. This vertical organization allowed efficient treatment of patients. At the time, public hospitals charged for procedures and medicines, but the State-set prices were affordable for most people.

During the Cultural Revolution, which began in 1966, the role of Party leaders and the bureaucracy was reassessed. The widening disparities between urban and rural areas, between intellectuals and manual workers, and between Party leaders and the people were among the major dysfunctions denounced by the Cultural Revolution's chief instigator, Mao Tse-tung. In a directive of 1965, he reproached the Health Ministry for giving precedence to urbanites and neglecting the needs of the peasantry. In the years that followed, tens of thousands of urban health care workers were sent to the countryside on a permanent basis or as part of mobile medical teams. In 1975, rural areas numbered 1.6 million "barefoot doctors" who—despite their shoddy medical training (a 3-month program before being sent into the field) and the political turmoil of the Cultural Revolution—achieved a substantial improvement in health conditions and public hygiene.

A few years after Mao Tse-tung's death, the Chinese experienced a decisive turning point in their lives: the advent of economic reforms. The outstanding productivity gains that they induced have led to sizable improvements in real income, nutrition, and housing—and hence a decline in overall poverty. But this progress has benefited only a minority: the mainly urban populations of the eastern seaboard. At the national level, inequality has widened. Moreover, economic growth has not favored the pursuit of the health transition. The egalitarian ideology, whose top goal was to serve the people (*wei renmin fuwu*), soon gave way to the notion that it was better to let some people get rich. Once under the responsibility of people's communes, the health care system, now decentralized and on the way to privatization, has ceased to operate as a public service: patients are required to pay for treatment, while doctors and hospital managers must meet profitability criteria. Rural medical cooperatives, which provided medical insurance for a flat fee to 90% of the rural population in the late 1960s, now cover less than 10%. The State's fiscal allocation to rural health care shrank from 21% of the total health care budget in 1978 to 10% in 1991 (Cailliez, 1998, p. 38–45). Medical care has become unaffordable for the poorest citizens. The gap is widening: in 1997, a rural household spent an average 62 yuan per person on health care—three times less than urban dwellers (179 yuan). In 2001, the outlays came to 97 and 343 yuan respectively, an increase of 56% for the first group and 92% for the second (NBS, 2002). Decentralization and tax reform have transferred health care–system financing to local governments. Faced with a deep cut in subsidies, the system has been privatized in anarchic fashion. As most of its resources come from patients, it has neglected the unprofitable aspects of its mission. As a result, inequality has increased. Urban residents in the developed regions are getting the lion's share: an estimated 15% of the population absorbs 60% of public health care expenditures. China has no shortage of pharmaceuticals or doctors, but the improvements of the past 20 years are concentrated in cities. Most peasants have access only to village and canton facilities. Regional disparities in health statuses are extreme. According to World Bank data, in 1993, health care expenditures per capita in urban Guangdong were 33 times as high as those in rural Tibet. The differences measured by the main health care indicators are naturally just as large. For example, in the late 1980s, the maternal mortality rate was 18 per 100,000 in Shanghai, but 108 per 100,000 in Ningxia. Rising costs and the total loss of medical insurance have deprived a sizable proportion of the rural population of access to health care (Cailliez, 2002, p. 409–420).

Inequalities exist not only in access to health care, but in the quality of care. The canton medical centers (*xiang*)—a legacy of the people's communes—are usually able to treat serious cases and perform surgical procedures. But their medical personnel typically have no university training, only "hands-on" experience. A 1990 Health Ministry survey of 90,300 village doctors revealed that 73% did not go beyond secondary school. Many of them are former barefoot doctors whose title, for those who passed their formal exam, was officially changed to village doctors in 1981. Those who failed the exam became medical assistants. The care they provide is not always appropriate. For patients, the risk exposure can be high. Moreover, since 1985, clinics no longer have the monopoly of drug supply. It is now in the hands of profit-conscious private-sector producers, and there is no longer any way to effectively control the quality of pharmaceutical production (Chen, 1989).

The health care statistics compiled for the entire country are fairly reassuring. The average number of doctors per 1,000 inhabitants is rising steadily, having moved from 1.16 in 1982 to 1.67 in 2000. But the rural fringe of the population has been largely bypassed by these advances: the average number of doctors measured against the total population is 2.7 times smaller than in urban areas. The countryside gained 106,000 doctors between 1982 and 1990, but only 23,000 between 1990 and 2000. The total increase was 19% between 1982 and 2000 in rural areas, versus a doubling in urban areas; 187,000 hospital beds have been eliminated in rural areas since 1982, while their number was multiplied by 2.3 in urban areas: the ratio per capita in the countryside is at one-third the level in urban localities (Table 112–3).

TABLE 112–3 Medical Infrastructure in Urban Areas (Towns and Cities) and Rural Areas (Districts), 1952–2000

Type of settlement area	1952	1970	1982	1990	2000

Source: NBS, 2002.

The overall health status of the population has been stagnant since the start of economic reform. A decline in the effectiveness of preventive and remedial care thus seems to have offset the improvements due to the rise in general living standards. Having underestimated the consequences of its laissez-faire policy, China is struggling to cope with the negative effects of economic reform on the health care sector. The health gap between social categories is widening. The ratio of the infant mortality rate in rural areas to that of urban areas climbed from 1.67 in 1981 to 2.21 in 1989 and 3.17 in 1998; the ratio for life expectancy at birth fell from 0.94 in 1981 to 0.92 in 1998 (Attané, 2002b, p. 108–109, 372). The health of rural households, especially in the low-income bracket, is therefore feeling the impact of trends in the health care sector: a decline in prevention and quality of care, collapse of the social security

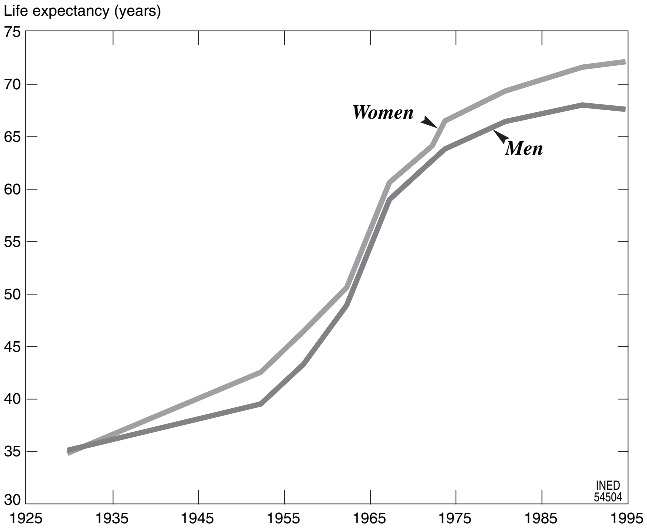

FIGURE 112–3 Chinese life expectancy since the 1950s. (Source: Peng and Cambois, 2002.)

system, and escalating medical costs. A growing share of the population now lacks any form of social protection. By 1983, only 40% to 45% of villages were still covered by the collective medical system. Between 1993 and 1998, the proportion of uninsured urban and rural residents rose from 46% to 58% and from 87% to 90% respectively. The poorly managed collective medical systems have lost credibility. Many people preferred not to subscribe when membership became optional in the 1980s, as the benefits offered usually proved inadequate. Nearly everywhere, the insurance covers only minor expenses, and families must bear the largest share of catastrophic medical expenses.

The government, increasingly aware of the problems created by the transfer of Welfare-State functions to the private sector, has recently conducted a major review of its health policies. This has resulted in embryonic reforms that, for the moment, consist merely of local initiatives tested in pilot projects.

IV. CONTROLLING FERTILITY

On taking power, the Communists promptly set up an authoritarian system designed to serve the regime's interests by regulating individuals and controlling their mobility. At the time, however, the Communists had no intention whatever of regulating population growth. Far from viewing it as problematic, socialist ideologues saw a large population as a force for economic prosperity: unemployment—incompatible with socialism—was not to be feared; collectivism would make food, health, and education available to all. Moreover, even if the Communists had considered such an intervention, it would have lacked a scientific basis. Absent reliable sources, very little was known about the demographics of the world's most populous country. In 1949, China was believed to have fewer than 500 million inhabitants—well below its maximum carrying capacity, arbitrarily estimated at 800 million. The early years of the regime were therefore marked by openly pronatalist rhetoric. Regulating fertility was "reactionary" and "capitalist," and the most precious capital of revolutionary China was its vast population.

The first republican census (1953) revealed that the population was 590 million, or 100 million more than expected. This sparked fears that excessively rapid population growth would compromise economic development. Only then did young socialist China engage in a Malthusian debate. Temporarily convinced by birth-control advocates, Mao Tse-tung declared in 1956: "Except for areas inhabited by national minorities, it is necessary to publicize and popularize fertility regulation and promote birth control in all densely populated regions" (Zou, 1986, p. 4). A few months later, the first birth-control campaign was launched. The contradiction between population growth and economic development was abruptly denounced. China started producing contraceptives and liberalized sterilization and abortion.

Owing to the lack of efficient methods, the shortage of skilled personnel, and the traditional Chinese reluctance to discuss sexual matters, family-planning propaganda remained confined to urban areas. This initial attempt had no visible effect on fertility. The campaign against right-wingers unleashed in 1957 put intellectuals—and birth-control militants along with them—on trial. Demography, like the other social sciences and the humanities, became a taboo science again. Population growth ceased to be regarded as a problem per se; it was now a phenomenon that should self-regulate. Industrial development was restored as a priority. With the Great Leap Forward, launched in 1958, the authorities feared that the labor supply would fall short of what was needed to build socialism. The link between population and production triggered a violent attack on family-planning advocates. All reference to population control was viewed as a reactionary opinion. Efforts to regulate fertility suddenly stopped, and contraceptive production was halted.

A few years later, however, birth control was back on the agenda. In the Black Years (1959–1961) that followed the Great Leap Forward, a terrible famine caused an estimated 30 million deaths, exacerbating the imbalance between food supply and population. The birthrate plunged. In 1960—the darkest year—

deaths exceeded births, causing a net population decline of 3 million people. Then came the recovery. The millions of children whose conception had been postponed because of famine, political instability, and the economic crisis swelled the ranks of already large cohorts. China registered an exceptional baby boom in the 1960s, with 25 to 30 million children born every year. The government discreetly drew the lessons from the Great Leap Forward. It made agriculture a priority again, and the problems of population growth were no longer ignored.

In 1962, a second campaign was launched. To reduce the number of births, the authorities opted for "soft" methods: delayed marriage and wider distribution of contraceptives. The number of children was limited to two or three, with a mandatory spacing of 3 to 5 years. The propaganda machine swung into action. Young people were warned of the negative effects of overly precocious sexual activity on their physical and intellectual health. Early love and marriage were stigmatized for undermining revolutionary enthusiasm and so jeopardizing the construction of socialism. Abortion was still liberalized in 1962: it could now be performed at the sole request of the pregnant mother and it was free if she was married. The intra-uterine device (IUD or loop) was introduced and vasectomy strongly encouraged. This second attempt at birth control, better organized and more pragmatic, was relatively successful in some big cities. But before it had a chance to spread to rural areas, it was swept away by the fervor and turmoil of the Cultural Revolution in summer 1966.

In the first two decades of socialism, official positions therefore oscillated between ideological dogmatism and economic realism, each outweighing the other in turn. Not until the end of the Cultural Revolution did a consistent discourse finally emerge. Malthusian pragmatism prevailed—lastingly.

At the start of the 1970s, the demographic transition was still modest. Mortality was declining. Life expectancy had gained 20 years since the 1949 Revolution, from 41 years in 1950–1955 to 60 years in 1965–1970 (Huang and Liu, 1995, p. 4) (Figure 112–3). But the birthrate kept rising, to all-time highs. With fewer deaths and more births, population growth peaked at more than 2% per year, hitting 2.8% in 1968. Twenty million people were being added each year. After having been forgotten for some years, birth control became a national priority again. In 1971, the Council of State's Directive 51 marked the official launch of the third birth-control campaign, which would be pursued relentlessly in the following decades. Three directives were issued in 1973, summarized by the slogan "late, spaced, few" ("*wan*, *xi*, *shao*"), that is, marry late, space births, and have fewer children (Attané, 2002). Annual birth quotas were imposed. However, the infinite diversity of settlement patterns, cultures, contexts, constraints, modes of production, and other factors did not escape the promoters of this third campaign. The population was officially classified into three groups: urban, rural, and ethnic minorities. From the outset, urbanites were subjected to the strictest rules: no marriage before 25 for women, before 28 for men, and no more than two children. By comparison, peasants were privileged: they were allowed three children and their minimum legal age at marriage was set at 23 for women, 25 for men. Both urban and rural dwellers, however, were required to space births by at least 3 to 4 years. No prescribed conduct was defined for ethnic minorities. In any event, as small groups mostly confined to low-density peripheral areas, they did not have a major role to play in fulfilling the birth-control objective. (For more information on the implementation of birth control among ethnic minorities, see Attané and Courbage, 2000; Courbage, 2002.)

In less than 10 years, fertility was halved—from an average 5.7 children per woman in 1970 to 2.8 in 1979 (Table 112–5 and Figure 112–4). This was the steepest decline ever recorded in the world in so short a time span. In urban areas, women were already having fewer children than needed for cohort replacement: the number had fallen to 1.4, compared with the 2.1 required to ensure that two children replace their two parents, allowing for mortality. The results were so good that observers later concluded—correctly, in

fact—that the Chinese population, both rural and urban, was simply awaiting a modest incentive from the authorities (as it turned out, better access to modern contraception) to have fewer children. Infant mortality had fallen sharply, from 175% in 1953 to 76% in 1969 (Peng and Cambois, 2002, p. 99). Parents thus no longer needed to maintain as large a "store" of children to offset early deaths and provide for their old age.

China owed this extraordinary success also—indeed, mainly—to the tremendous efficiency of its collective institutions. Nobody could escape the strict control and extreme vigilance of people's communes and neighborhood committees. Their arsenal included intimidation visits to private homes, public denunciations, collective pressure, and deprivation of ration coupons. Women's menstruation calendars were posted at factory gates; any woman suspected of pregnancy was hounded. The work unit conditioned every aspect of private life—not only work, of course, but also health, children's education, housing, food supply, and so on. The means of coercion were formidable. Whoever tried to evade the family-planning injunctions took huge risks. This also explains why birth-control measures were obeyed so unanimously at the time.

At his death in 1976, Mao Tse-tung left China with an ailing economy, in the wake of a Cultural Revolution fraught with heavy economic and social consequences. In the demographic sphere, by contrast, the birth-control program had already achieved remarkable results and dispelled the threat of a population boom that the country could not have supported. But this was still not enough. Signs pointed to a resurgence of the birthrate that threatened to jeopardize these fragile gains. Birth control had to be tightened even further. The reform and opening policy (*gaige kaifang zhengce*), inaugurated in 1978 by Mao Tse-tung's successor Deng Xiaoping, was therefore assigned a second objective: to curb population growth in order to finally ensure economic take-off. The then-Premier, Hua Guofeng, declared in 1979: "We must control population growth effectively and plan births. This is a prerequisite for the development of the national economy, and a problem that we need to solve so that we can achieve the Four Modernizations" (Chen, 1979). To meet this goal, the new policy—officially announced in January 1979—imposed the draconian rule of the single child. Moreover, the rule applied to almost all of China: 95% of urban dwellers and 90% of rural dwellers were supposed to comply. To promote the measure, the authorities established a reward system. Couples had to pledge to have only one child by signing the one-child certificate (*du sheng zinü zheng*). In exchange, they would receive various compensations, which varied considerably from one locality to another: monthly bonuses of a few yuan, free medical care and education for the child, easier access to housing, allocation of an additional small plot for peasant families, retirement bonus for employees of State-owned businesses, and so on. These benefits were not negligible, at least in theory (in some of the poorer regions, such commitments were hard to honor in practice). Some certificate signers merely received a thermos bottle or a blanket. Couples who resisted the government injunctions—particularly those who gave birth to a second child despite having signed the certificate—faced a variety of penalties, such as the obligation to reimburse the bonuses received, income deductions, fines, partial confiscation of the family plot, and dismissal for recidivist employees of State-owned businesses. (For more details on the implementation of the one-child policy, see Croll *et al*., 1985; Banister, 1987; Bianco, 1989; Aird, 1990.)

A quota system was introduced in 1973. Defined at the national level, the quotas were quite simply permissions to have children. They were distributed among the regions, down to the smallest administrative units: the village or, in towns and cities, the neighborhood. The cadres at these lowest levels were in charge of allocating the quotas among couples who wanted to have a child. As a rule, priority was assigned to young married couples, eager to make their unions fertile. Once all the quotas had been handed out, attempts were made to convince the other couples to give up their plans to have children, at least temporarily. If the birth nevertheless occurred, it was counted as an "out-of-quota" birth (*jihua wai shengyu*). In the late 1980s, 40% to 45% of rural births, or 7 to 8 million a year, were unauthorized. The cohorts of women born in the early 1960s (1959–1963) had reached childbearing age when the one-child policy came into effect. After only10 years of fertile life, they had already reached or exceeded the maximum allowed number of children in three-quarters of all provinces (Table 112–6) (Attané, 2002a, p. 103–113).

The one-child requirement was in total conflict with the interests of families, particularly in rural areas. It sparked stiff grassroots resistance (Attané, 2000b). As a result, the government was very soon forced to relax the conditions it had imposed on rural couples wanting a second child. The decision was officially announced in April 1984 in the Central Committee's Document no. 7 (Blayo, 1997, p. 184). While the stated goal was to allow a greater proportion of couples to have a second child, the main aim was to "open a small breach to plug a bigger one" (*kai xiao kou du da kou*), that is, to legitimate a few exceptions to the one-child rule in order to avoid the largest number of them. Since then, China's birth-control policy has been a two-speed process.

Limiting births became a constitutional duty in 1982: "The State encourages family planning to ensure harmony between demographic growth and economic and social development plans" (art. 25); "Husband and wife alike have the duty to practice family planning" (excerpt from art. 49). (For more information on the causes and manifestations of this resistance, see Attané, 2000b.) This obligation is also stipulated in the 1980 Marriage Act: "Family planning is practiced" (excerpt from the 1982 Constitution of the People's Republic of China [*1982 zhonghua renmin gongheguo xianfa*]) (excerpt from art. 2). However, until very recently (September 2002), no legislation had been passed to set out the principles of birth-control policy at the national level. (The provisions of the act are described in the Appendix.) Because of China's immensity and diversity, its leaders have generally preferred the adoption

of provincial regulations that take local conditions into account. Accordingly, each province enacted its own birth-control regulations in the 1980s. They are unanimous as regards the minimum legal age at marriage: in compliance with the 1980 Marriage Act, it is set at 20 years for women and 22 years for men in all provinces. All the regulations also stipulate that anyone "who is of reproductive age and is not preparing to conceive a child legally must use a reliable contraceptive method." Some even prescribe the method suited to each situation: "a couple with one child must use contraceptive methods with long-term efficiency [*chang xiao*]" such as the IUD (loop), and "a couple with two or more children must undergo sterilization." In the event of unplanned pregnancy, most regulations require taking remedial measures (*bujiu cuoshi*), namely, immediate abortion. (For the texts of these regulations, see *Zhongguo renkou ziliao shouce* [Chinese population data], 1985.) Other regulations, as in Sichuan, also stipulate a contribution to be paid monthly starting in the early months of an unplanned pregnancy. Most provide for economic penalties—in the form of fines (50–200 yuan in the mid-1980s) or withholdings on wages (10%–30%)—for women falling pregnant without permission. These sums are to be fully refunded, however, if the couple undergoes an abortion. Fines for out-of-plan births now run into the thousands or even tens of thousands of yuan—sometimes more than the household's annual income (1 yuan is currently worth about 0.11 euros).

Since 1984, the one-child rule is thus no longer systematically enforced in rural areas. There, families—in particular among certain ethnic minorities—are generally allowed to have a second and even a third child. The eligibility criteria for a second child, however, can vary from one province to another and sometimes even from one district or village to another. Residents of the southern province of Guangdong, for example, are not necessarily subject to the same measures as their compatriots in the north or west, in Shanxi or Sichuan. Each administrative division has enacted its own child-quota regulations and defined rewards and penalties—all, in theory, respectful of the local context. China is administratively divided into 22 provinces, 5 autonomous regions, 4 municipalities, and 2 Special Autonomous Regions (not included here): Hong Kong and Macao.

The official indicator produced by the central government in the mid-1980s spells out birth-control targets at the provincial level (Table 112–4). This indicator, called "completed fertility officially stipulated in the framework of the birth-control policy" (*zhengce yaoqiu zhongshen zong shengyu lü* [ZSSYL]) (Yin, 1995), theoretically defines the ceiling for the cohort fertility quantum. However, it has not been used as such, but has been translated into a period indicator setting the maximum mean number of children per woman at 1.62. Its values range from a low of 1.28 in the heavily urbanized municipality of Shanghai to a high of 2.40 in the autonomous Uigur region of Xinjiang, where urbanization is weak and most inhabitants belong to national minorities.

Today, more than 20 years after the adoption of the one-child policy, family planning still relies on the same weapons: persuasion, coercion, and fines. But reforms have led families to gradually emancipate themselves from collective institutions. Birth control is slipping out of the hands of the regime's cadres, and coercive measures are failing. To remain effective, regulations need to be adjusted. By promoting local initiatives, decentralization has made it possible to institute new types of penalties more directly targeted at family interests. A district in Guangdong, for example, developed a family monitoring system in 1989. Every couple that meets the requirements of the family-planning authorities receives a birth-control certificate (*jihua shengyu zheng*) that must be produced when applying for certain administrative authorizations. Rule-breakers may be denied a driver's license for a motorcycle or the mandatory permit for starting a retail business. If a woman conceives without permission, cadres have a right to cut off her water or electricity supply. In the same district, the fine for an out-of-plan birth came to 17,000 yuan (1,800 euros) in the mid-1990s. Couples who fail to comply with the required birth spacing pay a fine of 5,000 to 8,000 yuan. The mere presumption of prenuptial conception (any child born to a couple married for less than nine months) also entails a 5,000-yuan fine. A woman who has not made one of the four annual visits to check her IUD is liable to a 1,000-yuan fine; if she has not been sterilized within four days of the birth of her second child, she must pay 10 yuan per day of delay. (On this topic, see Guangdong Licheng qiangya fünu [Women forcefully taken away in Licheng, Guangdong], *Ouzhou ribao,* March 26, 2002.)

The Population and Birth Control Act passed in September 2002 (see Appendix) reasserts the goal of strict limits on the number of children. However, recent developments suggest changes in the means used to reach the objective. The program's emphasis has been shifting toward voluntarism for two reasons: (1) because it is increasingly difficult for the authorities to interfere in couples' private lives and (2) because the threat of unsustainable population growth has now been eliminated. The new focus is on health: reproductive health, education, and information are the main priorities.

V. TOWARD REPRODUCTIVE HEALTH POLICIES

The International Conference on Population and Development (Cairo, 1994) and the World Conference on Women (Beijing, 1995) were milestones in China's approach to its demographic issues. Its natural growth is now curbed, at a rate of less than 1% a year since 1998 and only 0.7% in 2001. Accordingly, China has decided to redefine the objectives of its family-planning program, hitherto exclusively centered on the changes in demographic indicators. Without abandoning its strictly demographic concerns, the program is gradually shifting toward the broader concept of reproductive health, focused on individual needs and the quality of services.

With the participation of the Chinese Family Planning Association and its local branches, pilot experiments are being tested in several regions. There, birth quotas have been scrapped, births are no longer subject to prior approval, and couples can decide by themselves when they want to have children. Contraception is no longer mandatory: couples are now free to choose the contraceptive method they prefer. Financial punishments for couples violating birth-control regulations have been abolished. The emphasis now is on information about reproductive health and child education. Demographic indicators such as the birthrate are no longer the sole criteria for assessing the program's performance. At present, these experiments have been extended to more than 800 districts (*xian*) and prefectures nationwide (see Gu *et al*., 1999, 2001).

For many years, the single objective was to curb population growth—at the expense of reproductive health. That is one of the reasons for the strong current prevalence of various infections of the reproductive system and sexually transmitted diseases. In many rural regions such as Yunnan, more than half the women suffer from such conditions. With financial support from the International Planned Parenthood Federation (IPPF), the local branches of the Chinese Family Planning Association offer help for diagnosing and treating these diseases. Other programs are designed to promote awareness of reproductive health and AIDS-related issues among adolescents. In 2002, more than 150 districts launched projects on teenage reproductive health, but these initiatives are still in their infancy.

As regards AIDS, China has started to launch information campaigns to warn about the risk of transmission. For example, in the Hunan city of Huaihua—a major center of emigration of young workers, particularly to Guangdong—the Chinese Family Planning Association has distributed information manuals for migrants and their families. A prevention campaign was launched in Henan, one of the provinces hardest hit by AIDS.

TABLE 112–7 Awareness of Sexually Transmitted Diseases and Access to Preventive Care, 2001

Women's level of awareness	Proportions of women (%)			
	All China	East	Center	West
Have heard about sexually transmitted diseases	63.6	69.8	65.2	53.4
Have heard about AIDS	72.7	78.4	75.1	62.1
Have been tested for infections of the reproductive system	42.8	50.1	40.3	35.6

Source: Gu Baochang, 2003, p. 6.

The wide interregional disparities in access to information and services reflect economic gaps and the unequal access to medical care. Here as well, the central and western regions lag the east, with a lower public awareness of sexually transmitted diseases and reproductive diseases, and less access to medical care (Table 112–7).

In every respect, the central regions and, even more so, the western regions are disadvantaged in terms of reproductive health. Access to contraception is much more restricted, and childbirth in hospital—the norm in the developed eastern provinces—is very infrequent: one in four births in Guizhou, one in five in Tibet (Table 112–8). While infant mortality rates in Beijing and Shanghai converge toward those of the most developed countries (approximately 5%), in Xinjiang more than 1 in 20 children die before their first anniversary. Maternal deaths have reached residual values in Beijing and Shanghai (fewer than 10 per 100,000 women), but are10 to 40 times as frequent in the western provinces: over 140 per 100,000 in Guizhou, Qinghai, and Xinjiang, and 466 in Tibet. By emphasizing reproductive health, the government hopes to eventually cancel these huge disparities.

VI. ASSESSMENT

In the past 50 years, China has experienced drastic upheavals—not only political and economic, but also social and demographic. In many ways, today's China bears no comparison to Mao's, which, in turn, saw itself as the antithesis of imperial China. These upheavals, driven by all manner of authoritarian policies, have been anything but spontaneous. In regard to

TABLE 112–8 Reproductive Health Indicators in Selected Eastern and Western Provinces, 2000

Province	Contraceptive use (%)	Childbirth in hospital (%)	Infant mortality rate (per 1,000)	Maternal mortality rate (per 100,000)
Eastern provinces				
Beijing	87.8	99.6	5.4	9.7
Tianjin	91.1	99.0	9.4	18.6
Shanghai	91.0	100.0	5.1	9.6
Jiangsu	91.1	98.9	11.2	28.5
Zhejiang	91.1	98.7	15.6	19.6
Western provinces				
Guizhou	90.1	25.8	38.8	141.7
Tibet	71.1	20.1	35.3	466.3
Gansu	87.5	55.3	28.9	108.8
Qinghai	86.9	38.0	41.0	142.0
Xinjiang	82.7	56.6	55.5	161.4

migration, health, and the demographic transition, the present situation is largely the result of government initiatives. In the past half-century, China has thus resorted extensively to population policies, which have left deep marks on the current demographic landscape.

Assessing these policies is difficult because of their all too frequent lack of clearly defined initial objectives. The goal of controlling individual mobility was unquestionably met—at least for as long as the measures were strictly enforced. The urbanization process was largely curtailed between 1950 and 1978, sparing China the negative effects of the rural exodus that was already afflicting many developing countries at the time. But it is hard to say as much for the recent period. To satisfy the labor demand generated by economic reforms, but also to provide new jobs for the excess workers freed up by agrarian decollectivization and the restructuring of State-owned companies, China is now turning a blind eye to massive internal migrations. As many as 130 million Chinese (1 in 10) are believed to be working and living—at least temporarily—in a locality other than their registered place of residence. Yet, in the formal regulations, almost nothing has changed. Officially, every Chinese is required to reside in his or her place of birth, despite the fact that this rigidity is in total contradiction with the interests of the new market economy.

The reason for this caution is obvious: the government is reluctant to loosen its policy because it fears having to cope with an even more massive influx of rural dwellers into towns and cities—with all the attendant consequences. Rather than legislate on the issue, it is content to tolerate these internal migrations, which, in any event, serve its economic objectives; in so doing, the authorities reserve the right to tighten their control if and when needed.

The same can be said about birth control. Instead of openly relaxing its policy, China has opted for a measure of laissez-faire—even though a liberalization would, in the longer run, slow the aging process and attenuate the sex imbalance at birth due to the strong preference for sons. For now, the regime prefers to tolerate some resistance and is merely setting up pilot projects without changing its official rhetoric. The Population and Birth Control Act (2002) remains unambiguous, its wording identical to that of earlier regulations: "Couples are encouraged to have only one child" (see Appendix). The policy has ultimately met the official objectives. In 1980, Hua Guofeng announced that the population should not exceed 1.2 billion by the end of the century. The official figure from the 2000 census is a not too distant 1.265 billion. The target has since been revised upward: the latest official declarations state that the population should be kept at under 1.4 billion between now and 2010, which will manifestly be the case. (Population goals: less than 1.4 billion by 2010, *China Daily*, November 6, 2000). The goal of strict controlled population growth may now be regarded as having been reached.

But can we speak of clear-cut success when we see the extent to which individual freedoms have been violated in order to obtain it? (see Aird, 1990).

Or when we see the extent to which the reduction in fertility has been achieved at the expense of girls, whose percentage of the total population is becoming ever more abnormally small in the youngest age groups? The sex ratio of births was normal on the eve of the implementation of the one-child policy, at 105.8 boys per 100 girls in 1979. By the 2000 census, it had risen to 116.9. Or when we observe that nothing has been done, concurrently, to try to improve the health and status of women? (see Attané, 2002a).

We shall not take the risk, therefore, of describing Chinese population policies as failures or successes. What we can say is that, until now, China has never spared any effort to attain its goals. It sought to curb population growth: it succeeded. It set out to develop its economy: it is doing so. But at what price? The world's most populous country is now also one of the most inegalitarian. But it is also a country in which, despite a lingering totalitarianism, authoritarian measures are being accepted with ever-greater difficulty when they seek to regulate the family and personal intimacy. China is opening up to the world, and the world is getting involved in China. Therein lies the hope that, in future, Chinese population policies will be less coercive and more respectful of people.

APPENDIX

Description of Population and Birth Control Act of the People's Republic of China (enacted September 1, 2002)

The first allusion to the need to promulgate such a law dates from 1978, a few months before the implementation of the one-child policy. But the diversity of local conditions and the difficulty of legislating at the national level on so sensitive an issue delayed its drafting and adoption for more than two decades. The Act was eventually completed in December 2001, consolidating the provincial regulations that had formed the basis for Chinese birth-control policy since the 1980s.

The Act chiefly provides a legal framework, and no longer a merely regulatory framework, for family-planning activities. But it does not introduce any major change in the goals and implementation of birth-control policy.

Birth control remains a "fundamental national policy" (excerpt from art. 2).

Decentralization is still a guiding principle: "People's local governments supervise family-planning work in their administrative jurisdictions" (excerpt from art. 5).

"People's local governments at the district level and above, based on the population development plan, shall prepare a population and birth-control plan and shall be in charge of applying it at the local level. The departments of family-planning administration in the People's local governments at the district level and above shall be responsible for the field implementation of the daily family-planning activities set out in the population and birth-control plan" (excerpt from art. 10).

The Act's injunctions concerning the proper behavior for limiting births are virtually unchanged from those of the provincial regulations.

> Couples must practice late marriage and procreation [*wanhun*, *wanyu*]. They are encouraged to have only one child. Those who meet the requirements spelled out in legal and regulatory provisions may have a second child. [. . .] Ethnic minorities are also required to practice birth control, in keeping with the specific measures in effect in the provinces, autonomous regions, and municipalities [to which they belong]. (excerpt from art. 18)

"Birth control rests on the use of contraception. [. . .] The State must create the conditions that will enable citizens to choose and use safe, effective, and suitable means of contraception in order to control births" (excerpt from art. 19).

"Couples that already have a child are encouraged to use a contraceptive method with long-term effectiveness [*changxiao*, i.e., IUD or sterilization]" (excerpt from art. 34).

"Couples of reproductive age shall use family-planning methods to prevent pregnancies and control births. Couples shall prevent and reduce the number of unwanted pregnancies" (excerpt from art. 20).

"Couples of reproductive age shall have free access to contraceptive methods and family-planning technical services. The State shall reward couples practicing birth control, in accordance with existing regulations" (excerpt from art. 21).

Couples volunteering to have only one child shall be issued an "honor certificate for one-child parents" (excerpt from art. 27).

The subsequent articles contain a set of provisions already included in other legislation, such as the Protection of Minors Act (1991), the Women's Rights and Interests Protection Act (1992), and the Mothers' and Children's Health Act (1994).

"It is strictly forbidden to use ultrasound scans or any other technique to detect the sex of the fetus, except for medical purposes. It is strictly forbidden to terminate a pregnancy [for the sole purpose of selecting the child's sex], except for medical reasons" (art. 35).

The following crimes shall be punishable in accordance with law:

1. Illegal practice of surgical family-planning procedures on a third party;

2. Performance of ultrasound scans or use of any other technique on a third party to detect the sex of the fetus, except for medical purposes, and the voluntary termination of a pregnancy for the purpose of selecting the child's sex;
3. "Performance of false family-planning procedures, issuance of false medical certificates or false family-planning certificates" (excerpt from art. 36).

A State civil servant who commits one of the acts listed below in the course of his or her family-planning activities [. . .] shall be prosecuted, in accordance with law:
[. . .]
1. requesting or accepting a bribe [guilty of corruption]
2. falsifying birth statistics, under-reporting, or refusing to register a birth. (excerpt from art. 39)

India's Population Policy in the Face of Demographic Momentum

S. IRUDAYA RAJAN AND JACQUES VÉRON

Center for Development Studies (CDS), Kerala, India

Institut national d'études démographiques (INED), Paris, France

In 1951, India's population numbered 361 million. In the same year, not long after gaining independence in 1947, the country launched its First Five-Year Plan, one section of which dealt with population policy implementation. Already the Indian government was stressing the importance of the "population problem" and the difficulty of boosting the country's development in a context of "rapid population growth" (GOI/PC, 1951). The fact that this population growth accelerated during the 30 years preceding the plan's adoption only heightened awareness of the demographic problem.

Half a century later, over one billion people are living in India. Does this mean that India's population policy was a failure? Admittedly, the measures adopted initially did not have the expected results; population policy changed course (sometimes radically); and the country's extreme economic, social and demographic heterogeneity, made it difficult to apply a uniform policy. However, we should not conclude that family planning measures were completely ineffective, as the tripling of India's population might suggest. Those responsible for family planning had (and still have) to contend with demographic inertia in a country that has acquired considerable growth potential in its population age structure.

When redefining national population policy in 2000, India restated its demographic objectives: a total fertility rate of 2.1 children per woman in 2010 and stabilization of India's population by 2045. In reality, however, the Indian government has been pursuing the goal of zero population growth for over 50 years. Although fertility is indeed falling throughout India, and is only just above, or even below, replacement level in the south, the most populous states are still those where family size remains the highest.

Population policy is not only concerned with measures or programs intending to reduce fertility but it also may deal with the population's health or spatial distribution, or with living conditions among the elderly. Moreover, any development policy has a bearing on the type of population policy that can be implemented. In India, although the government's main thrust has been toward fertility control, it has also introduced other types of policy, such as those concerning health, in 1983 and 2002. Incidentally, although several of India's plans have mentioned the excessive population growth in its large cities, India has not yet adopted a policy on migration.

I. INDIAN POPULATION POLICY: STAKES AND DIRECTIONS

1. Indian Population Dynamics before Independence and the Beginning of Demographic Malthusianism

India's family planning history began in 1916, with the publication of a pamphlet by Shri Pyare Krishen Wattal, titled *The Population Problem in India*, in which its author campaigned for family planning (Sinha, 1979). The first family planning clinic opened in 1925. V. C. Sinha explained that the Neo-Malthusian League was formed in Madras several years later. Margaret Sanger also encouraged family planning during her visit to India in 1935–1936.

As early as 1940, before independence, Jawaharlal Nehru was already conscious of the need for a fertility reduction policy. President of the Indian National Congress at the time, he declared:

> In the interests of social economy, family happiness, national planning, family planning and limitation of children are essential and the state should adopt a policy to encourage these. It is desirable to lay stress on self control as well to spread knowledge of cheap and safe methods of birth control. (qtd. in Chandrasekhar, 1976, p. 38)

It is hardly surprising, therefore, that Nehru ensured that a national population policy was adopted as soon as he became Prime Minister of India. Meeting to draft the policy's outline, the Indian Planning Commission over which he presided restated the importance of a family planning program: without a reduction in the population growth rate, it asserted, increasing efforts would be needed just to maintain consumption at its existing level.

Fertility was around 45 per 1,000 (Table 113–1) at the time Nehru and the Planning Commission were stressing the importance of getting it under control. With the crude death rate still just above 30 per 1,000, India's population growth rate was only 1.4% during the years 1931–1941, and even slightly lower in the following decade, apparently as a result of even higher mortality. Since the early 20th century, however, overall mortality tended to decrease: between 1901–1911 and 1941–1951, life expectancy at birth rose by 10 years for men, and nearly 9 years for women. Nonetheless, at 32.5 years for men and 31.7 years for women, the average expectation of life in India was still short (Table 113–2). During the period preceding independence, fertility hardly changed: the total fertility rate, which oscillated around six children per woman in the period 1881–1891, remained at this level until the 1960s (Véron, 1997; Naïr and Véron, 2002).

2. The First Five-Year Plan: Recognizing a Complex Population Problem and Adopting a Family Planning Program

The First Five-Year Plan (1951–1955), presented to India's parliament in December 1952, specifies the nature of India's demographic problem (GOI/PC, 1951). With mortality falling during the previous decades, mainly (but not solely) because of advances in hygiene and medicine, and without any reduction in fertility, population growth sped up. In the Planning Commission's view, whereas science and medicine made it possible to expect growing production capacity, "it is clear that, under present conditions, an increase in manpower 'resources' does not strengthen the economy but, in fact, weakens it" (GOI/PC, 1951, p. 16). This Commission recognized the complexity of the population problem as well as its diverse economic and social components. Reducing the birthrate appeared indispensable, if only to meet basic needs (food and clothing in particular) at a level comparable with pre-war conditions. The planning document contains a reminder that growing pressure on inevitably limited natural resources could only compromise economic and social progress. It emphasizes the importance of reducing the birthrate, although without establishing a quantitative goal.

India's First Five-Year Plan clearly states the need for population policies. The section dealing with methods for curbing demographic growth, however, is only titled "Family Planning." This was perceived as a priority for slowing population growth, but also as only the first step, as it would later be important to be able to improve children's health in particular. If it initially focused on educating public opinion and on the need to limit numbers, this was because "a programme of limitation must be a social movement" (GOI/PC, 1951, p. 206), mobilizing both families and public

TABLE 113–1 Crude Birth and Death Rates, India, 1901–1951

Decade	Crude birthrate (per 1000)	Crude death rate (per 1000)	Natural growth rate (%)
1901–1911	49.2	42.6	0.66
1911–1921	48.1	48.6	–0.05
1921–1931	46.4	36.3	1.01
1931–1941	45.2	31.2	1.40
1941–1951	39.9	27.4	1.25

TABLE 113–2 Life Expectancy at Birth, by Sex, India, 1901–1951

Decade	Men	Women	Difference
1901–1910	22.6	23.3	+0.7
1911–1920	19.4	20.9	+1.5
1921–1930	26.9	26.6	–0.3
1931–1940	32.1	31.4	–0.7
1941–1950	32.5	31.7	–0.5

Source: Davis, 1951.

opinion. The Planning Commission believed the State could play only a limited role in this sphere.

Thus, developing cheap, reliable, and effective contraceptive methods suitable for all population categories was a key objective. It was also necessary to explore other ways of reducing family size besides contraceptives—by increasing girls' age at marriage in particular. From 1951 onward, making sterilization more accessible was also added to the agenda.

3. Educating the Public: A New Priority from the 1960s Onward

The Second Five-Year Plan (1956–1961) was an extension of the first (GOI/PC, 1956). More dynamic action was taken, notably through making contraceptives more widely available, but the strategy remained the same: it gave priority to family planning clinics responsible for providing services and sensitizing the population to birth control ("clinic oriented approach," Srinivasan, 1995). The first family planning programs were based on the premise that a demand for contraception exists, and that providing contraceptives to satisfy the demand will actually reinforce it. It quickly became apparent, however, that the development of essentially hospital-based services was not enough; the adoption of the Third Five-Year Plan (1961–1966) marked a shift in family planning strategy (GOI/PC, 1960).

Educating the public became the priority. As spelled out in the Third Five-Year Plan, this was essential to create the social conditions for a broad-based family planning program. The plan also envisaged integrating family planning into the health services, while continuing its policy of making contraceptives available and encouraging sterilization. During the course of the Third Plan, it was decided to extend the education approach (GOI/PC, 1960) to encourage public support for the small family norm. The years 1966–1969, a period of transition, were not covered by a plan per se. The Fourth Five-Year Plan (1969–1974) was written in the spirit of the previous plan, attempting especially to intensify mass education and programs of incentives (GOI/PC, 1969). All contraceptive methods were promoted, although the intra-uterine device was expected to play a major role in controlling births because it had the advantage of being effective, reversible, and acceptable. In reality, few couples chose this method to limit the size of their family.

In addition, a law legalizing abortion (Medical Termination of Pregnancy Act) was passed in 1971 and revised in 1975. This law authorized abortion for medical reasons (the health of mother or child), or for social and economic ones (if the mother's economic and social environment threatened the health of the child to be born). It also allowed abortion in the case of contraceptive failure, but only among married mothers (Retherford and Roy, 2003).

After this, during the mid-1970s, Indian population policy passed through various episodes that tended to discredit it.

4. From Family Planning to Family Well-Being

As K. Srinivasan noted (1982), it became apparent how limited was the success of family planning programs from the start of the Fifth Five-Year Plan (1974–1979). In reality, Indian fertility had begun its decline (Figure 113–1) but, largely because of the relative success of female sterilization, mortality was falling even more rapidly (Figure 113–2), and population growth was accelerating (Table 113–3).

In June 1975, the then–Prime Minister, Indira Gandhi, declared a state of emergency. The following year, the government launched a National Population Policy through a statement to the press made by Dr. Karan Singh, then Minister of Health and Family Planning. In his communiqué of April 16, 1976, Dr. Singh declared that the population problem should rank among national priorities (Singh, 1976), and that it was no longer possible to wait for the effect that education, as well as economic and social developments, would have on fertility—all the less so because of the vicious circle linking population and economic development. "Our real enemy is poverty," Karan Singh also declared, "it is as a frontal assault of the citadels of poverty that the Five-Year Plan has included the Minimum Needs Programme" (Singh, 1976, p. 309–310). He considered necessary to resort to

TABLE 113–3 Population Growth in India, 1901–2001

Census year	Number of persons	Annual growth (absolute numbers)	Annual exponential growth rate (%)
1901	238,396,327	—	—
1911	252,093,390	13,697,063	0.56
1921	251,321,213	–772,177	–0.03
1931	278,977,238	27,656,025	1.04
1941	318,660,580	39,683,342	1.33
1951	361,088,090	42,427,510	1.25
1961	439,234,771	78,146,681	1.96
1971	548,159,652	108,924,881	2.20
1981	683,329,097	135,169,445	2.22
1991	843,387,888	163,058,791	2.14
2001	1,027,015,247	180,627,359	1.93

Source: 2001 census (Registrar General and Census Commissioner, 2001).

all sorts of methods to gain control over demographic growth.

Among the methods put forward to reduce population growth were a higher age at marriage, female literacy ("informal" education should be promoted; the effect of female literacy on fertility was assumed), and child nutrition (taking into account the association between mortality, ill health, and fertility). In reality, these were all direct and indirect methods for fertility control. The young were also encouraged to plan their family size. The population policy contained "multimedia motivational strategies," directed especially at the rural population. It also increased the financial rewards granted to couples limiting their family size to two or three children. The idea of compulsory sterilization was discussed, and the Indian government authorized the states in the Federation to pass a law making sterilization obligatory. However, when the State of Maharashtra proposed compulsory sterilization for certain categories of couples, through the 1976 Maharashtra Family Act, it did not obtain the Federal Government's authorization (Gwatkin, 1979). The fact that the population's alarming growth makes it impossible to stamp out poverty is one of the preambles to this law, which should guarantee that couples have no more than three children or four, if the first three are of the same sex (Chanrasekhar, 1976).

In this same year, 1976, the government's stated objective was to reduce the crude birthrate from 34 per 1,000 to 25 per 1,000 by 1984, a goal that was not in fact reached until 2002. Taking mortality decline into account, the population growth rate should have been 1.4% in 1984; the actual annual growth rate for the most recent intercensal period (1991–2001) was still close to 2%.

The fall of Indira Gandhi's government appears to mark a new era in population growth control, with wide condemnation of the abuses committed during the state of emergency, especially with respect to sterilization. The Family Planning Program thus became the Family Welfare Program. But the Janata government, the Congress Party's successor, was itself greatly concerned by the population problem. As Nortman (1978) noted, "like its predecessor the Desai government is alarmed by the possibility of an Indian population of one billion by the year 2000, a level implied by the current 2 percent per annum growth rate" (p. 277). As Gwatkin (1979) observed, with unobtrusive but crucial measures, it was striving "to keep the government's family planning machinery intact" in order to be able to use it once the mistrust toward the previous population policy had evaporated. Asok Mitra (1977) noted that the national population policy declaration of June 29, 1977 broadly replicated, in its substance, that of April 16, 1976.

In power once more, Indira Gandhi presented the family planning program's priorities in terms very different from those used during the Emergency era:

> The real answer [to curb population growth rate], of course, is development from both angles: first the development to provide what the people need, to open up areas, and secondly, because development itself curbs families, I mean

> people who reach a particular standard are more conscious of their duty to the child. That is, they want something more for their children than they had; and, therefore, they themselves think about smaller families. But ultimately, of course, size of the population has to be tackled at various levels not just through development, but through persuasion of people (Gandhi, 1981; p. 168)

Nehru's daughter thus stressed the fact that the birth of a child should be a question of choice for the two parents, and that persuasion is not coercion. During her Inaugural Address at the first national conference of the Indian Association of Parliamentarians on Population and Development, Indira Gandhi spelled out her vision of family planning: "Family planning must become a people's movement—of the people, by the people, for the people—only then can our hopes be realised" (Gandhi, 1981; p. 559). Beyond these public speeches on reducing family size, and despite all the effort invested, the Indian population continued to expand during the 1990s at an annual rate of around 2%. In 2000, a new population policy emerged.

5. A New Population Policy Approach

The policy approach taken in the year 2000 shares some features with independent India's first planning program, as it still aims to satisfy the demand for contraceptives and, as in the 1960s programs, it also stresses the need to "promote vigorously the small family norm." Some of the stated objectives in 2000 are strictly demographic in nature, while others are more closely related to the health or well-being of the population. The government announced targets of replacement level fertility by 2010, as well as infant mortality at less than 30 per 1,000 and maternal mortality under 100 per 100,000. It also aimed to immunize children against all illnesses that could be avoided through vaccination, and to raise age at marriage for girls—not before the age of 18 years, and preferably after 21. The 2000 population policy also specified that schooling should be free and compulsory for all children until 14 years of age.

Fertility in India has fallen substantially, particularly since the early 1980s. Very strong demographic inertia in India's population structure means, however, that the demographic growth rate has rarely fallen, and was still at 1.93% during the last intercensal period (1991–2001). Moreover, fertility decline has been very uneven across the different states, although it has taken place in such a way that makes it impossible to distinguish the impact of more or less dynamic family planning programs at the individual state level, from the effects of economic and social development.

II. FERTILITY, FAMILY PLANNING AND DEVELOPMENT IN INDIA: NATIONAL AND STATE LEVELS

1. National Population Policy: Frequently Revised Goals

In the early 1950s, the Indian government expressed its desire to see the birthrate fall "to the extent necessary to stabilize the population at a level consistent with the requirements of the national economy" (Srinivasan, 1995). The population growth rate was only 1.25% when the first family planning program was adopted (Table 113–3). Between 1951 and 1981, however, population growth accelerated (Figure 113–3), with a one-point increase in the growth rate (which reached 2.22% during the period 1971–1981). The pace slowed later, giving a natural growth rate of 1.69% in 2002, according to the Sample Registration System (see Table 113–7).

With population growth speeding up while family planning programs were active, and with growth rates reluctant to fall, must the conclusion be that India's population policy has been a failure?

India's fertility has dropped significantly during the last 25 years, but, because of its young population, the decline has had only a partial effect on lowering birthrates (P. Visaria, 1995). During the same period, birth and death rates decreased in parallel (Figure 113–2). With hindsight, it thus appears that, in its desire to stabilize the population as quickly as possible, the Indian government established overambitious or overoptimistic goals, as it had failed to take into account the constraints imposed by population dynamics (Table 113–4 and Figure 113–4). Each new Five-Year Plan provided the opportunity to evaluate the preceding one; the limited success of family planning programs was regularly emphasized. Thus, referring to the Seventh Plan, the Eighth Plan (GOI/PC, 1992) observed, "In spite of massive efforts in the form of budgetary support and infrastructure development, the performance of the family welfare program has not been commensurate with the inputs." The plan then specified that "containing population growth" was one of its six main objectives. The next plan repeated that "population stabilization is an essential prerequisite for sustainability of the development process" (GOI/PC, 1992).

Demographic inertia is therefore largely responsible for the difficulty in achieving the birthrate targets established regularly by the Planning Commission. The population age structure effect plays an even greater role in accelerating growth than would mortality if it declined faster than fertility. According to a

National population policy for the year 2000	Total fertility rate at replacement level in 2010		

Sources: Singh, 1976; Srinivasan, 1995; GOI/PC, 1997, 2002; GOI, 2000; Registrar General, 2002, 2004; Various *Sample Registration System Bulletins.*

recent estimate for the early 2000s, once the level of infant mortality and other socioeconomic factors are taken into account, 60% of the population growth rate stems from the importance of the population of reproductive age, 20% from a higher fertility than desired due to an unmet demand for contraception, and the other 20% from desired fertility levels (GOI/PC, 2002).

Aware of the force of demographic inertia, the Indian government distinguished three types of goals in its year 2000 Population Policy, according to the time horizons with which they were associated:

1. An immediate goal, involving the satisfaction of contraceptive needs, health infrastructure and medical personnel, and the provision of integrated reproductive and child health services;
2. A medium-term target of a total fertility rate of 2.1 children per woman by 2010;
3. A long-term goal of Indian population stabilization by 2045.

If fertility reaches replacement level by 2010, India's population will continue to grow during the following 35 years because of demographic inertia; the number of Indians will first overtake the number of Chinese, and then reach 1.5 billion in the middle of the 21st century.

2. Development and the Demographic Transition

Family planning programs are not the only type of change likely to have an effect on fertility in India. During the 50 or so years since independence, age at marriage has increased, rates of literacy have improved, and health policies have been implemented. It is impossible to separate the population policy effect from the development effect with any sort of precision, since the two are clearly not independent, as the regional analysis demonstrates.

Governments in India have long been preoccupied with raising the age at marriage. In 1951, the average age at marriage for women in Andhra Pradesh was 12.6 years; in Uttar Pradesh it was 13.8 years, and in India as a whole it was $15\frac{1}{2}$ years (Agarwala, 1967). Marriage frequently used to be celebrated before this age, as is shown by the fact that the 1955 Hindu Marriage Act set the minimum age for celebrating a religious ceremony at 18 years for boys and 15 years for girls. The 1976 National Population Policy emphasized the need to change India's marriage model, not only because of its effect on population growth, but also to assist the move toward "more responsible parenthood" and improve the health of women and children (Singh, 1976). In 1976, the Child Marriage Restraint Act raised the minimum age at marriage to 21 years for boys and 18 years for girls. Although both men's and women's average age at marriage rose over the course of the last decades, according to the National Family Health Survey (NFHS) in 1998–1999, the median age at marriage was hardly above 16 years (Table 113–5). As noted previously, the National Population Policy (2000) set an age at marriage for women of not less than 18 years, and preferably above 20 years, as one of its sociodemographic objectives for the year 2010.

Other changes are also likely to influence fertility trends; this is especially true for progress in education for girls, because it promotes higher status for women. The 2000 Population Policy reported on the need to develop education for the young. Although it is true that female literacy rates increased fivefold between 1951 and 2001, only just over half of Indian women were literate in 2001 (Table 113–6). Substantial regional differences remained, with a female literacy rate of 87% in Kerala compared with 34% in Bihar.

In all its Five-Year Plans, the Indian government emphasized the importance of reducing maternal, infant, and child mortality. At the start of the 1970s, the level of infant mortality was still at 130 per 1,000. It fell steadily afterward (Figure 113–5), halving the rate 30 years later (63 per 1,000 in 2002).

Adopted in 1983, the First National Health Policy aimed to develop a primary health care network well dispersed throughout India, while at the same time promoting health education; it called on health volunteers to play in intermediation role, and aimed at treating patients at a decentralized level as far as possible. A new health policy was implemented in 2002. It restated the infant mortality target of 30 per 1,000. It also aimed to halve mortality from tuberculosis and malaria by the year 2010, and check the spread of the AIDS epidemic by 2007. From the demographic point of view, this 2002 health policy was an extension of the 2000 population policy.

With strong demographic, economic, and social heterogeneity in India, a regional analysis provides a complementary view of the respective effects of development and population policy on fertility. Given India's great demographic diversity and heterogeneity, Leela and Pravin Visaria suggest a multifaceted approach to strengthen family planning and slow population growth (Visaria and Visaria, 1995).

3. Regional Variations in Fertility: What Role Did State-Level Population Policies Play?

In 2002, demographic growth rates still varied greatly from one state to another (Table 113–7). Growth was slowest in the south of the country, particularly in Kerala and Tamil Nadu, where annual rates were barely

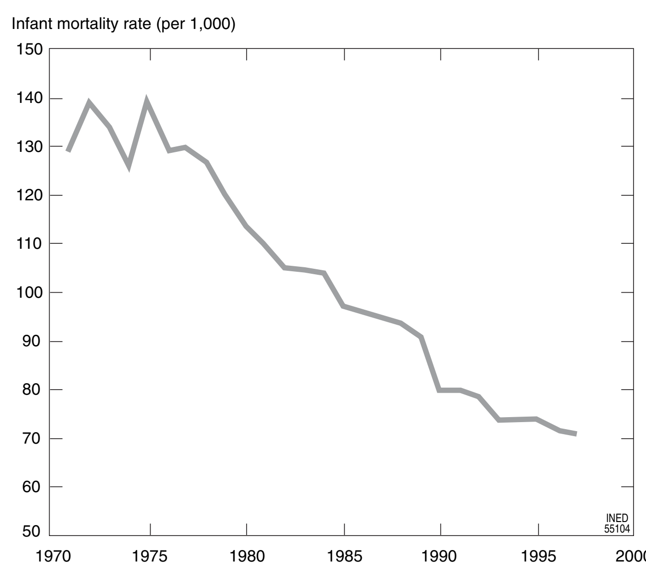

FIGURE 113–5 Infant mortality trends since 1970. (Annual Sample Registration System data.)

TABLE 113–7 Birth, Death, and Natural Growth Rates for India's Largest States, 2002

States	Birthrate (per 1000)	Death rate (per 1000)	Natural growth rate (%)
Andhra Pradesh	20.7	8.1	1.26
Assam	26.6	9.2	1.74
West Bengal	20.5	6.7	1.38
Bihar	30.9	7.9	2.30

over 1% (Rajan, 2005). Rapid population increase continued in the country's most populous states ("Bimaru states"), on the other hand, with growth rates exceeding 2% per year. One of them, Bihar, is still increasing by 2.3% annually. These states are going through the demographic transition, a process that is already complete in the states of southern India: birthrates in Bihar, Madhya Pradesh, Rajasthan, and Uttar Pradesh were still over 30 per 1,000 in 2002, and fertility well over 3 children per woman.

Kerala's demographic evolution is worth mentioning, as fertility and birthrates plummeted particularly quickly in this state: the crude birthrate fell from 44 per 1,000 in the 1950s to 17 per 1,000 in 2002, and the total fertility rate (TFR), at 5.6 children per woman in the 1950s, is now under 2 (Mari Bhat and Rajan, 1997). In his analysis of Kerala's rapid and extreme fertility decline, K. C. Zachariah (1997) explored the role played by official population policies. He suggests that various factors may have contributed to the fall in fertility: an increase in age at marriage and in the prevalence of contraception, sterilization, maternal and child health programs, rising female education levels, and the State's political involvement in social action. Zachariah estimates that 30% of fertility decline between 1968 and 1978 was due to the increase in marriage age. He also notes that contraceptive prevalence rates rose from 37% to more than 72% between 1981 and 1992, and that the universal vaccination program, launched in 1985 and reaching half of the children, reduced infant mortality. In his opinion, Kerala's high population density sharpened its awareness of the population problem. Finally, this state implemented reforms leading to greater equality; according to Zachariah, this also played a part in triggering the demographic transition, and in its timing. In this Indian demographer's opinion, however, such rapid fertility decline is explained above all by the strong interaction between the provision of family planning services and changes in the socioeconomic context. Improvements in child health through the Maternal and Child Health program also made an important contribution to this reduction in family size.

Fertility decline was also strong in Tamil Nadu state: today, the average number of children per woman is around replacement level. As in Kerala, a higher age at marriage contributed to the drop in fertility up to the 1980s. According to S. Krishnamoorthy *et al*. (2005), the importance of poverty, women's high status, the existence of a family well-being program, and a movement in favor of social reform and media action are among the other possible causes of this reduction in family size.

It is generally acknowledged that the family well-being program and the ideas spread by the media helped popularize the small family size norm. Couples also cite the reduction in infant mortality as a reason for their lower fertility. Although the state of Tamil Nadu has not experienced any real economic development, it appears that people feel that the cost of educating their children has increased. Parents, aspiring to a better life for their children, wish to send them to school more systematically: the expense of educating children has thus increased the cost of raising them. In the case of female births, the dowry also represents a burden for family. Finally, as in Kerala's case, the interaction between family planning programs and social change explains why fertility fell so much and so quickly. Conversely, in the Bimaru states, where social change has been slower and less substantial, family planning programs cannot experience the same degree of success. These states accumulate vast populations who are impoverished, uneducated and the like.

In Kerala and Tamil Nadu, as everywhere else in India, sterilization remains the main means of controlling fertility, known by all and preferred to other birth control methods.

III. FIFTY YEARS OF BIRTH CONTROL IN INDIA

1. Fertility Control Based on Sterilization

From the early 1950s, the Indian government has encouraged couples to use sterilization as a way of limiting births. At that time, the main emphasis was on male sterilization (vasectomy). Economic incentives were set aside for men undergoing sterilization, or for those who encouraged others to do so. Then, in the 1960s and 1970s, the attempt to encourage sterilization intensified (Véron *et al*., forthcoming). From 1966 onward, those responsible for family planning estimated the annual number of sterilizations needed to achieve demographic targets. The degree to which these objectives were attained varied: 119% in 1967–1968 and less than 42% in 1973–1974. Between the mid-1960s and mid-1970s, there was an upward, but irregular, trend in the number of sterilizations (Figure 113–6).

The 1970s was an important decade for sterilization. At the start of it, two mass sterilization camps, each lasting one month, were set up at Ernakulam in Kerala, and led to almost 20,000 sterilizations being carried out. The idea that an effective family planning program was possible was proved (Krishnakumar, 1972). Shortly afterward, the decision was taken to launch a massive vasectomy campaign at the level of the whole Gujarat State (Thakor and Patel, 1972). The initial goal was 150,000 vasectomies but, during the 8-week campaign, over 220,000 men were finally sterilized. On the other hand, although much energy was invested in encouraging them, the decision to be sterilized was to be a matter of choice, at least in principle. In 1975, however, Indira Gandhi proclaimed a state of emergency and, influenced by her son, Sanjay, who was extremely concerned by India's population problem, the Indian Prime Minister lent her support to authoritarian fertility reduction measures, which in the end were applied very little (Gwatkin, 1979). Nevertheless, while 4.3 million sterilizations was the target for the 1976–1977 financial year, the actual number reached 8.26 million—three-quarters of which were vasectomies—because of certain particularly zealous states. The question of making sterilization compulsory was even raised; during his presentation of the 1976 Population Policy, Karan Singh asserted that the population was ready to accept more coercive family planning measures. In the same year, through the Maharastra Family Act, the government of Maharashtra intended to impose sterilization on parents with at least three children, under certain conditions, but it did not receive the Indian government's authorization to implement this document (Chandrasekahar, 1976, p. 131–143).

The electoral defeat of Indira Gandhi's party in 1977 appears to mark the return to couples' free choice over birth control. The need to promote methods for spacing births was restated regularly. At under a million in 1977–1978, nevertheless, the number of sterilizations started to rise again, reaching an average of 4 million annually. Today, however, women are almost the only ones sterilized (Figure 113–7). From 1970 to the present day, the rate of contraceptive use has evolved remarkably, more than quadrupling. Although the gap between the curves for all contraceptive methods combined and for couples protected by sterilization has gradually widened, since the mid-1980s, the latter nonetheless remains the most common means of fertility control (Figure 113–8).

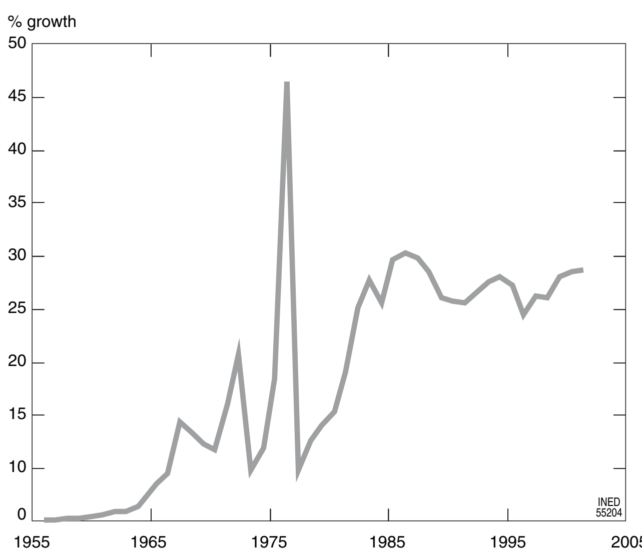

FIGURE 113–6 Annual evolution of number of sterilizations. (Source: Véron *et al*., forthcoming.)

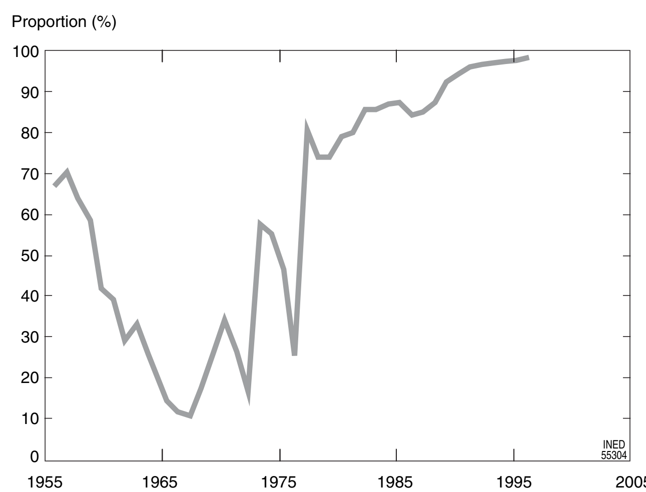

FIGURE 113–7 Proportion of female sterilizations as a proportion of the total number of sterilizations. (Source: Véron *et al*., forthcoming.)

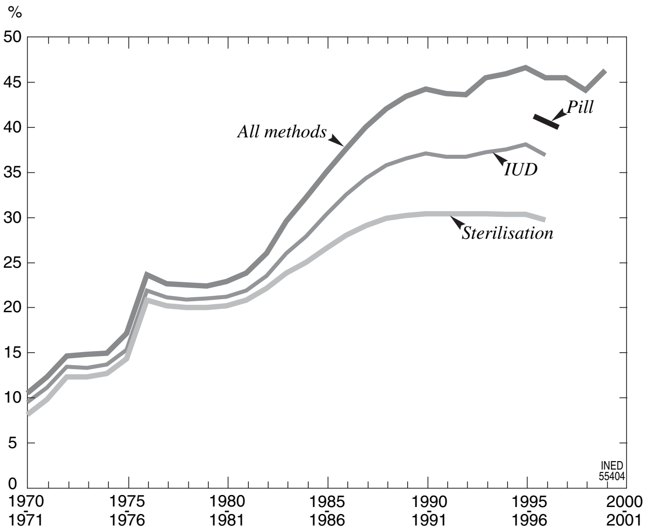

FIGURE 113–8 Contraceptive use by type of method. (Source: Véron *et al.*, forthcoming.)

2. Sterilization Creating Its Own Demand?

According to the NFHS and NFHS-2 surveys, over 80% of sterilized women had used no birth-spacing method prior to sterilization; in addition, at the NFHS-2, 65% of women who were not using any form of contraceptive at the survey stated their preference for female sterilization as their future means of birth control. Can we conclude from this that a real demand for sterilization emanates from couples themselves? Is it a real choice? To what extent do women decide on sterilization?

India's most developed states are also those where sterilization is the most widespread. Thus, the highest proportions of couples protected by sterilization are found in the southern states (Kerala, Tamil Nadu, Karnataka, Andhra Pradesh), in Maharashtra, Punjab, and, to a lesser extent, in Haryana. The percentage of sterilized women lessens with their level of education, but close to 40% of the most educated women in Andhra Pradesh have been sterilized. Women's average age at sterilization is also lowest in the South Indian states, where the average number of children per woman is also the lowest. Couples appear to create the desired number of children and then opt for the terminal contraception that sterilization constitutes.

The fact that a demand for sterilization arises from couples themselves should not make one ignore the "offer" effect. Improvements in sterilization techniques (minilaparotomy and laparoscopy) have played a role in the high prevalence of this birth control method, as has the possibility for a woman to be sterilized in hospital immediately after her child's birth. Fertility control appears to remain women's business, even if it does not express freedom of choice. The Tenth Five-Year Plan intends to promote male sterilization, considered to be more reliable than female sterilization.

IV. THE OTHER COMPONENTS OF POPULATION POLICY

1. Population Health

The 1983 National Health Policy stressed the importance of encouraging the small family size norm (GOI, 2000). When adopting this policy, Parliament emphasized the need to separate national population policy, focused primarily on fertility reduction, from health policy. The 2000 National Population Policy set health objectives (with respect to maternal and infant mortality) because higher child survival rates and better maternal health favor fertility decline.

The 2002 Health Policy (GOI, 2002), taking a "holistic" approach, established its priorities at the same time. It sought to fight both "historical" diseases, such as tuberculosis and malaria, and emergent ones, like AIDS.

In this 2002 Health Policy, the Indian government also showed concern for equal access to health services. Regional and social inequalities, as well as rural-urban differences, were so marked that placing the accent on primary health care was the only way to make this equity goal even slightly realistic. Improving the quality of health services was another challenge; doubling the percentage of the GDP allocated to health was an additional target for 2010.

The evolution of life expectancy at birth gives an indication of progress in the health sphere since the adoption of the first population policy in the early 1950s. At that time, the average life span was around 30 years; a half-century later, it had doubled (Table 113–8). Differences in life duration between men and women are minor. Even though urban-rural disparities are still substantial, they are less marked than they were in the early 1970s.

2. Population Policy and Development Policy

It is difficult to isolate the respective effects of population policies, development policies, and development itself on demographic change; the analysis of Kerala's demographic transition is a prime example. Population policies, in their broader acceptation, are in

TABLE 113–8 Life Expectancy at Birth since the Early 1970s

Period	Men			Women		
	Total	Rural	Urban	Total	Rural	Urban
1971–1975	50.5	48.9	58.8	49.0	47.1	59.2
1976–1980	52.5	51.0	59.6	52.1	50.3	60.8
1981–1985	55.4	54.0	61.6	55.7	53.6	64.1
1986–1990	57.7	56.1	62.0	58.1	56.2	64.9
1991–1995	59.7	58.5	64.5	60.9	59.3	67.3
1995–1999	60.8	59.7	65.5	62.5	61.0	65.5

Source: L. Visaria, 2004.

any case close to development policies. Legislation on age at marriage, or advances in the country's education level, can at least partly explain the drop in both mortality and the birthrate.

On the other hand, the national population policy adopted in the year 2000, whose main goal is still to stabilize India's population, also includes such socioeconomic objectives as compulsory free schooling until the age of 14 or vaccinations for all children. In addition, the holistic approach that inspired the elaboration of this population policy further recognizes the importance of improving women's status. It also mentions the circumstances of several hundred million shantytown residents; without ensuring these individuals access to drinking water, and without the benefit of primary health care, it is illusory to aim at a sizeable reduction in infant mortality.

3. Population Density and Urbanization

India's remarkable century-long population growth translated into a considerable increase in density, particularly in some states (Figure 113–9). At the 1901 census, the country's average density stood at 77 persons per square kilometer; 100 years later it reached 324 persons per square kilometer (Registrar General and Census Commissioner, 2001). The population's spatial distribution was very uneven, with densities varying from 1 to 9. Excluding the special case of Delhi's almost exclusively urban population, the highest densities are found in Kerala (819 persons per km^2), Bihar (880/km^2) and West Bengal (904/km^2). The presence of a huge city can explain extremely high density—as is the case for West Bengal, with Calcutta's urban agglomeration—but it can also occur independently of urbanization, as in Kerala. Managing extreme densities raises serious problems for development and the environment, and the same is true for urbanization.

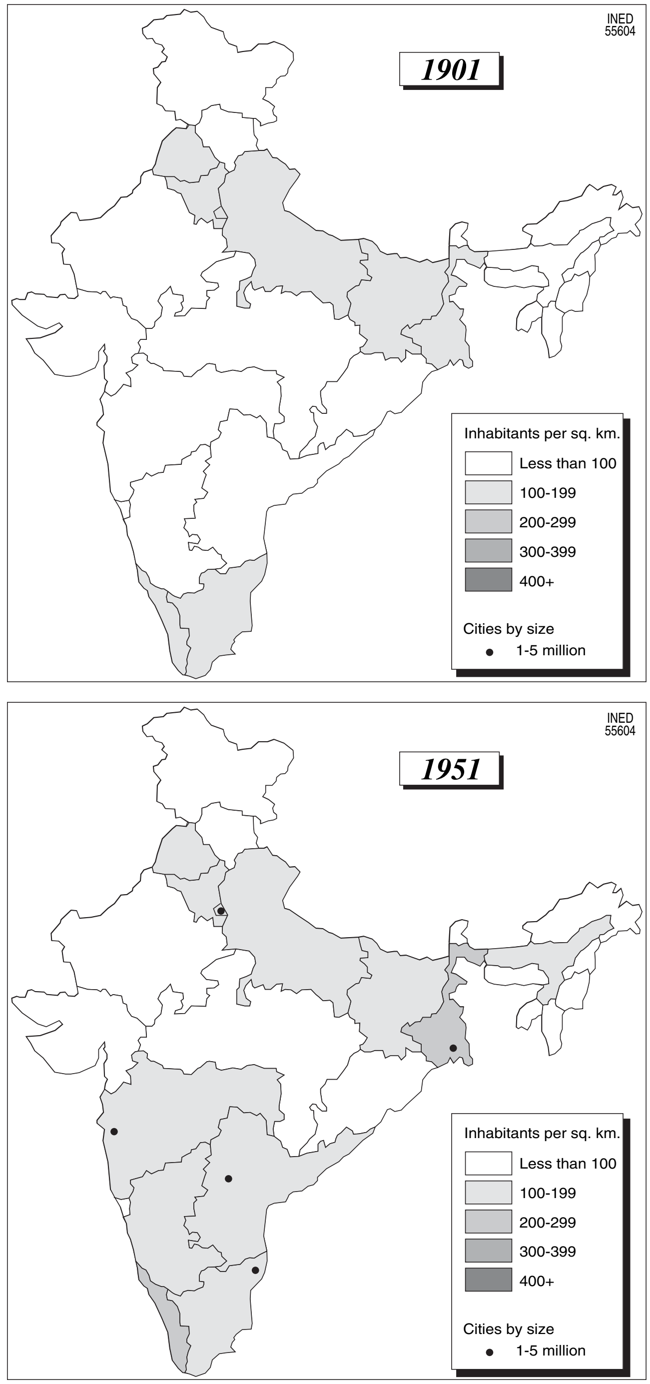

FIGURE 113–9 Population density by State and principal Indian cities by size, since the beginning of the 20th century.

India is characterized by a relatively low level of urbanization and a sizeable urban population (Table 113–9). At the 2001 census, there were more urban residents in India than there had been Indians in 1931. No policy in India explicitly aimed to limit the rural exodus, for example, or curb growth in the very large urban agglomerations. The Eighth Five-Year Plan

(GOI/PC, 1992), while recognizing urbanization as the inevitable consequence of development, nevertheless revealed a deterioration of the physical environment and quality of life in the large cities, and promoted the creation of small and medium-sized towns. To be effective, urban development policies had to be linked with policies for industrial development policy, as labor-force migrations were involved. The Ninth Plan (GOI/PC, 1997) mentions the global aim of "development of urban areas as economically efficient, socially equitable and environmentally sustainable entities," and more precise ones, such as improving the habitat, fighting poverty, developing an effective and cheap public transport system, and the like.

CONCLUSION

This analysis of 50 years of population policy in India, a country characterized by very strong demographic, economic, social, and cultural heterogeneity, shows that family planning programs were only truly effective when accompanied by development: some southern states experienced a particularly rapid fertility decline. In the very populous northern states, the demographic transition is still in progress: fertility has declined substantially, but demographic inertia is so strong that annual growth rates still exceed 2%.

Regularly obliged to revise its population objectives, the Indian government has come to understand the meaning of demographic inertia; replacement level fertility in 2010, and population stabilization 35 years later, were the stated goals when India's new population policy was introduced in 2000.

Nowadays, population growth is no longer the Indian government's only concern, as new problems have arisen. Curbing the spread of AIDS has become a priority, and the government also needs to fight the strong discrimination against little girls; the 2001 census revealed the presence of such discrimination in some states, the Punjab and Haryana in particular, leading to frequent abortions of female fetuses (Nanda and Véron, 2005).

As for the states that have completed the demographic transition, and practically resolved their problem of population growth, they need to start worrying about demographic aging.

Population Policies in Mexico

MARIA E. COSIO-ZAVALA
Université de Paris X-Nanterre, Nanterre Cedex, France

Two periods can be distinguished in the development of population policies in Mexico: 1974 to 1994, the period of the first steps and the implementation of a Malthusian policy, and from 1994 to the present day, the revision period of the methods and objectives. It must be stressed that these two different population policy models were largely inspired by the discussions and the changing objectives within the international community, Mexico having been particularly active in the preparation of three world conferences on population: Bucharest in 1974 (with Antonio Carrillo Flores, a Mexican diplomat, as Secretary General), Mexico City in 1984, and Cairo in 1994. The turning point of Cairo was particularly distinct and coincided in Mexico with progression from the Malthusian model, which, in the Mexican population policy, resulted in the adoption of quantitative objectives, to the new inspired model of Cairo where protection of reproductive health and individual care for men, women, and families was central.

The decline in the total fertility rate (TFR) was considerable, falling from an initial level of 6.5 children per woman in 1975 to 2.8 in 2000. This rapidly entailed a decline in the natural growth rate, which in the same period fell from 3.1% to 1.6% (Table 114–1). On the other hand, the improvement in the population's standard of living, the complementary objective in population programs, suffered from two lost decades in Mexican economic development, with negative gross domestic product (GDP) growth rates (–0.44%, between 1980 and 1990 and since 1999), and an increase in poverty (which was estimated as affecting 54% of the population in 2000).

I. GENESIS AND IMPLEMENTATION OF A MALTHUSIAN POPULATION POLICY IN MEXICO[1]

After the results of the 1960 census revealed that Mexico's population was growing at a rate close to 3.5% per year, the country adopted the United Nations viewpoint and became one of its best pupils. The first Mexican Population Law was adopted by Parliament in December 1973, just prior to the United Nations International Conference on Population in Bucharest (1974). Previously, a debate had been started by some Mexican economists regarding the relationship between population growth and economic growth. Debates developed on this subject, notably from 1960, when those in favor of interventionism, including the most authoritative, clashed with the supporters of laissez-faire (Cosio-Zavala, 1994).

Following the example of Mexico, the issue of population policy was then discussed by all Latin American countries at the government level, during preparations for the Bucharest conference. As Léon Tabah, Director of the United Nations Population Division, stated, the Conference was doubtless the clearest demonstration at a global level of the concept of intervention in population issues. The most comprehensive text on this point was the *World Population Plan of Action* adopted by 136 governments (Tabah, 1976). In all of these discussions, Mexico appeared convinced of the importance of population policies,

[1] This section reiterates the basic points of an earlier article on population policies in Mexico up to 1988 (Cosio, 1989).

TABLE 114–1 Population Indicators, Mexico, 1975–2000

Indicator	1975	1985	1995	2000
Population				
Total population (thousands)	59,083	75,462	91,138	98,872
Annual rate of natural growth (%)	3.1	2.2	1.8	1.6
Proportion of 0–14 years (%)	46	42	36	33
Proportion of 60 years and over (%)	6	6	6	7
Fertility and contraception				
Total fertility rate	6.5	4.2	3.1	2.8
Fertility rate at 15–19 years (per 1000)	116	95	77	70
Proportion (%) of contraceptive users (all types)	30	53	67	71[a]
Proportion (%) of modern contraceptive users	23	45	58	n/a
Mortality and life expectancy				
Female life expectancy at birth	65	71	75	75
Male life expectancy at birth	60	64	69	70
Infant mortality rate (per 1000)	69	47	34	31
Urbanization				
Proportion of urban population (%)	63	70	73	74
Urban growth rate (%)	4.3	3.2	2.1	1.9
Percentage of population aged 6–14 years attending primary and secondary schools				
Primary/secondary school attendance (%) of women	72	87	88	90
Primary/secondary school attendance (%) of men	83	90	89	90

and very advanced in the definition of their implementation, in a context of integrating population issues into development projects. The Mexican population policy thus served as an example for other countries in Latin America, Asia, and Africa until 1994.

1. The Population-Resource Debate

The western neo-Malthusian stream was echoed in Benjamin Viel's resounding book on the population explosion, published in 1966 in Chile. This Chilean physician sounded the first alarm in Latin America, sensitized by his daily confrontation with poverty. Abroad, mainly in the United States, neo-Malthusian thinking developed in a climate which Pierre Pradervand (1974) described as fear caused by the population growth of the Third World in general, and of Latin America in particular. In his preface to Adelyne More's publication (1917), William Robinson, by proposing to "preach the gospel of birth control among the peoples of Russia, China, Japan, India, and Mexico," demonstrates the obvious political agenda behind the choice of the countries mentioned. For example in Mexico, population growth was still very low at the beginning of the 20th century, and an immigration policy was considered necessary. However, in 1974, Pradervand wrote,

> Fear, which is the main motivation for neo-Malthusian thinking—and for many Western reactions vis-à-vis the Third World [. . .] will only reinforce the illusion that the rich countries can continue to prosper materially while the Third World becomes poorer (relatively), and delay the moment when the truth will break out, all the more violently as we have sought to repress it.

In Mexico City, in 1970, the first Latin American regional population conference provided the opportunity to develop the different points of view that are the bases of Latin American population policies. Economists such as Raúl Prebisch, who at the time was Director General of the Latin American Institute for Economic and Social Planning (ILPES), lobbied for structural social reforms, for vigorous economic growth, and for a more egalitarian distribution of revenue, for which it is necessary to support family planning,

> because the Latin American economic system in general, as it operates has demonstrated its incapacity to cope with the phenomenon of the productive absorption of the extraordinary increase in the work force which results . . . from the population growth that started 15 or 20 years before. (Prebisch, 1970)[2]

During this conference, senior officials, such as Carmen Miró, director of the Latin American and Caribbean Demographic Center (CELADE), Victor Urquidi, a Mexican economist and chairman of the Conference's organizing committee, and representatives of the Mexican government of President Díaz Ordaz, stressed the need for a coordination of the various sectoral development policies that would be able to take into account the interdependence of the problems in question. The proposal of integrating population policies into economic development policies and of not locking them into the narrow framework of family planning was at the core of Latin American thinking in general, and Mexican thinking in particular.

Nevertheless, at the beginning of the 1970s, a section of scientific opinion remained largely hostile to direct intervention in family planning supported by the United States and considered as a North American neo-imperialist instrument, based on the neo-Malthusian assumption of population growth as a major obstacle to economic development. However, the official North American theses, and especially the foundation of economic theory that supports them, were refuted in Latin America by economists (Fucaraccio, 1970; Herrera *et al*., 1976) who notably criticized the analyses of Ansley Coale and Edgar Hoover (1958) on India and Mexico, according to which population growth was preventing economic growth. These authors notably demonstrated that the neo-classical hypothesis according to which economic growth depended on investments and growth in household savings could hardly be applied in Latin America, where poverty was largely structural, as a direct result of a very unequal distribution of income.

Indeed, between 1941 and the end of the 1960s, high economic growth and high population growth went hand in hand in Mexico, and also in Brazil, Venezuela, Colombia, Peru, Chile, and other countries. These were the years of the "Mexican miracle" (Ham Chande, 2003). All the studies on the empirical comparative analysis of the relationship between population growth and economic growth reached the same conclusion: that there was no significant negative correlation between the two phenomena, which destroyed one of the basic arguments of the neo-Malthusian theories. In particular, according to the United Nations' Economic Commission for Latin America and the Caribbean, unequal development modes were far more responsible for poverty, unemployment, and the urban problem, than high population growth and the rural exodus toward the large metropolitan areas.

However, it was generally acknowledged by economists and demographers that the accelerated growth of the Latin American population was an exacerbating factor in the problems of underdevelopment and that a reduction in mortality alone should not be counted on to cause a spontaneous reduction in fertility (Tabah, 1987). Social differences and inequalities in the attribution of development benefits were to blame for the extremely high fertility of the end of the 1960s (Cosio-Zavala, 1994). However, Latin American economists and demographers were determined to dissociate themselves from the institutions that supported policies based only on family planning, and which were justified due to their low cost and high effectiveness (Fucaraccio, 1970).

Thus, Carmen Miró demanded a population policy "because the success [. . .] of government programs to ensure free and egalitarian access to the benefits of development for everyone should not be delivered randomly from a so-called systematic adaptation of demographic behavior"[3] (Miró, 1970). But, for Carmen Miró, family planning measures were not population policies, because in Latin America of the 1970s, they were neither coordinated, coherent, nor integrated into national development policies. The definition of a population policy for the Latin American nations was so complicated and had "such a wide meaning that it included nearly all the objectives of development"[4] (Miró, 1970).

Furthermore, foreign intervention in family planning clashed with highly developed nationalist feelings, both on the right and the left. In Brazil, there was a scandal in 1968 regarding sterilizations carried out

[2] "El sistema económico latinoamericano en general, tal como está funcionando, ha demostrado su incapacidad para hacer frente a este fenómeno de absorción productiva del incremento extraordinario de la fuerza de trabajo, que ha resultado y que viene resultando . . . adel incremento de la población iniciado 15 o 20 años antes"(Prebisch, 1970).

[3] "Asegurar el acceso libre e igualitario de los beneficios del desarrollo a todos los habitantes [. . .] no es posible dejar librado al azar de una supuesta adaptación automática del comportamiento demográfico, el logro de las metas específicas de la política estatal" (Miró, 1970).

[4] "Una acepción tan amplia que practicamente quedaron englobados dentro de ella todos los objetivos del desarrollo" (Miró, 1970).

on Amazonian Indian tribes, which resulted in the expulsion of North American missionaries. The Bolivian film *La sangre del Condor* (The Blood of the Condor), by Jorge Sanjines (born in La Paz in 1936) and co-signed by physicians, was also a protest against the sterilization programs carried out in Bolivia on indigenous women without their knowledge.

2. Adoption of a Population Policy in Mexico

Despite these different points of view, the principles used by the Mexican government as a basis for implementing a population policy were reinforced by the emergence of a Latin American position regarding population policies. In Caracas in 1967, the ministerial conference organized by the Organization of American States (OAS) and the Pan-American Health Organization on population and development policies in Latin America tacitly accepted that "there is no population policy but rather a development strategy, and there can be no development without a population policy" (Concepción, 1970). This was surely a reflection of a compromise between the pro-birth stance, which was that of the majority (including Mexico) at the time and the more Malthusian stance of other countries (e.g., Colombia), closer to that of the large multilateral agencies and some of the people in charge of economic and social policies.

However, the declaration in 1972 of Mexico's president, Luis Echeverría, at the third UN Conference on Trade and Development (UNCTAD), in Santiago, Chile, was quickly followed in 1973 by the promulgation of the Mexican law on population, the aim of which was to reduce the rate of population growth, thus making Mexico the first Latin American country to officially adopt an explicit population policy.

President Luis Echeverría's decision, although he displayed populationist opinions at the beginning of his mandate, was finally made during 1971, under the influence of arguments by economists who demonstrated that the Mexican population would experience high growth with direct damaging effects on a labor market incapable of absorbing the annual flow of young people starting their working lives. According to Raúl Benítez and Gustavo Cabrera's population forecasts (1966), Mexico's population would double in the 20 years between 1960 and 1980, and this is exactly what happened.

Luis Echeverría thus declared in Santiago: "We should not forget that the human race will double in a single generation. Although reducing the population growth rate is desirable, the first task for the Third World is to give its economic development a vigorous push"[5] (United Nations, 1972). In this context, the means of achieving this objective was through the reduction of population growth.

Following the adoption of the World Population Plan of Action in Bucharest in 1974, in spite of the divergences between different Latin American countries, a common attitude regarding population policies began to develop. The second Latin American population meeting, held in Mexico City in 1975, recognized the rights of individuals and families to decide on the number and spacing of their children and the state's duty to provide them with the information and the means to practice family planning. Put in these terms of equality and individual freedom, the concept of guaranteed access to family planning became not only acceptable, but also desirable for governments. In 1975, the Mexico Declaration (CEPAL, 1975) also proclaimed each nation's sovereignty regarding population policies.

The principle of integrating population policies into development planning was reaffirmed in Mexico City in 1984, during the second International Population Conference (CEPAL, 1984). The Latin American position therefore benefited from a general consensus among the developing countries during various regional and international meetings, a position that was defined notably during the Regional Latin American preparatory meeting for the Mexico City conference held in Havana in November 1983.

It can be summarized as follows:

To respect the national sovereignty to freely make decisions regarding population policies.
To integrate the population policy into economic and social development planning.
To respect the rights of individuals and families to freely decide the number and spacing of their children;
To provide the necessary information and means to give individuals and families freedom in their decisions regarding reproduction.

In these general terms, it can be said that Mexico's political doctrine on population served as a basis for the common Latin American position developed during the various international population conferences which, apart from these principles, also included an explicit reference to solving the food problem, to reducing mortality, to the right to health care, and to

[5] "Tampoco hay que olvidar que la raza humana va a duplicarse en una sola generación. Si entonces es deseable una reducción de la tasa de crecimiento de la población, la primera tarea que incumbe al Tercer Mundo es la de dar a su desarrollo un impulso viguroso" (United Nations, 1972).

planned regional development. The Havana Declaration (CEPAL, 1984) was adopted in November 1983 during the Latin American regional preparatory meeting for the International Population Conference held in Mexico City in 1984. Since 1984, the state's principle of intervention in population problems was thus widely accepted in Latin America, particularly with regard to guaranteed access to modern contraceptive methods for couples and the necessity of modifying the spatial distribution of the population, which a large majority of the country considered as being significantly imbalanced.

3. Implementing the Mexican Population Policy (1974–1994)

During the 10 years between the United Nations Population Conference in Bucharest in 1974 and the one in Mexico City in 1984, awareness of the primary importance of population problems in economic and social development strategies, as well as planning, had increased. Mexico thus equipped itself with the legal and institutional means to implement a population policy and integrate it into various national development plans. It was based mainly on a national family planning program and an internal migration policy. Programs concerning health, mortality, and morbidity also had demographic consequences, as did both educational programs relating to population and legal provisions relating to international migration, but they were not an explicit part of the Mexican population policy. Their consequences on the population were indirect, resulting from other priorities pertaining to health, education, or foreign policy. Furthermore, the growing concentration of wealth that accompanied Mexican economic development resulted in an exacerbation of the economic and social gaps between rich and poor regions. The reduction of these differences has never specifically been taken into account in population policies, either directly or indirectly.

The continuous monitoring of government perceptions and policies relating to the demographic situation and to its evolution in the development context resulted in a series of UN surveys which made it possible to trace the governments' positions on population policies every two years. Yet, Mexico declared that life expectancy levels in 1976 and 1986 were "acceptable" and did not provide a quantitative objective for mortality (Table 114–2).

It is true that the regular and significant increase in life expectancy at birth since 1930 (Figure 114–1), obtained mainly due to the decline in infant mortality (Figure 114–2), provided proof of the adequacy of health policies, which relied on the large public health bodies (particularly the Mexican Institute of Social Security and the Ministry of Health).

The objectives of the health programs pertained only to specific actions targeting certain categories of the population (infants and children aged under 5 and their mothers), or certain particular causes of mortality (e.g., infectious diseases). Health program objectives were generally limited to the health sector, with

no reference to the general population and development policy. Regarding international migration, the Mexican authorities considered that the flows observed were satisfactory and should be generally maintained at their levels (Table 114–2).

On the other hand, regarding fertility, recognized as an essential component of population growth, Mexico began constitutional and legislative reform. The changes made in 1973 to Article 4 of the Constitution concerned the right of individuals to choose the number and spacing of their children and expressly encouraged responsible paternity. Development planning referred explicitly to rapid population growth as an impediment to economic and social development.

The population policy was coordinated by the *Consejo Nacional de Población* (National Population Council [NPC]), which was created in 1976. The NPC's missions are to develop, monitor, and coordinate the national population program. Up to the early 1980s in Mexico, both the NPC and the Council for the Coordination of National Family Planning Program within the Ministry of Health were responsible for the family

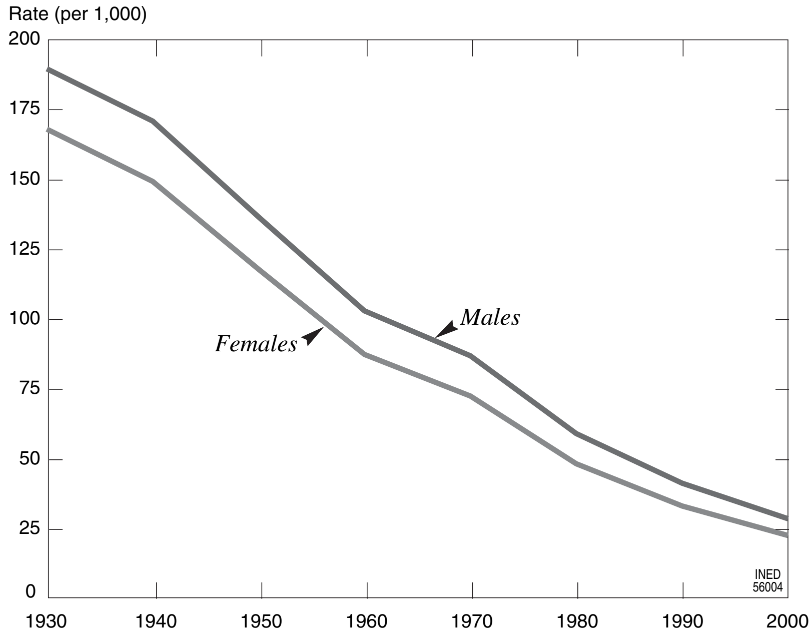

FIGURE 114–2 Trend in infant mortality rate since 1930. (Source: United Nations, 2002.)

planning programs of all institutions. Of the two councils, the only one that still exists today is the NPC, which since 1983 relies on the State Population Councils of the 32 states which make up the Mexican federation and which regulate the Ministry of Health's reproductive health programs.

At the beginning of the 1980s, the international community encouraged the government to intervene in population policies. Furthermore, physicians and economists were largely in favor of this. The only institutional opposition came from the upper hierarchy of the Catholic Church, following the objection that was officially made by the Vatican on July 25, 1968—The Encyclical of Pope Paul VI on Birth Control. However, surveys have proved that religious practices have very little influence on the reproductive behavior of the Mexican population (Brito, 1971; Leñero, 1979).

4. Laws, Regulations, Institutions

Once the presidential decision to authorize a population policy and a birth control policy (in 1972) had been taken, legislative changes made its application possible. Article 4 of the United Mexican States' political constitution was amended on December 31, 1973. This amendment established the equality of men and women in the eyes of the law, the protection of the family, and the free and informed choice of each individual regarding the number and spacing of his/her children.

The government's basic principles were as follows:

The population policy does not replace the economic and social development policy; it is fully integrated into it and its objective is a long-term one.

The State has a duty to inform, educate, and guarantee the freedom of individuals and families regarding procreation. Responsible paternity is a right, guaranteed by access, free of charge if possible, to family planning.

The State has a duty to protect the family; in particular it should protect women and children in their health and education, and their physical and social well-being.

The General Law on Population of December 11, 1973 was published in the *Official Journal* on January 7, 1974. The decree specifying how the law should be enforced (*Reglamento*) dates from November 1976 and the programs were implemented beginning in 1977, within the new development planning system of President José López Portillo (1976–1982). The first global development plan covered the 1980–1982 period, and the second covered the 1983–1988 period. The national family planning program was presented on October 28, 1977, with the objective of reducing the rate of population growth to 2.5% in 1982, and then to 1% in 2000. It gave the responsibility of extending access to contraceptive methods to the entire population mainly to the national public health institutes, such as the Mexican Institute of Social Security (IMSS) and the Ministry of Health. Furthermore, the first global development plan also defined economic and social measures in the fields of employment, health, education, housing, food, industry, trade, agriculture, and stock farming. But no explicit link was established with the demographic objectives, as these were considered as useful per se.

The results of this policy became rapidly visible in the massive improvement of the entire population's awareness and of access to family planning services; the use of contraceptive methods, considered lawful, became generalized within public health bodies. The proportion of women of child-bearing age using contraception thus increased from 30% in 1976 to 71% in 2000 (Tuirán *et al*., 2002).

Figure 114–3 shows the trend in TFR and completed fertility between 1900 and 1995, which confirms that fertility had already begun to decline from around 1968 onward, that is, 10 years before the promulgation of the national family planning program. The latter had therefore been well accepted, with contraceptive use preceding legislation, notably among the small urban and educated minority group known as the "family planning pioneers" in Mexico (Cosio-Zavala, 1994). Indeed, this is why the Population Law received the sanction of the members of Parliament, as they themselves belonged to these pioneer groups.

5. Spatial Distribution and Internal Migration Policies

During the first period of development planning in Mexico, government bodies were mainly concerned with planning economic activities, without explicitly taking into account the demographic consequences of actions undertaken at regional and local levels. During the preparation of the Mexico City conference in 1984, the associations between development policies and population policies were the subject of numerous studies, and consideration of this theme led the Mexican government to take a position. Mexico considered that the distribution of its population in the national territory was inadequate at a regional level and wished to modify it. Among the main social problems in the country were unemployment and poverty, associated with the rapid and poorly controlled development of urbanization. The urban growth rate was estimated at 3.2% in 1985 (United Nations, 2002).Policies for the spatial redistribution of the population were therefore developed. They were based on four general recommendations:

1. Policies aimed at maintaining and retaining the population in the departure zones, encouraging the maintenance of a significant proportion of the population in rural zones with the aid of productive investments, an increase in the quality of human resources

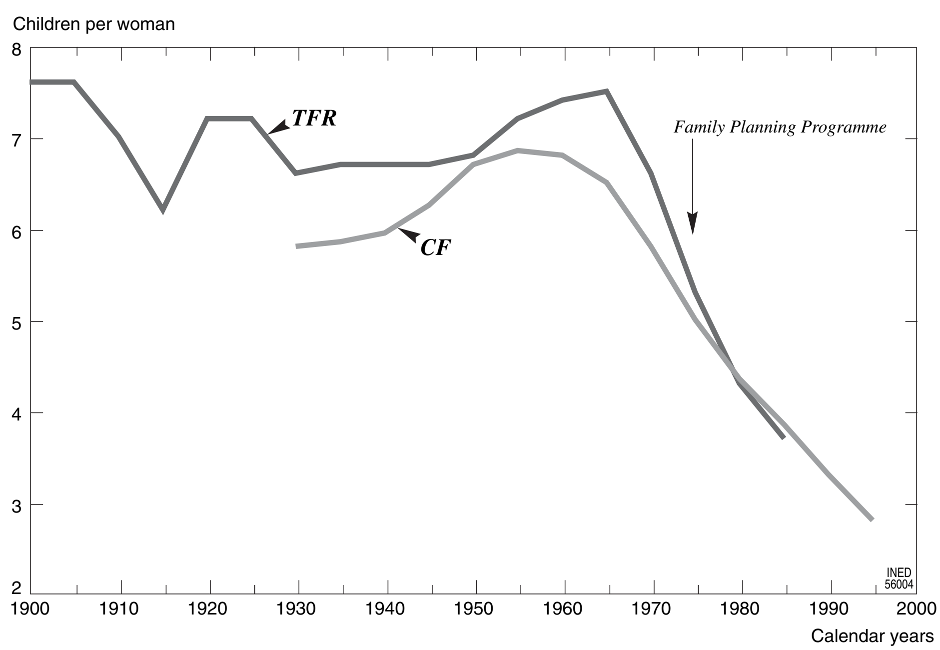

FIGURE 114–3 Trends in total fertility rate (TFR) and completed fertility (CF) during the 20th century (CF is represented with a difference of 26 years which corresponds to average age at maternity). (Source: Cosio-Zavala, 1994, p. 207.)

in agriculture, and the creation of nonagricultural employment in rural regions;

2. Policies for the reorientation of migratory flows to divert migration from the large metropolitan areas to other towns, in particular medium-sized towns; examples of these policies were provided by strategies for development areas, in particular surrounding industrial areas, ports, and mining areas; a coastal development program was prepared, in a country where the population is largely concentrated at an altitude above 1500 meters, a historical inheritance linked to climatic and geographical factors.

3. Rural development projects, projects for the agricultural colonization of new zones or the development of new agricultural techniques or new produce in traditional rural zones; these projects frequently invited rural populations from the most underprivileged or overpopulated areas.

4. Decentralization policies, with the goal of slowing the growth of the large urban zones, in particular by limiting the creation of new employment in the major cities, through restrictive measures for setting up companies, and for the public sector and administrative services, by moving civil servants and administrative services out of the large cities. Mexico wanted to place some federal administrative services outside of Mexico City, but this was only approached timidly by moving the National Institute for Public Health to Cuernavaca, only 70 kilometers from Mexico City, and INEGI (*Instituto Nacional de Estadística, Geografía e Informática* [National Institute of Statistics, Geography, and Computer Science]) based since 1987 in Aguascalientes.

The four principles stated above have defined an explicit policy for internal migration since 1979 called "the three R policy" (*retención, reorientación, reubicación,* [retention, reorientation, and decentralization]) (CONAPO, 1978), which is the program for population distribution in the national territory, and has been the subject of specific and coordinated measures with the sectoral programs of the National Development Plan. (In Mexico, planning is implemented in large sectoral programs, which correspond partly to social policy and partly to economic activity sectors.) The various intervention zones were defined according to regional demographic characteristics, through the State Population Council of each of the 31 states and the federal district. Relations between the population policy and economic and social planning were identified in order to integrate population and development. However, the NPC did not have the necessary tools nor the specific resources to implement its policy, which implied the population policy's subordination within the sectoral plans, which were sometimes in opposition in terms of results. For example, certain aspects of the regional industrial policy, boosted by the governors of dynamic states, were likely to be in opposition to the regional policy of decentralization defined by the NPC at a federal level. This is why the results of the policy for the spatial distribution of the Mexican population are generally regarded as disappointing. The programs implemented had few positive results. Control of migratory movement was difficult to ensure while the components essential to regional and international economy were beyond the control of national planning, notably due to the principle of laissez-faire applied to productive investments. This is why population distribution continues to be extremely polarized and concentrated in the very large cities (Figure 114–4).

Indeed, policies regarding population distribution in Latin America (as in almost everywhere in the world, including in developed countries) have never been very successful. Even with the existence of political good will, such as in Mexico, the intervention methods were frequently missing. The expected results of these redistribution policies were often thwarted by the side effects of macro-economic and sectoral development policies (UNFPA, 1984).

6. Assessment of the First Phase of the Population Policy in Mexico (1974–1994)

The population policy in Mexico was developed under extremely varied forms and with a strong impetus and an explicit will for a population policy in all fields (population structure and growth, fertility and birth control, internal migratory flows, and spatial distribution). However, it is the policy instruments more than the policy formulation that determine the results. Regarding fertility, the progress in medical techniques and the intensity of interventions in the area of contraception, in the context of health systems, had a significant effect on family planning programs, particularly for the most underprivileged sections of the society, with low incomes and low levels of education (Brugeilles, 2002).

The huge intervention of the public health bodies' family planning programs quickly caught up with the NPC's policy of education regarding population, promoting women, and social communication. The activities carried out throughout the health system were based on highly effective, and even radical, medical techniques such as sterilization, not dissimilar to the route taken by the mortality decline, in a period before the emergence of the concept of a population policy, when the Pan-American Health Organization had

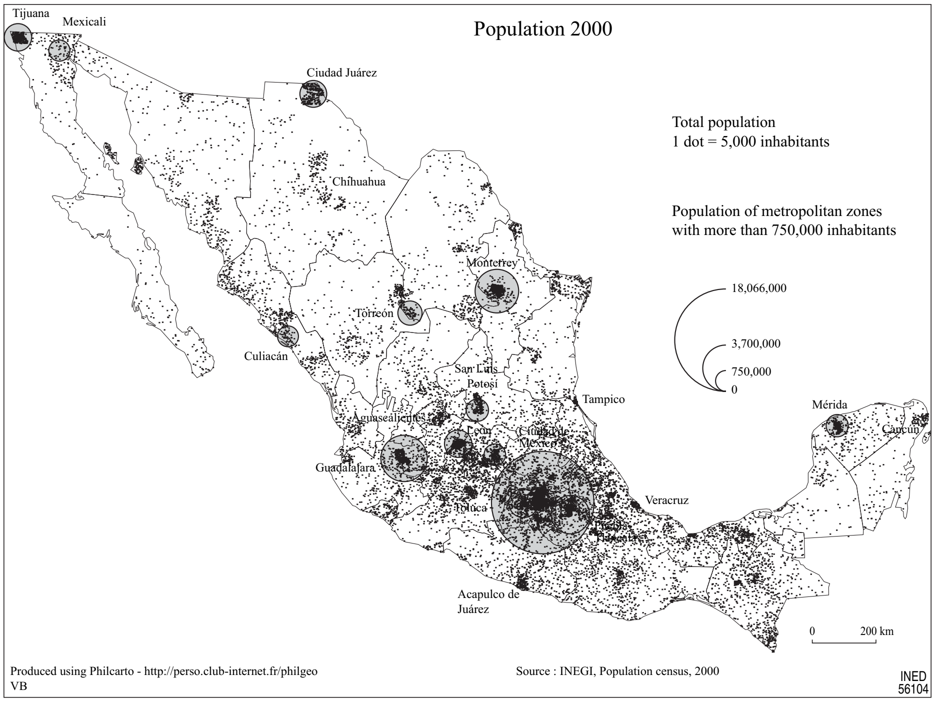

FIGURE 114–4 Geographic distribution of the Mexican population (dots), and metropolitan zones with more than 750,000 inhabitants in 2000.

already been implementing coordinated public health policies for several decades (since the 1930s).

The experiments on the spatial distribution of the population were considered rather disappointing, due to lack of effective tools for controlling internal migratory movement.

Finally, it seems that, until the 1990s, Mexico's population policy only had a real effect on contraceptive practices, despite the more ambitious starting principles of raising the standard of living and reducing social inequalities. Steps were taken after 1994 to widen this policy of reducing fertility by generalizing access to both information and contraceptive methods, and by integrating the policy into social and educational policies and policies for increasing women's status.

II. THE POPULATION POLICY IN MEXICO AFTER 1994

The objectives of the 1977 National Family Planning Program—a natural population growth rate of 2.5% in 1982 and 1% in 2000—were not achieved, as evidence by a natural growth rate of 1.6 in 2000, 60% higher than the 1% hoped. The objectives were actually badly defined, as the annual rate of natural growth depends on age structure which, in a young country, in itself contains an immense growth momentum (see Chapter 4, Volume I). The 1995–2000 National Population Program modified these objectives by aiming to reach replacement level by 2005 (i.e., a TFR of 2.1 children per woman by that date). This objective was confirmed by the 2001–2006 National Population Program. In order to achieve this, the proportion of women using contraception must reach 73.5% of all women of childbearing age living with a spouse. This forecast seems realistic, as the progress required is lower than that observed in the 1997–2001 period. The extrapolation of recent fertility trends is even leading the NPC to forecast a TFR of 1.68 children per woman in 2030 (Tuirán *et al*., 2002).

After the 1994 Cairo Conference

Since the International Conference on Population and Development held in Cairo in 1994, the World Population Plan of Action was oriented in new directions and Mexico, like many other countries, modified its population programs. As Louise Lassonde (1996) explained, the reproductive health and family planning programs became independent from demographic targets (population stabilization) and acquired a legitimacy based on the fact that individual well-being and health are ends in themselves. Could this change in perspective divert attention from regional or global demographic issues as Louise Lassonde fears? In any case, it has, to its credit, placed the emphasis on new themes, such as preserving the environment and improving women's status.

Reproductive health is one of these new themes. It includes the fight against sexually transmitted diseases, AIDS, maternal and child mortality, illegal induced abortion on the one hand, and on the other hand, promoting reproductive and sexual rights, that is, the consensual realization within a couple of each other's reproductive and sexual aspirations, for both men and women. Family planning is part of this, but is not the only aim of the programs, of which quality and adaptation to the couple's needs take precedence. In order to conform to these objectives, the programs implemented so far have had to be significantly reorganized. In a continued effort to improve the status of women, the fight against inequality in the social relations of gender, violence, and the denial of women's rights are also part of the new programs.

Education regarding population has also become a priority, within formal education on the one hand, and within mass communication on the other hand. It is addressed first and foremost to young people, by developing positive values and civil behavior in the context of the family and the community. It also aims at overcoming retrograde attitudes, notably with regard to adolescents' sexual education and information on contraception. *Gente jóven*, an experimental program, was developed with young people from Mexico City's working-class neighborhoods, based on their peers as promoters of reproductive health (Marston, 2001).

Another important theme discussed in Cairo was the issue of the population's well-being. In a context of neo-liberal, economic policies and the regulation of employment through market laws, we observe the state's retreat in the fight against social inequality and a significant deterioration in the standard of living of the increasingly numerous poorest sections of society. Mexico, as well as the other Latin American countries, is looking for political alternatives to redefine the economic and social role of governments in the current context of globalization (Welti, 1997), as centralized economic and social development planning has reached its limits and become largely obsolete.

The concept of sustainable development emerged with a view to preserving the environment, nonrenewable resources, quality of life, and conserving the natural environment for future generations. After the 1992 Rio de Janeiro Summit on the environment, the ecological damage in the Amazon could no longer be ignored, no more than could the general deforestation, the great fires caused by illegal clearing (such as in northern Mexico during the summer of 1998), the insalubrities of the slums of the large cities (called *tugurios* in Mexico), or the serious atmospheric pollution in Mexico City, as well as that in many other large industrial cities.

The themes of migration and urbanization are also part of the priority actions for a readjustment of the population's spatial distribution, urban decentralization, and also the reception of migrants in arrival zones, notably those who have been victims of forced migration or are looking for refuge from political violence (such as the Guatemalans in southern Mexico during two decades). International migration has also become a priority political issue, even though its effect on population numbers remains low. Thus, the net Mexican emigration to the United States estimated at 300,000 per year, only corresponds to a net emigration rate of 0.3%, which is however the highest rate in Latin America. Since 1996, the Mexican government has attempted to control migratory flows and to encourage the emigrants to return, in clear discontinuity with the previous policies of nonintervention in the face of migration levels that were previously considered as satisfactory (Table 114–2). However, the Mexican government's willingness to negotiate a veritable international migration policy with its powerful North American neighbor came up against the events of September 11, 2001, and with President Bush's consequent refusal to discuss it further.

In the context of the discussion of the state's role and the questioning of governmental monopoly of social policies, there is strong support and mobilization in favor of Cairo's objectives in Mexico, insofar as they are concerned with the well-being of the population and the protection of human rights and women's rights. Private institutions and nongovernmental organizations have in the past demonstrated their effectiveness and their capacity to intervene alone or in collaboration with state social programs (e.g., in the area of the family or child health). This is what Benítez (1999) calls "a new demographic culture." It will have positive effects due to the participation of all citizens encouraged by the current context of political democratization in nearly every country (Welti, 1997).

However, a major theme of discussion in the Cairo conference was the Catholic Church's reaffirmed traditional opposition to contraception and induced abortion and many Latin American countries officially supported this position, notably Argentina. Indeed, the governments formally accepted this point of view, including Mexico, a secular country which has accepted the separation between the Church and the State for a long time but had not dared to publicly oppose the Catholic hierarchy on the issue of legalizing induced abortion when it was publicly debated at the beginning of the 1980s. On the other hand, the Catholic Church is far less vehement regarding official birth control programs. The Catholic Church is the only institution that is opposed to modern contraceptive methods, but generally it turns a blind eye to the issue, particularly in the poorest sectors. Finally, zoning by sectors of economic activity or by branches of social policy has been replaced by zoning according to the socioeconomic and cultural characteristics of the population to be protected in their reproductive and sexual rights. Groups with different socioeconomic extremes coexist in Mexico: some of them are well integrated into economic and social development (in the large cities, sectors with high cultural and economic capital), and some of them are very marginalized (such as rural, indigenous, uneducated population groups with high infant mortality). Furthermore, a significant increase in the differences between the poorest and the richest groups is observed. In this context, differences in fertility are considerable during the same period, with for example in 1995–1997, TFRs ranging from 1.66 children per woman among executives to 4.7 among uneducated women (Tuirán *et al.*, 2002). Despite these differences, the growing economic cost of children to parents in an increasingly developed consumer society where there exists a generalized medical culture, exposure to mass media, generalized social protection, and improvement in women's social conditions in both education and health has led to the spread of the reduced family model, including in the more marginalized population groups. As for the medical culture in Mexico, reported that 82% of deliveries were carried out by physicians in 1994–1997 (Tuirán *et al.*, 2002). As for Mexicans' exposure to mass media, in 2000, 86% and 85% of the population had a television and a radio, respectively, compared with 31% and 76% in 1970. With regard to generalized social protection, the Mexican Institute of Social Security (IMSS) covered 47 million people in 2000, compared with less than 10 million in 1970, which is respectively 47% and 19% of the national population.

Since 1995 (and up to 2006), the Mexican population policy includes specific actions for the protection of vulnerable population groups, notably in the fields of education and health. It is associated with the poverty reduction program PROGRESA (*Programa nacional de Educación, Salud y Alimentación*), which covered 300,000 families in 1997 (Tuirán *et al.*, 2002) and by 2004 covered 4 million. It aims to promote opportunities for children to succeed and to improve women's participation in society, providing them with more egalitarian living conditions and eliciting more autonomy for women from men with regard to education, employment, and health. This occurs in particular through the provision of study grants for children, particularly girls, so that they can attend school and prepare for working life. PROGRESA benefits for the vaccination, feeding, and education of children are paid directly to the mothers.

CONCLUSION

Since 1995, the Mexican population policy has therefore become above all a poverty reduction policy, partly decentralized, with family benefits based on the poorest families that it aims to protect in areas of health, feeding, and education. It is concerned with bridging the gap that separates the poorest social groups from the richest, with the objective of attaining replacement-level fertility (2.1 children per woman) or even below (1.68 children per woman forecast by the NPC in 2030), by developing access to contraception. The NPC therefore continues to coordinate the family planning policy at a national level, despite the decentralization of health policies at the state level.

The implemented actions are aimed at improving the standard of living of the most vulnerable social groups. Priority to the Malthusian objectives of the 1980s has therefore been abandoned, and the idea that their achievement would automatically result in the social progress desired as a consequence of the moderation in the rate of population growth has also been abandoned. This simplistic idea has been contradicted by the facts. The reduction in the population's growth rate has not reduced the considerable social differences; on the contrary. The government has reoriented its population policy in order to achieve this objective, through new poverty reduction programs (such as PROGRESA), which, far from aiming only to control fertility through family planning, also aim at directly reducing the gaps between the poorest sections and the rest of the population in terms of education, children's health, and the promotion of women's economic activity and their participation in social life.

Population Policy in Kenya

VALÉRIE GOLAZ AND CAROLYNE WANJA NJUE

Institut national d'études démographiques (INED), Paris, France

Population Council, Nairobi I, Kenya

Few African countries adopted an explicit population policy before the 1990s; Kenya is one of the rare exceptions. At different moments of its existence this country engaged in voluntarist demographic policies, in relation to the population's spatial distribution and to health and fertility. Many studies have focused on the two latter issues, particularly since the 1980s. No synopsis on population policy, however, relates health and fertility policies to those concerned with population distribution. In Kenya, nonetheless, the justification for both types of intervention draws on the relationship between population and resources, particularly land.

One particularity of this country stems from its physical characteristics, with a vast semi-arid area contrasting sharply with very fertile and densely populated regions in the highlands and along the coastal strip. This physical polarity has important implications on the settlement patterns, lifestyle, and health of the inhabitants of different regions. But, quite independently of these contrasts, conflicts over resources have long existed in most of these ecosystems: conflicts over fishing in Lake Victoria, over access to water among pastoral groups in northern Kenya, and over access to land among agro-pastoralists in more populated regions. If the existence of these conflicts testifies to deep-seated defense and attack strategies within traditional Kenyan societies, their frequency and violence reflect the fact that Kenya, unlike most other African countries, has a weak ratio of resources to population.

The population's spatial distribution derives not only from the country's physical characteristics, but also from its administrative history. Most present-day conflicts can be seen as a direct consequence of administrative measures taken by the colonial government, rather than of population growth as such. In this chapter, it is therefore essential to assign an important place to the colonial era.

The history of the state of Kenya has three distinct stages (Figure 115–1): its birth, with the early days of British colonization (1895–1945); followed by its transition to, and the first decades of, independence (1945–1984); and, finally, the period of consolidation of Daniel arap Moi's rule (1984–2002) up to the arrival in power of Mwai Kibaki in December 2002. It is certainly too early as yet to say whether this recent political turnaround will be reflected in the demographic arena. While fully aware of the artificial nature of all boundaries, we have nonetheless chosen to use political markers to trace the evolution of population policy, as the timing of political change appears to coincide with modifications in health and fertility.

I. COLONIAL UPHEAVALS

Most of Kenya's current problems originated during the colonial period. Without wishing to lay the entire responsibility for Kenya's contemporary social and economic problems on British colonization, it is nonetheless important at this point to recall the policies adopted by the colonial authorities and the place reserved for the African population. After presenting the problems encountered by the colonizers on arrival, we discuss their handling of population

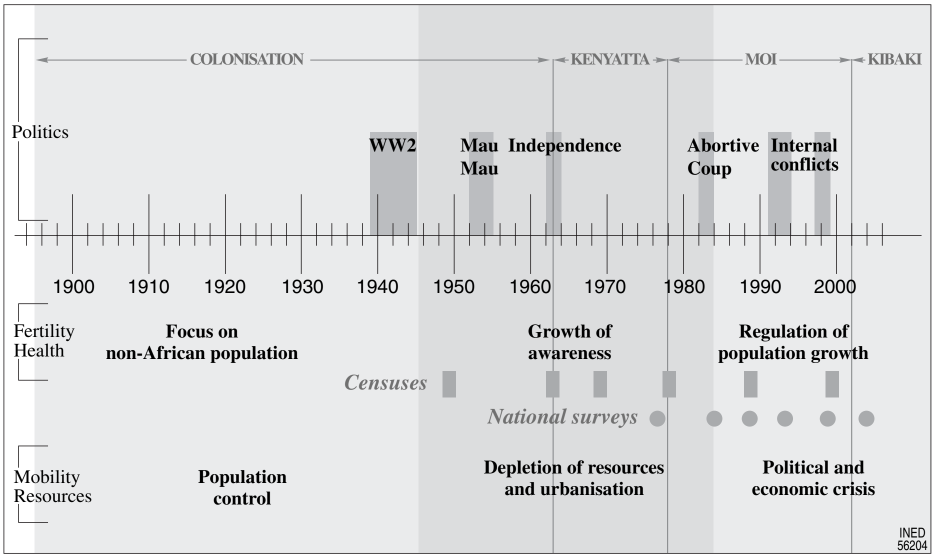

FIGURE 115–1 Chronology of political events and attitudes toward population issues.

settlement and their ignorance of African population demographics.

1. The Colonial Government's Initial Difficulties

On arrival, in 1895, the colonial authorities had to administer as a single entity a set of relatively distinct societies, with diverse ways of operating, different forms of political organization, and with some more closely linked than others. Thus, highly stratified societies (such as the kingdom of Wanga) were grouped with completely acephalous societies into a single state. Furthermore, the end of the 19th century was a period of demographic devastation: epidemics, wars, and famine followed one another, decimating East Africa's cattle and human populations.[1] One might expect, therefore, that the government's first public policies would be directed toward improving health, on one hand, and agricultural production, on the other. But before there could be any question of population policy, the British colonial authorities had to put all their energy into controlling and administering the territory, while ensuring their own survival, a common problem in the early years of colonial Africa. Except on the coast, missionaries only began their work in Kenya after the first settlers arrived and work on the railway, which was to cross the country from east to west, had started in earnest (Maupeu, 1998, p. 144). Under Maasai control, the country's heartland remained for many years an impassable barrier for 19th-century caravans, who therefore preferred to use more southern routes across what is now Tanzania. Only in the 1890s was a new commercial route established between Mombasa and Uganda, following closely the construction of the railway linking the coast to Uganda between 1897 and 1902. Unlike Uganda, where the kingdom of Buganda provided the colonial administration with a ready-made infrastucture, no Kenyan group stood out in terms of its ability to dominate, or even influence, the entire country.

The British colonial administration generally employed a system of indirect rule (which transformed into local government during the 1940s), seeking its base among precolonial political authorities. In Kenya, such authorities simply did not exist in most of the country (Bourmaud, 1988, p. 7–31). Colonial chiefs were created within the groups to be governed, but their efficiency was questioned because they lacked legitimacy.

2. Controlling the African Labor Force and Creating a Special Territorial Framework

After pacifying "rebel populations," such as the Nandi, the colonial government's first priority was to

[1] During this period occurred a smallpox epidemic in 1892 and cattle plague in 1890–1891 and 1898. Harvests were destroyed by locusts in 1894 and 1899 and the drought of 1900–1901. In addition, intense warfare between different Maasai groups and their neighbors was observed (Lonsdale, 1992, p. 17; Muchoki, 1998, p. 79–82).

revive agricultural production; however, the colonial administrators were so deeply dissatisfied with the attitude of the African peasants and the local leaders they had selected that they excluded the African population from export production. With policies encouraging foreign settlers, the country's second administrator, Sir Charles Elliot, succeeded in attracting land-hungry Finns and Boers, as well as those from the Punjab (Lonsdale, 1992, p. 34). In this way, an alternative population base emerged in the colony at the very moment that African population numbers were particularly weak; these settlers occupied interstitial areas traditionally separating the African populations, thus serving as buffer zones by filling the territorial gaps between the African ethnic groups (Lonsdale, 1992, p. 34–36). The new colony's economic basis rested on the export of agricultural products from its large plantations, with wheat dominating initially. But, like the country's general administration, these estates operated through the existing African male labor force, for both agricultural work and road building.

Thus emerged very rapidly a dual system, based on a physical and racial separation between micro- and macro-exploitations, with Africans restricted to subsistence agriculture while the foreign settlers took charge of cash crop cultivation and exports. Pastoral groups were the main victims of this system in which they had no legitimacy. In practice, the administration was built on a segregationist model: racial segregation (social and spatial) between Africans, Indians, and Europeans, as well as separation of the various African ethnic groups within the reserves. Already, European settlement in the margins of land between the African groups led in that direction but, beyond this, the permanent goal of all successive administrators was to govern territories with homogeneous populations. Internal boundaries were therefore drawn up. This ethno-territorial definition of populations went hand in hand with the identification of individuals with a single ethnic group and a single location. Consequently, place of birth grew to have an unparalleled importance for African populations (Peatrik, 1998, p. 66).

The Maasai's displacement southward from the northern section of the Maasai Reserve was the first element of population policy to have a direct impact on the African population in Kenya. The first waves of this transfer and relocation were organized between 1905 and 1911, although the relocation process of the Maasai sections, Uasin Gishu and Moitanik, extended over a period of more than 40 years. In reality, individuals from very diverse origins found themselves within these relocated populations, forced to migrate by the government or having chosen to do so for a variety of reasons. The officials responsible for organizing this population movement described the mix of origins in, for example, the 1929 Annual Report produced by the District Commissioner of Narok (DC/NRK/1/1/2, 1929): "They came from Timboroa and are in fact the sweepings of many tribes who were squatting on farms near Eldoret. A large number of them are cave-dwellers from Mt. Elgon. Some cannot even speak Maasai."

The transfers of population continued despite complaints from the Trans Mara administration. Moreover, the migrants' mixed origins, coupled with the fact that most had already worked on European farms, meant that the so-called Maasai cooperated better with the local administration than the others. They were willing to return to work on European farms, and most spoke ki-Swahili, which facilitated communication (DC/NRK/1/1/2, 1926).

At the start, land pressure in the African reserves was not enough in itself to incite men to look for paid work, and the colonists were hard put to find farm laborers. A taxation system was put in place, therefore, to refill the coffers (emptied by the construction of the railway line to Uganda) and encourage the departure of men toward the large white plantations in search of wages.

After World War I, in 1920, a system of permits, or identity cards—*kipande*—was instituted to control the employment of native workers on European farms. Only workers were allowed to live on these estates. In Nairobi, where segregation was strong, Africans were not allowed to stay more than 24 hours (Médard, in press). *Kipande* was also necessary to go from one African reserve to another, and forced relocations were frequent.

The colonial government increasingly used the *kipande* system with the express aim of restricting internal migration in the country which, according to the archives, appears to have been a major preoccupation. Necessary for employment outside African reserves and, in theory, indispensable for crossing any administrative boundary, *kipande* was compulsory for all men over the age of 16. In practice, however, the system encountered some problems: not all men were registered, and some were registered several times so as to conceal their true identity (Kuczynski, 1949, p. 139). What could theoretically have been a very precise source for population estimation suffered from additional problems, arising principally from the fact that the registered population was significantly higher than the adult male population possessing a *kipande*, because deaths and emigration were not systematically reported; in addition, the population was not registered at all in certain parts of the country (Kuczynski, 1949, p. 140–141).

In practice, although the *kipande* system did not always provide correct population estimates, it nonetheless permitted a real control of migration, in particular toward European farms. This control was also established at the boundaries of African reserves, and transfers from one reserve back to another were frequent.

To solve the problem of rapidly increasing population densities, mainly in the Kikuyu reserve, a system of squatting that had been practiced for many years was legalized: in exchange for 180 days of labor in a year, a man could settle with his family on a large estate and cultivate a small piece of land for his own subsistence (*kaffir farming*). This preserved the dual agricultural system (large plantations vs. small farming), the aim of the Kenya Land Commission (Ghai and McAuslan, 1970).

3. The Government's Ignorance of, and Indifference toward, the African Population

Paradoxically, the African population itself received very little attention during this period, as illustrated by the fact that the first censuses apply only to the country's non-African minority (four censuses were taken in Kenya between 1911 and 1931). The possibility of a complete population census had been envisaged as early as 1925 (Kuczynski, 1949, p. 130–132), but the idea was discarded several times for fear of achieving even less satisfactory results than those obtained by the local administration. In 1931, however, one section of the indigenous population was included: residents in the municipalities of Nairobi and Mombasa, plus some living on the European plantations, although they comprised only 2% or 3% of the total African population. The pessimistic view of the probable outcome of such an operation in the African reserves was linked to fears that the census would be badly received by the population as a whole and that its harmful effects would outweigh any benefits to the government. There were certainly many who deplored the absence of reliable data on births and deaths in the African reserves; chiefly, however, a census would have made it possible to improve taxation among the African population and gain insight into the impact of illegal migrations, such as the overflow from densely populated reserves into less populated ones (Kuczynski, 1949, p. 130; Kuczynski quotes McLellan Wilson on the Kikuyu settled in a Maasai reserve near Narok). The tax system, based on a hut count in the reserves, was hampered by the extensive demolition of homes that preceded the count. Yet even this prospect, completely in line with government actions, was not enough to launch an operation whose successful outcome appeared difficult to achieve.

Locally, however, population growth was raising questions for colonial administrators to deal with, quite outside the national policy sphere. Among the Meru, for instance, no territorial expansion was possible (bordered on all sides by enemy groups or by Mount Kenya's infertile lands). The very strict traditional social system acted as a powerful restraint on fertility, through late initiation and marriage, a prohibition on reproduction outside marriage, and a prolonged period of abstinence (2 years) after each birth. The frequency of abortions, the ensuing maternal mortality, and the low level of Meru fertility worried successive administrators; their efforts to extend the reproduction period by reducing the age at initiation, on the one hand, and to limit maternal deaths following abortions, on the other, brought about a marked social evolution (Beck, 1970, p. 143–144; Peatrik, 2002).

In contrast, among the sedentary populations in most other Kenyan regions (e.g., in Kisii), it was rapid population growth that alarmed administrators although they were concerned more with controlling the population's territorial expansion than with limiting its growth.

Although interest in population growth was restricted to the local context, the need for medical personnel and educated chiefs became increasingly obvious, and led to the creation of schools and public health services. In the early years, health and education remained the prerogative of missionaries, while the colonial government dealt exclusively with the immigrant population.

The colonial ideology reinforced social differences between ethnic groups (Eshiwani, 1990, p. 1–2). Public schools were gradually established, however, if only to provide an educated workforce for local administration. The situation within the health sector can be described in similar terms. At the start of the 20th century, western medicine was practiced only by Europeans for Europeans. In rural areas, medicine was left in the hands of the missionaries (Iliffe, 2002, p. 39). Ann Beck (1970, p. 145–146) showed that the colonial government was ready to join the struggle against the high level of African mortality, but only up to a certain point, for fear of the ensuing increase in population. It was World War I that alerted the colonial authorities to the poor standards of health in the African reserves. The government, therefore, decided to subsidize certain mission hospitals and then established a small number of its own health facilities (Iliffe, 2002, p. 39–40).

The example of the colonial authority's attitude toward the Maasai is striking. Assuming that venereal diseases, such as syphilis, were rife, colonial administrators feared the extinction of the Maasai; yet nothing was done to improve the situation, attributed to cultural norms strongly condemned by officials (Coast, 2000, p. 192). A single government intervention is worthy of note: in 1939, treatment was offered at a price, in the sole hope that the Maasai would sell cattle in order to obtain it, thereby stocking the Nairobi market (White, 1990, also quoted by Ernestina Coast, 2000). This can hardly be described as a public health policy, however.

At that time, the extension of health care to the African population was hampered by a lack of personnel. No medical training was available locally until 1929 (Iliffe, 2002, p. 44). In practice, a sick African seeking treatment had three options: to fall back on traditional medicine, to visit a mission hospital (which might not be possible because of the distances involved), or to find a small private clinic, generally run by former mission hospital employees (even a former sweeper, at times) (Peatrik, 1998, p. 72–73; Iliffe, 2002, p. 41–42). At that time, most Europeans preferred to employ uneducated Africans, fearing confidence and arrogance among those who were the first to be educated.

This half-century of colonial rule was characterized by significant economic development in the country, through land alienation, taxation, and paid agricultural labor. Largely in the hands of the colonizers, this economy allowed Kenya to enter the international market. During this period, however, the colonial government had failed to take account of the demographic factor, whose power became apparent from the 1950s.

II. TRANSITION AND INDEPENDENCE

On the eve of independence the situation began to evolve. On one hand, the state's control of population movements weakened and, on the other, the African population started to gain the upper hand, politically and socially. The first family planning clinics emerged, African education developed, and the infrastructure and policies for a public health system were set up.

1. The Decline of Colonial State Control

Little by little, the population's spatial distribution evaded state control. Arising out of the growing pressure on land in Kikuyu country, the Mau Mau movement (1952–1954) overturned the colonial land order and paved the way to independence. Until the 1930s, the settlement of squatters and their families on large plantations matched the European colonizers' high demand for labor. As mechanization progressed, however, it was no longer possible to justify the presence of so many dependents, particularly as the squatters' strong demographic regime tended to reinforce their numbers on these estates (Buijtenhuijs, 1998). The colonial government had no hesitation in forcefully repatriating unwanted squatters into the Kikuyu reserve, a place completely unknown to some (Médard, 1999, p. 353). Migration to cities, especially the capital, increased and the population of shantytowns, which had already existed illegally for several decades (Rodriguez-Torrès, 1995), grew sharply from the 1940s onwards. A massive urbanization emerged. As the government no longer had the authority to tackle these issues directly, indirect attempts were made to limit them. Fear of a new rebellion redirected the government's policy interests toward the African reserves. The need to make reserve lands support growing numbers of people led to a policy of agricultural development involving the individualization of land tenure, sanctioned by the registration of small farms (called the Swynnerton Plan, 1954) (Médard, 1999, p. 310–311). Cash crops were gradually introduced, 30 years later than on European farms, but always on a small scale so as to limit competition between African reserves and European states. Restrictions on the number of trees or the size of holdings depended on the place and the era (see, e.g., Barnes, 1976, p. 124). In the political arena, the period preceding independence was one of debate on the national representativeness of a president. Above and beyond the choice of an individual, questions arose about how the country should be administered. Access to resources was at stake, particularly to former European holdings that were in the process of being sold off to Africans. Most of these lands were situated in the Rift Valley province, and Kalenjin groups were making claims to them in the name of reinvented historical rights (Médard, 1999, p. 353). Ancient Kikuyu rights to these lands were equally well established, however; Kikuyu settlement in the area had been consolidated by the kaffir farming system in place during a large part of the colonial era.

The first Kenyan political parties were formed along ethnic lines, founded essentially on the cleavage between minority and majority groups. KANU, the alliance party between Kikuyu and Luo, the two largest ethnic groups in Kenya, stood in opposition to KADU, a coalition of parties representing the smaller ethnic groups in the population, principally Kalenjin, Luhya, Maasai, and Mijikenda populations. KADU advocated a federal constitution granting the administration of land to the regions (the *Majimbo* constitution, which means "regions" in Kiswahili) (Médard, 1999, p. 88–89), and the massive decentralization it wished for received the backing of the Europeans, Indians, and the British government, who feared that the birth of a centralized independent state might be contrary to their interests (Bourmaud, 1988, p. 81–82).

From 1959 onward, the population of European origin became gradually less involved in the country (Leys, 1975, p. 55). The policy of redistribution of their lands was long debated: should large plantations be preserved at the expense of small ones? Should the estates be split up or, on the contrary, should the dual agrarian economy put in place at the start of the colonial period be preserved? (This agrarian debate has been much argued by agricultural development specialists, economists, and political scientists; see, e.g., Orvis, 1993.) The government attempted to ensure the continuity of the two-tier agricultural system, hoping that Africans would take over the large European farms. But European departures from the country were hasty at times, necessitating a speedy reorganization of their farms. Faced with a lack of potential African buyers, some states, especially those close to a reserve, were divided up, constituting the first land settlement schemes from 1961 onward. This operation, which later proved to be a financial failure, allowed a small fraction of squatters to legalize their situation and some of the better-off reserve inhabitants to flee the pressure on land by settling on European properties. The underlying idea was to meet the demands of landless peasants while at the same time providing land to curb the process of urbanization.

In May 1963, the KANU party won the elections and, from 1964 onward, the centralization of Jomo Kenyatta's regime put an end to the devolution of any significant powers to the regions. Little by little, KADU party members associated themselves with the party in power.

Transfer of former European farms continued up to the 1970s. Under Kenyatta, "land companies" were created. These associations acquired land in their own name and then redistributed it among their members. The majority were failures, however. In practice, social networks determined how land was distributed, and people were not equal in this regard. Thus, some powerful men benefited more than the others, and this system facilitated Kikuyu migration within a strictly legal framework (Médard, 1999, p. 355).

Some regions retained special status at independence, however, with the aim of protecting their population's access to resources: one example is Trans Mara district, which remained a "closed district" until 1967 (Matampash, 1993), open only to individuals possessing a *kipande* until 1972, and where strangers to the region were forbidden to buy land.

Outside these protected districts, the transition period and first decades of independence are characterized by successive waves of settlement on land alienated for European settlers at the start of British colonization, almost all of them situated in Rift Valley province.

2. Early Public Policies for the African Family

From the point of view of African families, westernization was gaining momentum. In 1949–1950, 26% of Kenyan children of primary school age were educated (compared with 6% in French-speaking West Africa) (Iliffe, 1995, p. 222). The urban employment market was developing, fed by a migration that was henceforth tolerated.

Population flows toward the city exacerbated urban economic and social problems. Extremely high population densities in the Kikuyu reserve and the pressing need for land in the rest of the country presaged an even stronger growth in internal migration. Rather than focusing exclusively on resources, as it had earlier on, the government also turned its attention to the country's African populations. Knowing these populations better seemed to be the key to improved planning.

At the end of World War II, however, nobody could provide an estimate of the African reserves population or even sketch demographic characteristics. Only in 1945 did the government start preparations for the first general census (Kuczinski, 1949), finally carried out in Kenya and its two neighboring countries, Tanzania and Uganda, in 1948. Fears about difficulties with data collection were justified, and these first national censuses are of low quality. The population count, especially of young children, is underestimated (Thomas, 1998). These problems are relative, however, and, compared with earlier estimates based on hut counts, the 1948 census results are appreciable. Moreover, this first attempt served as a basis for subsequent censuses, which could only improve on it. The whole operation was therefore hailed as a great success (Martin, 1949).

Probably because the population had been significantly underestimated until then, the 1948 census figures were alarming. In 1952, the first family planning associations were created in Nairobi and Mombasa. These associations provided the public with the whole gamut of services, from information to the distribution of contraceptives (Uche, 1974, p. 9). They amalgamated in 1961 to form the Family Planning Association of Kenya, the first such association in tropical Africa to be affiliated with the International Planned Parenthood Federation in 1962.

Despite creating a national program much early on, Kenya reached a natural growth rate of over 4% by the end of the 1970s, with a total fertility rate of over 8 children per woman.

In 1966, Kenya became one of the first African countries to profess an official view on this subject (Uche, 1974; Chesnais, 1979, p. 207; Greeley, 1988, p. 212–213; Locoh and Makdessi, 1996, p. 12). As early as 1967, a national program was created, in association with the already existing program for maternal and infant health improvement. Its main aim was to establish a network of clinics and health centers to deal with maternity and birth control (Uche, 1974). The program achieved its objective, but had no immediate effect on fertility; quite the opposite, in fact, as fertility levels rose between 1969 and 1979. It was not until the 1980s, 15 years later, that government family planning policies began to have an impact. The government's emphasis on family planning services and its lack of attention to the population's indifference to these services explain the program's lack of success. Nothing had been done to promote a reduction in the demand for children (Frank and McNicoll, 1987, p. 222). At that time, the program was entirely responsible to the Ministry of Health, whose focus was maternal and infant health (Kelley and Nobbe, 1990, p. 41).

In parallel to government policies, the more targeted efforts of several nongovernmental agencies (NGOs) (Family Planning Association of Kenya, Family Planning Private Sector, and the National Council of Churches of Kenya, in particular) should be mentioned. Until the 1980s, access to this type of service depended entirely on these organizations.

This period of political transition was also a period of transition in population policy. More and more, the Kenyan population was becoming the object of analysis and measurement, though these studies remained disconnected from the population's real needs. Presented at the macro-demographic level, the family planning program appeared to serve the interests of the State more than those of families. Population growth reduction was still viewed from the macroeconomic perspective. Economically speaking, the transition to independence was one of continuity, with the unequal redistribution of alienated lands perpetuating the dual colonial system.

III. A DIFFICULT END TO THE CENTURY

The year 1984 marked a turning point in Kenya's history. Several events made it an exceptional year. A failed coup confirmed the authority of Daniel arap Moi, in power since 1979, and his ideas increasingly shaped national policy. It was also the year of the great East African drought, which had direct repercussions on the Kenyan economy. In addition, the first cases of AIDS and a new strand of malaria, resistant to quinine, appeared toward the end of the 1980s and grew more and more devastating each year. Finally, with the country's record population growth sounding the alarm bells at the international level, a more assertive approach was taken to policies for fertility control: a national survey was conducted that year, and the government took a stronger line on this issue and invested more in it. For instance, the population action program was partly decentralized, with the creation of the District Population Program.

During the 1980s and 1990s, the Kenyan population's economic and demographic situation evolved rapidly: mortality increased, sending life expectancy at birth back to 45 years; fertility plunged by around 50% in the country as a whole; primary education became quasi-universal; interethnic tensions, already perceptible at independence, came to the forefront of the national political scene; forced migrations and refugee waves became recurrent.

1. Public Health Unable to Keep up with Demand

At the end of the 1970s, Kenya possessed an extraordinary public health system for an African country. The system had not managed to keep pace with population growth, however. Even though reproductive health care generally continued to improve through projects developed specifically in this domain by both the government and NGOs, the rapid emergence of new diseases—AIDS evidently, but also malaria, resistant to chloroquine by the end of the 1980s—seriously undermined the health system. The vaccination rate, which had reached 80% of children in 1993, for example, had dropped to 65% by 1999.

From Policy to Practice: The Case of the AIDS Epidemic in Kenya

AIDS did not receive the attention it deserved in Kenya for a long period, which explains why the illness spread so widely during the late 1980s and early 1990s. At this time, AIDS was viewed as an "unclean" disease, affecting unclean people who used unclean needles or indulged in unclean sexual practices. The conservative nature of Kenyan society, coupled with the fact that men controlled the sexual sphere, tended to stifle the question of AIDS. Screening was uncommon; often unavailable, it was in any case too expensive for most of the population and, as a result, HIV carriers remained unaware of it. Publicity about birth control methods was nonexistent, and the young, potentially the most receptive group to safer sex practices, were totally ignored by policymakers. The rate of condom use even decreased between 1984 and 1989 (Kelley and Nobbe, 1990, p. 48). During the same period, Kenya's economic recession contributed to the development of the prostitution market. In the 1990s, AIDS was above all a concern for the health authorities. Yet, according to John Iliffe, a study conducted in the mid-1990s shows that 30% of AIDS victims died without ever having benefited from the health system (Iliffe, 2002, p. 235). Gradually, however, a large part of the population became actively involved in the struggle against the pandemic. Politicians, religious leaders, and the media started to condemn various cultural practices that could contribute to the spread of AIDS (such as the sexual purification of widows, circumcision using the same knife, etc.) and called for them to be abandoned to reduce the risk of transmission. At this time, despite a high level of awareness of the disease, most policymakers within the government and other sectors chose not to define policies to help control the spread of the disease and moderate its effect on society and the economy. Only at the end of the 1990s did the government realize that the AIDS epidemic could be detrimental to development projects and, from then on, every possible effort was made to fight the disease.

AIDS continues to be a powerful threat in people's lives. It is no longer perceived today uniquely as a question of public health, but also as a problem for development; a whole chapter in the current national development plan is devoted to HIV and the impact of AIDS on social well-being and economic growth. In a country where AIDS was scarcely mentioned in public discourse only a few years ago, it is now commonplace to hear politicians refer to the disease's socioeconomic consequences, citing examples from the regions they represent. The Kenyan government, aided by NGOs, missions, and private institutions, continues to extend its activities in the realm of prevention and to improve treatment of sexually transmitted diseases and health care. The AIDS epidemic's negative effect on Kenya's economic and social development has provided an added incentive for the government and its partners to become actively involved in promoting awareness of the problem, and increased the need for strong, well-coordinated policies. Such measures were essential to prevent additional disastrous socioeconomic consequences of the epidemic, and to limit those that had already started. Toward 1997, strategic and collaborative policy development, coupled with concerted efforts made to reinforce NGO influence over national policy in the HIV/AIDS battle, started to show tangible results in Kenya. The government, with aid from a broad spectrum of disciplines—technical, legal, and ethical—prepared a national policy for the fight against AIDS, which led to significant improvements in Kenya, better mechanisms for reinforcing HIV prevention and care, as well as specific changes in official policies.

Moreover, in response to its increasingly profound effect on society, the Kenyan government integrated priorities and strategies for the fight against the epidemic and its catastrophic consequences. Official strategies were of two types: (1) to prevent to spread of HIV and (2) to reduce the disease's impact on society. Working through the existing network, improvements in HIV prevention and treatment gradually started to appear. Recently (October, 2002) the *Kenya National HIV/AIDS Strategic Plan*, developed by the *National AIDS and STD Control and Prevention Program* (NASCOP), was elaborated, covering different aspects of AIDS. Among other things, it provides national guidelines for home care services and patient counseling. Private companies and NGOs adopted policies, or made plans to do so, aiming to curb the spread of the disease among their workers, and certain religious groups made a public commitment to provide support for their adherents with regard to prevention. Some gaps and ambiguities of the Kenyan law were also a focus, such as women's inheritance rights, HIV screening, confidentiality, rape and sexual abuse, and so on. Legislation was debated in parliament to arrive at new policies for HIV/AIDS prevention, disease tracking, treatment, and counseling.

The newly elected government has intensified its efforts to reduce the spread of the AIDS epidemic. The latest actions have been the institution of the Cabinet Committee on HIV/AIDS, with the President of the Republic as president, and the creation of the AIDS Initiatives by the President's wife, an association offering assistance to AIDS orphans and disadvantaged young people. Advocacy networks, NGO coalitions, and religious groups have been created or have also intensified their efforts: promoting awareness, integrating HIV prevention, establishing Voluntary Counseling and Testing Centers (VCTs) throughout the country, taking charge of counseling and sexually transmitted disease management in both the public and private sector. Private sector employers are also developing on-site programs that include discussions with their department directors on the policies and projects to adopt in the fight against AIDS, and peer-group counseling. In 2001, the statistics indicated that the national HIV prevalence rate had fallen to 10.2%, and by 2003, the prevalence had fallen to 7%.

2. Growing Emphasis on Population Policy

Pressure from financial backers prompted the Kenyan government to modify its population policy. In so doing, the government, other policy decision makers and planners proved that they were well aware of the importance of population policies, designed to alleviate the weight of demographic growth, for the country's economic and social development. The creation of this new population policy went hand in hand with a considerable drop in fertility. On the national scene, nonetheless, population growth remains a sensitive and controversial topic.

a. The Decline in Fertility

Although the government had adopted a national program of family planning as early as 1967, its *Sessional Paper No. 4*, a guide spelling out the implementation of national population policy didn't appear until 1984, 17 years later. Meetings were then organized between policy decision makers, local consultants, and university experts to ensure as comprehensive an approach as possible during the preparation of policy projects by sector. Debates taking place in population conferences (e.g., the First African Population Conference in Accra, Ghana, in 1971 and the World Population Plan of Action in Bucharest in 1974) had a strong influence on this policy. The strategy document and the national population policy, henceforth multisectorial, were presented to the public during a national conference and revised in the light of criticisms before being definitively adopted as law. It should be noted that, at that time, Kenya was still relatively advanced compared with other African countries; it was not until the 1984 Arusha conference that African political representatives as a whole accepted the validity of family planning for the first time.

In publishing this sessional paper, the government finally recognized that the country's population constituted its most precious resource, acknowledging that the population factor—centered on the assumption that fertility decline was largely dependent on social and economic development and that family planning programs could not succeed unless a certain development threshold was reached—could not be isolated from its socioeconomic context and that purely demographic interventions should be avoided; it also suggested a much improved population program.

Implementing these policies brought substantial results, especially with regard to campaigns encouraging Kenyans to adopt a small family size as the norm. Quite remarkably, the population's annual growth rate dropped from 3.8% in 1979, to 3.3% in 1989, and to 2.8% in 1999. The decline in fertility was as late as it was radical, perhaps precisely because fertility levels started from so high. Estimated to have reached 8 children per woman at the end of the 70s, the total fertility rate fell below 4.7 children per woman according to the Kenya Demographic and Health Survey (KDHS) of 1998, a drop as unforeseen by international organizations as had been its rise during the 1960s and 1970s.

This decline in fertility can be associated with the increase in contraceptive use throughout the country. The Contraceptive Prevalence Survey (1984) and Demographic and Health Surveys (1989, 1993, and 1998) carried out in Kenya showed an increasing use of birth control. The proportion of women aware of at least of one method of birth control increased from 81% to 97% between 1984 and 1998. The rate of contraceptive use among women in a couple, all methods combined, rose from 7% in 1978 to nearly 40% in 1998. Also among women in a couple, ideal family size has oscillated around four children since 1989 (Table 115–1).

Numerous studies have examined the factors responsible for the Kenyan fertility decline (Van de Walle and Foster, 1990; Kizito *et al*., 1991; Robinson, 1992; Caldwell *et al*., 1992; Brass and Jolly, 1993; Egerö and Mburugu, 1994). The debate continues, however: what prompted this speedy decline—the politico-economic-health crisis or public policies? At the macro level, Patrice Vimard (1996) makes the association between the Kenyan fertility decline and the transition from a period of economic growth to one of stagnation. Progress during the period of growth (in terms of education and access to information and birth control) makes it possible for value systems to evolve during a period of economic stress. In Kenya, the decline in fertility can be linked in particular to the increasing scarcity of land—the primary resource in a predominantly rural population (Caldwell *et al*., 1992).

TABLE 115–1 Fertility Decline in Kenya

	KFS 1979	KCPS 1984	KDHS-I 1989	KDHS-II 1993	KDHS-III 1998	KDHS-IV 2003
Estimated population	15.3 m	—	21.4 m	25 m	28 m	32 m
TFR	7.9	—	6.7	5.4	4.7	5.0
Knowledge of contraceptive method	—	81%	—	—	97%	97%
Prevalence of contraceptive use	7%	17%	27%	33%	39%	39%

TFR = total fertility rate.

Despite the government's efforts to set up a suitable political environment, rapid population growth in the 1970s and 1980s hindered economic growth and led to an unprecedented level of population pressure on agricultural land that reduced the advantage of large family size. Higher rates of female literacy engendered new attitudes, especially with regard to family size. Increasingly, parents sought a better education for their children, despite rising school fees. These trends stimulated a demand for family planning. The government became highly involved in this issue and committed itself to providing accessible and diverse methods of birth control, a crucial factor in the success of any population program. As a consequence, use of these services increased and fertility rates dropped substantially. More than three-quarters of the population have access to health services, and more than three quarters of men and women aged 15 and over can read.

Factors that have had a positive influence on the policies of the last decade include the political involvement of the government, decision–makers, and higher-level partners; the increasing availability of well-trained personnel; and the inclusion of population issues in programs relating to development, the environment, the economy, and society. The whole structure being developed also encouraged these policies: legal reforms setting the possibilities and limits of success of national policy, national seminars on population and development, recommendations based on population and development research conducted by the international community, and the creation of pertinent guides and manuals for efficient policies.

Despite the successes achieved so far, however, there are areas in which progress is still possible. For instance, family planning needs in Kenya are not completely satisfied and birthrates will certainly go on decreasing as those needs are met. According to the *Economic Survey* (MPND, 2003), lack of resources is a key constraint on the national action program, with the government having nowhere near the funds necessary to implement it. The root of the problem lies in the withdrawal, by international monetary agencies, of part of their funding in the 1990s because Kenya failed to fulfill the necessary conditions—zero tolerance toward corruption, in particular.

Some questions remain particularly tricky, such as young people's access to information and services concerning sexual and reproductive health, still a controversial issue. Religious and secular groups have failed to reach a consensus on school syllabus content and on condom use, with some believing in the importance of talking to sexually active adolescents about condoms and sexual fidelity, and others insisting that only the value of abstinence should be taught. The Catholic Church, opposed to all initiatives that promote condom use, has a strong influence on Kenyan media and public opinion in general (see Ajayi and Kekovole, 1998). Thus, Kenyan religious authorities even exaggerate positions taken by the Vatican; certain eminent members of the religious hierarchy, from simple priests to the archbishop of Nairobi, regularly express their views in public against condom use, going so far as to deny their efficiency, and even invert the relationship between the diffusion of condoms and HIV. Campaigns organized by the government and NGOs to educate the general public are followed by campaigns of disinformation organized by religious leaders. According to Steve Bradshaw, reporter for the BBC,

> In Kenya—where an estimated 20% of people have the HIV virus—the church condemns condoms for promoting promiscuity and repeats the claim about permeability. The archbishop of Nairobi, Raphael Ndingi Nzeki, said: "AIDS [. . .] has grown so fast because of the availability of condoms." [. . .] In Lwak, near Lake Victoria, the director of an AIDS testing center says he cannot distribute condoms because of church opposition. Gordon Wambi told the program: "Some priests have even been saying that condoms are laced with HIV/AIDS."

The criminal polemics initiated by some Catholic groups have spread to other religious groups since the mid-1990s. Muslims and Adventists have rallied to the fight against condom use, so much so that a vast number of Kenyans share these views, as numerous references in the national press testify, and this despite the high incidence of HIV in the country. As a result, the whole debate on sexual education in schools is far from being resolved.

Fortunately for the national action program and for the Kenyan population in general, the Church does not control the funds used to fight AIDS or teen pregnancies. Most Kenyan population programs are financed by foreign funding agencies, which made it possible to maintain existing activities and create new ones in the area of reproductive health and in the fight against HIV/AIDS throughout the 1990s, despite pressure from the religious lobby.

Donors have the right to decide how their money will be spent, however, and as a result, many programs are centered on objectives chosen by the funding agencies, regardless of the population's real needs and cultural norms. For instance, the American government has offered vast sums of money for family planning programs, on condition that they promote abstinence rather than condom use in the fight against HIV/AIDS and teen pregnancy, joining ranks with the most extremist religious movements. Rechanneling the funds in this way meant that the supply of contraceptives (condoms included) to many NGOs was halted. Marie Stopes International, for example, closed its reproductive health clinic in Nyanza province, the province with the highest incidence of HIV in Kenya, and many other health services were reduced in scale. Such demands and restrictions from funding agencies can have an influence on national population policy, and many countries could be forced to set up inefficient programs that may even put the lives of women, children, and whole families in jeopardy. According to Amy Coen (2003), president of Population Action International,

> The Global Gag Rule is yet another example of how the Bush Administration is allowing political ideology to trump science. The policy shows no respect for scientific evidence and proven public health practices, and no compassion for the millions of women around the world engaged in a daily struggle for existence. Under this policy, foreign NGOs are forced to choose between desperately needed family planning funds and the ability to provide medically ethical information or participate in public debates over their countries' abortion policies.

b. The Political Face of Demographic Growth

The issue of population policy needs to be viewed within the context of national construction and budget distribution. In Africa, numbers are often perceived both as a means to power and as its justification. In Nigeria, budgets are allocated according to the size of the population administered in a given region, and this led to an escalating problem of population overestimation until the 1981 census (Omoluabi and Lévy, 1992).

The dichotomy between minority and majority ethnic groups is Kenya's main source of antagonism. During the period of consolidation in power of Daniel arap Moi, independent Kenya's second president (1984–2002), this rivalry heightened. Although the regional *majimbo* ideology, spearheaded by Moi in the early 1960s while a member of KADU, advocates the rights of minority groups with respect to majority ones, the predominance of the latter nonetheless remained an obstacle to his authority. So Moi played a double game: on one hand, he defined himself as a minority group member while, on the other, he sought to compete with majority groups on their own ground, namely numbers. He made use of a variety of methods to ensure the numerical strength of the Kamatusa groups (Kalenjin, Maasai, Turkana, and Samburu), his main electoral basis.

First, he juggled ethnic categories to strengthen his position. From 1979 onward, the category "kalenjin" was created and used officially in population censuses to merge seven ethnic subgroups with related languages: the Kipsigis, Nandi, Keiyo, Marakwet, Tugen, Sabaot, and Pokot groups, of which five were already the product of a regrouping of distinct communities. This made it possible to raise the rank, numerically speaking, of one of the Kamatusa components to fifth place among Kenyan ethnic groups. Finally, the very emergence and use of the term *Kamatusa* made it possible to swell numbers even more.

Second, the 1989 census was manipulated in such a way as to raise the Kalenjin group from fifth to fourth rank in Kenya's population composition. Not only was data quality not up to the mark, but a new step had also been taken: no longer a simple matter of juggling categories, it had become a straightforward case of data manipulation, poorly camouflaged in the published document, whose aim was to consolidate the Kalenjin position in the country as a whole and in the Rift Valley province in particular. Recalculating census figures shows that the Kalenjin's rise in demographic rank at the national scale is patently due to the addition of 20,000 Kalenjin in the Rift Valley province (Golaz, 1997, p. 115, 120).

Third, although the official position fed to funding agencies was one of fertility reduction throughout the country, some Kamatusa groups were, on the contrary, encouraged to maintain a high birthrate. In 1993 the Minister of Public Works, Jonathan Ng'eno, advised the Maasai and other minority ethnic groups to give up family planning "since the last general elections showed that we cannot command if we don't have the numbers" (DN, 01/08/93). The following year, the

Maasai political leader, Ntimama, asked the Maasai to reject birth control (DN, 05/12/94). When influential politicians offer a public invitation to certain ethnic groups to put no limits on their fertility, such advice can undoubtedly sway them; it can also trigger off a chain reaction among other ethnic groups who were not involved, regardless of current public policies. The same speech delivered to the Maasai was later repeated to the Kuria, a Bantu-speaking ethnic group, by their deputy, Shadrack Manga (DN, 23/06/97).

Even though practice does not necessarily correspond with official discourse, this type of attitude betrays a two-tier policy that can only be understood within a framework much wider than that of the simple diffusion of contraception.

3. Attempts at Spatial Redistribution of the Population

Even after fertility has started to decline, however, population structures evolve slowly and demographic imbalance aggravates economic deterioration, as a report from the International Labor Office had foreseen long ago (ILO, 1972). From the late 1980s, overcrowding and the unequal distribution of land within the population were used to justify disputes rooted in much more complex issues. Thus, although not part of the government's official policy, people close to the President, eminent members of the government, ministers, deputies, and so on, were involved in the 1990s conflicts that caused, in addition to thousands of deaths, waves of internal refugees unprecedented in Kenya.

Moi's doctrine, "*nyayo*," which means "in the footsteps" in ki-Swahili, implied political continuity between Kenyatta's government and his own; the reality, however, corresponds to a highly distorted sense of the expression: any continuity with Kenyatta's policy exists only insofar as it serves Moi's community and the Kalenjin group in general. Regionalism resurfaced with his arrival in power, as did Kamatusa leaders' land claims to the whole Rift Valley province. In the wake of the privatization of former European lands, the Rift Valley has become the most mixed province in Kenya; to adopt a *majimbo* system would mean expelling millions of people from the Rift Valley (HRW, 1993, p. 12–13). The "majimboism" of the 1990s can be viewed as a warped version of the regionalism that marked the beginning of the 1960s.

At the end of 1991, under pressure from the population and international bodies, Moi legalized the multiparty system and thus consolidated his position at the head of the Kenyan state (Grignon, 1993, p. 20). In December 1992, thanks to the protectionist power endowed on him by the State (i.e., purchasing of votes; in the Mathare Valley shantytowns, many people describe how the authorities tried to bribe them in the months preceding the elections) (Rodriguez-Torres, 1995, p. 66), but mainly because of divisions in the opposition, he was re-elected head of state. From 1991 to 1994, however, as economic growth hit its lowest level since independence after yet another drought, politicians close to power fueled conflicts between communities of different ethnic origins in and around the Rift Valley. Generally, these were Kalenjin and Maasai attacks on the Luhya, Luo, Kikuyu, and other groups settled in the region, in the hope of making them flee, or retaliation by these groups (National Assembly, 1992; HRW, 1993; Médard, 1996, 1999). This attempted ethnic cleansing in the Rift Valley created more than 300,000 refugees (NCCK, 1994, p. 9), not including those who were able to return directly to their family, and left at least 1,500 dead (Médard, 1999, p. 193–194). In 1997, as the following elections approached, hostilities flared up again in two stages. First, on the coast, the town of Likoni was hit by a wave of violence toward immigrants from the west and center of the country, forcing hundreds of thousands, mostly Luo and Luhya, to flee (Médard, 1999, p. 242). This scandal, in one of the most popular tourist resorts in Kenya, hit the country's main source of foreign currency hard. In the interior, on the other hand, pre-electoral tensions and scheming by local politicians rekindled old, unforgotten disputes, giving rise to a wave of violence comparable to that of the first half of the decade. Division in the opposition, partly the result of these conflicts, were such that Moi won the ballot once more.

In addition to Daniel arap Moi's two successive re-elections in 1992 and 1997, the displacement of Kikuyu, Luhya, Luo, and Gusii populations from lands that had been settled by some for many decades, and even many generations, meant that the government could use access to this land to buy the support of some Kamatusa communities from the Rift Valley province (Médard, 1998).

These refugee migrations within Kenya went unnoticed at the international level, however, partly because of the lack of publicity surrounding them. When looking globally at refugee flows, Kenya undeniably appears as a host country rather than as a source of refugees. Lacking any formal infrastructure, most refugees from the 1990s conflicts, registered by the National Council of Churches of Kenya, disappeared somewhere between the cities, their region of residence, or the region from which their family originated. This is not the case, however, for refugees from the Horn of Africa who, since the early 1990s, have found political asylum in Kenya where vast refugee camps were set up under the aegis of the UNHCR (United Nations High Commission for Refugees). Since 1992, more than 100,000 international refugees have been hosted in camps in the Dadaab region (Garissa district) in northwestern Kenya (Cambrezy, 2001). Another refugee camp, Kakuma, in Turkana district, also in northwestern Kenya, mostly shelters Sudanese refugees. According to the UNHCR's last calculations, 128,700 Somalis are currently living in Dadaab, and 67,300 Sudanese in Kakuma (UNHCR, 2003). Many other camps also operated in the 1990s, but are now closed. It is impossible to estimate the number of refugees living outside these organized camps, but it certainly exceeds the 10,000 or so people declared by the UNHCR for the city of Nairobi, for instance.

What are the consequences of these many years of economic degradation and political conflict on urban growth? Urbanization in Kenya never reached the alarmist levels predicted by urban planners in the 1970s. It is not possible to calculate the country's rate of urbanization from the most recent census of 1999. In addition to the classical problems of population underestimation in the poorest urban areas, the creation of new, bizarrely defined municipalities[2] in the 1990s prevents from any relevant interpretation of aggregate urban figures. The fact that the rural-urban dichotomy is undermined by the extremely high population density of some primarily agricultural parts of the country (800 inhabitants per sq. km. in Vihiga district, 700 in Gucha district) (Figure 115–2), makes it all the more difficult to reach any conclusion on the issue.

Apart from the asylum given to international refugees, mostly orchestrated by the UNHCR, Moi's regime ended in bloody internal conflicts. Globally, the whole settlement of Rift Valley province was questioned and, locally, hundreds of thousands of people were chased out. But no specific policy ever addressed the question of the population's spatial redistribution in Kenya, and the time may have come to place access to land among the priorities of Kenyan politics.

The procedure for formulating explicit population policy is now familiar territory to the Kenyan players. Still too often, however, creating efficient programs to meet policy objectives remains problematic. Integrating population policy and action plans into government priorities is not helped by the urgency of the country's politico-economic situation. Moreover, each ministry is responsible for its own sphere of policy implementation and at times it proves extremely difficult to maintain any coherence between them; this is despite both the multi-sectorial approach, whose aim is to harmonies the different facets of national policy, often closely linked to one another, and the efforts of National Council Program for Development (NCPD), mandated to coordinate them, on the other.

The NCPD's Unit of Population Planning, for example, is attached to the Ministry of Planning and National Development. It is the technical body responsible for national population policy, in terms of both the global coordination of policy formulation and its application. The Ministry of Health, on the other hand, is responsible for coordinating technical issues linked to reproductive health (i.e., it coordinates projects, evaluates results, and monitors spending at all levels of the population program). Another case, more serious still, the AIDS epidemic falls under the control of the Office of the President, though many believe the Health Ministry should be responsible; this creates confusion and conflict, over funding in particular, worsened still by the country's growing interest and financial investment in the struggle against the epidemic.

In the face of such massive challenges, the government needs to implement clear and efficient projects if the current policy guidelines are to prove their worth. Kenya's economic development perspectives are largely dependent on the government's success in its attempt to speed up efforts to expand family planning services and to fight AIDS and maternal and infant mortality. In a decentralized system like Kenya's, achieving this would require integration and cooperation between actors in the different ministries, donors, NGOs, the electorate, researchers, and politicians, all of whom influence government priorities.

Further decentralization of the policy formulation and implementation process could be envisaged at both national and district levels, giving more power to population management teams in each district, whose role it is to develop programs of action on the ground. This would make policies and the projects themselves better adapted to local needs. Even so, it should be mentioned that responsibilities were, at times, transferred before local authorities were sufficiently competent to take charge, which spelled failure for the programs. There is also, now and permanently, a need for relevant, accurate data on which to base new population policies, for qualified personnel, and for

[2] For example, Kehancha municipality includes the whole district of Kuria (Nyanza province), which is more than 90% rural. Our thanks to Claire Médard (IRD) for drawing our attention to this.

additional studies that analyze both the interaction between population and development and the real needs of the population.

CONCLUSION

The National Rainbow Coalition (NARC), the new party elected to power in December 2002, is certainly attempting to meet these challenges, offering free primary schooling to all Kenyans, for example, and taking up the torch in the fight against corruption, a measure that enabled Kenya to benefit once more from International Monetary Fund (IMF) funding in 2003. By reformulating its public health programs of action, by improving the health system particularly with respect to reproductive health and by investing in information campaigns, the new government hopes to improve awareness of family planning, AIDS and other reproductive health problems. Dynamic campaigns for HIV prevention and for treatment of sexually transmitted diseases and AIDS are emerging. By offering free education, making preventive methods such as Information, Education and Communication (IEC) and condoms available at low cost (subsidized), and by giving attention to the problems of women and other vulnerable groups, the NARC government is tackling the most fundamental social problems.

The Kenyan population's demographic growth remains high. Even though fertility levels have dropped considerably, the population's age structure means that numbers will continue to rise uninterrupted for several decades to come. In some parts of the country, the very rapid rise in rural and urban population densities (Figure 115–2) will bring a proportional increase in their needs. Development of the labor market, and that of other facilities (e.g., health and education), however, has suffered from the country's years of politico-economic drift.

Like the health situation, the problem of access to resources appears extremely difficult to resolve. Kenya may be one of the few African countries to have started registering by the end of the 1960s, but some areas have still not been surveyed yet. The first plots to be registered have since been subdivided, sometimes several times, usually without official backing. As a result, there are various land ownership statuses. The same plot of land may even have been legally acquired by several people, if one includes the owners before and after the 1990 conflicts. In a country with a primarily rural population it is essential to solve the land question as fairly as possible—a formidable challenge for the new government.

Whether from the perspective of planners, the government, or researchers from the international community, the lack of high-quality demographic data remains a problem even though, compared with the rest of sub-Saharan Africa, Kenya's data are relatively reliable, plentiful and well preserved. Demographic and health surveys, of which four have been carried out since 1989, are only moderately well adapted to the country's diversity of social contexts and only cover the areas of health and reproduction. Censuses have suffered from the country's political drift since the 1980s. It is time to reinstate this indispensable tool, the basis for all population projections, as well as policy and program planning.
